The study of MEs in the four analysed cities suggested that port authorities, not unlike other key local organisations, are interested in taking part in these processes, albeit this could be the result of pressures arising from expectations around their involvement in such important events for the city. Nevertheless, port authorities are positioned along the abovementioned spectrum. For instance, Valenciaport took part in the organisation of MEs, albeit retaining a landlord position. Havenbedrijf Rotterdam N.V. could be considered closer to the developer extreme, considering its key contribution to the cultural and artistic life of the city (for instance in the case of large-scale cultural events such as the Port of Rotterdam North Sea Jazz Festival). Genoa and Hull displayed milder attitudes, although the UKCoC 2017 in Hull did contribute to stimulating Associated British Port’s interest in culture in an unprecedented way.

As cultural events of national and international relevance, MEs also raise issues of authenticity and commodification of culture (Getz and Page, 2016; Gruneau and Horne, 2016), which can negatively impact local heritage. In the context of European port cities, MEs and their homogenisation power operate in a context where traditional maritime practices and socio-cultural links are being eroded, through a process of demaritimisation (Musso and Bennacchio, 2002) which could include a loss of maritime culture.

In the case of Rotterdam, for example, the ECoC 2001 and the following event policy implemented by the City Council, together with waterfront redevelopment schemes, are arguably promoting a reconnection between the city and the River Maas. However, this reconnection appears based more on the use of water as an architectural element, rather than on recalling the city’s history and present as a port. In Rotterdam and Genoa, historic port areas – either redeveloped into urban areas or still harbouring maritime functions – are spectacularised through iconic architectures or even panoramic viewpoints (albeit the latter involve ‘clean’ and saleable port practices and facilities such as cruise and ferry terminals, Figure 8).

8. Headquarters of Rotterdam's Port Authority and former terminal of Holland America Line, next to the cruise terminal (left). Panoramic lift on the Bigo in Genoa (right).

The study of MEs in the four selected port cities has also underlined how overlooking established socio-cultural port-city links and geographical settings in event-led regeneration processes may led to unintended consequences. For example, despite the massive investment and regeneration in Genoa's Porto Antico and city centre, the latter has witnessed a process of 'counter-gentrification' as migrants have concentrated in this area. In addition, informal economies have settled in the redeveloped leisure port. In Valencia, the top-down attempt of established a strong connection between the city and the sea, despite the traditional separation between Valencia and its port, led to years of underuse of the leisure port built for the America's Cup 2007.

Conclusions

This paper has explored port-city relationships through the impact of MEs and event-led urban regeneration, to suggest that these events play a role in the evolution of port-city links themselves. The experience of Hull UK City of Culture 2017, Rotterdam (ECoC 2001), Genoa (1992 Specialist Expo and ECoC 2004) and Valencia (America's Cup 2007 and 2010, Formula One European Grand Prix 2008-2012) have been analysed from a comparative perspective to shed light on the impact of such events on the socio-spatial and socio-cultural relations between these cities and their ports.

The paper has briefly outlined and commented the impact of MEs on the socio-spatial port-city relationships, suggesting that MEs, as culture-led urban regeneration more broadly, are factors contributing to the retightening of port-city relationships after decades of detachment. However, it has been pointed out that MEs may have considerably different direct impacts in relation to their position along trajectories of urban regeneration and that they can also produce spatial disparities. Permeability at the port-city interface still remains an issue, which can be considerably worsened by poorly planned MEs and their unmanaged legacy.

Socio-cultural impacts of MEs on port-city relationships were also discussed, showing the role of port authorities as either landlords or developers within these processes and commenting issues of authenticity, commodification of maritime culture, cultural demaritimisation and unintended consequences of event-led regeneration, such as underuse of cultural facilities and public space and counter-gentrification.

Further research should focus on the tension and spatial contradictions between cultural – and urban more broadly – uses that MEs – whether directly or indirectly - encourage at the port-city interface, in a moment where ports are still urban (Hall and Jacobs, 2012) and lighter maritime functions tend to locate on waterfront areas in proximity of city centres.

Spaces for tourism, Venice planning topographies

Luca Velo

Università Iuav di Venezia

lucavelo@iuav.it

Abstract: In Venice and in the whole Venetian Region, tourism has become one of the first economic powers over the last decades. During the years of crisis, tourism was virtually the only economic source which seemed not to show any recession set against the manufacturing industries and industrial production in general. Although the Venice Region has a long touristic vocation related not only to its historic heritage but also including winter sports, as well as coastal (sea and lake) and health (springs or thermal baths) resorts, some conditions have changed. Many changes have occurred since the 70s, considered the period of extreme expansion of spaces, in terms of buildings and infrastructures for tourism in the Region by expansions of large parts of villages or local settlements with the direct consequence of a huge amount of land use. Venice today faces peculiar conditions where the struggle for inhabitants to keep their residential and daily lives comes up against the huge power of private investments oriented exclusively towards tourism. According to recent surveys there is no longer accommodation for longterm affordable renting throughout the island. Many local associations have striven, through provocative actions and initiatives, in order to defend a specific right to live the city. Following this general framework, the paper aims at documenting how the city has changed in terms of physical space, modification in use of public spaces and the lack of administrative local policies to defend local inhabitants in the city. Meanwhile, over the last five years some studies and researches, especially in the University IUAV in Venice, have stressed the accent to reuse and recycle spaces for living or collective purposes, though local administration and public opinion generally shows itself to be unresponsive to these suggestions. Is there the need to display a reflection much more related to space and the its specific role in a peculiar city like Venice? This kind of work is oriented to read this phenomenon via a spatial lens through maps, re-drawings and interpretation of data coming from different sources. In order to show how the impact of tourism is apparently affecting the daily and ordinary spaces in the city of Venice, the study focuses on potential spatial planning initiatives towards a possible, hopefully alternative, scenario for the future.

Keywords: mass tourism, mapping, Venice, built spaces

Poorly controllable phenomena

Tourism, despite geopolitical, environmental or social factors, continues to grow to the point of becoming the first economic listing for the Veneto region featuring figures for presences of 70 million per year. In fact in Veneto for 2017 the tourist economy generated about 17 billion euros in turnover, up 6% compared to the figures for 2016, constituting more than 20% of the regional GDP, defying any comparison with the regular turnover of the more traditional regional economies such as agriculture, food, textiles and commerce. The Veneto Region ranks third among the Italian regions after Lazio and Lombardy, and if Rome receives €6 billion 743 million (+ 20% compared to 2016), the takings for Venice are 3 billions 769 million (+ 19.4% on 2016), (CISSET, 2018). The entire region is focusing on a massive tourism promotion campaign, seeking on the one hand to consolidate given traditional destinations, on the other by wagering on new forms of tourism, such as the rediscovery or

reformulation of local traditions or the definition of new chains of relations with the latest trends related to food, wine and the experiential dimension of travel. It can be said that the years of the economic crisis experienced by the Veneto region were particularly tough and that tourism has been the constant driving force behind the forms of recovery in the region. The immense growth of the tourist phenomena (Deramo, 2018) which has involved parts of the planet, until recently considered of little to no interest, has been even more extensive in Venice, producing effects hitherto unseen in the city throughout its millennial history. The history of Venice, made up of an inclusive approach and a substantial openness towards the new populations who came there to work, trade or simply to visit the city, today seems to have come to an end. More and more people are experiencing conditions of intolerance, annoyance and closure towards a mass tourism that leads not only to a distortion of the city layout, but above all to that of the life of those who live or work there. One is faced with a constant paradox that never seems to be resolved and that sees on the one hand a tourist demand that is constantly growing and on the other a contraction of the city in terms of its residential, work and service offer, compelling residents-users of the city to adapt to forms of precarious housing, which fall far short of defining Venice as an ideal city in which to live. The policies of local administration also seem to be not up to the task of tackling a problem that only apparently concerns the island city of Venice but which has actually taken on a scale that encompasses the entire territory. If inscribed within the Venetian metropolitan system, the island city seems to suffer from a tourist pressure that does not only concern the historical boundaries of the city (Venice and Mestre) but also and above all neighboring areas, inadequately infrastructured and equipped to receive and tackle modern tourism. In fact, this becomes the result of phenomena that see contemporary society relate to a global system in which tourists no longer know where their boundaries lie, nor can they safely identify the center from the periphery or outskirts. The image of the territory loses its external margins and its internal hierarchies and the subject is merely left with his or her own interpretation of reality, to build itineraries and look for goals and things to achieve (De Marco, 2018). The tourist destination moves from the margins of a space-time system to which the subject belongs (the coastlines, the deserts, the mountain ranges, the historical matrices, the frontiers of the future) to places endowed with specific and autonomous meanings such as given neighborhoods and locations attractive from a predominantly economic point of view, but not entirely associated with quality or spatial value. Each place becomes a potential object for drawing the tourist's gaze, in a sort of global competition between local spaces, each of which tending to accentuate its own characteristics and enhance its own image, in the context of complex tourist regions, capable of offering inexhaustible possibilities of choice and experience. Thus the tourist space expands beyond the specialized areas of the historic city of Venice, comprising its identifying and highly iconic places, manifestly emptied of their social values, involving the spatial resources of smaller towns and inland areas and designing new social and human geographies. Observing the tourist phenomena from the point of view of spatial modifications means identifying the characteristics of tourist movement, its territorial dimensions and the networks through which new strategies are defined, where new images of the territory and not least where new visions for the future can be built. Venice is a paradigmatic example of how, from a dimensionally contained city, the web of a tourist region with multi-purpose images is derived. Here physical-morphological features such as the sea, the lakes and the rivers, the large water reserves, no longer form frontiers but, through the major infrastructures for mobility (mainly road), become connective elements linking the resources of a new territorial subject - the more or less sustainable excursionist or hiker - prone mainly to moving on foot or by bike but able to present themselves on the global scene (Fabian, Velo, Donadoni 2015). The communicative rhetoric behind this image is very consolidated, using the term VENICE as an easily recognizable and acknowledged commercial brand. An example is the tourism

section of the Veneto Region website that defines the region as The Land of Venice, or the advertising slogan of the Winter Olympic Games: The Dolomites, the mountains of Venice.

Looking for new spaces for tourists

In Venice, day-trippers not only exceed the number of overnight tourists but the sum of the two exceeds that of residents, now just over 53,000. According to official estimates, the figure for the resident population is destined to fall further, in line with demographic rates on a national scale. This is inevitably a symptom of a profound deterioration of the residential and, at the same time, tourist quality for the city. Yet some studies¹ (Belgioiso, 2018) underline how the migratory phenomenon from the water city of Venice is constantly growing (fig.1). This is associated with local and national reports that denounce daily situations of intolerance on the part of the residents, phenomena of vulgar behavior or lacking any respect towards the city by tourists and basically a malaise felt by both parties. Clearly, they are certainly not phenomena circumscribed to Venice, even many other cities such as Barcelona, Amsterdam and Berlin are facing similar situations with profoundly different morphological, political and social conditions. The question falls on the understanding of how a city can adequately respond to a stress of similar intensity. The feeling is that we are progressively moving towards the acceptance of a form of development that continually requires resources, ground and raw materials and that above all is made up of services, which the diffuse urban forms of the Veneto have not been able to establish and absorb over the years. Tourist economies manifest themselves by requiring a large amount of space, accepting consolidated practices, linked to services, but also unpredictable ones associated with needs and public safety, which it is essential to guarantee in the form of standards of urban welfare. The studies carried out so far do not highlight the impact of tourism in Venice on the physical and built environment. We never talk about how much water and energy consumption is required by a city made up mostly of hotels, hostels, b&bs and apartments for tourist use where those who pay feel entitled to consume more than they would at home. Over and beyond the need for specific data collection, defining the impacts would result in a catastrophic scenario for the city, where the terms sustainability and balance in the use of resources become completely meaningless. In support of this consideration, the public administration of Venice has demonstrated, on the basis of unspecified data how, according to daily water consumption, the city on average presents a number of inhabitants equal to twice that declared, trying to placate any controversy on the depopulation of the city and the absence of policies in support of residential housing².

A map that changes according to the eyes of the beholder

The problem of data in Venice is a serious one, since collection and access, not to mention control of the same is at times impossible. Official and other data released would allow a quantification of some direct and indirect phenomena of tourism. Some examples may become paradigmatic: the number of

¹ Margherita Belgioioso, assistant professor at the Brunel University in London, using official data from the Venice Municipality, created some diagrams proofing the number of residents who moved away from the old city is higher than the new born residents, denying official version referring the lack of new born.

² In March 2019, the local press reports that starting from the multi utility hydrological service (Veritas), the city counselor Paolo Pellegrini, belonging to the current major list, states in Venice there are at least 100.000 inhabitants, calling them “*non resident-residents*”.

vacant, closed or uninhabited dwellings seems to be completely impossible to attain, both for reasons related to the uncertainty of the data, and for the physical spatial conformation of the city. Another example of lack of accessibility to data, for example, is the attempts at obtaining aggregated data from the web platforms (Airbnb, booking.com, Homeaway etc.) that do not allow a true monitoring of the actual situation, denying the possibility of exact quantification and above all of any representation of the activities of the same. These data could become indicative by being aggregated by indicators (accredited accommodation facilities, municipal monitoring, vehicular passages etc.) though certainly not exhaustive since they do not include a series of data, such as that relating to accommodation, offered by web search and sharing economy platforms that, in the absence of regulatory agreements, do not issue data on the number of presences. If the data is not enough or cannot be directly controlled the description of the city and the phenomena related to tourism becomes highly complex (*The airification of the cities*, Siena Laest).

Describing the repercussions of tourism within the urban space leads to training the eye to recognize particular indicators that alternate in some parts of the city with a certain recurrence. Venice, which can traditionally be considered a tourist city, shows the wounds of an intensive exploitation of its urban fabric for tourism purposes, carried out without too many scruples. Not only in some parts of the city where interminable sequences of commercial and catering services are concentrated, but above all the ground floors of the buildings, that have been turned into places of access to tourist accommodation and storage and supply facilities mainly for the same. If this concerns the ground floors of the buildings that show a main front, the fate of the lateral part that face onto the courtyards and the alleyways is that of becoming access spaces to residences or tourist apartments, the above mentioned goods storage spaces or emergency exits for large hotels. There is therefore a logic of high intensity of uses and functions in some parts of the cities, mainly concentrated in some areas or along some preferential routes, accompanied by a sprinkling of empty spaces at the ground floor level, which belong to a idea of 'gray ownership' (the *Laboratorio Venezia* is a report, curated by Laura Fregolent, Massimo Gheno and Filippo Farronato, that demonstrates the replacement of commercial activities for residents in favour of product and sales presentation). But if what has been said so far refers to the ground floors, it becomes interesting to try to build some maps that illustrate phenomenologies, even in an iconic and in some ways provocative way, that allow a description and mapping of the upper floors as spaces dotted with tourist accommodation considering the constructed ground (Pollak, 2006) that makes Venice so unique.

In other words, we are dealing with the possibility of describing the repercussions of the phenomenon of tourism in a highly subjective way that leads to the definition and elaboration of very different perceptual and sensorial data (Colin, Troiano; 2014). The resulting map is one traced by tourism as a phenomenological subject and one of power (Brossat, 2017), that defines new geographies [fig. 1] that plays a key role in the decision making where the city is planned, strongly influencing the choices, defining paths and directions the city must undertake for the future, establishing itineraries and hierarchies between the parties and the subjects involved.

The rules dictated by tourism involve entire buildings or apartments, modifying them spatially, weighing them down with services and infrastructures required for contemporary ways of life and above all by placing spaces on the level of (economic) convenience rather than sharing and the common good. If you build a map of what might be called tensions in Venice, the number and polarizations that would result could be immediate. There are many places where over the five years

local residents have managed to put up a fight, the outcome of which for the most being entirely negative. We are talking about the area of the former Gasometers, the ex-Actv area, the former Teatro dell' Anatomia, the former Cà di Dio retirement home, Villa Herion in Giudecca and the list could be even longer. Tourism determines the list of spaces and goods to be sold, defines functions and needs but overlaps with a layer, much more complicated to construct and to define, that coincides with that

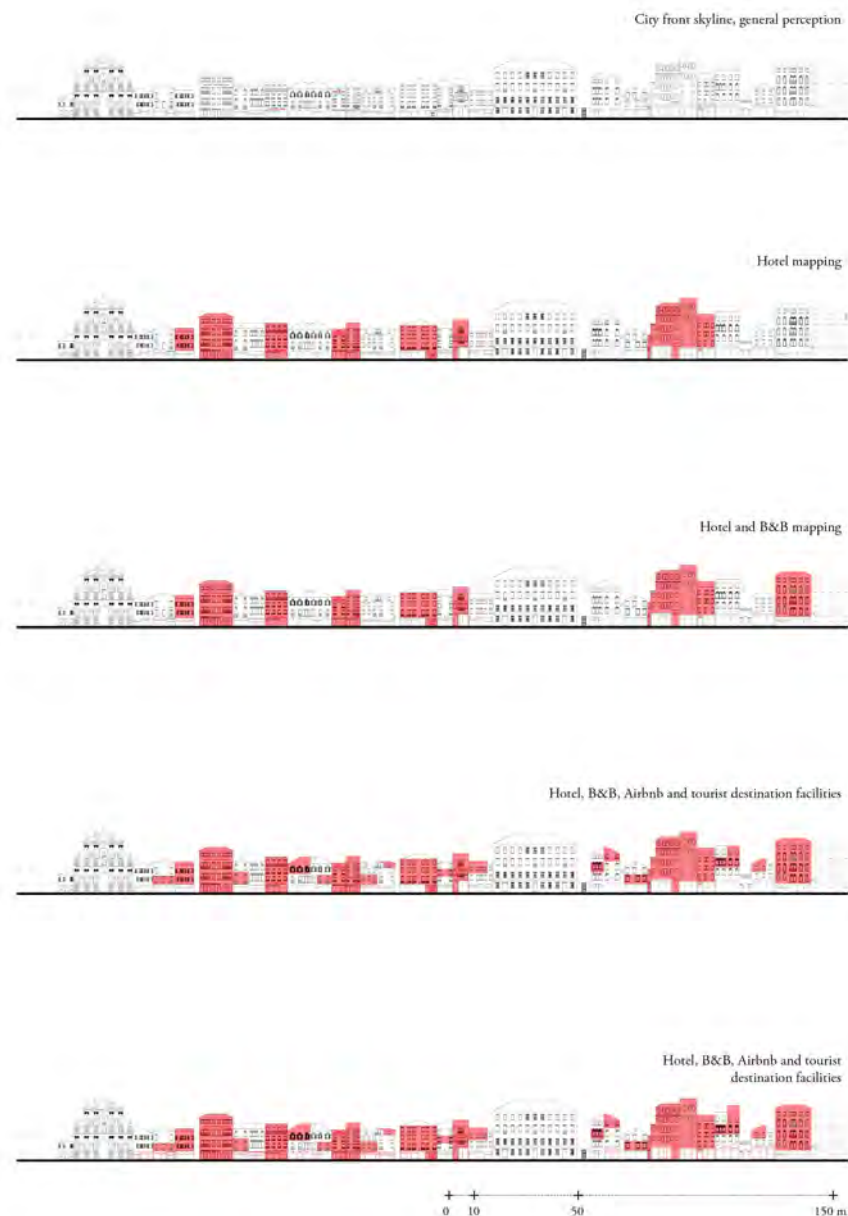

Figure 1. The section demonstrates, through a sample of the city, how in Venice the touristic destination is a pervasive power, infiltrating the largest part of the built heritage.

of resistance to tourism itself, creating a mixed reality (Masi, 2018) made of tacit approval, protest and indifference. Individual buildings or groups of buildings that constitute urban aggregates typical of the urban building fabric that, alongside rendering up their fascinating history of stratification and modification, also cede to today's practices imposed by tourism. The perception is once again called into question alongside the speedy and energetic restructuring that takes place, like with the use of the same type of window, the presence of air conditioning, the absence of names and surnames on the doorbells and front doors, are the clear indicators of tourist destinations within. Thanks to this kind of mapping that could be resorted to on the one hand via individual monitoring, data sharing and search for responses, we could work towards a more accurate control and determination of the effect and action of tourism on the city.

The images that can be obtained, for example, can sometimes entail a more provocative value since it could be useful to represent the hotel areas as urban voids, usually spaces that are not inclusive and not open to the communities that live there. It is the map of a future vision of the city where the void, the absence, corresponding to the hotels, becomes the figure that builds the image of the city, of its practicability and accessibility [fig.2]. An exercise of this type refers to the concrete possibility of building new interlinking space chains that intercept tourist, accommodation and residential presence in the same place where, depending on the different hours of the day, some spaces can be used according to different functions: in the morning as a breakfast room, in the afternoon as a space for courses, in the evening and pre-evening hours spaces for public meetings or encounters among local citizens. In this way perhaps even the heterotopic figure, typical of the hotel within the city, could fit into a process of modification of uses and practices, as well as forms, typical of densely inhabited contexts.

The city and tourism, Venice, a laboratory in which to monitor, experiment and imagine

To reach the practicability of similar evocations - the word scenario is not specifically used here - there is no lack of difficulties and elements for further exploration, the loss of the *fine-grain city* (Ward, 1989) is no more under control. How the public and social system and the private system can collaborate must be understood the same way as how regulation and free enterprise can exist side-by-side. The commercial and economic dynamics argue that the most severe of certifiers is the customer who brings with him his own format, his own vacation (expectations) and references to his own contexts of comfort and service. It must be said that in Venice tourism has always been seen as a revenue where demand is unlimited, a revenue that appears to be guaranteed, offering politicians and policymakers the possibility of not making any effort. This is an inescapable aspect that must be combined with the possibility and capacity of a local urban context. In 2016, the Italian government, with the "Pact for Venice", provided the city with substantial financial support, declaring it a test case in order to define governance policies for mass tourism. This provision provided an extraordinary economic and financial starting point for studying, testing and putting into practice far-sighted and far-reaching policies capable of contrasting and initiating solutions to issues such as housing, urban and physical degradation of the lagoon. The local administration actually issued a summary of the proposals that individual associations or groups or individuals had sent to the municipality. It is clearly a symptomatology of how much this administration is inattentive to mapping in listening to the proposals and needs of citizens in the face of a global phenomenon of which perhaps few are aware.

Hotel mapping

Hotel and B&B mapping

Hotel, B&B and AirBNB mapping

Hotel, B&B, Airbnb and tourist destination facilities mapping

Figure 2. The maps show how could be displayed a hidden layer dealing with the multiple touristic purposes of the urban tissue (white boundaries). This way of mapping demonstrates the need of a direct approach and observation in representing effectively the touristic phenomenon in urban space.

With regards to awareness, some thematic maps illustrating the real penetration of the tourist phenomenon in the urban fabric of Venice, the degree of modifiability and compromise could have a more efficient and more effective result in perceiving the issues. It is a question of reflecting on the problems of urban planning efficiency, so today the theme of the representation of phenomena is very important. It is a question of highlighting the plurality of values, of social dynamics that lead to the construction of new arguments with an impact on the disciplines to which they could refer (Latour, 1998).

The intention is perhaps to try to attain a form of representation for urban phenomena and the city of Venice itself which incorporates semiotic and imaginative readings, dictated by the practice and direct experience of the city, which do not refer to retro-utopias (Velo, 2018) full of memories and nostalgia but that look to the future with radicality and conscience and that refer to a social pact (Fabbri, 2018) in a complex medium and long-term operation that requires technical, regulatory and economic analysis and that finds its specific driving force in the agreement of the different social dimensions of the city.

A simulation that graphically describes the degeneration of the city in its aspects of places of encounter, of work, of free time and of living, salient elements for the design instances decided by the *Athens Charter* (1933) would show a city in strong contraction, with marked polarities of concentrations in some days or particular instances with places of permanent abandonment and voiding. Mapping and amplifying could argue the question of designing for visibility broadly, ranging from catalogs and instruction manuals to map and infographic systems (Manzini, 2015). The city should have and collect this kind of maps, displaying the possible project as extreme effort of imagination contributing vividly and radically to deal with these problems, exploring differences and possibilities as powerful criticism to the present (Secchi, 2000) . This is why Venice becomes a laboratory of continuous experimentation and identification of new modes of working in which the role of the researcher, architect and urban planner could perhaps find new voice and strength to affirm decisions and indicate solutions where, according to the teachings of Lefebvre, space can regain its political office once again.

The Impact of Cultural Creative Industries and Tourism Development on the Authenticity of Historic District from the Perspective of Spatial Production: A Case Study of Tianzifang, Shanghai

Hui Xu¹

¹Tongji University, xuhui36@qq.com

Abstract: In the transition period of urban renewal in China, micro-renewal by means of function replacement has gradually become a popular mode of historic district renovation. However, the impact of industry injection and tourism development on the authenticity of district has become increasingly prominent. Based on the theory of spatial production, the (re-)production process mechanism of authenticity under the influence of creative industries and tourism activities in Tianzifang is analyzed. It shows that: Tianzifang has experienced the (re-)production process from the place of residence to the place of cultural creative industries, and then to the place of modern tourism consumption culture; The main body of Spatial Practice has gradually changed from original inhabitants to artists, businessmen and tourists, with its social network reshaped in varying degrees; For *Representations Of Space*, the physical transformation of buildings carriers is relatively light, but their functions have undergone a change from residential living space to cultural (re-)production space and then to cultural consumption space; For the *Spaces Of Representation*, the cultural authenticity has gradually evolved into the staged authenticity, with the symbolization and commercialization. In addition, the effects of space production is summarized from the reconstruction of material space, spiritual space and social space.

Keywords: Urban historic district; Authenticity; Creative Industry and Tourism Impact; Spatial Production

1. Introduction

Historic districts are rich in historical relics within a certain range, which can truly reflect the traditional features or local characteristics of ethnic groups in a certain historical period, including not only tangible structures, but also values, lifestyles, organizational structures, customs and habits (Zhao, J., 2017). Nowadays, with the rapid spread of urbanization, coordinating the protection, renovation and commercial development of historic district is one of the difficult problems for many China's cities in transition period. The core value of historic district reconstruction lies in the protection and presentation of its real cultural scenes. However, with the development of tourism, the authenticity of more and more historic districts has gradually been transformed into the stage authenticity (MacCannell, 1973, 1989), which becomes a pseudo-event (Boorstin, 1962) and leads to the convergence of historic districts in transition period.

Space has three attributes: material, spiritual and social (Lefebvre H, 1991). The renewal process of historic district is the (re-)production process of material space, spiritual space and social space. Through the reproduction and redistribution of its resources and interests, its spatial pattern, cultural atmosphere and social relationship structure are reconstructed. At the same time, the inevitable conflicts of value, power and interests among different subjects are also facing the predicament of unjust space production (Zhu Z, Wang Q, 2018). According to Lefebvre's theory of space production, *space practice* refers to the daily activities in physical space and the production and reproduction of society; *representations of space* is a conceptual space dominated by the knowledge and ideology of planners and scholars; *spaces of representation* is a symbolic system composed of images, which realizes the overlapping of space experienced by the subject and material space of space practice (Lefebvre H, 1991).

2. Research object and method

Tianzifang, a renovated historical district of Shanghai's unique Shikumen complex, is selected as the research object. It is located at 210 Lane Taikang Road, Dapujiao Street, Luwan District, Shanghai. Originally as a popular mixed-function old district in the center of Shanghai, its northern and Western adjacent areas of the district were originally high-grade residential areas of French Concession, medical and educational institutions, and there were many common old-style lanes scattered in the south. Later, with the upgrading and transfer of industry in Shanghai, factories gradually idle, facing the pressure of demolition and transformation. With the active participation of artists, original inhabitants and the community, it has gradually been renewed into a characteristic cultural and creative district. At present, it has become one of the famous representative districts of tourism and leisure in Shanghai.

The main research methods include literature analysis, field survey and in-depth interviews.

3. The Process of Spatial Production in Historic District

3.1 The *Spatial Practice* of Tianzifang

3.1.1 *Specific Process*

In the early 1990s, with the upgrading of the industrial structure in the center of Shanghai, the old industrial buildings in the neighborhood were gradually idle. Depending on the Art College, the government plans to turn Kangtai Road into a cultural and artistic neighborhood and start renting idle factories to artists.

Around 2003, government-led renovation projects in old districts were launched, and real estate developers obtained the right to renovate through bidding. At this time, residents began to participate in the game of space production because of dissatisfaction with demolition compensation, and began to rent out their own houses. Galleries, studios, etc. gradually spread from the old factory site to the surrounding old-style residential neighborhoods. In addition, some scholars and artists began to publicly oppose the mode of demolition and reconstruction, and the voice began to attract the attention of the mainstream media. Finally, the reform and development plan was put on hold gradually. The government began to relocate Tianzifang as a historic district of cultural and creative industries, adopted a protective development model, and invested in the construction and improvement of the infrastructure in the district.

Since then, commercial capital in the neighborhood has continued to infiltrate. Besides the original inhabitants, the second landlord and the third landlord began to emerge, which doubled the rent. Many artists have to move away, which indicates that the literary industry is in a difficult position to survive. At present, Tianzifang has developed into a famous tourist attraction in Shanghai, attracting a large number of domestic and foreign tourists.

3.1.2 Change of Space Subject and Its Role

Renewal has changed the spatial subject of Tianzifang historical district from a single government/resident subject to the government, artists, residents, and then to the government, residents, business operators, artists, tourists and other multiple subjects. The government formulates protection management rules, artists become the direct producers of Tianzifang district space according to professional aesthetics, and merchants become the direct producers of Tianzifang district space according to market demand. Most of the local residents move out of the neighborhood to start a new life by rent, and become the biggest beneficiaries of the renewal of the neighborhood. A small number of residents are still living in the neighborhood, continuing the production rules of traditional cultural space. Tourists indirectly influence the production and practice activities of tourism stakeholders through the imagination of traditional street space in Shanghai, thus indirectly realizing the production of district space.

3.1.3 The Change of Social Relations of Space Subjects

The revitalization of Tianzifang historical district not only deconstructs the spatial subject of the district, but also reproduces the social relationship between the new spatial subjects. With the breaking of the boundary between the original industrial space and living space and the emergence of new land-use mixtures, such as commercial-residential mixing, the neighborhood ties in the original social relations are also destroyed. The commercial interest relationship between residents and operators, the management relationship between government and space users, and the consumption relationship between tourists and service providers quickly evolved into a capital interest link to maintain the community social structure. The main body of district space has changed from a single neighborhood relationship to multiple social relationships such as business cooperation and competition, tourism services and consumption. At the same time, each of them seeks superior resources in the development of historical districts and maximizes its own interests.

3.2 Reproduction of Representations of Space

3.2.1 Reproduction of Buildings: Protection and Development of Carriers

Architecture is an important carrier of the style and features of historic districts. The original building types of Tianzifang historic district mainly include: factory building, Shikumen building, traditional residential landing building and Western-style house. Most of the factory buildings were small-scale buildings built in the 1970s and were replaced by artist studios in the 1990s. Shikumen Architecture is a unique integration of Chinese and Western architecture in Shanghai, which can attract both Chinese and foreign tourists. Traditional residential buildings carry the daily life culture of the old Shanghai residents' alleys. At present, they have been transformed into low-level shops, two or three-floor coffee shops or theme shops. The high-rise and back streets are difficult to rent because of their low commercial value. Western-style houses are mainly distributed in the northeast of Tianzifang, with a special exotic flavor. In the transformation, elements with visual impact are designed, which are reflected in the facade decoration, accessories, window display and other aspects, paying attention to visitors' experience.

3.2.2 Reproduction of District Function: From Space of Cultural Production to Space of Cultural Consumption

From the perspective of spatial morphology, the original spatial texture of Tianzifang has basically been well preserved, but the function of the district has undergone great evolution, as shown in Figure 1. The residential space originally carrying the residents' life memory is gradually eroded by commerce and transformed into the production space carrying tourists' consumption activities. The area of creative workshops originally relying on artists' studios is gradually shrinking and replaced by retail business functions.

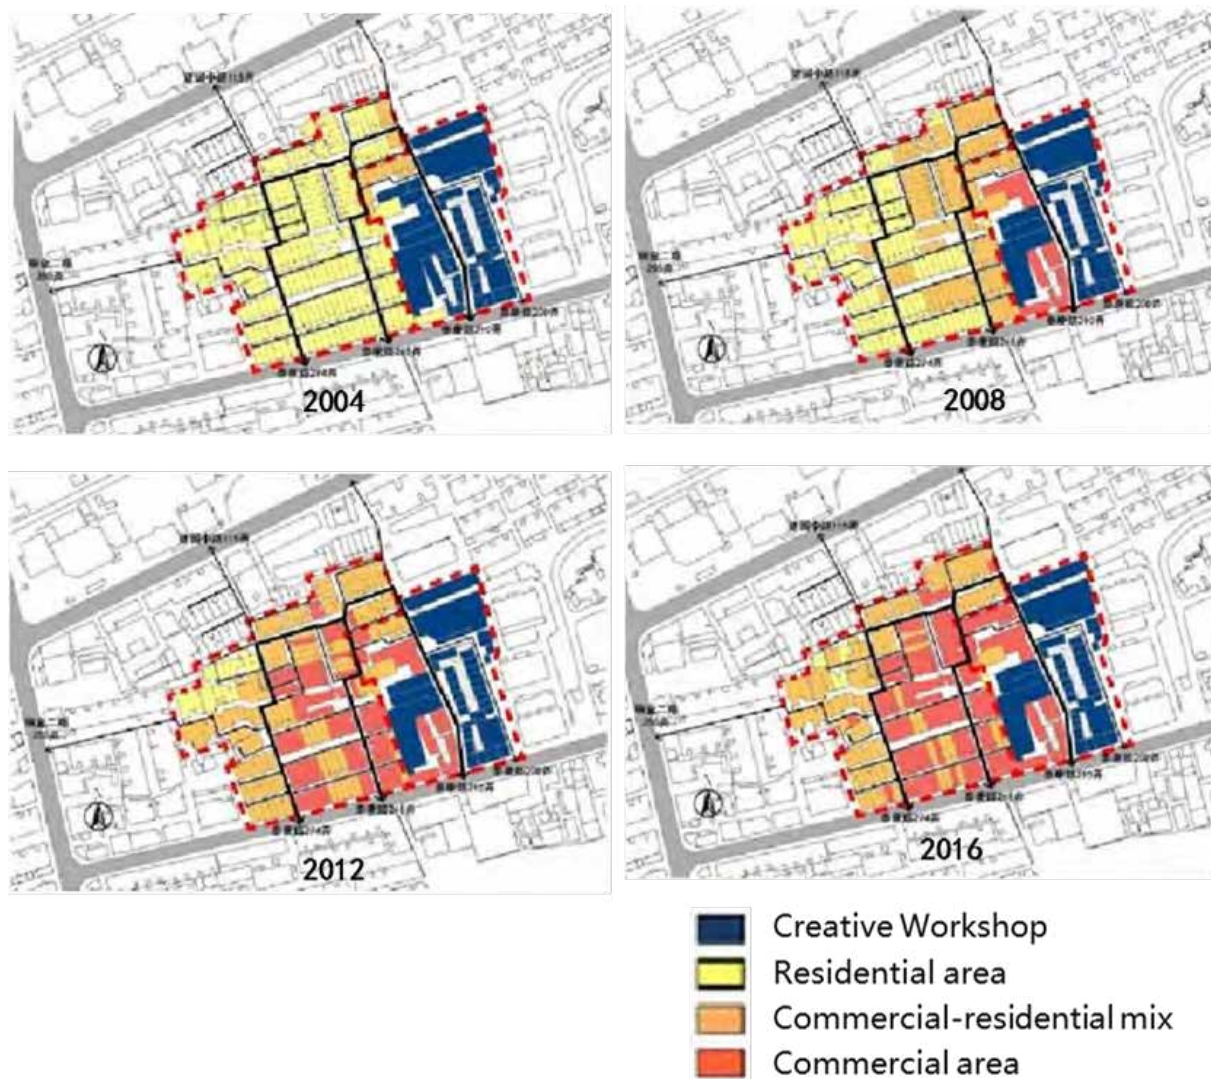

Fig. 1 Analysis of Functional Evolution of Tianzifang District

(Source: Zhu Xiaoyu, 2017)

3.3 Reproduction of Spaces of representation

In the process of reproduction, the objective and authentic culture of the historical district itself gradually recedes into the background or even declines. What presents to tourists in the front is the staged authenticity packaged by commodification and symbolization, and the two cooperate with each other to reshape the space.

3.3.1 The decline of Authentic Culture behind

Before the renewal, the original culture of Tianzifang district includes: the material space culture represented by Shikumen Architecture reflects the trace of integration of Chinese and Western architectural styles in history, the original creative and artistic cultural foundation of the plot, such as the footprints left by artists here, and the city life culture represented by the daily living environment of the original inhabitants' neighborhoods.

In the process of transformation, although the decision-makers have little interference in the original material carrier building itself, the outmigration of a large number of original inhabitants has directly led to the

fundamental disconnection between the original life subject and the district cultural carrier, and the traces of the original cultural celebrities have gradually been forgotten.

3.3.2 Reproduction of Symbol Culture ahead

Cultural symbols are highly concentrated in cultural representation. The excavation and reconstruction of cultural symbols is the key to pushing historical districts to mass tourism consumption. In the early stage of the transformation, the government and planners positioned Tianzifang as a cultural and creative industrial district, so the function of Tianzifang was mainly based on cultural and creative shops, with a small amount of catering and other ancillary services. To a certain extent, the injection of literary creativity activates the lost street space. However, with the impact of commercial development in the neighborhood, a large number of cultural and creative stores have been relocated. New cultural symbols such as souvenir stores, catering stores, clothing stores, bars, coffee shops and beverage stores of foreign chain brands have become the main land use trend.

New commercial functions have injected new cultural symbols, reflecting the projection of heterogeneous leisure cultural symbols in the district space. The symbol culture in the front has gradually infiltrated and merged with the traditional culture of the district and occupied the main space. At this time, life, art and culture rooted in the historical districts themselves are gradually given the current leisure significance. Some traditional life memory cultures in the neighborhood can also be displayed to tourists in new forms (such as the construction of retro decoration in theme bar). Therefore, it can be said that the construction of new cultural symbols has enriched the connotation of traditional culture in the neighborhood and regenerated the culture conforming to the trend of the new era.

4. The Effect of Spatial Production in Historic Districts

4.1 Material Space Turning: From Bearing Collective Memory to Meeting Consumer Demand

With the extension of capital profit-seeking antenna from traditional manufacturing industry to urban material environment transformation and the second and third capital cycle represented by culture and service consumption (Zhou Yu, 2013), Tianzifang's material space experienced the reproduction of preserving the shape skeleton and repackaging content. The memory of its original daily life scenes has almost disappeared, and a small number of indigenous people living in the corner of no commercial value are deeply affected by tourism activities. In addition, with the increasing number of visitors, the demand for consumption is increasing. The rapid spread of various modern commercial activities and the constant creation of characteristic consumption themes have promoted the reproduction of infrastructure, architecture and landscape in the neighborhood towards the consumption demand of the tourism market.

4.2 Reshaping Spiritual Space: Demonstration Effect and Cultural Acculturation

In the process of space reproduction in Tianzifang district, besides the active implantation of new cultural symbols, the new space service objects (tourists) also influence the ideological changes of the direct space producers (tenants) and the original residents (landlords) behind them by their own tourism activities (such as promoting the double growth of rent through the effect of tourism scale). Thus tourists have the demonstration effect on space producers (Fan, Q.B., 2013). In this process, some old cultural forms have further alienated in order to meet the needs of tourists' tastes or media propaganda. For example, the daily production process behind the scenes of the original craftsmen has gradually turned into a special "performance" activity for tourists to visit and display. Furthermore, the cultural demand represented by tourists' consumption and the cultural supply represented by the symbolization of tenants constantly collide with each other. With the passage of time, this kind of communication brings about a certain degree of integration between the two, and eventually realizes

the dynamic balance of demand and supply culture step by step. This is cultural acculturation (Salusa et al., 2017).

4.3 Reconstruction of Social Space: Gentrification and Space Justice

Gentrification refers to the fact that poor tenants who originally rented here were forced to move away because they could not afford the rising rents in the central urban areas, and were replaced by the middle class who could afford the rents, which made the original social relationship structure of the settlements constantly change (Richard Schaffer, 1986). In the process of space production and reproduction of Tianzifang district, there are mainly two gentrification processes.

The first is that before the transformation, because of the poor living environment, in Tianzifang neighborhood, besides the local original residents, there are a large number of workers and poor tenants in the original factory. After the factory of industrial replacement and upgrading in Shanghai was idle, with the support of the government, many artists began to settle in. The rising cultural atmosphere in the neighborhood led to the rise of land prices. Workers and poor people were forced to move to other low-cost areas. Most of the artists are non-local people. The differences between their cultural needs and living background and the aborigines complicate the original social relations.

The second is due to the 2010 World Expo held in Shanghai, Tianzifang's tourism reputation has improved significantly. The failure of the artist group to compete for rent with commercial capital has led to the replacement of most of the artists in the neighborhood by commercial operators. At this time, a large number of local aborigines moved out, and the social relations among the residents who were forced to stay and the business operators, tourists and other groups became more complicated.

In the process of gentrification, the replacement of the neighborhood tenants makes the social network of the neighborhood continue to undergo irreversible restructuring. The authentic neighborhood relationship has been reproduced many times, greatly weakening the personality of the district and gradually becoming homogeneous with other historical districts. After such repeated reconstruction of social space, the original different classes gradually formed social segregation, which had an irreparable negative impact on spatial justice.

5. Summary and Discussion

From the perspective of space production, Tianzifang historic district has experienced the process of reproduction from the place of residence representing the culture and life of Shanghai School to the place of cultural and creative industries, and then to the place of modern tourism consumption and culture dressed in historical and cultural clothes. The main body of its space practice has gradually changed from the original inhabitants to artists, businessmen and tourists, and reshaped its social relations in varying degrees. Although the physical transformation of district building as a carrier of spatial representation is relatively light, its function has undergone a change from residential living space to cultural production space and then to cultural consumption space. At the same time, the reproduction of representational space is accompanied by the reconstruction of symbolic culture, which makes the authentic culture gradually decline. Generally speaking, under the production and reproduction mechanism of Tianzifang historical district, its material space, spiritual space and social space have been reconstructed to varying degrees, accompanied by a series of spatial effects such as symbolization, commercialization and gentrification, which make its authenticity gradually reconstructed and alienated.

In addition, how to retain the collective memory of the authenticity of historic districts, coordinate the production relations among power, capital and residents in the overall transformation, reflect on the role of cultural reproduction in the renewal of historic districts, and ensure the realization of spatial justice are related to

the process of urbanization in the future and the value orientation of protection and development of historic districts in China, which requires further in-depth exploration.

CHARACTERISTICS IN THE SPACE RESHAPING OF CREATIVE CLUSTER DURING GENTRIFICATION: THE CASE OF TIANZIFANG IN SHANGHAI

YI YANG¹

¹Tongji University, 598425280@qq.com

Abstract: This paper explores the process of gentrification of Tianzifang creative cluster and analyzes the space reshaping characteristics during this process. The study finds that: due to the gentrification of the population and surge of leisure businesses, there are five main driving forces that reshape the space: 1) space consumption and experience demand of tourists, 2) space competition and privatization demand of businesses owners, 3) space renovation and defense demand of local residents, 4) space renovation demand of creatives, 5) space control and guidance of local government. As a result of five main driving forces, the space has shown new characteristics including reserved space structure, mixed functions, segregated living space, commercial space sprawl, privatized public space. This paper provides suggestion that coordinating the relation among diverse stakeholders will be the key to promote transition of urban space and maintain social justice.

Keywords: gentrification; creative cluster; space reshaping characteristics; diverse stakeholders

1. Introduction

With the deepening of globalization process and rise of the new economies as well as great shift of urban and regional development mode since 1980, the “Creative Industry Cluster” expand rapidly. Historical areas, waterfront areas and industrial areas have become important space foundations for promoting creative industries. Therefore, space reshaping and social network reconstruction of the creative cluster have become the core of urban sustainable development research.

As a new urban social geographical phenomenon, gentrification has been developing for decades in Western countries (Huang Xing and YANG Yongchun, 2012). With the diffusion of globalization gentrification has been widely produced, operated and consumed worldwide as a “Global Urban Strategy” (Smith, 2002). Creative cluster in the inner city learns from this “Global Urban Strategy” to some extent. Therefore, some investigators have recently turned to research whether there is a “Creative based Gentrification process” and the answer is “yes”. Jamie Peck (2005) argument in *Struggling with the Creative Class* that:

In the field of urban policy, which has hardly been cluttered with new and innovative ideas lately, creativity strategies have quickly become the policies of choice, since they license both a

discursively distinctive and an ostensibly deliverable development agenda. No less significantly, though, they also work quietly with the grain of extant ‘neoliberal’ development agendas, framed around interurban competition, gentrification, middle-class consumption and place-marketing quietly...

A considerable amount of research has been made on social network reconstruction of the creative cluster during gentrification, but little research has been made on space reshaping. Many researchers pointed out that there has significant correlation between the cluster of cultural creative industry and the change of social-structure feature: those areas that cultural related industrial cluster obviously are always the neighborhoods of higher social class (GAN Xinyue *et al.* 2017), which means there is a “Creative based social-structure change process”. With the changes in the social-structure, the people who live and use the space have changed, the needs for space of different people are different. Therefore, how do different people use the space in different ways and what are the conflicts between local residents and the newer users during the space reshaping? It is desirable to carry out surveys of the “space reshaping” characteristics of creative clusters during gentrification.

2. Gentrification process in Tianzifang

Tianzifang, a Creative Cluster in Shanghai, shows a “Creative based Gentrification process”. Tianzifang is located in Luwan District the central area of Shanghai (Figure 1). The block was formed in 1920s, as a result of expansion of the French Concession. At that time, it has been used as residential quarter and industrial area. After renovation in 1988, it’s now become a creative cluster, also a charming landmark for both local residents and foreign tourists. Not only has the creative industry made Tianzifang area turn from a traditional, local, private and poor area to a fashionable, international, open and rich area, but improved local image and at the same time makes the social relationships more complicated (KONG Xiang and QIAN Junjie, 2011). The gentrification process of Tianzifang can be divided into four stages.

Figure1 The location of Tianzifang (left) The past and present photos (right)

2.1 Informal arrangements between the factory managers and artists

Tianzifang became well known as a creative park in the late 90s when internationally renowned artist Chen Yifei moved into the area and rented one of the factories as his art studio. From 1998, the government of Luwan district decided to regenerate the area to attract more artists came here and rent industrial factories as their art studio. Development had to be negotiated with the factory owners and every one of the local residents. Although most of the houses in Tianzifang area are nationalized, for historical reasons, the renting in this area is permanently rented (SUN Shiwen and ZHOU Yu, 2015). The complex ownership structures in the area make it difficult to demolish and rebuild the area.

2.2 Informal arrangements between local residents and creatives

The relaxed, vernacular feel which benefits from the artists made Tianzifang a highly attractive destination. More and more artists wanted to move into the area. So, the local subdistrict established “Office of the Art Street Management Committee” in 2004 which is responsible for the investment of Tianzifang. The spillover creative space needs and economic interest promoted local residents began to lease their own houses and to move out to houses in other places bought with the rents obtained. As a result, more and more creatives move into the district replacing local residents and turning the residential area into non-residential functions which is illegal. Although the government has planned to demolish and rebuild the Tianzifang area as a new business center, due to the rapid development of the Shanghai real estate market, the housing prices in this location have risen rapidly, causing residents to be dissatisfied with the government's compensation for demolition and resettlement fees and tend to make informal agreements with creatives to obtain higher income.

2.3 Formal arrangements between local government and local residents

The local government finally had to accept this popular informal creative cluster and redeemed land sold to developers in 2008, because creatives' reshaping of space has indeed improved the environmental quality of the Tianzifang area and the voices for protecting historical districts are high. Government's acceptance made it legal that local residents change their houses' function from living to non-residential functions which attractive more leisure and lifestyle businesses that generate economic benefits. Formal arrangements between local government and local residents have promoted the overall renewal of this area.

2.4 Complex social network and gentrification

From this time on, creatives have gradually moved out of the Tianzifang area, as both the government and local residents seek for maximum benefits raising the rental price of houses and welcoming more leisure and lifestyle businesses brought into the area to replace the less profitable creative businesses. As a consequence, the creatives and local residents have been replaced by newer business owners and the rent became much higher than before, even the land price of area adjacent to Tianzifang became higher as well. In the end, the renewed attractiveness in turn leads to a gentrification of the population and a revaluation of land and real estate. At the same time, a complex diverse stakeholders social network has formed among the government, local residents and businessmen during gentrification (Figure 2).

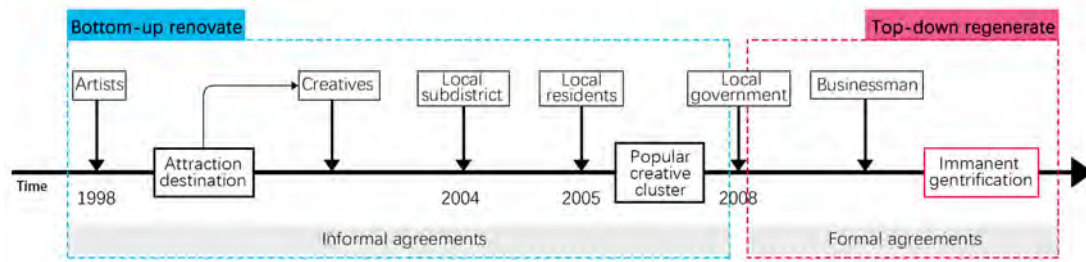

Figure2 Gentrification process of Tianzifang

The sociality of urban space originates from all kinds of human activities and their mutual relations in urban space, and the essence of urban spatial diversity is the diversity of social structure (YANG Guiqing, 2017). Consequently, the reconstructed social network in turn reshapes the land use and space structure. How does these diverse functions co-build the space? What are the characteristics of space reshaping? How do they use the space in different ways? What are the conflicts between local residents and the newer businesses result from space reshaping?

3. The characteristics of space reshaping

3.1 Reserved space structure

Tianzifang was one of many laneways in Shanghai that had an organized space structure. After renovation, it still kept the old laneway space structure which formed by “Main lanes - Secondary lanes – House” spatial organization and diverse space scale (Figure 3). The reserved structure benefits from the bottom-up independent renovation and local residents’ resistance to demolition of the area. The main public space of the area is on the laneways which means activities and communication of local residents, tourists, business owners, creatives are both organized by laneways. This special space structure not only limits users’ behavior about how to use the space, but also be the main influence factor of forming complex stakeholders social network.

Figure3 Figure-ground relation of Tianzifang

3.2 Mixed functions

Tianzifang was formed in 1920s, as a result of expansion of the French Concession. At that time, it was formed by variety townhouses, a few businesses along the street and centralized factories. A variety of cottage factories grew up during the 1930s and 40s serving the immediate needs of the industrial city center, but most of them were closed down in the 1980s and left vacant factory

buildings. As we can see in Figure 4, the space of the neighborhood is mainly composed of residential buildings and laneway factories. These laneway factories were embedded in local communities offering local residents work. As a result, a close social connection in Tianzifang area was formed by the functional layout of job-housing balance.

After renovation in 1988, the functions were transferred to creative studios, leisure and lifestyle businesses step by step. First of all, famous local artist and art companies found the low rent and superior space environment of inner city and moved into the vacant factory buildings, and after that, a large number of creatives continually moved into the neighborhood through renting local residents' house changing the residential function to non-residential function. Creatives make this area attractive and bring consumers in who have little taste for art and design goods. This also start to make businesses embedded in local communities means more leisure and lifestyle businesses brought in to the area replacing the less profitable creative businesses. The mixed function combining residence, business and studio (Figure 5) makes diverse stakeholders use same public space bringing a diverse stakeholders social network. The space function transformation changes the social network and the social network in turn reshapes the space.

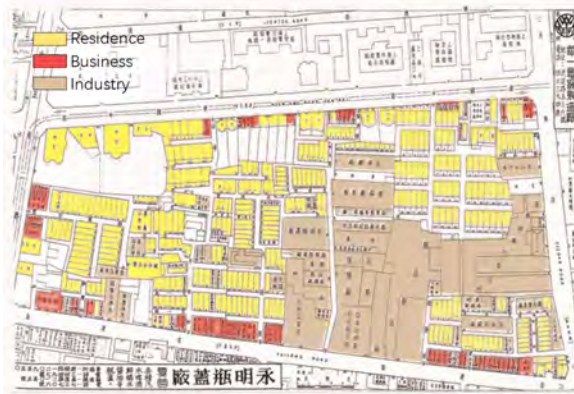

Figure4 Mixed functions in 1947

Figure5 Mixed functions in 2013

3.3 Segregated living space

The embedded studios and businesses segregated living space, even segregated internal space of residential building through using different floors of one house for different functions. This kind of space segregation blocks the original close social connection in the area.

After renovation, the embedded studios and businesses replace half of the residential area making the residential area segregated (Figure 6-A). The community space organization used to be integral, because of local residents renting houses to creative businesses and leisure businesses, the community space has become fragmented. Furthermore, the reason why the residential area preserved located on the periphery of the neighborhood, especially in the north and west is that the luxury shopping mall opposite the Taikang Road making residential area on the Taikang Road side almost transfer into commercial area.

Not only was the overall layout of the houses segregated, but even the residential building internal space was segregated due to different functions in different floors (Figure 6-C). Because the first floor can be rent out to commercial use easily for its accessibility, the residential buildings were used in

three different ways. First way is that the whole building is for residential use. Second is that only the first floor is for commercial use and other floors still use as housing. Third is that the whole building is for commercial use. The residential building internal space was segregated because different functions needs different kinds of space and users' needs are diverse.

As a result, segregated living space brings separated social connection. Especially, there are conflicts between the first floor users of restaurants or bars and the second floor local residents. What's more, due to the internal space of residential building was used as non-residential functions, the space residents used to associate with others has changed (Figure 6-B). More specifically, the main lanes and secondary lanes used to be main space for residents' communication, but now used for visitors. Besides, the new cross-street building links are built for tourists. Finally, residents' lives are disrupted and the community social connection are separated.

Figure6 Segregated living space in Tianzifang

3.4 Commercial space sprawl

Driven by maximizing benefits, local residents and less profitable creatives moved out the neighborhood and commercial space sprawled (Figure 7-A). The commercial area used to be along the street, but with more leisure and lifestyle businesses brought into the area, it occupies almost half of the neighborhood now. Mixed commercial and residential areas bring a lot of social problems because of the way in which space is used.

First, when the old building has a new function, the users do not change the structure of the building, only divided internal space and decorate it (Figure 7-B). The space reshaping changes people's behavior. Second, the commercial functions not only change the internal space of old buildings but make courtyard a place for tourists' entertainment (Figure 7-C). What is controversial is that the courtyard used to be a public space, but now become more proprietary. The space reshaping affects the daily life of residents and leads to the disappearance of original scenes of the local neighborhood. Third, the new businesses usually grow on the old buildings and occupy as much outdoor space as possible to make more profits (Figure 7-D). There are five common ways in which new businesses grow on the old building including arrangement of outside stalls, outside seats, glass boxes, cross-street buildings and porches. The space reshaping leads to conflicts between tourists and local

residents because the public space is crowded with too many tourists that local residents have no space for their daily lives.

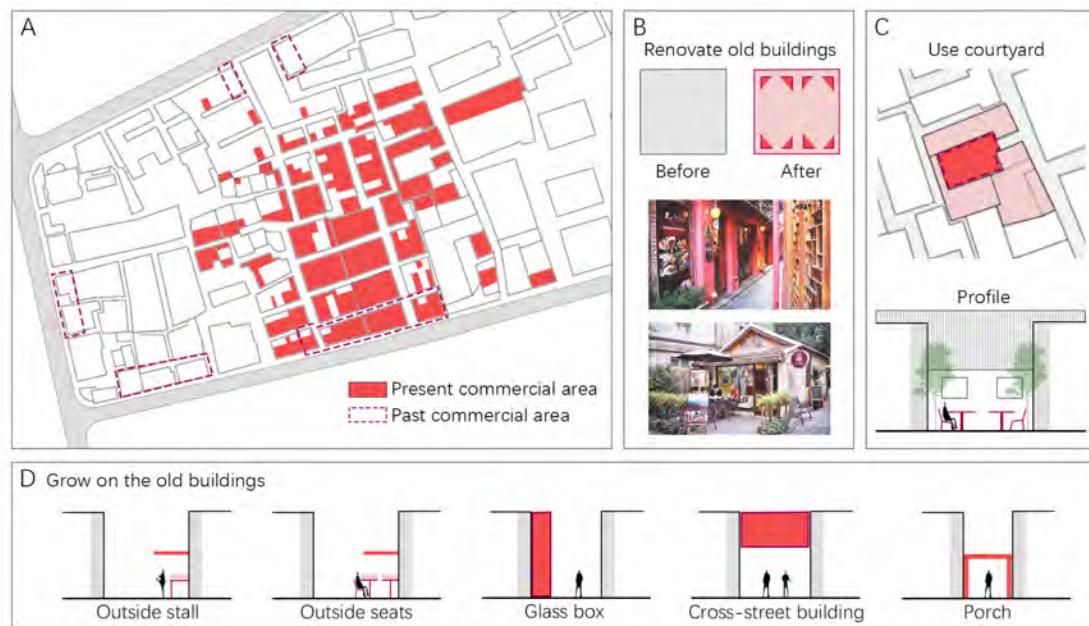

Figure7 Commercial space sprawl in Tianzifang

3.5 Privatized public space

Public space should be open to everyone, but with the further development of the gentrification process in the area, public space has become privatized. Commercial space invades more and more public space and uses it as its own space causing three main problems.

The first problem is that disappearance of neighborhood lives. The privatization of public space is reflected in the commercialization of laneways and courtyard which used to be the places residents lived in and communicate with each other. As a result, the traditional local neighborhood lives are disappearing and neighborhood relations gradually drift apart and the local residents face the risk of being marginalized. To a certain extent, it confirms the typical representation of "class substitution" in the theory of gentrification (ZHANG Juan and WANG Maojun, 2017)

Secondly, the privatization of public space brings mutual interference in the use of diverse spaces. First of all, the living space of local residents is affected by tourists. Secondly, the scope which visitors can visit in is affected by local residents.

What's more, the privatization of public space causes neighborhood security risks. First is the lack of patency in laneways. People who lived on both sides of the street used to observe the behavior of strangers making this area safe. What's more, the privacy of neighborhood life is destroyed and the residents' lives cannot as safe as before.

4. Conclusion

The attraction to the leisure and lifestyle business of Tianzifang leads to a population gentrification and because different people have diverse space use characteristics the space have been reshaped during the gentrification process. There are five main driving forces that reshape the space (Figure 8).

First, space consumption and experience need of tourists. Second, space competition and privatization need of businesses owners. Third, space renovation and defense need of local residents. Fourth, space renovation needs of creatives. Last but not least, space control and guidance of local government. As a result of five main driving forces, the space has been reshaped and show new characteristics including reserved space structure, mixed functions, segregated living space, commercial space sprawl, privatized public space.

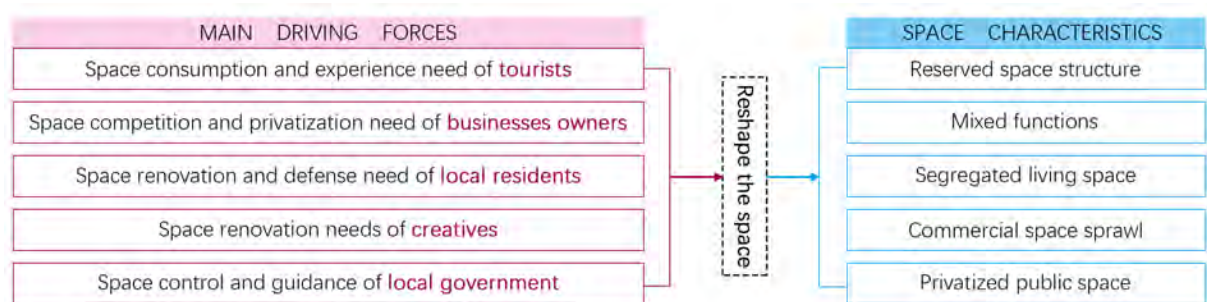

Figure8 Space reshaping process

Under the global symbolic economic, cultural production and innovation displace material production (Zukin, 1995). The space of creative cluster will be reshaped during the globalization process, and coordinating the relation among diverse stakeholders will be the key to promote transition of urban space and maintain social justice.

Acknowledgements

The author would like to take this opportunity to thank a number of classmate who have offered invaluable assistance in the preparation of the investigation. Secondly, I would like to express my heartfelt thanks to all the professors and teachers whose insightful lectures have well prepared me for the completion of the thesis.

Privatization, Marginalization and Reuse of Waterfront Space in New Town——Taking Zhangjiang Science City Zhongshi Unit as an Example

Abstract: In the past ten years, China has ushered in a new era of urban development. The urban renewal project has gradually changed the original urban pattern. In the suburbs, the construction of new cities has replaced the old towns and formed two types—an industry-led new towns and life-oriented new towns. The Zhangjiang area is one of the earliest industrial zones in Shanghai. It is currently in an important period of transition from industrial zones to the urban area. The comprehensive improvement of scientific research capabilities, living environment and urban vitality is its development goal. The long-term industrial development has led to the relatively closed industrial parks in the Zhangjiang area. The high-end communities have been built everywhere but the supporting facilities are insufficient. This has led to the emergence of city-industry separation, and separation of jobs and residential in the Zhangjiang area. These problems are particularly prominent in the Zhongshi units. In the process of building a fast new town, Zhangjiang Old Town, which was originally water-based, gradually declined, and was replaced by a new town with roads as the development axes. Planners used modern and mature design methods to design high-end residential communities and spacious car roads, but also brought public space with no vitality. Taking the Zhongshi unit of Zhangjiang Science City as an example, this paper first analyzes the existing characteristics of public space, and takes the waterfront space as the research focus. It is found that the waterfront space is characterized by privatization and marginalization. After that, some urban design method was used to redesign the form of waterfront space, function, and relationship with the surrounding area in order to realize the reuse of the public space.

Keywords: waterfront public space; urban renewal; privatization and marginalization;
Zhangjiang Old Street

1 New town development model and existing problems

1.1 Two models of the development of China's new town

With the continuous development of China's economy, the urbanization process is also accelerating. In 2018, China's urbanization rate is close to 60%, and the city is undergoing rapid changes and transforms. In the core area of the city, the urban renewal project with the main contents of comprehensive renovation, functional change and demolition and reconstruction of existing buildings, infrastructure, public facilities, streets and environment is changing the original urban pattern (Chen, 2019). Tianzifang, Xintiandi in Shanghai and other urban traditional street reconstruction projects have become a model for urban renewal in the country. Due to the expansion of the city's scale and the need for development, there is no land and space for urban development in the city center or the old city. As a result, various new town and new district planning and construction projects have been carried out across the country to meet the needs of industrial development or urban population expansion.

New town or new district is a relatively independent unit planned for political, economic, social, ecological and cultural needs(Feng, 2015). After more than 30 years of construction, China's new town and new district has formed a huge and complex system. There are many types and development models of new urban new districts. Many new town developed from industrial parks have become important economic growth poles besides the core areas of the city. Due to the rapid development of the new town, it is also facing problems such as city-industry separation and lack of vitality. The development model of the new town needs to be transformed. The relationship between industry and urban space has always been an important issue in the development of new towns in China. The problem of city-industry separation has seriously restricted the healthy development of cities. Scholars have conducted in-depth research on the phenomenon , the classification and causes, and the path of city-industry integration. At present, China's new town and new district can be divided into four categories: residential new district, industrial park, high-speed rail new town and science and technology new town(Yang and Lin, 2017). Its development model can be classified into the following two situations.

The first is new town formed by industrial agglomeration, represented by industrial development zone. Most of the industrial development zones are located in the suburbs, relying on the construction of industrial parks to form industrial clusters, and promote the economic development of the new town. In terms of space, large-scale closed spaces such as factories and parks have gradually replaced the more densely populated old towns and farmland. People live

in places with good housing conditions and supporting facilities in the city center, and only work in the new town during the day. Second, new town relying on opportunities such as high-speed rail with the residential area is the main function. In order to share the population pressure in the city center, large residential areas are built on the edge of the city or in the suburbs. Lower prices and larger space meets the housing needs of people working in the city center. However, there are certain problems in the current two development models. The new town with industry as its main function cannot provide supporting service facilities. The new town with residential function as the main function lacks industrial support. It will be less attractive to talents, so the ability to absorb the population is limited. The space differentiation between jobs and residences causes the industrial park to become a "ghost town" at night, and the strange phase of the residential area becomes "empty town" during the day. It leads to the lack of vitality in the city and the low sense of identity of the crowd.

1.2 Development and transformation background of Zhangjiang area

Zhangjiang High-tech Zone is located in the center of Shanghai Pudong New Area, adjacent to Lujiazui Financial Center and Shanghai Disneyland (Figure 1). Since the establishment of the Zhangjiang Hi-Tech Park in 1992, it has experienced the development phase of the exploration period (1990-1999), the incubation period (2000-2005), and the development period (2006-2011), and entered a new era of transformation (Wang and Huang, 2013). After the implementation of the "Zhangjiang" policy in 1999, a large number of high-tech industries gathered in Zhangjiang. The area of the park continued to expand, and the industrial functions were further strengthened and improved. It became the vitality point of the economic development in Pudong, and its influence continued to expand. In 2011, Shanghai was approved to establish China's third national independent innovation demonstration zone, and named after Zhang Jiang. The word Zhang Jiang has become synonymous with Shanghai's high-tech development, and Zhangjiang region has entered a new era of transformation and development.

In 2017, the "Zhangjiang Science City Construction Plan" was approved (Figure 2). The plan is based on the original Zhangjiang High-tech Industrial Development Zone. The area is increased to 94 square kilometers, and a science city integrating production and urban space is to be established. With the concept of open agglomeration, integration of diversity and green communication as the planning concept, the transformation and development of Zhangjiang Science City will become the creation place of new knowledge and new technology in China and the world, the breeding place of new industry, modern new livable city and municipal public center. And built into a world-class science city.

Figure 1 Zhangjiang Science City Bitmap

Figure 2 Land Use Planning of Zhangjiang Science City Construction Planning

1.2 Main problems in the construction of new towns

Zhangjiang Science City began construction in the 1990s. Planners use advanced planning concepts and design techniques to design clean, modern and urban areas. However, in the past 30 years of, some contradictions and problems have been exposed. The livability and vitality of the new town have not met the vision of the government and planners. The Zhongshi unit is located in the north of Zhangjiang Science City. It is the earliest developed unit in Zhangjiang area. The northwest corner of the unit is an industrial park, the east is a large-scale residential area with mature and mature construction, and the southwest corner is a newly-planned software park. It presents a pattern of intertwined collages between residential areas and

industrial areas. From the perspective of the Zhongshi unit, the main problems reflected in the new town include the following aspects.

First, the industrial park area and the residential area are relatively independent and the supporting facilities are insufficient. The density of public service facilities in residential areas is enough but unevenly distributed, lacking comprehensive hospitals and cultural and sports venues. Second, the road is wide but not suitable for walking, which makes it empty. Each urban cluster has a fence, which is closed to the public. People mainly work in residential areas or work inside industrial parks. The street only bears the traffic function. Although there are walking and running lanes, there is no corresponding supporting function on both sides, and the road is too wide, the radius of the turn at the intersection is large, causing people to lack the desire to travel. Third, the ecological base is rich, but the accessibility and continuity are poor. The landscape function of the green space is greater than the public activity function, and it is not systematic. There is a fault zone in the waterfront activity space. Fourth, ignore the inheritance of historical context. The old town of Zhangjiang are damaged, the intangible cultural heritage lacks the space carrier, and the emerging culture lacks the output platform and space.

2. Introduction to the water environment of Zhangjiang Old Street

2.1 Impact of urban development on river systems

The Yangtze River Delta is a typical plain river network area. The water system of the Pudong New Area is vertical and horizontal, with a typical Jiangnan water town style. The water system and the town are interdependent. As an important part of the urban public space, the waterfront space can not only improve the urban micro-environment, but also improve the environmental quality. It is also a public place for residents' activities. In the planning of the new town, the planning of the waterfront area is a key design area to display the image of the city. The dynamic waterfront space design can drive the economic development of the surrounding area and become a symbol of the region. However, the construction of the new town is often accompanied by the destruction of the original river network. In the construction and development of the Zhangjiang High-tech Zone, in addition to the rivers or main streams in the center of the city are preserved and redesigned, many tributary water systems are landfilled into roads or the construction of the park. The original farmland was requisitioned, and the water environment of some water systems was also invaded by industrial pollution, causing the river network to shrink and the water surface rate to drop. Bai Yiqin (2010) compared the land use and water system remote sensing data and water environment quality in Pudong New Area over the years, and found that with the acceleration of urbanization process, the length, area and

quantity of river network decreased. Small and medium-sized rivers and village-level rivers disappear faster. In the central urban area, the network is relatively systematic, while the river network in the urban fringe area maintains the original natural form. (Figure 3).

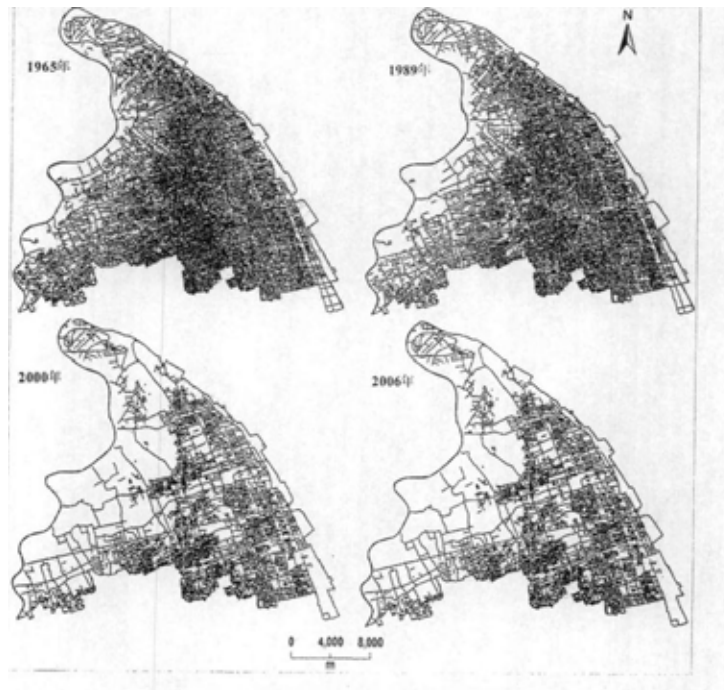

Figure 3 River network changes in Pudong New Area from 1965 to 2006(Bai, 2010)

2.2 Water resources around Zhangjiang Old Street

There are many rivers in the Zhongshi unit. The main two rivers, Majiabang River and Lvjiabang River cross in the middle of the unit (Figure 4). The river from west to east is the main traffic in the hinterland of Pudong. Transporting waterways, nowadays, has lost its transport function and has become a landscape river. The north-south Majiabang River was dilapidated and digging through the original Libang channel. In addition, there is a river called Taohe passing through the east of the unit. The river sets the Majiabang River and Lvjiabang River together in the interior of the block to form a ring structure.

Figure 4 Existing river in Zhongshi unit

The intersection of the two rivers of Majiabang River and Lvjiabang River is the location of Zhangjiang Old Street. Zhangjiang Old Street is a spontaneously formed market town formed during the Ming Dynasty (1567-1572). It retains the longest historical memory in the Zhangjiang area and the original spatial pattern of the Jiangnan water town. The old street extends along the east and west sides of Lvjiabang River, and the enclosed courtyard space is arranged in layers to form a deep spatial feature of the courtyard. A main street is set up in parallel with the water system to form a house-street-river spatial pattern. A number of lanes are perpendicular to the water system and extend to the bridgehead, the water system intersection, and the intersection to form an open space (Figure 5).

Figure 5 Zhangjiang Old Street courtyard and water street space pattern

3. The role of waterfront space in the change of Zhangjiang Old Street

Up to now, the surrounding area of Zhangjiang Old Street has been replaced by modern industrial parks and residential buildings, and the construction of new town is still in progress. Zhangjiang Old Street is also facing demolition, and some indigenous people have left their long-term residence. In the process, Lvjiabang River transformed from the original main

transportation channel into a landscape river channel, and the waterfront space was transformed from a lively and energetic public space to a place where no one cares. From a historical point of view, the change of Zhangjiang Old Street witnessed the entire process of industrial park development changing the old market town space.

3.1 Late Ming dynasty to the Republic of China: prosperous period

The history of Zhangjiang Old Street can be traced back to the Ming Dynasty. It is said that there are two phoenix trees on both sides of Lvjiabang River. Therefore, the old name is Gutongli. During the Longqing period of the Ming Dynasty, there was a man named Zhang Jiang who opened a ceremony here. He built a fence as the boundary between the east and the west, so it was named "Zhangjiangzha". At this time, the river channel is the main means of transportation. Both the cargo ship and the passenger ship to and from the sea and Shanghai have to transport each other through the rivers. As one of the main transportation waterways in the hinterland of Pudong, the Lvjiabang River has frequent commercial trade on the river. Zhangjiang Gate has also developed as a major market town along the Lvjiabang River. By the time of Qing Emperor Qianlong, Zhangjiangzha had formed a commercial market town with more than 200 shops. The number of households exceeded 1,000, and it formed a 100-meter-long east-west street and a north-south street and sugar shop across the Lvjiabang River. Street (Figure 6). By the time of the Republic of China, Zhangjiangzha was already a major town in the northern part of Nanhui County, and a water and land transportation hub, known as the "North Gate Key." Until the 1950s, Zhangjiangzha has always been a commercial and trade center in the district. The waterfront space is mainly commercial activities. The merchant ships that come and go are docked at butou for loading and unloading goods. There are many shops, tea houses and pubs on both sides. The commercial atmosphere is strong (Figure 7). It can be said that ZhangJiangzha has developed and expanded by relying on the transportation of the Lvjiabang River River. The waterfront space is the most popular public space in Zhangjiangzha, and it is also the place where people interact and trade.

Figure 6 The whole territory of Nanhui County, Qianlong, Qing Dynasty

Figure 7 Zhangjiang Old Street Historical Image (1948)

3.2 After liberation: privatization of space brought about by the transformation of functions

After the founding of New China, with the start of the economy, a large number of urban construction activities occurred frequently. Chinese cities entered a stage of rapid development. Due to the change of transportation mode, land transportation has gradually replaced water transportation and has become the main mode of transportation. A large number of roads were built, and influenced by the traffic location, commercial and other public functions began to gather on the road. In Zhangjiang, the new town center was established on the west side, and the shops concentrated on the roads, forming a pattern along the ZhenXixin Street, Chuanbei Road, and Zhangjiang Road (Figure 8). The original commercial functions of Zhangjiang Old Street were gradually replaced into living spaces. Old Street lost its status as a core city and became a town dominated by residential functions. This process is spontaneous and not government intervention. Since 2000, Guanglan Road

has been constructed, and Zhangjiang Old Street has been divided into two parts (Figure 9). The old street of Zhangjiangzha has entered a decline period. The functional changes on both sides of the river and the decline of water transport have also made the riverside space The original commercial vitality space has been transformed into a living space for residents.

With the improvement of people's quality of life requirements, the living conditions of Zhangjiang Old Town are becoming more and more crowded, and the waterfront space is showing a trend of privatization. In the period of our investigation, the aborigines have not yet fully moved out, and we can see the imprint of life that has been preserved on both sides of the river bank. Some illegally built sheds extended from the residential houses to the river banks. The fences blocked the waterfront roads. The riverside stood many poles for drying clothes, and it became the home of the residents on both sides of the river.

Figure 8 Zhangjiang Old Street Historical Image (1948)

Figure 9 Zhangjiang Old Street Historical Image (1948)

3.3 The construction period of the new town: the marginal space in the development of the new town

Since the 21st century, urban construction in Zhangjiang has entered a stage of rapid development. As mentioned above, the changes in the river system of Pudong New Area have also been staged around Zhangjiang Old Street. Now the water system around Zhangjiang Old Street faces the following problems, affecting the vitality of waterfront space.

First, the tributary water system lacks management and the waterfront space is poorly accessible. On the south of Zhangjiang Old Street, there is a river that runs through Pudong New Area and is 28 kilometers long and about 70 meters wide. It is also one of the main main streams in Pudong New Area. The city-level public service center will be built on both sides of the Chuanyang River. The implantation of science and technology and public service functions will greatly stimulate the vitality of the riverside space on both sides of the Chuanyang River. The Zhongshi unit where Zhangjiang Old Street located is in the northern part of Science City. Its status and role are much lower than those on the banks of the Chuanyang River. The tributary water system such as Majiabang River is neglected, the river channel is narrow, and some riverside landscapes are poor and lack of management. In addition, due to the complex property rights on both sides of the Lujiayu River and the Majiabang River, the public shoreline has not been integrated into unified management and planning. Most of the shorelines are in a closed management mode and are not open to the public (Figure 10). Besides, the collapse of many river-crossing bridges has not been repaired (Fig. 11). The river banks are filled with domestic garbage and building materials, so the connectivity and accessibility of the riverside space is poor (Figure 12). This is also one of the main reasons for the openness and vitality of the riverside space.

Figure 10 Waterfront space with closed management measures

Figure 11 Bridge collapse

Figure 12 Analysis of the Traffic Situation between Ma Jiazhen and Lu Jiayu

Second, the river bank line is simple and lacks design, and the waterfront space is difficult to get close. Take the Majiabang River River passing through Zhangjiang Old Street as an example. The south side of the eastern section of the river is Guanglan Park. Combined with the streamline design of the park, the walkway and the hydrophilic square are set up in the waterfront space, and the space is relatively open. On the other side of the Guanglan Park, the embankment is relatively simple, with fences as the mainstay. Although the passage space of the old street waterfront was preserved, it was undesignated and the vegetation was overgrown, which made it impossible to get close. In the important urban core area, the waterfront area is a place where vitality gathers. But in the non-core area such as Zhangjiang Old Street, the waterfront space exists only as the “back of the street”, and the waterfront space is neglected and becomes the edge of the city. (Figure13, Figure 14).

Figure 13 The difference between the two sides of the Majiabang River River is obvious

Figure 14 Straight shoreline with vegetation

4. Design strategies of waterfront space: reuse and vitality

In order to preserve the spatial pattern of the water town of Zhangjiang Old Street and enhance the vitality of the waterfront space, we designed the area around the cross-shaped river formed by the Lujiayu River and the Majiabang River, covering an area of about 33 hectares. A design response strategy is proposed for the waterfront space. The land includes Zhangjiang Old Street and some Zhangjiang Townships built after the 1990s. Existing buildings are dominated by industrial, residential and businesses. It is hoped that through the planning of space design techniques and theme functions, the waterfront space of Zhangjiang Old Street will be activated, thus driving the regeneration and development of the entire area.

4.1 Public function is concentrated in the river

Science and technology is the eternal theme of the development of Zhangjiang area. In the vicinity of the design scope, there are software parks based on R&D and innovation, as well as industrial parks that focus on parts processing and manufacturing and have future transformation and upgrading needs. However, there is a lack of places around the base for R&D personnel to rest and exercise. In addition, the surrounding cultural atmosphere is relatively strong. Zhangjiang Drama Valley, Zhangjiang 368 Cultural Industrial Park and

Changtai International Cultural Center are located in the Zhongshi unit, but these cultural industries lack a platform for export and publicity, resulting in insufficient influence. Therefore, we consider implanting technological innovation and cultural creativity related functions in the base to gather public functions to the river. The waterfront space serves as a space carrier for the external display and activities of the creative experience function, and promotes the regeneration of the riverside space with diversified functions.

Create a common core of science and technology at the intersection of rivers. The Chuangzhi Square, the Game Interactive Hall, the Comprehensive Experience Hall, and the Binhe Park are arranged around the river intersection to form a public activity center. The Chuangzhi Square on the west side is the main place for undertaking various kinds of performances. It is also a place for residents and researchers to exchange and gather. In combination with the outdoor space of the Exhibition Center, various technology product launches, creative markets and roadshows can be held. It is also a great place for watching the waterfront landscape. The north and south sides are equipped with small-scale buildings, which is a continuation of the old street texture. They allow small and micro enterprises to interact and experience offline and attract people. On the east side, a riverside park was designed as the most concentrated public space in the entire area, allowing busy people to relax and enjoy the natural beauty after work.

On the east side of the science and technology public core is the reserved Zhangjiang Old Street area, along the river to form a waterfront business district based on casual dining, and join the retail, experience, old street memory hall and other functions. Further to the east is the commercial service and leisure area formed by the Guanglan Road subway station. While continuing the function of the old street, it also adds functions such as parent-child activities, shopping and entertainment, and provides corresponding supporting facilities for the surrounding communities. On the west side of the science and technology public core, the current building quality is good. The main problem is that many closed blocks are formed due to the barrier of the wall, and there are more negative spaces. Therefore, the micro-update method is adopted to sort out the stock space, and the waterfront landscape is infiltrated into the area, and sports activities facilities and leisure plazas are arranged in places with large space as places for residents' activities.

Three theme routes are planned, which are the Old Street Discovery Tour, the Kechuang Experience Tour, and the Leisure and Recreation Tour. The public nodes besides River are connected in series to create a communication place (Figure 15).

Figure 15 Theme tours and public events

4.2 Reconstructed River Street Space

Due to the acceleration of the construction of the new town, the original river street space of Zhangjiang Old Street has been destroyed, and the modern waterfront space is obviously not suitable for this historic land. By combing the existing architecture and space texture, we summarize the past river-street relationship of Zhangjiang Old Town based on historical images, hoping to rebuild the river street space and continue the traditional space pattern of the old street. According to the existing building quality, the buildings that need to be demolished and can be reconstructed are selected, and new buildings are implanted to bury the damaged space. The original space texture of the old street is restored and continued. Some of the waterfront space design direct waterfront commercial interface, enhance the accessibility of the waterfront space, and form a continuous pedestrian street on both sides of the river bank. Thus, a building-street-river-street-building spatial relationship is rebuilt(Figure 16). The bridgehead is designed with a relatively small open square to form a small public node in the neighborhood. The riverside combines commercial buildings to form a good leisure and commercial space. The outdoor teahouse and viewing platform are set up to reshape the traditional watertown atmosphere.

Figure 16 Spatial relationship of river and street in Zhangjiang Old Street

4.3 Shoreline design for different people and functions

The waterfront space adopts a differentiated design approach to the functions of both sides of the river to create a variety of waterfront space forms and meet the needs of different groups of people. The shoreline can be divided into four sections according to its functions: the living section on the west side, the river intersection section, the Zhangjiang Old Street section, and the Guanglan Park section.

The living section on the west side: the riverside is dominated by talent apartments, commercial and residential areas, and the living atmosphere is strong. The riverside creates a community atmosphere and increases the space for residents to do some activities. The original single straight shoreline is partially widened to form a multi-layer retreat, and a continuous two-story water walkway is provided in combination with the two sides to provide a venue for fitness, leisure, and community activities (Figure 17, Figure 19).

Figure 17 Waterfront perspective of the living section on the west side

The river intersection section: At the intersection of the two main rivers-Majiabang River and Lvjiabang River, it is the most crowded place for crowds. Therefore, it is necessary to design a shoreline with a high degree of publicity to provide outdoor activities and make full use of the waterfront. The landscape creates a vibrant and open atmosphere. Design a shoreline form that is open to the surface of the water, and maximize the provision of a hydrophilic space by adding sunken plazas, waterfront terraces, and stepped slopes. Part of the waterfront building has a roof garden that provides a rich view space in the vertical direction (Figure 18, Figure 20).

Figure 18 Waterfront perspective of the river intersection section

Figure 19 River section of the living section on the west side

Figure 20 River section of the river intersection section

Zhangjiang Old Street section: There are many commercial buildings on both sides of the old street, and the shoreline has been redesigned. When the street is indirectly facing the river, it is completely open space. When the building is directly facing the water, the street is a semi-open space on the inside and becomes the backyard of the waterfront shop. The two ancient bridges, Zhong'an Bridge and Taiping Bridge, are restored, and the landscape and the directly hydrophilic steamed buns are intertwined to form an ecological and artificial mixed coastline. The traditional waterfront forms such as Shantou, plank road and wooden bridge are used to

link the waterfront street with the Lvjiabang River. The riverside space occupied by the residents is designed to open to the public, forming multiple riverside parking spaces and reshaping the atmosphere of Zhangjiang Old Street. (Figure 21).

Guanglan Park section: The south bank of the Majiabang River on the east is Guanglan Park. The landscape resources are good and the flow of people is dense. It is in stark contrast with the landscape on the north bank. The waterfront space between the two sides lacks contact. Design a waterfront revetment that is partially open to the river and form a contrast with Guanglan Park. The tour line in Guanglan Park is also close to the river. The hydrophilic platform is added to the narrow river. People can directly enter Guanglan Park from the north side, which also enhances the accessibility of Guanglan Park and the radiation capacity to the surrounding area. (Figure 22).

Figure 21 River section of Zhangjiang Old Street Section

Figure 22 River section of Guanglan Park section

4.4 Pay attention to walking space

The entire area requires people-oriented, paying attention to the walking experience and weakening traffic. The internal roads are dominated by narrow urban roads, and landscape and lifestyle roads are preferred. The two main rivers are the main open space streamlines, extending the public corridors, connecting the Guanglan Park and the Zhangjiang Theme Park on both sides, and infiltrating into the surrounding areas to increase access to the waterfront space to form a public space network(Figure 23).

Figure 23 Walking space system

5 Conclusion

Zhangjiang Science City is an outstanding representative of the construction of Shanghai new town, but there is still a phenomenon of low vitality in the north, and there are problems such as insufficient supporting facilities, lack of street life, unused waterfront space, and destruction of cultural memory. This reflects the lack of humanistic care and quality in the planning and construction of the new town. Zhangjiang Old Street bears a long history of Zhangjiang area, and the change of its waterfront space reflects the change of urban construction to the spatial pattern of old towns. Through field research, we found that the waterfront space in the Zhangjiang Old Street area currently has problems such as poor accessibility and simple bank line, which leads to the lack of waterfront space vitality. In view of the above problems, we proposes a redesign of the waterfront space with four strategies as follows: public functions to be concentrated in the river, shoreline design for different people and functions, and pay attention to walking space. We hope it can activate the entire Zhangjiang Old Street and even the Zhongshi unit.

PRELIMINARY STUDY ON THE RENEWAL STRATEGY OF THE NEW ESTATE FOR WORKERS : FROM THE PERSPECTIVE OF PLACE-MAKING

Yuwei ZHANG

Tongji University, College of Architecture and Urban Planning, happpyzyw517@163.com

Abstract: Public spaces could be the embodiment of urban culture, as well as the collective memory of the neighborhood residents. In the context of China's urban development transitions, paying progressive attention to quality improvement, this paper selected representative “the new estate for workers” in Yangpu District Shanghai, which providing to workers in the past planned economic system. From several aspects, such as “quantity, order, surface and shape” analyzing the site's physical spatial feature, founding that it faced the drawback of “old, worn, isolated and lack” in the development .Meanwhile from the perspective of place-making, exploring unique opportunities and resources related to the collective memory. Eventually, this paper proposed its spatial and environmental design update strategy in terms of “recall, live, experience and link”

Keywords: the new estate for workers; update strategy; public spaces; place-making

1 Introduction

In the 1950s and 1960s, when Shanghai experienced socialist transformation, a large number of “the new estate for workers” were built, because it showed the superiority of socialism on the one hand, and on the other hand, “the role of urban productive functions” requires the active participation and input of the working class (Luo Gang, 2007). Then, in order to comply with the development of China's different transition periods, the industrial upgrading and migration has received enough attention, but the “the new estate for workers” and other renovations have not been paid attention. At present, China's urban construction has gradually changed from quantitative expansion to qualitative improvement. Urban renewal as an inevitable stage and major challenges of urban development, the important connotation of high-quality development is urban quality and urban experience. In the post-industrial era, the construction of creative cities guided by human resources needs to bridge the fragmented social space and use the construction of old communities as a mean to improve the quality of urban public space to cause residents' spontaneous activities.

The quality of life of the old workers living in the new estate for workers has not improved. It is especially important to propose a space environment renewal strategy, to restore the life function of the streets and implement kind of culturally oriented urban renewal. The community as the basic unit needs to activate its innovation elements, update infrastructure and service supply requirements, and

provide more incubation space for the overall spatial and functional replacement of the "re-industrialization strategy" of upgrading the creative industry in Shanghai.

2 Lot analysis - quantity, order, surface, shape

2.1 Quantity: Spatial scale and scope

This article takes the example of the “Kongjiang Village” in Yangpu District, Shanghai, which is located on the northeast side of the central city of Shanghai, between the Inner Loop and the Central Loop, about 2km away from the Wujiaochang area, one of the Shanghai sub-centers (As seen in Figure 1). The scope of this study is from Songhuajiang Road in the north, Kongjiang Road in the south, Yingkou Road in the east, and Huangxing Road in the west. The total area is about 1.1km² . Within the scope, there are 14 residential areas in the form of “the new estate for workers” such as Kongjiang Fourth Village, Kongjiang Second Village, Kongjiang Fifth Village, Kongjiang Third Village, and Kongjiang First Village . Each district is almost 5-17ha, basically belongs to the layout of small neighborhoods (As seen in Figure 2).

Figure 1: Study area location map

Figure 2: Study area division map

The main roads in the study area include the Jingyu Middle Road, Yanji Middle Road and Yongji Road in the West-East way, and Jingyu South Road, Cangzhou Road, Shuangyang Road and Yongji Road in the South-North way . The width of Jingyu South Road and Jingyu Middle Road is about 10-12m, the width of Cangzhou Road and Yongji Road is about 12-14m, and the width of Yanji Middle Road and Shuangyang Road is about 15-18m (As seen in Figure 2 and Figure 3).

Figure 3: Field research photos

The top [from left to right]: Jingyu South Road, Jingyu Middle Road, Cangzhou Road

The bottom [from left to right]: Yongji Road, Yanji Middle Road, Shuangyang Road

2.2 Order: Spatial texture and order

Spatial texture and order is a manifestation of the localization characteristics of this area in the historical dimension. There are many residential forms in the study area. For example, "the new estate for workers" housing mainly in the form of patches for multi-storey buildings determinant layout and high building density from the architectural texture analysis. The other residential building types are mainly high-rise point layouts with low building density. Meanwhile, although the area dominated by some public facilities is mainly low-rise, the building covers a large area. Overall, the compactness is not high, and only the layout of the building is considered. The consideration of the external space environment is insufficient, and some public facilities also cause the mutation of the texture in the lot (As seen in Figure 4).

Figure 4: Texture analysis of the relationship between architecture and space

2.3 Surface: Spatial organization and interface

Starting from the spatial organization of different functions within the scope of research, the overall living space is mainly equipped with educational facilities, ministrant facilities, medical facilities and living and commercial facilities. Among them, the living space can also be divided into three different levels, the new estate for workers built in the 1950s and 1960s, the multi-storey residential quarters built in the 1980s and 1990s, and the high-rise housing buildings built after the 21st century in gated community . From the perspective of space and street interface, although there are many urban roads in the scope, the whole section is divided into 14 small neighborhoods, but the overall interface continuity is not high, and the road is only used as the skeleton of the division space. The east-west way road and street commercial interface creates a good vibrancy atmosphere, but the south- north way road is slightly insufficient due to the residential layout .(As seen in Figure 5)

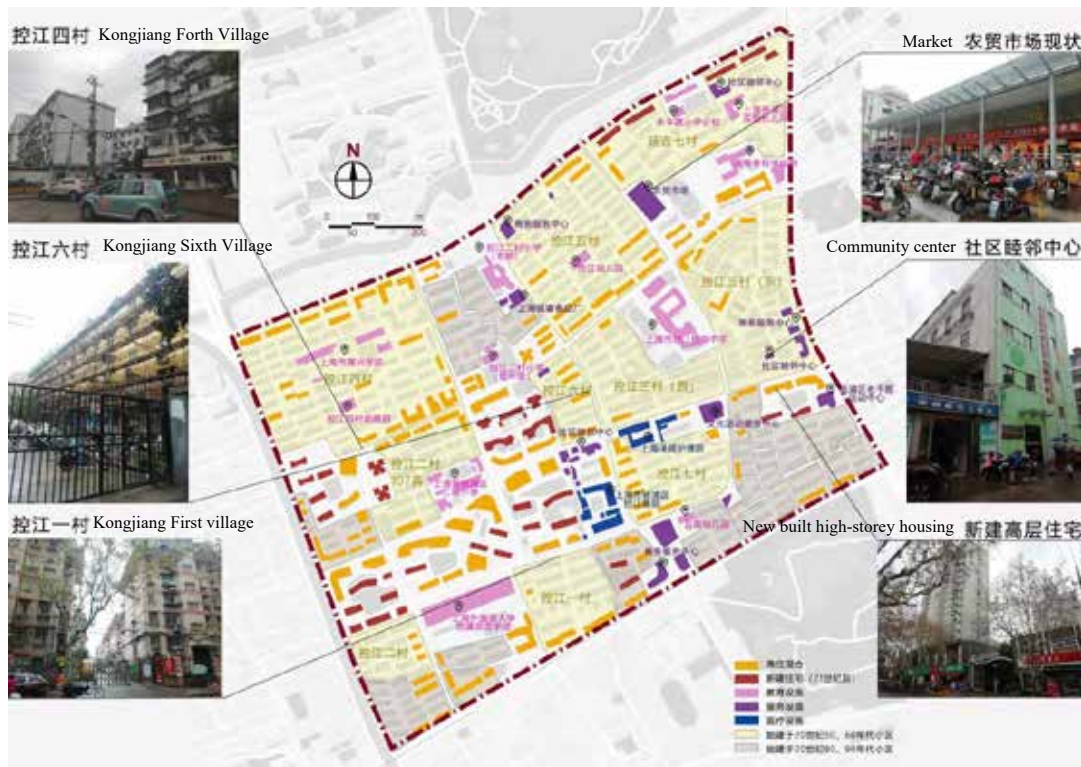

Figure 5: Spatial function organization analysis map

2.4 Shape: Spatial form and streamline

The spatial form is, to a certain extent, a microcosm of the era. As time goes by, the overall spatial form as a local continuation can also reflect the characteristics of the times. It can be seen from Figure 6 that most of the houses built before the 21st century are mainly low-rise and multi-storey, and their architectural forms constitute the main spatial form within the scope. However, with the development and construction of the real estate market, some gated communities have appeared. It appears in the high-rise point or plate form in the section, resulting in a morphological feature of overall disordered chaos.

Figure 6: 3D map of buildings and spaces forms

After excluding the educational facilities, the medical facilities, and the newly-built gated communities, it can be seen from the analysis of open pathways district 3, 8, and 14 have high connectivity with the surrounding roads, and the connected roads are not interrupted by the above-mentioned land use ; but district 4, 6, 7, 10, and 11 are occupied by the above-mentioned land use, resulting in poor connectivity. From the perspective of open green space, there is little room for residents to open up and use, and there is a shortage of open space. At present, two examples can also be seen that there are few people in use and insufficient space for activities (As seen in Figure 7).

Figure 7: Open pathways ,traffic sites and open green space maps and field research photos (①on the top right and ②on the bottom right)

3 Problem analysis - old, worn, isolated, lack

3.1 Old: The living population is aging, and the corresponding service system is imperfect

According to investigations and interviews with some office staff, the majority of the residents in the study area are old retired workers from the typical factory, such as the Shanghai cigarette factory, and the average age is about 60 years old; and there are two relatively complete medical facilities in the scope. However, currently it is less suitable for elderly activities in terms of activity space and environment. to meet the diversified needs of the elderly, not only indoor activities, but also outdoor spaces. (As seen in Figure 8).

Figure 8: The elderly are resting in the community service center

3.2 Worn: Buildings, space and environment facilities are worn and have poor livability

Most of the houses within the study area were built in the 1950s and 1960s , at that time ,its kind of the product of company welfare in the planned economy period, even after the 1990s renovation also capped nearly three decades ago, the overall architectural space livable poor . Although some buildings have applied for painting renovation of the facade of the housing, the lack of consideration for the systematic renewal of the residential environment of the urban community, the material space system composed of the building and space environment lacks complete planning and design.

3.3 Isolated: closed space partitions cause social interaction barrier

Due to the construction of a number of closed communities with commercial houses, there are high walls around them to ensure their safety. However, the security and openness of space are always two contradictory features. The physical isolation of material space may even lead to the gradual isolation of neighborhood interactions at the social level (As seen in Figure 9). How to construct semi-public space and semi-private space is a problem that should be considered as a planning designer. From the means of creating space, to reduce the barrier of social interaction, we should provide communication space and platform for the harmonious coexistence of neighborhoods.

Figure 9: Gated residential district entrance signage

3.4 Lack: lack of continuity protection in a unique cultural background

As a microcosm of an era, " the new estate for workers " is an image of a cultural concept and a spatialization of political ideology (Zhang Wei, 2005). How to seek new development in the current era? After research, there are very little response to history in the lot, except for the texture layout of the building and part of the road based the historic layout, the other environmental facilities are lack of consideration of the cultural background, precious historical and cultural resources are lack of sustainability protection and extension.

4 Strategies preliminary - recall, live, experience, link

4.1 Recall: built on the collective memory of the place

When Shanghai pursues a superior global city, history should not be forgotten. In the new development context, more attention should be paid to creating space that echoes historical and cultural memories, considering its unique cultural background and protecting its sustainability. So that residents living in the area have memories have resonance.

Habwah defines collective memory as: "The process and outcome of a member of a particular social group sharing the past. The condition for ensuring the inheritance of collective memory is that social interaction and group consciousness need to extract the continuity of the memory." The construction of the site also provides basic material conditions for the formation and review of memory. The relationship of place identity is also interdependent, providing a material basis for the identification of individuals, society, and even historical memory through the construction of buildings, spaces, and environments (As seen in Figure 10).

Figure 10: Schematic diagram of place identity

After the analysis of the current situation resources, we will construct a site based on collective memory within the scope of the whole research, and try to reorganize the overall spatial structure. For the typical roads, the section

transformation is shown (As seen in Figure 11 and Figure 12). Yanji Middle Road is the main traffic-type road within the scope, and the height of the buildings on both sides of the road section is inconsistent. The strategy proposes to construct a continuous commercial interface and activity interface, to guarantee the continuity of space by constructing a miniature park. While the width of Jingyu Middle Road is narrow, the height and width ratio of the road is close to 1:1, which is suitable for constructing life-type roads, proposing the addition of a characteristic guiding sign system and cross-section processing of continuous activity space. Both transformation methods are to expand the pedestrian activity space as much as possible, so that the vehicle space is controlled to the lowest level. The reference for the miniature park can be found in the reconstruction project of Sujiatun Road in Yangpu District, Shanghai (As seen in Figure 13).

Figure 11: Reconstruction of Yanji Middle Road Section

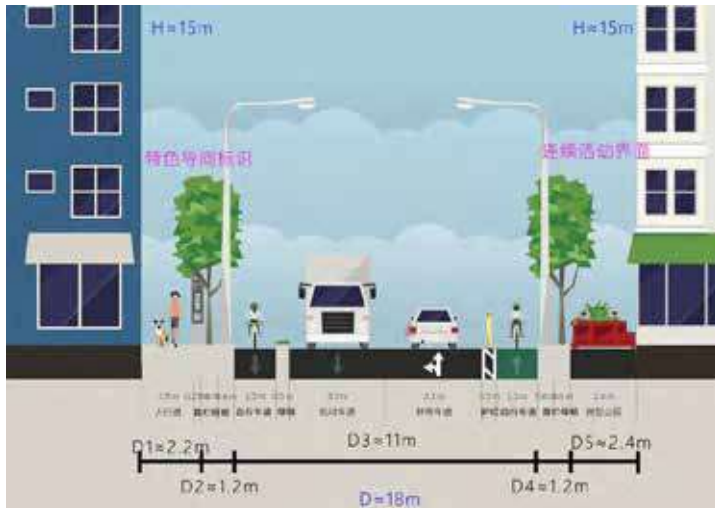

Figure 12: Reconstruction of Jingyu Middle Road Figure 13: Miniature park case

4.2 Live: Networking reshapes the vitality of public spaces

Urban space contains social concepts and human values, which are reflected in the lives of the people in which they live, which can be clearly experienced in the old area of the city (Zhoujian, 1996). How to reshape the vitality of public space, first of all, we can focus on the accessibility of space, put more indoor activities in the urban space, implanting the vitality of the living scene for the city. Meanwhile we should focus on strengthening the external communication of the event space. The road network density of the encrypted open path provides more open space, which is conducive to agglomerating more public activities to enhance the attractiveness of its space. In the strategy, we try to integrate the design of the openable residential area, connect the “communication interaction loop”, and set up the open center of the area in combination with other facilities in each area to improve the accessibility of each service function (As seen in Figure 14).

Figure 14: Spatial structure network analysis

Secondly, the construction of public space can not be renewed from a single location or facility. It should be combined with the dynamic street interface, living area and other linear surface space, taking into account the network reshaping measures from the entire scope to create a compact and continuous space interface. It can help to form the diversity and agglomeration of public life, and consider the diversity of time meaning in the overall order, so that the entire area is full of vigor and vitality. In the strategy, we try to order the main street as a major comprehensive axis, at the intersection of the lot as a core node to create; connecting the Jingyu Middle Road, Jingyu South Road and Yongji Road to create a "*dynamic living loop*" putting to provide comprehensive services to the leisure life of residents; and constructing the Cangzhou Road as a characteristic memory street, build a sample street as a place; building a small "green heart" at each major road node, and adjust the overall network planning to reshape the vitality of the site. According to the author's research, the reconstruction project at Sujiatun Road and Fuxin Road in Yangpu District, Shanghai is worth learning (As seen in Figure 15 and Figure 16).

Figure 15: Fuxin Road Pocket Park

Figure 16: Sujiatun Road Miniature Park

4.3 Experience : Enhance the intuitive feeling of identity and orientation

The mutation of spatial scale and texture will form the spatial identification. Whether it is for the architectural scale or the street space, the attention to the identification and orientation of the construction space can enhance the intuitive feeling of the residents; for example a building balcony , enclosed courtyard or in the life street, event plaza, identify and guide space are based on site-specific feature shape. At the same time, focusing on the construction of the iconic venue can also provide more interesting space in the lot. However, when creating such a space, attention should also be paid to the isomorphism of the local space, following the basic road network or architectural texture, and usually selecting the necessary nodes in the daily life path of the residents, by establishing a visual focus. So that the attractive space landscape is shaped and styled. We can also use design techniques such as color change, height and size contrast to enhance the visual perception of its identification and orientation. At the same time, attention to the establishment of the landmark will not only affect the research scope or even the impact of the development of the lot and the region from a larger scope.

Taking the core node transformation as an example, the current space is divided into three types of typical space (As seen in Figure 17). Space ①, ④ Can be summarized as the surrounding street space for service business, and both of them have the opportunity to create varying space; space ② due at the exit of the bank, at present, the vitality is only poor. Just a kind of street waiting space; space ③ is a rare public open space in the district, but there are fewer people in there because of the lack of interesting and vivid activities. Through the above analysis, we try to propose the following transformation means: considering different use functions, combining a variety of guidance and service facilities in a large space, setting up an activity space, and creating a "mutation" in the space, through color change, scale change. Different facilities are set up , combining with the small scale space, different service facilities add fun to the pedestrian space and increase opportunities for interaction. Small-scale facilities such as newspapers, signs, etc. can be set up in a limited space. (As seen in Figure 18).

Figure 17: The current situation of the core node space of Yanji Middle Road

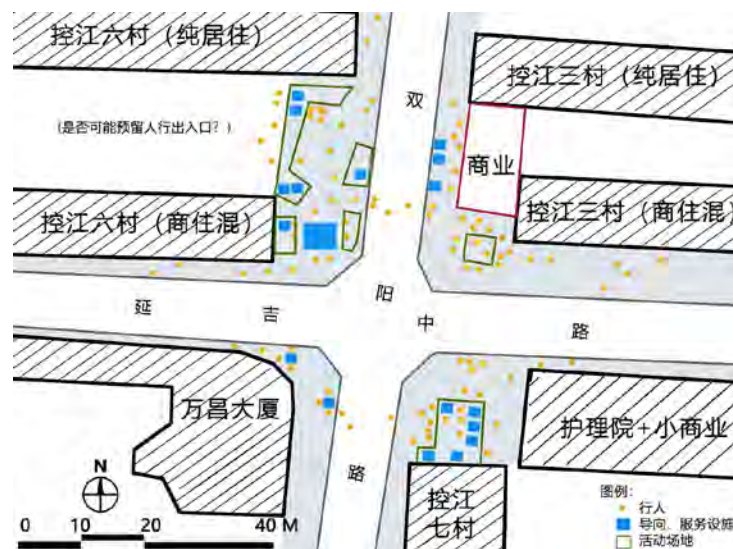

Figure 18: core node space transformation concept map

4.4 Link: Moderately mixed development guarantee smooth Neighborhood Communication

Moderate mixing use and open positive spatial construction are important foundations for building a harmonious neighborhood. Residents living in the same area have the responsibility and obligation to contribute their own homes and create a livable living environment. From the perspective of space, more private and semi-private spaces will be transformed into semi-public and public spaces (As seen in Figure19). Meeting the needs of construction of space environment for different ages people, we can consider the optimization of mixed arrangement of functions such as business, leisure and amusement. Different leisure places providing a platform for effective communication among residents' neighbours.

Figure 19: Space-level hybrid concept map of transformation

We should also consider the streamline of residents' behavioral activities, comprehensively meet their life experience and service needs, and build a public space suitable for their communication based on the scale of people. Usually small- scale space will also give people a sense of security and intimacy, making residents more willing to communicate with each other. In this case, it is based on small-scale public space construction, moderately mixing peripheral service functions, and providing the possibility of ensuring smooth communication in the neighborhood. Taking the Cangzhou Road constructed by the proposed characteristic street as an example, firstly we could integrate the interface into the mixed layout of commercial and residential, and then the street space formed by different interfaces could be classified and guided. It can use the additional facilities space, green space, guiding behavior streamline and different interface processing on both sides to optimize pedestrian experience and ensure smooth communication (As seen in Figure 20).

Figure 20: The status quo analysis and transformation concept of the characteristic memory street Cangzhou Road

5 Conclusion

This paper takes the example of the “Kongjiang Village” in Yangpu District, Shanghai, from the aspects of spatial scale and scope, spatial texture and order, spatial organization and interface, spatial form and streamline, analyzing the spatial characteristics. Then through the analysis of the problem, it is found that its’ unique cultural background lacks continuous protection, closed space partitions cause social interaction barriers, space environment facilities are old and worn, and livability is poor. The author tries to construct an urban renewal strategy based on the perspective of place identification, and proposes suggestions for the renewal and development of the “the new estate for workers” section from the aspects of site construction, network reshaping vitality, enhanced identification and orientation, and moderate mixing. At present, the sense of place identity that is gradually weakened, it needs to be intervened from the means of space, and gradually restore the public value that workers should have in the new village. As a review of the memory of a generation, a realistic image of history, and the continued inheritance of a cultural resource, we have the responsibility to think and inspire its protection, development, and transformation. From the perspective of the development of time dimension, in the future, we can comprehensively consider the co-construction, co-governance and sharing of the old public housing community, and actively use the open street system to enhance its comprehensive service functions, to build more low-density low-intensity mode to achieve internal and external linkage. Realizing the cultural-oriented traditional community renewal and demonstration, attracting more entrepreneurial, innovative and creative people for urban development, and enhance the identity of the new and old integration.

Urban and Regional
economics of transition

Woman Labor in Transition Process from Agriculture to Industry Sector

Reycaan Çetin¹

¹*Yildiz Technical Universtiy, reycancetn@gmail.com*

Abstract: Through the change in rural development plans, non agricultural sectors are supported in rural areas to decrease rural poverty, specially for women. Creating employment opportunity have an important role in women empowerment. But traditional gender roles build huge obstacles in front of women. Understanding these gender roles and the resistant mechanisms that are invented by women is really important to create new strategies for decreasing women poverty and deprivation.

Keywords: women labour, rural development, agricultural industry, gender roles.

Introduction

From 90's the inequalities between cities and rural areas increased dramatically. Rural areas became poverty and deprivation places. Immigration from rural areas to cities increased very fast and to keep population in rural areas, regional and rural development polices are needed to have another direction. Rural development plans started to support non agricultural sectors instead of agricultural growth. The industry investments on rural areas offered women paid jobs. Woman's working outside the house challenged the gender roles but found a way to continue.

Geyve-Pamukova region is a rural area in Sakarya, Turkey. In last 20 years two large-scale factories and some small factories opened in this region. And women transformed from unpaid family worker to paid workers. In this paper it will be discussed how this transition effects the physical and social structure of this region.

For the study, the women who works in the large scaled-factories and their employers are interviewed. It is seen that women don't transform the place, but they become more mobile and have more right in decision making process in family. But there are some gender based barriers for women empowering. These barriers are not only created by husbands or employers but also women feel unease because they can't perform their "wifhood" or "motherhood" duties properly. In this study the social change caused by working women, the barriers in front of these change and the resist mechanisms of women will be discussed.

Rural Development and Women Labor

The rural areas had a great importance when the agriculture had a high share in employment and gross national product, but the development of mechanized agriculture and the industrialization in urban areas put the rural areas in the second place and so rural areas became places of deprivation by comparison with urban areas (OECD, 2011).

The inequalities between rural and urban areas and the deprivation in rural areas became an issue firstly in the 1950s, to eliminate these inequalities the concept of rural development has been increased. The first rural development models, which took economic growth as a target by state aid. This method increased the growth and efficiency in the agricultural sector but this growth was not reflected on the life of rural society (Ellis and Biggs, 2001).

With the global competition in the 1990s, the differences between rural and urban areas have deepened. The deprivation in rural areas and the sectoral diversity in urban areas caused decrease of population in rural areas. For the first time in 2007, the population in urban areas has passed through the rural population and the rural population has decreased much faster in developing countries. (data.worldbank.org).

In rural areas, the development of agricultural growth which provides by state aid deepened the problem instead of solving. It revealed that a change in the policies for rural areas is necessity. In addition to economic growth, creating high quality living spaces and improving social life has been the main target of these new rural policies. Today's rural development policies also aim to increase the competition in the global system by developing non-agricultural sectors in the countryside, to provide the physical and social infrastructure that will attract the investor to the rural area, and to create qualified workforce to work in these new sectors. (OECD, 2011).

The economic growth-oriented development strategies which are adopted before 1980 have deepened not only the rural / urban inequalities but also the women / men inequalities in rural areas. In 1979, the United Nations drew attention to the inequalities experienced by rural women in the Convention on the Elimination of All Forms of Discrimination against Women and proposed solutions to these inequalities. The Article 14 addresses directly the women in rural areas. This article makes contracting countries responsible for providing certain rights for rural women. These rights are the right to participate in the plans, the right to access to health services, the right to access agricultural credit and marketing facilities, and the right to housing. This convention also recommends to develop empowerment policies which will help women to access technology or credits for enterprising. (UN, 1979).

It is important to provide employment opportunities as suggested by rural development plans in resolving rural women's poverty and lack of access to services. But without analyzing the social acceptances which are shaped by gender roles, the obstacles to women's participation in paid employment and reactions of women to these obstacles, creating employment opportunities can be only a limited solution

The social life in the rural areas is mainly based on ensuring the continuity of agricultural production and shaped by natural conditions and traditions. Gender roles are also directly related to agricultural

production and traditions. The rural women work on the fields as men for agricultural production but they are also responsible for other jobs as taking care of animals, drying the products, feeding the workers. These jobs are handled at home with the woman's reproduction duties. And the most important difference between men and women labor is the women are not paid (Berlan-Darque, 1988; Massey, 1994; Little, 2009). The woman labor is a free labor which is transferred from father's house to husband's house by marriage. Just because gender roles do not allow them to leave the house for a long time; women continued to deal with labor-intensive tasks while men use knowledge and skills and marketing of products. In this system all of the family income is controlled by men, women are excluded from domestic decision-making mechanisms.

Inclusion of non-agricultural sectors in rural areas means both employment for rural people and cheap labor for the investor. Sectors like agriculture and textile (which employs women) being predominant in rural areas created job opportunities for rural women. Working in the factory means not only getting out of the private area and taking a part in public area for woman but also means getting paid for their labor. But working outside of the house doesn't mean that women are not responsible for domestic work anymore. Taking care of elders and children and domestic works mean double work for women. And giving the control of the money to the husbands as head of households can mean working out of house is a burden for rural women not a tool for empowerment. So to reduce women poverty the rural development policies have to analyse local social acceptances, gender roles and the limitations which are build by these roles and social acceptances.

This paper aims to understand how gender roles and local social expectations shape working women's daily experiences by interviewing industrial worker women in a rural area. The field of study is Geyve Pamukova region, which is a rural center and locates in Sakarya, Turkey. The regional development plans aim to reduce women poverty and empower women by creating employment opportunities.

Rural Development in Turkey

Turkey adopted planned development firstly in 1960s. Until the 1990s development used to mean basically economic growth. Development plans in this period were largely limited to modernization in agriculture and infrastructure improvement.

The worldwide changes in rural development policy effected development plans in Turkey too and in the second half of the 1980s the concept of rural development has began to change in Turkey. The country development plan which was prepared in 1989 aimed that facilitating the service and information flow in accordance with contemporary needs for the rural area; supporting agriculture-based industrial investments and increasing non-agricultural economic activities (DPT, 1989).

In the first decade in 2000s Turkey started a localization process in governance under the effect of European Union harmonization process. This localization changed the concept of development policies. The central development policies transformed into regional development policies. State Planning Organization was closed and 26 regional development agencies were established. These

Regional Development Agencies aim to build a cooperation between public sector, private sector and civil society organizations, to control utilization of natural and human resources, to accelerate regional development by using local potential and to decrease inequalities between regions. Reducing inequalities between urban and rural areas has a special importance to keep population in rural areas.

Regional and Rural Development Plans for Study Area

The study area, Geyve Pamukova region is located in the north west of Turkey and 170 km far away from Istanbul, the biggest market of Turkey. This region is in TR42 district with Sakarya, Yalova, Düzce and Bolu provinces. East Marmara Development Agency is responsible for this district and defines these cities as old agriculture cities which lose their character under pressure of Istanbul's deindustrialisation process. In 1980s industry was decentralized from Istanbul and the located in nearby cities. These nearby cities were agriculture cities, the population mostly used to live in rural areas. And this process from agriculture to industry changes nature, working habits and all social structure. The first development plan aim that the cities keep their own character as much as possible to sustain agriculture product and educate labour to adapt this process.

Figure 1: TR42 Cities and Istanbul

The second development plan (2014) divides the district into three regions by considering socioeconomic qualities: Global Region, Dynamic Region, Periphery Region. Adapazarı, İzmit and Gebze are the important economic centers of Global Region. The 94% of population lives in urban areas in this region. This region has the highest development level and most of the industrial investments. For this reason many people migrate to this region from Dynamic and Periphery Regions. Dynamic Region is a transition zone. This region has still rural characteristic but state and private sector create new industrial zones in this region.

Figure 2: Three Regions and Study Area

The Periphery Region has the biggest areameter and lowest population density. The study area is in this region. The lowest development level, mostly rural population, problems in accessibility and reachability to the services are the main characteristics in this region. The economy is not industrilized and mostly based on supplying raw material. Only 13% of the population lives in this region. And throughout the district population growth rate in the total district is 18% but in Periphery Region is only 3%. In the upcoming years there is a risk of losing population in this region.

2014 - 2023 Development Plan has three main purposes: Liveable Region, Competitive Region and Learning Region. And there are goals under these aims that are specific to needs of each regions. The vision of Periphery Region is sustaining agricultural production and supporting Global Region. To keep the population in rural areas plan gives a critical role to agricultural development and raising welfare level in rural areas. Building an integrated production system is an important key for rural development. To achieve this goal rural areas should process the raw material and sell products afterproduct. In order to process raw materials, it is frequently mentioned that the human resources must be enriched and the labour should be prepared for this new production system by providing the necessary education.

Regional development plan considers gender inequality and rural women poverty. Social diagnosis studies aim to discover employment rate of women, accessibility to social services and educational status of women. And by discovering these problems local solutions will be provided. The plan also suggests to support women entrepreneurship and provide micro credits for women entrepreneurs.

For Geyve Pamukova rural region, supporting agricultural industry investments has an important role the decrease rural poverty. Agricultural industry will create a huge employment opportunity and and alternative to agricultural production. According to plan creating women employment will raise women welfare level and women will access services more easily. All these strategies are important

and effect women's life but positively but they don't consider local life, social structure. They don't analyse social reactions, obstacles and gender roles.

For this study, 45 women worker and three managers from three different factories were interviewed. The oldest of the factories provides service for twenty years and the newest one for ten years. The gender roles and social living were shaped by traditions in study area and women's participation in paid employment challenges these traditions and social living. The interviews questioned that why do the women work, how do they spend time after work, in what do they spend their money, decision making processes in family, with whom do they share domestic work. With these questions it was aimed to understand how does the working effect the lives of women, can the women workers access the services easier, the obstacles for women to gain strength and the resistance mechanisms created by women for these obstacles. Hopefully this study will be a framework for future investments and development plans.

Interviews with Company Representatives

Two factories belong to food companies and one of them was opened in 1992, and the other one in 1996. Both of these factories were located outside of the settlement, on the road to Istanbul. The third factory is a textile company and was opened in 2002 in Geyve Organized Industrial Site, closer to the settlement. In all these factories workers work in shifts. Regional development plan gives an important role to these companies to create women employment, specially food companies. So the the interviewees are chosen mostly from the food companies

Reasons to Choose This Region

Firstly it was asked to company representatives that why did the company choose this region. Three of them told that the location is very determinant in making this choice. This region is close to the Istanbul, which is the most important market in Turkey. The rural character of the region do not provide any advantage for cheaper labour for food companies and they also don't consider clustering because the both of them use their own infrastructures. The textile company is located in Organized Industrial Site and moved there during the Istanbul's de-industrialization process. For the textile company, it is important to be close to the Istanbul market but they also benefit from the advantages that are provided by Organized Industrial Site. The company representative also told that the region provided an unexpected advantage, labour force. Specially finding women worker is not an issue for the textile company.

Thoughts About Female Workers

The advantages and disadvantages of employing women were asked to company representatives. The social life in the region was shaped by traditions. The women do not spend time with men if they are not from family. The friendship between a woman and a man is not approved by society. But in these factories women and men work together in the same place. It was asked to the representatives if that caused any problem.

One of the company representatives is woman and she told that organizational culture of her company supports women employment. The company has branches on all regions in Turkey and employs women in production, distribution and management. In this factory, there are 220 women and 305 men workers. 208 women work as blue collar workers and 8 women work as white collar.

The company representative doesn't think that there is a difference between women's job and men's job in production. The maximum weight, break time, needed skill are same for women and men in production process. The company doesn't hire part time or seasonal workers. Women and men get the same wage. So they don't need to choose one gender and try to keep a balance between number of men and women employees. The management of the company also supports the women to be machine operator or forewomen when they are experienced. The company considers to empower women but they also know the limitations which are shaped by social life in the region. Production process has different production lines and mostly workers of each line have the same sex.

The company representative explained this situation by employees' own choices. She also told that if women and men work together in the same line there is always a foreman. Because the male workers don't want to receive orders from women but also the women hesitate to give orders to men. She thinks that working together in factory helps to normalize women men relationships but there is a still long way. Even the company has zero tolerance for gossips and slanders it is impossible to stop people talking about their coworkers.

The representative of the other food company defines his company women friendly too. There are 900 workers in the factory and about 100 workers are female.¹ 10 women work as white collars in quality control department, rest of them work as blue collars. These company representative thinks that there are two important difference between male and female workers: women are physically weaker and they have domestic works beyond the working in factory. So they give the physically less tiring jobs to the women and let the women to regulate their shifts in a way to taking care of their children and home. The company also organizes special events in Mother's Day, that women can join with their families and give to them presents. Despite the company representative emphasizes the respect to motherhood, the company has no day care center or nursery room. Another women friendly policy of the company is employing the women who really need to work. It is important to understand which women really need to work according to company representative. The company representative and the owner of the catering firm that provides catering and cleaning services to the factory support women to work if they really need. And the women who really need to work are widows who have no support from family and have to feed their children. Catering firm owner thinks that the women who insist on working and earning their own money are greedy. When they earn their own money they become rebel, don't respect the head of house and the families come apart.

¹ This company representative didn't give the exact numbers because of company policy.

Lastly, in textile company there are 520 blue collar workers and 390 of them are female. The company will increase the employment capacity and hire 200 more women in 2019. The company representative defines the job as an intricate job that requires maximum attention and women are much better in these jobs. So the company prefers to employ women. Female workers are mostly single or childless young women. The women do not prefer to work when they got married or having kids. The company representative thinks that women's priorities are changed once they got kids and they don't want to work anymore.

All of the three companies define themselves women friendly but none of them have daily care centers or nursery rooms. Only the female company representative accepts that it is a huge problem. It is not a choice for company, but the current conditions causes this deficiency. The factory campus is noisy and smelly. And also delivery from the factory continues during all day. These conditions are unhealthy and dangerous for the kids. If local government offers an appropriate place the company is ready to build a daycare center.

The representatives of the other two companies don't think that their companies are responsible for daycare centers. According to law, for food company providing daycare service is not an obligation by considering the number of female employees. And the employees of textile company are mostly single or childless women. The company representative thinks that leaving the child in daycare center is an abnormal thing for the women in this region. The women don't want to leave their kids with strangers, they prefer to get help from their mothers or mothers in law. The only daycare center in Geyve provides service to the white collar women, as teacher or officer.

Interviews with Female Workers

The thirty two of the interviewees are married with children, eight of them are single and five of them are divorced. The youngest interviewee is twenty two one years old and works in the textile company for eleven months. The oldest interviewee is sixty years old and works in one of the food companies for sixteen years. The highest education level is secondary school and none of the interviewees is illiterate.

The interviewees mostly live in town centers which are defined as rural centers by regional plan. The shuttles of companies provide transport service to the women who live in central neighborhoods, but the women who live in nearby villages need to arrive closest shuttle point. These women always travel with their husbands or male family members. None of the interviewees use their private car. The family cars are used by husbands or fathers.

Reasons to Work and Spending Items

The women were first asked why they worked and where they spent the money. While single and childless women spend the money mainly for themselves, married women with children put the family support and the needs of children first. Clothing, self care and fun come last. There are two main motivations to continue working life. one is the dream of retirement, the other is to buy a house. Having your own house also has a symbolic meaning in this region as well as throughout

Turkey. Women are very familiar with the home ownership of their relatives, neighbors or colleagues. These statements are very common in interviews “husband and wife worked together to buy a house” “despite of all the hardworking they couldn’t afford to buy a house” “they don’t have a house but spend money too thoughtlessly”. Almost all married women see women's work as wasted labor if they cannot buy a house. In a sense, buying a house is seen as a tangible equivalent of the efforts.

In this region head of the house is traditionally husband or father and has the control of the money. In families, that make a living with agriculture, when women work as paid agricultural workers, their wages are usually paid to their husbands or fathers traditionally. For this reason, women were asked who had their salary cards. The majority of women keep their salary cards themselves and find it normal to keep their own money. However, immediately after saying that they had control of their money, they felt the need to state that they spend their money for their families and they did not have any luxury expenses. . Women are better than their husbands in determining the needs of children, as well as basic needs, trips with children are paid by women's money. Women take great pride in taking their kids for weekend trips, cinema or other activities.

One of the three women who did not have her salary card said that she handed her salary card to her married son. The sixty-year-old interviewer woman does not want to shopping because she is exhausted in the factory that is why his son does it for her and others by using woman’s salary. Other two women’s salaries are in their spouses. One of the women did not understand the accounting affairs and the other said that she was working because of her husband's debts and that the money she earned was taken by her husband and deposited in the bank.

The companies don’t have seasonal or part time employees. The female and male employees work under the same conditions for same working hours and get the same wage. However women’s wage was accepted as a contribution to the family budget. Married women say that decisions about buying expensive goods such as furniture, car or house were made mostly by husbands. Husbands prefer housewives rather than working ones when women make too many comments on how to spend money.

A interviewee explains her reason to divorce with this attitude. Her ex husband wanted to spend the money that she earned by working hard and she didn’t let him and got a divorce. Divorce is not very common in her family and community but she has a “honest job” and works “chastely”. So she got support from family and friends.

All the interviewees emphasized this “working chastely”. Working outside the home is still a new concept for this region. In factories women and men work together and it causes gossips about men women relationships, and these gossips reach family members. For this reason female workers care to limit their relationships with male worker. They don’t chat with male workers, they only communicate with male workers if it is necessary for work. None of interviewees wanted to talk about details of these gossips. But they told that there is no gossip about women who cares only her job and works chastely. For the interviewees behaving chastely and limiting the relationship with

male workers are women's responsibility. Men are just men and women have to be careful if she doesn't want to cause gossips.

Spare Time Activities

The spare time activities of women were asked through interviews. The women that are married with children spend their time with family specially with their kids. Domestic works take most of their time but they believe that earning money gives them opportunity to spend more quality time with their families. They have picnic in nearby areas, visit historical and cultural places, go to cinema and shopping in urban center. And all these activities are possible when the family has two wages.

Women spend their spare time with their female workers too. Workplace provides also socialization opportunity for women. When their shift ends on the morning, women go to breakfast or drink tea in a cafe. Husbands are not jealous or unpleasant, because they know the other female workers and trust them. Spending time with other women are refreshing for the female workers. These women are mostly single or have school age children. The women with young children can't have their own time.

Sharing Domestic Work

Thirty five of the interviewees are married with children. And most of them do domestic works themselves. When a woman has an unemployed daughter, she helps to mother in domestic work. Oldest interviewee has an unemployed daughter in law and despite she has her own house she cooks and cleans for her husband's parents too. And by her help the interviewee can continue working. The interviewee is glad with this sharing, she thinks that domestic works are much harder than working in factory.

For child care women get help from other female family members. Mothers, mothers in law and unemployed sisters care the children when the mothers are at work. Women with young children can not socialize with their colleagues. They feel guilty when they don't go directly home and free the carer of the child. Only one interviewee told that her husband couldn't find job when their children are young and took care of their three children. He also cooked and cleaned house. Despite all the critics and mocks from family and friends she thought that her husband did a good job and she could earn the money without worrying for children.

Husbands don't take responsibility in domestic work or child care. And women basically accept this organization. They don't complain about difficulties of work life they think that the double working make their life harder. The job in factories is physically exhausting but when they leave the factory the job is finished but responsibilities of home continue for seven days and twenty four hours.

Conclusion

Investing in non-agricultural sectors in rural areas created employment opportunities for women and play an important role in empowerment of women. Getting paid for their labour made the

women more independent. They became more self confident because they can create quality time for their family and themselves.

Despite all these positive effects, women face many difficulties in working life. According to the community working and earning money is not a right but a privilege for women. Women have to behave decently to have this privilege. To keep their names clean they have to be always careful. However companies do not employ first degree relatives in the same campus, some friend or neighbor watches the actions of the women. The male worker don't respect the female workers. They think that the women are not good enough to make qualified jobs, so they need to be thankful and don't argue with male workers.

Women mostly have control of their money for daily needs. But as a wife and mother they put their own needs wants in second place. They don't spend money for education, self care or making savings. The important decisions are made by husbands. They work hard with their husbands to buy house or car but these properties belong to their husbands.

And the biggest problems that women have to face are caused by gender roles. Women have to cook, clean and take care of the children and elders. Factories have no day care centers or nursery rooms. Women feel guilty about living their children or take a break from working. They identify themselves as mother, daughter or wife. They can easily give up on working woman identity.

Companies have their own policies about employing women, women job definitions and opening day care centers. There is no regulation or incentives in regional plan strategies about these policies. The regional agency need to analyse local social life carefully to determine the social obstacles that stand in front of women empowerment.

Is there a housing shortage? A post-Keynesian economics approach to the financialisation of housing in England

Richard Grace¹

¹*Market Dynamics Limited, rpgrace@gmail.com*

Abstract: The overwhelming dominance of neoliberal economics has come under question following its failure to understand, let alone predict, the barrage of global financial crises that began in 2007/8. Heterodox economic theories, Post-Keynesian school of thought in particular, have since assumed much greater significance during the last decade as much broader and more encompassing theoretical conceptualisation of economic behaviour is established. Land and property development stands at the centre of these debates due to the fundamental importance of property in providing collateral to the private banking system when money is created. Furthermore, the neoliberal exclusion of the role of debt and financialisation in determining the growth of the global economy has encouraged a fundamental misallocation of resources. The significance of excluding debt has permitted a deep-seated narrative to evolve amongst policy makers, in which the high price of land and homes in most developed countries is indicative of a shortage of supply, whereas it is likely that the role of debt driven demand is a more plausible culprit. This paper explores the role of financialisation and money creation in the UK to better understand the impact of debt upon the presumed shortage of housing supply in England. The unswerving belief of a housing shortage in the UK is beginning to be questioned. Between 2016 and 2018 the UK government substantially reduced its 25-year projections of increased household requirements by some 1.1 million units, reducing annual needs by more than 25% to 159,000 units. The implication of such a substantial and sudden shift in projections will inevitably have a broad impact on urban planning requirements and highlights the usefulness of heterodox economic thought in untangling the complicated transition of urban planning to meet future needs.

Keywords: heterodox economics; financialisation; mortgage debt, house prices

Introduction

Just 20 years after radical government financial deregulation in 1985, the humble Building Society movement became the centrepiece of the 2007 and 2008 global financial crisis in the UK. The most dramatic disruption occurred in mid-September 2008 when long queues formed outside the branches of Northern Rock Bank in the cities and towns of England, the first bank run since 1866.

So what had wrought such devastation across the formerly humble and venerable English Building Society movement with its long and stable history of mortgage provision to the housing market, a history that dates back more than 150 years? In a word the answer is “banking”.

Northern Rock was just one of a former group of building societies which had expanded rapidly into the fast paced world of credit funded banking. Other banks, which had also

previously made the switch from Building Society to bank, like the Bradford & Bingley and the even the bigger Halifax Building Society, also became insolvent in 2008 and were either taken under state control or forced to merge with larger banking institutions.

The introduction of modern banking practices resulted directly from a government policy of wide ranging financial deregulation in the mid 1980's. The deregulation set off a chain reaction of bank created debt, widespread mortgage accessibility and rapidly rising house prices that eventually consumed almost the entire independent mortgage industry. What had once been the centuries old Building Society movement, providing almost the entire mortgage market for house purchases, was destroyed in the financial crisis of 2007/2008.

This paper explores the institutional changes within the mortgage and housing market in England that directly followed that deregulation of the financial sector in 1985 and highlights how strong house price growth is likely the result of those significant institutional changes in the banking system and the process of money creation. The advent of massive growth in mortgage availability necessarily impacted the property market directly through the demand for housing and is likely a major contributor to the substantial rise in the price of house prices over the last 40 years. Despite this financialisation of the property market there is still a predominant narrative throughout industry and government that ignores financial aspects and attributes the cause of high prices to a lack of supply resulting from unnecessarily restrictive planning policy that prevents house building meeting the projected need.

This paper will first review the evidence for a shortage of supply and then review the long-term changes that have occurred in the financing of the property stock in England.

The Housing crisis and the shortage of supply

A common refrain in the British press is that Britain is suffering from a shortage of 300,000 houses a year and that new house building is falling far short of meeting that need (Torrance, 2019). But it is hard to blame the press alone when the source of those headlines comes from the government planning department itself.

In February 2017 the Department for Communities and Local Government published a white paper announcing their housing planning policy called 'Fixing our broken housing market' and the first paragraph stated:

"The housing market in this country is broken, and the cause is very simple: for too long, we haven't built enough homes. Since the 1970s, there have been on average 160,000 new homes

each year in England. The consensus is that we need from 225,000 to 275,000 or more homes per year to keep up with population growth and start to tackle years of under-supply.” (DCLG, 2017,p.9)

A year later in a statement to the Houses of Parliament by the Secretary of State for Housing, Sajid Javid confirmed that the government planned to “deliver 300,000 homes a year in England by the middle of the next decade” (HC Deb 05 March 2018).

It is difficult to establish the exact origin of the 300,000 number but it is likely derived from the projected growth in the number of households for the whole of the United Kingdom (UK) published by the renamed Ministry of Housing, Communities and Local Government (MHCLG) and is approximately in line with their projections for England from 2014 (MHCLG, 2018). Given that England has a population of some 85% of the UK total, a figure of 300,000 may derive from that. Other studies also suggested similar projections for household formation. In 2004, the government commissioned a wide-ranging study of housing supply (Barker, 2004, p5.). Barker estimated that 245-260,000 new homes would be needed to prevent rising house prices in England. A further widely quoted study (Holman, 2013) with revised estimates for annual household formation, estimated that from 2011 to 2031 there would be a need for 240,000 new households each year. Current government policy as laid out in the National Planning Policy Framework (NPPF) was updated in February 2019 and emphasises in particular, government guidance on how planning permissions are to be granted to meet housing needs (MHCLG, 2019) and it appears that household projections from 2014 data are the basis for this guidance. The household formation projections from MHCLG are therefore a crucial input to the entire planning policy in England.

Current UK planning policy for household development.

Unfortunately, the history of projecting the formation of new households for a planning horizon one or two decades ahead was not straightforward. The key determinants for the growth of new households are

1. *Population projections, births and deaths*
2. *Migration.*
3. *Average household size, by persons.*

Population projections are provided by the Office for National Statistics (ONS) and are periodically revised. They are subject to considerable revisions as shown in the Table 1

Table 1. Historical Population Projections for England (millions of persons)

Year	2008 based survey	2014 based survey	2016 based survey
2011	52.5		
2016	54.8	55.2	55.2
2021	56.8	57.2	57.0
2026	58.7	59.1	58.5
2031	60.3	60.8	59.8
2036		62.4	60.9

Source: ONS (2019) Table 401 and earlier versions.

The most recent figures from the 2016 based survey show a reduction in the projected population for the year 2036 of 1.5 million persons against the previous 2014 based survey just 2 years earlier. This reduction reflects a significant narrowing of the birth/ death rate, as life expectancy is currently estimated to grow less quickly than previously thought.

Migration projections are very difficult to establish. As Chart 1 below shows, net migration was small and slightly negative until the mid 1990's when it began to rise significantly.

Chart 1.

Source: ONS (2018) Table 2.04.

The total numbers of migrants clearly has a direct bearing on projected household formations but when the level of migration is higher, it also has an impact on average household size because newly arrived migrants are less likely to form single family homes. The tendency in the government statistics has been to overstate the growth of the natural population death/ birth rate and to underestimate the growth in migration. To some extent the revisions to these two variables offset each other.

Chart 2 shows the long-term trends and revisions for projected average household size in England by number of persons.

Chart 2.

Source: ONS (2018a) Table 401.

Average household size estimates have been significantly revised since 2008, when it was believed that household size would continue to reduce following the pattern of the preceding 20 years. More recent data tends to confirm that the historical fall in household size is flattening out and has remained static at 2.37 persons per household for almost 20 years.

The consequence of these substantial revisions to the major determinants of new household formations is shown in Chart 3.

Chart 3.

Source: ONS (2018a) Table 401

The steady reduction in the estimates for the projections of household formation is striking. For example, the projection published in July 2016 and based on 2014 data (drawn in red on Chart 3) showed projected households for 2031 at 26.5 million. The household stock for 2016 is given as 23.6 million, implying a requirement for 193,000 new houses per year. But the most recent publication in December 2018, based on data from 2016 (drawn in black), projects household numbers at 25.35 million for the year 2031, or 1.1 million less households than were projected just 2 years earlier. The most recent numbers imply a requirement for some 164,000 new households each year, almost 18% less than that projected just 2 years earlier; significantly below the headline figures of 240,000 -265,000 discussed above.

The National Planning Policy Framework (NPPF) appears to be based on statistics derived from data from 2014 and earlier and does not appear to be adjusted for recent reductions in household projections just described. Nonetheless, the emphasis within NPPF guidance on

building more houses is having some effect. Data for the actual number of new household completions are rising. Table 2 shows the number of net additional dwelling for each of the last 10 years.

Table 2. Housing Completions in England (net additional dwellings)

Year	Net additional dwellings
2006-07	193,080
2007-08	200,300
2008-09	157,630
2009-10	124,200
2010-11	117,700
2011-12	128,160
2012-13	118,540
2013-14	130,340
2014-15	155,080
2015-16	163,940
2016-17	183,570
2017-18	195,290

Source: MHCLG, (2018) Table 120

Following the financial crisis in 2007/2008, household completions fell sharply from just above 200,000 dwelling to a low of 117,700 in the preceding 3 years, a fall of more than 40%. It is understandable that at that level of new completions there was growing concern about a shortage of supply across the entire housing market and it was against this background that the UK government began forming its agenda to radically overhaul the planning policy towards building more houses. Table 2 shows a steady recovery in annual housing completions since the nadir in 2010/11. The latest figure for 2017/18 shows completions rising to levels last seen in the boom days just before the financial crisis. Commentary in the British press continues to highlight that the government is still well below its objective of providing 240,000 to 265,000 new dwellings each year for England (NAO, 2019). But it is noteworthy that the most recent data shown in Chart 5 has annual requirements projected at 164,000 each year, if that is so then the actual supply of housing is currently exceeding need

by more than 25,000 dwellings each year. If completions continue to accelerate, England could be facing a glut of housing in the next few years.

Are High House Prices the cause of the crisis?

The discussion above has highlighted the difficulty of projecting the future need for housing in England but there is little in the discussion about house prices, even though high house prices are usually cited as the result of a presumed supply crisis. For example, in the foreword to the white paper introducing the governments new planning policy in 2018 the British Prime Minister stated:

“Our broken housing market is one of the greatest barriers to progress in Britain today”

“Today the average house costs almost eight times average earnings – an all-time record.”

“The starting point is to build more homes.”

(MHCLG, 2018)

The rise in house prices is not in doubt. Chart 4 shows the long-term relationship between household disposable income and the average house price in the UK.

Chart 4.

Source: (BIS, 2019); (OECD, 2019); (BoE, 2019)

Chart 4 shows that house prices have increased sharply above incomes. Whilst house prices exhibited periods of volatility in the 1960's and 1970's the tendency was for booms to be followed by busts and with house prices moving back in line with incomes. From the 1990's onwards the rise in prices is much stronger than in previous episodes and the tendency to fall back in line with incomes has not occurred.

Whilst it is intuitively appealing to suppose that the elevated level of house prices reflects a shortage of supply, it is equally possible that the increase is driven by an increasing demand. Mainstream economics has tended to ignore the impact of credit and debt by presuming that debt and loans merely transfer spending power from the lender to the borrower and cancel out in terms of the impact on the real economy. But following the financial crisis in 2008 it became clear that credit and debt were important drivers of activity in the real economy. The theories of heterodox economists that had been largely ignored before the crisis have been given much greater exposure in recent years. Hyman Minsky for example shot to posthumous fame after a life of relative obscurity with his 'financial instability hypothesis' (Minsky, 1992). This theory postulated a very dynamic role for debt, whereby long periods of steady growth in the economy would encourage increasingly speculative investment bubbles endogenous to the financial market. Ultimately, the leverage in the economy becomes so great that it increases fragility in the financial markets, such that any small downturn in the economy would trigger large financial distress. Following Minskys lead more economists began investigating debt and concluded that banks actually did create debt, rather than acting as an intermediary between borrower and lender and concluded that debt was a fundamental driver of the economy (Wray, 2015), (Keen, 2017, Chp4). Even the Bank of England (BoE) confirmed that debt and money is created by primarily by the commercial banks in a groundbreaking article in their Quarterly Review (McLeay et al., 2014).

The economic and financial history of the English mortgage market provides a good example of the impact of the growth of debt, credit and banking leading to fragility in the real economy. A change of institutional financial structures in the mid 1980's when the Building Society movement was drawn in to the world of commercial banking was the start of a very long-term Minsky type business cycle.

The Building Society movement in England

The Building Society movement in England dates back to the middle of the 19th century and evolved from mutual clubs that were formed to provide finance to their members so that they could build themselves houses and homes. Initially the members pooled their savings and

built the homes one by one. When houses had been built for each member the mutual society would be wound down and closed. In time however, the success of these mutual groups in providing finance developed into larger business' and new savers were recruited to take the place of the initial members. In this way some of the mutual groups became more permanent and indeed the word 'permanent' would often be included in their names. In fact the hapless Northern Rock that suffered the collapse and bank run in 2008 was itself the result of the merger of a number of smaller building societies including one called the Northern Counties Permanent Building Society (originally founded in 1850).

The Building Society movement grew steadily over the next one hundred years and established a well-earned reputation for conservative but reliable provision of mortgages to the English property market. Mainly for institutional reasons the mortgage industry in England never attracted competition from the large commercial banks. In part this was due to the retail nature of the mortgage market where large numbers of small short-term savers were required to fund the larger long-term mortgage loans that house purchasers needed. Consequently, the mortgage market remained an almost entirely separate and segregated market from the wider banking industry that funded the larger part of the British economy. So what changed that caused the Building Society movement to become such a large part of the banking crisis in 2007 and 2008? The answer can be found in the substantial liberalisation of banking and finance that occurred in the mid 1980's which was itself the result of economic policy changes brought about by uncontrollable inflation of the previous decade, the 1970's.

Some economic history: free floating exchange rates and the implication for money creation.

In the early 1970's, the global economy had become extremely volatile. In the UK, the government struggled to contain rising inflation, growing unemployment and heavy downwards pressure on its currency, the British Pound. Until 1972 the British Pound had been fixed against the US Dollar under the Breton Woods exchange rate agreement. The US Dollar in turn, under that agreement, was fixed against the price of gold. The widespread economic turbulence of that era witnessed a relentless outflow of gold from the US Treasury, such that the global fixed-exchange regime became unsustainable. Whether by design or necessity the link between the US Dollar and gold was abandoned by President Nixon in July 1971. Thereafter, everything changed. No longer backed with gold its exchange value against other currencies was left to float or sink as determined by the vagaries of the foreign exchange markets. The same applied to all the other developed countries that were a part of that system. The world henceforth was to be conducted with fiat money – money backed solely by government decree.

In many ways this was a much more momentous change than was generally appreciated. In particular this affected the banking industry. Because governments were no longer constrained by maintaining fixed exchange rates for their currencies they were able to explore more flexible methods to control the money system. Quantitative controls on commercial banks balance sheets were removed and monetary policy was directed towards controlling the money supply by using interest rates. Technical operations of banking had mostly been considered an esoteric matter and of little overriding concern for economists. Economic theory always explained banking by what was known as the 'quantity theory of money'. In essence the quantity theory states that commercial banks will create loans in some multiple of their reserves. Reserves are simply funds held on account at the central bank and are used to settle accounts between each other. As for example, when a customer makes a payment to a person with a bank account at a different bank, the two commercial banks have to switch the funds between themselves and will do so via their reserve accounts at the central bank. Beyond holding a prudent level of reserves to enable payments to other banks, any bank is free to offer their remaining customer funds as new loans. Under this mechanism it appears that the amount of reserves in the system will control the total amount of loans that the commercial banks can create and the level of customer deposits in the whole banking system will determine the money supply. However, once fiat currency became a reality in the 1970's and free floating currencies were no longer constrained by fixed rate to either the US Dollar or gold it became apparent to more heterodox economists that bank money creation was not constrained by reserves at all. In reality commercial banks create new money when they grant a new loan to a customer. The loan then becomes a deposit in the banking system. The amount of money in the system is only constrained by the commercial bank that decides whether it believes a customer is a profitable prospect and is prepared to make a loan.

No longer constrained, commercial banks began to look at new markets and began to offer mortgages in competition to the building societies. By the mid 1980's the British government embarked on a very broad liberalisation of the entire financial system, colloquially known as 'big bang'. For the property market the significance of this development was the introduction of a government bill, The Building Societies Act in 1986, allowing the building societies to act like banks and fund their mortgages, not just with savers deposits but, if they so wished, with up to 20 per cent of funds borrowed on the short-term money markets. In effect they had become banks and indeed were permitted to convert to full commercial deposit taking bank status under the new laws, if they wished.

The impact on the mortgage market was dramatic. Availability of mortgages broadened substantially and financial services such as checking accounts and instant access accounts became available to savers in the retail mortgage market.

Very quickly the provision of new mortgages began to outpace almost every other type of loan, far exceeding the growth in commercial business loans or for private loans to consumers. From a banking perspective, property loans have a considerable advantage over other assets because the property behind each mortgage provides very safe collateral that is relatively easy to value. Certainly compared to a small business loans that requires considerable diligence by the lending bank, a residential property loan is a much simpler proposition.

Whereas in the 1960's and early 1970's mortgage finance represented approximately 20% of the total income of the country (or Gross Domestic Product, GDP), some 30 years later this has increased to more than 70% just prior to the financial crisis. The growth and importance of mortgage finance in the overall UK economy is shown in Chart 5.

Chart 5.

Source: (BoE, 2019b)

The value of the mortgage credit as a percents of Gross Domestic Product(GDP) is shown in red and labelled as “Secured Housing Loans”. The early part of the chart shows mortgage credit representing less than 20 % of the economy

As the banking industry was deregulated in the 1980's and the mortgage market and the Building Society movement was gradually subsumed within the commercial banking business Chart 5 tracks the explosive growth in mortgage credit. By 2007, just before the financial crisis the mortgage market was by far the largest component of the balance sheet of commercial banks. The other fast growing item of the UK money supply was 'financial credit' (shown in Chart 5 in purple) and this includes much of the notorious shadow banking finance that was also a big driver of mortgage credit.

The relationship between the growth of mortgage credit and the price of houses is shown in the chart below.

Chart 6.

Source: (OECD, 2019); (BoE, 2019).

Chart 6 shows that there is a strong relationship between house prices and the change in mortgage credit. Whilst, correlation does not prove causation it would be hard to suppose that without the availability and easy access to billions of pounds of mortgage credit that UK house prices could have been driven so high.

Conclusion.

The housing market in England is in crisis but the crisis is one of high house prices not one of housing availability. Apart from high prices it is far from clear that the crisis is related to a shortage of supply. Much more likely is that the crisis is one of affordability. The growth of mortgage credit over the last 30 - 40 years has been dramatic and now approximates £1,414,763 million. This sum is so big that it represents the largest component of bank credit in the economy. Clearly the cost of holding such a large amount of credit is a substantial burden upon house buyers. Also, following the line of argument of Hyman Minskys instability theory, the accumulation of so much debt must substantially reduce the soundness of the UK economy. The cost of holding that amount of debt is given by multiplying it by interest rates, which have been driven down to extraordinary low levels in order to support outstanding debt. But when the debt is so large it is readily apparent that any significant rise in interest rates would carry a high risk of triggering another financial calamity.

There is also another possibility for triggering a crisis if debt burdens are close to the limits of sustainability. The evidence presented in the first part of this paper indicated that the current supply of new dwellings now exceeds the projected need from growing population and migration. If the government policy of increasing that supply even higher towards their stated target of 250,000 additional dwellings, any resulting pressure on house prices could, ironically, trigger a much more serious financial crisis.

The Role of Taiwan's Industrial Diversity In Regional Employment Growth - A Comparative Study on Digital Economy Industry and Cultural Innovation Industry

Chung-Chun Huang¹

Cheng-Yi Lin²

²*Department of Social and Regional Development, National Taipei University of Education, Taipei Taiwan, justlinci@tea.ntue.edu.tw*

Abstract: Urban-regional and national economies are more vulnerable to external events and turbulence, such as the impact of the 2008 financial crisis, resulting in a global economic downturn. Recently, understanding the regional (un)related variety is central to create new regional industrial structure, such as digital industry sector and cultural creative industry sector. This causality has been argued and emphasized in evolutionary economic geography, but empirical analysis in the causal influence of related variety on regional employment growth remain less examined in Asian cities.

This paper aims to examine the impact of related and non-related variety on employment growth of digital economy industry (DEI) and on cultural and creative industries (CCI) in Taiwan. This paper use spatial regression and spatial lag model analysis to examine this issue through comparing 350 samples of two different industries (DEI and CCI) under the level of towns and cities in Taiwan during 2001 to 2011. Main data comes from Industrial and Commercial Survey in Taiwan.

The empirical result shows that related diversity will increase employment growth, while non-related diversity will reduce unemployment growth. And this result will become more significant as the degree of urbanization increases. In addition, digital economy industry are more significant than cultural and creative industries. This research contribution can provide more accurate data analysis for regional economic planning or labor market policies.

Keyword: Diversity analysis, Digital Economy Industry, cultural and creative industries, Employment growth

Introduction

In the era of information and knowledge intensive, innovative and creative industries are dominated by digital economic industries and cultural and creative industries. According to the statistical information network of the Republic of China, the output value of Taiwan's digital economy industry grew by 1.1 (trillion yuan) from 2008 to 2015, and the proportion of GDP in the whole country grew from 17.3% to 20.3%, an increase of 3 percentage points. As shown in Figure 1, Taiwan's digital economy industry has always been a key industry and has grown rapidly, which is bound to drive the employment growth of Taiwan's digital economy industry in the future. However, the development of cultural and creative industries in Taiwan can be traced back to 2010. The proportion of GDP of cultural and creative industries has declined by 0.41 percentage points from 2010 to 2015. Because the change of employment ratio will be affected by the output value of cultural industries in the previous year, the employment growth rate has shown a reverse upward trend despite the decline of the proportion of GDP after 2013, as shown in Figure 2.

Figure 2-Business cycle of cultural and creative industries: gdp proportion and employment growth chart

Reference : World Bank Open Data: Cultural Bureau Cultural Statistics

In view of this, the above-mentioned causal relationship between industrial innovation and development for employment growth can be roughly divided into two types: the innovation and development of industrial economy and the orientation of urban space. The first is to explore the measurement index of innovation with the effect of agglomeration economy, with entropy index. The (entropy) indicator is a change in the index of computational diversity (Frenken, Oort, and Verburg, 2007; Frenken, van Oort, Verburg, and Boschma, 2005) and the spillover effect on the diversity between specific industries. empirical objects to explore the specific internal industry diversity whether it can drive industrial growth. The other is the urban type. Although the urban type variables have been adopted for specific developments in different townships, different urban types have different developments for the industry, such as the degree of urbanization in each township. The difference in the degree of human capital, in other words, due to different urban development conditions, the relationship between various industrial diversity factors and employment growth rate will form a spatial difference. Based on this, this study combines these two research perspectives and considers the relationship between the innovation and development of industries in the urban space and the growth of employment.

To investigate the effect of the industrial structure for the diversity of job growth through research design purpose of this study, using multiple regression model research tool. Based on the results of this study, the government will provide data support for the implementation of the human resources structure and industry's innovative development strategy in the space location.

Overview of related variety concepts

Agglomeration economy

In the theory of agglomeration economy, there have been many studies on the spillover effects of urbanization economy and localization economy(Glaeser, Kallal, Scheinkman, and Shleifer, 1992). Frenken, van Oort, Verburg, and Boschma (2005) put forward a new empirical framework to explain the spillover effect of agglomeration economy. Proposed the variety

index is divided into related variety and unrelated variety, however Lazzeretti, Innocenti, and Capone (2017) added regional variety variables in the analysis of a specific industry diversity, different from the unrelated variety and related variety is related to 4-digits level according to industry classification for data analysis, the regional variety of variable is 2-digit level Industrial variety classified by benchmarks. Before discussing the impact of the externalities of sector variety within a specific industry on regional economic development and employment growth, we must first understand the theoretical basis and context related to variety indicators.

Firstly, Frenken et al. (2005) points out that there are three kinds of relationship between variety and economic development, the first is in addition to a spillover effect between intra industry manufacturers, the industry also has spillover benefits, variety of a region, this region can bring additional economic growth (Glaeser et al., 1992; Jacobs, 1969; Van der Panne, 2004), this is not said Only input and output will affect the development of regional economy, when the region exists in the composition of a particular industry will also affect the quality of the regional economic growth, and the spillover effect is a geographical proximity (Jaffe, Trajtenberg, and Henderson, 1993; Porter, 1998), focused on the development of mutual complementary regional industry and the economic growth will focus on the development of complementary products to Industry is higher (Frenken et al., 2005).

The second is to consider variety as a risk-dispersing strategy in a portfolio to reduce the impact of external shocks on a region (Attaran, 1986). When there are diversified sectors in a region, external shocks will only have a slight negative impact on economic growth and employment. Conversely, if a region concentrates only on one area or sector with the same demand, the impact will lead to long-term economic recession and high unemployment risk.(Martin, 2011; Xiao, Boschma, and Andersson, 2018)

Finally, the variety and evolution of relationship between geography and economic development approach, if an economy is not increasing over time other industry variety, regional economic development will be affected by structural unemployment, and eventually fell into recession (Cantwell, Andersen, and Technology, 1996), Frenken, Oort, and (Verburg 2007) pointed out that an economy in the new Department issued Exhibition needs to absorb the surplus labor force in the original sector, which is the result of the product life cycle of the existing industries. This phenomenon is also reflected in the spatial development, because new industries usually appear in urban areas, while older industries are mainly in rural areas. This also shows that the surplus labor force is mainly produced in rural areas, while new employment opportunities arise in rural areas. In the highly urbanized areas.

And related variety is believed to stimulate employment growth, because new combinations will bring new products or services(Hidalgo, Klinger, Barabási, and Hausmann, 2007), thereby creating new employment opportunities. On the contrary, the localized economy where

specialized firms cluster will enhance process innovation, as expertise is used to improve production processes in existing industrial chains. These innovations stimulate labour productivity, but they do not necessarily lead to more jobs. Therefore, the concept of variety is consistent with the theory of product life cycle, which indicates that young industries with high product innovation rate create employment opportunities in different urban areas, while mature industries with high degree of specialization stimulate the productivity of surrounding areas.(Content and Frenken, 2016; Duranton and Puga, 2001)

Research design

Conceptual model

According to Figure 3, according to the data analysis method of diversity indicators, three main variables of diversity within two digital economic industries and cultural and creative industries are calculated. The control variables of population density and human capital with spatial differences are added into the multiple regression equation. The variances are tested by regression analysis at 350 Township scales and among different industries. Finally, the conclusions of this study are sorted out.

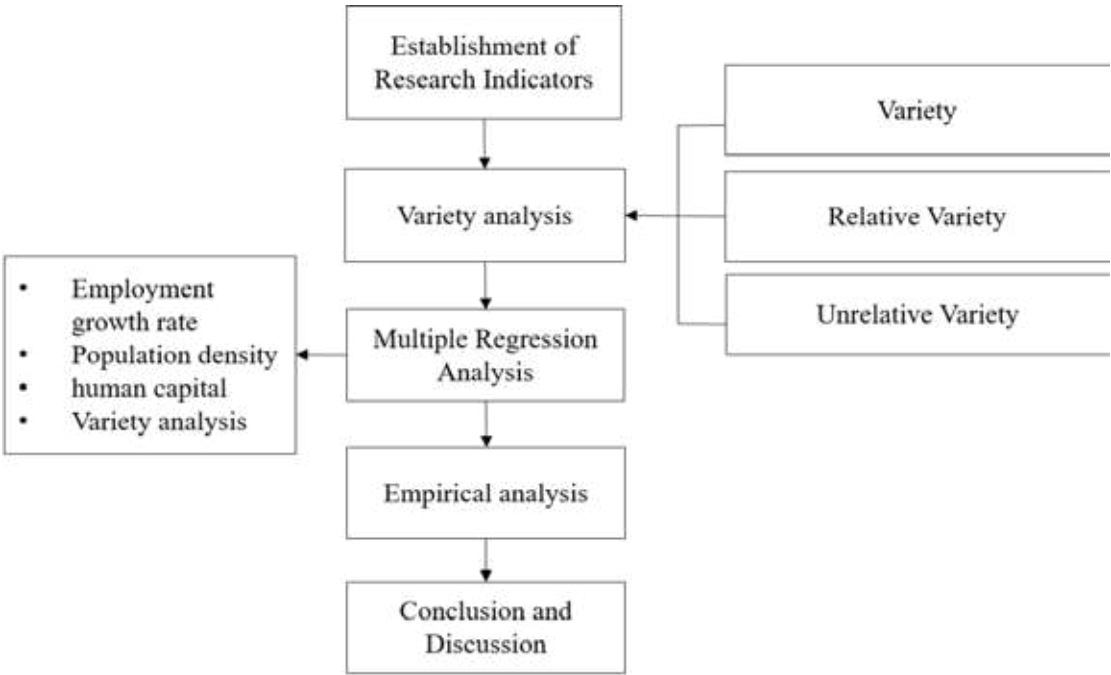

Figure 3 Research framework

Reference: Drawing by this study

Research methodology and variables

The purpose of this section is to establish a model to verify the relationship between the diversity of Taiwan's digital economy and employment growth. Commercial census categories of the General Accounting Office of the Executive Yuan is used 4-digit level for the data base. Based on this, the following formulas are listed to calculate the diversity. (Frenken et al., 2005; Hartog, Boschma, and Sotarauta, 2012; Lazzeretti et al., 2017)

Relative Variety, RV

Among them, the proportion of the total number of employees in each sub-industry in a certain regional economic scale is expressed as follows:

$$p_{ij} = \frac{\text{Population of the industry (region)}}{\text{Total Employed Population (Region)}} \quad (1)$$

Among them, i : the number of employments in 4-digit level, j : town, 1,...,350

Assuming that there are g middle-class industries in a certain regional economic scale, the G middle-class industries are subdivided into n sub-industries. The employment proportion of the middle-class industries is the sum of the employment proportion of the sub-industries, that is:

$$P_g = \sum_{i \in S_g} p_{ij} \quad (2)$$

Among them, p_{ij} : the ratio of employment in each township, S_g : the middle sector, $g=1,...,G$, P_g : $p_{ij}, g=1,...,G$.

As mentioned above, the related diversity is composed of four-digit industrial codes classified in the same two-digit codes in the industry standard classification. In order to obtain the diversity of specific industries, the digital economic industries and the literary and creative industries identified in the industry standard classification are classified into a group of related industries: S_g . Finally, the I industry in the industry standard classification is calculated. (Subcategory) In regional economies: the ratio of the number of employed persons in the P_{ij} industry to the total number of employed persons and the proportion of each relevant diversity in the regional economy (P_g). Using these ratios, the degree of diversification of the sub-industries within the same industry can be expressed as the following entropy in the (H_g):

$$H_g = \sum_{i \in S_g} \frac{p_{ij}}{P_g} \log_2 \left(\frac{1}{p_{ij}/P_g} \right) \quad (3)$$

In order to measure the degree of diversification of the fine industries with strong technological connections within the middle industry, it can be expressed as follows:

$$RV = \sum_{g=1}^G P_g [H_g] \quad (4)$$

Which type (4) as the target calculation formula, and the digital economy industry related diversity. Taiwan industry announced a total of four categories are categories, categories, categories and small categories, g value in industry categories, each industry is divided into several small classes industry. (1) calculated fine industry the area proportion of total employment, (2) belong to the same type of (3) Formula for calculating the diversification level of the fine industries in each medium industry.

Unrelative Variety, UV

Unrelated variety is to explore the correlation between different industries. The high level of unrelated variety means that the correlation between industries is not high, and they are not in the vertical or horizontal industrial chain.

$$UV = \sum_{g=1}^G P_g \log_2\left(\frac{1}{P_g}\right) \quad (5)$$

$$p_{ij} = \frac{\text{Population of the industry (region)}}{\text{Total Employed Population (Region)}} \quad (6)$$

$$P_g = \sum_{i \in S_g} p_{ij} \quad (7)$$

UV: unrelated variety

p_{ij} : The ratio of 4-digit level employment to 2-digit level employment in each township

P_g : The aggregation of the same 2-digit level category in the industrial category and the ratio of the employed population in the digital economic industry

Formula (5) is the objective formula to calculate the non-related diversity with the digital economy industry. (6) Formula (7) calculates the proportion of the fine industries in the region to the total employment population of the total industries. (7) Formula (7) is the sum of the ratio of the fine industries in the same middle class.

Employment growth

$$\text{Employment growth} = \frac{\text{Number of employed in that year} - \text{Number of employed in the previous year}}{\text{Number of employed persons in the previous year}} \quad (8)$$

Calculation of employment growth rate as shown in formula (8), base for a year before the employment population, this research of employment growth in 2006 and 2011, the annual employment population using data for the number of employment population in 2011, a year before the number of people in employment the number of employment population in 2006. Then we calculate the total industry employment growth rate, as well as digital the employment growth rate of economic industry is used to analyze the impact of related variety and unrelative variety on employment growth.

Empirical Research

Model and Hypothesis Verification

Based on the empirical process mentioned above, the section illustrates the establishment of the model, which is divided into two parts: confirming whether the diversity of digital economic industries in different townships affects the regional employment growth. Referring to the regression model (Lazzeretti et al., 2017), the relationship between industrial diversity and employment growth in different townships can be expressed as follows (9):

$$\Delta Y_t = \beta_0 + \beta_1 Rel[Val]_t + \beta_2 Un[Val]_t + \beta_3 Pop[Dens]_t + \beta_4 Human[Cap]_t + \varepsilon_t. (9)$$

Y_t : Employment growth rate

X_{1it} : RV

X_{2it} : UV

X_{3it} : Human capital

X_{4it} : Population]density

Among them, the total employment growth rate of all industries is taken as the strain of the three models, and the independent variables are the diversity of digital economic industries, related diversity, non-related diversity, population density and human capital, which measure the degree of urbanization, and t is expressed as time. The sources of all independent variable and dependent variables are shown in Table 1.

Table 1 list of multiple regression variables.

Item	Variables	Statistical units	Expected symbols	Source

Estimation of results and discussion

Table 2 lists the regression results of digital economic industry diversity and employment growth. In the first model (model 1), the overall diversity of digital economic industry is positive and significant, which shows that there is a positive relationship between the overall diversification of digital economic industry and employment growth. In model 3, the overall diversity of digital economic industry is used. In addition, The control variables of population density and human capital are also added. This model can find that population density is negative and human capital is not significant. The overall R2 increases slightly, and the overall diversity of digital economy industry is still positive and significant. Therefore, this model shows that various digital economy industries have a positive impact on employment growth.

In model 2, the variables of digital economic industry diversity are replaced by digital economic industry related diversity and non-related diversity. The model finds that both related diversity and non-related diversity are not significant, which means that companies engaged in digital economic industry can not generate employment growth in related or unrelated sectors. The spillover effect may be related to the industrial structure, or it may be because during the past decade, the industry has shown a saturated state, which slows down the growth of employment, resulting in a non-significant causal relationship between inter-departmental diversity and employment growth. However, after adding other control variables in Model 4, R2 has increased, and the related diversity of digital economic industries has also shown. Positive significant impact, while other variables show the same symbols and meanings, which indicates that a large number of technology companies are set up in interrelated departments, and the spillover effect has a positive impact on employment growth.

The regression results of cultural and creative industries and employment growth presented in Table 3 show that the regression methods are the same as those of digital economic industries, but the results are quite different. The results show that cultural and creative industries are not significant in the first six models. Only the irrelevant diversity in Model 7 has a positive and negative impact on regional employment growth and population density. This shows that the related industries within the cultural and creative industries can not promote the employment growth of the industries, but the non-related industries within the industries have a positive impact on the regional employment growth, which shows the concept of risk diversification, and the protected areas are not affected by external shocks leading to the regional total employment growth. It also shows that the unrelated departments within the cultural and creative industries can communicate with each other and produce spillover effects.

Conclusion

In the past, the research on related diversity mainly focused on all industries in the region, such as service industry and manufacturing industry. This study takes township administrative divisions as the research scope, defines emerging industries with 4-digit level, and lists explanatory variables for urban spatial differences. Finally, the spillover effects of related diversity in different industries and regions are analyzed.

Limitation of the study

The area identified in this study is 350 townships in Taiwan. There is no data on unemployment, and it is not possible to verify the hypothesis that irrelevant diversity can reduce the unemployment rate.

The original data used to classify the digital economy industry are classified according to the relevance of the nature of the work in advance, without taking into account the correlation between the input and output of the company and the export commodities of the company. Such a classification may be underestimated.

Contribution of the study

Analysis of the results of the two industries shows that the spillover effects of diversity are different for different industries, and non-related diversity in cultural and creative industries can also lead to employment growth, which has not been found before, but the R^2 of the general model is not high, which may be due to the lack of key variables, such as: company size, industrial returns, infrastructure. And so on, because of the relationship of product life cycle, for mature industries, on the contrary, because of the improvement of labor productivity, so as to reduce employment growth rate, which may lead to cultural and creative industries can not reflect the relationship between the spillover effect of diversity and employment growth.

Track 16: Urban and Regional economics of transition

Financial or societal returns? Exploring the ambiguous role of intermunicipal energy company Fluvius in the energy transition in Flanders

Griet Juwet¹, Laura Deruytter²

Abstract: Energy systems are key sites of spatial and socio-political transformation. This paper explores the role of distribution network operator Fluvius in the energy transition in Flanders. We examine the tension between the societal expectation for this public company to contribute to a more sustainable energy system, and the financial and spatial conditions for its operation. The analysis is based on 20 in-depth interviews, and advances the three spatial concepts of density, spatial selectivity, and scale, to highlight the socio-spatial tensions surrounding energy distribution. It reveals questions around energy tariffs for dense versus sparse areas, locational choices for collective heating and renewable production, and the spatial redistribution of the cost of energy transition. Although fundamentally political, the regulation and management of such issues is often framed in technocratic and economic terms, leaving spatial planning and redistribution implicit. By revealing these spatial and political dimensions, the research contributes to a broader debate about the role of energy distribution in a more sustainable and democratic energy system.

Keywords: energy distribution, implicit planning, socio-spatial redistribution, dispersed urbanisation

Introduction

Transforming urban energy systems has become a key element of spatial and socio-political urban change (Bulkeley *et al.* 2014). Rather than a merely technological challenge, the energy transition is therefore about a fundamental transformation towards a more sustainable and inclusive energy system (Morris and Jungjohann, 2016). This requires understanding and rethinking the arrangements of who owns, operates and finances these systems, and how they are spatially configured.

However, energy infrastructure networks are often characterised by a strong inertia since they are embedded both materially and spatially in the existing territory, and connected socio-technically to the energy ‘regime’ (Frantzeskaki and Loorbach, 2010, Markard, 2011). Spatial planning and design have started to explore the energy transition as a spatial question, showing how energy infrastructure transformation is connected with broader processes of spatial change (Juwet and Ryckewaert, 2018,

Sijmons, 2017). Transition studies have often focused on ‘niche’ innovations, but are increasingly interested in the role of regime players in transformation processes. Incumbent players in the energy sector are under pressure to adapt to a context of liberalisation and unbundling, decentralization and digitization, decarbonization and denuclearisation. As many urban infrastructures in Europe are privatised and increasingly financialised (Pike *et al.* 2019), in countries like Belgium, but also Switzerland and Germany, energy distribution largely remains in public hands (Mühlemeier, 2018).

This research focuses on the case of electricity and gas distribution networks in Flanders. These networks are 100% publicly owned by the municipalities, and managed by a single operating company called Fluvius. The research explores the ambiguous position of Fluvius by analysing the tension between societal expectations about its contribution to a more sustainable and democratic energy system, and the financial and socio-technical conditions in which it operates. Hypothetically, this tension can be identified both at the level of the municipalities and of Fluvius itself. While municipalities increasingly formulate strong climate ambitions, they also expect and depend on a yearly dividend from the network operator. Fluvius claims the ambition to become carbon neutral, and has public service obligations to promote energy efficiency and facilitate the uptake of renewables, but also has vested interests in the existing fossil gas network and a revenue that is relative to the kWh of energy supplied. This paper will focus on how these tensions materialise in the way Fluvius deals with questions of spatial planning and socio-spatial redistribution.

In the context of Flanders’ dispersed urban landscape, the relation between the spatial and organizational configuration of energy networks, and processes of urbanization is a particularly relevant dimension of Fluvius’ societal role. Many authors have showed how technical networks have historically facilitated and reproduced Flanders’ nebulous urbanization (De Block, 2014, Ryckewaert 2012, Van Acker, 2014). Heavy transport infrastructures such as canals, railways and later highways were often part of formal plans that had the ambition to modernise and industrialise the nation. Bruggeman shows how lighter supply systems, such as the electricity networks, can be read as an example of how collective consumption was organised through different governance and spatial arrangements within this urbanising territory (Bruggeman, 2019). Usually considered a rather technical question, the spatial organisation of the energy network was rarely an explicit object of formal spatial planning. However, as in other domains like transport or economic policy, many forms of ‘implicit’ planning have contributed to territorialisation processes (Ryckewaert, 2011).

Today the ecological and social limits of Flanders’ dispersed spatial organization are increasingly clear (Van Broeck and van Ypersele, 2019). Understanding the implicit mechanisms that reproduce or could potentially counteract these urbanization patterns therefore becomes crucial and could also inform formal processes of spatial energy planning. Looking at Fluvius today, this paper therefore explores in particular how the organisation of the energy distribution network relates with processes of spatial development, and what forms of implicit spatial planning are at stake in the way it is operated, financed and regulated.

Methodology

The key empirics of this case study research are based on 17 in-depth interviews with 20 people that took place between March and May 2019. The interviewees included staff members from several departments within Fluvius, such as financial management, strategy, and business. We also interviewed multiple stakeholders, such as representatives and civil servants of municipalities, civil society actors (environmental movement, labour unions, energy cooperatives), the Flemish energy regulator VREG, and the Flemish government energy agency. The interviews were semi-structured and lasted between 1 and 3 hours. Interviewees were asked about their role in, or relation with Fluvius, and about the societal, political, spatial and financial aspects of how Fluvius operates. We complemented the interviews with desk-research on secondary documents, such as the Flemish Energy Decree, annual reports of Fluvius, the Fluvius website, and reports by the regulator. The transcribed interviews and most relevant documents were coded and analysed with the software MAXQDA.

Introduction of Fluvius as a case study

To introduce Fluvius as an object of study, we use recurring descriptions by interviewees, as they highlight diverse perceptions of Fluvius' current and potential role as a public actor in the energy transition.

Fluvius is regularly described as *'the extension of the municipalities'*. It is the operating company for electricity and gas distribution for 11 locally organized 'intermunicipal companies' ('opdrachthoudende verenigingen', distribution network operators or DNO's, Figure 1). Ultimately, the shareholders of these intermunicipal companies are the 300 Flemish municipalities, that have transferred the construction and operation of the energy distribution system to Fluvius.

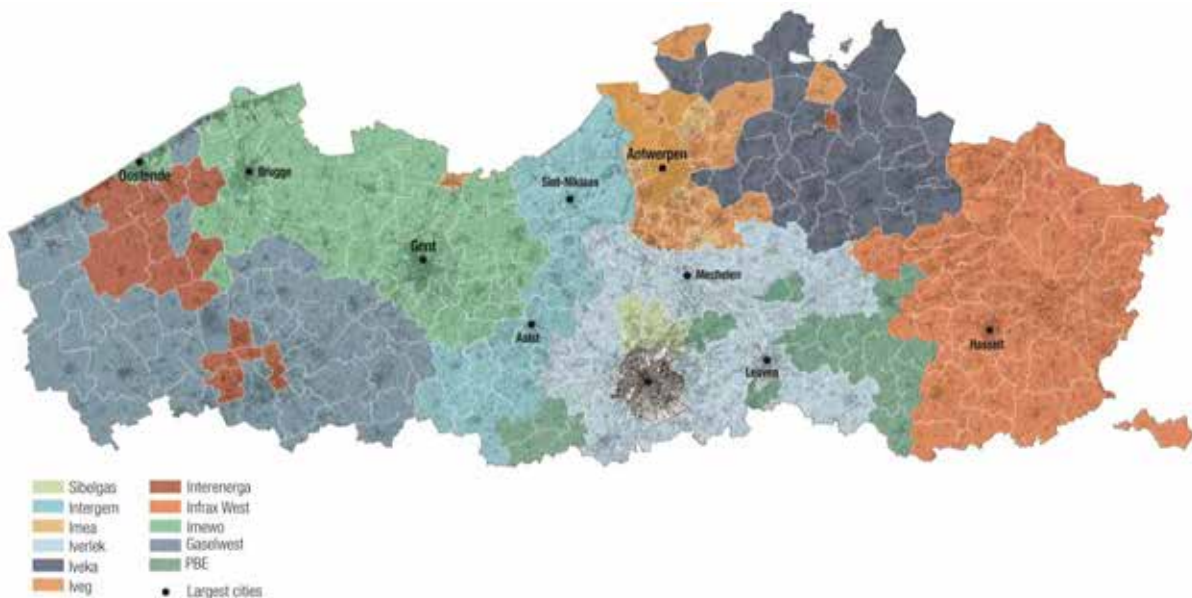

Figure 1. Map of Flanders showing the intermunicipal energy companies for electricity distribution.
Source: elaborated by author based on Fluvius.be, May 2019

Next to operating Flanders' electricity and gas networks, in several areas Fluvius also operates some sewerage, tv cable, public lighting, and district heating. Providing this range of services, the company is referred to as '*the manager of the underground*'. Today, Fluvius explicitly positions itself as a multi-utility company with the ambition to become 'the' network operator for Flanders. On top of its core business of 'managing underground assets', Fluvius also ventures into other activities, sometimes assigned through the Flemish Energy Decree, other times developed independently by Fluvius. This has raised questions about what its 'core tasks' as a public company should be.

As an operating company Fluvius is the result of a merger between the two formerly existing distribution companies Eandis and Infrax. Eandis worked for the so-called 'mixed' intermunicipal companies (historically combining public and private shareholders), while Infrax operated the network for the 'pure' intermunicipal companies that had only public shareholders. Fluvius' current monopoly for energy in Flanders, and multi-utility position explain its perception as '*a tanker*', for which it is difficult to change direction. This monopoly position also challenges the work of the regulator as a comparable benchmark is missing.

Findings and discussion

In the context of an increasing awareness about the ecological, social and economic consequences of Flanders' dispersed urbanization, it is particularly relevant to understand the spatial mechanisms behind the operation of the energy network. How does the organization of the distribution system support or reproduce dispersed forms of urbanization, or does it offer opportunities to rethink these processes? These are crucial elements in understanding the network operator's role in the transition towards a more sustainable energy system and territorial organization. This section therefore focuses on the findings related with the spatial logics behind how the distribution network is planned, operated, financed and regulated. The three concepts of 'density', 'spatial selectivity' and 'scale' will be used to structure these findings. Based on an earlier literature review (Juwet and Ryckewaert, 2018) and on the empirical material, they emerge as useful notions to conceptualise the relation between energy infrastructure and spatial morphology, and to reveal some of the tensions and ongoing debates about Fluvius' role in the energy transition.

Density: energy tariffs and the cost of sprawl

The spatial dimension of the distribution system becomes explicit in discussions about the relation between energy tariffs and spatial morphology. This is particularly relevant in the context of a broader societal debate in Flanders about the 'cost of urban sprawl', and the transition towards a less space- and energy-intensive form of urbanization (Van Broeck and van Ypersele, 2019). This section will illustrate how a planned tariff reform is nevertheless treated as a technical question and public debate about the cost of this extended utility network remains limited.

Today, connection fees for electricity and gas are independent of a customer's location, even though denser areas need less infrastructure per building. Differences in distribution tariffs exist between DNO's, but are related to a historical valuation of the network assets, rather than to the density of urbanization (Figure 2).

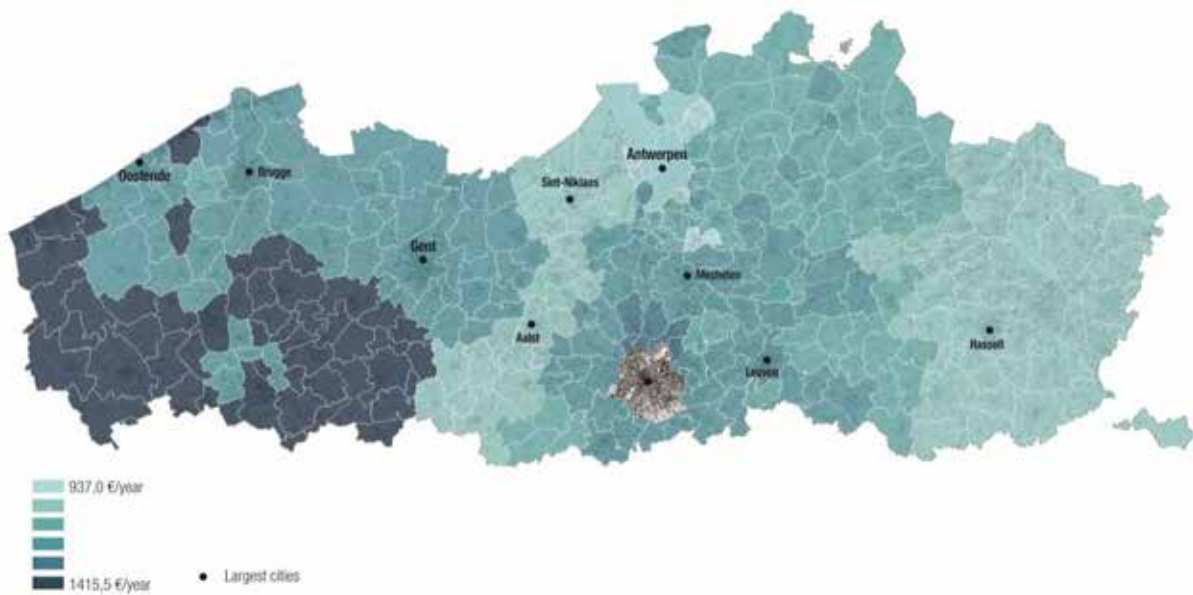

Figure 2. Map of Flanders showing the tariff difference (network cost + charges) for electricity and gas for an 'average family' in each municipality.

Source: elaborated by author based on tariefchecker.be, 2017

Today, a thorough reform of the energy tariff structure is under investigation by the Flemish regulator. Instead of a tariff based on energy use (€/kWh), the reform proposes a tariff based on the capacity of the connection (€/kW), to make the tariff more 'cost reflective' as required in the Flemish Energy Decree. Interestingly, this Decree also specifies that *"when introducing a capacity tariff, the tariffs take into account regionally objectifyable differences"* (Energiedecreet, 2015). One interviewee indicated that *"this passage was added explicitly on demand of the city of Antwerp"* because if energy tariffs would be homogenised in Flanders, *"the city, and other cities probably, would want to keep their comparative advantage of lower tariffs"* (interviewee 1).

The regulator is therefore investigating which 'regionally objectifyable differences' could be identified that influence the network cost, and what criteria these differences should meet. A first study by an external consultancy firm analysed the legal context for such criteria and the use of regionally diversified tariffs in Norway and the Netherlands (Vanden Berghe *et al.* 2018). While the regulator aims to identify these criteria through a scientific study rather than engage in policy discussions, it also recognises that the percentages used to judge the 'significance' of a particular difference, have 'an arbitrary character' (cons-2018-03, p. 8). Possible 'differences' to be considered could range, as they did in the Dutch and Norwegian cases, from landscape characteristics (canal crossings, terrain slopes ...) to technical aspects (number of substations, underground cables), differences in governance (local charges, malpayments ...) or aspects of spatial morphology (distance to roads, building density, connection density, proportion of villages or cities ...) (Vanden Berghe *et al.* 2018).

This rather technical discussion is related to a broader understanding of the historically shifting role of public actors in the provision of basic energy services across the territory, brought up by multiple interviewees. *"When those networks emerged, the private [sector] was only interested in the cities, and they left the 'sparse' areas for the public sector"* (Interviewee 17). But today, the societal cost of this extended provision of utility networks is questioned. *"Yes, energy is a basic need and therefore*

everyone has to have it, and then we [the public sector] have to put a huge amount of money into it. And then you have to ask whether that is the solution, or whether we have to bring people where the opportunities are. That has to do with densification, strengthening centres and such more” (Interviewee 6). That is why some actors are in favour of diversifying energy tariffs according to (building / population / connection) density. *“Moreover [next to paying for capacity], in far-away-land, you probably have a kilometer of cable just for you, so we’ll have you pay for density as well”* (Interviewee 6).

On the other hand, some interviewees doubt the relation between density and network cost. *“At first you would think: such lengths, you’ll have to put more pipes... but one forgets that in the country you only have to ‘pull a cable’ in a ditch. In the city you have to break open the streets, the footpaths, [...], try putting a cable in Antwerp! [...] It has to do with the proportion between investments and maintenance, and the balance between both. [...] My prognosis is that there will be differences, but they will be limited: the disadvantage of being dispersed, is compensated by the complexity in urban areas”* (Interviewee 1).

Interestingly, a study about regionally objectifiable differences for the Netherlands, was inconclusive about the potential factor of ‘connection density’ because there wasn’t enough objective information to recognise this aspect as a regional difference (Vanden Berghe *et al.* 2018). A recent study quantifying the cost of urban sprawl in Flanders, confirms that the investment and maintenance cost per meter of energy infrastructure is higher in urban than in rural areas (85€/m vs. 30€/m for electricity distribution). However, because the length of infrastructure per building in very dispersed areas (86,2m/building) is much higher than in urban areas (9,2m/building), the total cost of energy infrastructure per building is around 3 times higher for dispersed areas (Vermeiren *et al.* 2019, p. 62).

A complex aspect of researching these regional differences, is identifying the appropriate scale to analyse factors such as density. In theory, both tariff differences between intermunicipal companies, and within the area of a distribution network operator are possible. *“As far as I’m concerned, you just look at the level of the DNO, what is the density [...]. For Antwerp it would be best if you would do that per municipality, or per street. But that’s not workable, you shouldn’t make it more complex than it already is”* (Interviewee 6). But investigating regional differences only at the level of the DNO would, in the case of spatial density, even out more significant differences at smaller scales. *“[...] We can’t just say ‘for Gaselwest it’s like this, and for Imea it’s like that. [...] If the one would be purely city, and the other purely villages, you could say there’s a difference. But they are both a mix of cities and villages”* (Interviewee 18). While data gathering and calculation on a finer resolution might be more complex, it would better represent the actual morphology within a region. Therefore, a crucial question is whether data about infrastructure and maintenance costs are available at smaller resolutions, and what approach and spatial data will be used to conceptualise and analyse ‘density’.

Another complication is the suggestion in Europe’s Clean Energy Package (2017) that distance-related factors should be part of the connection cost rather than the distribution tariff: *“We agree that transmission and distribution tariffs shall not be distance-related since distance of a customer from the network is not a cost driver for the operation of the network. [...] therefore, it has to be clarified that only connection charges, in order to be cost-reflective and give locational signals, may well be distance-related”* (Vanden Berghe *et al.* 2018). Some interviewees indicated that such technocratic European guidelines limit the possibility to use tariffs as part of a broader (spatial) policy approach.

Europe assigns competency on tariff matters to the VREG, which indeed treats the regional tariff differentiation as a purely technical question. *“The government can give a few guidelines but can’t say ‘this has to be payed through the tariff, and that not’. Then the VREG says ‘we determine the tariffs, the government can’t decide anything about that’”* (Interviewee 20).

Consequently, public and political debate about spatial tariff differentiation remains limited. To a stakeholder consultation organised by the VREG, only a limited number of actors responded: the Farmers’ syndicate (‘Boerenbond’), FEBEG (Federation of the Belgian electricity and gas companies), and a collective response by several DNO’s. A wider stakeholder consultation could have contributed to a societal debate about the future of the energy system, and include perspectives from civil society or the Flemish Department of environment and spatial planning. However, as emphasised by FEBEG in response to the consultation, *“the introduction of regionally objectifyable criteria can’t be used as a policy measure. Tariffs are only to cover the costs of the DNO, they are not a policy instrument”* (cons-2018-03, 2018, p. 14).

Other interviewees have the opposite view: “The regulator has an independent role, a bit too much for my taste. [...] Those objectifyable differences, ‘objectifyable’ is a word too much for me, you can objectify or de-objectify everything. [...] These are things [...] that should be determined much more by the Flemish government and parliament. Not the technicalities, that should be done by the VREG, but the political choices, for example should we use density and even how to use it [...]. That is a choice you make, but one where it might be easier later-on to hide behind the regulator. My opinion is: make a political choice and defend it” (Interviewee 6). Indeed, diversifying energy tariffs based on density is a very sensitive issue, especially since the dispersed urbanization of Flanders has long been supported by public policy, among which the ubiquitous and cheap connectivity to energy supply systems. It is therefore especially important not to treat energy tariff reforms as a technical matter, but to understand and publicly discuss their socio-spatial implications as an inherently political question.

Spatial selectivity: energy transition and the cannibalisation of the gas network

Electricity and gas networks became historically structured around centrally produced energy, distributed ubiquitously across the territory. But renewable energy production and in particular sustainable heating solutions (individual or collective systems) will be more localised, and therefore spatially selective. Indicative of this evolution is that the obligation for Flemish DNO’s to increase the degree of connectivity to gas networks - up to 99% for urban areas and to 95% for ‘rural areas’, implemented after the oil crisis in the 70s - was lifted recently. It then becomes crucial to understand how decisions are made about what type of infrastructure will be provided where, what criteria are used and who makes such choices. In this section we illustrate how investment decisions by Fluvius are rather justified by arguments of rentability, than through explicit political or spatial planning objectives.

In recent years, Fluvius started developing district heating projects. While the company has a monopoly on electricity and gas, the emerging heating sector is not yet strongly regulated. Fluvius is only one of the district heating developers next to commercial firms and citizen cooperatives. Often such projects are initiated following a request by a municipality: *“We get a lot of questions around heating, it’s a hot issue. Especially when elections are coming up. Then [...] every municipality wants its district heating project. And every request gets answered”* (Interviewee 2). Several interviewees

confirm that the economic feasibility, is the decisive factor for a district heating project. Fluvius looks at the availability of residual heat, the heat demand density, and the business case¹. *“That whole cost (transport, pipes, construction, maintenance, measuring) needs to be earned back through the price people pay, that is a purely economic story.”* From that perspective, this interviewee sees only a limited role for government: *“Who decides this? At those who put money on the table, that take economic risks to build the pipes, supply the heat, or use the heat. [...] What should the government do? We have to make sure the pipe gets in the ground, that the permits are there...”* (Interviewee 6).

According to these criteria, district heating is only feasible for Fluvius in areas where the linear heat demand density is high². *“[drawing a map of Belgium] Here you have Antwerp, Ghent, Brussels, maybe Liege and some other cities that have some waste incineration will have district heating. All the rest will be a mix of everything: all-electric solutions, gas, maybe some geothermal”* (Interviewee 2). The feasibility also depends on local context: *“District heating is interesting in areas with a lot of public buildings: swimming pools, hospitals, elderly homes,... [...] But new allotments, unless we’re talking about low temperatures, classical district heating? No!”* (Interviewee 2). Another respondent explained: *“As a society, we have made a choice for natural gas in the past. Today, district heating is technically and economically not justifiable anymore”* (Interviewee 17). This difficulty to ‘make the business case work’ was confirmed by Fluvius: *“It is an interesting story, but not an easy one. Untill now it [district heating] is making a loss”* (Interviewee 2). At the same time, investing in these projects is also seen as part of Fluvius’ societal role, investing in infrastructure that is not (yet) commercially profitable (Interviewee 2). Another respondent explained: *“Intermunicipal companies have much longer depreciation periods than commercial firms. If you would do this commercially, you’d want to earn back the investment in 7 years, for us that’s after 20 or 30 years. So in that sense there is a great advantage in doing this as an intermunicipal company”* (Interviewee 6).

In practice however, several district heating projects developed by Fluvius, are located in greenfields, sometimes in strategic central locations, but also in peripheral areas with lower densities. Crucially, all the realised projects are located in sites where no natural gas network existed. As one interviewee remarked *“At a certain moment, these intermunicipal companies, Fluvius, that are now developing district heating, are canibalising their other assets, the gas network”* (Interviewee 5). Asked about this internal conflict of interest, one Fluvius employee responded: *“We should nuance this impact on the natural gas network. We see very little projects where we switch from natural gas to district heating from one day to the next. [...] In the total investment needed to realise the energy transition, the residual value of the natural gas network is a marginal fact”* (Interviewee 4). When calculating the feasibility of district heating projects, the company does not (yet) include the cost of ‘stranded’ gas assets (Interviewee 2). Simultaneously, Fluvius emphasizes that the gas network does not have to be a stranded asset. *“The gas distribution network doesn’t hold back a sustainable future. It is often associated with a fossil story, but you can also transport green gas, hydrogen gas, carbon dioxide... such a network can still have value in a sustainable future”* (Interviewee 4).

¹ using the principle that the ‘total cost of energy’ for heat has to be lower than for the alternative, today considered as a gas boiler used for 15 years..

² This interviewee mentions a minimum of 4 or even 5 MWh/m, while other analyses often use an indicative ‘rule of thumb’ estimating that district heating is feasible above 3 MWh/m (Nussbaumer & Thalmann, 2014)

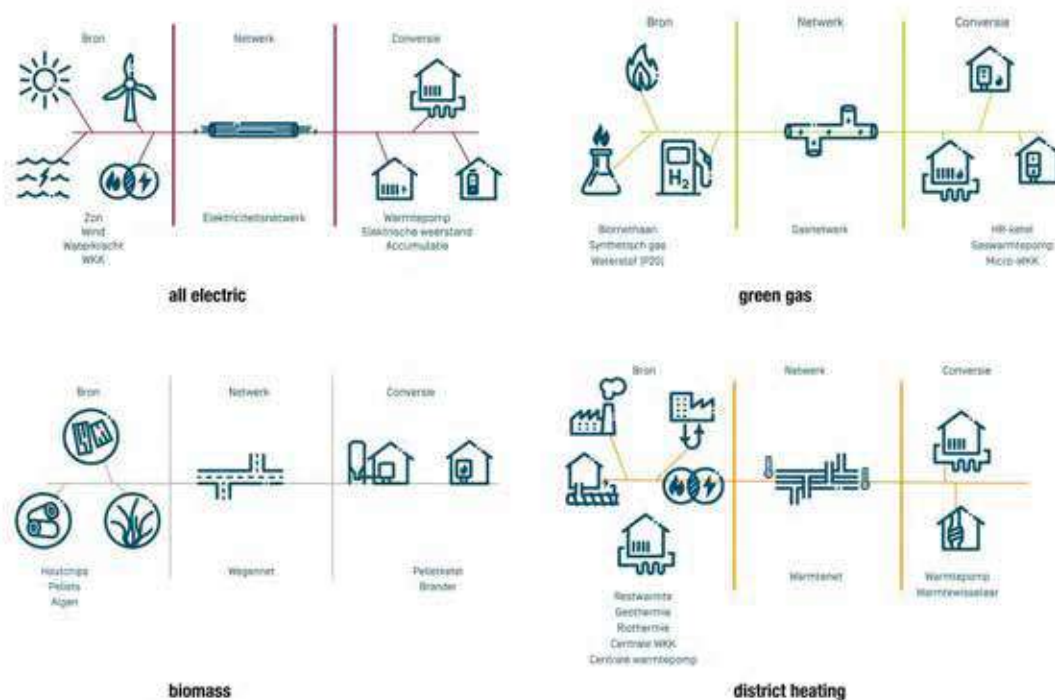

Figure 3. Climate neutral energy concepts. Framework for the approach to energy transition.
Source: Fluvius, December 2018

From that perspective, it is interesting that Fluvius has developed four ‘sustainable heating concepts’ (Figure 3), and sees a role for itself in all electric, green gas and district heating solutions. The status of these concepts remains unclear. Several interviewees hinted at the need for spatial heat planning, but so far Fluvius is not developing plans about which technology would be appropriate where, and suggests this is a question for municipalities and/or the Flemish government. Some consider this a rather technical exercise: *“I think we need the same approach for heating [as we have for sewerage]³. The Flemish energy agency or regulator should make comprehensive zoning plans, based on the heat demand map and residual heat offer”* (Interviewee 5). Others recognise the heat planning efforts of several larger cities, and would like Fluvius to be more involved in those exercises, such as the SEVIA project by the city of Antwerp to develop a ‘Strategic Energy Vision’ (Interviewee 2). On the other hand, the company is often not represented at heat planning workshops organised by local governments. Moreover, it could support such heat planning initiatives by making data about current energy use, but also about the gas network (planned investments, financial value, remaining lifespan) available more easily and at higher resolution.

The question of spatial selectivity also appears in the location of renewable energy production. The integration of intermittent energy sources like solar and wind, challenges Fluvius to reconfigure the distribution network from a one-directional to a multi-directional and smart system that can flexibly balance production and demand. However, rather than trying to steer siting choices for renewable production, Fluvius rather responds to concrete requests for connection. *“When the government imposes certain obligations, the networks have to follow. It would be ideal if a calculation would be*

³ Since 2006, every Flemish municipality was obliged to develop a zoning plan indicating where public, collective or individual water cleaning infrastructure would be developed.

made beforehand to understand what it will cost and keep that under control. But in a dense country like Belgium this should not mean a big added cost, wherever those installations will come” (Interviewee 18). Eandis and Infrax commissioned such a study about ‘reception capacity’ (‘onthaalcapaciteit’) together with transmission network operator Elia in 2012 (VITO, Infrax, Eandis, Elia, 2012). But in practice, the location of wind turbines for example, is determined by many other factors beyond the optimal network configuration. Overall, Fluvius appears to prefer anticipating trends in the energy sector and responding to requests from municipalities, rather than planning or directing the energy transition. *“We can answer questions that exist, but we shouldn’t try to answer questions we don’t know will come. [...] It has to be planable”* (Interviewee 2). Another Fluvius employee explained: *“It is true that we determine what infrastructure comes where, and that the availability of infrastructure has far-reaching consequences for the decisions people will take in the future. We have to make sure that we don’t block better alternatives, but it is very hard for us to know, in 50 year, what will be best?”* (Interviewee 3). This interviewee positions Fluvius as a neutral partner for municipalities: *“We are very neutral, literally, we are an independent, objective partner to think along with municipalities about what is possible, what is sensible and what is not. We’re not there to sell heat pumps or gas boilers. Is it a natural gas net or an electricity net or a district heating system, we’ll build it. For us, it doesn’t matter what goes in the ground, as long as it is durable. Why? In 20 years we’ll still exist, and if it isn’t a durable solution we’ll have to deal with the costs”* (Interviewee 3).

On the one hand it is problematic that Fluvius often justifies investment choices based on arguments of rentability and ‘business cases’ without recognising their spatial consequences and inherently political character. No spatial decision or choice for a specific infrastructure is really ‘neutral’ in a context where energy networks are an essential part of a territorial organization and energy system in need of fundamental transformation. However, such structural decisions transcend Fluvius’ role as operating company, and point to the need for a clear mandate, either from its Board of Directors or from the Flemish government. This mandate should be based on a societal discussion, that sets out the strategic lines for the appropriate energy distribution system of the future.

Scale: socio-spatial redistribution and the cost of transition

A third dimension of how the distribution system is spatially managed, relates to the scale and composition of the intermunicipal companies who own the network and represent the municipalities. This configuration influences how costs are redistributed spatially and socially through the different components of the energy tariff. The companies’ ongoing (re-)composition creates or forecloses possible operational synergies, strategic planning advantages, and coherence in governance arrangements.

Historically, governance of the energy network has evolved towards increasing homogenisation and upscaling. Electricity systems have diverse origins, being set up by entrepreneurs or cooperatives, initiated as public firms by municipalities or expanded through provincial policy Bruggeman, 2019). *“It started with electricity after WWI. In the village you had a brewery, they installed a generator but they had some surplus electricity and started a line to the church and the town hall... and that is how public lighting started. [...] These ‘gemeentelijke regies’ started to grow, and neighbouring municipalities often said: ‘let’s do this together’. Then you had the ‘intercomune’: intermunicipal company. Some did it themselves, but others gave a concession to a local electrician. That is how the*

‘pure’ and ‘mixed’ intermunicipal companies emerged” (Interviewee 2). Over time these local companies gradually merged: “Since 1954-55 the electricity sector was centralised more and more. [...] At a certain moment, the ‘mixed’ intermunicipal companies owned 80% of the distribution networks, and the municipalities had 20%. Those that survived were the ones that organised more efficiently” (Interviewee 17). Since 2003, Eandis and Infrax acted as the operating companies for respectively the ‘mixed’ and ‘pure’ intermunicipal companies. Following the European directive to ‘unbundle’ electricity distribution and production, private shareholder Electrabel was bought out of Eandis and the mixed intermunicipal companies, leaving them 100% in the hands of local municipalities. Eandis and Infrax ultimately merged into Fluvius in 2018.

This process of centralisation also led to a homogenisation of governance arrangements. Several historical constellations, that spark interest in current discussions on remunicipalisation or citizen participation in urban utility governance, have disappeared. Considering several Flemish cities are discussing the possibility to start a public energy company, in the spirit of the German Stadtwerke, it is relevant to know that the city of Ghent, for example, used to have an urban utility company: *“At that time you had the EGW in Ghent: ‘Elektriciteit, Gas, Water’: and urban company like you have in Germany, and the only one of that scale and that integrated in Flanders. But it was sold after the elections in 1983” (Interviewee 17). In light of demands from civil society about citizen participation in the energy sector, and with the increase in citizen energy cooperatives (Interviewees 10, 11, 12, 13), it is interesting to see that customer participation has also existed in the distribution sector: “We used to have something fantastic here at IVEG. We had a ‘consumer association’ where people could buy a certain amount of shares and then got a reduction on the energy tariff. [...] Overall, you had a return of 11%, it was succesful! This association [...] had a voice in the Board of Directors. We wanted to continue this but because of the decree on intermunicipal collaboration of 2001 we had to abolish the association as private capital was no longer allowed in the intermunicipal company” (Interviewee 1).*

Several interviewees mentioned advantages of this increasing centralisation. “Many small municipalities can achieve standardisation this way. By working together they can get better conditions. [...] For example Sibelgas, the smallest DNO, is composed of only six municipalities so the solidarity is limited, the weight of one becomes much heavier” (Interviewee 4). Fluvius’ scale was also seen as an advantage for knowledge and equipment for another respondent. Although he was critical about the level of innovation within Fluvius, he still preferred this arrangement: “So I think you better struggle for your intermunicipal company to become more effective and future-oriented, than to start doing everything on your own” (Interviewee 7). Others regret that the increasing scale of the network operator changed its relation to municipalities: “The position of municipalities diminishes: the distance, it becomes technically complex, it exceeds the level of the average local representative...” (Interviewee 1).

The historical evolution of the intermunicipal companies and the former competition between Eandis and Infrax for municipal concessions, has sometimes resulted in geographically incoherent associations (Figure 4). Moreover, a recent change in the Energy Decree stipulates that municipalities have to contract the same operator for electricity and gas. The process of integration and rationalisation is therefore ongoing. It simultaneously follows two directions: on the one hand forming more geographically coherent and sometimes larger-scale entities, and on the other integrating different types of utilities in one operating company. Such mergers between intermunicipal companies

were realised in the Antwerp region and the Limburg province in April 2019, and considered in Flemish Brabant as well.

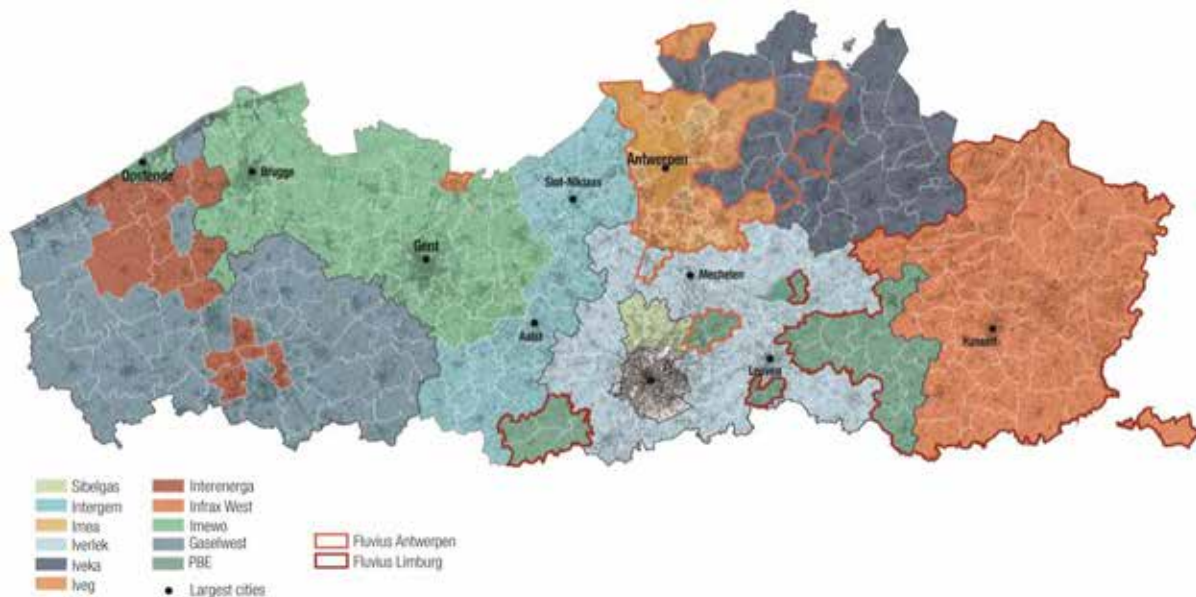

Figure 4. Recent mergers of intermunicipal network operators.

- Antwerp region: Iveg (formerly public, electricity + gas + sewerage) + Imea (formerly public-private, electricity + gas) + Integan (cable) > Fluvius Antwerp (April 2019)
- Limburg: Inter-Energa (electricity+gas) + Inter-Aqua (sewerage) + Inter-Media (cable) > Fluvius Limburg (April 2019)

Source: elaborated by author based on Interviewee 1 and Fluvius.be, May 2019

Because the public companies under Infrax often managed not only electricity and gas networks, but also sewerage and cable infrastructure, Fluvius became a multi-utility company. It publicly claims the ambition to develop further in that direction, and started to realise that aspiration with the mergers in Antwerp and Limburg. “I would like Antwerp to be the first to bring water, gas, heating, electricity, cable, sewerage, all together and say: all my underground assets are in one hand, and one hand will operate and try to manage it better” (Interviewee 6). One of the advantages of integrating different utility systems in one operator is that synergies, and therefore cost optimisation, between different infrastructure works would become easier. Avoiding nuisance from road works was mentioned as an important concern for municipal representatives.

Other interviewees were more critical about Fluvius’ increasing scale and monopoly in energy distribution. “It risks to become a state within the state. From a democratic perspective that is really a point of attention” (Interviewee 1). This concern also resonates with other interviewees, who asked for more transparency, and better stakeholder participation to complement the stepped political representation of municipalities. On a strategic level, more spatially coherent and integrated regional utility operators would provide a stronger governance base to plan and implement regional spatial strategies for energy and other utilities. An interesting reference are the ‘transport regions’ that were recently introduced in Flanders.

Costs of energy infrastructure and ‘public service obligations’ are redistributed on different spatial scales through different components of the electricity tariff (Figure 5). Fluvius is charged with social obligations (eg. supplying energy to customers dropped by their commercial supplier) and ecological

obligations (eg. awarding subsidies for rational energy use investments, buying ‘Green Energy Certificates’ for connected PV installations). These different costs are recuperated through the distribution tariff at the intermunicipal scale, and through Flemish and federal charges on the tariff. These mechanisms organise a social and spatial redistribution that has historically allowed energy to be available as a basic service for almost everyone.

Figure 5. Socio-spatial redistribution of cost for public service obligations on the intermunicipal, Flemish and federal scale. Source: author based on vreg.be, 2019.

However, this system is criticised for multiple reasons. On a structural level, several civil society actors argue for a shift of charges from electricity to fossil fuels. They also criticise the fact that these charges apply only for customers of the low-voltage grid while energy-intensive industries are directly connected to the transmission grid and pay no fair share in the societal cost of the energy transition. These redistribution mechanisms were also a main element in critiques from civil society about the planned introduction of a capacity tariff: *“This includes all kinds of redistribution aspects. Concerning the low-voltage customers, we’re roughly speaking about the redistribution between poor families and families with very low consumption, and rich middle-class families and small SME’s, a butcher and a bakery. The more the capacity tariff works as a fixed cost, the better for the high-consuming low-voltage customers, and the worse for the low-consuming customers. But that has an economic and a social impact!”* (Interviewee 15). However, the regulator’s competency on tariffs, independent from politics, and its technocratic focus on ‘cost reflectivity’ seem to limit the possibility and impact of a more fundamental political debate on the topic. Interestingly, the Flemish water sector shows that it is possible to translate policy objectives into the tariff structure, in this case by distinguishing between a ‘basic consumption’ tariff below a particular threshold and a much higher tariff for ‘luxury consumption’.

Because the cost of buying up Green Energy Certificates is higher in regions where more PV installations were installed, than in others, a solidarisation between different DNO’s was arranged. *“Eandis had 80% of the energy network and Infrax 20%, but Infrax had 30% of the solar panels, and Eandis 70%. Infrax was historically always a pioneer in supporting rational energy use. But it could also be because Infrax had more rural areas and there are more roofs to put solar panels”*

(Interviewee 1). This imbalance is also criticised as an unwanted socio-spatial redistribution: *“Antwerp inhabitants are paying for the solar panels of people in Limburg who have more financial means and live in a detached villa where you need a very long cable to connect, while Antwerp people live in an apartment or rowhouse and the number of connections per cable is much higher. Urban inhabitants are paying for the solar panels on the countryside, and those urbanites are in general less well-off”* (Interviewee 6).

These discussions indicate how governance arrangements for the energy distribution system are part of bigger societal questions about socio-spatial redistribution. They are particularly relevant in understanding and negotiating how the societal cost of the energy transition is distributed, an aspect that will become even more pertinent as more alternative heating solutions are implemented. Sustainable heating systems can be individual or micro-collective installations or larger-scale district heating systems, each with different costs and tariffs. A crucial societal question is therefore how to ensure equality in access to sustainable heating solutions, and a just social redistribution between a diversity of technical and governance arrangements.

Conclusion

While Fluvius’ work is often framed as ‘functional’ or ‘neutral’, and justified through technocratic and economic arguments, the research reveals that investment decisions, tariff structure and regulation, and network governance have fundamentally spatial and political dimensions. We showed how the concepts of density, spatial selectivity and scale allow to expose and analyse these dimensions in seemingly technical discussion.

A first aspect regards the relation between energy tariffs and density. The dominantly technical approach of the Flemish regulator to tariff reform and the inclusion of ‘objectifiable regional differences’, fails to recognise the social and political dimension of spatially diversified energy tariffs. This discussion should be part of a broader societal debate to rethink the mechanisms that support or reproduce dispersed spatial patterns. To grasp the social, economic and political complexity of this question, the insights of civil society, Flemish energy and spatial planning departments, municipalities and other stakeholders need to be brought together. This dialogue should inform a political debate and decision about the energy tariff structure, that forms the basis for a technical elaboration by the regulator.

Second, the energy transition signifies an evolution from a territorially rather homogeneous energy system towards spatially selective and more context-specific energy solutions. Despite Fluvius’ interests in the existing gas network, and while holding the key to the successful integration of decentral electricity production through operating the distribution network, the company positions itself as a ‘neutral’ partner of municipalities. Fluvius doubts the ‘planability’ of the energy transition and prefers to ‘keep all options open’. At the same time it recognises that without clear policy choices the European climate targets won’t be reached: *“Natural gas consumption is declining, despite the fact that there are more connections every year. [...] When we look at 2050, we see a reduction by 50%. That sounds a lot, but if we compare that to the plans of Europe, the ambitions to be climate neutral in 2050, we see a discrepancy between current policy and the ambition, because that would*

mean that carboniferous gas consumption in 2050 should be quasi zero” (Interviewee 3). Most interviewees agreed that strategic decisions about a future energy system should not be made by Fluvius alone but should result from a societal and political discussion. Moreover, the company should support this debate with its expertise and data, pro-actively organise dialogue with stakeholders and engage with energy planning efforts at Flemish and (inter-)municipal level. Co-creating a vision about the future of electricity, gas and heat distribution would allow Fluvius to plan its future investments more effectively and orient its societal role explicitly towards a climate-neutral energy system by 2050.

Third, the discussion about the increasing scale and continuous recomposition of the intermunicipal companies, reveals how governance arrangements for urban infrastructure matter in optimising energy systems. More spatially coherent and integrated multi-utility regional governance structures could provide a stronger basis for operational synergies and strategic future development. These governance arrangements include the redistribution of Fluvius’ ‘public service obligations’ on different scales through different components of the energy tariff. This illustrates how socio-spatial redistribution mechanisms are inherent to the organization of the distribution system in Flanders. The network operator and regulator therefore have a key role to ensure a fair distribution of the societal cost of the energy transition. But also federal and Flemish politics and the Flemish Energy Agency have the responsibility to create a policy framework for a just transition. Civil society has demanded a more transparent and democratic network governance, and more attention for the impact of tariff changes and energy efficiency policy on vulnerable households. More openness from policy-makers and from Fluvius towards these demands is crucial. Particularly in the emerging transition towards sustainable heating alternatives, where solutions are particularly context-specific and technically diverse, a thoughtful approach to redistribution, compensation and support mechanisms will be essential.

By making these socio-spatial dimensions explicit, this research aims to contribute to a broader societal debate that rethinks the role of the distribution network towards a spatially and socially sustainable energy transition. On the one hand this would require Fluvius to further develop a more open attitude towards civil society and policy-makers at Flemish and municipal level. On the other hand, it is a reason for spatial energy planning initiatives at local, regional and Flemish level to consider Fluvius as an essential partner in the energy transition and insist on a more open collaboration.

Abstract: Following the economic booming in Taiwan since 1950's, the housing prices increase in a fast pace, especially in the capital city area (Taipei) in northern region of Taiwan. However, there is an immense difference of rising degree by regions from north to south. The heterogeneity of regional spatial development forms the differences of housing environment attributes and results in different housing price distribution for local regions. In this study, we select three metropolitan municipalities regions in Taiwan, including Taipei, Taichung and Kaohsiung as the empirical areas to construct the so-called the Regional Housing Price Model (RHPM). The RHPM will be constructed empirically in Taiwan area to take into account of the spatial heterogeneity, spatial spillover effects, local environment attributes by metropolitan municipalities regions, and the Taiwan macro-economic factors as well. We investigate how national and regional elements impact on regional housing market by using spatial panel data model. Different from the past studies, this paper considers both spatial heterogeneity and dependency simultaneously. We found that the spatial spillover effect is positive in the northern region, negative in the central region, but insignificant in the southern region of Taiwan. It also shows that the three regions were in distinct stage of development, causing the characteristic of regional housing market to present differently.

Keywords: Housing price, Region Spillover effect, Panel data, Taiwan

Introduction

As seen in Figure 1, The housing price in Taiwan kept increasing in recent years, however the rising of regional housing price is inconsistency. Each housing market has different condition due to the unbalanced development of regions. Taking closer to it, we will discover there is an unbalanced issue in Taiwan. Besides being partial to the construction of western half of Taiwan, government of various periods make development focus region move from south to north (In western half of Taiwan, it can be divided into northern, central and southern regions). In general, unbalanced problem in Taiwan becomes worse and worse, northern region takes role of stronger development core, while central and southern regions are relatively periphery in current situation.

Following upper statements, the regional housing market failure may happen because that the differences of built environment, population, public service and so on, making the mechanism of housing market differs from region to region. The characteristic of regional development plays an important role in housing market, including not only the national and regional factors, but also spatial heterogeneity and spatial dependency.

Previous studies have shown that the national and regional factors have impact on regional housing price. Besides, by the use of panel data (combination of cross-sectional data and time series data, the structural differences(time-invariant) among regional housing market which may causing bias can be controlled. However, the problem of spatial dependency still remains. Instead of operating independently, regional housing market are interlinked, which should be considered in countries or areas where regions are strongly connected to each other. This paper was concerned with the construction of a housing price model that captures not only spatial heterogeneity but spatial dependency.

Spatial panel data can be seen as an extension of panel data with spatial units. By using spatial panel data, the problem of spatial heterogeneity and spatial dependency can be considered at one single model. This study developed a regional housing market model based on previous study, then extended it to spatial panel model to consider not only national and regional factors, but also estimated the spatial spillover effect in northern, central and southern region in Taiwan, with the data in which the spatial units are 19 cities and counties in Taiwan from 2002 to 2014.

The results showed that the three regions were in different stage of regional development, causing the different characteristic of regional housing market. Northern region, where facing the problem of extravagant housing prices, the demand of housing investment affected housing price more than housing consumption. The spillover effect in northern region was positive, meaning that the cities and counties in northern region will affect adjacent cities and counties. The demand of housing investment in central region was not significant, and the spillover effect was negative. The results might due to the reason that the central region is less developed than northern region. In southern region, the elasticity of demand for Housing consumption is the largest in all regions. The spillover effect was insignificant, meaning that there is no spatial interaction in the cities and counties in southern region.

Figure 1 – Average trend of median housing prices in Taiwan counties

Literature Review

In the past, many researches have proved that there were numerous factors which may affect housing price. In terms of supply and demand, if demand of housing is higher than supply relatively, the HP will become higher. Take household as cardinal number, let it be multiplied by income and we will get the result of residential demand (DiPasquale & Wheaton, 1994). A supply and demand equilibrium model was established. The model assumes that HP will reflect changes in national and regional factors differ from regions. Residential demand is regional factors such as new house quality, population, income, employment rate, loan value ratio, etc. With nine regions in the United States as the empirical regions, it is found that the increase in the population or household quantity in six regions will increase the demand for housing, which in turn will increase housing prices (Reichert, 1990).

From the point of housing purchase decision-making, the employment rate and income of the employment market in different regions are distinct. If the employment rate is high, it will have a positive impact on regional housing prices (Reichert, 1990; Tabuchi, 1998; Baffoe-bonnie, 1998; Hsueh *et al.*, 2003). In addition, in terms of the maximum utility of housing, public finances and other consumer goods in the region, a model bases on that theoretical basis was established. Then access the cross-sectional data analysis and found that public finances in schools and other areas are one of the factors affecting population migration, which in turn affects housing demand and regional housing prices.

In theory, if interest rates are low, funds tend to flow into the real estate market or other financial markets to fight inflation, so interest rates represent the opportunity cost of investing in the residential market, and the impact on regional housing prices is negative (Reichert, 1990), but interest rates may also change in the same direction with regional housing prices (Ashworth & Parker, 1997; Meen, 1999), similar to the Pigou effect concept proposed by Pigou (1943), that is, if people's actual property increase (for example, due to rising interest rates or falling prices) will stimulate demand for consumer spending, causing suppliers to produce more goods, increase employment opportunities, etc., which is a positive cycle. This concept can explain why interest rate and housing price have same direction. The phenomenon, as the interest rate rises, increases the actual property of people, stimulating the consumption demand of the house, and the Pigou effect appears between the two. In addition, the rapid growth of housing prices can reduce the cost of residential capital, so the rate of change in housing prices is also a factor affecting investment demand (Reichert, 1990).

The cost of building a house is also a decisive factor in the supply of housing. Due to limited land resources and geographical differences in regions, the supply of regional housing is limited, and the results of different regional planning controls also make regional housings have inconsistent supply (Case & Mayer, 1996; Mayer & Somerville, 2000), the elasticity of housing supply has been reduced due to strict planning controls, which in turn has caused residential prices to rise.

Housing supply	Housing supply quantity	-	Case & Mayer(1996); Mayer & Somerville(2000); Chang & Chiu (2013)

The interaction of the regional housing market is derived from the population and capital flows between the regions, and the characteristics and reasons of the flows can be examined by the interactions triggered by economic activities between different regions of the regional economic system.

Friedmann (1966) divided the regional development into a four-stage Core-Periphery model, as seen in figure 2. In the initial stage of regional development, that is, the first stage, the regions have no relationship and independent development. Later, some regions grow relatively fast due to external factors, and regional development has entered the second stage. Compared with other slower growing regions, the faster growing core area becomes the dominant spatial structure. The resources of other periphery areas have been diluted cause the absorbency from core area, making the core area increasingly strengthened. Periphery area is declining, that is, the absorbing effect is greater than the extension effect, until the resources in the core area overflow to the periphery area, which makes the periphery area stimulated and begins to develop. At this time, the extension effect is greater than the absorbing effect, which is the third stage of spatial structure evolution. In the fourth stage, the region became a multi-core zone, and resources were closely intertwined with each other, and the economic system was integrated.

In the same way, regional housing prices are affected by their own regional factors and overall factors, or because the regions are not closed, population movements and information, resources are circulated between regions, etc., causing regional housing markets to interact with each other to generate extension and absorbing effect.

Figure 2 – Friedmann's Core-Periphery theory – model of 4 stages

Reference: Friedmann, J. (1966). *Regional Development Policy: A Case Study of Venezuela*: M.I.T. Press.

Spatial heterogeneity is unique and complicated characteristic of region. It will affect the housing demand and housing price, and it might be ignored because it is hard to be observed, quantified or only works in specific area. Previous relevant research noticed the existence of spatial heterogeneity, often expressed by the assumption that housing prices in different regions are affected by the same factor. Reichert (1990) established a regional housing price model based on regional housing demand and housing supply, and classified the United States into six regions for empirical analysis. It was found that the effects of overall economic factors and regional factors on regional housing prices were not consistent. Hsiao (1986) proposed to use panel data to solve the problem of bias caused by individual heterogeneity (such as region, person, company, etc.), to exclude the influence of heterogeneity on the explanatory variables, and to exploit the characteristics that heterogeneity does not change with time. After superimposing the cross-section data of different periods, it becomes the comprehensive time-space panel data, and controls the influence of the individual effects on the explained variables. Although the reason for heterogeneity is still can't be identified, the influence of other factors on the explained variables is no longer biased by the heterogeneity.

At present, some studies in Taiwan have explored the reason of regional housing price differences. Kuo (2011) used housing price ratios of each two houses in the six metropolitan areas of Taiwan as explanatory variables, with eight indicators within economic and social aspects, and access the panel data explores the relationship between residential price differences and socio-economic development gaps, and finds that employment opportunities have the greatest impact on regional price differences, followed by public expenditures. Although panel data allows the inclusion of individual heterogeneity, if the individual is a spatial unit, there is another obvious problem, that is, the spatial units are non-closed and may interact with each other. Although the previous researches considered the spatial heterogeneity and apply the panel data, due to the study of regional housing prices, the assumption that the regions are independent of each other is unlikely to be established in reality. There are often populations, industrial resources flowing between adjacent regions, and regional residential markets change simultaneously. Therefore, this study intends to introduce the concept of spatial econometrics, further expand the panel data into spatial panel data, and incorporate the possibility of spatial dependence into the model.

Empirical Approach

To consider both spatial heterogeneity and spatial dependency, this study modified a housing price model based on an investment decision model referred to Meen (1999) with fixed effect and spatial spillover effect. For city i in time period t , the 7 independent variables were interest rate ($IRATE$), the number of household (HH), income (INC), the unemployment rate (UER), the amount of housing supply (HS), capital gain (CP), and amenities (AMT). γ_i represented spatial time-invariant heterogeneity in city i . λ is spatial spillover effect, if it is significant index, it can prove that there is the impact the housing price in contiguity city j have on city i .

$$HP_{it} = \gamma_{1i} + \lambda \sum_{j=1}^N w_{ij} HP_{jt} + \gamma_2 IRATE_t + \gamma_3 HH_{it} + \gamma_4 INC_{it} + \gamma_5 UER_{it} + \gamma_6 HS_{it} + \gamma_7 CP_{it} + \gamma_8 AMT_{it} + \varepsilon_{it} \quad (1)$$

The data included 19 cities and counties (6 metropolitan municipalities, 3 provincial cities and 10 counties) in Taiwan from 2002 to 2014. The data was collected from Construction and Planning Agency Ministry of the Interior and National Development Council.

Table 2 – Narrative statistics of variables

Variables	Average	Standard deviation	Maximum	Minimum
Housing price, HP (NT\$)	4,878,000	2,202,000	16,060,000	2,370,000
Income, INC (NT\$)	784,000	175,000	1,344,000	475,000
Amenities, AMT (NT\$/person)	39,064.9	9,621.5	70,778.7	19,321.3
Household, HH (unit)	400,116.4	372,035.2	1,497,018.0	74,353.0
Housing supply, HS (m ²)	1,630,709.3	1,783,541.2	10,494,515.0	90,081.0
Unemployment rate, UER (%)	4.500	0.607	6.000	3.400
Capital gain, CP (%)	0.016	0.104	0.354	-0.371
Interest rate, $IRATE$ (%)	1.962	0.567	3.375	1.250

Results and Discussion

After empirical test, the final model is as followed:

$$\ln[HP_{it}] = \gamma_{1i} + \lambda \sum_{j=1}^N w_{ij} \ln[HP_{jt}] + \gamma_2 \ln[HH_{it} INC_{it}] + \gamma_3 \ln[HS_{it} HH_{it}] + \gamma_4 CP_{it} + \gamma_5 \ln[IRATE_{it}] + \gamma_6 \ln[AMT_{it}] + \varepsilon_{it} \quad (2)$$

As seen in Table 3, the results show that the spatial spillover effect of housing prices in Taiwan's counties and cities is significantly negative. It means that if one county's housing price increases, the adjacent counties' housing prices will decrease. It is inferred that on average, the absorbing effect of Taiwan's county and city housing markets is stronger than the extension effect. Because the high price of the county or the city means that they are more attractive, which stimulates the concentration of housing demand. Capital also flows into the more attractive counties and cities from the areas which has relatively weaker attractiveness. The gap in attractiveness is increasing, the number of high housing prices continues to increase, and those with low housing prices continue to decline, making the effect of space spillover negative.

The key factor affecting the housing prices in Taiwan's counties and cities is the capital gain rate (CP). Considering the definition of the variables in this study, the capital gain rate is calculated by deducting the last year's housing price from the current year's housing price, then divided by the last year's housing price. If the current housing price changes by 1% compared with the previous period, it will increase the current housing price by 22.3%. This conclusion is similar to the conclusion that Reichert (1990) uses the United States as an empirical region.

The income scale of the area (HHINC) has a significant positive impact on the housing prices of the county. The variable is defined as the average disposable income per household multiplied by the number of households, which represents the sum of the income of each household in the area. If the income scale increases by 1%, the average housing price in Taiwan will rise by 1.059%, and the degree of change between the two is equivalent. The amenities (AMT) measures the quality of public services. The model results are in line with expectations. It positively affects housing prices. It is inferred that people will measure the quality of public services in area when they choose their place of residence. In the case of a city with better public services, there are naturally more people willing to move to the city.

Moreover, the rise in interest rates (IRATE) will lead to an increase in housing prices in the region. This conclusion conflicts with the assumption that deposits and residential market investments are substitutes. However, the model results show that the higher the interest rate, the higher the housing price in the region. This conclusion supports the theory of the Pigou effect, which increases the actual wealth of people due to rising interest rates, stimulating housing demand and increasing housing prices.

Table 3 – HP models by regions

Variables	Region							
	Taiwan (pooled)		Northern (Taipei)		Central (Taichung)		Southern (Kaohsiung)

Note : *P<.1, **P<.05, ***P<.01,

In the three major regions of north, central and south, only northern and central region have significant spillover effect index. Northern area is positive, while central area is negative. As seen in figure 3, there is a schematic diagram to show the spillover effect result of this empirical study. In this figure, red color means increasing housing price, blue color means decreasing housing price and gray color means no change of housing price. In terms of northern area, if core city's (Taipei City) housing price is on the rise, adjacent regions' (New Taipei City which covered by red) housing price increase, too. The spatial spillover effect of northern region has a value λ of 0.291, which means that if the price of one city in northern area increases by 1%, the housing price of the neighboring counties in northern area will rise by 0.297%. However, central area has negative index, it means that if core city's (Taichung City) housing price is on the rise, but adjacent regions' (Nantou County, Changhua County and Miaoli County which covered by blue) housing price decrease. If the price of one city in central area increases by 1%, the housing price of the neighboring counties in central area will fall by 0.235%. On the other hand, southern area has insignificant spillover effect index. It indicates that there is no spillover effect happening. In summary, the result of spillover effect shows that the three regions were in different stage of regional development, causing the different characteristic of regional housing market.

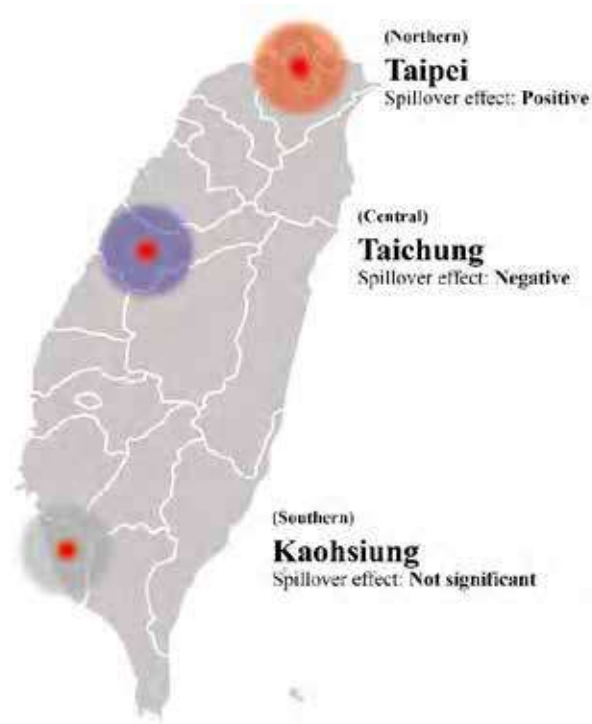

Figure 3 – Spillover effect of housing price in Taiwan

According to Friedmann's Core-Periphery theory, the development current situation of northern region from housing market which belongs to 3rd or 4th stage. In addition, the capital gain rate (CP) of northern region has a significant positive impact on housing price. If CP increases by 1 unit, housing price will rise up by 17.7%. It means that the demand of housing investment affects housing price more than housing consumption.

The demand of housing investment in central region is not significant, and the spillover effect is negative. The results may due to the reason that the central region is less developed than northern region, and central region may absorb resources from neighboring regions. It belongs to 2nd stage of Friedmann's Core-Periphery theory.

In southern region, it is inferred that although southern region developed earlier, but economic development and resources were weaker than northern and central region in late period. Development of region still belongs to 1st stage of Friedmann's Core-Periphery theory. Moreover, compare to the other two regions, the income scale (HHINC), amenities (AMT) have biggest effect among three regions, while capital gain rate (CP) has least effect. It means that household of southern region will be stimulated by increase of actual property. And southern region also has least Pigou effect.

Conclusion

The cities and counties in Taiwan not only have specific characteristic, but also spatial interaction due to the convenient transport facilities and high density population. This study combines panel data model and spatial model to consider both spatial heterogeneity and dependency. The results show that there are structural differences in regional housing market. Through literature review, the differences of regional development are the main reason.

The study limitation

First, this study can only collect data from 2002 to 2014. The number of samples is not sufficient enough to consider more independent variables and discover more phenomenon in housing market, such as the relationships between real estate cycle and the characteristic of regional housing market. Second, this study assumes that the housing price will reflect the changes of the dependent variables in the same period, but it may take times to reflect the changes in reality. Finally, in the model, the interest rate and capital gain are hypothesis to have impact on housing price without considering the possibilities that housing price may also influence interest rate and capital gain.

The study contribution

To investigate the regional differences of housing price in Taiwan, this study combined panel data model and spatial model to consider spatial heterogeneity and dependency simultaneously, finding out that not only the impact of the key factors but also the spatial spillover effect on housing price differed from region to region.

USING VALUE-ADDED HIERARCHY METHOD TO ANALYZE INDUSTRIAL SPATIAL PATTERN IN THE BACKGROUND OF ECONOMIC TRANSITION -- A CASE OF GUANZHONG PLAIN URBAN CLUSTER IN CHINA

XueYan Wang¹, YeYuan Zhou²

¹College of Architecture and Urban Planning, Tongji University, 501332552@qq.com

² College of Architecture and Urban Planning, Tongji University, 913525267@qq.com

Abstract: The "Belt and Road" strategy shoulders the important mission of promoting economic transition among nations and regions. The Guanzhong Plain urban cluster, located in the inland center of China, is an important gateway to the western region. The industrial division of Guanzhong Plain urban cluster will be conducive to further promoting the economic network along the "Belt and Road". In 2018, the "Guanzhong Plain Urban Cluster Development Plan (2017-2035)" and the implementation plans of three provinces were compiled to define the industrial division mainly based on the geographical proximity. This paper probes into the rationality of industrial spatial pattern of Guanzhong Plain urban cluster in the perspective of urban division and cooperation. By the statistical data of 11 cities related in the Guanzhong Plain urban cluster in 2017, the research divides all cities into five categories by using the method of value-added hierarchy, reveals the characteristics of industrial spatial pattern, and compares the industrial policies and position defined in the relevant plans. The result finds that the planning does not take the current advantages of industries and urban characteristics into account. Based on this, the paper put forward some optimization suggestions to coordinate development and promote the economic construction.

Keywords: economic transition; industrial spatial pattern; value-added hierarchy; Guanzhong Plain urban cluster

1. Introduction

In the report of "the Nineteenth National Congress", Xi Jinping pointed out the strategy of coordinated regional development. In November 2018, the "Opinions of the Central Committee of the CPC and the State Council on Establishing a New Mechanism for More Effective Regional Harmonious Development" put forward the idea of establishing a new mode of urban cluster development which is led by central cities and promote regional development, in order to promote the integration between regions. It can be seen that the urban cluster is of great significance in the regional coordination strategy, and it can achieve the optimal allocation of resources and enhance the leading role of radiation in a wider range. The "Belt and Road" strategy in China shoulders an important mission to promote economic transition among nations and regions. The latest rising urban cluster, Guanzhong Plain urban cluster, is the starting point of the ancient Silk Road, giving full play to its geographical advantages of connecting the East with the West and connecting the North and the South, which is conducive to

leading and promoting the development and opening up of the northwest area, optimizing the radiation effect of the urban cluster in the western region, and promoting the construction of the “Belt and Road”.

This paper discusses the industrial spatial pattern of urban cluster and takes the Guanzhong Plain urban cluster as an example. It compares and analyses the current industrial spatial pattern and related industrial planning requirements by using the method of value-added hierarchy and explores the rationality of industrial layout policy in the urban cluster development planning and tries to put forward optimization suggestions.

2. Research Basis and Background

2.1 Theoretical basis

Under the background of economic globalization, capital, technology, human resources and other factors of production flow around the world, resulting in the transformation of the spatial economic structure from “*industrial chain*” to “*value chain*”. Through different but interrelated production and operation activities, enterprises constitute a dynamic process of value creation (Fujita M. Krugman P. and Venables A. J. 1999). Logitech's “*Smiling Face value chain*” is just a typical case, in which research and development (R&D), assembly, marketing, management and other behaviors cooperate in the value chain. These behaviors are scattered in different enterprises in different places, and the final production is distributed in various intermediary behaviors in different enterprises (Henderson, J.V. 1974). Value-added hierarchy is the link that produces different values in the value chain.

In the world urban system made by the international labor division of transnational corporations, the horizontal spatial economic structure characterized by “*industry sector*” is changing into the vertical spatial economic structure characterized by “*value sector*”, forming an obvious hierarchical system based on value sector. In the global production network, cities are located in different value zones of international labor division, thus forming a world urban system characterized by “*value zones*”.

By using the method of “*value-added hierarchy*”, Zilai Tang investigates the evolution characteristics of urban system in the Yangtze River Delta urban cluster and analyses the evolution of industrial structure in different regions. Then some scholars do the research of the advantages and disadvantages of the value sections of Jing-jin-ji urban cluster, Yangtze River Delta urban cluster, Pearl River Delta urban cluster and some other urban clusters.

2.2 Background of Urban Cluster Development

Guanzhong Plain urban cluster is the latest national-level urban cluster proposed now in China. It is an important gateway to the western region and an important fulcrum of the Eurasian Continental Bridge. It has a unique strategic position in the pattern of modernization and all-round opening up. The construction background of the “Belt and Road” has promoted the important role of Guanzhong Plain urban cluster in coordinating regional development in economic globalization. Therefore, it is necessary to apply scientific method to analyze its industrial spatial pattern, so as to explore the optimization of relevant industrial planning requirements.

Guanzhong Plain urban cluster radiates outward from Xi'an as the center and is the second largest urban cluster in the western region. It is positioned as a national-level urban cluster with international influence and a new highland of inland reform and opening up. According to the actual development, Guanzhong Plain urban cluster is not bounded by the administrative scope of prefecture-level cities. The specific scope is shown in the table below (Table1). The total land area is 107,100 square kilometers.

Shaanxi Province		Shanxi Province		Gansu Province		
Xi'an, Baoji, Xianyang, Tongchuan, Weinan, Yangling demonstration zone	Shangluo	Yuncheng	Linfen	Tianshui	Pingliang	Qingyang
	Shangzhou District, Luonan County, Danfeng County and Zhashui County	Except Pinglu County and Yuanqu County	Yaodu District, Houma City, Xiangfen County, Huozhou City, Quwo County, Yicheng County, Hongdong County and Fushan County		Kongtong District, Huating County, Jingchuan County, Chongxin County and Lingtai County	Qingyang urban area

Table1: Scope of Guanzhong Plain urban cluster (source: author sort out according to the Planning)

3. Industrial Spatial Pattern of Guanzhong Plain Urban Cluster

3.1 Statistics of industrial data

This paper uses the analysis method of industrial value-added hierarchy proposed by Tang Zilai and other scholars for reference. The first thing is to do the statistics of industrial data of Guanzhong Plain urban cluster.

Statistical objects are 5 prefecture-level cities (Xi'an, Baoji, Xianyang, Tongchuan and Weinan) in Shaanxi Province and 6 prefecture-level cities (Shangluo City, Yuncheng City, Linfen City, Tianshui City, Pingliang City, Qingyang City) where more than 20 districts and counties are located in three provinces in Guanzhong Plain urban cluster planning scope (Figure1).

It should be noted that: 1) The use of prefecture-level cities as research units takes into account the consistency of statistical caliber and the availability of data.; 2) Yangling Demonstration Area in Shaanxi Province was originally located in Xianyang City. It was in 1997 a national agricultural high-tech demonstration area was set up independently there so that it has become a prefecture-level city. But its total economic volume is relatively low, so it is classified into Xianyang City in statistics. 3) The data are selected from the statistical yearbook of cities in 2017(i.e. data of year 2016), which is also the base year of the “*Guanzhong Plain Urban Cluster Development Planning (2017-2035)*” (Hereinafter referred to as “*the Planning*”).

Figure1: Planning boundary of Guanzhong Plain urban cluster and administrative boundary of 11 prefecture-level cities (source: author draw according to “the Planning”)

Drawing on the classification method of industrial types (Tang Zilai, 2010), the industrial types are divided into eight sectors (Table2). Among them: the construction industry has its particularity and is generally not considered; cities with a large proportion of mining industry accounts for other industrial categories are considered separately as special types. The ranking of the six industrial sectors included in the classification ranges from low to high is: agriculture, other services, labor-intensive manufacturing, capital-intensive manufacturing, technology-intensive manufacturing and producer services.

Industry	Industry sectors		Classification of National Economic Industries
Primary industry	Agriculture		Agriculture, forestry, animal husbandry and sideline Fisheries .
Second-ary industry	Manufacturing industry	Labor-intensive Manufacturing Industry	Agricultural and sideline food processing industry, food manufacturing industry, textile industry, textile and apparel, shoes and hats manufacturing industry, leather, fur, feather and its products and shoes manufacturing industry, wood processing and wood, bamboo, road, brown and straw products industry, furniture manufacturing industry, paper and paper products industry, printing and record media reproduction, cultural and educational sports goods manufacturing industry, rubber products industry, plastic products industry, non- Metal Mineral Products industry, Metal Products industry
		Capital-intensive Manufacturing Industry	Beverage Manufacturing, Tobacco industry, Petroleum Processing industry, Coking and Nuclear Fuel Processing industry, Chemical Raw Materials and Chemical Products Manufacturing, Chemical Fiber Manufacturing, Black Metal Smelting and Calendering industry, Nonferrous Metal Smelting and Calendering industry, General Equipment Manufacturing, Special Equipment Manufacturing, Transportation Equipment Manufacturing
		Technology-intensive Manufacturing Industry	Pharmaceutical Manufacturing, Communication Equipment, Computer and Other Electronic Equipment Manufacturing, Instrument and Instrument Manufacturing, Culture and Office Machinery Manufacturing
	Other industries		Petroleum and natural gas mining industry, power and thermal production and supply industry, gas production and supply industry, water production and supply industry, non-metallic mineral mining and dressing industry, non-ferrous metal mining and dressing industry, coal mining and dressing industry, ferrous metal mining and dressing industry, and other mining industries
	Construction business		Construction business
Tertiary industry	Productive Services		Financial insurance, real estate, leasing and business services, information transmission, software and information technology services, scientific research and technology services, water conservancy, environment and public facilities management
	Other services		Agriculture, forestry, animal husbandry and fishery services, transportation, storage and postal services, information transmission, computer services and software industries, wholesale and retail businesses, accommodation and catering industries, residential services and other services, education, health, social security and social welfare industries, culture, sports and entertainment industries, public administration and social organizations

Table2: 8 Industry sectors based on value-added hierarchy (source: according to Tang Zilai, 2010)

According to statistics, the proportion of added value of six major industrial sectors in the gross domestic product of each city is obtained. (Table3)

Province	City	Agriculture	Other services	Labor-intensive Manufacturing Industry	Capital-intensive Manufacturing Industry	Technology-intensive Manufacturing Industry	Productive Services	GDP (¥100 million)
Gansu Province	Qing	14.2%	25.9%	0.4%	16.5%	0.1%	9.6%	598
	Pingli	28.1%	30.4%	18.2%	1.6%	4.6%	16.7%	367
	Tianshui	16.8%	38.8%	1.4%	8.0%	4.9%	11.3%	590
Shaanxi Province	Baoji	8.9%	19.6%	11.1%	11.8%	2.6%	7.6%	1932
	Xian	14.4%	18.6%	18.2%	12.0%	4.8%	8.1%	2396
	Tong	7.7%	27.2%	23.7%	4.2%	2.6%	11.9%	312
	Xi'an	3.7%	42.0%	2.4%	8.4%	7.7%	18.9%	6257
	Weinan	15.1%	28.6%	8.7%	9.5%	2.4%	10.1%	1489
	Shan	13.9%	24.7%	12.9%	1.2%	6.9%	7.9%	699
Shanxi Province	Yuncheng	16.4%	32.3%	3.0%	7.1%	4.8%	13.4%	1222
	Linfen	8.0%	29.8%	-0.5%	-5.8%	0.1%	15.5%	1205

Table3: Statistics of the proportion of added value to GDP (source: author)

3.2 Analysis of value-added hierarchy

3.2.1 Data-based Urban Classification Analysis

Using SPSS software to cluster the data of the proportion of added value to GDP of six major industries in each city, the results of urban classification are obtained (Table4).

Type	City
Type 1	Xi'an
Type 2	Shangluo
Type 3	Qingyang, Baoji and Yuncheng
Type 4	Xianyang, Tongchuan and Weinan
Type 5	Pingliang, Tianshui
Special Type	Linfen

Table4: Cluster analysis and classification results (source: author)

Then, using the statistical method of mean deviation from standard deviation (STD) multiple, the value segments of various cities are characterized by the 'eigenvalue T'. The calculation method of industrial 'eigenvalue T' for each region is shown in formula (1). Among them, 'x' is the average of the proportion of added value of certain industry in GDP of a certain type of city, ' \bar{x} ' is the average of the proportion of industry added value in each type of city, and STD is the standard deviation of the proportion of industry added value in each type of city. If the

eigenvalue of the ‘m-sector’ in the ‘type-n city’ is greater than 1, then the ‘m-sector’ has obvious characteristics in the ‘type-n city’.

$$T = \frac{x - \bar{x}}{STD} \quad (1)$$

According to the statistics and calculation results of 2016 (Table5), the division of urban industry characterized by value-added hierarchy in Guanzhong Plain urban cluster has been formed, but it is not significant yet.

Type	Agriculture	Other Services	Labor-intensive Manufacturing Industry	Capital-intensive Manufacturing Industry	Technology-intensive Manufacturing Industry	Productive Services	* Other industries
Type 1 (Xi'an)	-1.50	1.51	-0.79	0.26	1.58	1.62	-0.69
Type 2 (Shangluo)	0.08	0.31	0.46	-0.90	1.26	-0.10	0.01
Type 3 (Qingyang, Baoji, Yuncheng)	-0.03	-0.42	-0.50	0.81	-0.51	0.46	0.46
Type 4 (Xianyang, Tongchuan, Weinan)	-0.15	-0.58	0.93	0.29	-0.21	-0.49	-0.09
Type 5 (Pingliang, Tianshui)	1.40	0.80	0.09	-0.32	0.41	0.55	-1.28
*Special Type (Linfen)	-0.84	0.12	-1.14	-2.03	-1.50	0.95	2.14

Table5: Calculations of the eigenvalues of five types of cities (source: author)

Type 1 cities: There is only Xi'an in this type, which shows the obvious characteristics of technology-intensive manufacturing, producer services and other services (deviating more than one-fold).

Type 2 cities: Shangluo is in this type, whose technology-intensive manufacturing industry is significant, and other services and labor-intensive services are higher than the regional average.

Type3 cities: Qingyang, Baoji and Yuncheng in this type, whose various sectors are not obvious, only capital-intensive. The concentration type is relatively high (0.81 times deviation from the average).

Type 4 cities: Xianyang, Tongchuan and Weinan, each of which is not obvious, and the labor-intensive manufacturing industry is close to one-fold deviation (0.93).

Type 5 cities: Pingliang and Tianshui, and their agricultural ministries are significant, while the two types of services are higher than the average by more than 0.5 times.

It is worth noting that Linfen's manufacturing industry characteristic value is less than - 1, which shows the weakness of manufacturing industry in the region is very significant. However, Linfen's other industrial ministries are very significant (deviating more than two times), and the obvious characteristic is that it's a resource-based

city depending on the development of mineral mining industry, which should be taken into account in industrial planning.

3.2.2 Spatial Analysis Based on Urban Classification

The spatial distribution characteristics of the 5 types of cities can be observed when they fall into space (Figure2):

On the whole, it presents a circle model with Xi'an as the center. The core circle of Xi'an service industry and high-end manufacturing industry occupies the first place in the region.

Xianyang, Tongchuan and Weinan, which are close to Xi'an, are the second circle, and are all type 4 cities where the lower-end manufacturing industry, labor-intensive manufacturing industry, is more prominent. These cities rely on the location advantages of neighboring Xi'an and the convenience transportation network around Xi'an. So they have gathered a large number of labor-intensive enterprises.

The third circle composed of Qingyang, Baoji, Yuncheng and Shangluo, which belongs to type2 or type3 cities, with prominent middle and high-end manufacturing industries. These cities are often rich in oil and gas mineral resources (Qingyang is rich in oil, Baoji and Yuncheng are rich in non-metallic minerals), which have resource advantages for the development of capital-intensive manufacturing industries.

It is the fourth circle composed of Tianshui, Pingliang and Linfen. In this circle, Pingliang and Tianshui have limited mineral resources, mainly agriculture and low industrial value, while Linfen presents the phenomenon of excessively single industrial structure that other industrial sector is abnormally prominent and the manufacturing level is far behind the regional average.

Figure2: Industrial pattern of Guanzhong plain urban cluster based on value-added hierarchy (source:author)

3.3 Summary

Based on the analysis of the current situation of 11 prefecture-level cities based on industrial data, the five-level classification of cities is obtained, and the industrial value section of urban cluster is interpreted as a circle structure in space. It is found that the surrounding cities of Xi'an develop low-end manufacturing mainly by means of resource adsorbing power of core cities, and the cities farther away from Xi'an develop capital-intensive manufacturing, agriculture or other industries mainly by means of local resources. The industrial division system between cities is more obvious, and the industrial spatial pattern has taken shape preliminarily.

4. Comparison of Industry Orientation and Current Situation

4.1 Planning interpretation

In February 2018, the National Development and Reform Commission approved “the *Guanzhong Plain Urban Cluster Development Planning (2017-2035)*” (hereinafter referred to as *the Planning*). The Planning period lasts until 2035. The spatial layout and industrial system of Guanzhong Plain urban cluster are clearly defined in “*the Planning*”: Taking the construction of National Central City and regional key node city, Xi'an, as the carrier to accelerate the development axis and growth pole and build the overall pattern of ‘one circle, one axis and three belts’ (Figure3). And build an important base of advanced manufacturing industry, strategic emerging industries and modern service industry in China, promote the industry from the low end of the value chain to the high end, and promote the development of northwest and surrounding areas by radiation. While deepening the core functions of Xi'an, it also emphasizes accelerating the development of regional coordination.

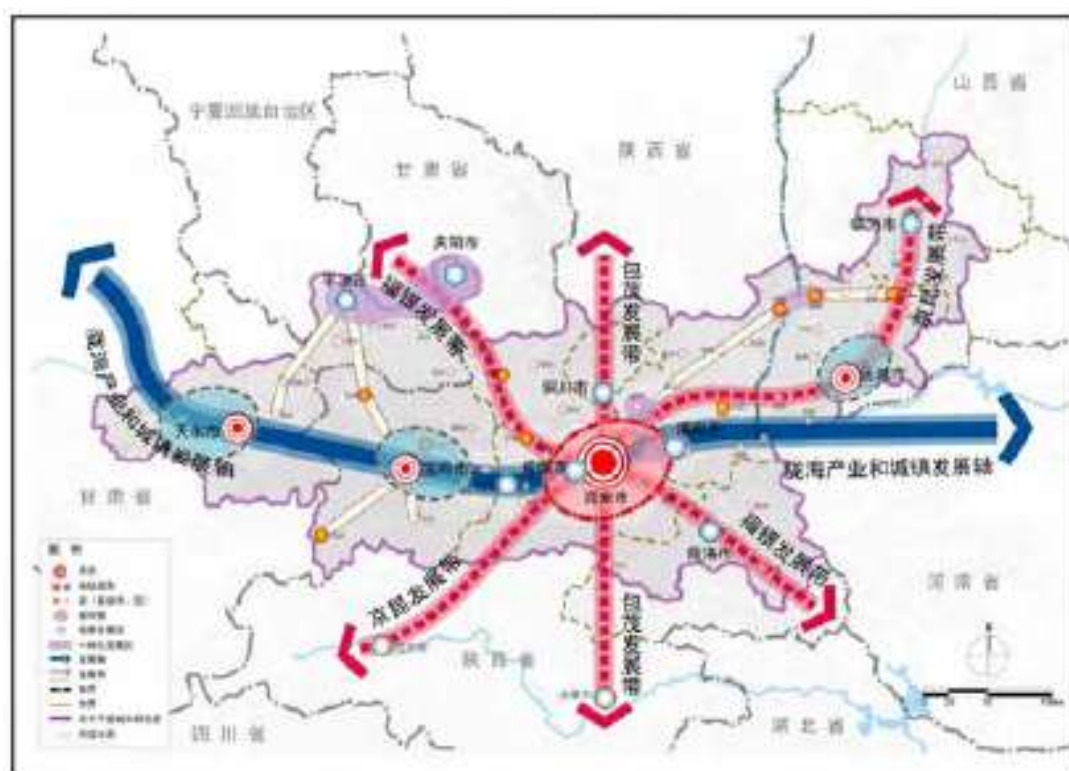

Figure3: Spatial pattern of Guanzhong Plain urban cluster (source: translate according to the *Guanzhong Plain Urban Cluster Development Planning*)

With the development of Guanzhong Plain urban cluster rising to national strategy, Shaanxi Province, Shanxi Province, Gansu Province have also issued Implementation Planning to further clarifying the industrial positioning

and planning requirements of each city. According to the related description of the planned industrial positioning, the author sums up the cities' industry sector according to the leading industry function of each city. (Table6)

Province	City	Industry Sector
Gansu Province	Qingyang	Agriculture
	Pingliang	Capital-intensive Manufacturing Industry
	Tianshui	Other services
Shaanxi Province	Baoji	Productive Services
	Xianyang	Other industries
	Tongchuan	Labor-intensive Manufacturing Industry
	Xi'an	Productive Services
	Weinan	Other industries
	Shangluo	Agriculture
Shanxi Province	Yuncheng	Other industries
	Linfen	Other industries

Table6: Industrial sector of cities in Guanzhong Plain urban cluster (source:author)

According to “the Planning” and the implementation schemes of Shaanxi, Shanxi and Gansu Provinces, as well as the industrial sectors summed up before, the urban classification of the planning is obtained. (Table7)

Type	City
Type 1	Xi'an
Type 2	Baoji
Type 3	Yuncheng, Tianshui
Type 4	Xianyang, Weinan, Tongchuan, Pingliang and Linfen
Type 5	Qingyang, Shangluo

Table7: Urban classification under relevant planning oindustry requirements (source:author)

4.2 spatial analysis

Based on the above-mentioned planning interpretation of industrial system and urban classification, return the classification to the space, and it is found that the pattern centered on Xi'an is still obvious, but the regional industrial system presents a distinct banded structure (Figure4). Compared with the current spatial pattern of Guanzhong Plain urban cluster (Figure3), the overlap degree between industrial division of labor among cities and the main axis of regional development is relatively high, especially in the western section from Xi'an to Tianshui, which is obviously higher than that of surrounding cities and decreases in a ladder shape. On the one hand, such a zonal industrial structure is conducive to the division of labor and dislocation between cities, and to the formation of a spatial economic structure characterized by value-added hierarchy with good "political rationality"; on the other hand, the subjective interference of such zonal structure is intense, and whether it has "technological rationality" is worth further verification.

Figure4: Industrial pattern of Guanzhong Plain urban cluster based on "the Planning"(source:author)

4.3 Discussion on the Rationality of Orientational Industrial Spatial Pattern

4.3.1 Type1 City

According to the relevant planning interpretation, only one city in Xi'an is a first-class city. Its current situation has the advantages of high value sector industry department, and its future leading position in the development of urban cluster industry can be maintained. (Figures5 and 6)

Figure5: Distribution of eigenvalues of technology-intensive manufacturing industry in 2016 (source:author)

Figure6: Distribution of eigenvalues of productive services in 2016 (source:author)

4.3.2 Type2 City

According to the planning, Baoji is the second type of city in Guanzhong Plain urban cluster. In the planning, Baoji is positioned as a "sub-central city of Guanzhong Plain urban cluster" and a "national comprehensive transportation hub" to develop modern service industry, modern agriculture, automotive parts supporting industries and other productive services and capital-intensive manufacturing industries. According to the author's analysis, the rationality of Baoji's second-class city positioning is insufficient. The reasons lie in:

(1) From the angle of the eigenvalue of industrial sector: the value of its superior industries is relatively low, and capital-intensive manufacturing and labor-intensive manufacturing are higher than the regional average, but not significant (less than 1 times). Therefore, from the point of view of the current industrial structure, Baoji City does not have prominent superior industrial sectors.

(2) From the angle of the Population Growth: Comparing the growth rate of permanent population in Baoji City and Shaanxi Province from 2010 to 2016, we can find that the growth rate of population in Baoji City has been lower than the average of the whole province since 2010, which shows that the current population attraction of the city is low, and the urban agglomeration is insufficient, and it is difficult to support the goal of the sub-center. (Figure7)

(3) From the angle of traffic planning: “The Planning” puts forward the schematic plan of traffic planning for urban cluster at the end of the planning period (Figure8). Compared with Tianshui on the west side of Baoji, only one more general railway is under construction, while Tianshui has a civil airport. Therefore, the target taking Baoji as a national comprehensive transportation hub is too high, which is slightly inappropriate as a second-class city.

Figure7: Population Growth Rate of Baoji and Shaanxi Province (source: author draw according to the Statistical Yearbook of Shaanxi Province in 2016)

Figure8: The traffic network planning of Guanzhong Plain urban cluster (source: author draw according to “the Planning”)

4.3.3 Type3 City

According to the planning, Yuncheng and Tianshui are the third type of cities in Guanzhong Plain urban cluster. Yuncheng and Tianshui, which belong to Shanxi Province and Gansu Province respectively, are important node cities on the East and west sides of urban agglomeration.

The planning of Yuncheng is reasonable.

The relevant industrial planning of Tianshui requires the development of microelectronics design, electronic information and other industries, and the establishment of national advanced manufacturing and high-tech industry transformation base. These requirements correspond to the technology-intensive manufacturing industry. However, as a national historical and cultural city and an excellent tourist city in China, Tianshui has significant characteristic values of other services (including accommodation, catering and other tourism-related industries). (Figure9) Although agricultural and technology-intensive manufacturing industry is higher than the regional average, it has not become the dominant one. Therefore, it is difficult for Tianshui City to transform into a technology-intensive manufacturing industry in the future.

forms a technology-intensive industry cluster area with Xi'an. The planning requires that its industry return to agriculture is counter-trend and unreasonable.

Figure 11: Distribution of eigenvalues of capital-intensive manufacturing industry in Guanzhong Plain urban cluster in 2016 (source: author)

5. Comparison of Industry Orientation and Current Situation

Based on the industrial spatial pattern of Guanzhong Plain urban cluster in 2016 and the related industrial positioning requirements, the above discussion finds that the industrial planning has not taken into account the current industries and the characteristics of the city. According to the analysis, the following suggestions are put forward for the industrial development direction of some cities:

- It is suggested that Baoji should focus on the development of capital-intensive manufacturing industry in the near future and clarify the dominant industries.
- It is suggested that Tianshui tap tourism resources to make up for the shortcomings of manufacturing industry with the development of high-quality service industry;
- It is suggested that Pingliang develop high-quality agriculture, combine agriculture with service industry, and avoid falling into the competition of homogenization with labor-intensive manufacturing industry in surrounding cities.
- It is suggested that Linfen attach importance to mineral resources, gradually transform into capital-intensive industries related to mineral processing, and gradually optimize the urban industrial structure.
- It is suggested that Shangluo change its industrial orientation of vigorously promoting agricultural development, respect its manufacturing development status, strive to upgrade the transformation of manufacturing industry and climb to a higher value zone.

The Guanzhong Plain urban cluster is proposed to make use of the urban agglomeration to drive the regional coordinated promote the integration between the regions. At every stage of development, the industrial division system should be suitable for the urban cluster, and the industrial spatial pattern of the region should be clearly defined, so as to better grasp the opportunity of the "The Belt and Road " and promote the development of the western region in the new stage.

Transition histories

Progress in the nineteenth-century: planning, building and managing the modern urban infrastructures in Coimbra

Margarida Relvão Calmeiro¹

¹*University of Coimbra, mrcalmeiro@uc.pt*

Abstract: During the 19th century, cities throughout Europe faced a period of transition. The rise in technical skill, the hygienic theories, the urban sanitation and the new forms of transport created an unprecedented transformation in European cities and dictated the emergence of urbanism. Portugal, a small, peripheral country also faced this transition. Moreover, this change was not limited to the urban fabric, it was necessary to create a body of technicians capable of planning and carrying out the major infrastructure works. It was also required to create institutions capable of programming these processes and municipalities had to form technical entities, commission the first topographic surveys and demanded a large dose of politicians' boldness. Coimbra, a medium-sized city, but until the beginning of the 20th century, the settlement of the only Portuguese University, was an example of these process of modernization. However, the size of the city and the lack of entrepreneurs made it difficult and delayed the process. This paper aims to show how during the second half of the 19th century, Coimbra managed to dare to replicate the improvements in progress in Europe and, beyond the expansion of the urban fabric, introduced modern urban infrastructures into the city.

Keywords: sanitation, urban planning, infrastructure networks, public service

The begging of the nineteenth century and the emergence of public health

In Europe, the nineteenth century is a period of transition. Following the industrial revolution, cities changed, not only because of the increase in population and urban area but also because of the new technology and the introduction of new urban infrastructures and new conditions for comfort (Hall, 1997; Sutcliffe, 1980 and 1980).

At the beginning of the century, Coimbra was a medium-sized Portuguese city, yet the seat of the only Portuguese University, a fact that placed the city among the most important Portuguese Cities, just after Lisbon and Porto. However, faced serious health problems, in particular, because of the Mondego River that recurrently invaded the lower part of the city and because of the lack of the modern public infrastructures.

Moreover, the development of medicine and science had led to a growing concern about the urban conditions of cities and the concept of public health. With the emphasis on the French investigations focusing on the health of buildings and spaces carried out by the *Société Royale de Médecine* and by the *Académie des Sciences*, and which underlined the importance of urban conditions in containing epidemics. The concept of *Public Health* was, then, disseminated, published in texts by some doctors who defended the need to create and impose public hygiene regimentations to improve the health of the people.

In Portugal, we must highlight the work of Ribeiro Sanchez, who published the book *Tratado de Conservação de Saúde dos Povos* (Treaty of Peoples' Health) in 1756, one year after the Great Earthquake of 1755. In this book, he defended the need to preserve human health and argued that the population is the first source of national wealth and so should be protected. This idea, at that time, reveals the rise of a new understanding of government, where what mattered was no longer the individual but the people as a whole. This text was very innovative and defined restricted sanitary police regulation, extended to architectural forms and to the organization of cities, pointing out the dimensions and form for squares and green spaces, as well as the location of temples, convents, hospitals, prisons and housing itself.¹

Despite this innovative thought, only after the cholera morbus epidemic, which devastated the whole of Europe, did the need to reform the city begin to emerge in the early nineteenth century. In this sense, in 1848 London published the Public Health Act and the Law of August 31 which created the General Board of Health, inaugurating a new form of city planning which was to have repercussions throughout Europe, emphasising the importance of urban infrastructure networks, especially water supply and the sewage system for the health of the city.

In Portugal, at the beginning of the nineteenth century was created the *Junta da Saúde* (Health Board) with responsibility for defining a new Health Regulation and for monitoring the country, assessing the "state of cleanliness of the different Cities, Villas, and Places of the Kingdom, and the most effective and convenient way to set up the necessary cleanliness when it does not exist."² After the liberal Regime created the first draft of the General Regulation of Public Health in 1821, however, this was a period of great social, political and economic instability and it took fifteen years to publish the definitive regulation and create the Council of Health and the medical district delegates. In the following years, a set of legal documents was published which shows the difficulties and the resistance to the implementation of some of these measures, which implied new habits and ways of life.³

The main changes concerning urban planning and the sanitation of cities came after two new cholera epidemics in the years 1855-1866 and a decade later in 1865. As a consequence of these epidemics, most cities built public cemeteries and increased their concern with the water supply of the city.

¹ According to miasma tic theory, epidemics were the result of poor air quality, caused by the putrefaction of organic materials or the polluting fumes of industries, so it was necessary to guarantee the cleaning of streets and dwellings, especially in the less wealthy zones of population.

² Ordinance of August 28, 1813, Article X and XII. (Portuguese Court, 1836)

³ This resistance lasted through the century, for example, concerning burials in cemeteries or the generalization of vaccines.

The installation of modern urban infrastructures. The difficulties of a medium-sized city⁴

Coimbra in this period was one of the most important of Portuguese cities; however, the city was mono-functionalized around the University and lacked other activities, namely industry. Nevertheless, the University had a huge influence on what happened in the city, if during the Ancient Regime, the presence of the University was compulsory in the City Council. Later, during the Liberal Regime, this influence prevailed, this time, conquered by vote. In fact, between 1834 and 1934, most of the elements of the City Council and the Municipal Senate were professors of the University.

This may explain some of the innovative projects that were planned in the city, like the early initiative in January 1835 to establish a public cemetery in the city – eight months before the first national legislation that established the obligation of the Municipal Council to create spaces for burials.⁵ This was probably a consequence of the difficulties experienced during the epidemic that devastated the city in the previous year, and despite this, this measurement reveals the knowledge of the Municipal Council about what was happening in Europe and the will to transform the city in accordance with modern hygienic principles. Thus the council asked for two fences of old monastery buildings, one on each side of the river to create two cemeteries. However, it was only on May 4, 1843, that the government ceded land for the implantation of the municipal cemetery, in the former farm of the College of Tomar. Yet this land was unsuitable for establishing a cemetery and the City Council had to buy Conchada Farm. After many technical and financial problems, the city finally blessed the municipal cemetery in September 1860.

In addition to this improvement, the city required some measurements to prevent the Mondego river flooding, like the upheaval of the low neighbourhood and the construction of a new river bank. The wetness of the land and still water were the focus of unhealthiness, which worried the Municipal Councils who repeatedly asked the government to make these improvements. But while on the one hand, the Mondego had this destructive nature, on the other hand, it was the largest source of water supply for the population. Its water was sold by water sellers in the streets and it was used for washing clothes and for bathing. While the water in the public standpipe was scarce or of poor condition. The municipality tried to solve these problems by diverting the watercourse of some springs on the limits of the city, but the problem persisted.

The first attempt to resolve the situation definitively was in 1865. When António Augusto da Costa Simões, a former mayor and a professor of medicine at the University, went to Paris on a scientific visit and during his visit, offered to hire a technician to study a water supply project through the capture and elevation of the Mondego River water. This idea arose in sequence to a series of analyses carried out in the University's laboratories of the city's water sources in the year 1862, in which it was concluded that the best water for

⁴ This paper is based on the work developed by the author's in her PhD dissertation, in this sense the main reference is Calmeiro, M.R., 2015, *Urbanismo antes dos Planos: Coimbra 1834-1934* (Coimbra: University of Coimbra).

⁵ On January 10, 1835, the mayor asked the government for some land from a former monastery to "establish in this city [...] convenient locations for public cemeteries". However, the first national decree to fix the need to create public cemeteries was that of September 21, 1835, in line with the European sanitary legislation created after the cholera epidemic that plagued Europe in the early nineteenth century. Representation of the Chamber of January 10, 1835. In Arquivo Histórico Municipal de Coimbra, Registration of Correspondence, Volume IV, 1829-1835, fl37. Decree of September 21, 1834, (Portuguese Courts, 1837)

consumption was river water. (Simões, 1890). The Municipal Council accepted the offer and Professor Costa Simões hired the engineer Louis- Charles Mary, a well-known engineer (responsible for the water supply project of many European cities like Lisbon or Barcelona), to start the project. Meanwhile, a new Municipal Council was elected, and the project was postponed. A few years later a new council decided to continue the project, but the French engineer's fees were too expensive. Thus, the municipality decided to create invite tenders from companies interested in planning, building and then exploring the new water supply network for the city. There were two proposals, with the winning one from Professor Costa Simões in partnership with engineer Cândido Xavier Cordeiro, a Portuguese engineer who had studied with Mary in Paris. The provisional contract was signed on January 27, 1872. However, this partnership needed to find a construction company with the financial and technical capacity to build their project. Unfortunately, they failed to interest any company and had to request the restriction of the contract in November of that year. The following year, tenders were invited again and Professor Costa Simões and the engineer Cândido Xavier Cordeiro won again, but once again they could not find investors interested in taking on the risk of undertaking the building and exploiting the water supply network of Coimbra.

However, Professor Costa Simões would not abandon the idea. A few years later, as director of the University Hospital, he gained the support of the director of the University Botanical Garden, Professor Júlio Henriques to jointly request a project to supply water to the University. They contacted the engineer Adolfo Ferreira Loureiro, Director of the Improvement Works of the Mondego River. This experienced engineer, confronted with the proposal and recognizing the need to provide this service to the whole city, designed a project that could be extended to the whole city if there was financial support from the central government. On June 20, 1876, the project was presented to the Ministry responsible for the hospitals and the University, but they received no answer.

Meanwhile Professor Costa Simões, again on a study visit in Paris, decided to consult companies to supply the necessary equipment for the execution of the project and was able to establish a partnership with a metallurgical entrepreneur, Hermann Lachappell, for the supply of all the machines and pipes. A new contract was signed with the municipality in February 1879 but the desired water supply network from the Mondego River was postponed once again. The expansion of the project to supply the whole city had tripled the initial budget, and the French businessman was unable to achieve what he had set out to do. But this time Costa Simões managed to pass the contract to an English industrial engineer James Easton, in July 1881. This entrepreneur was trying to build the water supply network in Seville, Spain and the work of the water supply of Coimbra could enhance more projects in Portugal. In December 1881, after finishing the final studies for the network he proposed to also project, construct and explore the sewer network, evoking the reduced number of inhabitants and profit. Despite the need for this improvement, the municipality had no financial capacity and as a consequence, the entrepreneur refused to sign the final agreement and in September 1887 the contract with the English industrial was rescinded, with serious damages to the city, which continued with a water supply from standpipes and faced scarcity and poor quality of water, as well as the lack of any sewage network.

In 1887, a severe outbreak of typhoid fever affected the upper neighbourhood and the university area. According to experts, this fever originated from a water distribution aqueduct, contaminated by a break in a sewer pipe. Because of this incident, the mayor, Professor Luís da Costa e Almeida, asked the government "for the means necessary to undertake the necessary improvements in the city, especially in the sewer pipes and since this was the setting of a remarkable scientific establishment where every year hundreds of students from all parts of the country come"⁶. He also claimed that this crucial work for the University and especially for the University

⁶ Representação de 16 de Junho de 1887. In AHMC, *Representações às Cortes e ao Governo, 1881-1892*.

Hospital should be carried out by the government or at least with its financial support. In response, the government delegated the engineer Adolfo Ferreira Loureiro with the elaboration of a project to create the best sewage system for the city.

Transition in the municipal administration, abandoning reliance on private enterprise and spearheading the installation of the new public services

In 1886, the municipality, headed by João José Dantas Souto Rodrigues, tired of the various attempts to create a modern water supply network and embarked on a new and decisive phase, not only for the water supply but for the future of the city administration. They decided to assume responsibility for the execution of this improvement and undertake the construction of the new water supply network from the Mondego River by their own means. For this, they hired the engineer Adolfo Ferreira Loureiro to update his project approved in 1879. On January 5, 1888, a contract was signed with Eugène Béraud and the work began in March.

At the beginning of 1889, the water pumping station at Porto dos Bentos was ready to operate and in May of that year, the network started to operate. Just nine years after Lisbon and three years after Porto, Coimbra had a modern network of water distribution by mechanical means, with the particularity of it being the exclusive responsibility of the municipality.⁷

Shortly after the construction of the water supply network, the engineer Adolpho Loureiro submitted to the government and the Advisory Board of Public Works and Mines the project and budget for the sewage network for the city. It proposed the use of an innovative solution, applied in Paris, called the *Berlier Metallic Pneumatic System*, composed of a network of iron pipes and collectors connected by pneumatic devices that ensured that the pipes were always empty. It also had the advantage of being easy to apply and completely impermeable and on the other hand, the sewage flow would be reduced, facilitating its use for fertilization of farms along the Mondego valley. Unlike most of the systems applied at that time, this system was designed only for sewage; there was another network for rainwater and this duplication increased the costs but safeguarded the drainage network during river floods. The minister approved the project, but the innovation of the system generated great discussion in the city and as a consequence, when the government invited tenders for the works, the possibility was opened to propose a different solution.

The winners were the engineers José Cecílio da Costa and João da Costa Couraça, who proposed a *System of Continuous Circulation of sewage*, a unitary system for the network of rainwater and sewage. To reduce costs and facilitate implementation, they proposed a set of small section pipes, three main collectors and a reservoir, set up in the Padrão area, which would raise and discharge sewers directly into the irrigation fields of the Mondego valley. (Costa, Couraça, Bessa, 1893)

The construction works began in November 1897 with the main collectors, after which the remaining works would be conducted according to the financial availability of the municipality and with the progressive growth of the city. In fact, at the end of the 19th century, when the city began to build several neighbourhoods and expand its limits, the sanitation network started operating but without the Padrão reservoir, and sewage was

⁷ In Paris, this method of water pumping was used since 1782 and in London at least since 1829. In Lisbon, the method was used early in 1869 but the system had a large deficit of flow and only becomes effective after the water pumping station at Alviela in 1880. (Custódio, 1994 and Pinto, 1972). In Lisbon, the water supply system was leased to Companhia das Águas de Lisboa since 1867. On the issue of municipalization of the Companhia das Águas de Lisboa see Álvaro Ferreira da Silva.(1998 e 2004).

launched directly through the drains of Coselhas into the river Mondego, without treatment and without having been used for fertilizing the fields. The fragmented construction of the network compromised the performance, and only at the beginning of the 20th century was the situation solved.

From the municipal water supply network to the municipalization of all urban services

At the end of the 19th century, in addition to the modern water supply network and the sewage network, Coimbra had a gas network for individuals and public lighting. Thanks to the English entrepreneur Hard Hislop, who was also responsible for the installation of the Porto gas network, the streets and streets of Coimbra had been illuminated by gas since October 1, 1854, one year after Porto and only six years after Lisbon. (Custódio, 1994 and Caetano, 1998)

Regarding the creation of a public transport network, the process was not so fast or simple. The first attempt occurred in 1874 when American Car started to connect the railway station to the city centre (as seen in Figure 1) but lasted only eleven years. In 1885, the new train station near the river in the downtown led the Conimbricense Railroad Company to close. Before that, they had proposed a new line to connect to the Alta, but the new Santa Cruz neighbourhood was not yet built, and the proposal was considered impracticable.

Figure 1 American car route in 1874 (Calmeiro, 2015: 285)

Seventeen years later, the entrepreneur Augusto Eduardo Freire de Andrade, owner of the *Coimbra Carris de Ferro Company*, presented a proposal for the creation not only of a line but of a network articulated with the growth of the city. Although the proposal had the support of the local press, the mayor Manuel Dias da Silva was unwilling to implement it because he wanted an electric system instead, for both public transport and lighting. For this, he invited tenders to introduce electricity in Coimbra. However, the small size of the city did not arouse the interest of external investors and there were no proposals. With this setback, the concession to the Coimbra Carris de Ferro Company was approved and at the beginning of 1904 two lines began to operate, one between the train station and *Largo Príncipe D. Carlos* and another between *Estação Nova* and the Castle.

However, this system of traction using animals soon proved to be inefficient for the slope of the city streets and two years later the concessionaire proposed installing electric traction with the financial support of the municipality. Despite the subsidy, the company started to face financial difficulties, worsened by the death of Augusto Eduardo Freire de Andrade, and the work was postponed.

Meanwhile, the municipality continued trying to install electric light in the city and in 1903 signed a new contract with a Portuguese company, *Almeida e Santos, Lino & Companhia*, but a series of delays led to the termination of the contract. This, in turn, led to a new way for the municipality to work and a new understanding of how urban public services should be managed. The mayor Professor Manuel Dias da Silva tired of the dependence on foreign investors for the municipality decided to repeat the process carried out to install the water supply network and install electricity with municipality resources. Thus, it municipalized the gas factory to create an electricity factory and a new network of electric lighting for all the city.

A few months later a new mayor, Professor Marnoco e Sousa, was elected, a law professor with a new vision of the role of the local administration in the planning and development of cities. As a defender of public service, he was highly critical about the participation of private companies in the city services, affirming even that "the regime of concessions has had its time since only serves to favour the interests of the private companies to the detriment of the community"⁸. Thus, one of his first measures was the municipalization of public urban transport to install electric traction. He claimed that with this municipalization, Coimbra had "the three industrial services of city municipalized – water, lighting, and transport. These services help each other [...] Water is needed for the electricity factory, just like the coke produced by the gas factory. On the other hand, the transport facilitates the transportation of the by-products of the gas factory and helps with this transportation of the coke to the water supply station, solving, in addition, the problem of lighting the great avenues and wide streets of the city with voltaic arcs [...]"⁹

The following July, the Chamber of Deputies approved a loan for the municipalization and installation works for electric traction. On February 11, 1909, the project of the engineer Guilherme de Lima Henriques was approved and work started in September.

On the first day of the year 1911, the electric urban transport network was inaugurated in Coimbra, which became the fourth Portuguese city to have this service, but the first municipality responsible for the service. Shortly after, the electric power of the trams started to be used to light the main streets.

Integrated city planning - planning and management of infrastructures and the city by the municipality

Throughout the 19th century, a new way of planning the city was developed. (Tarr and Dupay, 1988; Tarr 2008) This was as a consequence of the growth of cities and their hygiene and sanitation needs, but also of the new infrastructure networks. These networks introduced new ways of living, a new idea of comfort and can be considered as one of the marks of progress in the urban form. The introduction of these networks required a new city form but also large investments and technical expertise that municipal administrations did not have. Thus, this infrastructure became a private enterprise supplying goods and services. The new public services were dependent on private capital to build and manage them and public administration was limited to the regulation of the concession contracts.

In Coimbra, a Portuguese medium-sized city, this model was not applied. After years trying to build a water supply network by concession, the municipality decided to undertake the installation of the water supply network from the Mondego river, as well as the sewage network, two crucial improvements for the health of the city. A few years later, at the beginning of the 20th century, the innovative procedure continued, with the municipalization of the energy and the public transport networks to install new electric energy for transport and lightning. This new way of acting implied some constraints and delays caused by the financial weakness of the municipality and the lack of technicians working in the municipality. However, this would allow the municipality to plan the city in an integrated way, planning the new neighbourhoods and public services together. Thus, the new public transport lines or the new water, sewage and electricity network were drawn up and planned according to the municipal plan for the city's expansion. The new neighbourhoods were planned together with the new urban infrastructures.

This innovative and integrated means of action gave the municipality a new role in urban planning that had consequences in the evolution of Portuguese urban planning. However, this was only possible due to a group of daring and knowledgeable mayors together with a group of skilled and well-trained technicians.

Tram City, Motopia and Light Rail Commercialism in Canberra

Karl F. Fischer¹, James Weirick²

¹*University of Kassel/ffischer@uni-kassel.de*

²*University of NSW, Sydney, J. Weirick@unsw.edu.au*

Abstract: One of the long-term trajectories in urban development since the late 19th century has been determined by changing modes of movement. Following the city of the pedestrian plus bicycle and horse & carriage and that of trams and railway suburbs, the rise of the automobile city saw the decline and often total disappearance of streetcar systems. Then, the 1980s experienced a wide-spread renaissance of rail transport. Futuristic projections have accompanied these visions right through to current developments around driverless cars and trackless trams. Based on the case study of Canberra, this paper analyses these projections and their legacy in terms of success, failure and portent. The original plans of the Griffins (1911-1918) had proposed a model streetcar city financially supported through income from the leasehold system. These ideas were supplanted by a Motopia vision, which morphed into plans for a linear city shaped by land-use-transportation studies – an automobile-dependent suburbia, yet with the potential for a rapid transit public transport spine. Light rail was eventually introduced in 2019. Financed through the sale of public housing and creating high-rise development along the route, this is resulting in a profound transformation of Canberra's urban form with real-estate values as the central shaping factor.

Keywords: Streetcar cities; Motopia; urban form; Canberra

Introduction

In urban development (as in other fields, too) phases characterised by rapid transitions, by new visions and vigorous new developments tend to alternate with protracted periods of stagnation and periods in which base innovations take effect step by step and in which plans are carried out and gradually modified, before the next wave of innovations breaks its new path, again accompanied by fresh visions and a corollary of individual innovations.

What is the role of planning history in this context, particularly in the phases of rapid transition? When can insight provided by planning history be appropriately harnessed for innovation? And, by contrast, what are the consequences of disregarding planning history or of exploiting history in a manner that is at best selective? A well-known case in point is that of radically modernist urban renewal, which often painted the legacy of the preceding period in dark colours to justify the demolition of valuable historic structures.

In the field on which this paper is focusing, it appears that today we are at a point in time at which innovations in transportation technology associated with advances in fields such as electronics, digital technology and Artificial Intelligence have gained momentum and

are leading to significant changes in urban form and structure. Self-driving vehicles, trackless trams and high-speed trains have already transformed urban regions in parts of the world and are foreshadowing patterns soon to be followed globally. These developments are closely linked with transitions in the fields of the economy, energy and a plethora of related changes in the planning context.

Canberra

In our local case study of Canberra, plans for a tramway system were an essential element of the original design of 1911, but evaporated in 1920 to be replaced by motopia visions in the 1950s. Efforts for the introduction of a tram system following the European models emerged in the 1990s but remained without success for several decades. It took until 2009 before a new dynamic was introduced through a Labor-Greens political alliance leading to the inauguration of light rail in 2019. Although a success of sorts, the result is nevertheless not broadly seen as the desired triumph of the persistent struggle for sustainability. The reasons lie in a combination of issues in the narrow field of transportation planning and the wider, more complex economic and urban development context.

At the heart of this problematic lies the strategy of financing the light rail infrastructure largely through the sale of public housing and land and through value capture from new high-rise development on up-zoned properties along the light rail route. This is resulting in a profound transformation of Canberra's urban form. In order to 'sell' the associated change in character to the public and real estate investors, remarkably aggressive strategies of re-branding the city have been applied over the last decade. They are designed to transform the image of Canberra from what is depicted as a boring garden city and 'bush capital' into an exciting metropolis of luxury high-rise apartments. The Canberra Metro, as the light rail is called, is an integral part of this concept.

In tune with modern information technology and current themes such as fake news and media wars, the Planning Minister (today Chief Minister) and big developers are involved in campaigns via Twitter and You-tube that are based on a selective (re-)writing of planning history in order to advance their joint agenda. In this perspective, today's Canberra is depicted as the product of an old-fashioned plan that has escaped from a Simpsons' Family cartoon, unfit for adaptation to today's challenges and defended only by NIMBYs and senile locals. This sarcastic narrative runs parallel with an interesting mix of thoroughly researched work on the Griffin Plan, real estate spin and selective readings of later phases of planning. In order to sort out fact, fiction and critique, aspects of Canberra's planning with relevance for our theme are laid out on the following pages before analysing the most recent developments.

The Tram City of the Griffin Plan 1911-1920

Conceived very much as a complex "Gesamtkunstwerk", the original plan for Canberra is impressive at many levels – whether as an achievement integrating urban design, landscape planning and sustainability principles (Fischer and Weirick 2014), as a manifestation of "democratic symbolism" (Weirick 1998) or as the artwork drawn by Marion Mahony that was listed as UNESCO world cultural heritage in 2003. Walter Burley Griffin's reports go well beyond explaining the features of the design by embedding the whole in a planning theory context (Griffin 1912, 1913).

In his treatise on land use/transportation, density and building height, Griffin elaborated in which way "the transit system affects the density and character of the city, allowing for a horizontal distribution of building mass that maintains the city in scale with its landscape and increases access to open space. With a liberality of public space... and

directness and speed in communication between all points, the necessity of making these large units stand on end as in the congested American cities, can be avoided" (Griffin 1912:83).

Designed to overcome such disadvantages of the "congested American cities" Griffin's low-rise medium-density city was constructed around a skeleton of avenues with a suburban railway and "a streetcar system that was so simple, logical and comprehensive" (Weirick 2012) that "some 90% of the population would live within a five-minute walk (500 metres) of the service" (NCA 2004:74). This feature was explored in a careful analysis of long-lost plans by officers of the National Capital Authority in 2004. More revolutionary than this was Griffin's idea of free tram travel "perhaps supported financially in the same way out of rents as the lift or elevator" (Griffin 1913:32).

The progressive character of these planning principles was, however, not appreciated. They were alien to the Australian culture of the first half of the 20th century. Already in 1909, architect John Sulman had warned in his explanations for the international competition for the capital: "the European boulevard with its street cafés would be unappreciated in Australia" (Sulman 1909:606), but as we know, the Griffins did not heed Sulman's advice and produced one of the world's most beautiful plans for a city of avenues and tramways.

Figure 1

A closer look also reveals that the plan for Canberra is really that of a multi-modal city, even though the most conspicuous elements of the 1912 version (Figure 1) are the *Railways* and *Street Car Lines*.¹ However, as Griffin pointed out in his 1912 report, the plan

¹ It is only in the 1912 plan, which was drawn while the Griffins were in America that the term streetcar instead of tram is used.

is shaped by *two* new modes of transportation, "tramway and fast vehicle traffic, which mean a very different distribution of trade than where walking range [had] been the determining factor" (Griffin 1912:101). The Griffins were of course well acquainted with the developments in the automobile field through their experience in Chicago and their connections with Henry Ford, for whom Marion had designed the Fairlane estate (Van Zanten 2011:106).

These perspectives vanished from common knowledge after Griffin's demise in 1920, and from the 1950s to this day, re-assessments of the Griffin Plan have frequently been marred by assumptions that the plan dated back to the pre-automobile horse-and-buggy days (Senate 1955:78) and could not be anything than quirky and old-fashioned (Barr 2010). On the other hand, such positions were counterbalanced by people who really dealt with the original materials, beginning with Canberra's Chief Town Planner Peter Harrison in the 1950s and James Birrell, one of Griffin's biographers, who drew attention to the surprising fact that "no major concept in town planning has been put forward in the (then) 40 years since the city as designed that is not incorporated in the original scheme" (Birrell 1963:92). In addition to the plan's urban design qualities praised internationally by Edmond Bacon, John Reys and Peter Hall, the sustainability principles of the plan impress to this day (Fischer and Weirick 2014). Had they been applied in the development of the city, many of the problems of climate change would have been mitigated. However, the rich semantic content of the plan was watered down and impoverished in the following years.

From the doldrum decades to "Fast Forward" in the Fifties

Following Griffin's demise in 1920, the basic change in the conception of Canberra was that from a capital city of clearly urban character to a suburban "garden town with with simple, pleasing, but unpretentious buildings, mostly single storey" (FCAC, 1924, p.8). In terms of the perspective of this paper, this meant that traffic was not much of a theme and public transport did not exactly have an easy task in the "seven suburbs in search of a city". The most memorable feature of the traffic scene during the stagnation of the inter-war years may have been the long row of cars making their way on Sundays to the pubs of the neighbouring town of Queanbeyan leaving the "dry territory" during the years of prohibition.

The dramatic change in Canberra's planning history came in the 1950s with Prime Minister Menzies' program of transferring the majority of Commonwealth Government departments hitherto headquartered in Sydney and Melbourne to the national capital. In this situation, a new set of ideal concepts in planning emerged from the late 1950s on. It was triggered by the initiatives taken by Prime Minister Menzies; it was shaped by the war-time experience and by the break-through of the automobile culture; and it was orchestrated by engaging international networks and by founding an all-powerful organization for planning and development.

A first key person in the international context was the British architect and town planner Sir William (later Lord) Holford. Well known for his work on the reconstruction planning of London, as chairman of the adjudicators on the designs for Brasilia and with connections to Canberra dating back to his appearance at the 1951 *Federal Congress on Regional and Town Planning* there, Holford was personally briefed by Menzies during an overseas visit in London. His *Observations on the Future Development of Canberra* published in 1957 were a clever 'tour de force' presenting ideal concepts with an immediate appeal to his target group of Australian planners and politicians.

Canberra, Holford said, faced two alternatives – to retain the provincial character of the city, with grazing and gravel digging (!) around Parliament House, or "to become a unified

city" (the lake had not yet been created) ... "a cultural and administrative centre and a national capital" (Holford 1957:6). He acknowledged that this would call for "an all-out combined operation of the kind which is so much more difficult to achieve in peacetime than during war." This is why Holford emphasized the necessity of creating a bold, unified design "on a scale sufficient to make an impact on people's imagination" (Holford 1957:7) beginning with the creation of the lake.

In addition to a range of planning proposals including the location of the new permanent parliament building, Holford identified three important objectives for the whole city:

- The development of Canberra into a cultural centre - "the sort of city which people would want to retire *to* rather than *from*"

- the "maintenance of a garden city character in the residential parts of the city, [which] is more important than raising the density"

- and the development of "a modern system of traffic circulation" (Holford 1958:9).

This began with the construction of a freeway link across the length of the northern lakefront. Named "Parkes Way" after federalist Sir Henry Parkes, this six-to eight-lane freeway link is characteristic of the U.S.-American "parkway" concept designed for automobile drivers to experience the world through the windscreen of the moving automobile. Hailed as the epitome of modernity, speedways of this kind were rapidly cutting off urban areas from waterfronts all over the world. Everywhere, the struggle to reduce the negative effects on urban life took decades, and Canberra is still looking for solutions.

In Canberra, the parkway approach has been serving as a model for the urban development plans until today. The organization that conducted the planning and development until the late 1980s came into existence on 1st March 1958. Named *National Capital Development Commission* (N.C.D.C.), its task was "to carry out the planning, development and construction of the City of Canberra as the National Capital of the Commonwealth." Endowed with a large, single-line budget and a high degree of planning control based on continuation of the leasehold system, the Commission's professional planners enjoyed planning conditions that their colleagues elsewhere could only dream of. Over a period of three decades, the planning organization acted as benevolent dictator in a city that was managed like a company town without self-government until late in 1988.

Motopia - triggers, transformations and trajectories

The plans produced in this situation were extreme in their concessions to the 'bungalow-automobile syndrome'. If the post-war decades marked the break-through of automobile culture, then Canberra was an ideal location for translating this into urban development plans, or so it seemed at the time.

The NCDC was convinced: "We are unique - we are in a better position to meet the challenge of this 'growth pressure' than any other capital city. We have the opportunity to benefit from the mistakes made in other capitals and the methods that they use in endeavours to find a solution." Taking advantage of "an opportunity untrammelled by any of the normal inhibitions of planning, and aided by modern science and technology" (N.C.D.C. 1964:2) the planners in Canberra could aim for something that had proved impossible in other "auto-reliant communities of similar size" - to develop a road system that could always stay ahead of traffic demands.

Little wonder that the NCDC's first official long-term metropolitan development plan (NCDC 1965) projected a utopian or rather a "motopian" vision (Figure 2)

Figure 2

that soon revealed its true nature as dystopian (Figure 3). Designing a freeway system that would remain congestion-free even at peak hour for the corona of dormitory satellite districts converging on a CBD expanded close to North Canberra's green belt of Haig Park would have drowned the city centre in a vast sea of asphalt (Fischer, 1989, p.178; Reid, 2001, p. 259). For North Canberra, the plan would have implied the atomisation of the existing residential areas into small islands, some containing no more than eight to ten houses surrounded by expressways and speed ramps.

Figure 3

This insight led to last-minute redesigning which indeed managed to save the central area from being devoured by the asphalt desert of early 1960s' urban expressway planning; and it led to a radical transformation of urban form from radial-concentric to linear.

From Motopia to the Perfectionist Garden City Metropolis

The next plan was no less extravagant in terms of the consumption of space (Figure 4). The congestion that would have choked Inner Canberra was now to be avoided by stretching the urban area into a linear corridor of considerable length.

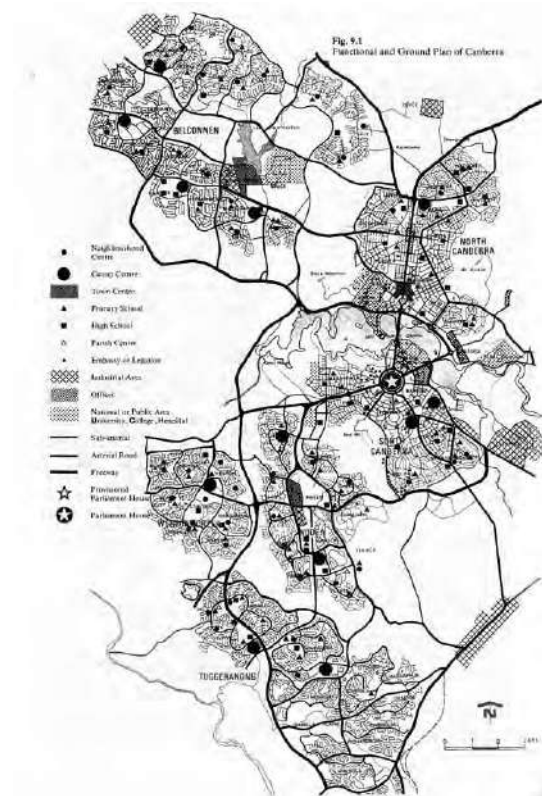

Figure 4

Two important conclusions were drawn on the basis of a Land-Use-Transportation Study (Voorhees, 1967): First, instead of developing a conventional CBD, a significant share of the retail functions and offices would have to be decentralized into the satellite 'New Towns'. This term was chosen in order to indicate that a high level of self-containment was intended. Second, the new districts had to be stretched into the form of a linear city with 'old Canberra' in the middle, and the expressways passing through the whole length of the districts would be connected by peripheral freeways and a central public transport spine. This would allow for the introduction of rapid transit once the 500,000 population level was reached. Dividing the city at its northern end into two branches was intended to make public transport on this spine more effective. The frame of this 'Y Plan' was fitted out with housing and shopping centres, community facilities and streets organized into perfect hierarchies.

Utopia realized?

The product of this approach might be called 'the perfectionist garden city metropolis' (Fischer, 2013, p. ix). One of its amazing features is the degree to which the planning concepts of that period have been implemented. This can be impressively demonstrated

by comparing a visionary artistic rendering of Canberra drawn in the late 1960s, with an actual aerial photograph from 2000. The drawing depicts the city in the manner of an aerial photograph as it was expected to look like in the early twenty-first century. The two images are surprisingly similar, if we exclude the conspicuous new Parliament House (1988), which shows up in the aerial photograph, but which the artist could not have foreseen in 1969.

In a similar way, the city's functional and ground plan drawn up for the book *Canberra – Myths and Models* in 1984 looks very much like a diagram from a planning textbook (Fischer, 1989, 184). In fact, however, it displays the built reality of the then existing city, demonstrating that the hierarchical planning principles were applied with utmost perfectionism: Canberra was a perfectionist manifestation of planners' ideal concepts in the Fordist age – albeit in a non-industrial city. A critical key to this concept lay in the government's power to achieve a balanced disposition of employment centres through its control of the land and the location of its own offices. This, however, began to unravel as early as the 1970s.

Transition into Neoliberal Times

Following the dismissal of the Federal Whitlam Labor Government (1975) the succeeding conservative Fraser Government ended the 'company town' practice of building and owning its own office complexes, creating instead a market for private commercial development underpinned by long-term leases from government departments. The privatisation of office accommodation led in due course to the creation of powerful development interests, which successfully lobbied to concentrate office development in the central city at the expense of the New Towns.

The underlying shift in planning culture (Fischer 2004, Fischer and Weirick 2016) was part of a broader shift to the Australian version of neoliberalism (Harvey 2005) under the heading of 'economic rationalism' (Pusey 1991, Yeatman 2017). In fact, fundamental changes towards a neoliberal agenda had already begun as early as 1970 when, in the fever of a Canberra by-election, the leasehold system was emasculated by replacing land rent with municipal rates, thereby transforming property in the ACT from leasehold to virtual freehold tenure (Brennan, 1971).

While the high level of planning control was not immediately affected, the economic consequences were significant. A result at the short-term level was a windfall benefit to the property sector. In the long term, the ethos of Canberra's development was shifted from the 'common wealth' to conventional property speculation. What the fathers of the leasehold system had once been conceived as a sustainable method of supplying building land at equitable cost for the homes of average citizens was turned into its opposite with land policy now focusing on the maximisation of land values.

The new arrangements also laid the foundations for a new way of financing the capital; and this became important when the Commonwealth Government decided to divest itself of financial responsibility for the city beyond core national capital functions. In the administrative sphere this underpinned the decision to force self-government on the reluctant population of the city, who were only too aware of the privileges they would lose in the process. In 1989, Canberra was finally granted self-government – a step that appeared long overdue in a democratic society.

The system devised in this situation, however, entailed serious defects at different levels (Powell, 2012) and it marked the beginning of a long phase of turbulent political reforms continuing to this day (Fischer and Weirick 2018). At the economic level, a 'city-state' (ACTPS 2011) without a productive hinterland could not operate in the same way as the Australian states raising revenue from mining, manufacturing and industry. Therefore,

the ACT still depends on Federal subsidies, but in a system set up with the intention of minimizing Commonwealth expenses, federal grants proved to be a continuing bone of contention.

Self-Government and Land Sales as a Source of Municipal Revenue

As a consequence, the ACT government has to finance a significant part of its revenue through the sale of its principal asset, greenfield lands (Corbell, 2005; ACT Government, 2005; Sansom, 2009). Unfortunately, this approach is unsustainable given the limited extent of developable land in the ACT. Over time therefore, the strategy of drawing income from up-zoning land for high-density redevelopment gained importance. And by 2012, it turned out also to be an important basis for financing light rail infrastructure.

Right from the start, the exigency of raising revenue for the day-to-day requirements of the territory budget increased the pressure to achieve rapid returns from greenfield development and weakened the ACT Government's negotiating power with the development industry. The low-density, car-based city, which the local government had inherited from the national government thus continued to expand with long-term costs overlooked in favour of short-term gains. To maximise these gains, the process of suburban development was privatised and in the push for low infrastructure costs and maximum yield, 60 years of exemplary neighbourhood planning in the National Capital was overturned, creating some of the worst suburbs in Australia in terms of environmental impact and environmental amenity (Fischer 2004). In this process, the latest district developed at Canberra's northern edge, Gungahlin, emerged as "Canberra's unhappiest new town with... a jungle of badly designed houses and townhouses, unsatisfactory community facilities and a poor quality of social life... a nightmare of planning" and bad transport connections (Clack 1995). At the beginning of the twenty-first century, it seemed as though the neoliberal turn at national and local level had reduced Canberra planning to a travesty of its former self.

Triggering New Visions of Strategic Planning

A turnaround, however, occurred – and from a most surprising source. In 2001, the OECD – that paragon of market economy orthodoxy – was invited to report on Canberra as part of its 'urban renaissance' studies of sustainable urban development in selected cities worldwide. The major findings of the OECD investigation included the lack of a strategic plan for Canberra, and the lack of effective community engagement in the planning of the city (OECD 2002).

Facilitated by the election of a local Labor-Greens coalition in 2001, the Territory government was able to move decisively to address both issues. It prepared a metropolitan strategy with a social plan, an economic plan, and a spatial plan projecting, urban consolidation, a more compact urban form and the introduction of a light-rail system. In recognition of community ideas for a creative, compact city freed from car-dependency, which date back to a path-breaking study of 1991 ('Towards a More Sustainable Canberra' by the pioneers of public transport planning, Peter Newman & Jeff Kenworthy) the Territory government began to draw up plans for the first stage of a light-rail system to connect that northernmost 'New Town' Gungahlin with the City Centre. It took another decade before another deal struck between the Labor Party and the Greens following the 2012 ACT election, at which Labor required support to form government, lead to the implementation of that 12km stretch of light rail.

The announcements by Commonwealth Government for financial contributions have varied significantly in the daily ups and downs of politics. This reinforced the policy of financing the infrastructure to a significant extent through the sale of public housing and through up-zoning land along the light rail corridor for high-density development. The

changes in the character of the “Garden City and Bush Capital” have led to controversial discussions in which the Planning Minister, the Property Council and the biggest local developer Geocon have pursued remarkably aggressive strategies to fight their fears, a low-density vision might constrain future development along the corridor. In 2010, the Planning Minister started this campaign by ridiculing the Griffin Plan by comparing it to the Simpsons Family small town of Springfield (Figure 5). In his role as Chief Minister, he has been continuing this strategy until recently.

Figure 5

In his role as Chief Minister, he has been continuing this strategy until recently, even though he has been praising the element of the tram or light rail that was essential to the plan. In recent years, campaigns by developer Geocon have attacked the garden city and bush capital image. One of their you-tube video films features a young lady smashing a ‘bush capital’ sign with utter disgust (Figure 6), as all around her, a brave new world of beautiful high-rise apartment blocks with beautiful people drinking champagne and jumping into the pool emerges.

Figure 6

These visions are linked to utopian statements by Geocon claiming that the extension of the light rail line to their new developments south of the lake is going to take the new residents into the city within ten minutes (Jervice Bardy 2019) – a remarkable propaganda war on the perspectives of real estate and light rail.

Alberto Sartoris: transitions to a possible urban utopia (1922-1989)

Cinzia Gavello¹

¹*Politecnico di Torino, cinzia.gavello@polito.it*

Abstract: The events related to the development of urban agglomerations started by Alberto Sartoris in 1922 highlight his uncommon attention to the themes of a transition to a possible utopia, whose structure is constituted by collective solidarity and rational subdivision, aimed at a rigorous use of strict design principles that aim to concentrate the population in specific parts of the city, such as in large buildings or neighborhoods duly sized, in the normalization of housing and traffic regulations. This approach to urban planning is evident observing the first so-called “urban compositions” conceived by Sartoris, such as the project for the Stadium or the University City of Turin, the project for the Satellite city of Rebbio in 1939, with Giuseppe Terragni, reaching the most recent urban plans of Punta Aspera in Varazze and Mont-Fleuri in Montreux in 1963, or the project for a “bridge city” in Barcelona in 1989, within which the unmistakable metaphysical matrix of rationalism is clearly recognizable. The aim of the proposal is to explore the challenges faced by Sartoris in the debate of the 1930s related to the development new urban scenarios and the exact role of the creative and humanist architect in the face of the interpretative change of that time.

Keywords: Alberto Sartoris; modern urbanism; Turin University City; bridge city.

Introduction

Alberto Sartoris (Turin, Italy, 1901-Cossonay Ville, Switzerland, 1998), Italian-Swiss architect and critic, was one of the most important figure in the birth of rational architecture and urbanism. The events related to the development of urban agglomerations, initiated by Sartoris, in 1922 highlighted his uncommon attention to the themes of a transition to a possible utopia, whose structure was constituted by collective solidarity and rational subdivision, aimed at a rigorous application of strict design principles that aim to concentrate the population in certain parts of the city, such as in large buildings or neighbourhoods duly sized, in the normalization of housing and a particular traffic regulations (Sartoris, 1930b). A founding member of Congrès Internationaux d'Architecture Moderne (CIAM) and a signer of the La Sarraz declaration with Le Corbusier in 1928, a “messenger of intelligence” (Belli, 1936) destined to export real examples of Italian architectural culture to South America in 1935 and chairman of the Swiss Permanent Committee on World Town Planning Day in 1949, Sartoris himself was considered a transitional figure respect to the Italian architectural *panorama*. His significant role in the development of European modernism and his lifelong activity have earned him a secure place in the history of twenty century architecture.

Despite the fact that his main books have been published by the Milanese publishing house Ulrico Hoepli¹, and notwithstanding being repeatedly defined as the “father of rationalism Italian” and the “founder of the new architectural culture” (Mariani, 1987), curiously in Italy Sartoris seemed to have never enjoyed the great fortune and recognition due to the spectacularity of his projects (Pozzetto, 1986). After an initial period of training in Turin, judged to be a Fascist in the 1930s, Sartoris was therefore able to conduct his professional activity in Switzerland, with works that included especially residential and religious constructions: with these projects, in the following years, Sartoris has successfully and stubbornly brought to light a so-called “project radicalism” (Pozzetto, 1986), with a stainless faith in rational architectural. Such obstinacy sounded like an offense to the Italian innovators of the time that was certainly difficult to tolerate. Considered as “transalpine” by the Italians and as a “transgressor of the Swiss order by the Swiss” (Gubler and Abriani, 1990), he has earned since the early years of his career a position of transit, even if not of isolation. He, in fact, didn’t remain on the sidelines, as he staying very active in the debates and controversies that have stirred up European architecture since 1928. This transit position has perhaps enabled him to question some of the theories of the great masters of modern architecture in the early thirties of the twentieth century.

The study of issues related to the design development of imposing urban agglomerations is made possible thanks to the analysis of the relationships that Sartoris has been able to establish with the main protagonists of art, architecture and urban planning of the twentieth century, such as, for example, Raimondo D’Aronco, Annibale Rigotti and Giuseppe Terragni. Sartoris’ approach to urban planning is evident observing the first so-called “urban compositions” (Sartoris, 1934a), such as the project for the Stadium or the University City of Turin in 1922, the *Cité-Crémaillère* for Geneva in 1931, the project for the satellite city of Rebbio in Como in 1939, in collaboration with Giuseppe Terragni, reaching the most recent urban plans of Punta Aspera in Varazze and Mont-Fleuri in Montreux in 1963, or the project for a “bridge city” for Barcelona, in 1989, within which the unmistakable “metaphysical matrix of rationalism” (Fagiolo, 1974) is clearly recognizable. His projects were therefore in a transitional phase in which the urban crisis occurred in the presence of an irreversible change in the state of the habitat and social practices. The figurative structure of entire parts of the city represented, according to Sartoris, the synthesis of those expressions considered fundamental for a rational planning, such as traffic, functions and their hierarchy and housing types. Within these interpretations, the search for synthesis, which in Italy can be largely pursued between technical and aesthetic needs in the modernization of cities, sees a deepening in the work of Sartoris and in his constant faith in the application of the principles of architectural rationalism and from which descend reflections on the city and on building in the built.

The focus on issues related to modern urbanism was a real chapter in Sartoris’ career and, at the same time, remained closely related to his reflections on the architectural and urban organism throughout his long professional and academic activity. In particular, during his long career and in his numerous writings, Sartoris tried to highlight the deployment of the design forces that could be activated on all

¹ See the three editions of *Gli elementi dell’architettura funzionale. Sintesi panoramica dell’architettura moderna* (1932, 1935, 1936), the three editions of *Introduzione alla architettura moderna* (1943, 1944, 1949) and the three tomes of the *Encyclopédie de l’architecture nouvelle* (*Ordre et climat méditerranéens*, 1948, *Ordre et climat américains*, 1954, *Ordre et climat nordiques*, 1957).

the transition nodes, between the building aggregate and the territorial network, which was considered his challenge to move towards new and significant images and urban scenarios. According to Sartoris, “We absolutely must resolve the problems soon in order to arrive at unsuspected visions of the city. It’s therefore necessary to realize, in the great urban agglomerations, almost superimposed cities, stratified cities, cities with bridges [...] to elaborate projects of penetration in the apparently abandoned city centres, to insert raised streets and squares, like the bent city, to create spaces and systems of vertical and horizontal circulation at every level [...] Innovation cannot spread if it does not take the road of its conquests that will flourish again under the injunction of the discoveries of the present in a sort of simultaneous emergency of the dimensions and values, past and present, of an urbanism that creates resources and new constructive orientations” (Fabbri and Pastore, 1991). Sartoris has been able to go beyond contingencies and has marked the future ways of becoming of architecture and urbanism, proclaiming the importance of spiritual and lyrical values.

Futurist debut and rationalist ascent

Sartoris’ most important works were not only the built buildings or unrealized projects, but also publications, “because it’s possible to build with words as with reinforced concrete” (Abriani, 1972). Sartoris’ study and publications reflected his theories on architecture and urbanism in a decisive way: his numerous writings revealed a certain vision of the city that was intimately linked to the methods of organisation of collective life and work, new systems of communication and circulation and innovative building materials. Sartoris’ interest in urban issues has been consolidated in the second half of 1929, when he began his collaboration with *La Casa bella*, directed by Guido Marangoni, and *La Città Futurista*, directed by Luigi Colombo, better known as Fillia. With the prestigious collaboration of Sartoris, these magazines began to publish articles aimed at disseminating the most current European experiences in the field of so-called “new architecture” (Sartoris, 1929b). Behind titles that summarized concepts, typologies or quality of materials – *Gli elementi della nuova architettura*, *Architettura standard*, *Introduzione all’urbanismo* – between the end of 1930 and 1936, Sartoris introduced readers to the most innovative architecture produced in Europe, presenting works and architects such as, for example, Le Corbusier, Jacobus Johannes Pieter Oud, Richard Neutra and Walter Gropius. A *panorama* aimed at confirming the transnational nature of rational architecture, later merged also into *Gli elementi dell’architettura funzionale*. *Sintesi panoramica dell’architettura moderna*, published in 1932 by Ulrico Hoepli publishing house (Sartoris, 1932a). The importance of this contribution lied in having identified the roots of functionalism in a broad panorama of avant-garde experiences in the artistic and architectural field, including the futurism and dynamism of Antonio Sant’Elia, from which Sartoris derived the supreme function of modern architecture, namely *urbanism*.

At the root of Sartoris’ work lied undoubtedly the futuristic matrix of Sant’Elia and his futuristic urban and architectural conceptions to which he seemed to have given an unprecedented rationality. First Sartoris’ projects took on a maximum concreteness in the exact geometry of the forms of the blocks of buildings. Since 1920 Sartoris in fact has contributed to the development, and subsequent dissemination, of rational architecture demonstrating that there was a precise and concrete method behind the “crazy” futurism of Sant’Elia:

“Without Antonio Sant’Elia – this heroic unknown – urbanism would not be what it is today. He dreamt of the new city before Le Corbusier and was, before him, the poet who prophetically presented the present and tomorrow’s hours” (Sartoris, 1990).

According to Sant’Elia’s prophecy, “the supreme function of architecture will be fully and totally realized: European urbanism in all its deepest functionality, to reach the building structures in their pure state” (Sartoris, 1990). The dissemination work initiated by Sartoris through his numerous publications focuses mainly on the issue of the so-called “modern urbanism” (Sartoris 1932b). In relation to the intense exchange of images and photographs that Sartoris undertook from 1928, the space reserved for the project of urban planning in the main specialized magazines and newspapers of the period is a fundamental tool to retrace the main stages that testify to the relationships established with the most important protagonists of architecture of the time (Sartoris, 1928). In this context Sartoris also mentioned as worthy of attention some of the most famous experiments conducted by the pioneers of the thirties, such as the *Cité-bloc intégrale* for La Pampa of Wladimiro Acosta, the *Cité verticale* of André Lurçat, the *Cité-ruche* of Richard Neutra, the *Cité-repère* of El Lissitzky, the *Cité en acier* of Szymon Syrcus, the *Cité volante* by Adolf Rading and the *Cité en Tensistruktuur* by Guido Fiorini, projects saturated with inventive and functional power in the wide composition of the structural elements, in the geometric course of the masses that create an ascending rhythm of clear and monumental evidence. Despite Sartoris’ strong adherence to the Italian Futurist Movement, whose *Manifesto* was promoted by Filippo Tommaso Marinetti in 1909, the drawings he produced during his long career as a theorist and designer showed a marked detachment from the representations of the utopian architecture of Sant’Elia or Mario Chiattone and from those produced by the artistic avant-gardes in the early 1920s. The essentiality of Sartoris’ urban projects is to be found not so much in the futurist works of Sant’Elia or Chiattone, but in the relations that he has skilfully established with the most important architects of that time².

Sartoris’ attempt to combine the originality of the Italian Futurist Movement with the themes of European Rationalism is evident when one looks at his famous axonometries (Bardi, 1932). From the very first projects illustrated with this technique of representation, a strong proactive search for that so-called new architecture could be traced. The result was a careful Sartoris’ study of the colour and proportions of the architectural composition. However, his best-known drawings remained the utopian axonometries of buildings suspended in space in which the elements that make up the external context are never represented: Sartoris in fact omitted to include trees, man and all those elements of the urban sphere that strongly characterize even the avant-garde painting. Only in some axonometries the context was represented through a simple line of land, an illusory trait that identifies an ideal imaginary plane, almost as if he wanted to let the viewer imagine a utopian contextualization. Sartoris’ rigorous use of axonometry was understood not so much as a reference to a corresponding built reality but, for its coherent abstractness, as an indicator of the rules of architectural space (Cattaneo, 1993). Therefore, spaces that were not always referable to geometrical or formal factors, but rather to practices of use, changing in time and space. The axonometry used by Sartoris starting from the urban compositions of 1922, reduced to essential traits and well-defined volumes of

² Sartoris was a tenacious supporter of the exponents of the artistic avant-gardes of the early 1920s and the relations with the Italian Futurist movement are documented and well known. See, for example, Sartoris, 1930, Sartoris, 1944, and Sommella Grossi, 1993.

immediate figurative perception, can be considered as the purified and geometrical variant of the one already used during Futurism that was utopian and imaginative. For Sartoris, the theme of axonometric drawing therefore fulfilled the function of a true *manifesto* of Rational Architecture and was highlighted by the numerous publications of the author himself and by his continuous presence and participation in international conferences and exhibitions (Abriani, 1972).

For example, the first axonometric project of the University City for Turin in 1922 can be considered as a sort of evolution of the project of the Stadium Square, area for which Sartoris will draw, in fact a few months later, the two design solutions of the University City. According to Sartoris, the Stadium, in fact, emblem of modern mass society, could quickly become a village, a neighbourhood or a center for university studies. The drawings of the two urban solutions of the University City represent the first project in which Sartoris uses the orthogonal isometric axonometry for the first time. The only two isometric solutions of the project mentioned, as well as the project for the district of Geneva and Orbassano and subsequent urban projects represent, according to Bruno Reichlin, an authentic “figurative statement” (Reichlin, 1979) on the concepts and methods of Sartoris related to architectural design. This project can therefore be defined as a “constructive diagram”, defined by Christopher Alexander as a sort of “bridge” between the requirements and the shape of the building (Graziano, 2016).

According to the critics of that period, with the project of the University City, Sartoris was able to use the means of his art, adapting them to the taste and practical needs of his time. Sartoris chose to ignore the traditional building and administrative procedures and followed the path of the so-called “utopia for optimization” (Sartoris, Angeletti and Carloni, 1979). The axonometries of this project were, in fact, part of a fantastic and unrecognizable territory. Looking at the project drawings fifty years after their execution, the urban layout of the University City still today retains all its attractiveness: the strictly symmetrical blocks are surrounded by a continuous grid absolutely undifferentiated, there are no elements susceptible to scale, there is no stylistic reference (Abriani, 1972). This type of representation is probably the result of the conviction of the theoretical priority of design, understood as an essential and not casual tool of architectural representation. The need to present architectural functionalism as a cultural and educational necessity was evident not only through its famous publications, but in all of *Sartorisian* production, so much so that his urban projects take on the character of a real *manifesto*. According to Sartoris himself: “only the architectural elements reduced to their simplest expression allow a current form, therefore always variable. Architecture is therefore no longer a definitive, perennial composition; it is no longer a closed whole since its dimensions and its plastic and utilitarian elements dynamically undergo radical essential transformations” (Sartoris 1932a).

Also the major innovating architects have insisted that man be led to know the most modern inventions of the new building art. The public, especially the young people, had to be brought intimately into contact with the wide range of architectural discoveries, because a fervent imagination also characterized certain minutiae and certain intimate details of functionalism for the construction of the future city. Already in June 1928, on the occasion of the first CIAM, as Italian delegate, Sartoris claimed that the preliminary examination of the problems related to standardization allowed the novice architect to learn not only the knowledge of the quality of special products but also the ability to find new materials that would allow him to build the future city. Sartoris has also been able to speak of a “metaphysics of architecture”: a trend characterized by a figurative *attitude*, “endowed with

a strong introspective tension, based on the wise dialogue between function and ornament” (Sartoris 1998): he identified, as a field of action, the fantasy, intended as a work of imagination, of the reasoned construction that is based, at the same time, on intuition (Sartoris, 1986). According to Sartoris, Rationalism must also be imaginary and vision architecture which may appear utopian but which are scientifically and plastically realizable (Fronzoni *et al.*, 1998). The international group of architects of rationalism (often solitary interpreters of a universe in full transformation, in full transfiguration) with their inventions for a functional urbanism imagined models of cities according to appropriate and fascinating hypotheses³.

Sartoris’ utopian urban approaches

From 1930 to the 1950s, Sartoris stated that urban planning studies developed on a massive scientific and social basis. Although he didn’t take an active part in the reconstruction activities in Italy with his projects, he affirmed that in order to remedy the damage caused by the Second World War, “regulatory, regional and national plans were drawn up, with heavy reconstruction interventions with the aim of rational remodelling of the cities. Urbanism was becoming the centre of attraction for all architecture” (Sartoris, 1943). In order to heal them, it must be revealed the true face of every city. From this scientific point of view, it will be possible to predict changes, avoid illogical extensions and present the future development of agglomerations with an exact sense of reality (Sartoris 1990).

“Now we find ourselves in the need to delineate precisely the new urban scenes and the exact role of the architect, creator and humanist in the face of the interpretative change of our time. We absolutely must solve the problems soon and this will lead us to unsuspected visions of the city. For example, one of these problems we face today, whether we like it or not, is that of the house that often develops in height, but that must necessarily be linked to the surrounding urban structure, through its characterization not only vertically, but also horizontally. It is therefore necessary to create, in large urban assemblies, almost superimposed cities, stratified cities, cities with bridges. In short, let’s think of a dynamic architecture and urbanism: capable of implementing the city within the city” (Sartoris 1991).

The end of the 1980s and the beginning of the 1990s brought Sartoris’ utopian visions to completion and, among other things, coincided with his latest writings, the most mature in which he identified and clarified his idea of architecture and his stainless faith in architectural Rationalism. Particularly worthy of attention are the studies conducted by Sartoris on the architecture of commerce and the so-called “integrated urbanism” (Sartoris, 1983), destined to the flourishing of buildings aimed at the development of merchants and able to play a capital role in economy’s field in general. According to Sartoris, another need was to develop projects to penetrate apparently abandoned city centres, to insert elevated streets and squares, to create spaces and systems of vertical and horizontal circulation at every level, to make room for new blocks with areas destined for commercial activities. On the other hand, in order to reintegrate the historical centres into vital urban agglomerations, he proposed a model, a system defined as a “dented city”, where, in order to respect the buildings of the past, leaving their stylistic characteristics to the perspective of the street, modern constructions should be backward compared to the pre-existing ones so as to enhance them at a glance. This could be the way

³ “I believe in mystery, I believe in miracles, and therefore I believe in the utopia realized” (Cometa, 1987, p. 20).

to discover the plastic surprises of the new architecture while walking. This idea can also be realized in the labyrinth city without widening the paths, but by creating porticos of disengagement, the new city would thus enter the old one without useless or excessive changes.

Even his latest works bear witness to how his faith in modernity has not resulted in sterile repetitions of stereotypes of his axonometries (Sartoris, 1999), but in a search for the evolution of language, which, while falling within the rationalist tradition, denounce how forms are linked to the epochs of production and linked to specific needs, as in the case of the project for the “bridge city” for Barcelona in 1989 and the recovery of the former woollen mill Bona in the city center of Carignano, in Italy, in 1995. This last project, in particular, is the emblem of how Sartoris was able to interpret the modern in absolute coherence and linguistic correctness, where the careful use of colour and materials indicate that it is still possible to evolve in rationalism. Since 1984, in the numerous opportunities for debate and confrontation relating to the future of the city center of Carignano, Sartoris proposed an interesting vision of the integrated city, in which the question of the adaptation of the cities of ancient formation is brought back, according to Sartoris to the examination of similar “models of transformation” in order to create new urban forms and formulas. In Carignano, in particular, the project of Sartoris was the result of the involvement of the political, cultural and economic forces that have engaged in study days, exhibitions and conferences in search of a suitable redevelopment of the entire industrial complex: from the eighties, on the future of the industrial complex is in fact triggered by a lively debate that, for the historical, cultural and social implications that sees involved also the citizens, transcends the limits of a simple intervention of building recovery. According to Sartoris, the recovery project should not consist in a mere demolition, restoration or simple replacement of the existing building, but in a real “organic metamorphosis” of the architectural and urban complex. The existing structures of industrial building were thus converted on the basis of new functional requirements and would have acquired the role, according to Sartoris, of “a city within a city” (Sartoris, 1994). The new building included new and more current functions, such as horizontal and vertical squares, municipal offices and a multipurpose hall with a stage and 400 seats. The former wool mill thus becomes a gigantic “public equipment” at the service of the citizen, a real “social agent” (Abriani, 1991). The aim of the metamorphosis of the city center of Carignano was to draw from it a renewed architectural and urban centre, destined to become, in the intentions of Sartoris, the revitalised heart of the entire city. According to Sartoris, in fact, recovering the architectural and urban heritage to rehabilitate it, means making the “built state” another “buildable state”: “It is therefore necessary to ‘reinforce’ and ‘refresh’ the existing heritage to make it survive in the functions of the so-called new architecture” (Sartoris, 1994). Before being a recovery plan, the study proposed by Sartoris was a “perceptual design” born from the experience of the transition that have produced a series of relationships and dense relationships that have crossed the area concerned since 1980s (Gavello, 2017).

The 1989 unrealized project of the “bridge city” for Barcelona carried out in collaboration with Daniela Pastore for the international competition *Vivienda y Ciudad* and which won the prize of honour, was also defined as a morphological archetype of elementary structures that can be harmoniously combined with each other. It was a project for a district of 250 residential units located on the *Avinguda Diagonal* of Barcelona, defined by critics as a stimulating “collective dream” (Forte, 1990). This plan showed efficient and impeccable structures with a predilection for the functionality of the spaces and the architectural solutions adopted. Sartoris has in fact identified solutions for

interior spaces that can be extended and rhythmically modulated, where light and air intervene in progressive structural divergence. In Sartoris' projects, his primary objective was very clear: to create transition spaces and new spaces that consist of absolutely essential operations. The proposal, never realized, was part of the utopian dream of reconciling the inexorable advance of technology, machines and progress, with a need for life based on a more human dimension. And also in this case, in order to be able to express the sense of evidence of its vocation with perpetually renewed and renewable acts, the site and the urban fabric must be in close correlation with experience, accomplishment, the present and the future. The phenomenon of architecture integration with life was linked to the idea of movement, dynamism and creativity. Around these reflections he affirmed that the heritage to be saved, to be safeguarded by updating and rereading it, was implanted on the research and on the organization of a new space that can project itself in the metamorphoses of the lived experience continuing the permanence of the invention⁴.

According to Sartoris, Rationalism and functional architecture were neither mechanistic nor formed according to dogmatic canons, but rather it was a dynamic and constantly evolving architecture which addressed contemporary problems with the newest technologies enriched by a "poetic and spatial sensibility". Modern architecture was not an imitation of old or new styles: instead it had to be characterized by the compulsion to give architectural expression to social forces which themselves were in continuous transformation. Change and evolution in architecture would mirror, Sartoris hoped, changes in society and social conditions. Some fundamental principles, some universal systems of art remained immutable because they contribute to the vital process of intellectual evolution (Holl, 1983). Those "eternal principles" of architecture that have become a sort of codes for almost all new European architecture.

For a long time Sartoris wondered about the fate of the metropolis of the future. Trying to imagine, among concrete examples, comparisons and projects that do not fear utopia, the cities of tomorrow that look so much like the cities described by Calvino. Of course, it will be a materially and spiritually new plastic universe, because in these cities the usual roads will be abolished. Heavy traffic (underground and various transports) will take place underground; medium traffic (small cars, motorcycles and motor bicycles) on the ground; light traffic (pedestrian traffic) on roads on piles placed a few meters above ground level and on flat roofs (linked together by the system of vertical lifts outside the New City of Sant'Elia, which will disengage all floors of the houses). These utopian cities will be linked to each other by elevated highways on piles and by aerial runways. The analysis of the documentation in Sartoris' vast archive at the Archives de la Construction moderne of the École Polytechnique Fédérale de Lausanne testifies his long and careful study of American urban planning, especially on solutions to reduce traffic congestion at crossroads in New York, the so-called "spiral roads", where the great arteries bypass each other by means of large radius spiral fittings. He treated also of a creative and humanist architect capable of creating large urban ensembles, overlapping cities, stratified cities, cities with bridges, cities that were penetrated between the ancient and the modern, where even the suburbs are given a persuasive structure (Sartoris, 1982).

⁴ "Architecture, like nature, is metamorphosis; in the history of architecture there is no evolution, only metamorphosis. The avant-garde is only the beginning of a metamorphosis" (Cometa, 1987).

With his latest projects and writings Sartoris considered that the serious social, architectural and urban problems to be solved could not be reduced to those of a reckless or simple adaptation, but gravitate around the categorical reminders of the invention. It is therefore possible to observe that Sartoris associated his figure as an experimenter with prospects of dreams that were strictly achievable. His futurism was however dedicated to the ideas that shake the present (Sartoris 1984).

Today, Sartoris' theories and practice of mechanical development contemporary civilization have given a new metaphysical and intellectual expressiveness to the nature of construction, the so called "building art" (Holl 1983, p. 33). Studies and research carried out by Sartoris, in a certain sense, are the forerunners of a "happy city", always announced through the use of axonometry, in which its architectures are the protagonists of a well-defined urban fabric but still in transition. In recent years before his death, he has been attributed many values: the forerunner of rational architecture, the interpreter of a cultural and operational line capable of maintaining the continuity of thought of the ideas of the great masters of the modern movement, the creator of a new stylistic unity to the cities as a complex of buildings, and a new distributive and typological concept expressed since 1922 with the project of the University City. Even today, the numerous exhibitions of his axonometries set up following his death on March 8, 1998, represent further opportunities to celebrate the activity of the Sartoris-urbanist through an exaltation of his many projects, mostly remained on paper, developed with the aim of defining "an inhabitable art" (Sartoris 1982). Twenty-one years after the death of the so-called "witness of a century" (Dell'Oro, 1995) these celebrations allow us to glimpse, even today, new horizons of research within its vast production.

Twentieth Century Technocracy – A Transition Aborted

Michael Hebbert

*Bartlett School of Planning, UCL, UK,
m.hebbert@ucl.ac.uk*

Abstract: This paper is based on a chapter in the recently published Policy Press book edited by Federico Savini and Mike Raco, *Planning and Knowledge how new forms of technocracy are shaping contemporary cities*. It shows how technocracy began in the early twentieth century as a campaign for the principle of government by experts, linked to Taylorism, scientific management, planning, and the Third Way; and how and why the term lapsed from political vocabulary in its original usage, expressing faith in social transition through science,. But then we see it reemerge in the 1960s in critiques of welfare managerialism, implying an improper capture of democratic institutions by unaccountable expertise. In this sense, top-down planning was commonly criticized as 'technocratic', in contrast to an anticipated transition to participatory democracy. The paper ends in the contemporary era of neo-liberalism, when populist free-marketeers have subverted healthy scepticism about the legitimacy of expertise to undermine all capacity for collective action on the most pressing issues of our time. The history of technocracy is also a history of utopian transitions awaited and aborted. In conclusion it's all the more important to reaffirm the nexus between democracy and science: the modern world needs more, not less, technocracy.

Keywords: technocracy, applied science, planning history

Introduction

Fifty years ago William Armytage opened his history of the rise of technocracy with the Homeric image of Laocoön, the priest of Apollo who tried to convince his fellow-citizens to reject the wooden horse left by the Greeks outside the walls of Troy. Just as he was making his case two serpents suddenly emerged from the sea and crushed him to death. Armytage comments: 'similarly latent, but aggressive, social forces emerge from below the "social horizon" to confound historians' (1965 vii).

Setting aside for the moment their relevance to technocracy, those serpents swimming below the surface are certainly an apt metaphor for neoliberalism. Kim

Phillips-Fein (2009) has shown how neo-conservative ideologues were secretively bank-rolled for decades by American businessmen and wealthy pro-marketeers. Nancy Maclean (2017) has called the radical right agenda a 'stealth plan'. The programme for dismantling the welfare state took shape below the social horizon until the 1980s, since when its offensive has been abrupt, implacable and all-pervasive. Neo-conservatism has shifted the fundamentals of social thought, enabling particularist knowledge to undermine the concepts of collective welfare and public interest. It has hollowed out the institutional apparatus of the nation-state and emptied the distinction between public and private sectors. It has caused local governments to abandon time-honoured methods of accountability and embrace quasi-corporate management structures and remuneration pyramids. The United Kingdom's local government map has been repeatedly redrawn, almost always in the direction of fewer, larger units devoid of municipal identity. The extent of its success could be measured by the extensive termination of local public services in the aftermath of the 2008 banking crash: a process best described, as Tom Crewe notes, not in terms of 'cuts' or 'austerity' but as the deliberate destruction of an entire social infrastructure (2016 7).

The neo-liberal era has brought a fresh cast of actors onto the stage with their own discourses, metrics, analytical techniques, and modes of communication, all of which are discussed in the new book from Policy Press being launched here at AESOP2019 (Savini & Raco 2019). The 'technocrats' discussed by my fellow-contributors include signature architects (Ponzini), brokers (Aalbers), deal-makers (Tusan-Kok), development engineers (Metzger and Zakhour), housing spreadsheet consultants (Layard), fixers (Mössner and Gomes), futurists (Webber), journalists (Livingstone), lobbyists (Hirvola), participation consultants (Brownill), scrutineers (Parker & Street), and smart city wonks (Kitchen). Some of their knowledges arise directly from neo-liberal economic relations, others reflect wider technical shifts in ITC, the ubiquity of smartphones, the integrative power of GIS, the locational pin-pointing of GPS.

To grapple with the changing nature of technocracy - the legitimization of power by expertise – is a continual challenge for planning theory. History is a necessary partner in this enterprise. Making sense of the new technocracy requires understanding of the old. The purpose of the present paper, which closely follows

Chapter 2 of Savini & Raco, is to put the critique of expert knowledge into historical perspective, looking back to the interplay of planning and technocracy in the century of two World Wars, the New Deal, the Welfare State and the Modern Project.

The First Wave

Let's begin with our keyword. The term 'technocracy' entered the English language a century ago and a Google Books Ngram frequency graph of its usage displays two clear peaks, the first in the mid 1930s, the second higher maximum in the early 1970s. Closer inspection reveals significant semantic shifts between the two occurrences.

The word 'technocracy' was coined by the prolific English-born, California-based engineer William Henry Smyth (1855-1940) and used in various papers he published from 1919 onwards (Akin 1977, Fischer 1990). Conjuring up a Trump-like tribe of Clam-Diggers descended from Irascible Strong and his wife Trixie Cunning, Smyth posed the question whether the mentality of primitive hunter-gatherers was adequate to the problems of machine-age society :-

'a nation (and above all an industrial democracy) should have a definite purpose, An army is officered by military specialists; a business organization is officered by business specialists; and industrial democracy – a democracy of technical industries – should be officered by technical specialists – should be in form and in fact a purposive *Technocracy*' (1926 284)

Smyth's useful term was taken up by Howard Scott, a floor polish manufacturer, political entrepreneur and self-styled engineer active in progressive Greenwich Village discussion circles in the 1920s. In 1929 Scott licensed a brand name - Technocracy Inc. - for a movement that briefly captured the public mood in the aftermath of the Wall Street Crash. Its platform was the application of scientific expertise to collective decision-making, and replacement of the monetary dollar with energy certificates, linking economic value to the environmental resource base. The transition held a double appeal: both ideological politics and the vagaries of the market would be replaced by the engineer's dispassionate quest for efficiency. From the late 1920s to the mid thirties 'technocracy' was a vogue term. But the political fortunes of Howard Scott declined precipitately when his

engineering qualifications were shown to be bogus, and the word tumbled with him. Technocracy Inc. remained in existence until his death in 1970 but was a mere shell without political significance.

Armstrong's Laocoön metaphor points to the powerful forces that swim below the surface in the history of ideas. Howard Scott emerged from the discussion circles around Thorstein Veblen at the New School for Social Research in New York City. His 'technocracy' platform blended elements of the Taylorism promoted by the Taylor Institute (followers of Frederic Winslow Taylor) and the Fordism preached by followers of Henry Ford, with the hugely influential Utopianism of Edward Bellamy's *Looking Backwards*. Armstrong contextualises it both historically and comparatively, tracing its antecedents through nineteenth century Utilitarianism and Positivism back to the origins of modern applied science and revealing the multiple connections between American technocratic thinking and European, Russian and Japanese counterparts. The doctrine of scientific management had few more enthusiastic promoters than the Bolshevik Gleb Maksimilianovich Krzhizhanovsky - in Armstrong's words 'the most portentous technocrat of them all' (1965 219) - whom Lenin appointed to chair both the Soviet State Planning Commission GOSPLAN and the electrification programme GOELRO. Soviet Five Year Plans in their turn influenced the American New Deal initiatives, especially its most ambitious spatial experiment, the Tennessee Valley Authority (TVA).

Walter Creese notes the close parallels between TVA's gestation and the Technocracy movement, both drawing utopian inspiration from the transformative potential of electrification (2003 70). However the launch of TVA in 1933 coincided with the collapse of Scott's movement, and the emergence of a different terminology - 'planning' rather than 'technocracy'. In the title of Julian Huxley's widely-read wartime account TVA was the supreme *Adventure in Planning*, a practical demonstration 'that there is no antithesis between democracy and planning, and that planning can not only be reconciled with individual freedom and opportunity, but can be used to enhance and enlarge them' (1943 135).

As Howard Scott's stock declined, technocracy's credit transferred to the wider quest for planning, an active participle with humanistic resonance, as applicable to individuals and social organisations, as to business corporations and governments at every scale (Doob 1940). In the United Kingdom Julian Huxley and his brother

Aldous popularised the perception of planning as a non-partisan Third Way out of the Depression through the medium of a think-tank, *Political & Economic Planning* - PEP - launched in 1931 with Sir Basil Blackett (Bank of England), I M Sieff (M&S) and Lionel Elmhirst (Dartington Hall). The following year President F.D. Roosevelt launched American's New Deal with a leading exponent of planning, Rexford Tugwell, as one of his closest advisers. When Tugwell left the Federal Administration in 1936 he became Chairman of the New York Planning Commission and subsequently Governor of Puerto Rico, in each context applying a planning methodology of data collection, collective goal-setting, and medium-term strategy. In the extensive literature on social reconstruction of the 1940s it was axiomatic that the future division of labour should include an expert-based collective planning system as a third sector, breaking the traditional duopoly of politics and the market. Routledge & Kegan Paul published a prominent series on the topic, the International Library of Sociology and Social Reconstruction, edited by Karl Mannheim, with a logo that showed the tree of science and the tree of life growing from the same rootstock. It included E.A. Gutkind's two volumes on *Creative Demobilisation* (1943) and Mannheim's own posthumous *Freedom Power and Democratic Planning* (1951). For reconstruction read transition. For planning read technocracy.

While Karl Mannheim's preached the doctrine of democratic planning from his new academic home at the London School of Economics his sceptical colleagues and fellow-emigrés Karl Popper and Friedrich Hayek laid the philosophical basis for its antithesis. Popper's *Poverty of Historicism* (1957) argued the impossibility of planning. He challenged both the epistemological basis of knowledge for collective action and the moral claim of its historical inevitability. 'You cannot centralise within a planning authority the knowledge relevant for such tasks as the satisfaction of personal needs or the utilization of specialist skill and ability' (1957 p.64). Given the fundamental flaws in the knowledge base for holistic planning the only rational basis for action, so Popper argued, was piecemeal incrementalism. Hayek's earlier book *The Road to Serfdom* (1944) offered a more polemical critique of the efforts of the planning movement to build a welfare state upon the basis of impartial expertise. He prophesied that specialists and single-issue reformers were being drawn by the promise that their agenda would be advanced in a future planned society: implementation of this utopia was bound to disappoint since it could only bring out the concealed conflict between their aims. Disappointment would trigger further self-defeating attempts to centralise control.

So democratic socialism was a slippery slope, leading inevitably to authoritarian denial of freedoms. Hayek's sophisticated advocacy of private property rights as the only guarantor of freedom appealed to the nascent American neo-conservative movement, causing the business activist Harold Luhnow to arrange for him to be appointed by the University of Chicago with a ten year subsidy on his salary (Phillips-Fein 2009).

Hayek's time would come, but for the first three postwar decades - *les trentes glorieuses* - the advocacy of the planning movement shaped the institutional design of the postwar world: at the local level, in systems of land use planning such as the UK's celebrated Town & Country Planning Act of 1947; in the seminal regional planning mechanisms of the French state, whose designer Paul Delouvrier deliberately excluded the possibility of 'sterile' political participation (Valade 2008 136); in macroeconomic mechanisms of five year plans, devised and implemented by the technical élites of the *grands écoles*, that drove the growth of the French economy over the three decades of *les trentes glorieuses*; and internationally, in the multiple expert-led agencies established under the auspices of the UN, or the Commission established by Jean Monnet as the foundation-stone of European integration. Faith in rationality lay at the heart of the Modern project (Benevise 1977). Technocracy shaped institutions and institutions shaped the contemporary city: in a direct and physical sense the built environment bequeathed to us by the later twentieth century embodies the values and solutions of its knowledge-providers.

The most direct and visible translation of knowledge into physical form occurred within residential neighbourhoods. Mass housing, supplied by the state and designed formulaically to scientific principles of the *existenzminimum*, had always been a defining vision of the Modern Movement. Implemented on a vast scale around the world, the planned residential landscape proved entirely unlike any earlier typology of human settlement (Urban 2012). Thanks to the intrinsic standardisation of mass housing it displayed remarkable similarities to either side of the Iron Curtain (Monclús and Díez Medina 2016). Salient common elements were the emphasis on output, standardisation, economy and movement of assembly cranes, and the disregard for user preferences, tenant convenience, residential mobility and local culture (Pawley 1971; Ravetz 1995; Cupers 2011). Discontent with the depersonalisation of mass housing contributed significantly to a wider disillusion with the supposedly omniscient planner.

The Second Wave

Reaction against the institutional landscape of postwar decades explains the second surge of interest in technocracy. Armytage's *Rise of the Technocrats* (1965) opens with that image of Laocoön and ends with a warning of the inherently hierarchical, authoritarian tendency of rule by experts. The political ferment of the 1960s had thrown open the postwar assumption that the technical knowledge of planners would serve a beneficent public interest, and that the trees of science and of life necessarily grew from the same root system. The Frankfurt school challenged that assumption through the critique of instrumental rationality by Max Horkheimer, Herbert Marcuse and then Jürgen Habermas (1970). Jean Meynaud's *Technocracy* (1968) traced the shift of power and accountability within the French state to autonomous agencies controlled by engineers and scientists, a process critiqued equally from the Christian anarchist perspective of Jacques Ellul (1964) and the humanistic Marxism of Henri Lefebvre. British town planners active in urban redevelopment found themselves challenged from the grassroots by affected residents and workers, their voices amplified by activist social scientists such as Norman Dennis (1970, 1972) and Jon Gower Davies (1972). In a pincer movement, the critique from specific and local considerations was matched by generic shifts of post-modern epistemology that undermined all forms of holistic expertise and emphasizing the relational, provisional nature of human knowledge.

So the word technocracy became, as Gunnell puts it, 'Janus-faced' (1982 p382). 'Few terms in political sociology are used as loosely' (Centeno 1999 p309). On the one hand it continued to be used to describe any institutional arrangement that empowers non-elected professionals, insulating decision-making from the play of political opportunity and market speculation. To take two examples from the relevant literature, Trevor Goldsmith (2011) shows how the Spanish Ley del Suelo of 1956, devised as a technocratic measure under Franco, became a corner-stone of municipal policy after the restoration of democracy. Miguel Angel Centeno (1993) analysing the phenomenon of technocracy among national policy elites of Pacific Rim states such as Mexico, South Korea, Taiwan and Singapore, notes how their acceptance is contingent on an ability to deliver sustained economic growth: should that falter so would the model.

The alternative and more common usage is pejorative. Measured against the implicit norm of democracy, it implies - like kleptocracy or theocracy - a capture of power from the *demos* by an unaccountable elite. Jürgen Habermas's *Lure of Technocracy* (2016) faults Jean Monnet, Jacques Delors and their successors not because they erected the European project on a foundation of independent, functional expertise but because they failed to develop the matching superstructure of discursive politics that would give it legitimacy. As Larochelle notes (1993 p124), this concept of technocracy as 'a deviationist syndrome' came to dominate the literature. Once seen as a solution, the t-word had become an imbalance requiring correction. This was the critique that played into neo-conservatism's emerging attack on public sector expertise. It fed the sea-serpents swimming below the social horizon of the Welfare State.

Technocracy and Neo-Liberalism

The accessions of Margaret Thatcher in 1979 and Ronald Reagan in 1981 marked a turning-point. Both brought advisers from the secretive realm of neo-conservative think-tanks and turned their libertarian conjectures into hard political reality. The shift was sudden and profound. As an illustrative example, consider the White Paper *Streamlining the Cities* published by the government of Mrs Thatcher four months after her second election victory in 1983. It posed an audacious challenge to the conventional wisdom that the governance of the modern metropolis required metropolitan-scale institutions (White, 1975; Barlow 1991). In the libertarian perspective of James Buchanan's Public Choice theory, all big-city governments were Gargantuas imposing redistributive levies to subsidize their inherent inefficiency. The alternative proposed by Vincent Ostrom, Charles Tiebout and Robert Warren in a classic paper for *American Political Science Review* (1961) was for big cities to be governed polycentrically, by grassroots municipalities contracting for shared services as their voters saw fit, and competing amongst themselves to attract population and investment (Bish 1971). *Streamlining* and the resulting Local Government Act of 1986 translated the New Right's theoretical blueprint into an operational design for England's seven largest conurbations. Many aspects of this rash, Nietzschean act (O'Leary 1987) proved unworkable and have been reversed over the past three decades, but the basic shift towards reliance on quasi-market mechanisms was prophetic and has proved irreversible.

It is worth remembering that the New Right were technocratic in both senses of the word. On the one hand they embodied the presence of social scientists at the seat of power: Martin Bulmer writes of the influence of Professors Brian Griffiths, Alan Walters and Milton Friedmann, 'paradoxically the free-market policies pursued by the Thatcher government provide impressive evidence of the impact which social science ideas may have upon practical affairs' (1988 p39). After all, as Centeno notes (1993 p 311) the market logic of non-zero sum games yielding equilibria through the invisible hand of competition might well appeal to the technocrat who aspires to abolish conflict through optimization and efficiency. On the other hand libertarians drew upon the prevailing concept of technocracy as an elite conspiracy. The anti-technocratic consensus, as DuPuis and Gareau (2008) call it, undermined the analytic base of general welfare economics and opened the door to methodological individualism, political particularism and a free play of sectional interest.

Conclusion

Narratives of the history of ideas are rarely linear. Concepts twist and reverse and their meanings are shifted through a process of historical dialectic. In the century since its first appearance, 'technocracy' started as a political movement to empower public expertise in the tradition of Saint-Simon, Auguste Comte and Thorstein Veblen; dissolved into the larger advocacy of planning within the Modernist project; reemerged as a critique of synoptic knowledge and advocacy of discursive pluralism; and has been overtaken a second time by the sea-serpents of Neo-Liberalism as they twine round the institutional structures of the mid twentieth century, privatising many, eradicating others, or penetrating their value systems to align with global corporate agendas.

The narrative can be summed up in terms of two transitions. The first promised technocracy as a destination, the second saw it as a trap from which discursive politics promised to escape. Neither perspective will serve us today. In the neo-liberal world depicted by Savini and Raco, public expertise is more victim than tyrant, squeezed along with every other aspect of the everyday infrastructure of local public services - schools, parks, housing, buses, social care, planning and the local state system that sustained it. The institutional capacity of local governments, built over a time-span of a century and a half, included expertise in strength and depth. Technocracy had its pathologies but was also an essential component of an effective public service.

The heart of this conflict is on the larger scale of environmental planning where the scientific advice of climatologists and environmental economists is pitted against the business interests of global petrochemical corporations for stakes of no less than planetary survival. The periodic reports of the Intergovernmental Panel on Climate Change represent a massive technocratic application of scientific knowledge to the central contemporary question of human welfare. The 1987 intergovernmental initiative to ban ozone-depleting gases (chlorofluorocarbons and methyl bromide) under the Montreal Protocol has often been held up as a successful precedent for greenhouse gas limitation under the Paris Treaty. But implementation of the methyl bromide phaseout has been slowed by the liberal allowance of exemptions, justified not through a general calculus of costs and benefits but through 'market disruption' impact on particular classes of users. In their important study of neoliberal knowledge, the decline of technocracy and the weakening of the Montreal Protocol, Melanie DuPuis and Brian Gareau provide a timely final message for our discussion of 'Transition Histories':-

'The legitimization of a particularist knowledge regime opens up policy making to domination by private interests playing the stakeholder game. Stakeholder input and particularist knowledges are important to democratic decision making. However, technical expertise, despite all its weaknesses, is a form of knowledge that remains necessary to the protection of the environment and public health'. (2008 p1212)

Re-positioning after the Fall of the German Wall: World Trade Centers Development in Cities of the former German Democratic Republic: Rostock, Dresden and Frankfurt (Oder)

Uta Leconte

Technical University of Munich, uta.leconte@tum.de

Abstract: The fall of the German Wall in 1989 symbolizes a fundamental system change for the entire global world order. As a physical boundary, the „Iron Curtain“ had symbolized the separation of Europe into an Eastern and Western block. After this divide, following the German Reunification, cities and regions in the former East took various efforts to re-position themselves within the new world order and its encompassing cultural, economic and political codes, with architecture serving as an agent to represent the new global system. During the early 1990s, for example, World Trade Centers have been established in cities like Rostock, Dresden and Frankfurt (Oder), utilizing the trademark licensed by the World Trade Centers Association, a global organisation that aims to foster a global trade infrastructure by referencing the iconic World Trade Center Twin Towers in New York. This paper asks: What were the intentions behind the establishments of World Trade Centers in cities of the former German Democratic Republic shortly after the fall of the wall, what were the effects? The aim of this investigation is to give an example of how architecture has been instrumentalized as representation of the global system within this transition period.

Keywords: German Reunification, Globalisation, Global Trade, Representation, World Trade Center

Introduction: ‘Wende’ as transition

Today, 30 years after the fall of the German Wall in 1989 and the following German reunification, a system change broadly referred to as ‘Wende’ (German: ‘turn’), remains subject to a variety of research fields far beyond the social, economic, historical and political sciences. The massive ideological, political and territorial changes following the fall of the German Wall obviously had a fast impact on the global system, Europe, and, in its most immediate societal dimension, in Eastern Germany, the area of the former German Democratic Republic (GDR).

The political, economic and societal system change has impacted the built environment in the former GDR on every scale, including rural areas, small and medium-sized cities, state capital cities and, most strongly due to its symbolic impact, the then re-united and reconstituted capital of Germany, Berlin. Large cities such as Berlin, Leipzig and Dresden commissioned star architecture firms for the production of iconic architecture, that would symbolize the new belonging to the global system and its encompassing values. At the same time, a wave of

historic reconstruction projects, pursued in the spirit to symbolically connect to an at times idealised German past and sometimes with an identitarian connotation. In between these two highly visible and critically discussed strains of post-socialist urban development in the former GDR, there has been a quieter and less visual urban development, mostly in small and medium-sized cities, that reflects the societal transformations since 1989. With the new political system, every-day life changed in vital aspects such as housing, job market and work environment, education, retail, leisure time, public life, the media, etc. In all these areas, an orientation towards the Western capitalist culture, its practices and symbols, took place as part of a societal re-positioning. A certain idealization of Western values has served as narrative to support the ideological transition from one political and economic system to the other. At the same time, the political, economic and financial opening, supported by financial development subsidiaries, allowed foreign countries to invest in the new regions and profit from the new market under the narrative of reinforcing national reunification.

The term 'Wende' describes the socio-political change within the GDR, eventually leading to its end and to the beginning of a united Germany. It also describes a system change, the transition from one state to the other. Other terminologies used are *revolution* and *reunification*. The transition taking part with the 'Wende' is one from a bipolar to a multipolar world order, from communism to capitalism, from planning economy to market economy, from a one-party system to a parliamentary democracy, from separation to unity, from a territorial position at the edge of Europe to the Center of Europe, from closed borders to open boundaries and, finally, from a state-governed urban planning system to an urban planning environment, which is dominated by public and private partnerships, developments and investors and highly driven by the global real estate market.

Most research literature describes the developments in post-socialist urbanism as 'transformations', considering the processual character of urban transformations. Oleg Golubchikov differentiates the terms *transformation* and *transition*, describing transformation as a particularized, area-related process, while transition is seen as a political and even ideological, totalizing tool of systemic change, implementing power. He suggests that transition should not be equated with contextual transformations, or else the totalizing power of transitions would be obscured. „Urbanization is a major institutional dimension of transition, not simply its playground“, he concludes. (Golubchikov, 2016)

This paper aims to provide an example of urban repositioning following the years after 1989, that reflects cultural change and its impact on architecture and the urban environment. During the early 1990s, urban planners and developers established World Trade Centers in the East German cities Rostock, Dresden and Frankfurt (Oder), utilizing the trademark licensed by the World Trade Centers Association, a global organisation, headquartered in New York, that aims to develop and strengthen a global trade infrastructure by referencing the iconic World Trade Center Twin Towers in New York as representation of not only world trade, but the global system itself. It aims to show how World Trade Centers have served as a tool to represent global trade and with it the global political and economic system of the free market economy, thus supporting the transition from one ideological system to another. In the following, this paper will first elaborate the specific role of World Trade Center development within the global system. Second, it will specify „World Trade Centerness“ at the examples of World Trade Centers developed in Rostock, Dresden and Frankfurt (Oder) after the 'Wende', describing intentions behind the development and effects. It will conclude by pointing out how architecture is being instrumentalized as representation of the global system within this transition period.

World Trade Centers, architecture and the global system

The term 'World Trade Center' is associated with the iconic New York Twin Tower buildings, which opened in 1974 and were destroyed in 2001 during the terror attacks on 9/11. Designed by Minoru Yamasaki and commissioned by the Port Authority of New York and New Jersey within a decade-long urban transformation of lower Manhattan. At the time, the Twin Towers were intended to serve as a globally visible symbol of power,

wealth and stability. The strong connotation of the World Trade Center name to the New York Twin Towers prevails widely across the world, many years after the physical destruction of the Twin Tower buildings. In fact, it is commonly unknown, that today, more than 300 buildings carrying the name „World Trade Center“ exist worldwide, more of them having been planned since the World Trade Centers Association had started to multiply the concept of World Trade Centers by offering the trademark and with it the promise of belonging to a global network to local planners, city governments, developers and investors. Looking at urban development in the early 1990s in the former GDR, the question arises why private developers together with cities like Dresden, Rostock and Frankfurt (Oder) decided to include the development of World Trade Centers within the process of urban transformation after the ‘Wende’ and the transition from one ideological system to the other.

Figure 1, World Trade Center Twin Towers, New York, 1974

Viewing the history of global World Trade Center development by the World Trade Centers Association, it becomes apparent that, often, World Trade Center development has been part of an urban transition process under the premise to re-position the identity of the specific location. Examples are an increased World Trade Center development in China in the context of China’s economic expansion and opening to the global economy, World Trade Center development in Southern Europe in the context of the global financial crisis in 2008, World Trade Center development in light of the territorial expansion of the European Union, or, as discussed in this paper, the transition of post-socialist cities after the fall of the Berlin Wall.

In the following, the concept of using the New York Twin Tower buildings as representation of world trade by the World Trade Centers Association is being outlined. The global organisation is briefly introduced to provide an understanding of how it operates in developing its global network and brand. Further, it will be argued that the World Trade Centers Association can be used as an example for a global organisation, which is both an effect of the global system and at the same time functioning as an agent of its permanent reaffirmation. Using the term ‘global system’, this paper refers to the process of globalization as it has emerged since the beginning of the 1970s, a timely coincidence with the completion of the New York Twin Towers. The establishment of a globally interrelated unstable currency system, which is seen as the beginning of a Post-Fordist socio-economic

system, along with the emergence of internet technologies, are considered to be key drivers of a paradigm shift, leading to a global society which would be prone to political, economic and financial instabilities and crises. (Spencer 2016). Characteristics of the condition described are increasing privatisation, marketization, competition, commodification in almost all aspects of life, often termed as neoliberalism. The role of cities under this condition has been widely analysed in urban and social studies, geography: Within this global system, cities function as hubs of financialization, inscribing a specific agency to the city, its buildings, places and inhabitants (Sassen, 2001). In response to the paradigm shift in the 1970s, cultural theoreticians started to engage in a broad examination of the cultural conditions of global capitalism, with a particular interest in architecture as representation of capital and as symbolic object. Marxist thinkers examining the conditions of postmodernity, such as David Harvey or Fredric Jameson, took on Marx' critique of ideology and his preoccupation with the dissonance between reality and appearance, the presented and its representation (Jameson 1991, Harvey 1990). In parallel to the preoccupation with representation in the socio-economic and political domain, new, semiotic and linguistic works emerged, discussing representation in the context of meaning, the relation of signifier and signified and the existence of a symbolic system of inter-referring signs. (Architecture, with its inherent double coding of both instantiating society and representing society (Delitz 2010) has been one of the centers of discussion in the discourse about representation and the economic conditions of cultural production. A closer look at this intersection of symbolic representation and the material production of space in European cities shows how these qualities are interwoven and cooperate in the production of the urban environment.

The described global system very much relies upon the narrative of its unity: the unisphere, the one world, the all-embracing global. This unity, however, can also be described as a totality, one that evokes terror and exploitation, as Jean Baudrillard writes in a provoking essay about the destruction of the New York Twin Towers during 9/11, in which he claims that the Twin Towers, representing global unity and the almost absolute exclusion of any other, were built to be destroyed by terror (Baudrillard 2012). As an effect, the unity of the global is presented in cities as well: Here, an exclusive *center* functions both as place and image of global power and connectivity, symbolizing its position and belonging to the global system. This unity, displayed for example in corporate towers, is maintained by the exclusion of the other, creating a system of devalorisation and exclusion. In this system, access and distance to the center is controlled by borders and other access-restricting barriers. The center is always exclusive, a symbol, power and with boundaries. The center itself has become a symbol of the unity and ubiquity of the global.

The World Trade Centers Association was founded in New York in 1970 by Guy Tozzoli, who was then overseeing the Twin Towers World Trade Center design and development in his role as Director of the World Trade Department of the Port Authority of New York and New Jersey (Glanz, Lipton 2011). In 1987, he managed to transfer the licencing fee to the rights of the World Trade Center name from the Port Authority to the World Trade Centers Association for the symbolic amount of 10 US Dollars. Since then, the association has been developing an „international ecosystem' of global connections, iconic properties, and integrated trade services“. (WTCA annual report 2018)

By acquiring the World Trade Center name, the World Trade Centers Association was able to reproduce the World Trade center effect, relying on its symbolic value and the recognizability of that meaning within the global sign system. But how do the World Trade Center buildings in Dresden, Rostock and Frankfurt (Oder) relate to the Twin Towers in New York other than by name, how do they relate to the more than 300 World Trade Centers globally? Contextualizing the building of the Twin Towers, the World Trade Centers Association and the global system, it argues, that the development of World Trade Centers in post-socialist urban planning in the former GDR happened to support the transition from one ideological system to another, the subsumption of the former Eastern Bloc by the global value system of the Western world. The presence of a building in an urban environment that is signified as World Trade Center symbolizes the belonging to the same system, which the

‘original’ World Trade Center, the New York Twin Towers, represents. It hence acts as an agent for unification. (Baudrillard 2012, Golubchikov 2016)

World Trade Center development in cities of the former GDR: Dresden, Rostock, Frankfurt (Oder)

In the following, the concept of „World Trade Centerness“ is being exemplified by looking at the World Trade Center development in three cities in the former GDR, which all took place immediately during the years following the ‘Wende’ in 1989. While the cities of Dresden, Rostock and Frankfurt (Oder) differ from each other in many aspects such as size, number of inhabitants, economic rates and heritage, it is argued in this paper that the World Trade Center development after the ‘Wende’, followed a similar agenda in all three cities: to re-position itself in light of the transition to an already existing global system. In an ongoing doctoral research, a closer comparative investigation into the various World Trade Center developments is underway. Within the restricted frame of this paper, however, a first overview on position, re-positioning effort, World Trade Center development within the transitional character of the ‘Wende’ are briefly laid out and put into context.

With more than half a million inhabitants, Dresden is by far the largest of the three cities in the former GDR featuring World Trade Centers today. The capital city of Saxony is the third largest city in the former GDR after Berlin and Leipzig, bordering the Czech Republic and situated at the river Elbe. Due to its rich heritage as a former royal residence, it features historic buildings, some of them lavishly reconstructed after the ‘Wende’ in an effort to reconnect to its pre-war identity, which had been disregarded and neglected during the times of the GDR. In addition, global star architecture, such as the UFA Filmpalast by Coop Himmelb(l)au had been added to the city. The World Trade Center in Dresden is positioned in the inner city, next to the city ring. Unlike the World Trade Centers in Rostock and Frankfurt (Oder), the World Trade Center Dresden inhabits a building that has been specifically commissioned and designed as such. Situated in the center of the city of Dresden, the building complex features a tower within a multi-functional ensemble, intending to symbolize the global connectivity of the World Trade center network with a filigree roof, spanning over the building complex.

Figure 2, World Trade Center Dresden, 1992

Half the size of Dresden, Rostock's urban identity is very much defined by its position at the Baltic Sea and the river Warnow. As a port city, it is culturally coined by the respective industries, tourism, as well as the connectivity to the bordering Baltic countries. While explicitly relating in its mission statement to the World Trade Centers Association with its chair in New York and the worldwide network, the World Trade Center building in Rostock features a highly inconspicuous morphology. Labeled „World Trade Center“, the Rostock World Trade Center has not much else in common with the New York Twin Towers other than its waterfront location. Situated at the shore, the building complex houses a Best Western Hotel and various business services in relation to international trade, portraying itself as a hub within global business network and its respective symbols of business travel, trade fair, congresses and corporate office culture.

Frankfurt at the river Oder is by far the smallest city of the three World Trade Center cities in the former GDR, with just below 60 thousand inhabitants. Its World Trade Center is positioned within an industrial area just outside the city, in its green belt. The World Trade Center is part of an industrial building complex and merely a nameplate among others. The building housing the World Trade Center is not designed for its specific function, it solemnly serves as address provider, signifying nothing. In lack of the signifier, the World Trade Center in Frankfurt (Oder) uses for its branding activities the image of the most iconic and visible building in the center of Frankfurt (Oder), the Oder Tower. Designed and built during the times of the GDR between 1968 and 1976 and renovated after the 'Wende' in 1992-1994, the Oder Tower serves as a symbol of the city's identity and as cohesion between the pre- and post-, 'Wende' era. Unlike Dresden, who managed to resume its previous wealth and cultural visibility, Frankfurt (Oder) is since suffering from urban shrinkage as well as poorer economic and social conditions such as high unemployment rates. Separated from Poland only by the river Oder, it also functions as territorial border and has been divided as a city since the Oder-Neiße Peace Contract, when a former district of Frankfurt (Oder) became the Polish town Slubice. As such, Frankfurt (Oder) became a symbol of the German separation, with the river functioning as territorial border between the Western and Eastern Bloc, dividing the city. While the city's marginal position before the 'Wende', situated at the edge of Germany, Europe, symbolizing the then bipolar world order shaped its economic and cultural identity, this changed with the end of the Iron Curtain. Suddenly, Frankfurt (Oder) found itself in the territorial center of Europe rather than at its edge, confronted with the opportunities of open borders rather than closed boundaries. As such, the World Trade Center Frankfurt (Oder)-Slubice positions itself as a door opener for Polish German business relations, building on its identity as bridge-maker, the symbolic place of the Oder-Neiße peace contract and cross border relations.

Figure 3, Oder Tower, Frankfurt (Oder), 1976

Figure 4, World Trade Center Frankfurt (Oder)-Slubice, 1992, Figure 5, World Trade Center Rostock, 1990

The cities of Dresden, Rostock and Frankfurt (Oder) implemented World Trade Centers during the same time in the early 1990s, following the end of the GDR and the beginning of a united Germany. Despite their differing sizes, positions, economic and societal situations, public-private endeavours were undertaken to implement World Trade Centers into the city within this post-‘Wende’ transition period. By joining the World Trade Centers Association, a relation to the Yamasaki-designed Twin Towers from 1974, symbolizing World Trade Centerness, is spanned. This relation is obvious in mission statements and other branding narratives; however, it varies in its modes and degrees of representation. While the World Trade Center in Dresden is positioned in the City Center, designed as World Trade Center, designed by an architectural firm, featuring a Tower and aiming to add to the city’s skyline and architectural identity, the World Trade Center in Rostock is less centered and is architecturally un-ambitious. Even more imperceptible is the World Trade Center in Frankfurt (Oder), which has an address within a peripheral industry park, and uses, in lack of an image of a real morphological building, the iconic image of the existing Oder Tower in the city centre as symbolic substitute. Regardless of these different scenarios, in all cases elements of World Trade Centerness and its function within the global system can be seen: the relevance of centerness, marketization, top-down development, the narrative of unity, the role of accessibility and visibility. When lacking visibility, the image of the New York Twin Towers, which is being evoked by the association with the World Trade Center Association, serves as image.

Conclusion: Unity, unification and the representation of world trade

With the geopolitical changes evoked by the ‘Wende’, the territorial, political and economic positions of all cities in the former GDR changed fundamentally; in its position within Germany, Europe, as well as the global infrastructure. This paper has outlined, how the establishment of World Trade Centers has served as a tool for the cities of Dresden, Rostock and Frankfurt (Oder) to re-position themselves within the new post-socialist global system. The three cities in the former GDR are different in many aspects such as population size, economic situation, heritage or industries, as are the World Trade Centers, that have been developed in the three cities in the early 1990s shortly after the ‘Wende’. While they vary in terms such as morphology, use, position, they are all examples of how the World Trade Centers Twin Towers, designed by Minoru Yamasaki in New York serve as representation and symbolic object of world trade and the belonging of the global system, even after their physical destruction. During the transition from one ideological system to another, the need for cities to re-position themselves in the new geopolitical and territorial system, symbolic representation of world trade served as a tool not only for the German unification, but also for the new unity of the global. With referring to the World Trade Center Twin Towers in New York, cities seek to position themselves as hubs within the global network, as participants of the one global system.

Abstract: Drawing from an ongoing research project 'SPLACH - Spatial Planning for Change, which aims to inform a sustainable planning transition of Portuguese metropolitan areas, this presentation identifies the planning paradigms which have guided the urban planning of Lisbon, its region and metropolitan area, during twentieth century. The influence of specific theories such as the Garden City (1898-1902), the Charte d'Athènes (1933-1943), the Doorn Manifesto (1954) and the Compact City (1997) on strategic planning documents including the 'Plano Director de Urbanização de Lisboa' (1938-1948), the 'Plano Director Municipal de Lisboa' (1954-1958), and the municipal and regional masterplans established after the 1974 Portuguese Democratic revolution are here identified. Such analysis is constructed through an overview of municipal and subregional plans and of neighbourhoods created in them, which allows an analysis of the metabolic and morphological transitions which have marked twentieth century Lisbon Metropolitan Area (LMA) urban planning history. By doing so, we seek to establish which were the impacts of these transitions, including on urban form, how have these changed the role of urban growth in LMA and how to interpret and optimize such built heritage today, when Sustainability urges for change.

Keywords: urban form, sustainability transitions, urban planning paradigms, Lisbon Metropolitan Area.

Introduction

Urban Planning is fundamental for the sustainability of cities and their regions, particularly in metropolitan areas. Global urbanization, with its pressing socio-environmental challenges has led scholars to question existing planning tools (Oliveira, 2006). This kickstarted studies of problematics like air pollution, waste production, greenhouse gas, etc. Such studies accounted for energetic and material balances occurring in specific areas. Developed by engineers, ecologists and civil engineers, these allowed the first metabolic studies of real cities like Tokyo, Brussels and Hong Kong (Kennedy *et al.* 2010). Metabolic data analysis and models to account such data were made available worldwide (Beloin-Sain-Pierre *et al.* 2017, Kennedy *et al.* 2010). Particularly suggestive was the 'black box' metaphor attributed to the city by many urban metabolism studies (Erb *et al.* 2016). The participation of other scientific areas, covering black box analysis, through physical form urged architects and urbanists to pursue a sustainability agenda. However, the application of such knowledge in transformation of the built environment proved to be slow (Jencks *et al.*, 2000). Clearly, urban form concurs to urban sustainability (Marat-Mendes, 2002), but the 'black box' needs to be better understood within architectural and urban design practices. Only then can planning authorities aspire to respond properly to the

sustainability agendas which international institutions (United Nations among other) were demanding, including the directives for the control of water and air quality.

The discourse of sustainability surpassed the engineering and natural sciences (Fischer-Kowalski, 1998) and generated societal pressures for politicians to promote adequate laws for maintenance of resources and planning of the built environment. The use of metabolism as a tool for design remains however inconspicuous in architecture and even urban design. In the beginning of the new millennium sustainability emerged a common goal for cities, and it suggested the need for effective transdisciplinary processes (Baccinni and Oswald, 2008).

The concept of metabolism would be re-examined in neighbourhood (Kennedy *et al.*, 2010) and metropolitan (Rosado *et al.*, 2014) scales, and it underlies recent planning paradigms, including the Compact City (Jencks *et al.*, 1996; Rogers, 1998), which turned into the corollary of the EU Urban Agenda (Schoffham and Marat-Mendes, 2000). Within thirty years, the consolidation and materialization of the first metabolic studies of cities changed urban practice and theory, spawning a new urban model and a proliferous research area. This long process exposes the time loop that a cultural-scientific-political-sustainability-transition process requires in practice, as already argued and identified by Tibbs (2011).

Assuming the existence of this time-loop, an ongoing research project 'SPLACH – Spatial Planning for Change', aims to inform future urban policies on sustainability transitions in metropolitan areas, identifying the impacts of planning paradigms and corresponding urban forms. The role of the food system in sustainability transitions of the Lisbon Metropolitan Area (LMA) is highlighted. However, the functioning of the food system is closely interrelated to land-use and urban form, as well as socio-cultural contexts (Marat-Mendes and Borges, 2019). Thus, identifying planning paradigms which led to the specific context of today, is an important contribution to inform any exercise aiming to change current planning priorities.

This paper focuses on three specific areas of the LMA, as well as three moments of the urban history of its region, while identifying specific paradigms that guided urban development, in their morphological and metabolic dimensions. Furthermore, we analyze socio-ecological potentials for each of these areas today towards a sustainable transition of the LMA territory.

Methodology

For our overview of the LMA urban history, we selected three case-studies, namely the Eastern end of Lisbon, between Vale Escuro and Olivais; the Alfragide zone in Amadora, particularly the Alto do Zambujal neighbourhood and finally, the centre of Oeiras, including the old centre and the neighbourhoods of Nova Oeiras and Santo Amaro (See Figure 1).

Planning instruments relevant for developing these areas include:

- The PUCS (Plano da Costa do Sol), a sub-regional masterplan including Lisbon, Oeiras and Cascais, started by Donat-Afred Agache in 1935-1936, continued and concluded by Étienne de Groër in 1948;
- The PDUCL (Plano Director de Urbanização da Cidade de Lisboa), Lisbon's masterplan, designed by Groër in 1938-1948;
- The PDUL (Plano Director de Urbanização de Lisboa), Lisbon's masterplan, designed by GEU (Gabinete de Estudos Urbanísticos), a municipal planning office;
- Several PDMs (Plano Director Municipal), the municipal masterplans initiated in 1982 by the democratic government.

The first three were designed during the New State, a conservative dictatorship which ruled Portugal between 1933 and 1974. However, from these, only the PUCS was fully approved. The PDM is more concerned for management than for planning itself, and so its nature is different from the remaining plans, as will be explained.

Figure 1 - Case-studies: 1 – Eastern end of Lisbon; 2 - Alfragide; 3 – Oeiras centre

Lisbon Metropolitan Area Urban Planning Evolution

The PDUCL and the PUCS and the Garden City paradigm

The first period under analysis represents the moment when urban planning was adopted in Portugal as strategic for the modernization and development of the Nation, but also as an emerging area within the curricula of Architecture Schools, whose urban dimensions were absent until then (Marat-Mendes *et al.*, 2014). Thus, some Portuguese architects were invited to conclude their architectural studies in foreign universities, including the Institut d'urbanisme de l'Université de Paris (IUUP). It was precisely from the IUUP that architect-urbanist Étienne de Groër came to work in Portugal, invited by the Portuguese Ministry of Public Works (Marat-Mendes *et al.*, 2014). The planning paradigm guiding Groër on his planning work was Ebenezer Howard's (1902) Garden City theory, as Groër (1945-1946) stated himself in his 'Introduction to Urbanism'.

Groër's work, justified in the written document that complemented the drawings of the PDUCL (1938-1948) attests the crucial role of Garden City concepts to the urban development of Lisbon and its region. He planned a rural zone conditioned by urban legislation, a buffer to urbanization he assigned for agriculture. Groër also worked on the urban design scale. Thus, he proposed building principles, and advanced solutions for street sections, urban grids, urban blocks and plots for several neighbourhoods in Lisbon and Costa do Sol. The family unit constitutes a basic issue in Groër's (1948) urban planning, determining public space organization according to family needs (creating schools, churches and

other equipment within walking distance) as well as private space (for instance the requirement of a private backyard for growing food and resting).

The PUCS allowed Groër to deepen his interpretation of the Garden City, working at a sub-regional scale. He established a maximum population for the city and its subregions – 1.100.000 inhabitants for Lisbon and 550.000 for the suburban municipalities (Gröer, 1948). Furthermore, Groër established a zoning system to delimitate different urban land-uses (industry, commercial, mixed, residential) to protect rural zones, prohibiting their urbanization. The green belts were implemented in the surroundings of the Lisbon municipality, as well as in Oeiras and Cascais subregion, known as Costa do Sol (Marat-Mendes, 2009).

Although the PDUCL failed to get approval from the central government, it was partly implemented and changed irreversibly the course of the Lisbon's development (Marat-Mendes and Oliveira, 2013). Municipal architects like Paulino Montez, Luís Benavente and Zinho Antunes drew specific plans for garden-suburbs, including neighbourhoods as Alvito (1937), Restelo (1938-1947), Caramão da Ajuda (1947), all in the Western end of the city, Alvalade (1945) in the north-central area; and Madre de Deus (1942) and Encarnação (1940) on the Eastern end.

The PDUL and the Chartre d'Athènes and the Doorn Manifesto paradigms

While the PDUCL and the PUCS were being developed, Portuguese architects started to urge for political changes and a new modern aesthetic to counteract the one established by the New State. In Europe, modernist urbanism, developed under CIAM – Congrès Internationaux d'Architecture Moderne, produced the 'Chartre d'Athènes', a synthesis for the new functional city.

Selections of the Chartre were translated into Portuguese in 1944 by Nuno Teotónio Pereira and Manuel Costa Martins for 'Técnica', a magazine of engineering students. From February 1948 to September 1949, the integral version was published in the monthly magazine 'Arquitectura', translated by Francisco Castro Rodrigues and Maria de Lourdes (d'Almeida, 2015).

These translations became a public statement of Portuguese architects – and engineers – pursuing new planning paradigms. Nevertheless, such transition would take time. After the approval of the Costa do Sol Plan in 1948, Groër concluded the PDUCL, but the central government did not approve it. New urban plans would be delineated for Lisbon, culminating with the 1959 PDUL elaborated by the GEU, which included 14 engineers, 15 architects and 2 landscape-architects. This new plan acknowledged Groër's contributions and confirmed the importance of the regional scale to tackle urban problematics including overcrowding, inadequate distribution of regional populations, and lack of regional unity which affected social, economic and environmental cohesion (PDUL, Int.3-4). However, the PDUL is closer to the principles of the Chartre d'Athènes, including mobility, functional zoning and high-density construction. The maximum population for the city coincided with Groër's, but the PDUL proposed new treatments for rural zones. While the PDUCL established a green belt around Lisbon (at the northern bank of Tagus) to prevent the city from extending to rural settlements, the PDUL omitted this possibility in the north side of Tagus river. Instead, it identified the green areas of protection (green belts) in the limits of the orographic valley areas (water streams) which constituted the natural areas of provision of open spaces for leisure. Only in the southern bank of Tagus, would the PDUL identify areas for agriculture to be preserved (PDUL, I.2.1-2.2/1). Despite its ambitious project for Lisbon, the PDUL failed to get approval. A new version coordinated by Georges Mayer-Heine was concluded in 1967 but approved only ten years later.

By assigning green areas for leisure, instead of agriculture and food production, the PDUL announces a transition of paradigm, as the ideas of international modernity were slowly being absorbed by Portuguese architects and planners. Moreover, greater attention is given to building structures themselves, instead of the family principles that guided Groër's (and even Howard's) planning ideas. Nevertheless existing rural ways of life were not neglected by the Portuguese architects, which by the late 1950s were highly interested in the debates around popular and traditional architecture (Marat-Mendes and Cabrita, 2015). Would this be a symptomatic reflection of the Doorn Manifesto?

The Doorn Manifesto was written in 1954 by Team 10, a collective formed by younger architects attending post-WW2 CIAM. Members came from collectives such as De 8 (Aldo Van Eyck and Jaap Bakema), MARS (Alison and Peter Smithson) and AT.BAT-Afrique (Georges Candilis and Shadrach Woods). Their previous projects included multi-religious neighbourhoods, new towns, public equipment and council housing (Borges, 2017). The document constitutes a direct challenge of modernist principles, including the partition of land according to functional categories, instead accepting the historical and accumulative processes that shape particular urban forms. It takes a strong influence from the regional geography of Patrick Geddes. The identification of communities with their aggregation patterns and the need to integrate different urban densities and scales also question the rationalist planning paradigms of pre-WW2 CIAM (Borges, 2017). In the 1956 Dubrovnik CIAM, organized by Team 10, the Portuguese group of architects presented a proposal for rural habitat, exemplifying the articulation of modern and local architectural references (Marat-Mendes and Cabrita, 2015) which brings Portuguese architecture of this time close to Doorn principles.

Unlike the Chartre d'Athènes, the Doorn Manifesto was not translated to Portuguese. However, beyond Portuguese CIAM participations, the ideas and projects of Team 10 were known in Portugal through articles and photographic reports in architectural magazines, particularly under the influence of Nuno Portas. The editor of 'Arquitectura', an architect in the Alegria Street Studio, where several council estates were designed (Tostões, 1997) and on the Lisbon GTH (Gabinete Técnico de Habitação), Portas helped the principles of the Chartre d'Athènes and the ideas of the Doorn Manifesto reach the development of Lisbon, including neighbourhoods like Olivais Norte, Olivais Sul and Chelas. This marked a uniquely significant shift in Lisbon's urban history.

Post 1974 – The emergence of the PDM

Since 1982 the PDM, or Municipal Masterplan, is the centre of land-use management and of the democratic planning structure in Portugal (Marat-Mendes *et al*, 2018). The 1982 Law of Soils marked a shift from earlier urban planning. Municipal planning stipulates land-use and corresponding regulations, based on a fundamental opposition between urban and rural, but the PDM is not an instrument for planning the development of territories, instead, it manages its development mostly led by the private-sector (Marat-Mendes *et al*, 2018). The 1982 law was only replaced by a more detailed Ground Basis Law in 1998, updated in 2014. These required PDM revisions every decade, although such rule is not scrupulously followed.

Active PDMs in the LMA have been written in different times, handling specific local, territorial and socio-economic problems. Eight of the 18 PDMs which integrate the LMA are prior to the first Ground Basis Law, while five date from 2015, leaving unclear which Ground Basis Law guided them, and only one was approved after. All municipalities include urban and rural soils, except Lisbon, whose land is entirely urban. Other classes included in other municipalities range from 'rural soils' to specific classes of agriculture, forestry, agroforestry, green protection and natural spaces.

With respect to the municipalities included in our examples, Lisbon, Amadora and Oeiras, they show very different planning situations. We will focus our overview on the most recent versions of their PDMs.

Lisbon published the newest version of its Masterplan in 2012, a lengthy document pertaining to answer problems like population decrease and unemployment, while acknowledging major infrastructure needs are met (PDML, 2012). Other problems identified are resource waste due to a diffuse growth patterns, air pollution and mobility (PDML, 2012). With respect to land-use, the whole of the Lisbon is classified as urban (PDML, 2012, Art.9), containing operative categories as well as functional categories, a relevant set of dispositions for the Municipal Ecological Structure (MES) and an articulating system of Structuring Corridors to connect green and urban areas (PDML, 2012). Given its emphasis on conservation and heritage, the PDM has highly restrictive regulations for new constructions, including on façade preservation, height and occupation of block and lot, with direct impacts on the density of new buildings. However, several important recent buildings have obtained approval from the municipality, despite visibly violating the PDM, particularly in business areas.

The Oeiras PDM, from 2015 defends growth, compaction and multifunctionality. It is one of the few PDMs in the LMA with a clear tendency towards a specific urban model –the Compact City. It seeks sustainable and qualified development (PDMO, 2015). The territory is divided into several systems with specific regulations – from the MES to Systems of Protection for Values and Resources – overlapping with the land-use system. Another important aspect is the defence of multifunctional centres (PDMO, 2015, Art.31). Changes in land-use are allowed and encouraged, announcing a territorial dynamic, perhaps more than a territorial program. There is a certain boldness to how this PDM understands its territory appealing to multifunctionality (PDMO, 2015, Art.25 and Art.30 and Art.31). In ‘Housing spaces’, the goal is conversion into central spaces (PDMO, 2015, Art.31-1), which include housing, services and commerce (PDMO, 2015, Art.30-1). In all of this, the Oeiras PDM meets the theoretical principles of the Compact City, namely the creation of high-density buildings with free space of mixed land-use. Moreover, in 2015, the municipality issued a Regulation for Urban Allotment Gardens (DL.162/2018 – March 14th), acknowledging urban agriculture for its role in environmental quality, soil maintenance, farming techniques and social leisure, but not its role in food-security.

Finally, Amadora presents the most precarious situation of the three municipalities. The active PDM was written in 1994 and is not structured around a clearly stated goal, although it has some interesting points, especially concerning the environmental quality of the municipality, not very common in PDMs written in the 1990s. Not only there are careful stipulation as to natural spaces (and equivalent ones), there is whole chapter on pollution, including dispositions towards preventing it in the air, the water and the soil. The land-use system (PDMA, 1994, Chapter III – Section I) merely establishes land-use classes with regulations on scale, lining and height. Land-use is further distributed in each Operative Unit, adding specific interventions according to the needs of particular zones. On the other hand, it must be added that this PDM does not necessarily envision a multifunctional space: it presupposes urban settlements with industrial parks and natural spaces (or equivalent) between them. Another surprising aspect is the lack of clear goals towards articulation with the Lisbon municipality other than transportation.

Planning paradigms at the neighbourhood scale

Here, we focus our overview on the neighbourhood scale. These are the Eastern end of the Lisbon municipality, the Alfragide area in the Amadora municipality, and the centre of the Oeiras municipality (see Figure 1). The first was urbanized during Gröer’s PDUCL and during the legal void left by the PDUL. The second had a municipal integral plan in 1982, but was mostly constituted by autonomous housing units. The third was one of the areas contained in the PUCS but continued to grow, revealing the non-accomplishment of several goals included in the Plan.

Eastern Lisbon

Figure 2 – Locations: 1 – Madre de Deus, 2 – Chelas, 3 – Olivaes Sul, 4 – Encarnação, 5 – Olivaes Norte

Eastern Lisbon was mostly occupied with industrial facilities near the riverbank, as well as some low-density housing areas, convents, large farms and some slums, most only demolished in the 1960s. The municipality constructed two neighbourhoods in the northern and southern areas of the Eastern end of Lisbon, both included in Gröer's PDUCL.

The Encarnação neighbourhood was planned by Paulino Montez in 1940 for the Northeast end of Lisbon, nearby the Lisbon Airport, also an element planned by Gröer. Housing types are by municipal engineer Jácome da Costa, single-family detached and semi-detached terraced houses with a small front lawn and a backyard. Encarnação is a large-scale neighbourhood and includes gardens, a school, markets, a police station, a church and other equipment. One of its streets was intended for commerce (Montez, 1958), and continues to be so.

The Madre de Deus neighbourhood was planned by architect Luís Benavente in 1942. With a radial plan rising over a hilltop, Madre de Deus is also constituted by Jácome da Costa's housing types. Some blocks are used as public gardens and the neighbourhood is topped by a small school and a green park. After its construction, some four-storey housing slabs were added to its higher and lower ends. The lower one is separated from the Xabregas area by a large guerrilla garden, while the higher eventually turned into Quinta do Ourives, a high-density estate designed by the GTH.

Both these neighbourhoods effectively created low-density housing areas with good living conditions. However, they also confirmed Howard's vision of a Garden City, with a rural area and connected to other satellite towns was not so influential in Lisbon as was the vision of a garden-suburb, presented in Raymond Unwin's 1909 'Town Planning in Practice' (Lobo, 1995).

Figure 3 - Madre de Deus plan by Luís Benavente

Figure 4 - Encarnação plan, by Paulino Montez

Figure 5 - Madre de Deus neighbourhood

Figure 6 - Encarnação neighbourhood

During the legal void left by the lack of approval of the PDUL, urban plans drew extensively from the interests of planners. The Olivais Norte and Olivais Sul neighbourhoods followed the principles of the Charte d'Athènes, the first starting in 1955 and the second in 1960. Olivais Norte is a relatively small development, in which housing slabs and towers are placed in a green park, according to a dynamic compositions independent from the structuring motorways and with free space and free circulation within its own limits (Gonçalves *et al*, 2016). Separated from Olivais Norte by the Encarnação neighbourhood, Olivais Sul expands on the planning principles of Olivais Norte. In a cellular partition, housing estates stand in urban green parks, all defined by a regular motorway structure. Traditional urban elements like streets, blocks and plots were rejected, and instead housing slabs, towers and tower-blocks were preferred. Vacant space was abundantly filled with grass and trees, which also harboured public equipment but dismantled pre-existing agricultural activities (Santos, 2015).

The further experience with the development of the Chelas Valley, starting in 1960, shows a different planning attitude from the GTH, more akin to the Doorn Manifesto. Like the Olivais Sul plan, it refuses conventional streets, blocks and lots, and opts for a cellular division. But most of the estates developed according to the original Plan are structured by continuous commerce and service pathways – some pedestrian and some for traffic – around which high-rise housing towers, blocks and slabs stem in informal and anti-geometrical compositions. The Plans for Zone I, Zone J and Zone N2 present several interpretation of these core principles, echoing those of residential neighbourhoods inspired by the Doorn Manifesto, including the Carrières Centrales by AT.BAT-Afrique (1951-1953), the Golden Lane Cluster City by Alison and Peter Smithson (1952-1953), the Park Hill-Hyde Park housing complex coordinated by John Lewis Womersley (1957-1965) and the Toulouse-Le Mirail town extension by Candilis-Josic-Woods (1963-1973). These projects share similarities with Chelas not only in the urban layout, but also in the employment of specific elements of urban form like unifying plateaus, pedestrian walkways, deck-accesses and city-buildings (Heitor, 2001; Borges and Marat-Mendes, 2019).

The impacts of these on urban form are decisive for the development of Lisbon. After more than a decade of new neighbourhoods planned according to the garden-suburb model, the need of optimizing construction and creating a significative amount of new houses led to the adoption of different urban models more accepting of mass-housing, but also more aware of the possibilities of State intervention for strategic planning of equipment, public space and transportation systems. The territory is transformed to a great extent – particularly considering that Olivais Norte, Olivais Sul and the Chelas Valley were previously agricultural areas – but so does the urban landscape, which, for the first time, sees the construction of integral high-density areas, whose urban development continues to this day. Yet, it must be noted that these plans were not totally implemented and considerable changes were made that distanced them from their original goals. Amongst these, transportation systems were paramount, and these areas were deeply affected by their segregation from the city.

Figure 10 - Olivais Norte neighbourhood

Figure 11 - Olivais Sul neighbourhood

Figure 12 - Chelas neighbourhood - Amendoeiras Estate

Figure 13 - Chelas neighbourhood - Lóios Estate

Alfragide zone

Figure 14 - Location: 1 - Alto do Moínho, 2 - Zambujal

The Alfragide area is now fully urbanized, although most of its area was included in the rural zone assigned by Gröer in the PUCS. Indeed, present-day Alfragide was, by the 1930s, constituted by three large farms, to which a growing amount of industrial facilities was added in the 1940s. The Alto do Zambujal neighbourhood was urbanized in the 1970s, in conditions similar to those of Eastern Lisbon a decade earlier. Its original council estates were however designed in different terms.

Alto do Moínho, on the lower end of the slope, is a low-density estate where urban and architectural form are merged, designed by Francisco Silva Dias. The ‘evolutive’ single-family houses are linked together in a series of slabs separated by patios and small flowerbeds. The estate occupies only a part of the land, leaving a large green area around the ruins of a pre-existing windmill, which are now occupied with small agricultural plots. The design has some distanced similarities to the garden-suburb paradigm, but its scheme is more overtly drawn from the experience of Silva Dias in a survey on popular architecture conducted in Portugal in the late 1950s (Bordalo, 2005).

On the higher end of the slope, the Zambujal estate was designed by Vítor Figueiredo and Duarte Cabral de Mello, a high-density area with several slabs built around urban parks and gardens. As the bottom of the slope is reached, the slabs become a block of two-storey houses. This estate shows a considerable influence of modern urbanism, although it belongs to a critique of the Chartre d’Athènes more than a wholehearted expression of it.

After the democratic revolution, the Alfragide zone continued to be developed, but private-sector urban developments targeted especially the middle-classes, as the Alfragide Towers, designed by the studio of architect Conceição Silva in a Brutalist aesthetic that does not necessarily follow the Doorn Manifesto principles from which English Brutalism emerged (Borges, 2017). Moreover, the Alto do Zambujal neighbourhood, which had been the object of an Integral Plan from 1973 to 1982 ended up being revised, towards greater densification. As such, most of its planned green areas have been urbanized, without a specific development strategy, but clearly guided by principles of compaction. However, as happened in many neighbourhoods influenced by the Compact City model, public transportation was not developed accordingly, and much of the mobility in the area can only be ensured by private car. Despite the relative lack of investment in improving public spaces in the Alto do Zambujal neighbourhood, there has been a considerable amount of community appropriation of vacant space, as several small areas within the urban park in the lower end of the slope are used as small allotment gardens. Moreover, in the terrain between the lower end of the Zambujal Estate, the Laboratório Nacional de Energia e Geologia (LNEG) building and the corridor of the CRIL highway, a large guerrilla garden has

been created by locals, adding another function to an urban area that includes residential, commercial and industrial activities.

The PUCS is a close interpretation of Howard, with an urban centre linked to satellite towns beyond a rural fringe. These formed a continuous structure of leisure, but mostly of agricultural and forestry activities valued for their role in balancing urban sprawl and ensuring environmental quality (Marat-Mendes, 2009). Gröer was also keen on ensuring the development of existent settlements which needed to grow. In the centre of the Oeiras municipality, he mostly focused on consolidating the old settlement, and integrating it in newly created neighbourhoods, mostly designed as low-density garden-suburbs. That is the case of Santo Amaro, the Eastern zone of Oeiras, in which Gröer planned such a garden-suburb, constituted by detached terraced houses and cottages, with several public gardens facing the beach.

The PUCS will also absorb the plan for Nova Oeiras, a new neighbourhood for the Western zone of Oeiras, with semi-circular streets with cottages placed around a housing estate fully tributary to the urban principles of the Chartre d'Athènes, designed by architect Luís Cristino da Silva.

Although Gröer planned the urban centres in the region, he understood these as parts of an integral scheme that included the rural areas. This shows the greatest changes in the Oeiras centre, as urbanized area has eliminated a considerable rural area. Between Gröer's Santo Amaro neighbourhood and the beach now stands a high-density estate, while on the northern end the Augusto de Castro neighbourhood was built, also with high-density tower-blocks. Other areas were since urbanized in the Oeiras centre, most of them high-density. However, this has often been made possible by land-use conversions which deeply affected the rural structure of the PUCS. This green belt is only visible in fragments now, and some of its remnants have not been prioritized in urban planning (Marat-Mendes, 2009).

Discussion

The case-studies enlighten transitions within the urban history of Lisbon and its region. These are verified at three levels. First, the political, with the development of planning instruments for multi-scale development of the territory. Second, the cultural, with different urban paradigms informing the urban design. And third, the socio-metabolic, with the regional transformation of landscapes, ecosystems and lifestyles.

Considering the ruralist politics of the New State, Gröer found in Lisbon a political climate favourable for exploring his interest in the Garden City – expressed before he came to work in Portugal (Gröer, 1932). He succeeded at planning low-density comfortable neighbourhoods but failed to predict the real changes the city would undergo and design solutions to tackle such problem. However, Gröer's vision is not without merit, as it balanced urbanization with the preservation of rural activities, with positive metabolic impacts.

Ideas emerging from modernist planning and its post-WW2 critics would eventually become influential in Lisbon, although the PDUL, which integrated those references, was not approved. High-density was a necessary solution for housing shortages in several urban centres of the region, and although most urban designs would plan great amounts of green space, these no longer negotiate with the agrarian past of their territories. A schism is assumed between urban and rural that lasts until today.

Democratic planning became more focused on territorial management, rather than planning, to respond to a liberalized market, but recent construction is moderately compromised with the principles of the Compact City in high-density construction, but less in transportation or reduction of car-dependency.

The case-studies reveal urban form contrasts in planned neighbourhoods according to their urban models. In these contrasts are implied different metabolic processes. In neighbourhoods planned during Gröer's PDUCL and the PUCS, the garden-suburb model is the most preponderant, as new neighbourhoods do not have particular relations with either the city centre or a rural hinterland, fundamental for the Garden City. Individual detached or semi-detached houses are the preferred type, with individual yards and public green areas providing free space and sometimes public equipment.

This changes in the 1950s. Given Gröer's unrealistic predictions for urban growth and the continued existence of slums in Lisbon, urban models reviewed in architectural publications were used by several architects working in the development of Eastern Lisbon. High-density solutions are accepted, and multi-storey buildings were incepted into green parks divided by large motorways in Olivais Norte and Sul. In Chelas, there are similarities with the Doorn Manifesto, as mass-housing estates cluster around a central motorway.

These neighbourhoods represent great metabolic changes– they stand on former agricultural land expropriated by the Lisbon municipality, and present a great variety of residential density, from single-family houses to massive tower-blocks within a large extension of green areas mostly meant for leisure and landscape. In Chelas, an horticultural park and guerrilla garden are the exception, while several guerrilla gardens of several dimensions can be found in the fringes of Madre de Deus today. Another important aspect is the conversion of pedestrian and low-traffic routes into motorways, and the appropriation of green areas for parking, showing a dramatic increase in car-use (and corresponding CO2 emissions), despite the presence of public transportation (except in Madre de Deus).

Either inspired by the Garden City or by ulterior ideas, these neighbourhoods are mostly linked with agricultural production (fundamental for Howard) through grassroots initiatives. That these and other initiatives did happen proves there were socio-cultural but also spatial conditions for their development, confirming space is the asset that allows urban change to happen (Scoffham and Marat-Mendes, 2000). However, aside from the Chelas Horticultural Park, the municipality seems to promote mostly urban rehabilitation and redevelopment in these areas.

Considering the Alto do Zambujal neighbourhood and its surroundings, one can detect a planning tendency towards compaction, as most housing is high-density and land-uses are relatively mixed. However, ease of access and public

transportation which are core to the Compact City model are lacking, as transportation is based on the major nearby motorways. The loss of green space in the Alfragide area is also noteworthy, particularly considering that nearly 100 years ago, it was an agricultural area. The guerrilla gardens in Alto do Zambujal are important counterbalances for such loss, but it must be noted they have no legal right to occupy the land.

Despite having been minutely planned, the PUCS rural structure was dismantled. Its network of farms decayed with lifestyle changes throughout the 20th century (Marat-Mendes, 2009). This also signals a socio-metabolic shift, with agriculture withering, along with local ecosystem, irrigation systems and soil-maintenance practices (Marat-Mendes, 2009). Furthermore, this effaces most of the Garden City principles applied in the PUCS, and often, low-density neighbourhoods planned by Gröer are surrounded by tower-blocks and large public buildings, showing an increase in construction, but also in population and urban activities. Gröer's restrictive planning of the urban centres, based on his own underestimation of population growth, may have determined the ill fate of the rural areas, since these were later considered less important than avoiding housing shortages. However, the urban forms of new housing schemes did not consider the implied metabolic changes in the territory, with great increases in traffic and waste, as well as corresponding infrastructure.

In Oeiras, the development of several high-density residential neighbourhoods runs parallel to a great emphasis on industrial and urban activities. Although the current Oeiras PDM encourages residential suburbs to become mixed-use, it is unclear if the envisioned multifunctionality is only directed at fundamentally urban activities. Although it is not discarded that rural soil may turn to urban (PDMO, 2015, Art.25-3), the opposite is less evident. The Compact City model implies high-densities and mixed land-uses, but also ease of transportation, while Oeiras remains strongly car-dependent with an underdeveloped public transportation system.

Concluding remarks

The socio-ecological urban history of Portuguese cities is a promising field of research, Lisbon in particular. Considering that after an earthquake in 1755, the city was rebuilt as the capital of the Kingdom of Portugal (Marat-Mendes, 2002), such urban vision would change drastically. Under the New State's rural politics, Portugal remained underindustrialized for a significant part of the 20th century. Many problems associated with the industrial socio-ecological regime (Fischer-Kowalski, 1998) arrive late to Portugal. The PUCS tries to turn the Garden City model to the regional scale, planning an integral sequence of urban and rural areas. Only after the planning of the Alvalade neighbourhood high-density solutions start to be accepted, to be taken to a greater scale in the GTH neighbourhoods in the Eastern end of the city. In Lisbon, these neighbourhoods were developed in land expropriated by the municipality, but elsewhere, as is the case in Oeiras, further development implied land-use conversions and significant subtractions from Gröer's green belt.

What has also been lost throughout the 20th century was part of the productive capacity of the LMA, particularly in urban centres and their surroundings. Gröer's strategies have perhaps too hastily been identified with the conservative politics of the New State. However, his municipal and regional plans emerge as those which more strongly identified the important role of rural areas for food-production. As the phenomenon of urban agriculture continues to grow in the city (Marat-Mendes et al, 2018), perhaps in the future we will need to articulate the high-density solutions that are adequate for the increasing urban population, with regional rural structures as those which have been decimated until now.

Abstract: Current and increasing transformation makes it more than ever necessary to develop an ability to plan and manage the different changes. Nowadays in order to make cities more resilient, policymakers are required to consider the various challenges that climate change related to urban development can bring under conditions of uncertainty. Within the conceptual framework that defines the design process as a decision-making process (ED 2014/89, Maritime Spatial Planning), climate change focus is changing from a problem-oriented to a decision-oriented approach. Considering the interaction among the cities several dimensions and the multi-level governance, it is possible to understand the complex governance system as urban transition management, in order to evaluate and implement alternatives within uncertain, dynamic and complex socio-ecological systems. The study objective is to experiment a transition model, taking into account adaptation and mitigation to climate change of the whole city, addressing the commercial port of the city of Naples (Italy) with its potential sustainable development.

Keywords: decision-making process; transition; sustainable development; port-city system

Introduction

Natural disasters due to climate change impacts, ecological crises and growing socio-economic unrest are just some of the challenges that contemporary cities and territories are facing. Considering that over half of the world's population lives in cities, in order to address the challenges of climate change and urban development, new policy instruments are required (Rosenzweig *et al.*, 2011). According to recent literature, in the context of climate adaptation science, the decision-oriented approach to analytical focus is replacing the problem-oriented one. To manage the change of urban systems under deep uncertainty, indeed, the decision makers need increasingly robust and dynamic adaptive instruments, through which assess and implement long-term, flexible and sustainable policy options (Wise *et al.*, 2014). Taking into account several studies in landscape ecology, the key environmental transformation is recognised as the primary driver responsible for the changes (Wu and Robbs, 2002). In turn it is believed that the landscape is strictly influenced by the relationships between humans and nature (Burgi *et al.*, 2004), so much as to claim that the history of the production, as much as economic and social relationships of that place have determined the structure of the landscape (Echeverria *et al.*, 2012). Studying climate change mitigation and adaptation, several approaches (e.g. incremental, transformative or reformist adaptation) and conceptual models (e.g. Adaptation Action

Cycles, Transition Handbook) have been adopted in order to direct the transition toward sustainable urban development and make cities more resilient and sustainable (Park *et al.*, 2012). Sustainability transitions have been defined as long-term and multi-dimensional transformation processes in which the governance play a relevant role with the aim of orienting socio-technical system towards more sustainable models (Markard *et al.*, 2012). These are flexible processes susceptible to change over time (Garud *et al.*, 2010) and characterized by long-term goals, in which the institutional actors cover the major role in forming the direction of the transition. In literature, the transition is approached from two main perspectives: the transition community and the adaptation community. Although both communities address transition studies in urban context from the system theory perspective, whereas transition community, assuming transition as non-linear long-term process, analyses how societal and technical systems coevolve over time (Smith and Stirling, 2010), the climate adaptation community approach, anticipating long-term change, responding to immediate shocks and recovering from such events, aims at improving the adaptability and transformability of socio-ecological systems. Indeed, starting from the concept of resilience, instead, the climate adaptation community analyses the capacity of socio-ecological systems to maintain function under changing conditions (Rijke *et al.*, 2013). Considering interactions between social and natural dynamics, the concept of adaptive management (Willows and Connell, 2003) is formulated starting from the adaptive cycle (Park *et al.*, 2012) through which changes in socio-ecological systems are described as the result of natural or socio-economic or institutional responses (Pelling, 2011; Bosello *et al.*, 2013). The concept derives from the integration of two thematic areas (Gunderson and Light, 2006): natural resource management (Gunderson and Holling, 2001) and self-governing institutions (Ostrom *et al.*, 1992). Adaptive management is considered more analytical and substantial than transition management, whereas the latter has a strong process orientation with a focus on sustainability (Williams *et al.*, 2009).

According to the above perspective, the paper aims to elaborate a methodological approach to the transition of the port-city system, able to taking into account at the same time specific sectors (e.g. energy and waste), and identifying planning and design criteria they have in common (e.g. land use, urban geometry and morphology, governance, socio-demographic aspects) (Mendizabal *et al.*, 2018). The multidimensional theoretical framework of sustainability, in fact, enables to consider environmental, societal and economic aspects in a long-term vision for energy generation and consumption (Folke *et al.*, 2005; Bloesch *et al.*, 2015; Vergragt and Quist, 2011), but also leveraging on social and governance dimensions, where sustainability transition has been recently defined as a radical transformation towards a sustainable society as a response to a number of persistent problems confronting contemporary modern societies (Grin *et al.*, 2010), integrating individual and societal perspectives. Port-cities, marked by natural and anthropic functions at once, is the pivotal hubs connecting coastline with the behind territory (Badami and Ronsivalle, 2008). The port areas are complex systems characterized by multiple functions, which involve multiple stakeholders, whose activities, relating to the environmental, social, economic and cultural dimensions, are able to have resonance both at the urban and territorial scale. The conditions of risk and uncertainty determined by the transformations of our time further problematize the already complex management of coastal areas compromising the balance of the ecosystem natural and therefore the quality of human life (Hein, 2014). The raised interest in urban transformation processes of port cities has recently opened new possible research fields on the risk conditions and on the anthropic pressures within port-cities planning. The growth of maritime commercial traffic, which is recorded due to the economies of scale triggered by globalization, has negative impacts/effects on the coastal areas. The data reported by The

First Global Integrated Marine Assessment, attest to a pressing state of decline that affects the health of the oceans (World Ocean Assessment I, 2015). "The seas and oceans have always played a predominant role in the evolution of human civilizations. [...] The twenty-first century will experience the most intense maritime activity in history. The economy will become increasingly maritime due to and due to globalization" (Global Ocean Science Report, 2017). In the light of all the above new policies are required that can manage change in a sustainable way. In this context, the paper provides a transition model approach, aiming to combine economic, environmental and social dimension, in order to pursue sustainable development. The paper analyses materials and methods in Section 1, describes the case-study in Section 2 and discusses the results in Section 3.

Materials and methods

Within the conceptual framework that defines the design process as a decision-making process (European Directive 2014/89, Maritime Spatial Planning), the governance of transitions is required to address complexity and uncertainty (de Lima *et al.*, 2016). Considering not only the interaction among the several dimensions of the cities, but also the wide range of stakeholders and multi-level governance involved in their process, we understand the complex governance system as urban transition management (Loorbach, 2010; Nevens *et al.*, 2013; Moallemi *et al.*, 2014), in turn framed within the adaptive governance approach (Timmermans *et al.*, 2015), with the aim of evaluate and implement alternatives within uncertain, dynamic and complex socio-ecological systems.

Assuming the stakeholder's engagement and collaboration with researchers as crucial in a successful adaptation process (Mimura *et al.*, 2014) the paper focuses on governance process and the methods and tools useful to support decision-makers in sustainability transition. The methodology adopted in pursuing the above-mentioned objective is the adaptive pathway assumed as a solid framework to manage city transition both from transition community and from the adaptation community. In order to support choice within the proposed adaptation pathway, a multi-methodological approach has been elaborated, taking into account four main phases (Figure 1).

The first phase, related to *knowledge structuring*, has been defined in two parts: the first one dedicated to the collection and elaboration of data, both quantitative and qualitative, that describe the territorial and socio-economic characteristics of the selected context and to the elaboration of a stakeholders map, able to identify the main interests of the possible key-players; the second focused on to the selection of some relevant good practices of port-city development strategies. This phase is relevant for the identification of evaluation criteria and related indicators necessary to formulate the alternative of transformation for the port-city system of Naples.

The second phase is focused on the *local actors' involvement* in order to identify their preferences. This phase has been articulated in two different steps. The first one oriented to enable the stakeholder's dialogue, with specific attention to Port Authority, Municipality of Naples, National Railway Company, Shipbuilding Company, and Shipowner Company. The second step was dedicated to the implementation of a role-playing tool involving traders, cultural associations and leadership.

In the third phase has an *assessment* process has been elaborated by the implementation of the Novel Approach to Imprecise Assessment and Decision Environments - NAIADE method (Munda, 1995) in order to identify the preferable choice. Among the multicriteria evaluation method, NAIADE allows the comparison of alternatives using uncertain information. Using a pairwise comparison technique

within a finite set of alternatives, NAIADe sorts the latter into ranking classes. Employing NAIADe two kinds of evaluation are carried on. Basing on the score of values assigned to the criteria of each alternative, the first evaluation is performed using an impact matrix (alternatives and criteria). The latter, expressed throughout equity matrix (linguistic evaluation of alternatives by each group of stakeholders), starting from conflicts among the different interest groups, aims at detecting the possible formation of coalitions according to the proposed alternatives. Basing on a comparison algorithm of the alternatives, the multicriteria analysis is carried out throughout the impact matrix, able to define a ranking of alternative. The process consists of successive phases: (i) defining impact matrix starting from criteria and alternatives; (ii) pairwise comparison of alternatives using preference relations; (iii) aggregation of all criteria; (iv) ranking of alternatives. From equity matrix, a similarity matrix is calculated with the purpose of undertaking the equity analysis. The equity matrix is the result of multi-group analysis and is oriented to identify a ranking of coalitions among the different stakeholders and face the possible conflicts that characterize their positions.

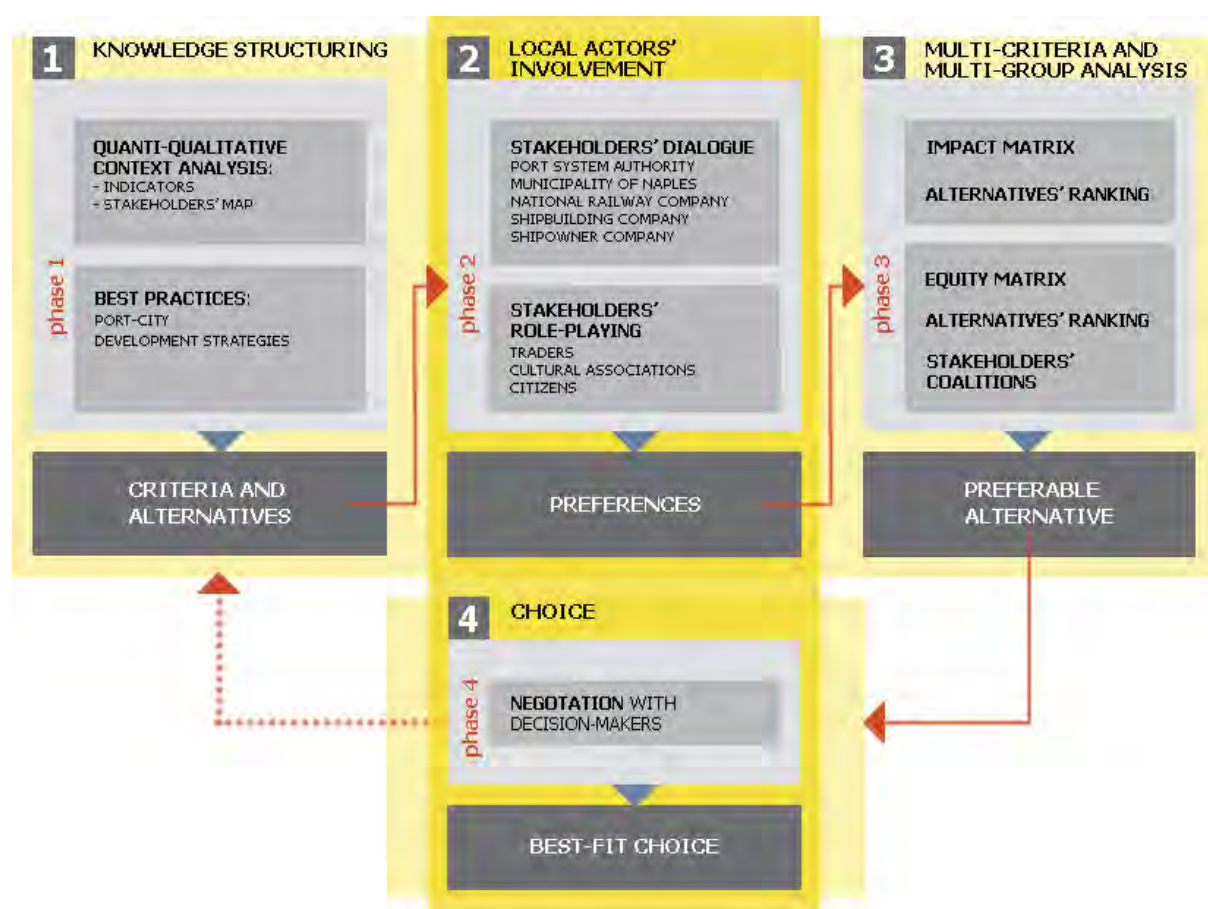

Figure 1. The multi-methodological approach

The fourth phase was that of *negotiation* with decision makers. In this phase, the results of the previous phases were discussed with the Port Authority and the Municipality of Naples in order to support the identification of the best-fit choice for the transformation of the Naples port-city. This last phase is particularly relevant because represents the conclusion of the decision-making process, but also the opportunity to improve the interaction among decision makers and the quality of the final choice.

Case of Study: Naples port-city system in transition

Over the last decades, various transformations have concerned Naples port-city, in the South of Italy, that is currently involved in the changing pattern of land uses. Owing to the process of de-industrialization, a strong decrease in demand for industrial activities has affected the productive fabrics of Neapolitan area, triggering an economic, social and cultural crisis of the city (Fusco Girard, 2012). The commercial port of Naples, located in the eastern part of the city, behind the industrial area, has been a driver for the whole urban settlement due to the economic and social connections that have crossed it. Nevertheless, the eastern side of the coastal strip has later become a parking area between the port and the surrounding districts. The area of interest is, indeed, currently marked by a large number of residential properties and abandoned industrial buildings and brownfields, making the coastline even more neglected and inaccessible. Located in the eastern part of the Gulf of the same name, it is bordered to the North by the industrial area, to the west by the central railway station of Naples and to the east by the Vesuvian municipalities, whereas to the South is bathed by the Tyrrhenian Sea. Nowadays the inhabitants are 11,159 and population density is approximately 6,841.9/Kmq. The unemployment rate is 36.5%, while the young unemployment rate is 69.4%. The administrative boundaries are regulated by policy systems of the Metropolitan City of Naples and Municipality of Naples and Port System Authority of the Central Tyrrhenian Sea (AdSP), which are the main stakeholders in force.

The present study, assuming planning as design-process is in line with national and European legislation on. Within the theoretical framework provided by the concept of Urban Transition Management (Drift, 2011), and recognising the policy guidelines prepared by the regulations, Maritime Spatial Planning could be regarded as a useful tool able to manage the transition, taking into account the interactions among the economic, social and environmental urban dimensions and the multi-level governance. More in-depth, Maritime Spatial Planning has been considered as a decision-making process (ED 2014/89, Maritime Spatial Planning), through which responding to real issues, through the definition of an appropriate management plan. Divided into several phases, the process includes the collection of information, decision-making, implementation, review or updating and enforcement control, within which different stakeholders are involved and the long-term transformations due to climate change are considered (Linee guida contenenti gli indirizzi e i criteri per la gestione dello spazio marittimo, Italy, 2017). Considering planning as a central tool for coastal zone management and maritime governance, the “Integrated Maritime Policy of the European Union”, recognises its character as a decision-making process and identifies it as a cross-sectoral policy instrument enabling public authorities and stakeholders to apply an integrated, coordinated and cross-border approach. In this context, a multi-methodological approach provided by integrated assessments is to be understood as a structured and simultaneously adaptive process, that guides and supports the decision process and the choice of preferable scenario (Cerreta, 2010).

According to the above perspective, within Master’s Degree Course Level II in “Sustainable planning and design of port areas”, Department of Architecture, University of Naples Federico II, starting from the adaptation pathway methodology (Mendizabal *et al.*, 2018), a cyclic and adaptive design-process has been elaborated with the aim of manage Naples port-city transition.

The study of the focus area has been approached according to the methodological process illustrated in the previous paragraph, with the aim of structuring the knowledge framework and identifying the

different stakeholders involved in the dynamics relating to the selected area of interest. Combining the information thus obtained with different city typologies pointed out under a preliminary desktop study, three strategic development scenarios have been defined. The latter ones, including also the development strategies underlying the project proposals allocated over time, are defined as no-intervention (A0), tourist port (A1) and commercial port (A2) (Figure 2).

Figure 2. The port-city system alternatives

The three above mentioned alternatives have been then presented to the stakeholders. The following phase related to stakeholders' analysis, has been addressed combining a top-down with a bottom-up approach. The applied methodology aims to build interaction between "common knowledge", which derives from experience, and "expert knowledge", deriving from scientific and technical knowledge. In order to detect social actors' preferences and their interactions with the context, a stakeholder dialogue (SD) (Terenzi, 2015) exercise has been carried on. Institutional stakeholders representing local authorities currently in force in the focus area, together with influent private companies have been involved. Each participant was asked to qualitatively evaluate alternatives. The results obtained from stakeholder dialogue have been successively combined with extracts from literature in order to simulate the sustainable transition on of port-city system. Assuming environmental and social issues as pivotal within transition management of the socio-ecological urban system, a review of the design-alternative proposed by Port Authority leveraging exclusively on the commercial development has been carried out. Has been therefore adopted a hybrid development strategy, taking on board, on the one hand, the principles underlying design-layouts proposed by government bodies, and the drivers of change identified from the desk analysis combined with literature extracts. Resulted scenarios have been, then discussed with citizenship. For this purpose, in the context of "City-port-System and the Waterfront as Common - IV International Workshop", role-playing approach (Adamatti *et al.*, 2005) has been applied. In particular, among the actors involved in local dynamics, some categories considered as the most significant have been selected: institutions (Port System Authority of the Central Tyrrhenian Sea, Municipality of Naples), National Railway Company (RFI), shipbuilding companies, shipowner companies, traders, cultural associations and citizens.

In order to analyse the implications determined by the implementation of scenario alternatives in relation to the different social and economic groups, the game of role approach focuses on bringing out social actors' preferences related to alternative of intervention.

The information so far systematized has subsequently been used for the third phase of the process related to the evaluation of design alternatives. In this context, structuring results according to the

systemic relationships means defining management model within the decision-making processes, in order to address complex situations, marked by divergent points of view, where clarifying issues and orienting choices is required. More specifically, aiming at defining an overall assessment of the different solutions proposed, the NAIADÉ method has been implemented because it allows to compare and sort alternatives into ranking classes of preference among a finite set of ones and using uncertain information too. Analysing different groups of actors' preferences in relation to different alternatives, NAIADÉ method allows to test possible coalitions, and in accordance with the latter to rank the alternatives. In addition, it is considered that the level of consensus informs on the ability of the design alternative to responding satisfactorily to the demands of social groups, taking into account the different views and expectations.

The first kind of achievable evaluation employing NAIADÉ method has been carried on structuring the impact matrix, in which the score of values assigned to the criteria of each alternative is shown. Quantitative and qualitative indicators have been associated with each criterion, in turn, identified taking into account the guidelines of the Sustainable Development Goals. Each indicator is characterized by a unit of measurement for which a “positive direction” has been indicated, as it may occur that the preference of an alternative over the others is obtained in the event that the value associated with the criterion considered has the greater intensity (positive impacts to be maximized), or in the event that this value has the lowest intensity (negative impacts to be minimized). In the first case, the symbol “max” has been associated with the unit of measurement, in the second case the symbol “min”. The impact matrix including 16 indicators grouped into 5 criteria classes has been structured as showed in figure 3. The final ranking (figure 4) identifies the alternative A2 as the preferable scenario according to the selected criteria. Then, a multi-group evaluation is allowed implementing NAIADÉ method. Through the equity matrix (linguistic evaluation of alternatives by each group) (figure 5), starting from conflicts among the different interest groups, possible coalitions according to the proposed alternatives have been detected. The different stakeholders have been described considering some main categories of clusters: governors, providers, influencers and users. Indicators of conflict between the different groups have been calculated, obtaining the “dendrogram of coalitions” which shows the views of the different groups on project proposals (figure 6).

In addition, through NAIADÉ method is obtained the so-called “veto diagram”, which explains the alternative on which all social groups are willing to form a coalition and sort out the other alternatives on which, instead, they have expressed their veto. Indeed, each node in the graph of the dendrogram is associated with a conflict indicator which reports the aptitude of all groups for a coalition. The lowest node at the top of the dendrogram, through which veto diagram is obtained, shows how the likelihood of coalition occurring at the alternative recognizable as the “social compromise solution”. On the other alternatives, on the whole, the various groups have vetoed. In particular, the veto diagram sorts out the three alternatives in a ranking structured according to the different groups' judgements. Alternative C, which corresponds to scenario A2, is preferable and represents the social compromise solution (figure 6). It may be pointed out that “expert knowledge” and “common knowledge” recognize the same alternative as preferable.

CRITERIA	INDICATORS	CODE	ALTERNATIVE 0	ALTERNATIVE 1	ALTERNATIVE 2	MAX/MIN VALUE
Economic Growth and Development	Construction costs	EGD1	0	77	653	-
	Job potential	EGD2	Very bad	Good	Good	+
	Unemployment rate	EGD3	Extremely bad	Good	Good	-
	Incidence of high-medium specialized jobs	EGD4	More or Less Bad	Very Good	Perfect	+
	Incidence of low specialized jobs	EGD5	More or Less Bad	Moderate	Moderate	+
Traffic Accessibility	Cargo handling (import)	TA1	536	536	1200	+
	Cargo handling (export)	TA2	499	499	1116	+
	Number of docks	TA3	200	828	500	+
Urban Metabolism	Air Quality Index (AQI)		40.9	40.9	150.3	+
	Community composting - OW-MSW recycled in the district	UM2	0	0	150	+
Society and Culture	Number of social-cultural association	SC1	0	0	390	+
	Number of cultural services	SC2	8	8	10	+
	Number of high school involved in cultural initiatives	SC3	10	10	18	+
Urban Landscape Quality	Walkability (length of pedestrian path)	ULQ1	2.23	1.32	5.29	+
	Drosscapes	ULQ2	62.03	27.05	1.91	-
	Green public spaces	ULQ3	3.66	4.36	9.7	+

Figure 3. The impact matrix

Figure 4. The ranking of alternatives

		ALTERNATIVE 0	ALTERNATIVE 1	ALTERNATIVE 2
CLUSTERS	STAKEHOLDERS			
GOVERNORS	Port System Authority of the Central Thyrrenyian Sea	More or Less Bad	Very Bad	Perfect
	Municipality of Naples	Bad	More or Less Good	Moderate
PROVIDERS	National Railway Company (RFI)	Moderate	More or Less Good	Very Good
	Shipbuilding companies	More or Less Good	Bad	Very Good
	Shipowners companies	More or Less Bad	Bad	Very Good
INFLUENCERS	Cultural Associations	Good	Very Good	Bad
USERS	Traders	More or Less Bad	More or Less Good	Good
	Citizens	More or Less Bad	Very Good	Bad

Figure 5. The equity matrix

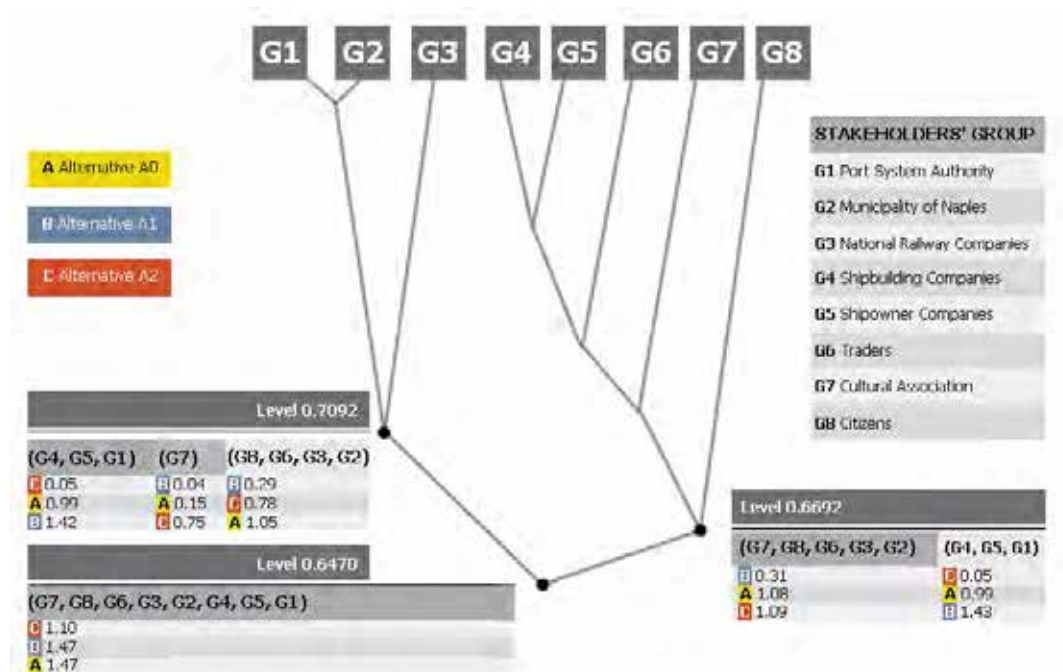

Figure 6. The dendrogram of coalitions and the ranking of alternatives by the veto diagram

Finally, the preferable design-alternative thus identified have been presented again to institutional actors, in order to obtain their approval. In short, starting from the identification of the stakeholders' preferences and their interaction with the context, within the wider framework provided by adaptation pathway methodology, an integrated and cycling conceptual model for transition have been employed.

Discussion and conclusions

A multi-methodological decision-making process can be conceived as an opportunity to integrate different knowledge and expertise, elaborating territorial strategies able to manage transformations over time and space. In this perspective, the ability to predict the trajectories of future development of the port-city is of fundamental importance for the definition of urban development plans. The current configuration of the territory has been significantly influenced by the economic, social and environmental dynamics at the urban, local and territorial scales. Therefore, a multi-dimensional approach is proposed for managing change in the context of a broader framework of a procedural nature, able to support the transition model. In this context, NAIADE method has been chosen with the purpose of rationalizing the decision problem and provide a framework for communication among stakeholders. Therefore it is deemed useful for policymakers in developing pairwise comparisons, which may reduce the degree of conflict between different social groups or stakeholders (Carbone *et al.*, 2000). In the absence of weighting being assigned to the criteria (Browne *et al.*, 2010), qualitative and quantitative data have been used to rank alternatives in order to identify the preferable scenario. The ranking alternatives basing on a set of evaluation criteria is performed by the use of an impact matrix (De Marchi *et al.*, 2000). Nevertheless, the goal of NAIADE is not the definition of the optimal scenario, but the opportunity to allow “an actor taking part in a decision process either to shape, and/or to argue and/or to transform his preferences, or to make a decision in conformity with his goals” (Munda, 2006). According to Multicriteria Decision Aiding (MCDA) research field, indeed, the decision process is considered as important as the final solution and involves both substantive and procedural reality. Carried out evaluation has led to a clear preference for alternative C corresponding to the scenario A2. Employing a multi-methodological evaluation approach a twofold result has been achieved. If on the one hand the preferable alternative has been identified, on the other improved understanding of the negotiation process leading to conflict resolution, increasing the transparency of the decision-making process and of the evaluation path, and allowing to build the choice that is able to reflect the different needs and expectations. In this perspective is intended to help local communities to become more aware both of their own opinions and preferences and of those of other stakeholders, building collaborative and shared solutions.

White Revolution: Planning Soft Transition to State Socialism

Azadeh A. Zaferani

Bartlett School of Architecture, University College London

Abstract: 1963 to 1979 marks a period in the history of Iran when the country went through a massive speedy development, a program that is often referred to as The White (bloodless) Revolution. This revolution was a socio-political transition that had land reforms, urban/rural developments, welfare, women rights, health and education at its core. Albeit, for scholars and involved parties, a sixteen-year program of reform was a megalomaniac endeavor that, in spite of its claims, mainly served the political agendas of the King in relation to local and international Leftist threats. In order to pilot this plan correctly, many efforts were made to question the project and pave a reasonable landing for it.

The ICA 70 or International Congress of Architects in 1970 was one of such effort that invited experts to Iran to collaborate with the ministry of Housing and Urban Planning, as well as the Association of Iranian Architects, in order to tie development plans to the international context. This happened through a process of questioning the relationship between the traditional (national) architecture of Iran and architectural practices abroad. Among the participants were Paul Rudolph, B.Fuller, George Candilis, Otto Hann, Yoshinobu Ashihara, Philip Will Jr, M. Oswald Ungers and Louis Kahn. Four years after ICA70, the second International Congress of Architecture took place in an attempt to discuss the effect of urbanization in Iran and other industrializing countries at a regional level. This round, Moshe Safdie, Josep Lluís Sert, Kenzo Tange and B.K Doshi were additional members. The outcome of this symposium was the “Charter of Habitat Rights,” which was edited by the group and presented by the government of Iran to the United Nations Conference on Human Settlements in Vancouver in 1976.

As a result of these congresses, the government of Iran hired many of the mentioned architects as active agents in urban planning reforms during The White Revolution. This paper will mainly focus on semi realized and unrealized projects that were the result of such interactions; projects that are reminiscent of a futuristic vision for a city in transition that ultimately remained on paper because of the Islamic Marxist revolution of 1979. Study of this meticulous planning, however, can reveal the current landscape of jump cut urban developments in Iran.

Keywords: Socialism, Planning, Revolution, Development

Introduction

A tea container, a glass of tea, a wine glass, a glass vase, a glass rosewater sprinkler, a glass lamp base, a glass bowl. All these glass objects are modest domestic elements rendering a colorful and delicate interior of an Iranian home during the reign of Qajar dynasty in late 19th century Iran. Albeit their humble and fragile domestic presence is elevated to a bold statement while being showcased in a museum of glassware in Tehran.

All of a sudden, a forgotten and outdated lifestyle creeps onto a lit stage demanding respect and attention. The object becomes a mediator through which history is told. This history, however, is far from the tea parties and religious rituals of pre-modern Iranian homes.

Figure 01: Selected Qajar glassware

This army of glass and ceramic objects sit in a neutrally-gridded black cube that is nothing but a strange oddity in the middle of a Qajari house that once belonged to Ahmad Qavam, a prominent and influential Iranian politician who stood against the nationalization of oil in 1952 — an act that united the National Front, Islamists, Socialists and the Tudeh (mass) parties of Iran in massive demonstrations against Qavam and Mohammad Reza Shah Pahlavi, the king of Iran. Years later, the same house was purchased by Farah Pahlavi's bureau (the Queen's office) in 1976, in order to convert the collective memory of this space into a museum that advocated for the development of a progressive future built upon the shoulders of a glorified past. The glasswares became traditional ambassadors of a lost identity within the modern black cube and floating mushroom pillars of Hans Hollein's design for a museum to be; a museum for a society in transition.

Figure 02 (above left): Interior of Abgineh Msuseum by Hans Hollein. Figure 03 (above right): Exterior of Abgineh Museum, former Qavam residence. Figure 04 (below left): Protests in favor of Nationalization of oil in Iran in 1952. Figure 05 (below right): Iranians carry posters of Mohammad Mosaddeq, the elected Prime Minister of Iran who was removed by the CIA in a coup in 1953.

Nevertheless, 1976 doesn't mark the start of Hollein's involvement with the Royal Commission of the museum. It is the end of a trail that goes back to the second International Congress of Architecture in Iran in 1974, when Hollein sat shoulder to shoulder with Safdi, Candilis, Doshi, Tange, Fuller, Ungers, Pei, Sert, Benevello, and many more renowned international architects in Shiraz, to discuss "the role of architecture and urban planning in industrializing countries." This congress itself was a continuation of the first International Congress of Architecture in Isfahan in 1970 with more names added to the list of architects; a congress where Zavaroni, Quaroni, Mistri, Kahn, Ashihara and many more elaborated on "the interaction of tradition and technology" in Iran. These congresses were unprecedented initiatives that nourished and legitimized the role of architects and planners in the building of a massive state structure that was ostensibly in the people's interest but had the stability of the monarchy against communism at its heart. When the Viennese-American architect Victor Gruen was commissioned to draw up a new master plan for Tehran in 1966, Iranians were busy processing the White Revolution of 1963 (a revolution that was commonly advertised as the peaceful revolution of the king and people). Albeit, the massive superimposition of Gruen's American city on the historical fabric of Tehran laid the ground for a more intuitive and participatory investigation towards the making of not only this "metropolis" but the whole country, a process that required many players to foretell the future of this expanding state.

Text format

Between Hollein's glassware museum and Ahmad Qavam's residence, our late 19th century brick house is the bearer of another defining story, a story that frames one of the main drivers of the White Revolution": the story of Iran and Egypt. The brick house with its glorious interior was sold to the Egyptians as the new premises for the embassy of Egypt, and remained in their possession for seven years. Iran-Egypt relations, however, were strained at the time of Abdul Nasser in the 1950s, resulting in the closure of the Egyptian embassy in Iran prior to its conversion into a museum. Egypt, a strong regional ally, turned into the enemy of Iran when Nasser led the overthrow of the monarchy in Egypt in 1952, nationalized the Suez canal, called for pan-Arab unity, and initiated major socialist measures and modernization reforms after his appointment as the president of Egypt. Nasser's skyrocketing popularity in the Arab world was quite alarming for a king who was an American ally and had his kingdom in the vicinity of a communist country. The rise of the Middle Eastern anti-imperialist movement, along with the Cold War between the United States and the Soviet Union, placed Iran in a tangled relationship that needed a survival plan; a plan that revealed itself through 16 years of rapid developments; A plan that was called a White (bloodless) Revolution.

Politically speaking, the Shah's position as initiator of the White Revolution was merely as the facilitator of a calculated move against the politics of the Left. Many scholars believe that the White Revolution was intended to address all the issues that could otherwise be exploited by the radical Left in Iran. These reforms were implemented in multiple formats, targeting novel economic concepts as well as social restructuring.

The re-established political relationship between Iran and the Soviet Union in the early 1950s was a key driver behind the flow of imported American ideals to Iran. Truman's Point IV Program of economic aid was of particular importance in regards to the Post WWII discourse about international development, and this included

Iran, which sought improvement in such sectors as health care, education, agriculture, housing and urban planning (Karimi 2013). Consequently, the Shah's White Revolution was considered a wise move against a socialist effect and was funded by many international agencies, such as the United Nations, the World Bank, and the government of the United States. While the early years of this bloodless revolution had its international financial supports, the Shah's development plans benefited from the spiked price of oil later in 1973, when the OPEC countries (including Iran) announced an embargo on petroleum exports — a phenomenon to which the Shah of Iran decisively contributed. Iran's oil revenues rose from \$34 million in 1954-55 to \$5 billion in 1973-74, and further to \$20 billion in 1975-76. In the course of 23 years, oil provided Iran with more than \$55 billion (Abrahamian 2018). It is no surprise that this petroleum state, or as some would say, a rentier state, was about to have the superimposition of an American dream city on the narrow streets and alleyways of its capital by the father of shopping mall design, Victor Gruen, in late 1960s. In an interview, Kamran Diba, the architect of the Tehran Museum of Contemporary Art (TMOCCA) and one of the active members of the two congresses says "The king paid us a visit at TMOCCA to check Noriyuki Haraguchi's oil installation in 1977. Incredulously, he dipped his hands in the pond and touched the oil to know this black volume that is reflecting everybody's image in its sheer darkness is really the "crude oil" upon which his pseudo-American modernized kingdom has taken shape" (Gholipour 2018).

Figure 10: Pages from *Petite Planete*, a travelogue by Chris Marker during his influential 1950s travels. The image shows the visual resemblance between oil refineries of southern Iran and remains of Persepolis in Shiraz.

The pseudo-American master plan of the capital was the framework for the satellite towns, apartment and office buildings, recreation and healthcare projects, parks, highways, road systems and many more facilities built in and around Tehran in 1970s. Describing Gruen's approach to town planning, Vanstiphout Wouter presents the Tehran master plan as a straight descendant of Howard's garden city movement:

" The plan is an enormous flowerlike structure, repeating itself inwardly as you come closer. The organic hierarchy of families, neighborhoods, communities, towns, cities and the metropolitan core are held together

by an elegant tracing of highways, embedded in a flowing of parks and other green landscapes. Around the metro core there revolved ten cities, each city consisting of ten towns around the city center and each town consisting of four communities around a town center, with lastly each community consisting of five neighborhoods around the community center ... The commission by the Shah of Iran to draw up the Tehran Comprehensive plan gave Gruen the chance to realize his metropolis in the scale and the way it was meant to be. The petro-dollar driven White Revolution provided him with the autocratic power and the ridiculous amounts of money he needed.” (Wouter 2006)

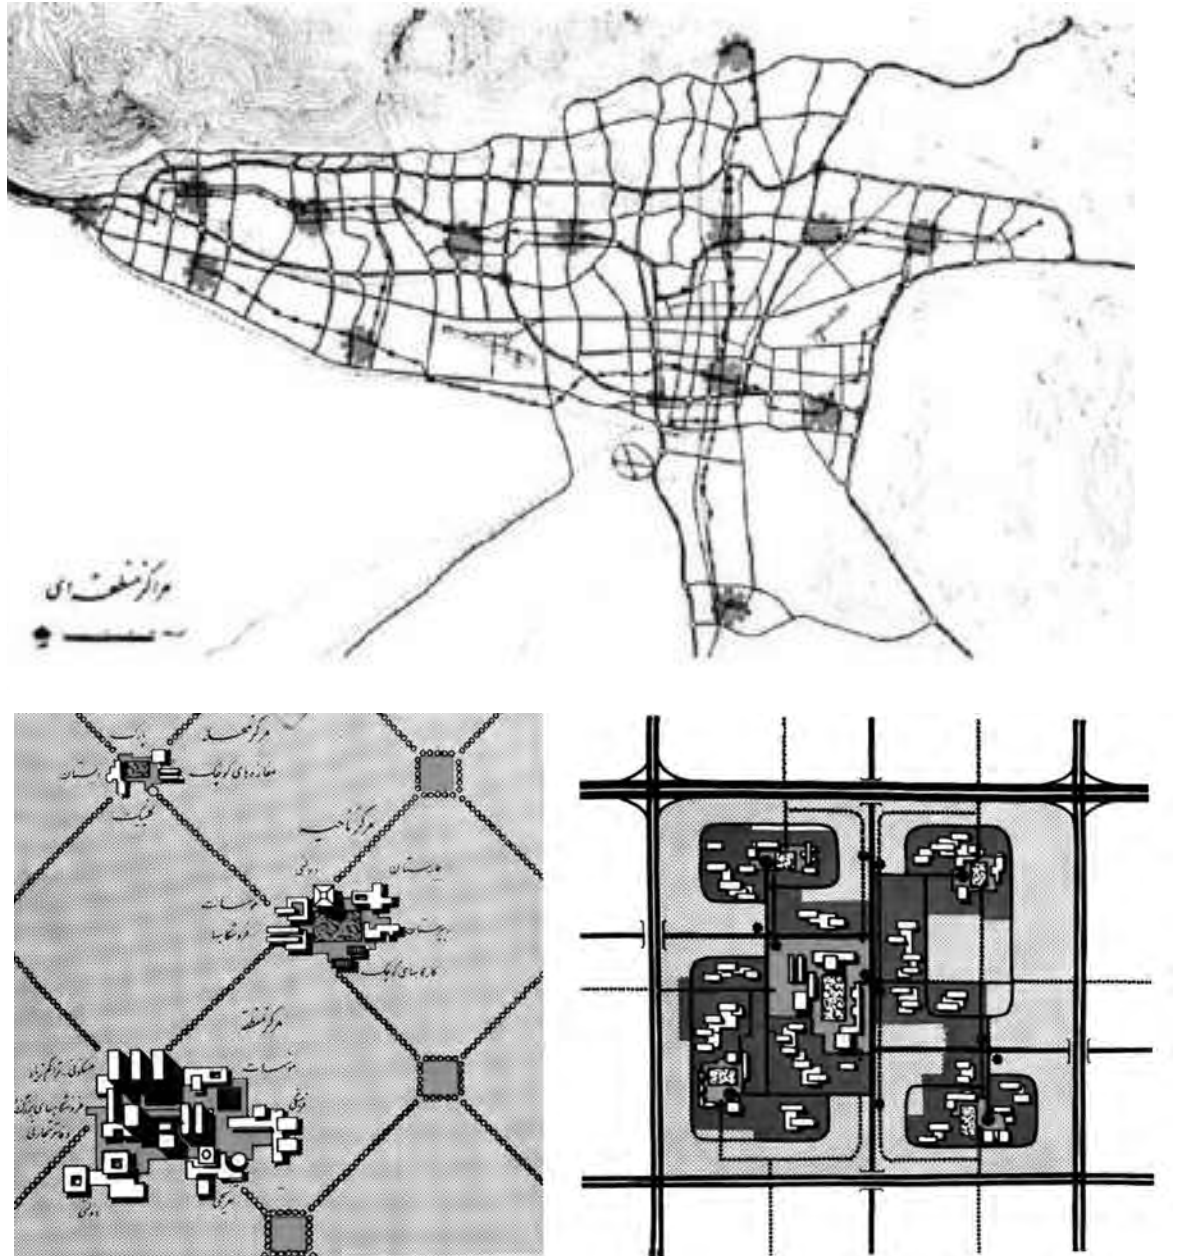

Figure 11: Diagrams from the comprehensive master plan of Tehran by Victor Gruen and Aziz Farmanfarmanian (1966) ©National Library and Archives of Islamic Republic of Iran.

In spite of many great efforts, the story of this master plan, like many other projects, was destined to be left unfinished after the 1979 Revolution in Iran. The initiative, however, became the blueprint for identifying

cultural gaps and differences in the field of the built environment and created new projects that were actually the realization of its metropolitan cores and flowing of parks in different parts of Tehran. The collaboration of Victor Gruen and Aziz Farmanfarmaian was the beginning of many collaborations that came out of the 1970 and 1974 International congresses — congresses that set out to rectify and enrich the realization of future plans such as Gruen's in first place. In this way, Iran's history of architecture in the 1970s is fulfilled by certain key commissions that went to leading international architects, such as but not limited to, the Tehran Hotel by Kenzo Tange, the Glassware Museum renovation by Hans Hollein, the Iran Museum of Modern Art in Shiraz by Alvar Aalto, the Imperial Medical Center of Iran by William L. Pereira Associates, the Industrial Credit Bank by I. M. Pei & Associates, and Tehran Habitat by Moshe Safdie. In the field of city planning, new development projects were undertaken on a vast scale, including the Shahestan Pahlavi by Louis Kahn, and later, the Llewellyn-Davies International and the Pardisan Environmental Park by Ian McHarg. Needless to say that most projects were under the leadership of Iranian architects working with an international team of professionals.

Figure 16: Interior of Abgineh Museum by Hans Hollein.

Yes, the projects were banks and hotels, but they were also houses, hospitals, schools and universities. They were promoting capitalist infrastructures of leisure and entertainment, but also Leftist goals of providing public health, community living and comfort for nuclear families. Even though these reforms were aligned with a global wave of modernizations and industrializations, they had a very particular tone and orientation to them. They were intended to render a triple position: fast-moving yet thoughtful plans that not only would turn Iran into an advanced nation with the help of Western technologies and finances, but to also present an opposing position against those imported Western modernization plans, and above all, to stand against the kind of modernization sponsored by the nouveau riche, oil-centered state economies aka the Arab states (Mohajer 2006). But what they all had in common was the presentation of a newborn culture that was both modern and Iranian. Therefore, as Peter Avery describes it in his book *Modern Iran*, Iranian culture started to become either the handmaiden of nationalist and rightist propaganda, in which case it ceased to be genuine; or sank into a sullen and shadowy retirement, meaning it was either inarticulate or articulated only in various forms of a rather arid pedantry (Avery 1967).

Figure 17: (Left) Imperial Medical Center by William L. Periera Associates ©University of Southern California, on behalf of the USC Libraries Special Collections. Figure 18 (right): Kavar health project

In an attempt to turn culture into a political instrument of power, the Shah established an alternative court and appointed the Queen as its chief advisor. In this way, the Queen, a former student of architecture at the École

spéciale d'Architecture in Paris, became the beacon of cultural advocacy; an attempt that transformed itself into many key organizations that were heavily involved in the artistic and architectural development of the country¹. And this is how architects, both locally and internationally, became active agents in construction of a triplicated plan for a bloodless revolution of the king and his people. But also, they became active agents in the conflict between the two courts: one promoting tenacious political ideas, and the other humanistic and cultural agendas.

Figure 19: International Congress of Architecture in Isfahan in 1979. The image presents Empress Farah Pahlavi together with guest speakers of ICA70.

In 1976, when under the influence of the Queen, Iran presented the “Charter of Habitat Rights” at the United Nation Conference on Human Settlements in Vancouver, the spark of an uprising was happening in Iran. The Charter was the outcome of CIA74 and was edited by Nader Ardalan, Jose Lluís Sert, Moshe Safdie, George Candilis and B.K Doshi. While the Charter highlighted that the problems of human settlements are not isolated from the social and economic development of their respective countries, and that they cannot be set apart from existing unjust international economic relations, the socio-economic gap between rich and poor was widening among Iranians in Iran. The White Revolution and the escalated oil price raised people’s expectations but did not necessarily meet them at the same pace. Three years later, the bloodless revolution of the king and his people was put to an end by the bloody Marxist-Islamist revolution of 1979; a new paradox that has shaped 40-years of troubled domestic and international affairs since then.

Strolls on streets and alleyways of Tehran can be very heartbreaking. This city proves that un-built plans are not only a bunch of lines on a stack of papers that gathers dust every day. These lines are the tangible and intangible scars on the face of the urban scenery. It was not long ago that I first stepped on the Tabiat Pedestrian Bridge, an Agha Khan award-winning project that made it into the news headlines of 2016. The strategic location of the

¹ *Queen Farah Pahlavi Foundation, Iran Cultural Foundation and High Council of Architecture and Urban Design* are of great importance in regards to Iranian architectural developments during the White Revolution.

bridge was reminiscent of many moments in the history of the modern and contemporary built environment in Iran. The elevated level of the bridge places the viewer at a height where the upward and outward flow of the city is quite tangible, an experience that has a meaning to those who are aware of the tale behind this magical scenery. Tabiat Bridge is a connection that stitches the city to the beautiful hilly landscape of the Abbas Abad district. This location was first introduced in the famous future master plan of Tehran as a potential site for a new urban city centre. Gruen's designated spot was later named "Shahestan Pahlavi," a grandiose project that was supposed to represent the best of urban developments during the final years of the White Revolution. It was a perfect example of the different paradoxes the revolution presented: a battle between tradition and avant-garde, a battle between artistic production and political statements, a battle between primary and alternative courts — and contrary to what it claimed — not the revolution of a king and his people but rather a battle between the public and the sovereign. The project started as a competition between two of the key speakers at CIA 70 and 74, Louis Kahn and Kenzo Tange, who were supported by the Queen. The two proposals were then combined in a third proposal by Arata Isozaki. The final plan, however, was commissioned to the British office of Llewelyn-Davies International in order to give the king a massive development worth \$3 billion with a focal point larger than Red Square in Moscow: an open space that was called the Shah and Nation Square. In 1975, Eric Pace, a New York Times journalist wrote:

“The Shah was on hand for a ceremony last week to present a 540,000 commemorative gold' plaque that was buried at the site before bulldozers began growling over the surrounding hills, which once were used by the Iranian Army for training. The Shah ordered the city of Teheran to take over the land in 1971. Though the Shah gave no explanation for the decision to highlight the square, the Mayor, in his opening address, stressed the importance of open space and greenery in beautifying the capital.” (Pace 1975)

Regardless of all the ups and downs, Shahestan Pahlavi ended up being a megalomaniac project that ended with the massive uprising of the 1979 Revolution. Even though a project like Tabiat Bridge revitalizes the nostalgia for a Shahestan, other corners of the city betray the aftermath of a failed plan in a spatial language. Gruen's master plan, like many other master plans, surpassed the life of its creators. It was meticulous, and well calculated and piloted for execution. Yes, it was a scheme of the Monarchy. Yes, it was a Western invention and, yes, it was doomed to exclusion after the Islamic revolution in 1979. However, it was too useful to be perfectly abandoned.

Given the post war situation of Iran in the late 1980s and early 1990s, this comprehensive plan could be a financial asset because of its exact calculation for the distribution of densities. The plan, therefore, could assist the city in selling off densities to whomever was interested in maximizing their built-up areas. Ignoring the five-year intervals in the expansion plan, the city accelerated the boundaries to the 1991 end-boundary in order to maximize the selling of densities. In this way, the abandoned master plan became a source of income through severe densification of the city (Wouter 2006).

Figure 21 (right): The New York Times, announcing the end of an era, Figure 22 (left): Master plan of Shahestan by Llewelyn-Davies Associates ©Jaquelin T. Robertson

While glimpses of residential or public structures were erected here and there, the executed plan is largely missing the basic principles of its original design: an industrial and modern metropolitan city with Shahestan as its core center; 10 logically-distributed, pivotal urban centers, with elegantly-designed cultural, institutional and recreational buildings, and parks, public spaces and commercial nodes as the hearts of the city. For as much as it is joyful to imagine the city in its original rendered view, and as it was envisioned, it is disturbing to realize that the cityscape of contemporary Tehran can be read as the result of a master plan that has been forced to eat itself (Wouter 2006). Strolls through Tehran, like the story of its modern plan, have always been open ended too. While first steps are nostalgic attempts, the last ones are always left hanging in the air; one wonders where to land them in order to rejigger the jigsaw landscape of an envisioned plan. Could they be among the lush greenery of the McHarg's Pardisan Park? Could it be among the Japanese-style gardens of Tange's hotel or the gigantic plaza of Jacqueline Robertson's Shahestan? Or instead, are they destined to land in haphazardly planned and isolated projects that never manage to define a sense of unity in what we know as "Tehran" today? In the last 50 years, Tehran has faced a revolution, a war, massive migration, multiple natural catastrophes and many environmental threats. The planning of the city has shifted from a collective and international effort to an isolated and domestic one. In the midst of such transformation, the major effort of the post-revolutionary government has always been to (un)make and (un)do all planning agendas of the previous regime. As a result, this metropolis has turned into a handicapped giant that is losing more and more functions day by day. The giant, unquestionably, is a bad version of its original blueprint. It is true! This is a dialectical process whereby a transition strategy has been challenged and morphed and switched to raise a question: how can collective planning envision a trajectory for this city that becomes the base for a transition? A transition that liberates or, perhaps, connects the city from or to its own past?

Placing Slums in the Globalized Tourist City: a performativity and Actor-Network approach

Maria Eugenia Altamirano¹

¹*Universitat Rovira i Virgili, mariaeugenia.altamirano@urv.cat*

Abstract: This paper aims to analyze the role of tourist practices and performances and their capacity, real and potential, to re-signify and transform the physical, social and cultural landscape of slummed communities at urban tourist destinations. Tourism in informal urban settlements is a phenomenon studied interdisciplinarily for about 20 years and covers fieldwork in destinations around the world. The transition of slums to tourist destination has been approached from its historical roots, tourist motivations, systems of representation, economic benefits and contested moralities. This paper seeks to address the literature on slum tourism and incorporate new insights from the Performative Turn and Actor-network Theory. This shift entails changing the focus from the representations of slums within a global audience towards the doings and behavior of human and non-human actors during slum tours and how the ordering of their relations and synergies -existing and potential- represent a possibility for new spatial-social-economic interpretations and representations of slums as urban agents.

Key Words: Slum tourism, Urban informality, Globalization, Performative turn, Actor-Network Theory

Introduction

Reflecting on Edward Said's (1978) conceptual analysis of Orientalism, Cohen and Cohen (2015) stay that the act of performing tourism is closely related with the tourist quest of *difference* from her/his everydayness: different natural landscapes to rest on or cultural scenarios to amuse with, different food to try out, gazes upon architecture icons and enjoyment of 'authentic' place atmospheres. Slums would not be traditionally considered as places to deliver such background for joy, diversion and relaxation; since they have historically embodied the "dark", the "low" and the "unknown" constructed by the hegemonic urban bourgeois as the place of the "Other". There is a contextual frame for this construction that allows the spatial-temporal mobility of this imaginary, as Steinbrink (2012) stays, every constructed otherness will exist as a mirror of current issues in society, targeting or forgiving certain social groups. In the case of some slums, they no longer represent only the place of the Other but the place of the "authentic" (Frisch, 2012).

The definition of “slum” carries with some structural difficulties because their characteristics, numbers and aesthetics are far from homogeneous. The UN Habitat (2003) defines them as a group of individuals living in an urban area who are lacking -one or more- of the following services: durable housing; sufficient living space; Access to safe and affordable water; Access to public or private sanitation; security of tenure. Slums are considered to be places of informality, dirt, insecurity, usually but not necessarily confide to the material poor and the cultural “Other”. For this analysis, poverty would be understood as a consequence of political and economic structural processes that define the material reach of individuals or sectors.

The shift from the Fordist model of organized capitalism and mass consumption-production to post-Fordism, placed the consumers individual needs and desires at the head of the production of goods and services and displaced industrial infrastructure from city centers to further districts. This transition has also been notable on the tourist sector. Poon (1993) defines ‘New Tourism’ to the flexible and customized travel patterns and tourist quest for ‘authentic’ experiences. The most evident aspects of the transition to a post-Fordist economy take place in cities, since they concentrate most of creative workforce that sustains such economic changes (Russo, 2012). Tourism -in its old, new and yet to come format- had and still have great deal of agency on the making and remaking of tourist cities, at a physical and symbolic scale.

Slum tourism (ST) defies traditional activities that tourists do while travelling. Despite the unclear boundaries in the ontology of ST, I will take Dürr’s (2012b:710) concept that defines it as a “type of mobility where tourists venture to an area beneath his/her own social category and beyond their socio-geographical space (Heap, 2009: 103)”. The hosts and guests asymmetry made ST controversial from its early beginnings, for contesting power relations and images of representation. However, as long as tours are complicit between visitors and locals, respectful of one and other, and mediated by local tour guides, the process of mutual recognition can be highly enriching for the actors involved (Williams, 2008).

Experiencing the Other is the most primitive reason for visiting slums and it can be traced back to the 19th century Victorian London (Steinbrink, 2012). With the advent of industrialization many cities went through a rapid demographic growth followed by a dramatic rise of urban poverty, and new actors -government and charities- were trying to manage the moral and physical crisis (Seaton, 2012). In London, by then the most powerful city in the world, the elites would often visit the East End either with a philanthropic agenda, impelled by social paranoia or mere curiosity to observe how people lived in the chaos of impoverished conditions (Steinbrink, 2012). Modern historians recognize that those encounters were key to have a better understanding and empathy among social clusters (OBrien, 2011). Organized slum tours started in the beginning of the 90’s in South African Townships with a strong socio-political focus showing livelihood in communities under the Apartheid regime (Rogerson 2004), and were short after followed by Brazilian *favelas* (Freire-Medeiros, 2009). Nowadays, a growing number of tourists looking for unconventional and exciting ways to experience cities have turned ST into a global phenomenon challenging stereotypes and power relations.

As Crouch (1999,2004) stays, tourism is a process rather than a product, shaped by what people *do*. In this process tourists emerge as both consumer and producer of spatial and social events through embodied practices -tourist encounter with material and semiotic space- and performances -tourist experience of places achieved after a set of actions-. This paper will critically address the literature to date on ST to contribute on

its theoretical debate importing concepts from the realm of performance studies and Actor-Network Theory (ANT). The aim is to analyze the role of -culture based- tourism practices and performances on the re conceptualization of slums as legitimate actors in the neo-liberal urban fabric. The focus is placed on the *material outcomes* of ST rather than the systems of representations (re)produced by it. The networks interwoven among hybrid (human and non-human) actors resulting of ST practices and performances are to be considered the material outcomes of tourism. I will overlap the theoretical framework on the case of Brazilian tourist favela Santa Marta to show how this analysis can give insights on the potential of networks to produce new social spaces, re-signify slums at a spatial, social, cultural and economic scale, and the agency that brings to slum dwellers to break with the isolation of the powered class/hegemonic city.

Tourist cities on the making

The latest report made by the Organization of United Nations (2016) states that 54,5% of the world's population lives in urban areas and it is expected to reach 68% by 2050. This tendency can be framed within the intermingled processes that entail Globalization, understood as the restructuring of global capitalism that begun roughly around the '70. The geographer David Harvey recognizes a set of geographical implications of Globalization, since it fostered the (re)production of spaces to enable its systematic growth and resistance, thus producing "new forms of uneven geographical development, a recalibration and even re-centering of global power (with far greater emphasis upon the Pacific and newly industrializing countries) and a shift in the geographical scale at which capitalism is organized" (Harvey, 2001:24).

Globalization was partly achieved through what Harvey (2006a, 2001) coined as the "Spatial fix". Taken from Marxist Theory, Capitalism has the constant need to place surplus to create new capital that would otherwise become stationary. Hence, the geographical expansion of capital becomes desirable and necessary to prevent the system from an over accumulation crisis of uninvested capital. To enable this expansion surplus was initially invested in innovations of transport and communications that then made possible to move on into physical building. Urban development proved to be an effective tool to fix capital through the build environment; therefore, the mobility of capital has the potential to reshape the geography of the place it is embedded and empower new economic sectors, mainly the construction and real estate industry.

The restructuring and reshaping of cities following capital flows encompasses a contradiction: foremost, investments are placed to produce space and connectivity infrastructure guided by the spatial trends of global capital; on the other hand, they are highly speculative since their profitability depends on the continuity of that flow of capital, commodity and people towards that space, otherwise it would be devalued and lost. The result of this dynamics is uneven spatial (urban) development in which the State would play a key role by allowing or denying the spatial allocation of capital relying on regulation, planning practices and ideology. The softened policies of neo-liberal States to rule on capitalist flows accelerated the polarization of cities and crescent inequality of wealth and power pushing 33% of global urban population to city's edges or to downtown encapsulated slums (Harvey, 2001).

Cities assumed a central role as places of consumption enabling the mobility of goods, people and information, and the spatial support for the production of a wide variety of economic, cultural and tourist activities. This development strategy has been used globally and made evident that the neo-liberal market forces are the ones now shaping the urban landscape (Harvey, 2012). However, as Harvey (2012:15) notes “how we view the world and define possibilities depends on which side of the tracks we are on and on what kinds of consumerism we have access to.” Hence, the wealthy elites not only are primal users and consumers of the city’s services and infrastructure but have legitimate authority to play an active role on the decision-making process that shapes the urban space, leaving the poor and marginalized to suffer the consequences of neglect. Spatial thinkers often rely on the romantic ideal of the latest to rise claiming the right to the city; nonetheless, this desire lacks of further guidance on a practical *modus operandi* for how to actually accomplish it (Garnier, 2012).

Tourism is a significant component to the political economy of many cities in the world. To thrive as tourist destinations, cities needed to go from good and services manufacture and distribution centers, to sanitized, safe, comfortable and service oriented places, affecting particularly down-town areas (Judd and Fainstein, 1999). Within the beautification, specialization and creation of what Judd & Fainstain (1999) coined ‘tourist bubbles’, often achieved by the use of violence and oppression, comes also a rise in the cost of living, gentrification and displacement of traditional local business and consequently creating not only new urban spaces but also new capitalist conglomerates (Yrigoy, 2014). This is the case heritage centers, inner-city areas (see Füller and Michel, 2014 on the case of Berlin-Kreuzberg) and former industrial neighborhoods (See Degen, 2003 for the case of Raval in Barcelona and Castlefield in Manchester) refurbished into hip and modern cultural hubs attracting dwellers from the ‘creative class’ (Florida, 2005), setting art galleries, shops and gastronomic enclaves that create a bohemian atmosphere attractive for tourists, commerce and real estate developments.

The discourse of local agents pushing towards strategic planning (that is to say the construction and service industry, political cluster, and the media) praise on the economic and cultural benefits of tourism within urban development. Given the competition of cities to attract global mobile capital investments, high skilled residents and visitors, almost every aspect of the everyday life can work as a commodity, having tourism, cultural and knowledge-based industries and the non-stop entertainment business on the bases of the city’s economic growth machinery. (Van Der Borg and Russo, 2008). Resuming the notion of the Spatial Fix, on his analysis Yrigoy stays that “the production of tourist spaces encompasses the double moment of the ‘spatial fix’: it implies a process of geographical expansion of capital, but also the fixation of this capital in physical buildings” (Yrigoy, 2014: 640). I argue that in the context of urban tourism, capital fixity may not only be materialized through physical buildings, but also through the material outcomes of tourism: the networks stitched between hybrid actors, as it would be more carefully developed.

The unexpected rise of a tourist attraction

The rivalry among tourist cities is so fierce, that unexpected assets have risen to become tourist attractions. Such is the case of a growing number of informal urban settlements in the Global South first and

then eventually also some in the Global North that have made their way to tourist attractions, often advertised by tour operators as an exciting opportunity to experience the “complete” and “real” life of the city. South African *townships*, Kibera in Nairobi, Dharavi in Mumbai, Brazilian *favelas*, Medellin *comunas*, the Parisian *banlieue* and the Neukölln district in Berlin, are some of the cases where informality was targeted by tourism global growth strategies pursuing the benefits expected from the tourist capital gear.

There won't be identical slums even within the same city, as they are compelled to the particular historical and physical context in which the slum is embedded; thus, tourism products -real and potential- will differ as well (Frenzel and Koens, 2012). Despite these singularities, the emerging of ST destinations show to follow a certain pattern highlighting the importance of mainstream events in the global projection of slums (Frenzel, 2012). The earliest slum tours developed in South African townships around 1990s for anti-apartheid activists and political motivated visitors and by the beginning of the 2000s they would become a “must see” activity for South African tourists (Rogerson, 2004). Almost simultaneously, attendees to the 1992 Earth Summit on Environment and Sustainable Development in Rio de Janeiro insisted on getting inside favelas; soon after this would motivate Marcello Armstrong to start Favela Tour followed by a growing number of favela tour providers (Freire-Medeiros, 2009). Similarly, Nairobi's massive slum Kibera was first toured by the attendees of 2007 World Social Forum (Mowforth and Munt 2009). Whilst in Dharavi, an English entrepreneur and his Indian partner opened in 2006 Dharavi Tours and Travel inspired by favela tours (Meschkank, 2011). And so the trend spread to slums in urban destinations North and South of the World.

Still, not every slum has the potential to become a tourist attraction. As Linke (2012) asserts, the success and expansion of ST is related with the (re)production of mobile images of slums. The media has a fair amount of responsibility on the creation of images and myths, and had successfully triggered ST destinations (Ma 2010). Brazilian slums experienced a popularity outbreak after the shooting of the polemic video of Michael Jackson's single “They Don't Care About Us” (1994) in favela Santa Marta; documentaries such as Favela Rising (Jeff Zimbalist and Matt Mochary 2005); mainstream movies like Cidade de Deus (Fernando Meirelles 2003) and Tropa de Elite (Jose Padilha 2008) successfully helped crafting an exotic, sexy and cool image of favelas that transcended geographical and political borders (Freire-Medeiros, 2009). Similar was the case of the movie Slumdog Millionaire (Danny Boyle 2009) firing the number visitors to Dharavi in India (Meschkank, 2011). Travel book guides promoting slum tours as “must see” also make their contribution: most tourists in Dharavi were drawn by the featuring of the tour at Lonely Planet (Ma, 2010). With the advent of Internet platforms and the high reach of social media, tourist themselves became the most suitable agents to produce new narratives based on their unique experience and understanding and reproduce them globally (Williams, 2008).

Bianca Freire-Medeiros (2009) places ST in what she coined “Reality Tours”, a kind of tourist practice under the wide umbrella of alternative tourism that promises authentic, interactive and extreme experiences involving an exoticized Other. She breaks this conceptual category in two relying mainly on their motives, even though their limits are far from clear while performing. On one hand, she names Social Tours to those trying to bring social awareness through participative experiences in under privileged locations; it also includes tourist products intending poverty alleviation for the host community, labelled by Ashley et al. (2001) as Pro-

poor tourism. I would add to this sub-field slum tours designed and operated following Community-Based Tourism principles by local entrepreneurs with the aim of enhancing the socio-economic and cultural implication of hosts in ST practices. At the other end, Freire-Medeiros places what Foley and Lennon (1996) call Dark Tours referring to those offering products based on commodified real suffering. I argue that, even though poverty is a constant in the context of every slum tour, therefore it is a decisive factor that makes it ST and no other kind of tourism, poverty and its aesthetics are not always the core feature that tour guides - especially among local tour operators- are supporting their narratives on.

Slum Tourism in Debate

ST was first opened up to debate on the academia after the *Destination Slum!* Conference in 2010 (Bristol, UK) gathering researchers with diverse backgrounds and nationalities. Most research is primarily compelled to ethnographic fieldwork in urban destinations of the Global South, mostly featuring: Johannesburg, Cape Town, Rio de Janeiro, Mumbai and Nairobi. Although, the rapid spread and diversification of ST products provided for a wide variety of cases of study enabling researchers to establish parallels and influences among them; the theoretical achievements are constraint to the contextual reality of every case study. This limitation is partly due to slums spontaneous nature and high dependence on external conditions (Frenzel and Koens, 2012).

Regardless the particularities of each destinations, analyses of slum tourists' motivations often show similar results: curiosity for the cultural Other and how this otherness live and function in a poor environment were noticed among the primal motivations in academic research (Coles and Hall, 2006; ; Rolfes *et al*, 2009 Ma, 2010; Dürr, 2012a; Mekawy, 2012); closely followed by the desire of urban tourists to explore and experience the "real"/"complete" scenario of a city a priori assumed as fragmented (Freire-Medeiros, 2009; Rolfes *et al*, 2009; Ma, 2010; Meschkank, 2011; Dyson, 2012); Chhabra and Chowdhury (2012) also point out tourists desire to contribute to the socio-economic development in Dharavi; Rolfes *et al* (2009) added the wish to interact with locals and get some knowledge on Townships cultural products. There is also a certain homogeneity regarding slum visitors around the world. Most of them come from Northern and European countries, especially from United Kingdom, Scandinavia, United States and Germany. After the tour, tourists often express their surprise by the friendliness of residents, and a shift on their original preconceptions in matter such as safety, sanitation, and infrastructure development (Rolfes *et al*, 2009; Ma, 2010). However, interaction between visitors and visited it is scarce mainly due to the tight schedule during the tour and language barrier between hosts and guests (Rolfes *et al*, 2009; Freire-Medeiros, 2010).

Understanding tourist motivations is key to draw on the moral debate around ST (Ma, 2010). Critics often recall to the allegory of slum residents as zoo animals showcased in a romanticized scenario of poverty, asserting that slum tours suppose an invasion to dwellers privacy and emphasizing on the asymmetry of host-guest relations (Scheyvens, 2007; Selinger and Outterson, 2010; Dürr, 2012a). However, such considerations are often isolated and paraphrased opinions, which in addition to ethnocentrism and the author's baggage can jeopardize their accuracy (Frenzel, 2015). In opposition to this scepticism, some scholars advert on the

potential of ST to be social and politically transformative, with educational and philanthropist value and an opportunity for economic development (Rogerson, 2004; Freire-Medeiros, 2007; Williams, 2008; Frenzel and Koens, 2012; Burgold and Rolfes, 2013). Freire Medeiros (2009) explains how tours represented an opportunity to break with the isolation of favelas in Rio de Janeiro and how they effectively helped to change negative stereotypes of communities. Similar results were noted by Rolfes *et al* (2009) in South Africa claiming that tourist negative images had improved after taking a Township tour.

Some tours follow a cultural agenda re-directing the spotlight into their sense of community, cultural production, creative survival and historical background, rather than showing the slums crudest privations and struggles (Rogerson 2004; Freire-Medeiros, 2009; Rolfes *et al*, 2009). Only ST practices based on such assets could lead to create social awareness, economic development and cultural inclusion (Phillips, 2003). However, offering a superficial reading of livelihood conditions in slums to visitors can lead to undermining the complexity of struggles and romanticize an idea of poverty, making it look “poor but happy” (Crossley, 2012).

To date, there is a great amount of research focused on how were slums globally (re)produced and consumed as tourist attractions by mobile images and narratives (Phillips, 2003; Williams, 2008; Freire-Medeiros, 2009; Dürr, 2012b; Frisch, 2012; Linke, 2012; Steinbrink *et al*, 2012; Burgold *et al*, 2013; Chege and Mwisukha, 2013; Frenzel and Blakeman, 2015). Economic benefits and inputs to poverty alleviation were also addressed (Rogerson, 2004; Chege and Mwisukha, 2013; Truong, Hall, and Garry, 2014). Empirical findings reveals hosts perspectives in different destinations (Freire-Medeiros, 2010; Kieti and Magio, 2013; Slikker and Koens, 2015); as well as tourist profile, motivations and their perceptions (Ma, 2010; Dyson, 2012; Freire-Medeiros *et al*, 2013; Frenzel, 2014; Nisbett, 2017). And of course, a long-lasting debate regarding power relations and the ethics of this practice (Rolfes, 2010; Selinger and Outtersen, 2010; Whyte *et al*, 2011; Chhabra and Chowdhury, 2012; Burgold and Rolfes, 2013; Goodwin, 2014; Iqani, 2016; Giddy and Hoogendoorn, 2018). Hereby, instead of going after symbolic traces of meaning, branding or myth creations of slums, the importance is placed on the materialities of tourists embodied practices achieved after certain spatial performances and the consequent relations interwoven between human and non-human actors.

Moving forward: Performing networks

John Urry’s concept of the tourist gaze has been used in the analysis of ST to draw on how voyeurism sets the power relations between the Self (mobile subject) and the exotic Other (immobile object). However, travelling entails more than the mere visual, it involves walking, touching, feeling, reflexive thinking, smelling, meeting others, tasting and so forth; as Urry and Larsen (2011) already noted on the latest edition of the *Tourist Gaze*: is a multisensory embodied activity, in which the gaze is also seen as a *performance*. The Performative Turn (See also Crouch, 2004; Edensor 2001; Bærenholdt *et al*, 2004) is formed in opposition to Urry’s initial theory of the Tourist Gaze and other representational approaches privileging the sight. It was inspired by sociologist Erving Goffman’s dramaturgical metaphor of the world as a stage and comes after the development in social sciences and humanities of Non-representational Theory, which places the individual as a thinking agent bodily engaged with the world it inhabits. It was applied on tourist studies by arguing that ““tourism

demands new metaphors based more on being, doing, touching and seeing rather than just “seeing” ’ (Perkins and Thorns, 2001:189; Cloke and Perkins, 1998)” (Haldrup and Larsen, 2010:3).

From this perspective tourism is seen as an encounter between people and spaces that entails a sensual set of *doings* (Crouch 2004). The negotiation of identities and power relations during ST encounter goes beyond the consideration of slums as object to be observed and tourist as passive observant subject. The comprehension that human actors may develop during that encounter is not only compelled on how they see each other, but on how they bodily experience and react to practices enacted in a certain time-space. Hence, a performative analysis of ST calls for redirecting the focus from the *posited meaning* -Representational Theory- of slum images (re)produced within the practice of tourism, towards the *material composition and conduct* of this representations (Dewsbury *et al*, 2002:439. From Haldrup and Larsen 2010). While playing tourists, the stages of tourism encounters come alive baring with the unpredictability of their behavior, producing and reacting to new images and myths whereas consuming the place and its hybrid elements, creating connections between people and the everyday, (re)structuring space and social life (Haldrup and Larsen, 2010). Hence, “Tourists emerge from this critical reflection on practice and performance as both consumers and, themselves, producers” (Crouch, 2004:86).

However, narrowing the analysis to ST practices and performances would fail to show the complexity of the interaction among people, objects and institutions and their implications at a spatial, social and economic scale. Actor-Network Theory is “an “alternative” social theory based on relationalism (Emirbayer, 1997)” (Van Der Duim *et al*, 2013:5) and influenced by post-structuralism that when applied to tourism studies shifts focus from *what* tourism *is* towards *how* tourism *works* (see also Law, 1999; Van Der Duim, 2007). This approach proposes to trace the practices of hybrid actors and their associations into more or less stable networks to describe the multiple and heterogeneous orderings of events. Actor-Networks link spaces that go from local to global setting fruitful conditions for different orderings to emerge and prevail. It can therefore give probabilistic insights on how tourist events make spatial/cultural sense of slums as urban actors, the collaborations and outcomes ST practices and performances are enhancing (Van Der Duim *et al*, 2013).

Identifying the Cast of Slum Tourism

Identifying the actors and the synergies (re)created by ST is crucial to understand the power relations that evokes or discharges. I will use the case of the tourist favela Santa Marta to overlap the theoretic principles of Performativity and ANT to analyze ST within processes of social and physical urban regeneration framed by globalized capital flows. I will identify the key actors playing on four scales at which power forces and negotiations are articulated: Local (L) for the supposedly immobile actors performing ST practices; Regional (R), for those whose actions reach the rest of the city and the State of Rio de Janeiro; National (N) referring on representatives and institutions with federal reach of action; and International (I) for the global stakeholders lobbying on tourism; the Tourist (T) will be the mobile actor (re)creating networks by consuming tourist services.

Favelas have been growing at a fast pace since 1920s in the biggest cities of Brazil and they've been target of public policies aiming their eradication since the 1970s. However, when Rio de Janeiro was being prepared to host of international events -specially the Olympic Games (2016) and the male Football World Cup (2014) (I)- the strategic relevance of favelas territory dragged even more the attention from the government, the media and private investors. With a double discourse of economic development and improvements in mobility and visitors/dwellers experience of the city, Rio's state government (R) allowed major urban development projects (such as the waterfront and port area regeneration, transport infrastructure, and sport and leisure facilities) that caused the eviction of informal settlements of the city center and southern area. Also, a special Pacification Police Unit (Unidades de Polícia Pacificadora, UPP) was set to sanitize communities, clear traffic gangs away and re-establish the State's lost power in the favelas (Freire-Medeiros et al., 2017). While some favelas were being displaced and replaced, others, especially those in the city center that already enjoyed some foreign popularity on their own, were thriving in the tourist sector and benefiting from investments and social projects, for instance: the Mayor's office (R) declared Morro da Providência (the oldest favela in Rio) an Open-Air Museum in 2005; the municipality (R) implemented housing and urban upgrading social programs that embellished house fronts and endowed communities with sanitation and infrastructure (mainly for transportation); favela tours are promoted officially by Brazilian Institute of Tourism (EMBRATUR) (N); EMBRATUR in alliance with CUFA (L) (an organization of young favela dwellers working to enhance education, sport, cultural and citizenship activities in their communities) developed an educational project to train young professionals for tourist related careers.

Santa Marta is a tourist favela located on a hillside in Botafogo, a middle-class neighborhood in the prestigious South Zone of Rio de Janeiro. This was the first favela to have an UPP (R), which contributed to improve safety standards for tours to succeed. Santa Marta also received public investments with the "Rio Top Tour – Rio de Janeiro from a new perspective" program (R) from the state government to upgrade tourist infrastructure in the context of urban regeneration for mainstream events. Probably the most iconic outcomes of that project is the construction of a funicular -free of charge- and the colorful painting of house fronts that will later on turn into the most featured image of that community. Even though the number of visitors have dropped due to the economic and political instability that have been shaking the country for the past years, tourists still take tours mostly during the weekends and demand rises in the summer season.

Favela Scene (L) is a community based tour operator performing tours in Santa Marta since 2012. The very first activity of the tour is taking the funicular: there tourists (T) would share with local residents not only their mean of transportation but their daily routine. This first encounter represents the primal spatialized ordering of hybrid actors triggered by a single tourist practice. At a glimpse, it could be schematized as: Tourist - Favela Scene - Funicular - UPP - Rio Top Tour - Megaevents. By the act of taking the funicular, made possible by the mediation of the local tour guide, tourist are justifying physical changes -by being consumers of it- that was initially motivated by international trends of capital investments allowed by the state government. Even though the utility and beneficiaries of these transformations are arguable, the display of networks shows the direction on the flow of capital, people and information, placing favelas no longer on the margin but on the center of certain political and economic decisions.

The example set before can be transposed to urban geography to draw on the mobility of capital and shows existing, potential and even failed synergies within ST. This practical focus goes beyond the analysis of ST (re)production of representations and contributes to have a more visual sense of the material outcomes of tourism and its capacity to shorten the semiotic and economic distances among urban spaces and communities. This approach encourages to deconstruct the system of representation of slums and reinterpret their spatial-social-economic status based on the ordering of relations with other hybrid actors, disclosing the political implications of ST and its potential to introduce material and practical changes.

Conclusions: towards an interdisciplinary research agenda

In this article I review the literature to date on ST deviating the scope from representations, ontologies and ethical concerns towards the material outcomes of tourism to assert the quest of how ST could be a potential avenue to legitimize slums as urban actors at a spatial, economic and symbolic scale at urban destinations. Applying notions of non-representational geography, I focused on spatially embedded and embodied practices and performances that trigger a certain ordering on the relations between ST heterogeneous actors. By departing from the stand that ST opens a contact zone for tourist, operators, institutions and dwellers, I argue that is during these encounters that actors have the opportunity to (re)negotiate and (re)define the representations on each other.

This field of study calls for interdisciplinary research efforts with a post-structuralist and holistic approach highlighting the entanglement of processes that make sense of the world. Urban geographers can enrich this debate by unveiling the spatial consequences of the power relations that ST entails at every range. At a political economy level, the exposure gained after ST practices and performances can redirect the fixation of capital towards urban slum and potentially re-signify communities due to the global reproduction of myths and images that represent them. On this scenario, slums could be relocated in the center of a political agenda conducted by actor-networks and materialized through urban development policies and tourism governance strategies.

The conceptual framework exposed on this article aims to be empirically applied in the future with field study in Rio de Janeiro. I sought to identify specific culture based ST practices and performances in tourist favelas and trace down the networks created along to draw on the influence these connections have on the making of slums both as urban agents and tourist destination. This methodology yet to be tested could be helpful to analyze the intermingled processes and events on the stages of ST destinations and enhance our understanding of the role that tourism plays on tourist cities all over the world.

WHOSE HERITAGE? CHALLENGES COMING FROM TURNING CITIES AS TOURIST PLACES.

Margarida Relvão Calmeiro¹, Adelino Gonçalves²

¹*University of Coimbra - Department of Architecture, mrcalmeiro@uc.pt*

²*University of Coimbra - Department of Architecture, amsg@uc.pt,*

Abstract: The tertiarisation of society along the second half of the 20th century and the correlated growth of culture and leisure industries created an unprecedented pressure for change on historic centres, creating paradoxical relations between tourism, heritage preservation and urban development. This model of development provided a more intense cross-cultural confrontation, with the corresponding differences in recognition of heritage(s) values. This paper intends to discuss the transformation of heritage from 'shared heritage' into 'consumer good' cross-checking its effects on middle-sized cities Portuguese. The desertification, abandonment and degradation of the old areas created the challenge of their repopulation and their reuse. In turn, tourism has provided reuse of buildings and built new social and cultural dynamics, making it necessary to discuss how can one preserve the values and meanings of historic centres, and for whom. Recently, the Portuguese government has created fundamental changes in housing, rental and rehabilitation policies, with specific financial and legal instruments. However, their effects have not prevented the emergence of local challenges in housing law because of tourism, nor have they contributed to the promotion of new social constructions associated with heritage(s) understood as shared heritage(s). That is, public investment has not been able to enhance the heritage of the historic centres as good of public interest. For its part, the 'touristification' shows it has the power to catalyse its rehabilitation but implies changes that we intend to discuss focusing the perspective of who visits and who lives and assessing the losses and the gains for the communities.

Keywords: shared heritage, heritage-led development, urban rehabilitation, tourism

Introduction

The newest international urban planning policies defend a change in development from the urban expansion model to a densification model, evoking the return to the city. (UN, 2016) The purpose is to reduce the urban sprawl and create sustainable, inclusive and resilient cities, which requires a shift of urban policies to reinforce urban cohesion that needs, in its part, an increase urban rehabilitation.

However, the ancient urban districts, especially since the eighties, were abandoned by the urbanisation policies focused on urban expansion and got decayed. This process is unsustainable but also represents a threat for our understanding of ancient cores as centres of identities, since with the loss of their inhabitants, which have switched the traditional areas for the new modern neighbourhoods built on the peripheries, with larger streets and more comfortable houses, we assist to a loss of significance and importance in urban identity.

Besides the new agendas advocating the return to the city and the need to shift urban development to a rehabilitation model, in Portugal, the 2008 economic crisis contributed to foster these desired tendencies. The

media and the governments defunded the idea that the solution to the crisis would be the investments in buildings rehabilitation and tourism. (Diário Imobiliário, 2016). Consequently, a new wave of interventions in the old cores is taking place, mainly the rehabilitation of buildings for housing and hostels. However, they are being made without any integration into strategic planning for the development of cities, as advocated by technicians and researchers. Many of them applied questionable criteria, and despite regenerating some ancient areas, they are also contributing to their desertification by the abandonment of the few inhabitants that still live in these areas. Due to the pressure caused by tourism or by new social classes, mostly foreign investors, inhabitants are leaving and/or protesting. This change of user from inhabitants to tourists creates new challenges regarding the authenticity and integrity of this heritage.

This paper, focusing on the case of Coimbra, a medium size city, whose university was inscribed in the world heritage list, in 2013, discusses the rehabilitation policies being put in place in Portugal in the last years, trying to understand the real impacts of those interventions and the contribution of tourism to the rehabilitation and revitalisation of the old urban districts. Moreover, it claims that local cultural heritage led development may integrate tourism as an added value.

Urban development and decay of the ancient cores

Cities in Portugal, like in the rest of Europe, have suffered an unprecedented expansion in the last five decades. Due to some political weaknesses and wrong options of urban plans, together with the ease of accessing bank credit to build residential neighbourhoods on the outskirts, many cities doubled their perimeter. The new urban areas solved some of the housing shortages and created easily accessible services and equipment, but at the same time contributed to the gradual abandonment of the ancient neighbourhoods.

The simultaneity of the development model of the last five decades focused on growth, the excessive restrictions of building interventions due to heritage policy, and the lack of private investments to improve the living conditions on old urban districts led to the weakening of its physical and socioeconomic framework.

In addition to these factors, the displacement of trade and services to more accessible areas or large shopping centres built on the outskirts has also contributed to the same effect. Progressively, the old districts, centres of identity, were abandoned and occupied only by the elderly and the poor.

Some urban rehabilitation programs were created to control the raising problems of the old districts, including the provision of financial incentives and the financing of the rehabilitation of degraded housing. Alongside the implementation of these programs, most of the municipalities made some improvements to urban infrastructures and public spaces.

However, as shown by the fragile condition of most historical centres, these policies had very few results, except for rare cases of success, such as Guimarães, although using different methodologies. The reasons for this are several, but they are related to an understanding of urban rehabilitation as a policy associated with safeguarding historic nuclei, with a protectionist purpose only. This purpose made sense in response to the urban transformations of the 19th century but at the end of the 20th century and today, the pressures in the city have changed. Today the city and the country population is sharply decreasing, and the most concerning problem of the ancient areas is the abandonment and the desertification.

Moreover, the interventions carried out within these rehabilitation programs were restricted to building rehabilitation and requalification of the public spaces, always limited to the preservation of its image, disregarding the most significant weakness, the lack of people and the need to attract people.

Today the challenge is to attract people and maintain the liveability of the ancient cores; however, this can become even more difficult when we consider the demographic projections for Portugal, marked by a low birth

rate and an ageing population. According to the National Statistical Institute (INE) by 2060, the Portuguese population will have decreased around 40 per cent (INE, 2014). With this framework, the question might be who will use this heritage? Moreover how? How will it be appropriated?

The previous models of urban management policies proved to be ineffective in attracting people and containing desertification, likewise the consequent degradation of the physical and social environment.

Tourism, rehabilitation and urban transformation

The World Tourism Organization (WTO) defines Tourism as "the activity of persons travelling and staying in places outside their natural environment for [...] no more than one consecutive year for leisure, business and other purposes." (WTO, 2005) Although not a new activity, it has developed mostly after the Second World War with the stabilisation of the middle class and in recent years it has grown more sharply, mainly because of the increase of low-cost airlines, which have made air travel accessible to a higher number of people.

As for cultural tourism, ICOMOS defines "all forms of tourism that allows visitors to get an experience of the cultural aspects of the place of destination, their way of life, gastronomy, topography, environment, cities and towns, as well as their sites historical, cultural and artistic performances." (ICOMOS, 1999) In this sense, culture and heritage become a factor of differentiation, attracting people and investments, and through tourism becomes an economic catalyst.

Today cultural tourism has crucial importance for the economic development of some countries, namely Portugal, directly promoting sectors such as hotels, restaurants and handicrafts, but also for the preservation and valorisation of cultural heritage as a distinguishing factor of each city.

In fact, in recent years, in Portugal, tourism has been seen as an opportunity for development and enhanced some changes in urban policies. The first measures were local and municipal initiatives and limited to sectorial actions, improving public space, rehabilitating some monuments and creating a set of cultural events to attract visitors.

At the same time, the government has encouraged private investment in rehabilitation through tax incentives and by a set of political measures, mainly putting into force the New Urban Rehabilitation Legal Regime (2014), which has simplified the rehabilitation process¹, and streamlined the New House Rent Law² and the first Lodging Law³. Also, some other initiatives such as the strategic promotion of tourism with marketing operations stressing the country's excellent conditions, with rich landscapes, good weather, but most importantly the

¹ The first Urban Rehabilitation Law (RJRU) was approved by Decree-Law 307/2009, of October 23, amended by Law 32/2012, of August 14 and by Decree-Law 136/2014, of September 9. Also noteworthy is the publication of Decree-Law 53/2014, of April 8, which creates an exceptional and temporary regime applicable to the rehabilitation of buildings or fractions built for at least 30 years or located in Areas of Urban Rehabilitation.

² The New House Rent Law was approved by Law no. 6/2006, of February 27 and amended by Law no. 31/2012, of August 14, by Law no. 79/2014, of December 19 and Law no. 42/2017 of June 14.

³ The first legal regime governing local lodging was Decree-Law no. 128/2014. This decree was the subject of the first (small) amendment in April 2015, with Decree-Law no. 63/2015.

climate of peace and security, and the affordable costs of living for most European countries. Finally, and the most contested measurement was the encouragement for foreign investment, by tax reduction for those who decided to live and invest in the country⁴. This measure enhanced a wave of building rehabilitation works in the ancient cores. Despite the advantages of the investments, this contributed to the rise of property prices and encouraged the abandonment of the local population that could not afford to live in the ancient areas.

This policy had more significant effects in Lisbon and Porto the most prominent and more accessible Portuguese Cities. In fact, in these cities, most of the rehabilitation interventions were focused on the construction of luxury housing, much of it for foreigners. Between 2010 and 2016, the numbers of foreigner people living in Lisbon increased from 43 142 to 53 470 (INE |SEF/MAI, PORDATA, 2011). Moreover, the prices of housing for rent increased and for acquisition increased up to 25,2% depending on the area of the city (Idealista, 2017). The abandoned of these districts and the gentrification process is becoming a severe social problem in the two major cities, Oporto e Lisbon. Also raises the issue of the authenticity of these heritage areas where the population that forms the basis of its identity and local culture tends to disappear or to be replaced by tourists.

Besides, these interventions are based only on the economic impacts of tourism and made for the tourist to see. Also, the focus is to preserve the exterior image and renewing all the interiors, in some cases even disregarding the urban pattern by connecting several buildings to increase the building area and changing the typology and the structure of the buildings. Although called rehabilitation, these new processes have nothing to do with the urban rehabilitation that experts have come to define and to advocate. However, they are the result of processes of adaptation and urban transformation that need further reflection and problematization, because they are more than design options and demand a new responsible urban policy.

The rise of the housing prices caused social protests, contesting the municipal policies or the lack of them. They required “the urgent adoption of a national and municipal housing policy that favours and stimulates leasing, public and private, with rights and duties, security and stability”.

Coimbra. Alta and Sofia World Heritage

Coimbra is an excellent example of the difficulty of maintaining and attracting population to its old nucleus. On the other hand, after the inscription of its University in the World Heritage List in 2013⁵ (UNESCO-WHC, 2013), the city faces an exponential increase in the number of tourists and have begun a new dynamic with the rehabilitation of buildings in the ancient core.

⁴ We highlight some measures to attract foreign investment, such as the very favourable tax regime for Non-Residents (since 2009) and Real Estate Investment Funds, as well as the Golden Visa or Residence Permit for Activity program of Investment. The effects of these measures were most pronounced in Lisbon and Porto.

⁵ On the basic criteria (ii) Exhibit an important exchange of human values over a given period of time, or within a particular cultural area, on the development of architecture, technology, monumental arts, town planning or landscape design (iv) Offer an outstanding example of a type of construction and of an architectural, technological or landscape ensemble, which illustrates significant periods of human history. (vi) Be directly or tangibly associated to events or living traditions, ideas, beliefs or artistic and literary works of outstanding universal significance. (UNESCO-WHC, 2013)

However, like all other cities, urban sprawl was responsible for the desertification of the ancient areas of Coimbra, in fact between 2001 and 2011, the population decreased around 20,4% in the four ancient parishes (Almedina, Santa Cruz, São Bartolomeu and Sé Nova), decreasing from 17 538 inhabitants to 13971 inhabitants.⁶ The opening of commercial areas in the new peripheral zones fostered this expansion, which resulted in the closing of the traditional commerce that characterized the Baixa, the old commercial district, situated by the river. Also, the construction of two university campus in the peripheral zone of the city fostered the displacement of students from the Alta area, that is, foundation hill where Coimbra's University is seated.

The desertification and the degradation of the ancient areas fostered some municipal interventions mainly in public spaces, improving the pavements and creating stairs or by technical and financial support to the owner who intended to rehabilitate their houses, framing these interventions in national support programmes. However, these incentives have not been able to reverse the depopulation trend.

In addition to these interventions, the municipality began to envisage a plan that would safeguard the ancient core and promote urban rehabilitation. In 2003 while the city staged the Portuguese Cultural Capital event, the municipality requested the University a detailed study of the physical and social characteristic of Baixa, to drawn up a plan. However, and despite this survey, the plan was never drawn up.

After years of abandoned and without policies, in 2012 was finally approved a strategic plan for urban rehabilitation of this, and another two areas, one for the riverside and another for Alta, including the University hill and the surrounding buildings. This strategic plan proposed a set of six objectives and defined a set of 30 structuring projects for urban rehabilitation. Meaningfully, two of the six objectives referred to the promotion of cultural heritage and tourism. The objective number five proposed *valuing the cultural heritage*, planning the rehabilitation of some monuments and particularly the revitalization of Rua da Sofia (a street built in 1537 to set the University) and the development of tourism, proposing an increase in the number of hotels in a specific area and the creation of facilities for tourists. (Parque Expo, 2012)

One year later, in 2013 the University was inscribed in the List of Mundial Heritage, and since then, the city faces a sharp increase in the numbers of tourists. This tourism has allowed the development of a set of private investments. However, at the public level, the approved plan and the structuring projects already built have not been able to encourage change and captivate more residents or even prevent the departure of existing ones.

While private investments are limited to the economic profit and do not question who lives in and who uses the ancient core, creating services for tourists use. Thus, the old residential buildings have given place to new lodging houses, like hotels and hostels. Only in four years, between December 2013 and December 2017 the capacity of lodging increased from 2348 beds to 3873 beds, this increase was sharper in the numbers of local accommodations, from 23 to 197 while the number of hotels increased from 19 to 20 hotels.⁷

⁶ The reduction o the numbers of inhabitants is not exclusively of the ancient parishes, but the decrease is much sharper, in the entire city the population decreased from 148 443 inhabitants to 143396 inhabitants, around 3,4%. (INE, 2011)

⁷ In December 2013 there were registered 23 local accommodations with capacity to accommodate 106 guests, while in December 2017 there were registered 197 local accommodations with the capacity for 1408 guests. Hotels, in 2013 were 19 with the capacity to accommodate 2301 guest and in December 2017 there were 20 hotels with the capacity to 2561 guests. (TURISMO DE PORTUGAL, 2017)

Similarly, the number of souvenir shops is increasing and replacing the local commerce and sell the same products sold in any souvenirs shop of any other Portuguese city, with no relation with the city, its unique values or its traditional products such as porcelain.

At the same time, the municipality has encouraged tourism by replicating attractions and events. Some are promoting the local culture, such as fado's recitals, gastronomy fairs and local folklore performances, others less typical, such as the mediaeval or handicraft fairs that are taking place in other cities.

However, the increase in tourism has led to the rise in the rents price and lead to the detachment of residents of these areas. Even the student rental market, which in the Alta of Coimbra was very important, is today at risk. The buildings occupied by students are giving place to local accommodations for tourists, and students are looking for housing in the periphery, next to the new university campus.

It is time to rethink what is happening and act before it is too late to do something. Tourism can and shall remain a driving force of Coimbra's development. However, local authorities must prevent the loss of the resident population. Otherwise, the old core might become an open-air museum or a large lodging facility.

Some notes and recommendations

Cities are much more than places of living, production, storage and socialising, they are attractive and consumer goods, mainly because of its distinguishing features and its built heritage. Tourism has become an essential activity for many cities. However, once tourism is primarily an economic activity, it should be considered that the city and its heritage by becoming a consumer product, must respond to the expectations and motivations of the market. In this sense, cities tend to become artificialized constructions (Ashworth, G. J. and J. E. Tunbridge 1990), such as thematic parks, replicating actions and models, such as "street markets", "ethnic neighbourhoods", "medieval fair" that we must counteract.

In the current competitiveness between cities, every city must be attractive, especially medium-sized ones (Gomes, 2012), however in a scenario of demographic decrease more than attract tourists; the older urban districts must attract residents. The resident population is the base of the ancient cores' identity and heritage.

The challenge is to establish a global vision for the city future and then define a policy and management framework for the city and its heritage that can articulate the various agents and articulate the development of tourism with housing, the central function of all cities.

Heritage-led development can be a driving force of local pride, enhancing the character of the neighbourhoods and increasing the attractiveness of a place to invest and live (Barrera-Fernandez, 2016). Besides, it is also necessary to reinforce rules for housing and local accommodation, ensuring the dynamics and variety of functions in these areas, thinking mainly in the more permanent residents; in their quality of life, in their needs, in their jobs, in their daily lives. Investing in public transport and urban mobility, in schools, in green spaces, in support for the elderly, in civic centres, in cultural spaces of proximity, create housing incentive programs with credit lines for those who want to live in these areas and develop areas of conditioned leases.

Also, drive policies that include those who inhabit and create this heritage, creating forums meetings, measures to listen to the needs of the residents as the participatory budget, among other initiatives. Moreover, involve the

communities in the advantages of tourism, for example, by preparing and sensitising the population so that they can be the tourist guide, showing the visitors their neighbourhood.

Moreover, the urban planning and management policies cannot be limited to the old centres but need to recognize the city as a whole, with a holist understanding. Nonetheless, more than traditional urban preservation policies is required an integrated approach that involves physical, economic, social and environmental initiatives, in particular, consists of the integration of residents into decision-making processes, ensuring consistent governance, shared and inclusive.

Only in this way, it will be possible to respond to the new challenges that desertification and tourism are placing, especially since the nomination of Portugal as the best European destination for the third year (Santos, 2019). This designation promises an increase in tourism which can only be sustainable with local management and policy capable of driving the transformation of the current urban development, and then "people [will] have rediscovered their land after a long time." (Távora, 2003)

Planning and designing
green infrastructures

Green Infrastructure: from benefits to planning

Simonetta Alberico,¹ Paola Vayr²

¹Città metropolitana di Torino, Direzione Sistemi Naturali - simonetta.alberico@cittametropolitana.torino.it

²Città metropolitana di Torino, Direzione Sistemi Naturali - paola.vayr@cittametropolitana.torino.it

Abstract: The increase of urban land use and in general human activities lead to disruptive effects on ecological functionality, environmental services, land naturalness and landscape quality, especially evident in peri-urban areas. Territorial planning and management have to aim at a better coordination among settlement and transport development policies, biodiversity and landscape protection, hydrogeological structure, land use for agricultural and forestry purposes. In this new planning scenario Green Infrastructure (GI) can play a strategic role. The MaGICLandscapes project, to which the Metropolitan City of Turin (CMTo) is taking part, focuses on how to identify, protect and enhance GI for the benefit of the environment and society at transnational, regional and local level. Collaborating with stakeholders, the project aims at providing land-managers, policy makers and communities with tools that help to assess and increase GI functionality. CMTo is testing the methodologies provided by the project in its case study area - Po Hills around Chieri - in order to assess GI functionality, to develop a Public Benefit Assessment Tool that takes over local specific needs and to provide the decision makers with an Action Plan in order to support them to maximize benefits provided from GI within their spatial planning and management process.

Keywords:: green infrastructure; ecological functionality, ecosystem services, landscape planning.

Introduction

Green Infrastructure (GI) is a concept, not a set of rules and there are many interpretations of this concept across Europe and the rest of the world.

As we all know, the benefits of well-planned and well-managed GI are manifold: they go beyond those often associated with natural green spaces such as providing space for wildlife. GI also provides the benefits and services that we as human beings require to thrive as well as to maintain a quality of life. GI should be considered as *multi-functional*, with different types providing different services/benefits dependent on local needs and circumstances. Those needs include making space for and protecting wildlife, providing access to nature, recreation and social interaction, reducing flood risk, improving despoiled landscapes (including those within our settlements) and reducing the negative effects of climate change among many others. A lot of research have already proven GI to be a sound investment with returns far higher than the initial investment (i.e a proven reduction in costs to health services where **GI** is accessible and promoted).

Finally GI is a key strategy in the European Landscape Connectivity Agenda aimed at reconnecting vital natural areas to urban hubs and restoring and improving their functional roles. It is an essential planning concept towards protecting natural capital and simultaneously enhancing quality of life.

While this approach is not yet implemented in Central Europe's landscape planning policies, which seldom consider the ability of land to deliver multiple benefits, ten partners from five Central European countries (Austria, Czech Republic, Germany, Italy, Poland) are working together within the project *Managing Green Infrastructure in Central European Landscapes* (MaGICLandscapes)¹ to introduce public to the GI concept, to improve its management and enhance the benefits and the services it provides.

The goal of MaGICLandscapes is to provide tools and information to help policy-makers, land managers and communities to manage GI in a way that meets local needs and maximizes the benefits it provides at the local, regional, national and transnational level.

The concept of GI

The first output developed by the MaGICLandscapes project was the *GI Handbook - Conceptual & Theoretical Background, Terms and Definitions*. It covers issues such as definitions of important terms or GI and its relationships to territorial laws/policies of the five partner countries and EU regulations and programmes. As a conclusion of this work the GI definition on which all partners agree is the one provided by the European Commission:

"a strategically planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services such as water purification, air quality, space for recreation and climate mitigation and adaptation. This network of green (land) and blue (water) spaces can improve environmental conditions and therefore citizens' health and quality of life. It also supports a green economy, creates job opportunities and enhances biodiversity. The Natura 2000 network constitutes the backbone of the EU green infrastructure (EU Commission 2016)"

As this Handbook covers the territorial/international needs for a green infrastructure approach, its contribution to sustainable development, and how a GI approach can address specific territorial and common challenges, we expect it to be used as a reference for stakeholders and target groups wanting to know more about GI.

To increase and maximizing the public benefit that can be achieved through GI approaches to issues such as health and well-being/recreation, mitigating climate change, flooding or loss of pollinators, supporting productivity of the land, protecting and enhancing our natural capital, as a second step, a guidance was developed to assess the structure and types of GI at the transnational level: the *Manual of GI Mapping - Decision support tool*. Also if there are manifold datasets available, only few are suitable for a transnational GI mapping. Due to its full coverage and a low amount of misclassification the CORINE land cover (CLC) dataset was proved to be the more appropriate dataset. The suitability of data provided by the European Copernicus Programme was chosen for assessing GI in Central Europe, together with the provision of a method for ground-truthing at a more regional level. At first a GI map on transnational scale for whole Central Europe was produced based on the transnational legend using CLC data from 2012. The CORINE classes were then classified in a simplified

1 MaGICLandscapes is a project cofinanced by the European Commission within the Interreg Central Europe 2014-2020 Program. <https://www.interreg-central.eu/Content.Node/MaGICLandscapes.html>

transnational legend with just three classes (GI, GI under specific circumstances or partly GI, no GI), based on a coordinated legend among the project partners., as seen in Figure 1.

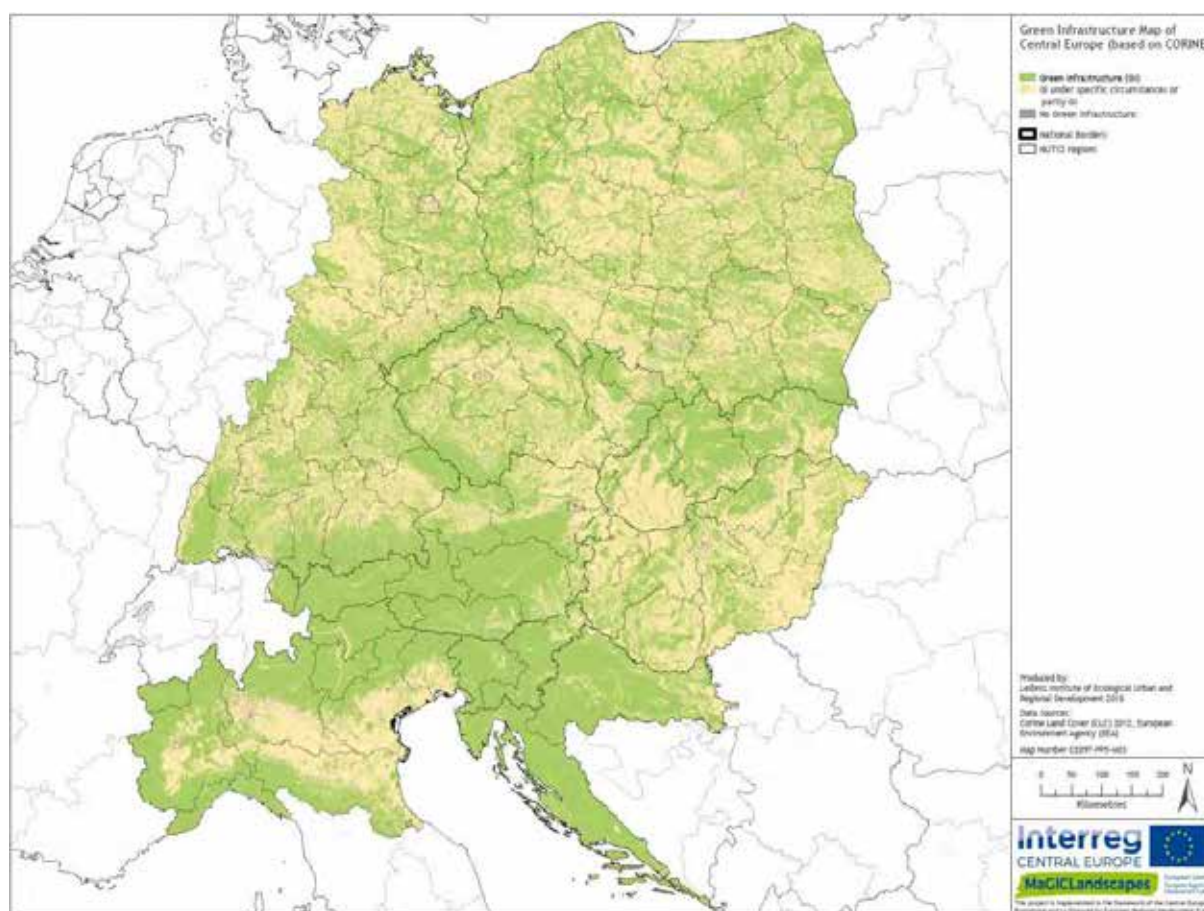

Figure 1: Map of green infrastructure for the Central Europe Programme Area – simplified legend (CORINE land cover data 2012)

Due to some shortcomings regarding transnational data, such as their spatial resolution, accuracy or the type and scope of the classified elements, the mapping was refined at the national/regional level and nine regional maps, one for each case study area, were produced. Among them CMT0 produced the map showing the GI/ GI under specific circumstances or partly GI/ not GI elements within its case study area “Po Hills around Chieri” as seen in Figure 2

Also if these maps provide a useful tool to raise awareness into the public of GI and its benefit to humans, a close cooperation with local stakeholders is needed in order to elaborate strategies and action plans for enhancing the existing green infrastructure resource in Central Europe.

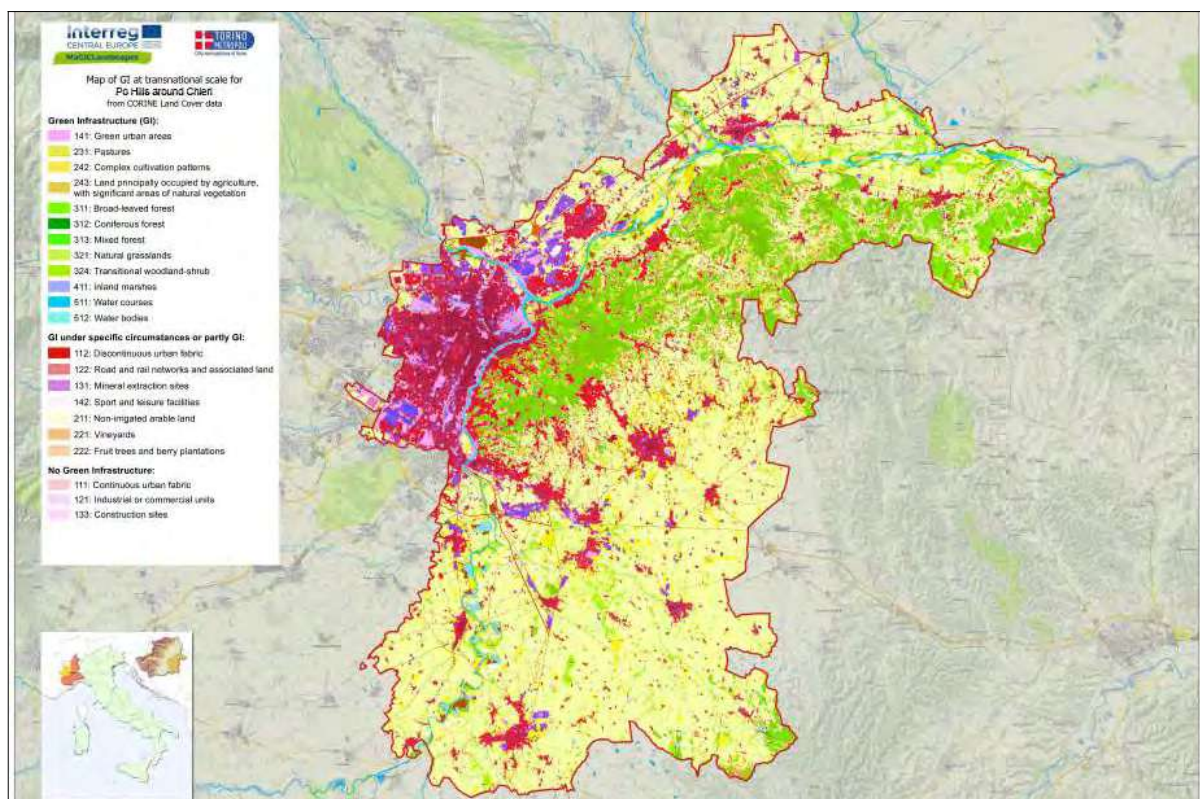

Figure 2: Map of GI for the Italian CSA Po Hills around Chieri based on the transnational legend using CLCdata from 2012 refined with Land Cover Piedmont data.

GI functionality assessment

The field survey is a key component for the testing of the assessment method for elements of GI. To gain in-depth knowledge of crucial zones within our case study areas (core zones, nodes, corridors, etc...) and to close gaps of coverage of geodata each partner tested a shared methodology for the assessment of the naturalness level of the main elements of GI. CMTo selected two sample quadrants of 1 square kilometre located in areas of special interest: the Natural Protection Zone of Arignano Lake and the "Isolone Bertolla" inside the Natural Reserve and Special Conservation Area of Meisino and Bertolla Island. Through a field work activity we attributed a range of local hemeroby² (human influence) according to a 7 degree scale for gradients of human influence: from the highest level (ahemerobic) = natural/non-disturbed to the lowest level (metahemerobic) = totally disturbed or "artificial", as seen in Table 1

In combination with the regional biotope catalogue based on the list of EUNIS habitats (level 3), produced by each project partner referencing the extract of EUNIS to their national/regional classification system, habitat types and landscape features were digitalized in a geographic information system (GIS) integrated with the information on the level of naturalness detected through the field surveys.

2 We adopted the Reference scale for hemeroby values of Joint Research Centre, European Commission - Institute for Environment and Sustainability

Hemeroby value	Hemeroby level	Degree of naturalness	Example	Processes/Human impact
1	Ahemerobe	Natural	Bogs, tundra	No disturbance
2	Oligohemerobe	Close to natural	Forest with species typical for the site, semi-natural grasslands	Limited removal of wood, pastoralism, minor changes in matter circles, emissions through air and water
3	Mesohemerobe	Semi-natural	Forest with species atypical for the site, extensive grasslands	Clearing and occasional ploughing, extensive grazing, rare and small doses of fertiliser
4a	β -euhemerobe	Relatively far from natural	Annual crops associated with permanent crops (extensive), agro-forestry	Use of fertilisers and biocides melioration, ditch drainage
4b			Intensive grassland, extensive arable land,	
5a	α -euhemerobe	Far from natural	Intensive arable land (short rotations), intensive vineyards	Deep plowing, planting, major changes in matter circle, drainage, heavy use of fertilizers and biocides
5b			Cereal monocultures, rice fields and irrigated crops (intensive)	
6	Polyhemerobe	Strange to natural	City green, golf courses, pits	Strong changes in biocenosis, covering of the biotope with external material
7	Metahemerobe	Artificial	Streets, buildings	Sealed surface, biocenosis destroyed

Table 1: Reference scale for hemeroby values (Joint Research Centre, European Commission)

Connectivity analysis

As in digital image analysis concepts of mathematical morphology are widely used (Soille, 2013) we opted to use the Graphical User Interface for the Description of image Objects and their Shapes (GUIDOS)³ to perform the Morphological Spatial Pattern Analysis (MSPA). The MSPA is a generic and universal pattern analysis framework provided by a custom sequence of morphological operators (Soille & Vogt, 2009) that performs a segmentation on a binary image to identify and localise mutually exclusive morphometric feature classes describing the shape, connectivity and spatial arrangement of image objects by mapping and classifying them into seven categories: Core, Islet, Perforation, Edge, Loop, Bridge, and Branch (Vogt et al., 2017) as seen in Figure 3.

3 GuidosToolbox is a free software collection by Peter Vogt (Joint Research Centre, European Commission) and offers a variety of modules targeted to investigate several spatial aspects of raster image objects, for example pattern, connectivity, cost, fragmentation, etc.

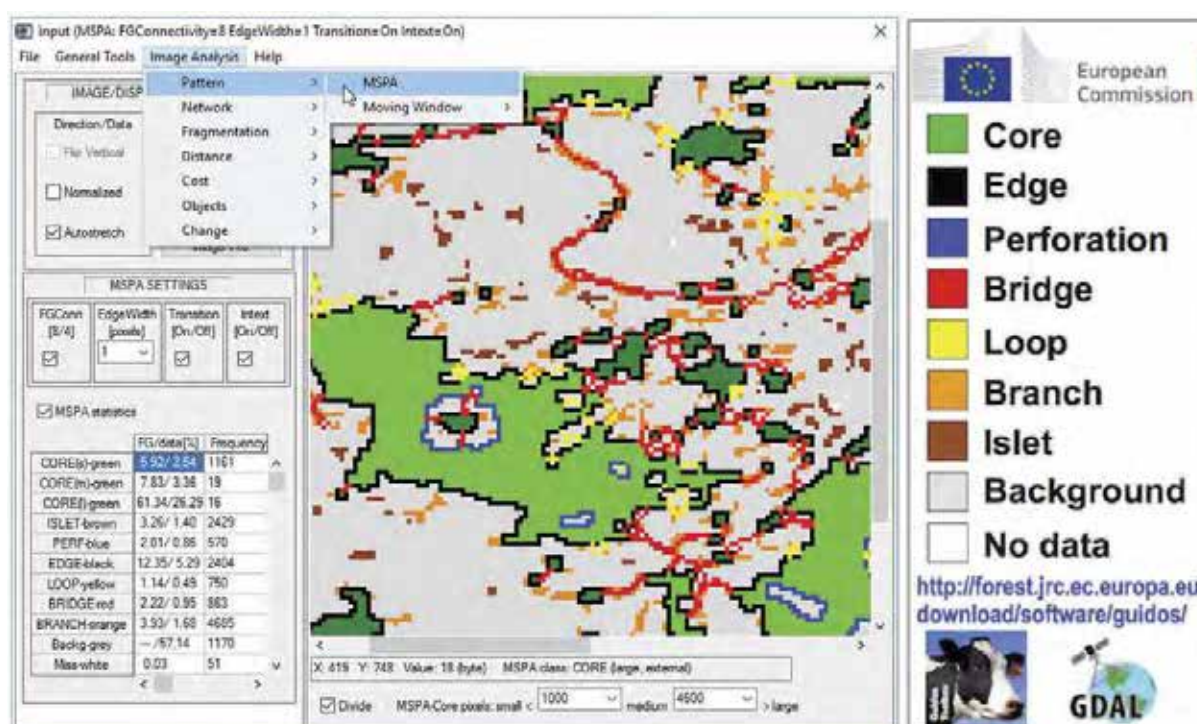

Figure 3: The GuidosToolbox software interface showing the MSPA pattern analysis illustrating various morphological feature classes: Small Core areas (dark green); large Core areas (green); Core area boundaries (Edge/external–black, Perforation/internal–blue); connecting pathways between different Core areas (Bridge–red) and returning back to the same Core area (Loop–yellow); isolated forest patches and too small to contain Core area (Islet–brown); and Branches (orange), reprinted from (Vogt et al., 2017)

In terms of assessment of GI connectivity MSPA uses a series of image processing routines to identify hubs, links (corridors), and other features after reclassifying the raster land-cover map into foreground (Green Infrastructure) and background (all other classes) (Vogt et al., 2007). To align the terminology of GI, the category of *core* was considered equivalent to hub, and *bridge* as synonymous to link (corridor). As the input map must contain only two data classes: foreground and background, we integrated the geodata-base with the attribution of each CLC class as GI or not GI element. The attribution of the patches belonging to the "partly GI" classes was performed considering as not GI all the artificial and anthropic surfaces, with the exception of the Green urban Areas and some specific typology of agricultural uses as shown in Table 2. Moreover, in the application of MSPA in MaGICLandscapes we used eight-neighbour connectivity and edge width values of five (5) respectively ten (10) (depending on the pixel size of 20 respectively 10 metres) corresponding an effective pixel size of 100 metres for this analysis.

CORINE Land Cover (CLC)			
Level 1	Level 2	Level 3	Revised
1. Artificial surfaces	1.1. Urban fabric	111 Continuous urban fabric	
		112 Discontinuous urban fabric	
	1.2. Industrial, commercial and transport units	121 Industrial or commercial units

Table 2: Correspondences between CLC classes and GI/not GI classes

In the CMTo case study area “Po Hills around Chieri”, as shown in figure 4, the MSPA produces a Core area of GI with notable extension in the upper half part of the area and some smaller ones along the rivers within the southern part of it. Both, the Po river and the Stura river are identified as bridge (red). The landscape structure in terms of provision of GI decreases from the north-east to the south-west due to the change in the morphology of the territory that passes from the hill to the flood plain. In the hilly upper area the cores of GI seem to be provided almost exclusively by broad-leaved and mixed forests with a more or less high level of hemeroby, while, going down in altitude mixed formations of complex cultivation patterns consisting of vineyards, wood-lots, pastures and land principally occupied by agriculture with few spots of areas of natural vegetation predominate. In correspondence of the city of Turin, instead, the flat territory at the foot of the hills on the left bank of the Po river is almost entirely covered by urban areas.

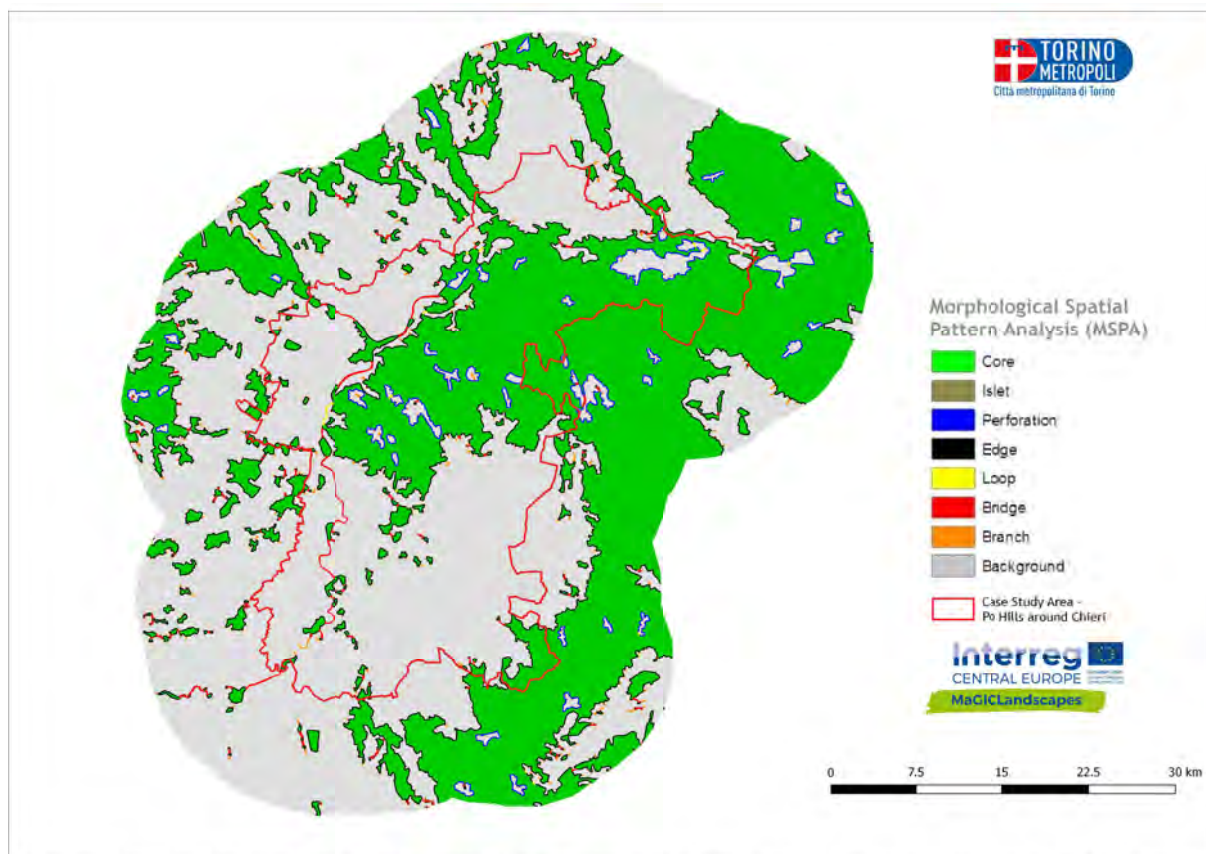

Figure 4: Result of the Morphological Spatial Pattern Analysis of the extended case study area “Po Hills around Chieri” in Piedmont Region – yellow circles indicate the primary links which should be reconnected.

In these zones, as in the southern part, , due to the fact that the land is mostly occupied by intensively farmed agricultural landscapes, complex cultivation patterns and, along the Po river banks, mining activities and sand and gravel extraction sites, there is a generalized lack of GI as shown in Figures 5 and 6.

Figure 5: Corridor cut by a urban settlement

Figure 6: Canalised water with poor occurrence of vegetation

Network analysis

Another informative feature of the Guidos Toolbox is the automatic detection of connecting pathways between core areas of image objects based on the results of the initial application of MSPA and their ranking with respect to the relative importance of each component, node and link, in a given network consisting of Nodes (MSPA class: Core) and Links (MSPA class: Bridge respectively connectors between various Cores); the remaining MSPA classes are neglected (Vogt et al., 2017).

This analysis shows the connectivity importance for each node and each link of the network, displaying their relative importance in decreasing intensity of black (nodes) and red to green (links) colour. (Saura et al., 2010).

Within the CMTo case study area, as shown in Figure 7, the network analysis highlighted two nodes, respectively of high and medium importance and value: the confluence between the Stura and the Po Rivers (actually a Protected and Special Conservation Area) and the upstream connected area, always along the Stura River: both these areas represent the main corridor through the flat plain that connects the Po hills with the mountain valleys. Its conservation and implementation in terms of connectivity preservation is therefore essential.

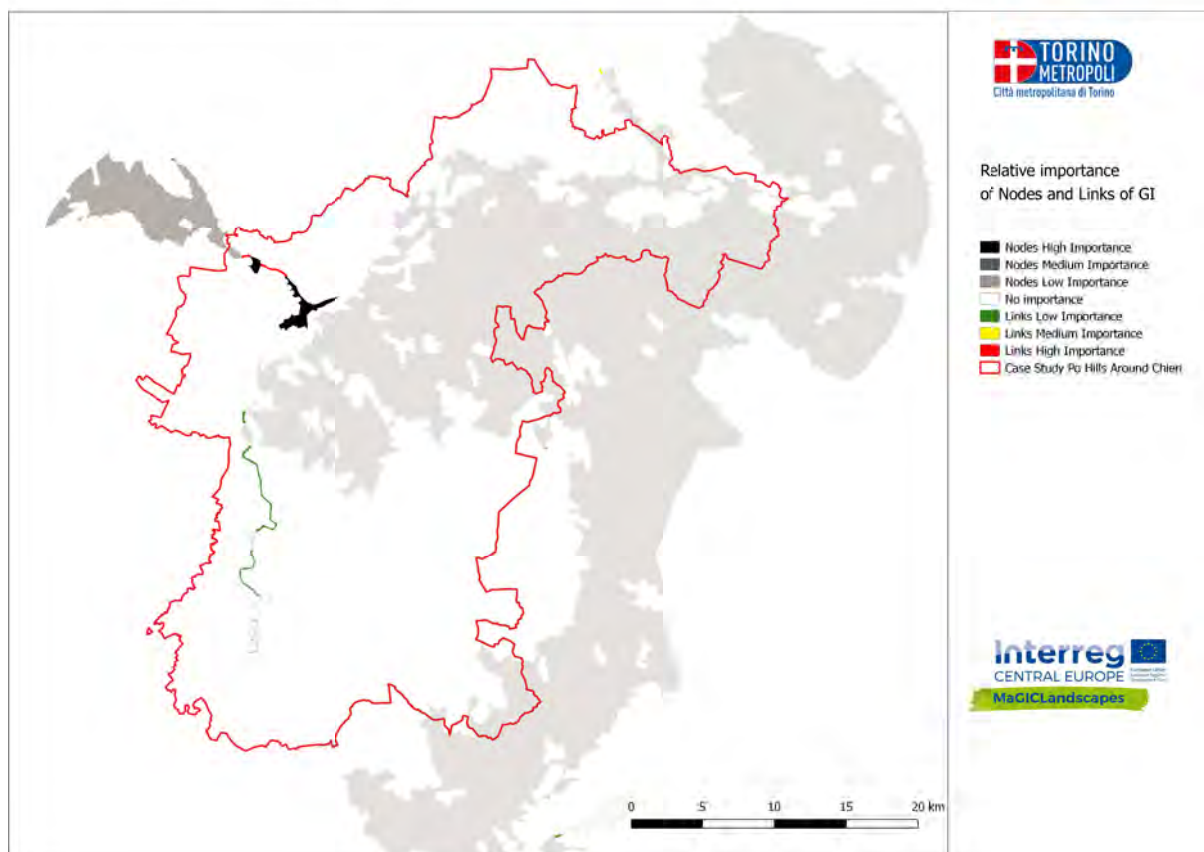

Figure 7: Result of the network analysis based on MSPA of the CMTo case study area "Po Hills around Chieri". In black the most significant areas in terms of connection.

Measuring Euclidean Distance

To measure the degree of intactness, shape and spatial arrangement of patches on a given binary map, the analysis methodology of Euclidean Distance and Hypsometric Curve (HMC) offers a practical and effective method of implementation. This module is available in GuidosToolbox, too and uses the same input data as the MSPA described above. This application creates maps of objects of interest showing the Euclidean distance map inside and outside those objects. This type of analysis may be further pursued to illustrate the influence zones of each object and to derive the pairwise proximity between neighbouring objects. Proximity, then, may be used for the establishment of cost-efficient reconnecting pathways in restoration planning (Vogt et al., 2017).

In terms of the connectivity of GI the generated distance maps provide spatially explicit information allowing for highlighting hotspots of highly fragmented areas or those dominated by well-established networks of GI. The spatial information of these distance maps of GI may be of high importance for monitoring, planning and risk assessment.

Additionally the simple, yet intuitive analysis scheme is easy to communicate and can be related to a variety of spatial planning measures by illustrating the degree of fragmentation or intactness.

Through the analysis of Euclidean Distance of elements of GI, as shown in Figure 8, existing connections and extensions in turquoise to blue colours illustrate both efficient links and reconnecting pathways useful to enhance the connectivity of the network of GI based on the Cores represented by the woodland and mixed formations of complex cultivation patterns displayed in green and red colours.

Deepening the investigation we can observe that the actual and potential connecting elements are represented almost entirely by the hydrographic network, both the natural as the canalised. The natural rivers Dora Baltea, Orco, Malone, Stura and Sangone, in addition, obviously to the Po river, form the main ecological network between the Turin hills and the alpine foothill area, despite the widespread presence of urban fabrics and roads.

But the results underpin the importance as an element of GI of the channeled streams, too. Also if they are often characterised by a lack of natural buffer zones like riparian strips, woodlands or wet meadows. they can be a useful support for the recreation of the ecological connectivity.

Figure 8: Result of the measurement of Euclidean Distance of GI in the extended case study area “Po Hills around Chieri” in Piedmont Region with highlighting of high value links that should be joined.

Conclusion

The considerations made above are the result of a large scale analysis. Deepening at a more local scale we noted that also within the hilly wooded areas, a less uniform and homogeneous situation comes out.

As the main objective of the MaGICLandscapes project is to provide local land managers, policy makers and communities with the tools and knowledge to ensure the persistence of GI functionality and the consequent benefits to society, of course they couldn't base managing choices on so raw data. For this reason, with the upcoming project activities, we are going to apply the MSPA analysis using the Land Cover Piemonte (2010) a more detailed geodata produced on the regional basis, to better survey the different typologies of land use cover.

Moreover a "Public Benefit Assessment Tool - PBA - is envisaged by the project to enable organisations to develop GI strategies and action plans based on evidence from GI assessment and local needs, opportunities, and threats.

The PBA will be aimed at producing an analysis of the Public Benefit situation on a local scale in order to allow the definition of strategies and action plans to preserve and increase GI in each partner case study area. Thanks to this integrated approach, strategies and action plans will be based on the evidence of the situation in the targeted areas and will respond to specific local and regional needs,

will mitigate the threats and will seize the opportunities for the local stakeholders to maximize multiple benefits from investment in GI.

The PBA procedure is going to be based on two contemporary processes:

- the assessment of the level of "available" public benefits provided by the territory of each case study and their location within the analysed territory
- the gathering of the information to identify existing needs and perspectives regarding the implementation of the Green Infrastructure network in as well as the collection from the territory and from the institutional stakeholders of additional data on the benefits provided by the existing Green Infrastructure (as an integration to what was obtained with the previous process).

On the basis of the land use, a series of maps will be produced presenting the distribution of the benefits supplied by each territory. Subsequently, on the basis of the single needs or the single opportunities linked to one or more benefits, each partner will identify the better policies and strategies that could support the drafting of the local action plans.

Acknowledgements

The authors thank all the MaGICLandscapes project partnership and, in particular, Marc Neubert and Henriette John from Leibniz Institute of Ecological Urban and Regional Development (IOER) for the coordination of the Work Package 1, Thomas Wrška and Florian Danzinger from Division of Conservation Biology, Vegetation Ecology and Landscape Ecology (CVL) of University of Vienna for the coordination of the Work Package 2, Gianluigi Rossi, Maria Rita Minciardi and Simone Ciadamidaro from Italian Agency for New Technologies, Energy and Sustainable Economic Development (ENEA) for the coordination of the Work Package 3 and, of course, Elmar Csaplovics and Christopher Marrs from the TU Dresden's, lead-partner of the project.

The Aniene River: a green infrastructure to set up a metropolitan strategy

Romina D'Ascanio¹, Anna Laura Palazzo²

¹*Department of Architecture, Roma Tre University, romina.dascanio@uniroma3.it*

²*Department of Architecture, Roma Tre University, annalaura.palazzo@uniroma3.it*

Abstract: The latest territorial government tools have embedded green infrastructure with the aim to preserve the natural character and to stimulate regeneration processes of public open space and social cohesion, especially in peri-urban areas, where suburbs melt with agricultural and natural landscapes, and along the rivers, often neglected. This contribution will investigate the preparatory works for the new General Master Plan of Tivoli. A special focus is about the Aniene River as a potential Green Infrastructure, capable of restoring continuity to the ecological and functional fragmentation of landscapes heavily compromised by urban growth and production pressure. During the last decades, peri-urbanization and industrialization phenomena in these areas have ignored the river basin. The results are features of brownfields, industrial archaeology sites, informal settlements whereas open space is abandoned or unfittingly occupied by landfills, junkyards, brownfields. The Aniene River system boasts a relevant geographical dimension in order to test a strategic metropolitan governance able to address different sectoral issues. In this direction, the Aniene River Contract, that has recently started its official process, complements the traditional planning tools and represents a main opportunity for participatory processes where the community turns out to be central.

Keywords: Aniene River, planning tools, green connectivity, cultural benefits, metropolitan strategy

Introduction

After the Second World War, urbanization was characterized by a multiplicity of settlement and land occupation patterns that do not convey an overall idea of the city. Definitely, due to a series of extensions, enclaves, settlement interruptions and resumption, the Roman area, the so-called 'Agro Romano', witnessed huge aggression of agricultural land and exploitation of natural resources. This contribution focuses on the linear city that lies between Roma and Tivoli along the low course of the Aniene River before its confluence in the Tiber River.

A specific feature of the so-called 'Tiburtina City'¹ is long term interdependence between the two outposts of Rome and Tivoli, favoured by the different uses of the river. Over time, it served as a waterway for the transport of essential goods like high quality olive oil, for the shipment of travertine and other construction materials extracted from the quarries, as a reservoir for domestic water demand, as an energy source for typical proto-industrial activities linked to paper mills and ironworks, and, lastly, for electricity needs for the Capital City.

Today, many plants are abandoned, standing as monuments of industrial archaeology among quarries, brownfields, factories still in use, illegal settlements, and shopping centres.

The low course of the Aniene basin, with some 800.000 inhabitants, falls under the jurisdiction of different local authorities (Figure 1) – the Municipalities of Tivoli and Guidonia Montecelio, the Roman Municipal Districts II, III, IV, V, VI – and is featured by a great variety of historical and natural assets displaying manifold landscapes thoroughly intertwined with the Aniene River.

¹ The term 'Tiburtina City' is here referred to the huge hook constituted by the eastern Rome districts and the Municipalities of Guidonia Montecelio and Tivoli, following the Tiburtina consular road and the Aniene River.

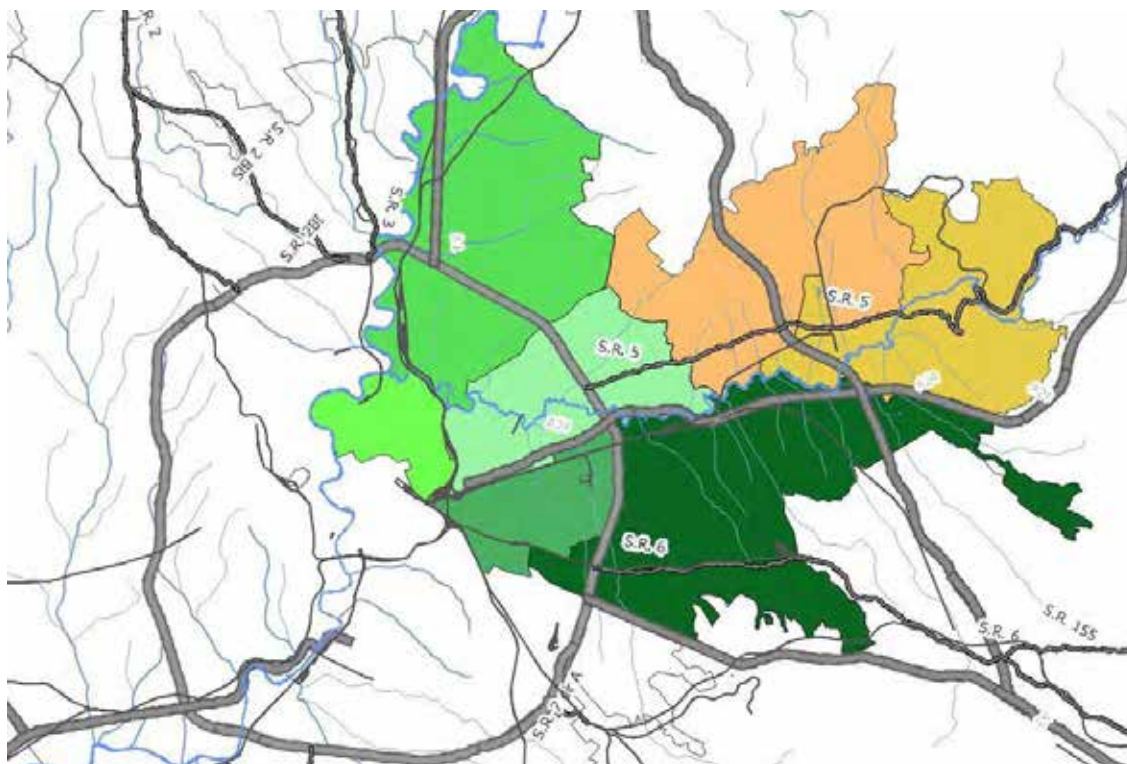

Figure 1. The Metropolitan area east of Rome. In green the Municipality of Roma, in yellow Tivoli and in orange Guidonia Montecelio.

GIS elaboration: Romina D'Ascanio. Sources: <http://websit.cittametropolitanaroma.gov.it/>, http://geoportale.isprambiente.it/tematiche_pt/idrografia/, <https://geoportale.regione.lazio.it/>

Despite being the backbone of such linear city gathering unsuspected naturalistic qualities along with excellence industry, the Aniene discloses settlement and environmental criticalities and is mostly perceived as no man's land. Thus, the future of the Tiburtina Valley is challenged both by the needs of an 'urban continuum' to be treated as a whole and by ecological connectivity issues. Although these aspects sound dissonant, convergence should be found in order to effectively intervene by matching sectoral policies, as proved in the case of ecological transition objectives reported in urban and metropolitan governance agendas all over Europe. Within this frame, the Aniene river is to be intended as the key connection factor, playing a strategic role in terms of resilience, and thus requires to be managed and designed on a case-by-case basis.

A glance of the recent history

In 1913², the Tiburtina area was a rural context – the 'Agro Romano' by the side of Rome and the 'Agro Tiburtino' by the side of Tivoli – controlled by huge estates: a mosaic of large tesserae dotted with rare farmhouses and extensive exploitation patterns. In the first post-war period, due to strong urbanization, the natural overflow of the city coupled with spontaneous or authorized 'urban nucleuses', such as suburbs, isolated allotments, hamlets or centers of agricultural colonization. Over the years, spontaneous settlement processes linked to migratory flows invested Rome and its hinterland in successive waves. Local concentration of an urban 'underclass' mixed with farmworkers due to persistent land ownership in the hands of few, and the strong production vocation recalled by the Aniene and the Roma-Tivoli railway, are among the main reasons leading the Regime to establish in 1941 the II Industrial Zone of Rome, for a total of 1,500 hectares, on the left bank of the Aniene.

² It is referred to '*la Carta dell'Agro Romano*' of Pompeo Spinetti, published in 1913, which shows the cadastral ownership subdivision

Housing needs of the second post-war period allowed for new hamlets and settlements randomly occupying and compromising the Agro. These enclaves variously display urban lifestyles on remnants of rurality: small residential plots are interspersed with agricultural uses wholly or partly efficient, with *terrains vagues* and industrial sites.

In fact, it is no longer possible to take into consideration the logics and the syntax behind previous arrangements related to the river and its multiple utilities. This reflection points out that landscape quality objectives and transformation rules need to be rethought from the opportunities stemming from residual open spaces, including both natural and historical signs still in place³ (Figure 2).

Nature and culture: planning tools and bottom up initiatives

Worldwide, ecological continuity has become crucial in addressing landscape fragmentation in new planning and management tools. On the one hand, it guarantees the biodiversity conservation and, on the other hand, it provides a wide range of benefits for people and society. In this direction, the European Green Infrastructure Strategy has prompted towards cross-disciplinary approaches linking biological and ecological issues to cultural and economic effects of well-being.

The Charter of Rome on Natural and Cultural Capital⁴ clearly underlines how the European natural capital is closely related to cultural values. Landscape construction is embedded in agricultural practices, economic systems, cultural backgrounds, communities’ traditions and habits and respectful use of natural resources. From this perspective, the Charter would like to strengthen the EU Birds and Habitat Directives (2009/147/EC; 92/43/EEC) goals to meet “ecological, scientific and cultural

³ In the Metropolitan City of Rome, soil consumption touches 71,000 hectares, increasing by 500 hectares between 2012 and 2015 at the expense of agricultural land.

⁴ In 2014, within the activities for the Italian Presidency of the Council of the European Union the Ministry for the Environment organized the Conference ‘The Natural and Cultural Capital: the Future of Europe’ at the Botanical Garden of Rome and, the informal EU Biodiversity and Nature Directors meeting at the Ministry of Foreign Affairs. The final working document was the ‘Charter of Rome on Natural and Cultural Capital’. It is a tool aimed at raising awareness of the important synergies between the Natural and Cultural Capitals, as well as increasing the integration of biodiversity issues into sector policies, also with a view to developing a greener economy. The main themes of the Charter concern the improvement of knowledge and investments on Natural Capital, the guarantee of a high functionality of natural ecosystems, the integration between Natural Capital and Cultural Capital and finally the creation of synergies between green infrastructure, rural and urban areas

requirements, while taking account of economic and recreational ones”. In this scenario, connections among natural resources, signs of history and human perceptions build up a complex system that also inspired the European Landscape Convention (2000) where, according to a holistic view, territorial vocations and communities’ expectations might converge.

Matters of fact and law – both the different uses and utilities along the river, and general and sectoral planning tools -, are actually raising relevant environmental, settlement and production conflicts. The issue of ‘open space’ as a *proxy* for connectivity is approached quite differently by the Regional Landscape Plan (RLP)⁵, whose aim is to preserve and enhance landscape patterns, and by the Provincial General Plan of the Metropolitan Area (PTPG, approved in 2010). This latter, in providing a strategic overview for local planning tools entrusted to implement its provisions, has drawn up the Landscape Ecological Network (LEN, Figure 3), that represents the main green infrastructure within the metropolitan areas (Blasi *et al.*, 2014). One of the most important purposes of this Plan is to acknowledge nature and history as main features of identity and environmental sustainability, and to assess consistency of ongoing transformations with the historical construction of the territory.

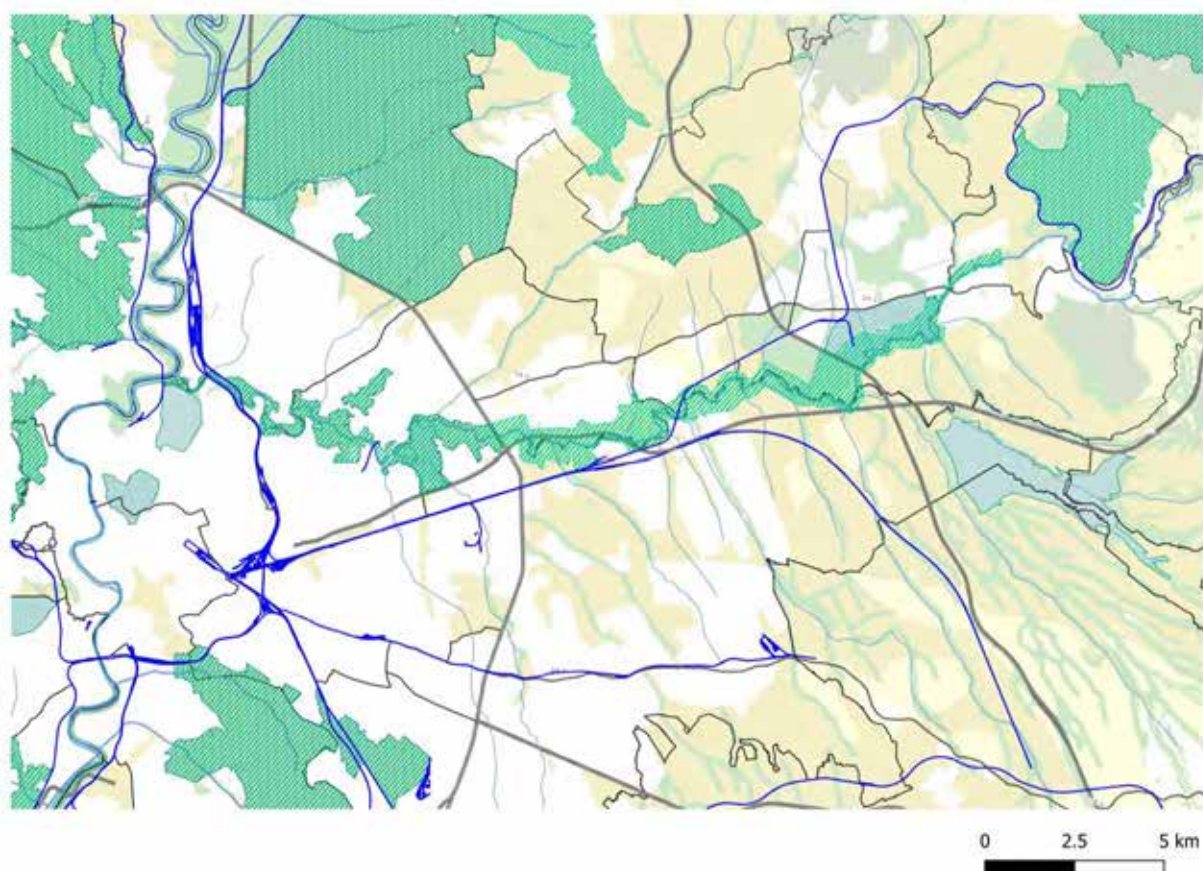

Figure 3. Landscape Ecological Network of PTPG, 2010.

GIS elaboration: Romina D’Ascanio. Sources: <http://websit.cittametropolitanaroma.gov.it/>, http://geoportale.isprambiente.it/tematiche_pt/idrografia/, <https://geoportale.regione.lazio.it/>

Furthermore, the PTPG takes as a frame the three general objectives proposed in several EU directives, such as the improvement of economic and social cohesion, the safeguard of natural resources and cultural heritage and the creation of a more balanced metropolitan competitiveness, explicitly calling upon the dimension of functional agglomerations, with their peculiarities. The ‘Tiburtina City’ is mentioned within this frame.

⁵ Despite having undergone procedural steps for some fifteen years, the RLP has not been approved yet.

At the basis of the strategy of the Plan there is the priority to enlarge some protected areas, such as the Aniene Park of a further 1,300 hectares⁶, in order to systematically protect, reconstruct and extend the allocation of naturalistic-environmental resources, promote the recovery of nature's features, even in the residual areas where naturalistic reconversion is possible.

The Landscape Ecological Network is based on levels of biodiversity and ecological functionality. It is constituted by core areas, buffer areas, and landscape connections.

The object of our analysis is mainly part of the so-called 'Lower Aniene Valley Unit' and has three core areas: the Site of Community Interest (SCI) '*Palude della Cervelletta*', the SCI '*Travertini delle Acque Albule*' and the *Valley of San Vittorino*. The Aniene River, together with its tributaries and the buffer boundaries provide landscape connection in natural and semi-natural areas.

Finally, a wide portion of the agricultural land uses may perform as ecological connection between agricultural land and settlement systems. The agricultural landscape mosaic corresponds to the still existing portions of the ancient 'Agro Romano Tiburtino' with a prevalence of olive groves.

At city level, the General Masterplan of Rome (2008) set up its own Ecological Network, but the municipalities of Guidonia and Tivoli still have General Masterplans dating back to the 1970s. During the drafting of these General Plans, both cities had addressed some criticalities, such as illegal occupations and land subdivisions, that have worsened over the last decades of building speculation. Overall, the demand for housing has seen private interest prevailing over the public one.

Since 2016, in order to face the obsolete and ineffective General Master Plan, the Municipality of Tivoli has set up a Special Office for the preparation of the new one, whose first results have been presented in May 2019. Due to the interference of manifold rules belonging to different planning tools (included the River Basin Management Plan, RBMP), and affecting the same areas, the main idea was to build a common ground and a common agreement around the Aniene system as the backbone of the entire settlement.

Being the Aniene River the core issue for the establishment of the Aniene Park, other areas, notably the protected sites, the UNESCO sites, several plots with olive oil groves, '*pizzutello*' vineyards or with typical quality agriculture productions still in place in the 'Agro Tiburtino', and plots with vegetable gardens, have been taken into account by the new General Master Plan: the overall idea is to structure the green network arranging even some minor ecological connections.

Paradoxically, the Aniene better performs the ecological role than the one linked to leisure time: to access it all along its course stays a critical issue. Time after time, morphology (deep slopes), property, illegal uses, poor mobility system, prevent people from enjoying free and safe use. Thus, the river is mostly perceived as a 'foreign element' in the community life, and only recently neighbourhood committees have claimed the need to regain possession of their historical and cultural heritage. These expectations couple with the emergent slow and eco-tourism fashion and with an increasing leisure time for citizens.

These insights have emerged along the path of the 'Aniene River Contract'⁷, for which the *Manifesto of Intent*s was signed in June 2018. As early as December 2018, the first three thematic working tables were held on the issues of water quality, hydrogeological risk and sustainable development for the three sections of the river - high, medium and low course - gathering wide participation from associations, local authorities and citizens. The path of the Contract, thanks to the awareness campaigns of the 'Aniene Committee'⁸, has been led by the Comunità Montana 'Valle dell'Aniene'

⁶ The lower course of the Aniene in the Municipality of Rome within the Grande Raccordo Anulare is already protected by the Aniene Natural Reserve, under the management of 'RomaNatura' Authority and 'Insieme per l'Aniene' non-profit organization. However, the area still suffers problems due to anthropic pressure and illegal activities.

⁷ The River Contract is an agreement that allows to adopt a set of regulations in which criteria of public utility, economic return, social value and environmental sustainability equally take part in the search for effective solutions for the river basin's recovery. (World Water Forum, 2000)

The River Contract is a voluntary tool of strategic and negotiated planning for the protection and better management of water resources, valorization of river landscape and mitigation of hydraulic risk, contributing to the local development. (Italian Environment Code, 2006, mod. 2015)

⁸ The 'Aniene Committee' is made up of numerous associations and citizens, committed to promoting concrete actions for the care of the river basin. They have been working together for more than ten years.

and currently collects about seventy actors among institutions, municipalities and associations. The River Contract (RC) has proved a new governance approach capable of matching nature, environment and historical landscape, able to create a common ground of discussion and shared ideas among all the stakeholders operating in the basin, trying to include private sectors initiatives by empowering communities and raising awareness in public sector.

Although this path is in its beginning with some difficulties in terms of organization, participation, economic support, the Aniene River Contract is aligned not only with the Water and Floods Directive, but also with the Green Infrastructure Strategy, both for environmental principles and community participation, with the perspective to enhance historical and landscape systems of great relevance.

Insights and perspectives

Along the ‘Tiburtina City’, different typologies of green infrastructure (Church *et al.*, 2014) can be found, such as forests, green space, protected areas, urban parks, blue infrastructure, farmland, historical parks, etc. (Figure 4).

The river itself could be seen as a green-blue infrastructure able to deliver different cultural ecosystem services to improve sense of place, by reinforcing the awareness of cultural heritage.

Figure 4. The Aniene River landscape. In the background the ‘Casale di Sant’Eusebio’, a medieval fortified settlement. Photo credit: Romina D’Ascanio, April 2019.

The cultural ecosystem services, which are one of the four key service components identified in the ecosystem services frameworks, are sometimes less tangible or measurable but strictly related to human well-being and social cohesion. The Millennium Assessment (2005) defines cultural ecosystem services as the non material benefits people obtain from ecosystems such as cultural diversity, knowledge systems, educational values, aesthetic values, social relations, sense of place, cultural heritage values, recreation, and ecotourism.

The opportunity to activate a comprehensive and shared strategy, starting from the river and the open space as reservoir of natural and cultural resources, represents a way to set up a convergent green infrastructure agenda matching planning perspective and bottom-up initiatives. A structured and participative strategy on the river could improve not only its environmental quality (air, water, biodiversity), but generate a variegated spectrum of wellbeing benefit, interacting between environmental space and practices (O'Brien *et al.*, 2017).

The need to build a vision focused on the main signs of nature and history able to overcome the inconveniences of our controversial recent urbanization, should be a key feature of the Roman area. Notwithstanding, on the grounds of heritage, despite century-old acquaintance between people and a huge legacy likely to better shape our everyday life by inspiring place-specific regeneration processes, general neglect is still the norm.

The 'Via Tiburtina' and the railway between Rome and Tivoli, which is being strengthened thanks to the construction of the second track, will enhance the metropolitan mobility system. The integration between such traditional infrastructure and the green one is expected to largely contribute to the regeneration of deprived neighborhoods along the Aniene River.

In such contexts, public promotion could activate widespread recovery interventions with particular attention to management issues, which are currently a relevant challenge in urban regeneration, taking into account compatible proposals from private initiative and community participation.

This scenario calls upon the new Metropolitan City, entrusted with additional powers to rule strategic planning processes and likely to play a decisive mediation role among stakeholders, identifying and addressing effective policies towards sub-functional areas homogeneous in terms of history and development trends. According to the subsidiarity principle, all government levels are advised to cooperate on the aspects that intercept their own scope for action. Environmental policies are most promising, since they advocate cross-disciplinary tools. They should provide governance models able to match top-down compulsory policies towards the primary ecological networks (Aniene Natural Reserve, Monte Catillo Natural Reserve, etc.), with bottom-up practices concerning local connections, stemming from municipalities and private action.

Complementarity, or rather solidarity, between city and country, currently assessed by reciprocal flows of tangible and intangible assets, and benefits in terms of ecosystem services, should be supported by green infrastructure and slow mobility networks.

Planning and designing green infrastructures

Milton Keynes, the “Forest City”

Malaury Forget¹

¹AE&CC, Université Grenoble Alpes, forget.m@grenoble.archi.fr

Abstract: This article presents the case of the British New Town of Milton Keynes. Programmed in 1967, this true urban laboratory is the setting of numerous experiments. From the origins of green infrastructure in landscape planning to city planning, we will explore how its designers contributed to preserving and creating habitat areas for wildlife. The landscaping project implemented is sophisticated and detailed, designed according to a search for efficiency in a long-term perspective. Milton Keynes foreshadows some of the current challenges related to territorial development and green infrastructure.

Keywords: Milton Keynes, landscape planning, road verge, park network

Introduction

To participate in this special session, I have chosen to present a case study of Milton Keynes, a New City in England. This article is organised in three parts. The first identifies the contextual elements necessary to understand the city's project and its challenges, the second details Milton Keynes' specific landscape planning and the third puts into perspective the contributions brought through this project in relation to current issues.

1. Origins of an urban laboratory

The New Town movement began in England in 1946, following the publication of the New Towns Act. This document preceded the planning of around thirty new cities over a period of about thirty years, exceeding by far the initial objective to develop ten cities. The creation of these cities or city extensions took place during the reconstruction period following the Second World War and aimed to unclog the capital city of London, which had become saturated by polluting industries and insalubrious. Milton Keynes is one of the last planned New Towns and is the most important and ambitious New Town developed in Britain.

Programmed in 1967, Milton Keynes is implemented at a later date and in different circumstances as compared to the first New Towns. Reconstruction in the context of the creation of the first New Towns is marked by a strong development of industries accompanied by an improvement of living

conditions and an increase in household consumption. The quest for opportunity and freedom of choice defines the time of Milton Keynes' construction.

Milton Keynes' master plan was designed between 1967 and 1970, just before the two oil crises of 1973 and 1979, which deeply impacted consciences and economies worldwide. These crises, among other situations, became triggers for ecological awareness. The 1970s and 1980s were defined by the development of a great variety of experiments around alternative lifestyles and autonomous housing systems. (Maniaque, 2014, p. 52-76)

Influenced by this historical context and the experience of previous New Town developments, Milton Keynes is projected to offer a new way of life, redefining housing, work, travel and entertainment. Abundant experimentation on sustainable housing was carried out in the 1980s and today autonomous vehicles are developed and tested in the New Town. Also, its urban planning is one of its most highlighted assets today, both in terms of its heritage value and as reference for future planning.

The development area designated for the implementation of Milton Keynes was made up of agricultural land and composed of about ten villages that were integrated into the city project. Several master plans were produced, the first one by Bucks County planner Fred Pooley and later by the planners of the Milton Keynes Development Corporation[1] (MKDC) before a feasible project could be achieved, taking into account the budgetary constraints imposed on the designers. Very different planning solutions were considered thanks to Milton Keynes' status as a New City, where almost everything was to be conceived and created from the beginning.

The city of Milton Keynes presents a number of specific urban and architectural features. We will focus on the development of green and natural spaces, one of the major aspects of city planning conditioning the quality of living environments. We shall see how issues that arise today related to territorial planning are already taken into consideration in this context.

2. Green infrastructure: policy tool and precedents

Today, fifty years after Milton Keynes' planning, European natural areas are degraded and their role as habitat for a great number of animal and plant species is compromised. To respond to this situation, the European Environment Agency (EEA) aims to develop green infrastructures as planning policy tools. And so, the European Union in its *green infrastructure strategy* recommends that they be fully integrated into spatial planning policies.

Gorm Dige (2015) explains that green infrastructure is a tool to understand the advantages offered to human society by nature, and to mobilise investments to sustain and enhance these benefits in order to generate ecological, economic and social services through natural solutions.

Here we borrow the EEA definition of green infrastructure as explained by Gorm Dige (2015) and defined as a strategically planned network of natural, semi-natural areas and green space that provide ecosystem services. These services, defined as supporting our well-being and quality of life, include water and air purification, biodiversity conservation, biomass production or the mitigation of surface runoff. A combination of services can thus be obtained from one vegetated area. Most of these services are essential but require significant investment and maintenance efforts when they are implemented as “grey”[2] infrastructure solutions, while green infrastructure solutions prove more socially advantageous and less expensive.

Green infrastructure is a spatial and ecological concept aimed at promoting the vitality and resilience of ecosystems. It helps to preserve biodiversity and promote ecosystem services for the benefit of humans, such as reducing the effects of global warming, identifying and preserving critical habitat areas and connecting them.

In 2015 the EU biodiversity strategy aimed at preserving and improving ecosystems and their inputs through green infrastructure by 2020 and for 15% of degraded ecosystems to be restored.

Once again, according to Gorm Dige, green infrastructure remains a new and complex concept for which there is no widely recognised definition. He also points out a lack of indicators and quantitative analyses.

However, Mayté Banzo (2015) explains that green infrastructure originates in landscape planning, which is defined as the development of the urban environment through the landscaping of “open spaces”. This planning model was introduced by Frederick Law Olmsted [3] (1822-1903) in the 1870s in the United States and aimed at ensuring a connection between landscape spaces at different scales, organising the city around public spaces and landscaped traffic lanes (Banzo, 2015, p. 7). The green belt imagined in Ebenezer Howard's garden city project (1850-1928) falls into the green infrastructure project category. In fact, Ebenezer Howard and Raymond Unwin (1863-1940), with whom he collaborated, as well as Patrick Abercrombie (1879-1957), who put into application his recommendations for the Greater London Plan (1944), incorporated what is known today as green infrastructure in their development projects (Banzo, 2015). The Modern Movement dissociates urbanised areas from agricultural or natural areas but integrates tree-lined walkways as part of the urban tissue (V7 walkways, according to the categorisation of roads proposed by Le Corbusier (1933)), mainly in linear form, which ensure the continuity of habitat of animal and plant species (Corbusier, 1933). According to Le Corbusier, parks and tree-lined walkways allow wildlife species to travel across the city. Their linear shape is similar to the layout of traffic lanes allowing vehicles and their users to move within or around the city.

Figure 1 - Grid road, park and river network plan, Milton Keynes. Source: from the author and Campbell Park, Silver photography, November 2018. field research. Source: from the author.

The green infrastructure, considered as a policy tool by the EEA, stems from previous work related in particular to landscape planning. It is therefore possible to enrich future green infrastructure projects with elements from theories and applications developed since the end of the 19th century. Consequently, Milton Keynes allows us to study the application of principles defining the green infrastructure approach.

3. Milton Keynes: supporting for the creation of natural habitats

Before 1967, most of the geographical area defined for the implementation of the New Town of Milton Keynes was composed of agricultural land hosting a small variety of wild animal species and few habitat areas. Wildlife in rural areas is therefore under great pressure from the use of pesticides (Kelcey, 1975) and monocultures. Animal species would take refuge in hedges, on roadsides and in the few remaining forests. Most of these habitats were already the product of human intervention.

When Milton Keynes was conceived, two linear parks crossing the city from North to South were designed with the aim of safeguarding natural areas as biodiversity reserves. The Grand Union Canal and the River Great Ouse are two pre-existing natural or semi-natural elements. They host a variety of fauna and flora that the designers of Milton Keynes chose to preserve. The two linear parks are connected through the Milton Keynes city centre, as shown in figures 1 and 2. It is an area of activities and businesses with a lower density of vegetation and a lesser variety of species as compared to the parks, but which aims at ensuring ecological continuity.

Figure 2 - Diagram of the park network, Milton Keynes. Source: from the author.

As Michael Edwards (2001) reviews the history of the City's planning project, he explains that the dense land reservations along grid roads result from specific traffic related changes. Initially the main roads had a speed limit of 50km/h and intersections were managed by traffic lights. Activities, housing structures and bus stops were to be implemented along these main roads. But as traffic lights are replaced with roundabouts, automobiles start circulating at 100km/h and houses and activities are pushed away from the grid roads and into the grid squares, as shown in figure 3.

The density and activity zones, initially located along the main roads, are moved and end up being implemented in the middle of sectors, which has consequences on the activity of local centres and on the use of public transport. The entire organisation of neighbourhood units is also affected. And so MKDC planners and landscape architects propose a landscape plan to be applied along the grid roads.

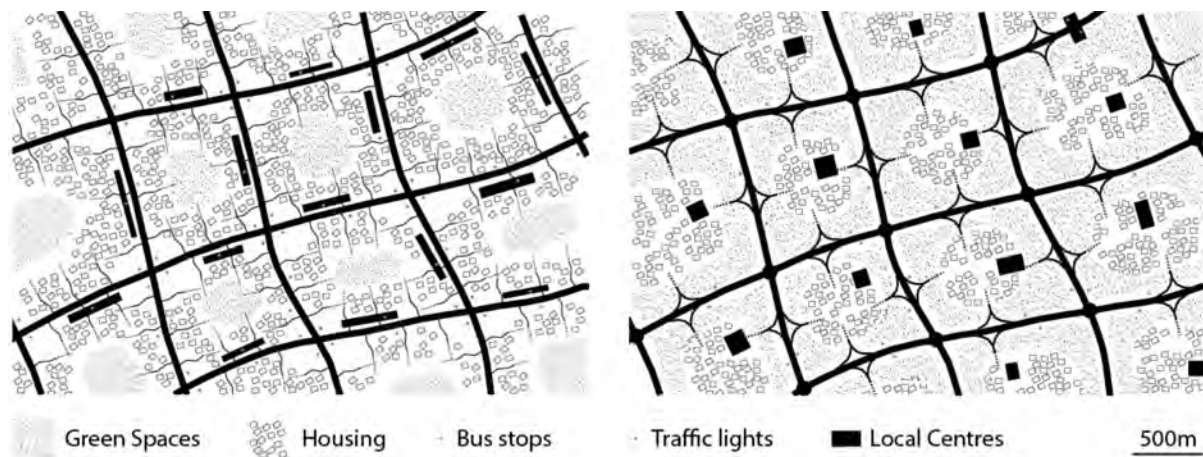

Figure 3 - Sector organisation around grid roads - project/development. Source: Edwards, 2001. Redrawn by the author.

4. Roadsides in the service of ecosystems

This landscape project is detailed in the *Ecological Studies of Grid Roads in Milton Keynes* (Kelcey, Milton Keynes Development Corporation, 1974). One year after the publication of the study, John Kelcey, a member of the MKDC, writes an article in the journal *Urban Ecology* (Kelcey, 1975) in which he analyses the development of road verges in the New Town from an ecological perspective, focusing on the diversity of wildlife habitat areas along roads.

Figure 4 - View of a grid road. Silver photography, November 2018, field research. Source: from the author.

The *Ecological Studies in Milton Keynes, Grid Roads* (1974) show that the design and implementation process developed into four phases and included recommendations for short- and long-term maintenance. Diagrams (plans, sections and drawings) shown in figures 5 and 6, were

Figure 5 - Section across a grid road verge sowing the zonal structure. Source: Kelcey and MKDC, 1974. Redrawn by the author.

Figure 6 - Plan of grid road zonal structure. Source: Kelcey and MKDC, 1974. Redrawn by the author.

produced in order to provide landscape recommendations for roadsides. The proposed spatial organisation is intended to produce variations that are pleasing to the eye. The diversity of plant species provides a wealth of habitats for animal species and can therefore accommodate a variety of animal species present on the site. Grid roads are a unique means of creating landscaped areas that can compensate for or even increase the quality and variety of habitats for animal species. This potential improvement is due to the fact that agricultural monocultures preceded the city, limiting the diversity of natural habitats.

The recommendations made are detailed and define planting areas and the vegetal species to be included, taking into account the maintenance required in the short term and long term.

In terms of design, roadsides are divided into zones, structured together. Each zone plays one or more specific roles. The plant species that make up each area and the frequency of their maintenance are specified in the landscape plan.

As shown in figures 5 and 6, Zone 1, a strip one to two metres wide, hosts grasses that require mowing three to four times per year while Zone 2 is occupied by medium-length grasses, to be cut once every year. Zone 3 is home to tall grasses that require cutting once every two to three years. Lastly, Zones 4, 5 and 6 require some intervention during planting and in the years following planting, and very little maintenance once the plants are developed. Zone 4 is mainly composed of shrubs that form a visual screen between the road and the residential areas. Zone 5 is planted with small trees and shrubs. And Zone 6 is composed of forest trees combined with plant species found in Zones 4 and 5. An urban planning rule determines that the tallest buildings may not exceed the height of the tallest trees. This landscaping treatment makes it possible to circulate on the grid roads almost without seeing the city. What makes MK its name as a forest city.

In addition to spatial instructions, the *Ecological Studies, Grid Roads* (1974) state that certain roadside areas are to be used to sow seeds and plants from threatened areas elsewhere in the city, particularly during the construction phase of the project. Other areas are saved to carry out experiments making it possible to assess the impact of the use of certain soil types. Specific recommendations are also given for the maintenance of green spaces. For example, it is specified that no herbicides may be used except under exceptional circumstances. These clarifications provide indications as to the designers' vision, leaning toward respecting wildlife and preserving soils.

5. A quest for efficiency and sustainability

The process of designing and setting up vegetated areas along grid roads unfolds over four stages, each playing a particular role to ensure the quality of the final result. As stated by John G. Kelcey (1975), the first stage concerns engineering and landscaping, that is, the study and development of

conditions for the implementation of the future green infrastructure. This involves levelling the ground, making embankments or excavations and managing the slopes and type of soil, which are mainly dictated by the layout of grid roads and can be modified by engineering design. For example, on portions of grid roads located near residential areas, the excavated soil generated through road construction activities is used to create mounds that reduce vehicle noise. The second stage consists of depositing a layer of soil on the surface of the developments carried out during the first phase, then sowing a mixture of grass and herbaceous plant seeds. The third stage concerns the planting and short-term management of vegetation. This stage extends until the canopy is almost closed and therefore includes the required maintenance to control the development of vegetation during the first five to six years. Once the canopy is closed, the weeds give way to woody plants requiring less frequent interventions. It is specified that landscape project design and maintenance activities are complementary and may not be considered separately.

This organisation demonstrates that MKDC aimed to take into consideration the investment and maintenance required to operate the infrastructure, from the design phase and with a long-term perspective. This reflects a systemic vision and a search for efficiency defining the overall project as well as guiding the design of all of the city's infrastructure and facilities. While efficiency issues and even profitability issues in some areas remain central, MKDC never underestimated the aesthetic value of all solutions considered.

6. The aesthetics of diversity

John Kelcey (1975) explains the decision to incorporate non-local plant species. England is not a region that naturally hosts a wide variety of plant species, so the designers chose to import plants from other regions that are compatible with the local climate in order to provide variety in landscaping. The designer made sure that these new species did not compromise the natural habitats of animal species or even increase biodiversity - variety was mainly sought-after due to its aesthetic appeal. The Ecological Studies on Grid Roads, (Kelcey, MKDC, 1974) specifies in Appendix 1 that trees and shrubs must be planted randomly in order to achieve a natural appearance.

The aesthetic research linked to landscape design carried out throughout Milton Keynes is often associated with the notions of variety and diversity.

7. Milton Keynes, an example in the face of current challenges

- The quality of the living environment

Philippe Clergeau (2012) invites us to consider environmental issues in the city as requiring an “act of construction and reinforcement” of natural spaces, instead of a few measures aimed at avoiding their degradation. Today, landscape design is an intrinsic part of sustainable development and is no

longer practiced for merely sanitary or aesthetic purposes. Indeed, many ecosystem services can be made available through green spaces and are classified into three categories according to the Millennium Ecosystem Assessment, as follows: provisioning (production of food and water, biomass), regulating (of ecosystems, climate, disease) and cultural (aesthetics, recreation). These three categories of ecosystem services contribute to the well-being of dwellers across the cities and territories concerned, through four essential components: security (food, access to resources), access to basic needs (a balanced nutrition, employment, housing), health and social relations. These four components grant opportunity and freedom of choice (Millennium Ecosystem Assessment, 2005), precisely one of the conditions that Milton Keynes originally aimed to provide (Milton Keynes Development Corporation, 1970a and b).

The three categories defined by the Millennium Ecosystem Assessment concern ecosystem services potentially provided by green infrastructure. In practice, oftentimes they remain under-developed or untapped. The first category of services, provisioning, is rarely effective. Indeed, the food sovereignty of cities is an issue in the transition debate, and today many cities are unable feed local populations. On the other hand, objectives in terms of aesthetics and recreation are most often met, and the importance of green spaces in connection to climate regulation issues is also generally acknowledged. Open spaces such as parks or tree-lined ways are used for walking, contemplation or to find a cooler spot when the weather gets hot. However, further information is still needed to determine the impact of vegetation on urban heat islands and to specify the species and forms that are better performing.

- Questioning density through mobility

Richard Llewelyn-Davies (1966), who joined MKDC at the time of its creation in 1967, invites us to start a reflection on density and urban quality. He questions density in relation to traffic, considering the fact that many households own one or even two vehicles and pointing out a strategic threshold beyond which the travel time savings made possible by density no longer compensate for the increased maintenance costs of the latter. Between hyperdensity and urban sprawl, the English choose an intermediary situation, whom R. Llewelyn-Davies himself qualifies as being either the golden mean or a combination of the worst characteristics of each of the two extremes.

As for Milton Keynes, we can mention oversized road infrastructures in relation to the density currently supported by the city. Indeed, one hundred and sixty kilometres of expressways criss-cross the New Town on a grid of about one-kilometre intervals, for a population of 250,000 inhabitants. Grid road traffic is congested at peak times due to the intensive use of private vehicles by a majority of unaccompanied drivers[4]. A shift toward new mobilities, collective or even autonomous, which

seems to be a trend in Milton Keynes, could allow for an optimised use of the road infrastructures already in place.

8. Conclusion

Milton Keynes, being a New Town, functions as an “urban laboratory” and as an experimental site for housing, mobility and landscape related developments. The aim of this article is not to offer recommendations for the implementation of efficient green infrastructure solutions, but to understand the objectives and choices made in this context by taking into account local characteristics and available resources. The case of Milton Keynes allows us to question aspects of urbanity that are being re-evaluated today, and which are common to many cities, such as density, mobility or our relationship to the landscape and to the ecosystem services on which we depend.

Browsing through studies and reports dating back to the city's construction period, we can see an evolution of the terminology and notions used in the field of landscape ecology. What was referred to as an interest in wildlife turned into a quest for the preservation of biodiversity and the search for a diversified flora involving ecosystems. Numerous and increasingly published studies on environmental issues have contributed to a redefinition of terms, but the designers of Milton Keynes put forward, as early as in 1967, a global vision that included life protection and soil preservation in an environment inhabited by humans. The proposed project is phased in the short term and in the long term and takes into account the management and maintenance of spaces from their conception. Many spaces are self-regulating, which testifies to the project's quest for efficiency and cost control. MKDC, the entity responsible for the design, financing and maintenance of green spaces and the entire city, aimed at creating and maintaining a quality environment for human life. The choice was also made to preserve soil quality and biodiversity. Operational, political and spatial dimensions linked to the development of parks and roadside areas prefigured the current notion of green infrastructure.

Milton Keynes, a project that stemmed from the New Town movement, is in continuity with the English garden landscape tradition while at the same time integrating elements from the radical break represented by the Modern movement. As such, this example helps to deconstruct the myth of a polluted, polluting city versus a rural, natural countryside. Urban areas can be a refuge for animal species driven away from cultivated areas by pesticides and other soil sterilisation processes. The landscape project is designed to represent the aspirations of the designers over the long term, i.e. seventy-five and one hundred or fifty years after its creation and so Milton Keynes may be perceived as a young and evolving venture, a future example and a viable context for experiments aiming for a more optimal use of ecosystem services provided by an existing green infrastructure.

Acknowledgements

This article is based on data collected during fieldwork conducted in April and May, 2019. I thank the SCUSI programme (Scientific Cooperation Project between ENSAG and the University of Oxford for the year 2018-19), IDEX University Grenoble Alpes and LabEx AE&CC for their support.

[1] The Milton Keynes Development Corporation was created to oversee the planning and design of the New City and coordinate its construction. It is a planning and governance body. The creation of each New Town is accompanied by the formation of a Development Corporation. Milton Keynes' was dissolved in 1992.

[2] "Grey" infrastructure involves the construction of elements such as roads or evacuation networks, often limited to a single function.

[3] F.L. Olmsted is known as the "heir" to Andrew Jackson Downing (1815-1852) - himself considered the founding father of garden art in the United States - because of the convergence of their work and the fact that Olmsted, with Calvert Vaux (1824-1895), designed New York's Central Park, while Downing was suspected of doing so but died early in a boat accident. Downing was greatly influenced by Humphry Repton (1752-1818) who was responsible for the first road segregation.

[4] Observations made during fieldwork, May 2019.

When constraints become assets in the design of blue-green infrastructures: an insight from two cases in the Western part of France (Loire River Basin)

Marie Fournier¹, Mathieu Bonnefond²,

²*Conservatoire National des Arts et Métiers (CNAM), HESAM, Laboratoire Géomatique et Foncier (GeF), Zone Atelier Loire, Mathieu.bonnefond@lecnam.net*

Abstract: Our presentation focuses on two recent projects of blue-green infrastructures located in the very heart of French middle-size cities in the Western part of France, in the Loire river basin (the Ile aux Planches in Le Mans and the Parc Balzac in Angers). They constitute good illustrations of recent and innovative approaches in the design of blue-green infrastructures. In the two cases, it is interesting to point out the major challenges that planners had to face. First, innovative solutions have been found to overcome technical difficulties (flood-prone areas, brownfield sites, heavy pollution and so on). Second, planners also had to address local conflicts during the definition and implementation of those projects. At last, we point out how those various constraints have been mainly turned into assets and synergies to design multifunctional blue-green infrastructures.

Keywords: multifunctionality; blue-green infrastructures; Loire river basin (France); middle-size cities

Introduction

Since a few years, green infrastructures have become a cornerstone in the urban projects of most major cities. Locally, they improve the quality of life and may contribute to the image of metropolis worldwide. Some cities such as Berlin, London or Toronto are at the forefront and provide great case studies (Kazmierczak, Carter, 2010) but we believe it is also interesting to explore smaller scale projects in medium-size cities, which are less invested but might be more easily replicated in most urban areas. In this context, our presentation focuses on two recent projects of green infrastructures in French middle-size cities, located in the Loire river basin (Western part of France). As stated by the European Commission (2013), those two cases are examples of “*strategically planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services*”. More specifically, they can be defined as blue-green infrastructures as they consist of a network of wetlands and associated open spaces along rivers (Ghofrani *et al.*, 2017). The “Ile aux Planches” in Le Mans and the “Parc de Balzac” in Angers are blue-green infrastructures which have been planned and designed around the years 2000. Those two cases are interesting to study together as they share

similarities and constitute good illustrations of recent and innovative approaches in the design of multifunctional blue-green infrastructures. The two of them are former urbanized or industrial areas, close to city centers. Planners had to face similar challenges: high-flood risk, heavy pollution but also the involvement of local inhabitants. In this presentation, we describe how planners turned those challenges and constraints into assets and found solutions to build synergies in their projects. In the two cases, water retention is the first objective, but multifunctionality is at the roots of those projects. Indeed, as often defined (Ahern, 2011; Hansen and Pauleit, 2014), the objectives of planners were to combine different functions (ecological, social but also economic) in limited space, also leading to various services for local inhabitants (before all flood protection).

All along this presentation, we mainly focus on the case of the “Ile aux Planches” (Le Mans, Sarthe) which we have studied extensively during the last 4 years (Gatien-Tournat *et al.*, 2016, Fournier *et al.*, 2017a, Thaler *et al.*, 2019) and we compare it with the “Parc Balzac” case (Angers, Maine-et-Loire).

Background

This presentation is mainly based on the results of the empirical phase of the TRANS-ADAPT project. TRANS-ADAPT is a JPI Climate Project (2014-2017) which examined bottom-up and community initiatives within flood risk management policies in four European countries: Austria, France, Ireland and the Netherlands. In France, it has received funding from the French National Research Agency (ANR). Three cases were carried out in the Loire River basin, in Le Mans, Angers and Blois. The case of the “Ile aux Planches”, in Le Mans, was one of them.

The “Ile aux Planches” is an urban park located on the Sarthe River. It is a 3-hectare island. Formerly it was a frequently flooded wide pasture which became an island in 1831 when a 680 meters canal was dug to make the Sarthe River navigable to boats. Several industries settled on the canal banks, including a gas plant in 1842. Owner of the site, the French Electricity Company (EDF) operated an electricity plant on the island until 1945. Then, it was used as a repair center and to store material and vehicles. The company progressively started to relocate its activities to another district in the late 1980s and until 1993. They decided to get rid of the site and make it profitable. In agreement with the city council, a housing project was launched. However, residents were vigorously opposed to this project. Instead, there were claims to turn the island into a public park. After several years of conflict, all parties reached an agreement and the park opened in 2008. Today, the “Ile aux Planches” is a multifunctional blue-green infrastructure, combining a recreational area, a flood risk mitigation area and a residential estate. Both flood issue and bottom-up pressure from local populations for more green urban spaces led to the planning and design of this multifunctional infrastructure.

Methods used

The empirical phase of the TRANS-ADAPT project was based on extensive desk-based analysis of academic and grey literature. It was accompanied by several semi-structured interviews with key actors involved in the implementation of those projects (more than 10 interviews for the “Ile aux Planches” case). These interviewees were mainly stakeholders of flood risk management initiatives at local level. They were representatives of different types of organization related to public authorities

(at regional or local level), market or civil society (Non-Governmental-Organizations (NGOs), land users and so on). Participants were questioned on the design and implementation of the project, their personal contribution and the integration of bottom-up initiatives at both definition and implementation phases.

Results

The two cases in Le Mans (“Ile aux Planches”) and Angers (“Parc Balzac”) share several similarities. Both sites are really close to the city center, along the main local river (Sarthe in Le Mans, Maine in Angers). The “Ile aux Planches” is a 3-hectare blue-green infrastructure, while the “Parc Balzac” is about 50 hectares. In the mid-1990s, they were still brownfield sites, heavily polluted. In Angers, 50% of the area was covered with alluvial meadows and 50% was a former controlled landfill. As described above, industries on the “Ile aux Planches” were derelict and most grounds were polluted. However, both sites were identified by local municipalities as potential areas for new urban projects. Their location is interesting. The “Ile aux Planches” is close to the train station and the city center of Le Mans. The “Parc Balzac” is located next to very recent urban estates. However, the 1995 flood strongly hit the two cities and solutions needed to be found to better deal with the risk. Local authorities decided to define and design mitigation projects on those sites. Since 2007, mitigation is identified by the Floods Directive as a key strategy within Flood Risk Management policies. As defined by Hegger *et al.* (2016), “*Flood risk mitigation focuses on decreasing the consequences of floods through measures inside the vulnerable area. Consequences can be mitigated by a smart design of the flood-prone area. Measures include spatial order, water retention within the protected area, or (regulations for) flood-proof building*”. In a nutshell, most flood risk mitigation projects include measures to retain water in the flood-prone area. If mitigation projects are quite common in several North-western European countries since the 1990s, it remains quite an innovative strategy in France (Fournier *et al.*, 2016). However, more and more French local authorities start to launch such mitigation projects (Fournier *et al.*, 2017b). Indeed, if central government authorities do prohibit building in the most exposed zones or limit this in moderate-hazard flood-prone areas that can remain constructible, developers, in these places, must consider various “necessities” and make sure they do not increase flood exposure either locally or at the level of the overall urban system. In this context, blue-green infrastructures constitute great potentials towards a “resilient urban planning” (Liao, 2012, Barroca and Serre, 2012, Barroca and Hubert, 2008) thanks to those “flood expansion areas”.

In our cases, the need to deal with those constraints had a great impact on the design of the two blue-green infrastructures.

First, both parks follow a gradient of several levels. The “Ile aux Planches” is a hydraulic system. A discharge channel is at low level on the island. It is about 50 meters wide and is covered by lawns which cannot be planted, so that water can run easily from the canal to the river. However, other uses have been defined and organized. A playground has been settled much higher. It is not accessible in case of flooding and several gates prevent children from running towards water. Tiered seats have also been installed on the side of the discharge channel, so that concerts, plays or any other public events can take place on open space. Seats are straight and not designed in curves, to facilitate the water flow. Extra costs were invested as the whole structure had to be reinforced with poles to sustain

walls at one end of the park. The southern part of the island is occupied by a residential building and a small patch of land remains non-accessible because of ground pollution. If the “Ile aux Planches” has become a key hydraulic infrastructure to mitigate the flood risk in the city center of Le Mans, the project was designed as a multifunctional blue-green project to meet other services (leisure and housing mainly). The objective of creating an urban park and the reduction of flood risk has been achieved. Multifunctional use is at operation but in case of flooding, the flood risk management function takes it all and no other use of the park is allowed.

Below, the illustration indicates the general organization of the site, when flooded (right side) or not (left side).

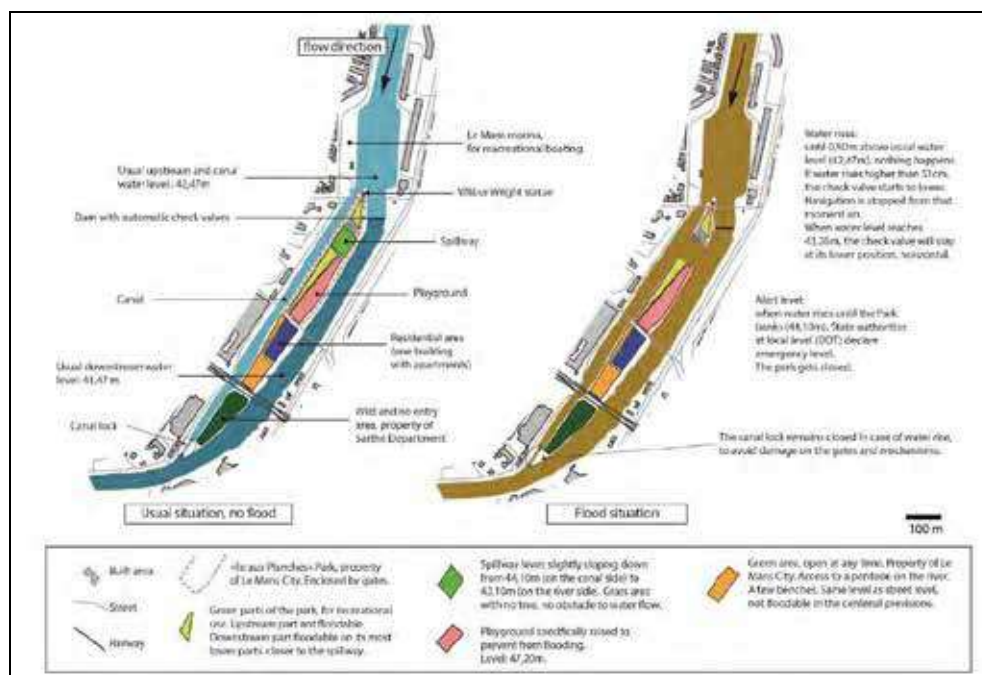

Illustration 1. The “Ile aux Planches” in Le Mans: no flood/flood situation (Gatien-Tournat, 2015)

The design of the “Parc Balzac” infrastructure in Angers is based on the same principle and makes the best out of local constraints. The whole project valorizes height differences to meet several objectives (environmental, social, safety). At low level, a network of ditches and channels has been dug and organized to restore a wide marsh/wetland (instead of the landfill). This wetland is flooded regularly in winter and spring. More than 1000 trees were planted on about 12 hectares (poplar trees, willows, alders and so on). The water level can be controlled with hydraulic works in this low wetland. This is particularly important in spring time as this network of ditches has also been restored to provide spawning grounds for fish. Higher in altitude, wet meadows were kept and cattle graze there. Planners chose rustic races (Highland cattle, donkeys (baudets du Poitou, ânes du Cotentin)) for extensive grazing, adapted to wetlands and able to stay outside for several days with little care. Thanks to cattle grazing, the whole area is kept as prairies, which is also interesting for biodiversity. Indeed, some protected bird species nest in those meadows (such as corncrakes protected by the Birds European Directive). More than 60 bird species have been identified in the park. Meadows are flooded when the river Maine is high (about once or twice a year) but most of the time, they remain out of water. In

some meadows, a landscape of “green dunes” has been created and vegetation varies depending on the altitude. When flooded, we can see waves from above. Information for the public is provided on several spots about various environmental issues (biodiversity, floods, landscape) and it is possible to walk all through the area (even in case of flooding). Higher in altitude, orchards with fruit trees but also bushes were planted so that a variety of birds may nest. About 120 family gardens were also organized and managed by a local association. This area is only flooded in case of major flood events.

Those two cases illustrate well planners’ current strategies in French cities to create synergies between various uses and services in blue-green infrastructures (Scarwell *et al.*, 2014). The need to give room back to rivers, even at the very heart of cities, has led to flood mitigation innovative projects. Safety is the key issue but planners design projects within which water flows and water retention areas are used to address other objectives (biodiversity protection, landscape, leisure and so on). Some synergies between the different functions of those infrastructures may appear. In the case of the “Ile aux Planches”, complementarities between functions are still limited. Most of the time, there is no water on the “Ile aux Planches”; when not flooded, there is no evidence of the hydraulic role of the site. The “Parc Balzac” project is much more integrated. Wetlands, prairies and water courses are at the core of the infrastructure. Water is always present in the landscape and the various uses and services of the area are regularly explained on site. As such, the project really can be described as a multifunctional blue-green infrastructure. However, to conclude on that aspect, it is important to remind that the “Ile aux Planches” project has also led to positive loops. Locally, aldermen acknowledged river banks in Le Mans were under-exploited and some projects have been launched to improve this situation.

Second, if those projects may seem quite innovative, it is important to point out that multifunctionality must not be taken for granted. It may be at the roots of projects, but it can also be the result of local negotiations during the definition and implementation phases.

In our two cases (“Ile aux Planches” and “Parc Balzac”), it is important to point out that there has been a strong involvement of residents and associations. In Angers, local inhabitants’ involvement was granted from the start. A first public inquiry was launched in 1992 to identify some potential uses for this derelict land. The municipality of Angers launched the definition and design phases of the “Parc Balzac” with local NGOs. The Ligue for the Protection of Birds (LPO) took an active part in the design of the orchards as well as in the definition of maintenance practices for the prairies. A local fishing association was involved in the design of the ditches’ network. Local gardeners’ associations (*Fédération des Jardins Familiaux Angevins* and *Association des jardiniers de Belle-Beille*) contributed to the organization of the family gardens. Today, those associations are still strongly involved in the management of the park. The LPO monitors bird populations and the fishing association participates in the maintenance and monitoring of the network of ditches as they are potential spawning grounds for fish (pikes). In spring time, the water level is controlled in this water network for fish reproduction. A gardeners’ association (*L’Amicale des Jardiniers de la Doutre*) is also responsible for the management of the family gardens. At last, biologists from the University of Angers are involved to monitor oak trees. Therefore, a variety of actors has been involved from the start in the decision-making process and the design of “Parc Balzac”. Today it proves to be quite successful thanks to this collaborative local governance. As already stated and discussed in literature,

this case is a good example of an inclusive governance leading to environmental and social benefits (Buijs *et al.*, 2016).

In the “Ile aux Planches” case, public participation started from a conflictual situation. By nature, planning projects often prove to be conflictual (Subra, 2014) as they transform local land uses and activities. Several authors also point out the various outcomes of those conflicts on planning projects (Melé *et al.*, 2004; Melé, 2013). In the case of the “Ile aux Planches”, it is interesting to see that the conflict between the municipality and local inhabitants contributed to the transformation of the initial residential project promoted by local authorities into the “Ile aux Planches” blue-green infrastructure as we know it today. In this case, we can speak of active citizenship, as defined by Moro (2012, quoted by Buijs *et al.*, 2016), that is to say, “*citizens’ ability to organize themselves in a multiform manner, to mobilize resources and to act in the public (...) in order to protect rights and take care of common goods*”. The conflict started during the 1990s, when the municipality of Le Mans decided to launch a housing project on this island which had been recently bought from EDF. Two public inquiries were carried out in 1996 and 1997. The commissioner came to the conclusions that the housing project was not beneficial to the ‘general interest’ and showed how vigorously residents were opposed to such a project on the island. Claims were written down to turn the island into a public park. A petition was initiated by a resident who had lived in the district his whole life, Mr. Marcel Bréjou. He went door to door for several weeks in 1998 and collected 800 residents’ signatures. After 2 years of failed negotiations with the municipality and EDF, the “Ile aux Planches” association was created to defend the project of an urban park. Active members were present every Saturday on the district market to inform residents and to collect ideas. Several press articles were published between 2000 and 2003. The members of the association were district residents, made of diverse socio-professional profiles. Aldermen and Department representatives also supported them. In the end, in 2003, the City Council approved the creation of a park. The safety issue and the need to build a protection system was a priority but local authorities and members of the association reached an agreement so that the area would be designed as a green park. After the project was completed, the island association began to lose members. However, some active members wanted it to continue and started to diversify its activities (towards leisure, entertainment and cultural activities). Today, the association is still active and carries out various educational and social projects. Every year, the association participates in several social events which take place on the “Ile aux Planches” and its members organize educational activities.

Discussion

If many French middle-size cities still lack public urban green spaces in the very heart of city centers, it is interesting to see how the flood risk issue and growing uncertainties about our capacities to deal with major floods lead to the definition of innovative projects in flood-prone areas. Today, the “Ile aux Planches” and “Parc Balzac” are key blue-green infrastructures in middle-size cities with few parks in their inner urban area.

The design of those blue-green infrastructures has been very much influenced by the various constraints that planners had to face, but those latter have succeeded to overcome them and even turn them into assets in their final projects. This is mainly the case in “Parc Balzac”, in Angers. Flood retention is the first objective, but the presence of water is also crucial for other functions (especially

biodiversity). In this case, the flood risk has been really changed from a constraint to an opportunity. If such a planning strategy is already quite frequent in other European countries like Germany or the Netherlands (Kerr, 2017), this remains very new in France. In Le Mans, in the case of “Île aux Planches”, all other uses still stop when a flood occurs.

Eventually, those two projects have been successful thanks to the great involvement of local inhabitants, various associations and the setting up of arrangements between all users. Such involvement is mainly explained by the variety of functions and services which have been identified in those projects. On that aspect, it is possible to compare with other similar projects in neighboring middle-size cities (for instance Blois (Morisseau, 2012, Bonnefond *et al.*, 2017)) where safety issue has clearly prevented support and involvement from residents.

It is also interesting to point out that both parks are now part of the networks of green infrastructures at the city scale. Even more, they constitute a connection between the river in the heart of the city and larger green areas at the outskirts of the urban area. As such, it is a major challenge for local authorities to integrate those blue-green infrastructures in a larger strategy.

To conclude, it would be interesting to analyse more how neighbourhood experts' techniques and know-how could be harnessed to great benefit in the very process of urban design, to better assess the risks, reduce vulnerability and enhance resilience in those projects. To successfully reduce vulnerability and enhance resilience at the scale of the city, urban, hydraulic, landscape and ecological issues must be articulated in a coherent manner. For this purpose, these projects must go beyond the current range of regulatory technical solutions and articulate urban project with blue-green infrastructures. On that aspect, there are different other examples or attempts in the Loire basin, as Matra Fluvial City project in Romorantin-Lanthenay (Rode *et al.*, 2018, Bonnefond, 2018). In this case, flood mitigation and blue-green infrastructure are central in this project which combines hydraulic modelling, urban, landscape and architectural conceptions.

Special session - Planning and designing green infrastructures.

Farming in a city without farmlands.

Cadastral mapping of agriculture in Turin and early
assessment of multifunctionality viability.

Mirko Greco¹

¹*DIST - Interuniversity Department
of Regional and Urban Studies and Planning, mirko.greco@polito.it*

Abstract:

In Turin, agriculture still does not officially exist in the zoning of the masterplan. Recently, the City opened to the opportunity to include agricultural areas in the plan, a subject still under discussion. Peri-urban agriculture is a controversial topic. Not only it is impactful on the landscape and on the ecosystem, but it also is scarcely profitable due to price volatility. However, peri-urban farming is often not negligible in dimensions. In the City of Turin, the productive farming soil amounts to at least 650 ha and it is even more extensive (10,000 ha) by looking at the cities of the first belt. The study shows that the agricultural sector of the City is currently struggling, and the very role of agriculture, in peri-urban areas, may be under discussion. Can agriculture, in Turin, become environmentally sustainable, integrate multifunctionality, recover its social value and dialogue again with the historical cultural heritage of the green belt? Before answering these questions, it was necessary to have a starting point. This paper will present the state of affairs of agricultural cadastral parcels and farmers in Turin.

Keywords: peri-urban agriculture; multifunctionality; mapping; productive green infrastructure

Introduction

This study was born within the proGIreg Project -Productive green infrastructure for post-industrial urban regeneration-, an EU Horizon project about Nature-Based Solutions (NBS) for Green Infrastructures. The local partners of the project are the City of Turin, the Metropolitan City of Turin, the Regione Piemonte, the DIST (*Dipartimento Interateneo di Scienze, progetto e politiche per il Territorio*), the DAD (*Dipartimento di Architettura e Design*) department, several cultural and trade associations; the international partners participating are Dortmund, Zagreb, Ningbo (China) as leading cities; Cluj, Zenick, Piraeus as follower cities; Aachen University, ICLEI as organizers and CNR (*Centro Nazionale di Ricerche*) as a partner for research and monitoring in Italy. The first phase of the work from the DIST, comprised within the proGIreg work package n.2.1 -spatial analysis in front-runner and follower cities- (Elisei, Leopa, 2018) focused on agriculture and farming in the City of Turin. The ratio behind this choice must be searched in the inherent nature of agriculture, which creates, on all effects, a diffuse productive green infrastructure on the territory. It is also necessary to assess how peri-urban agriculture can also fulfill the adjective *green* in *Green Infrastructures*, which is related to sustainability and support towards the ecosystems; a feature that conventional agriculture somehow lacks without applying proper farming methodologies (Power, 2010).

The study consisted in a direct survey of agricultural businesses. The broad objective of the work was to evaluate the opportunity to integrate multifunctionality in agriculture. Multifunctionality, in fact, can facilitate the conversion toward a more sustainable agriculture, and contribute to the requalification of the peri-urban territories. The *Comune di Torino* recently started an overall revision process of the main planning tool (Comune di Torino, 2017, 2018), also with the opportunity to add agricultural zoning, which was historically missing. The origin of the absence goes back to the original Masterplan of the City -PRG-, which purposely omitted this use of the land, distributing formerly agricultural areas in zones of further expansion of the City or, more recently, integrating them under the definition of *parks* and *green areas* (Area Urbanistica, 2018). Agriculture, with the urban expansion and the increase of the industrial production, was expected to become a marginal sector for the economy of the City. The recent opening of the administration toward this subject must be traced back to 2015 when the first 301 variants was originally proposed (Comune di Torino, 2015). Agriculture was further investigated in 2018, when the City undertook a path of deep revision of the main planning tool to integrate sustainability processes.

To understand the phenomena on a territorial standpoint, the priority was to build a database to distinguish between areas that are just maintained by farmers and surfaces where the agricultural production happens. This has been the main scope of the study since there was almost no direct nor complete source of data to obtain this information. It was also an important moment to study the current state of peri-urban agriculture in Turin from the point of view of the farmers and their farms, which represents a source of strategical information to develop future strategies and new policies. Before being able to successfully integrate multifunctionality and new concepts for green agriculture and ecosystem services, it is important to assess the readiness of the farmers.

The methods used

The work was carried out with qualitative and quantitative approaches, in four phases. A quantitative approach was used to collect and process the necessary data to analyze the farm enterprises activity on the territory of the City and to compose a GIS map. A qualitative approach, consisting of semi-structured interviews, was used to gather information about the condition of the farms from the farm holders (Russo, Tomaselli, Pappalardo, 2014).

The first phase entailed a review of the former works done on this subject on previous years in the City of Turin by the DIST. The data collected was in form of questionnaires, but it also provided a former mapping of the locations of the farm fields. The second phase involved interviews of the owners and collection of information on the farm about the quantities of production and the presence of threats to the farming activity. The third phase consisted in the scouting of the regional database and the use of cadastral maps to represent agriculture in Turin, with the support of local farming-trade unions and farmers, to identify more in detail which soils are kept by the farmers on the City and build a preliminary GIS dataset. The last phase was to identify, between the formerly collected data, which cadastral parcels are currently and actively used for agriculture, which are simply maintained by farmers but are not directly involved in production because are abandoned, have undergone urbanization processes or are occupied by parks or forests.

Quantitative analysis:

Agriculture is not directly planned in the uses currently regulated by the PRG *-Piano Regolatore Generale-*, and therefore little information is available about it in the City. In order to capture the spatial extension of agriculture in Turin, it was necessary to operate indirectly, using ownership, funding and cadastral data. To study the characteristics of the farms that are active on the territory the *Regione Piemonte* provided access to their *Unified Agricultural Registry* and data warehouse *Sistemapiemonte*.

The service is publicly available for use on the official site of the Region and can be queried about multiple issues regarding the agricultural sector (presence of livestock breeding, prevailing crops, Utilized Agricultural Area), with the capability to restrict the investigation down to the municipal level. For this work, however, the interest was on the cadastral data used by this system and, since it held sensitive information on the companies, the owners and on production, it was subject to a request for special access. In order to be as comprehensive as possible, the data extraction was extended to all the cadastral parcels owned by each company that declared at least one parcel on the territory of Turin. This was done to investigate the business dimension not only within the survey area, but also its extension into other municipalities.

The results, elaborated with the GIS, allowed to spatialize the data to better understand the agricultural phenomenon. The Regional dataset, although exhaustive in the quantity of information contained, is built on a yearly basis with the interactions that farm owners have had with the administration while applying for tax deductions and funding requests related to the Common Agricultural Policy. This means that the parcels declared by the farmers do not coincide with agricultural productive areas, but with all those areas in which farmers intervened, for productive purposes or maintenance. Fluctuations on the collected data can, therefore, alter the precision of the information. To contain these variations as much as possible and to make the sample as exhaustive as possible, the cadastral data were extracted for all the available years (from 2007 to 2018).

The data extracted from the Regional database served two purposes.

- A general analysis of the Farms: number of active companies in the Municipality of Turin, quantification of farms by class of UAA *-Utilized Agricultural Area-* the legal form of the company, the historical data of the farmlands, the ownership of land, the demographics of the owners, the variation of the UAA over the years; for which the extractions were used without reworking, to maintain the consistency of the content, and allow future comparisons and monitoring with the original database.
- The mapping of farmlands based on the cadastral survey and the GIS cartographic display of the cultivated surfaces in Turin. For the location of the surfaces of the agricultural land, UAA data of the farms distinct between Turin and the municipalities of the Metropolitan City, detail of the non-agricultural uses, surfaces of the companies inside and outside Turin, UAA within and outside Turin; an extrapolation from the *Sistemapiemonte* database, provided by the Region was

used. The contents of the database extraction were subject to a partial rework, due to the inconsistency in the records of the land uses inside the cadastral parcels (empty, partially filled, doubled database fields, overlapping uses and surfaces, differences in the registration methods depending on the municipality of origin).

Qualitative analysis:

The semi-structured interview is based on a questionnaire designed by *DIST, Coldiretti Torino* and *ODAF (Ordine dei Dottori Agronomi e Forestali)*. It is structured to acquire, from the farmer, qualitative and basic quantitative data together with observations on the state of health of the company, on the perceived quality of the environment in which the parcels of the farmer are located and on the possible external sources of threats (pollutants, illegal dumps, industries).

The information collected through the interview concerned the following topics:

- Company size and localization
- Type of Production
- Direct product transformation
- Cultivation methods
- Employees and economic yield
- Active Multifunctional activities
- Future/project multifunctional activities.
- physical limitations and threats to the land
- Necessity for new areas
- Livestock food supply dynamics
- Irrigation systems adopted
- Possible future company projects
- Need for new volumes or transformation of existing volumes
- Opportunities from proximity to the city
- Disadvantages of proximity to the city

The observations provided by the farmers were also useful to assess multi-functionality viability in the croplands of the City.

For the administration of the semi-structured interviews, the work was carried out together a current student in urban planning and with the help of *Coldiretti Torino*, which takes care of the company files of a large portion of the farms present in the City. The trade union association acted as intermediary with the farmers, selecting the companies that, for the purposes of this research, represented a relevant sample. These were a mix of small (family-led, less than 30ha), medium (again family led but with a greater amount of land between 30 and 100 ha, also outside Turin) and large (farming and livestock breeding companies over 100ha) farm enterprises, established in Turin or neighboring municipalities which farm land in the City under property, loan or rent. The questionnaires, for reasons of accessibility and timing, represent a sample, albeit significant, of companies with these characteristics.

Results

The city of Turin represents an attraction pole for farms operating in the Metropolitan context, that also reach the regional scale. This is due to the presence of the numerous wholesale and outdoor markets that attract farmers. From the data extraction on *Sistemapiemonte*, as of 2018, there are 360 registered farms gravitating on Turin, of which 41 also carry out livestock activities, for a total of 10495 animals.

Farms and farmers

Farms operating in the Municipality of Turin

Figure 1 – farms operating in Turin

Out of these 360, 270 farms carry out commercial activities in the City of Turin, 30 possess a building property, but only 60 of these declared a piece of land -used for production or just maintained- inside the boundaries of the City. Of the 41 livestock farms, 29 have their livestock in Turin, for a grand total of 1700 animals. It is important to refrain that if a farm declares the upkeep of a field, not necessarily it means that the field is owned by the company, or that it serves a productive agricultural function.

To better understand the phenomena of farming in Turin, the parcels declared by the farmers were differentiated between those inside the City of Turin and those inside other towns of the Region. The last ones were not spatialized since the farmers, usually, own land in several different municipalities, resulting counter deductive to show this level of detail in the data.

Graph 1 – proportion of land inside and outside Turin per farm.

In order to provide a more relevant representation it was decided to extrapolate a sample from the population of the 60 farms owning a piece of land in Turin. Only the companies whose surfaces, overall, fell inside the standard deviation, and were subject to the interview, were included. In graphs n.1 and n.2, each number represents a farm, and the bar split represents the ratio of land inside the City, and that in other towns of the Region.

Graph 2 – effective weight of each farm of the sample and distribution between inside and outside the city

The larger a company in terms of surfaces, the more likely these will be outside the City. A consideration taken for granted, given the limited agricultural land in Turin. However, we must also specify that the biggest companies, despite having potentially less interest in maintaining or protecting their possessions in the City, are interested in maintaining their relevance on the territory, given the large slice of demand coming from Turin. It is unlikely they will give up their presence in the area even in the event of difficulties or crises. Indeed, potentially, these are the farms that could acquire the land left vacant by farmers who will physiologically retire due to seniority. On the contrary, companies with land predominantly on the Municipality are smaller and often founded only on family management. These are the ones that run the greatest risk of losing relevance or disappear, given their relatively simple structure

and lack of economic differentiation. But they are also those that have deeper ties with the territory and can contribute more actively to preserve and maintain it.

Farms by class of UAA size in hectares

Graph 3 – classification of farms based on the dimension of their UAA

Even though farmlands in Turin are limited in extension, the average dimension of a farm is around 60 hectares. This data, connected with results in graphs n.1 and n.2 (that show an average split of 30% of land inside the City, 70% outside), tell us that, an average farm in Turin will hold 18 ha inside the City, and the remaining 42 ha in other Towns; which indirectly confirm the marginality of the sector in the Turin, where most of the enterprises need extensive farmlands outside the boundary to maintain their economic sustainability.

Tenure status of the land

Graph 4 – Tenure of property of the land declared by the farmers

Overall, 69% of the land is leased or loaned. Only 6% of the total land declared is owned in property, while 25% of the surfaces of the farms are mixed, with used surfaces that can be partially owned and partially under loan from third parties.

Graph 5 – farms by sex and age of the owners

On the 360 companies registered in Turin, the aging of the owners is noticeable. Half of the companies are managed by over 65 holders, 25% of the owners are between 55 and 64 years old, while the other quarter is divided among the residual age groups, where young owners (up to 40 years old) represent just a 9%. The data itself is not enough to draw up a risk profile of interruption of activity due to the lack of new generations interested in carrying out agricultural activity. It shows, nonetheless, a significant threat, which does not only affect continuity, but also competitiveness and profitability. Furthermore, it is not possible to know how many of the owners represented have a successor who can, or wants, to carry on the activity, or if there are any associated forms that guarantee continuity.

Farmlands in Turin

As stated before, the sources from which to obtain data about agricultural surfaces in the City of Turin are few, and their precision is not entirely reliable. However, the information registered on the data warehouse of agriculture by the *Regione Piemonte* represents a starting point. These surfaces are not strictly dedicated to farming, but are those declared by farmers, on which they also performed other agriculture related activities that are not necessarily connected to production (mowing and general maintenance for example, also in the parks and the forest areas of the City).

Year	Farmswith farmalands	UAA (ha)	Total surface (ha)
2007	90	602.04	670.29
2008	88	620.31	696.48
2009	84	640.66	720.34
2010	80	610.22	677.02
2011	78	637.70	702.98
2012	80	574.30	638.15
2013	95	539.44	642.86
2014	82	583.64	647.21
2015	92	514.33	587.51
2016	96	516.79	608.69
2017	91	536.95	638.69
2018	99	537.98	667.90
Average	88	576.20	658.18

Table 1 – Variations in the declared surfaces in the period 2007-2018

The data in table n.1 helps to determine the dimension of agriculture in Turin. It shows variations, which can also be steep, in the declared surfaces on a yearly basis. In the 12-year data series, on average, the active farms in the city are 90, and the declared land amounts to around 660 ha.

Graph 6 – Variations of the ration of UAA in the period 2007 - 2018

When the surface of each year is normalized to 100%, the quota of UAA fluctuates, with a tendency of reduction in the most recent record, where the non UAA surface comes near 20%, up from the typical value of 10% registered in previous years. The composition of non-UAA surfaces confirmed that more surfaces are being classified as non-agricultural in the data warehouse. Which may suggest that an increasing amount of surface has lost the original purpose. Although a more detailed survey to confirm this trend is needed.

Graph 7 – Crop categories in Turin, 2018

Graph n.7 highlights the prevalence of arable crops over the others, which is coherent with the prevalent vocation of companies covered by the interview. The graph highlights the monofunctional character of Turin's agriculture.

Graph 8 – different production techniques in the City of Turin 2018

Conventional agriculture is the cultivation system commonly used in intensive production. It involves the use of chemical aids to maintain soil fertility and defend plants. This can lead to the discovery of residues (which must be in any case below the legal limits defined by the EU) in products and environmental problems linked to certain practices (monoculture, continuous use of the same active ingredient in the pest control, etc.). However, even conventional agriculture currently moves towards a production model with a lower environmental impact that is, therefore, less intensive.

Integrated production is the food production system that uses methods and means of production and defense, against the adversities to agricultural production, aimed at reducing the use of synthetic chemicals and rationalizing fertilization, respecting ecological, economic and toxicological principles. For the integrated agricultural production of the *Regione Piemonte*, reference must be done to the commitments envisaged by the technical standards drawn up in compliance with the National Guidelines

for Integrated Production and approved with the “*Determinazione Dirigenziale del Settore Fitosanitario e Servizi tecnico-scientifici n. 230 del 14 febbraio 2018*”. The *Regione Piemonte* identifies specific practices and regulations for this method, detailing agronomic practices, fertilization, phytosanitary defense, weed control and plant growth regulators methodologies (Regione Piemonte, 2018). From the questionnaire component of the interview it results that, in Turin, 86% of the production is carried out with conventional methods and integrated production is only diffuse on the 13% of surfaces.

Graphs 9 and 10 – Destination of the production / Propensity of conversion to organic production

Farm owners declared that most of their productive lands are devoted to food production in Turin. Only a minor percentage of surfaces is dedicated to mixed uses, and just 2% of declared lands are devoted to non-food productions. The interview also exposed a very low propensity of the farmers to organic conversion.

The proximity of the City, the presence of multiple contaminated sites, the seniority of the owners and the very nature of the companies (intensive production for the purpose of food consumption and breeding) are often limiting factors that push farmers to renounce organic farming. Is important to notice that, on the metropolitan scale, the conditions change and the propensity to organic seems to be greater (a subject that needs deeper investigation), also because urbanization leaves more space for agricultural areas, reducing the factors of impact and making organic a more viable choice. Difficulties that companies encounter as regards the conversion to organic will be further developed in more detail in the qualitative analysis of the questionnaires and results.

External pressure factors on agricultural areas

Graph 11 – Farmlands surfaces by number of pressure factors

In the interview it was asked to the farmers what types of pressures and externalities their fields were under. The information collected, associated with the cadastral data, allowed to quantify the agricultural soils that are subject to external critical factors such as:

- expropriations and service infrastructure systems, which contribute to the fragmentation of production and ecosystems;
- proximity to landfills, also illegal, and abandoned or polluted land;
- presence of rights of way on the soils of the farm, which hamper agricultural activities.

The results are, of course, limited by the fact that the interview was on a sample of farms. This output covers a sample of soils inside the City and in the first belt (we asked to the farmers to identify, on a map, the lands they referred to, in order to quantify them with cadastral data). Nearly all the farmland of this sample was subject to at least two limitations, for a total of 250 ha analyzed in Turin, and 360 ha analyzed in the first belt of the City.

Interviews

Farmers were questioned on the topics described in the methodology, and asked to provide points of view, ideas, personal observations on the addressed issues. The sample consists of 45 farms of the City, and the interviews currently covered 25 of them, due to low response rate. The questions of the semi-structured interview concerned the following themes.

- *Propensity to conversion to organic farming* - on the environmental sustainability front, almost all the farmers interviewed showed a good sensitivity to environmental issues and to reduce the pollution of agricultural activities. The owners show awareness and try to reduce their environmental impact by containing the use of pesticides or artificial fertilizers. However, they expressed themselves, in most cases, negatively when asked if they are inclined to convert to organic production (96% gave a negative answer in Turin, while 69% gave a negative answer for the fields in less urbanized areas outside the City).

- *Observations on adopted cultivation methods and employees* - owners prefer to use as little as possible external personnel, taking over the workload of the farm almost entirely on a family level, thus failing to deal with alternative projects. Farms are therefore specialized on a limited number of productions that guarantee the maximum possible yield while keeping the commitment constant in terms of necessary working hours.
- *Propensity to multifunctionality* - at present, the interviewed farmers have shown little interest, and sometimes concerns about multi-functionality and the introduction of innovative agricultural practices (only 27% of farms are positive about multifunctional farming activity). Among other things, it emerged that farms that also breed livestock are less likely to differentiate their activities than those that only carry out agricultural activities.
- *Observations on physical limitations to land* - farmers are aware of the conditions of the land and the impact of large transport infrastructures, proximity to landfills or areas polluted by the presence of industries. Elements of risk that, in the periphery of Turin, are a constant. Contributing to the contamination of the lands are the frequent abusive discharges complained by the owners, especially those located in north Turin. These discharges take place on the street or in the irrigation canals and contaminate the waters and therefore the lands. Farmers in addition to complaining about this issue have also highlighted the difficulties in dealing with the abusive waste which, in some contexts, cannot be collected by the waste companies.
- *Observations on the irrigation system* - all the farmers expressed positively about the quality of the water they collect from the irrigation canals, which started improving with the gradual dismissal of industries. Today water quality is not a concern, however, the farmers with land near the border of the City complain about the disruption of the canal system by the urbanization processes. This results in fields that cannot be irrigated and, therefore, can only support non-irrigated crops.
- *Future company projects* - owners were tendentially negative about new projects to differentiate their activity. 82% answered negatively to the opportunity of experimenting with new crops, 88% would not try to process their own products in the company, 82% do not contemplate of opening a structure for direct on-site sales. On the other hand, 65% of the farmers have machinery renewal projects and 49% of them need new structures, but most of them do not have a clear idea or the funds to pursue these needs.
- *Opportunities and disadvantages deriving from the proximity to the City* - we observed a clear split. Owners of small farms mostly expressed negatively about the proximity, listing in the major disadvantages the fragmentation and the loss of land they had to withstand. For them the big demand of the City is not enough to offset the drawbacks. They often do not have the resources to counteract differentiating their activity. On the other side there are the big owners. They are often owners of livestock, that need extensive surfaces to feed their animals, or big cultivators that can offset the problems of the City with the fields they farm also in less compromised environments far from the city. For them the City still represents an opportunity. Livestock owners find easier

to sell their products, while other big farmers usually experiment multifunctionality in different ways, and try different productions.

All farmers agree on the main disadvantages of proximity to the city: pollution, landfills, abusive discharge of trash near the fields, conflicts with other citizens living near the farmlands, fragmentation of the soils due to the pervasive infrastructure system, and difficulty of movement with the agricultural machines on the roads.

Mapping

The mapping process to identify agricultural use and cultivated areas started with data collected in previous works (Sini, 2015) which has been integrated with the database extraction the *Regione Piemonte* (table 2) provided us, and an updated cadastral map of the City.

Table 2 – cadastre-parcel based database of declared farmlands, *Sistemapiemonte*

The first cartographic output was jointly checked with farmers, employees and managers of trade associations, to collect as much information as possible to complete the map with the missing -non declared- areas.

The last step was the identification of the areas that are effectively devoted to productive purposes. For this, the *Comune di Torino* provided a 4-band orthophoto (Red, Green, Blue plus near infrared) updated to 2019. With a multiple overlay of the orthophoto, the regional BDTRE database, the uses already declared and a raster analysis application for QGIS (*From GIS to Remote Sensing plugin*), the cultivated areas were discerned from other areas.

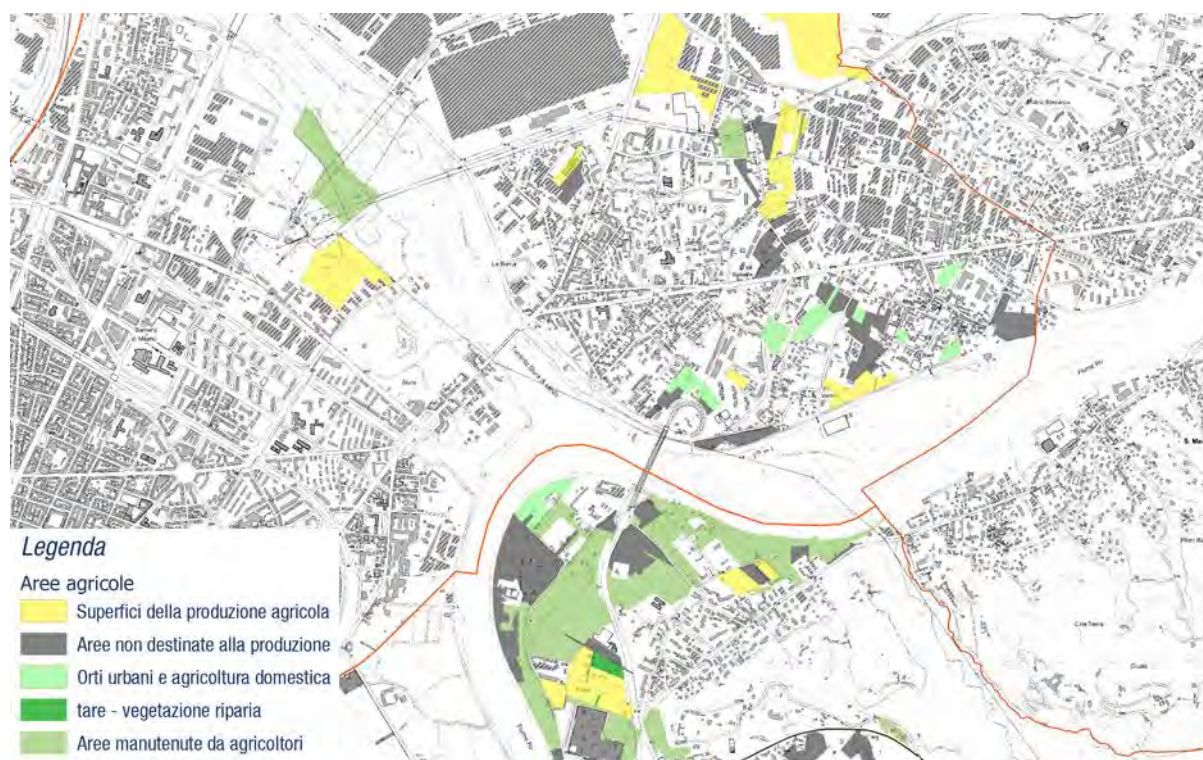

Picture 1 – agriculture related soils, previous data and information, 2015

Mapping initially involved the collection of previous maps created on this subject. The data was extracted for each available year, from 2014 to 2018, from the data warehouse. These were integrated on the Cartographic cadastre of the City of Turin, with GIS join functions. With the general map available, the next step was to integrate data about the owners of the farms from the database shown in table 2.

Picture 2 – 4-bands orthophoto- Torino 2019

At this point however, the map represented both the lands of the production and the parcels where the farmers were doing regular maintenance for third party or in the City parks, without a clear distinction. To detect the productive farmlands the former areas were, when possible, identified through the declared uses. The process to recognize the parcels that were not declared -but clearly served a productive function- was supported by the experience of the farmers and representatives of the farming trade unions active in the City, who helped to identify and confirm the areas. Some further areas were then located with the raster analysis tool for QGIS (Congedo, 2016).

Picture 3 – Final output and definition of productive farmlands, 2018

Graph 12 – Surfaces related to agriculture, 2018

In Turin, in late 2018, there were 658 hectares of parcels used for production, that (considering the UAA ratio of graph n.6) amount to at least 530 hectares of UAA on the City. With this study, moreover, it was possible to identify 85 hectares of land that are actively maintained by the farmers in public areas and parks. Public farmlands amount to the 34% of the total productive parcels and are given in conduction to local farmers by the City. Moreover, at least 41 hectares of parcels are occupied by woods and vegetation

related to farms. There still is an amount of parcel surfaces that need further examination to be clearly identified. It can be stated, therefore, that farming contributes to upkeep at least 780 hectares of land in the City.

Final Observations

The results, especially from the interviews, show that agriculture in the peri-urban space of Turin is currently under pressure. Agriculture's main problem is the resilience toward changes in the economy and globalization dynamics. The low added value generated (complained by all the farmers subject to the interview), in fact, make it susceptible to external pressures. The sensitivity is amplified in the peri-urban space, where the landscape has often little recognized value, and the soil represents a precious and scarce resource for many other, not always environmentally friendly, uses.

Farmers, in the peri-urban space of Turin, show low propensity to differentiation, and farms tend to be strictly mono-functional. This can be brought back to the next causes:

- The seniority of the farmers, who prefer to simplify the activity;
- the desire to reduce as much as possible the use of labor outside the family and the recruitment of employees;
- the low economic value generally attributed to agricultural production that favors latifundiums;
- the shortage of time and resources, not only economic, determined by the previous points.

A situation that does not lend itself to multifunctional agriculture activities and practices, making the penetration of new ideas and projects difficult. On the contrary, multifunctionality requires a different approach, more specialized professionals and asks farmers to project and plan with a business mindset (Zasada, 2011). Ideal conditions for this to happen may also be the reduction of the age of the owners and a greater attention to their training on the management. Substantial economic investments, supported by profitability evaluations, are also fundamental (problematic for companies that have difficulty in the update of the machines).

Needs that clash with the reality, were price volatility (European Parliament, 2017) hinder economic planning of major transformations or long-term projects in local farms. Proximity to the city is a natural opportunity for a farm that also carries out tertiary service functions. But it is also a threat, given the frequent landscape degradation of the residual rural peri-urban areas of Turin. Hardly a farmhouse inn will be economically sustainable near the belt highway, the numerous landfills the industrial areas or the incinerator. Moreover, all the interviewed farmers expressed a negative outlook towards their work and, in general, the agricultural sector in the proximity of the City.

Nonetheless, they also showed good sensitivity to environmental issues and about reducing the footprint of farming. However, in most cases they expressed themselves negatively when asked if they are inclined to convert to organic farming. Farmers are aware of land conditions, external pressure factors and territorial criticalities, such as large transport infrastructures, proximity to landfills or areas contaminated by the presence of industries. They show low propensity to undertake the process of conversion because the results are not entirely under their control.

The City of Turin owns 225 hectares of agricultural land, and leases or loans it to farmers. This represents an opportunity, as the administration can decide to implement, on these lands, practices and pilot projects aimed at multi-functionality and sustainable agriculture. A solution that would also make it easier to deploy the necessary facilities and infrastructures. The same principle applies for the implementation of sustainability policies. However, currently, the PRG includes rules about farming in the areas that are inside the parks, but still there is no clear planning strategy or framework for the *agricultural parks* that the City identified (NUEA, art. 21 - Parchi urbani e fluviali).

With regards to the mapping process, it was useful to better understand the layout of the soils that, in several respects, are related to farming or farmers. But the databases are currently not enough to directly understand which terrains are used for production. Besides, it was possible to discover that, apart from the productive soil, there are at least 85 hectares of land that are maintained with the help of farmers, and most probably this number is higher. Farmers, hence, already offer a service to the City, also on private land. Over 780 hectares of land are associated to agriculture and upkept by farmers in Torino.

The survey highlights how the issue of peri-urban agriculture needs to be addressed in a systemic perspective that transcends the municipal dimension. In fact, most of the analyzed companies have the largest part of their land outside the Municipality of Turin. In the first belt of the metropolitan area the agricultural system, whose offshoots penetrate inside the Turin peri-urban area, is much more relevant and many of the criticalities detected for Turin still apply. The complex of these areas constitutes a real infrastructure of agricultural production, a landscape that joins other not only anthropic but also natural and green infrastructures. In addressing the issue of green infrastructures, especially productive ones, the metropolitan area is an ideal field of study. Also it should be noted that, for the definition of any strategy about peri-urban agriculture and agricultural park, the local dimension is not enough, and areas identified by the city as Agricultural parks should be studied in connection to the system of rural and natural areas connected to them, also outside of the city borders.

The methodology used to assess agricultural areas in the City of Turin can be replied on the metropolitan scale, especially in the first belt, although with some adaptations. The interviews should be administered on specifically chosen farms, based on the identified issues of the study areas. Factors of pressure can be identified through spatial analysis and databases on polluted sites with the help of the administrations (especially the *Città Metropolitana*); cadastral data can be collected for a multitude of communities, thanks to a project (*progetto catasto*) which is a collection of GIS based cadastre files; the data extracted from the regional database can be reworked with semi-automatic methods, in order to fix the intrinsic errors already found during the development of this study. An addition to the method may also be the inclusion of the datasets of the project *Corona Verde*, which will add information on the historic and cultural heritage of this space, that is strongly connected to agriculture and can be an important source to define restoration policies integrated with agricultural production (Gottero *et al*, 2018).

To conclude, it is still difficult to implement sustainability practices in agriculture in peri-urban landscapes like the one of the City of Turin. Here agricultural land is an actual third space (Fanfani, 2006), sparsely treated on the local scale and still somehow overlooked at the regional one. For this space, a different planning framework is necessary, that does not rely on traditional planning practices. What is important to note, though, is the value of farmers' land management, which would be difficult to replicate

if the agricultural areas were converted to entirely different uses or hindered in their productive dimension. A value not only economic, but also social, since agriculture is one of the few activities that involve citizens in the active upkeep of land and soil. Before converting these spaces in parks (due to abandonment) or sacrificing them because of lack of interest from the farmers themselves, this should be kept in consideration. Multifunctionality can serve a role in this transitional phase, but it should be supported by a clear strategy. A possible answer for a more environmentally sustainable peri-urban agriculture would be to promote its conversion to integrated production. It would result in a higher control over the chemicals used in the soils, potentially recovering the ecosystem value of the farmlands (PAN, 2010). A move that can raise the quality of food production near the City and, therefore, positively impact also on its economic sustainability.

Contribution

This small work was an opportunity to deepen the knowledge about peri-urban agriculture in the City of Turin. The acquired information is a starting point that can be used to orient future research. More importantly, this work focused on the point of view of farmers, which was useful to highlight some of the weaknesses of the system on a socio-economic perspective. Multifunctionality, in agriculture strongly depends on the capabilities of the agricultural system. If the farmers do not have the necessary resources, policies will be difficult to apply. This represents a useful starting point to expose some of the factors limiting its diffusion.

The cartographic output of this study has already been used to implement the next City masterplan update. It may further prove to be useful to the City if new policies for agriculture will be discussed in the future. But mostly it is a way to highlight again that, also in a deeply urbanized metropolitan Capital, agriculture can still be relevant, not only for the production but also for the other services that farmers can carry out in parks and other areas. This document and its outputs can be a reference for the City to understand how to better exploit a territorial resource that is both material and immaterial.

Acknowledgements

This work has been possible thanks to the proGIreg project and all the experts, administrations and stakeholders involved. I want also to thank Chiara Favat, that helped me in the interviews, and professor Giuseppe Cinà, who started the work connecting the institutional actors and interacting with the administrations. Many thanks also to Umberto Tresso, Paolo Lana and Lucia Dentis, who supported the research with their experience in the agriculture of the city.

5. Planning and designing green infrastructures

Landscape and Ecological Networks in Urban Planning: Technical Standards for Implementation

Luigi La Riccia¹

¹*Politecnico di Torino, Inter-university Department of Regional and Urban Studies and Planning*

Abstract: This paper proposes a reflection on the possible role of landscape and ecological networks within the local urban planning practices. We are faced with a constant population growth in cities and peri-urban and marginal areas are increasingly subject to environmental degradation. Therefore, it is necessary to identify and recognize the ecological values of the environment to define plans and natural resources. This contribution, starting from some pilots conducted in Piedmont Region, reflects about the urban planning operational paradigms, the importance of green infrastructures and ecological quality for sustainable and resilient city is sustained by a proposal of local planning regulations. The paper aims to tackle the quest for a new forms of implementation based on the integration of the approaches to planning the urban and ecological problems with the aim of ensuring complete compatibility between urban transformation and the demands for environmental quality. The ecological regulations described in this paper propose an evolution of the meaning of the planning schemes, especially those applicable to green space: the regulations in fact consider the collective use of green infrastructures as a crucial requisite, while according priority nonetheless to the role of private areas as an invaluable factor in the environmental regeneration of urban tissue. Therefore, this contribution focuses on an innovative model of planning and management at the local scale, the role of ecosystem services, the relationship between biodiversity of the ecological network structural areas and periurban and agricultural residual ecological areas to be strengthened to improve connectivity between ecosystems.

Keywords: Ecological Networks, Regional and Urban Planning, Planning standards, Ecological Regulations

1. Introduction: ecological networks, protected areas and new urbanizations

Many researches in recent years focusing on how ecological networks and ecosystem services can contribute to healthy and resilience cities. Worldwide, more than half of us live in cities, and the number is increasing, making urban sprawl a specific fact of our common future: there can be little doubt that cities are where “our struggle for global sustainability will be won or lost” (United Nations [UN], 2012).

Meanwhile, in cities, peri-urban landscapes and beyond, concerns have grown regarding loss of biodiversity and degradation of natural resources, giving rise to recognition of the central role that ecological networks have to play in these territories. The European Commission [EC] in 2013 published a document to promote green infrastructure planning, and mainstream it in Europe (European Commission, 2013). This strategic document

underlines the green infrastructures may contribute to sustainable development, enhancing social cohesion, supporting the economy, and adapting to climate change, and highlights the importance of ecological networks and nature-based solutions in cities, where more than 60% of the EU population lives.

In view of these data, in recent years we have seen an exponential growth of urban land use towards more natural spaces: external urban areas (uncultivated land, cultivated land abandoned, the burnt areas, degraded forests) are often been confined to a “inessential” position and sometimes simply considered as “waiting for a new urbanisation”. Too often, this is due to poor operability of local plans to lead an urban development coherent with the preservation of natural areas and ecological connectivity. We can identify the consequences of these processes in 6 significant phenomena (Benedict and McMahon, 2002; Voghera and La Riccia, 2018):

- the substantial loss of natural areas: urban development has led in recent years, a reduction of natural areas (in the world, in the years 2000-2010, the rate of decline amounted to about 16 million hectares lost each year);
- the fragmentation of natural areas: a process that determines a breakdown of structural areas of ecological networks into smaller patches, and consequently more isolated from the point of view of connectivity;
- the degradation of wetlands, which have always been an important ecological function for the control of water flows, for the ability to block the sediments, for the support of plant and animal species (stepping stones function) and for the ability to provide nutrients for the ecosystems;
- the inability to ecosystems to respond to change and find a new ecological balance: that is to say a significantly reduced resilience;
- the loss of ecosystem services: natural systems have important “services”, such as the control of water, the filter functions for pollutants, the preservation of the climatic risks;
- the increased costs for public services, due to the response to natural disasters as a result of the ecological footprint by man.

Nature conservation in the city is one of the biggest challenges for sustainable urban development, as a result of a social and ecological coevolution. The value of nature in the city, however, goes far beyond its influence on the inhabitants’ quality of life or rather an intrinsic value: urban areas are surprisingly rich in biodiversity. The conservation and management of nature and biodiversity in urban areas is often vary complex (Antrop, 2001, 2004): there are more people, stronger development pressures, less space, a multiplicity of actors involved, etc. Often, the analyses reveal that the urban natural reserves are few but large and have a high density.

Large natural reserves can be especially important in urban landscapes, as the difference between the urban and natural environment can be high (Powell, Selman and Wragg, 2002). It should be noted, however, that the strategies of urban planning and those of nature are in Italy generally separated. One possible reason is that the protection of nature has favoured a purely “conservative” vision towards nature outside the city and has made trivial and distorted the vision of urban nature conservation.

However, the identification of urban nature is also part of a broader change in perspective within the conservation policies and remains as a necessary point of reference for a sustainable urban development. In many cities, this change of perspective was manifested through the institution of urban areas for nature conservation, supported by a general concept of “urban landscape”. In the urban context, the establishment of these areas has been started during the twentieth century as a reaction to the rapid degradation of the urban environment due to industrialization and the consequent urban growth. It was therefore seen as a necessary step

to keep nature and landscape away from private exploitations. Today, instead, the public interest is more oriented to the preservation of social values, biodiversity of nature and landscape. In the recent decades, in effect, the nature conservation and landscape policies have changed: today, a possible alliance between nature and landscape (Gambino and Peano, 2015; La Riccia, 2015) is assumed to be an essential condition for sustainable development and lays itself at different scales (United Nations Environment Programme [UNEP], 1992; European Council of Town Planners [ETCP], 2003; Hooper et al., 2005; Potschin and Haines-Young, 2006; Selman, 2006; International Union for Conservation of Nature [IUCN], 2012).

Until the 1970s, in Italian urban planning, we could not speak about a real ecological paradigm, but of “urban greening”, the distribution of which was generally expected in new districts as well as in historical centres. The creation of urban parks also became one of the focal points of the urban plans. Keeping them indicated a fundamental aspect of environmental continuity in urban space. The consideration of nature and landscape in the Italian urban planning tradition has privileged the aesthetic approach, oriented to the historical and cultural heritage of excellence. During those years, when in Italy the debate was focused on the general “crisis of planning” (Gabrielli, 1995), at the international level an important shift on focus could be observed towards the “landscape planning at the local level” (La Riccia, 2017), a new way of understanding the landscape in the plan, closer to the urgency of reducing ecological problems and supported by an emerging environmentalist currency in the cultural and political scenes. On the one hand, there was a growing need to put an end to environmental disasters; on the other hand, the issue of landscape merged forcefully in different disciplinary contexts.

Urban planning, rewritten through a new ecological paradigm, does not appear to be capable of solving the identification, convenient, of landscape with the natural environment, still promoting an approach, especially design, which remains “promotional”. Sustainable development requires more than designed landscapes that are created using sustainable technologies. Design is a cultural act, a product of culture made with the materials of nature, and embedded within and inflected by a particular social formation; it often employs principles of ecology, but it does more than that, enabling social routines and spatial practices, from daily promenades to commuting to work.

In the Italian experience, indeed, green areas acted as a common element for re-joining city and countryside, that is to say, for the redevelopment of the modern districts in order to reduce the pressures on both historic centres and new districts. The ecological paradigm is therefore a different vision and has guided the practice of urbanism towards a new direction. The environmental provisions now seem to articulate the new practices, coordinating behaviors and reconfiguring the spaces of the city: this means defining new and more ecological functionalist provisions.

To harness the full potential of local ecological networks, however, a carefully conceive, experience-based approach is required. This paper aims to support such an approach by providing information on how to plan for and develop local ecological networks. We can define local ecological network planning as a strategic planning approach that aims to develop and detail the networks of ecological structural areas, designed and managed to deliver a wide range of ecosystem services and other benefits at the local scale. Local ecological network planning can help also to tackle key urban and peri-urban challenges that cities face:

1. Protecting biodiversity
2. Adapting to climate change
3. Promoting green economy
4. Increasing social inclusion

Considering these challenges, local ecological network planning must be based on the integration and coordination of green infrastructures with the urban uses; creating and restoring connections to support and protect processes, functions and benefits that marginalised ecological structural areas cannot provide alone;

delivering and enhancing multiple functions and ecosystem services; and finally, including collaborative and participatory planning.

While these challenges provide a fundamental basis for local ecological network planning, certain supporting approaches could be also taken into account:

- *Multi-scale approach*, linking all spatial planning levels, ranging from regional to local scale;
- *Multi-object approach*, including all types of green and blue spaces, public and private, considered as part of a green infrastructure network;
- *Transdisciplinary approach*, linking disciplines, policies, and practices from different fields (landscape ecology, regional and urban planning, landscape architecture, etc.).

2. Local ecological network planning and new urban challenges

Since the Seventies, urban planning practices demonstrated the potential of ecological network to contribute to challenges such as health, species protection, biodiversity protection, climate change adaptation. When understood as part of local ecological network, these and other emerging challenges and trends must be considered not just as obstacles to overcome, but as important drivers for investing the future urban planning choices.

2.1 Protecting biodiversity

Despite the Protected Areas and Natura 2000 sites are now considered the “backbone” of the European policy for biodiversity, at the local level they are included with a clear difficulty within the urban policies and plans. The policies for the improvement of ecological networks are in fact necessary to overcome the fragmentation of the habitats and natural areas, which is the main cause of biodiversity loss in Europe. From this point of view, in fact, the Natura 2000 network, now implemented in 28 Member States and considered, at Community level, such as the exclusive policy for the conservation of biodiversity values, covering a total of 18.36% of the surface of the member states and It includes a set of sites of Community interest for about 60 million hectares. Then, there is a considerable overlap of these with the surface of Protected Areas that instead corresponds to approximately 22% of the surface of the Member States (European Environment Agency [EEA], 2017).

Loss of biodiversity is a major threat worldwide, requiring attention from policy-makers at the local, regional, national and global levels. Support for halting biodiversity loss has gained increasing attention since the release of the United Nations’s Convention on Biological Diversity in 1992. Major recent initiatives include the UN Strategic Plan for Biodiversity 2011-2020 (United Nations, 2011) and its Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Service [IPBES]¹, as well as the EU Biodiversity Strategy to 2020 (European Commission, 2011), in addition to many plans at the regional and local levels.

Biodiversity includes diversity within and between species, the variety of original, semi-natural and man-made biotopes (such as forests, dry meadows, or private green spaces) and, at the large scale, the diversity of ecosystems themselves. Although urban growth often negatively impacts upon biodiversity, urban areas can also

¹ IPBES website at: <http://www.ipbes.net/>

harbour significant number of species and habitat types, thus offering opportunities both for biodiversity protection and for people to experience nature. Through strategic, integrated coordination and management, local ecological network planning seeks to enhance these opportunities.

2.2 Adapting to climate change

As a matter of fact, whatever the warming scenarios and however successful mitigation efforts could be, the impact of climate change will increase in the coming decades because of the delayed impacts of past and current greenhouse gas emissions. Cities are increasingly facing the risk and consequences of climate change. Among them, flooding from heavy rainfall, heat extremes, drought, effects on health, higher energy demand for heating and cooling, and reduced availability of water and food (Wilby, 2007). This condition requires an urgent imperative to both mitigate the effects of climate change and adapt to them.

Therefore, adaptation planning is needed to deal with the unavoidable climate impacts and their economic, environmental and social costs. Due to the specific and wide-ranging nature of climate change impacts, adaptation measures need to be taken at all levels, from regional to local, aiming at minimising the risks connected to climate change, protecting public health by improving the adaptation capability of natural ecosystems and the social and economic systems. Climate change adaptation involves making changes to existing systems (natural and urban): this means anticipating adverse effects and taking appropriate action to prevent or minimise the corresponding damage, as well as seizing opportunities that may arise.

Adaptation differs from mitigation, and they should not be considered alternative or conflicting approaches. Rather, they both represent complementary aspects of a comprehensive and more successful policy to tackle all the impacts of climate change. While mitigation operates on a longer time scale and requires a world-wide coordinated approach to reduce gradually greenhouse gases emissions, adaptation acts mainly at the local level and can be modulated according to the different local situations (e.g. local impacts, vulnerabilities and resilience capacities, see Intergovernmental Panel on Climate Change [IPCC], 2014). Both mitigation and adaptation strategies are needed to address the impacts of climate change, however, it is important to be aware that they do not always work in harmony with one another.

Local urban settings show different features than rural and natural areas resulting in different vulnerability profiles concerning the sensitivity of local systems to climate changes (e.g. local dependency on ecosystem services and products, concentration of cultural values, economic activities, etc.), in relation to the adaptive capacity (availability of easily accessible infrastructures or public services). For instance, increasing ecological networks may reduce overall urban density and thus create less-energy-efficient cities, whereas urban densification may reduce the adaptive capacity of cities. For this reason, local ecological network planning can play a key role in strategies for climate change adaptation and, to a lesser degree, mitigation, by delivering ecosystem services (multifunctionality). Important, planned adaptation is more cost effective than emergency measures and retrofitting.

2.3 Promoting green economy

The recent global economic crisis and ongoing environmental challenges, such as climate change, have sparked a renewed interest in alternative economies and forms of growth. Among these, green growth and the transition towards green economy are the most widely discussed (United Nations Environment Programme [UNEP], 2012). A holistic approach to sustainability underpins the green economy concept, which aims for simultaneous environmental, social and economic benefits. Alongside the conventional goals of avoiding costs and fostering economic efficiency, competitiveness and business opportunities, a green economy seeks to improve the quality of urban environments, reduce resource consumption by creating synergies between functions, and provide opportunities for people to engage with each other and with their environment. It is an emerging concept yet to

be fully embraced by ecological network planning, although many cities already have planning objectives tied to related concepts like sustainable planning, green jobs, a low carbon economy, or attractive public spaces.

Local ecological network planning can benefit cities' economies in a range of ways, both directly and indirectly. Attractive ecological structural areas can not only improve the city's competitiveness as a destination for new residents, businesses and tourists, but also help to generate income (e.g. food and service industries, through leisure activities and special events, see Rolls and Sunderland, 2014). For local business owners, "greenery" has been linked to positive shopper perceptions, lower stress levels and increased walkability (La Riccia *et al.*, 2019): encouraging sales, while also increasing staff motivation. It could also support local food production and sale at farmers' markets. A green economy would see all such economic benefits weighted up against their corresponding social and environmental impacts in evaluating their net effect.

In addition to generating income, local ecological network planning can also help to avoid costs, e.g. by creating healthier communities or avoiding the damage caused by extreme natural hazards. About this, a study estimated the average avoided costs from flood damage to housing in a 100-mile-long green infrastructure along the Meramec river in USA to be \$7.7 million per year (Kousky and Walls, 2014).

2.4 Increasing social inclusion

Social inclusion can be understood as the capacity of a society to ensure the welfare of all its members, minimising disparities and avoiding inequality. It in general refers to the involvement of a wide range of social groups (including vulnerable ones that are often excluded) in all spheres of life. Making local ecological network planning socially inclusive demands attention to the needs of these different groups. Of particular concern are those with the most difficulties accessing information and articulating their interests.

Social inclusion is related to social cohesion, yet these are not the same. The latter concerns the outcome of local ecological network planning with regard to its social effects, while social inclusive ecological network planning is instead a process of including all social and cultural groups people in decision-making processes. Social inclusion is often talked about in association with the term *governance*, a concept entailing a widening of focus from state-centric government, to further include the role of non-state actors. The concept of governance has emerged in a context where the distinction between "top-down" and "bottom-up" is becoming increasingly harder to see. Instead, both approaches are often in play at the same time: e.g. when a local government authority moves to define a grassroots initiative.

Even though governance is emerging across Europe, recognition of the concept does not automatically lead to the involvement of all population groups and equal consideration of their interests, nor does it mean that social considerations are always given high priority. Recent projects on peri-urban green infrastructure development² found that economic growth motives continue to dominate urban planning decisions, and, while ecological protection is of growing policy interest, social justice concerns receive very little attention. Local authorities have a crucial role to play in mainstreaming social inclusion in local ecological network planning together with members of civil society who are empowered not only to participate, but also to take action.

Many levels of participation in planning are possible and these have often been represented along a spectrum, starting at one end with simply informing citizens, all the way to complete citizen control in decision-making at

² On this regard, see the EU-funded project of the Alpine Space Programme 2014-2020 "LOS_DAMA! Landscape and Open Space Development in Alpine Metropolitan Areas" at https://www.alpine-space.eu/projects/los_dama/en/home

the other end. In European cities, information and consultation processes are usually dictated by laws or regulations. Despite their formality, these processes can help to reveal citizens' point of view. However, ensuring that they sufficiently reflect all residents' interests requires different efforts to engage people. Consultation tends to be less formal in cities where citizens' landscape demand is part of the public policy culture and strengthened by bottom-up initiatives. To promote collaborative decision-making, some cities, such as Aarhus, have agreed on guidelines for people involvement from the outset of all municipal plans, strategies and projects³. Another way to think about participation is in terms of co-governance, where power is distributed between authorities and citizens. Citizens can be rewarded with increased influence over decision-making processes and outcomes, while governments may benefit from building trust with citizens and accessing non-traditional forms of local knowledge.

Allowing for and considering social participation in local ecological network planning is a step towards a co-governance framework: there are many ways to increase the willingness of citizens to express their preferences and participate in different stages of the planning process.

3. The construction of the ecological network at the local level

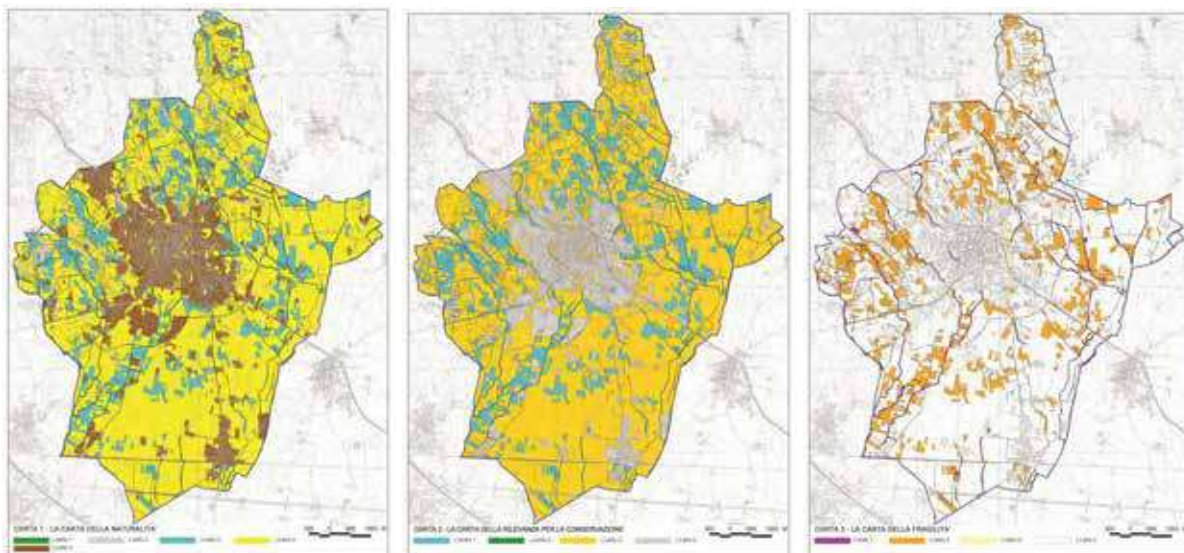

Attributing ecological significance and therefore an ecosystem role, not necessarily secondary, to territory means reflecting on a general renovation of the urban planning paradigms, considering the importance of productive, business and policy interests. Therefore, a clear need to define the objectives, which avoid simple "territorial schemes" of new ecological corridors, maybe excellent in aesthetic terms, but lacking of all meanings from the point of view of biodiversity. For this reason, it is important not to stop to analyse only the state of naturalness and diversity at different scales, but it is necessary go further to give priority to the pursuit of ecological coherence of the whole territory: that is to say to link the network with the impacts deriving from human activities and, more generally, to define a framework for urban planning operability.

In this context, several interesting experiences about this issue have been launched in the Piedmont region (Italy) with the aim to improve the overall ecological quality of the natural and landscape areas and specifically indicate the operational procedures to avoid the ecological fragmentation. Between 2014 and 2016 the research "Guidelines for the Green System of PTC2" (convention between Metropolitan City of Turin, ENEA and Polytechnic of Turin) and the "Operational proposals for the ecological network of Chieri" (Polytechnic of Turin and Comune di Chieri, Turin) were conducted with the objective of defining a proposal for the implementation of the ecological network at the local level in two municipalities of Turin (Ivrea and Chieri).

In these experiences, the approach proposed by ENEA was reconsidered to guide governments with specific measures to limit anthropogenic land use and, where possible, orient and qualify the conservation of ecosystem services. Habitats, natural areas and landscape have not been interpreted only by exclusively ecological point of view (a mosaic of ecosystems) but also considering a broader perspective that embraces cultural, social and economic aspects of the Ivrea area. The proposed methodology identifies the ecological character of the territory and defines the criteria for the evaluation of different types of land use: in the Chieri area 97 types of use, according to Corine Land Cover database, were identified. Subsequently, we applied five key indicators for assessing the ecological status (see Figure 1):

³ See more at City of Aarhus website: https://www.aarhus.dk/sitecore/content/Subsites/CityOfAarhus/Home/The-City-Council/The-Aarhus-model.aspx?sc_lang=da

- *Naturalness*: the types of land use are classified into 5 levels of naturalness, considering the closeness to the formations that would be present in the absence of disturbance (climax). So, the natural levels ranging from the 1st which includes all natural formations up to at maximum the 4th considering the types of land use at total anthropic determinism but not artificial (like almost all cropland) and the 5th level which includes the types of land use corresponding to artificial areas.
- *Relevance for conservation*: the types of land use are classified on four levels of relevance based on the relevance/suitability of land use for biodiversity conservation at the same time considering the importance for habitats and species. It introduces the concept of interest habitats for species of the Natura 2000 network including not only the habitats of Community interest but also the complex habitats whose conservation is necessary for the protection of species of the Natura 2000 Network.
- *Fragility*: the types of land use are classified in terms of intrinsic fragility due pressures such as pollution, ingression of exotic and invasive species, human disturbance in general. The 1st level includes types of land use that define both natural environments with very low resilience as rock fields or glaciers is semi-natural areas and significant anthropic determinism but easily fragile for both types of land use and poor resilience such as artificial water reservoirs or areas with sparse vegetation.
- *Extroversion*: the types of land use are classified on the basis of the potential “capacity” to put pressure compared to the neighbouring patches. We have considered the pressures in an integrated way that goes from pollution of productions to the spread of invasive alien species. It ranges from level 1st, which includes types of land use that coincide with the areas with the highest human settlement and able to exert pressure, to the 5th level, containing natural types of land use types of use of the natural ground.
- *Irreversibility*: the types of land use are classified on the basis of the potential possibilities of change in the intended use. The 1st level includes all artificial types of land use totally characterized by the irreversible intended use (for example: urban, commercial industrial zones).

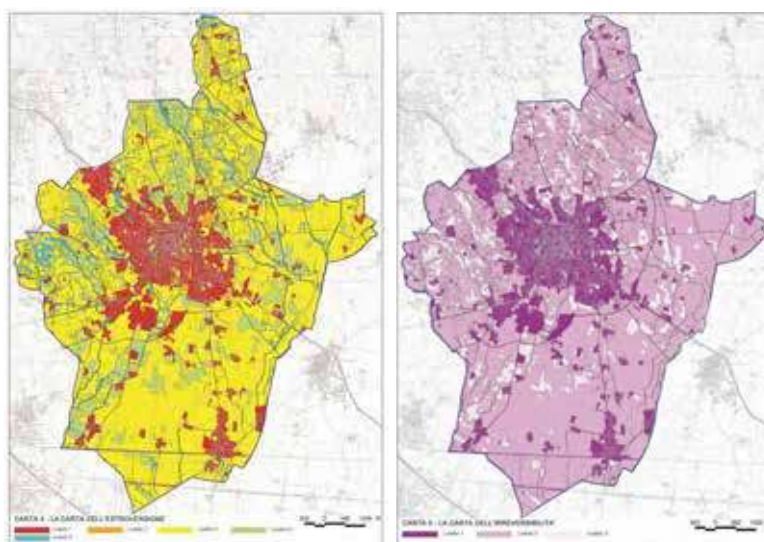

Figure 1. Maps of Chieri territory according to the considered five indicators (in the order of appearance): Naturalness, Relevance for the conservation, Fragility, Extroversion, Irreversibility. Processing Politecnico di Torino, 2016.

From the integration of the results of different indicators the so-called “Structural map of the ecological network” has been obtained (see Figure 2). This map shows the elements of the Local Ecological Network system, chosen on the basis of the levels of naturalness, ecological functionality, geographical continuity, and consists of three main elements:

- *Structural elements of the network* (primary ecological network), namely the areas of high and moderate ecological functions, as well as areas that hosting the specific conservationist emergencies, i.e. of natural and significant importance for the conservation of biodiversity.
- *Priority Network Expansion areas*, namely the at residual ecological function areas where priority action to increase the functionality of the primary ecological network and for which the implementation of protection measures for the maintenance of primary ecological network. These areas are further divided into: *Connection areas* and *Contiguous portions to the structural elements*.
- *Possible expansion of the network areas*, i.e. areas at residual ecological functionality, but on which it is possible implement new interventions aimed at increasing naturalness useful to protect the habitat and species of interest for the conservation of biodiversity.

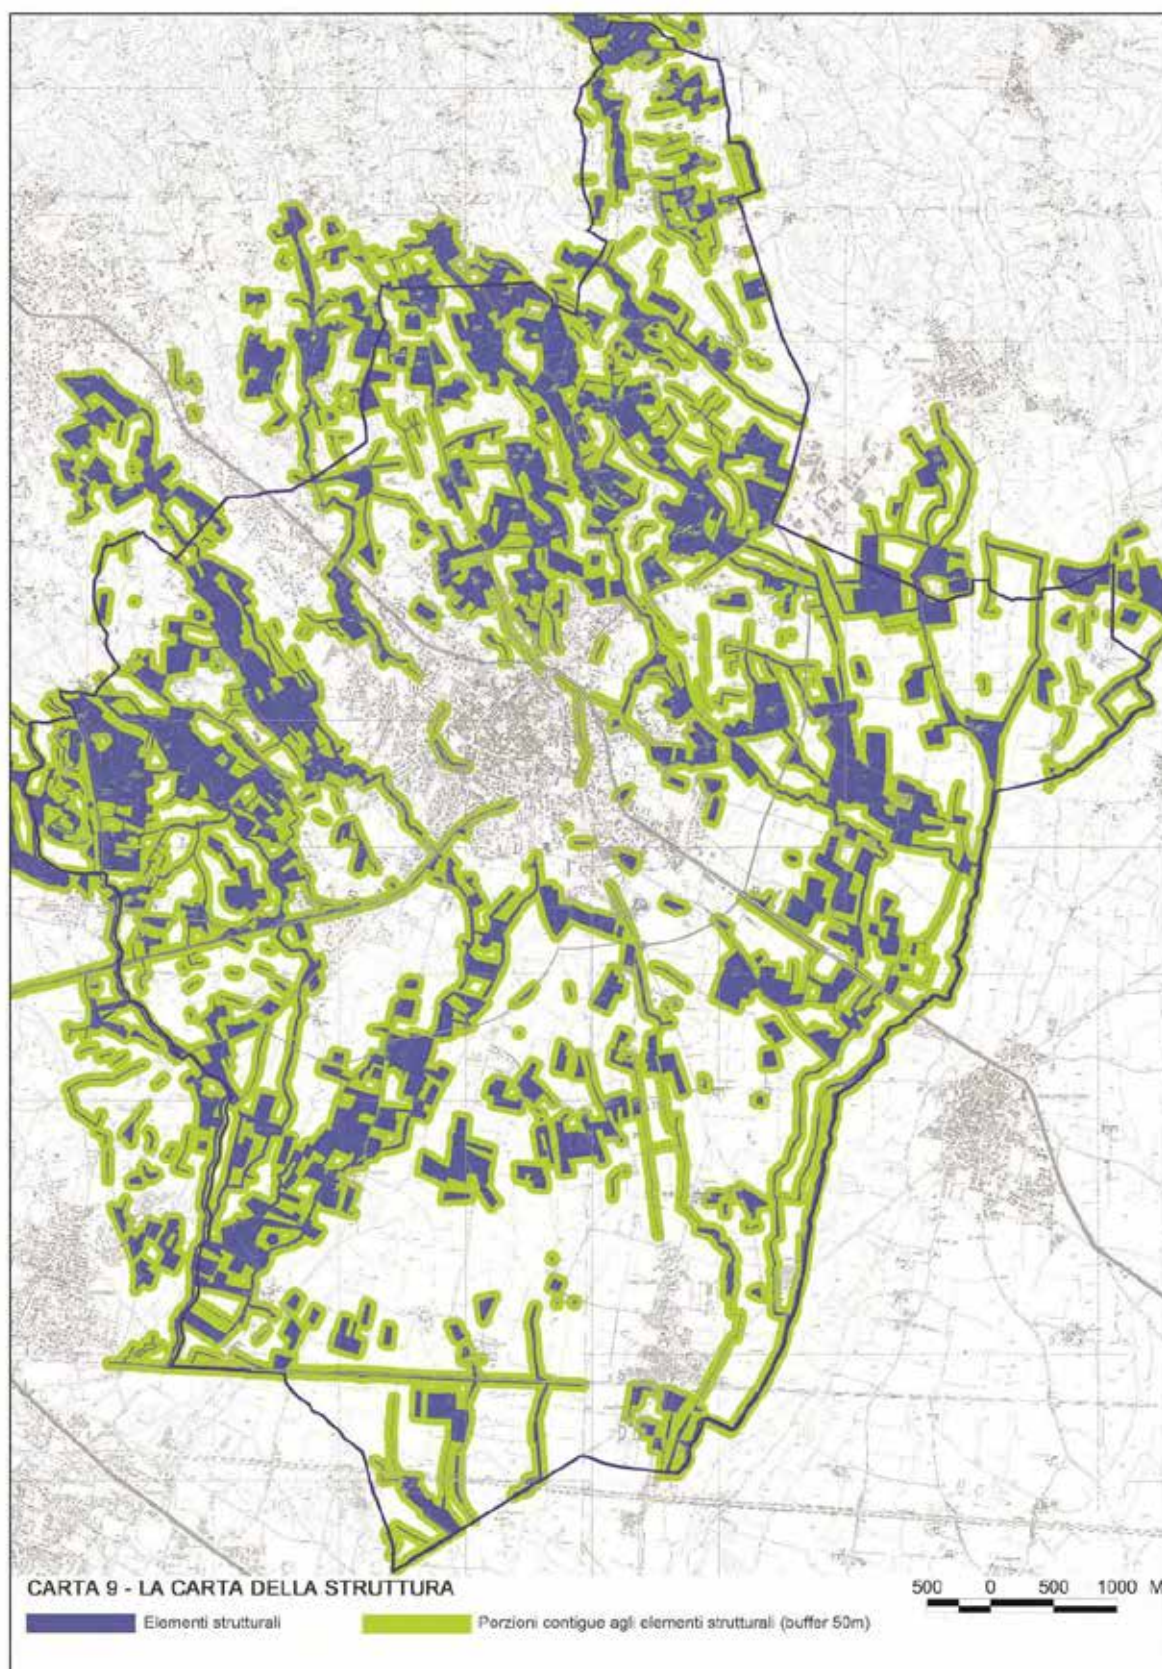

Figure 2. Map of the ecological structuring of Chieri territory. The picture shows the two components of ecological structuring (Structural elements and the Contiguous portions to the structural elements). Processing: Politecnico di Torino, 2016.

4. Rules for implementation of local ecological network in urban planning

In the considered case studies, from an analytical process (framing of the territorial ecological system and public consultation through negotiating tables) it has come to drafting of rules, directly integrated with the urban plans, which include provisions for the implementation tools, such as spatial equalization measures, compensation and mitigation of impacts and provisions for the urban green management.

These implementation mechanisms are designed to intervene where projects and actions included in the urban plan could lead to changes of the level of the local ecological functionality. The procedure for the definition of the compensatory measures for impacts not mitigated includes an analytical phase, an assessment phase, a phase of planning/design, an implementation phase and a phase of management and monitoring:

1. recognition and evaluation of the ecological relevance of the compensatory areas, through the evaluation of urban-environmental state;
2. definition of possible measures for improvement and protection of the ecological and landscape value, for each area identified for compensation;
3. setting priorities for action, to increase biodiversity and the sustainable use of the territory;
4. choice of the compensatory measures;
5. design of compensatory measures, based on the characteristics of each lot chosen;
6. updating the natural value of the areas subject to compensation.

For the implementation of the ecological network into urban planning the selected measures have to be concrete, feasible, included into the landscape framework and coherent with the sectoral strategies defined at higher levels. In order to enable institutions to act towards a well-implemented local ecological network the following factors need to be considered:

- provisions of incentives, funding and authorisation to enable local action;
- strategic direction through regional level strategies and action plans;
- regional coherence of local urban plans and measures through coordinating activities.

Some rules are introduced for the urban green: the idea is that urban green spaces can contribute, with the green development of the rural environment, to the landscape quality of the territory. The defined parameters for the green management integrated (i.e. in the case of the City of Ivrea) the list of plant species adapted to the general urban conditions (climate and soil), as well as the conditions imposed by the urban environment, such as the resistance to pollution and pests. In the selection of plant species, it is indicated to have to consider: at least 50% of native species or particularly suitable to the urban environment and less than 25% of non-native species or naturalized (hence excluding the weeds or plant with relevant on-going diseases).

The urban nature conservation requires also new conditions: ecosystems, such as landscape, transcend the scales, beyond just the urban area. We need to understand, within the rules and projects, that green is no longer just a mere architecture of context but contributes, primarily, to create a complex system, unitary consistent with historical heritage and environmental dynamics. We can identify five key passages through which to build this system (Voghera and La Riccia, 2016):

1. Transposing the ecological network elements at regional level and verifying the implementation and the possible expansion at local level (the network project must become an integral part of the territorial vision).

2. Defining the appropriate modalities for intervention favouring the natural use for the areas included in the network.
3. Making the local ecological network also through the institution of urban and territorial equalization models giving priority to the protection of rivers areas and public lands.
4. Ensuring the correct inclusion of allowed building work and the prohibition of definitive elimination of trees and shrub formations, including rows, hedgerows, etc.
5. Defining compensations and mitigation measures of impacts deriving from urban transformations, consistent with the goals of enhancing the local ecological network and the landscape quality.

An important section of the legislation on a local scale for the construction and implementation of the ecological network at local scale is represented by the penalty system, according to two main aspects. For the purposes of protecting the ecological-environmental system that constitutes an asset of landscape interest, the author of a damage in the matter of the protection of landscape assets must, alternatively, either restore the state of the places at his own expense or pay a sum equivalent to the cost to restore the damage caused by the administration. For the purposes of protecting the ecological-environmental system that constitutes an asset of landscape interest, the author of a damage in the matter of the protection of the landscape assets has two alternative measures: the sentence to the remittance in restoration at his own expense of the state of the places or of the failure realization of a project concerning the environmental system. In the first case, it will have to pay a sum equivalent to the greater amount between the damage caused and the profit achieved through the transgression, entrusting to the administrative authority in charge of safeguarding the constraint the choice, deemed most appropriate, between one or the other sanctioning measure. In the second case, it will be sanctioned with a fine equal to the payment of the expense to be sustained for the realization of the project increased by 20%.

5. Conclusions

The case studies have been shown to be an effective means of testing new approaches. They can encourage similar methodologies and convince decision-makers that an idea is worth pursuing. Learning from these examples can also help to adjust and refine a local planning strategy.

Before developing a planning strategy based on local ecological network implementation, local priorities need to be defined. Such priorities are often driven by widely-recognised challenges may present windows of opportunities for urban development and decision-making overall. The underlying principles of ecological network planning here need to be understood as part of a holistic approach based on landscape and need to be adapted to the local planning system, social, economic and environmental conditions, as well as the available stakeholders.

Local ecological network planning requires a complex whole of interventions useful for the optimal provision of services and the quality of living conditions, aimed at production and production public and private wealth distribution, characterized by an eco-systemic approach, with which the city is negotiable as a dynamic organism. Water, energy, waste are the cycles on which to intervene. Bring natural components into harmony different urban forms allow to recover relations between spaces open and built spaces, buildings, soils, morphologies. Production urban agriculture, new solutions for public lighting linked to sustainable mobility and energy production, the reconfiguration of urban fabrics to improve conditions microclimatic and for perceptive wellbeing, aesthetic quality and the functionality of the pedestrian and cycle paths, the connection among parks, city gardens, cultural assets are components a positive environmental balance, which, at the same time, favour

inclusion, propensity to care and sociality, restore degraded values, recover residual and abandoned spaces, produce common goods.

Therefore, urban planning it is not a field confined into the technical sector; it can be to become a collective field, assigning to social and environmental values an economic relevance, putting to centre of attention, habitability, defining new types of spaces public, overcoming the season of volumetric rewarding, for an effective and concrete solution to the inequalities: between centrality and marginality, between city and modern campaign, places, redeveloped parts and parts that will have to looking forward to the conditions to be reborn. With this change of approach, it is possible to change behaviours and lifestyles, financial costs and environmental factors associated with current urban conditions; new economies can be activated, together with job opportunities. It is time, therefore, to move from the technical standards designed for growth of the city to the facilities for the quality of the various urban forms, from destinations of use to activities, from predetermination to compatibility and environmental suitability.

Ecological networks are the key to planning the city of tomorrow, to strive to the settlement balance, to reduce risks, to promote policies integrated, adhere to the contexts and support the improvement of conditions of populations and productive capacities. The networks the operational fields of structural planning are no longer confined to municipal administrative limits, so as to provide territorial standards for citizens moving in the areas metropolitan and vast, interdependent ones. Finally, they involve the necessary integration of management into projects, to measure ecological quality and the supply of ecosystem services, abandoning an administrative approach based only on protection of territorial assets.

Abstract: Nature-based solutions (NBS) are broadly defined as the use of solutions based on nature and ecological functions to address societal challenges, such as climate change adaptation and mitigation, population health, food security, and natural disasters, through the delivery of multiple ecosystem services (ES). This paper aims to outline some of the main challenges associated to the development and mainstreaming of NBS in urban planning, providing valuable insights for the integration of NBS in urban planning processes and instruments. To this aim, five challenges are proposed and discussed in this paper, namely: to provide decision-makers with tools and methods for mapping and assessing ES that substantiate evidence of NBS effectiveness in providing multiple benefits; to use more flexible and qualitative planning approaches that can foster the implementation of NBS such as performance-based planning; to develop indicators that can be used to evaluate and compare possible NBS during strategic environmental assessment of urban plans; to include the assessment of ecosystem disservices that may emerge when considering and comparing NBS interventions; to develop adequate measures of progress for the monitoring of NBS effects over time to strengthen the evidence base for their benefits and co-benefits.

Keywords: ecosystem services; nature-based solutions; urban planning; assessment of co-benefits

Introduction

Over the past years, an increasing number of perspectives have reflected an anthropocentric view of the management of nature and natural resources, including biodiversity and the environment (Nesshöver *et al.* 2015, 2017), focusing on the benefits that humans gain from nature (Díaz *et al.* 2015, MA, 2005, TEEB, 2010, Nesshöver *et al.* 2017). The most recent entry to this discourse is Nature-Based Solutions (NBS), a concept that brings together well-established ecosystem-based approaches, such as Ecosystem Services (ES), Green-Blue Infrastructure (GBI), ecological engineering, ecosystem-based management, natural capital (Nesshöver *et al.* 2017, Nature Editorial, 2017, Raymond *et al.* 2017) and urban forestry (Escobedo *et al.* 2018) with assessments of the social and economic benefits of resource-efficient and systemic solutions that combines technical, business, finance, governance, regulatory and social innovation (European Commission, 2015, Raymond *et al.* 2017). Although NBS approach shares similarities with the abovementioned approaches, its objective towards the management of the natural resources for human well-being is quite different, indicating that such a topic has evolved over time. In fact, although NBS concept shares a similar root for example (and particularly) with the

concepts of ES and GBI, the latter pays more attention to the spatial pattern and connectivity of the natural network, whereas ES to the multiple natural functions that can benefit both nature and humans (Escobedo *et al.* 2018). Thus, the emergence of NBS denotes the recent expansion of the scope to particularly encompass the applications for addressing (i.e., resolving or mitigating) multiple urban environmental, socio-political, and ecological challenges (Escobedo *et al.* 2018), being directly relevant to several policy areas such as land use and spatial planning (Raymond *et al.* 2017). On a technological and applicative perspective, another difference with previous approaches, particularly ecological engineering, is the notion that NBS are explicitly considered as alternatives to human-made infrastructure that require large investments in materials and energy (Nesshöver *et al.* 2017).

The concept of nature-based solutions

Among the various definitions proposed for NBS, the IUCN (Cohen-Shacham *et al.* 2016) defined NBS as “actions to protect, sustainably manage and restore natural and modified ecosystems that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits”, while the European Commission defined NBS as “living solutions inspired by, continuously supported by and using nature, which are designed to address various societal challenges in a resource-efficient and adaptable manner and to provide simultaneously economic, social, and environmental benefits” (European Commission, 2015). The NBS concept suggests that natural (or self-regulating) ecosystem processes are essential for the definition and that it is implicit that a particular challenge or problem should be solved through the contribution of such ecosystem processes (Albert *et al.* 2019). In order to understand their functioning and added value with respect to alternative solutions, NBS can be described as actions that utilize ecosystem processes of green and blue infrastructure in order to safeguard or enhance the delivery of ES, which can in turn contribute to the alleviation of societal challenges, simultaneously providing economic, human security, social/cultural, and ecological co-benefits, in spite of technical alternatives which usually simply target the challenge without providing additional benefits (Albert *et al.* 2019).

Eggermont *et al.* (2015) classified NBS by considering two dimensions: (i) the required level of engineering of biodiversity and ecosystems involved in the NBS; and (ii) the level of enhancement of ecosystem services achievable by the NBS. Particularly, NBS are classified into three main types:

- Type 1 consists of “no or minimal intervention in ecosystems, with the objectives of maintaining or improving the delivery of a range of ES both inside and outside of these preserved ecosystems” (Eggermont *et al.* 2015). Solutions included in this typology are the ones that involve making better use of existing natural or protected ecosystems, such as measures to increase fish stocks in wetlands to enhance food security (Cohen-Shacham *et al.* 2016);
- Type 2 concerns “the definition and implementation of management approaches that develop sustainable and multifunctional ecosystems and landscapes (extensively or intensively managed), which improves the delivery of selected ES compared to what would be obtained with a more conventional intervention” (Eggermont *et al.* 2015). Solutions falling within this typology are based on the development of sustainable management protocols and procedures for managed or restored ecosystems, such as the re-establishment of traditional agroforestry systems based on commercial tree species to support poverty alleviation (Cohen-Shacham *et al.* 2016);
- Type 3 consists of “managing ecosystems in very intrusive ways or even creating new ecosystems” (Eggermont *et al.* 2015). Solutions included in this typology are the ones that involve the creation of new ecosystems, such as the establishment of green buildings – green walls, green roofs – to mitigate urban heat island effect and clean polluted air (Cohen-Shacham *et al.* 2016).

Examples of NBS are green buildings (e.g., green roofs, green walls), urban green areas connected to grey infrastructure (e.g., alley and street trees, railroad bank, house gardens, green playground/ school grounds), parks and (semi)natural urban green areas (including urban forests), allotments and community gardens, green indoor areas, blue areas (e.g., rivers, lakes, seacoasts, wetlands), green areas for water management (e.g., rain gardens or sustainable urban drainage systems), derelict areas (e.g., abandoned spaces with patches of wilderness) (Almassy *et al.* 2018).

Challenges for urban planning

As NBS development and evaluation spans the requirement of lowering of systemic trade-offs and increasing synergies (Maes and Jacobs, 2017), the task for planning and science is to critically assess, for each proposed intervention, to what degree it can alleviate the problem at hand and what kind of co-benefits and trade-offs the intervention might yield (Albert *et al.* 2019). The analysis of co-benefits and trade-offs (e.g., trade-offs among ES), as well as of gaps in ES supply and demand, can enhance the transparency and understanding concerning the respective advantages and disadvantages of proposed actions (Raymond *et al.* 2017). This enables more informed decision-making processes about sustainable development by informing urban land use and management decisions and maximizing an ecosystem's benefits to society (Lafortezza and Chen, 2016), implicitly referring to the spatial scale of the effects of an intervention. As the added value of the NBS approach is that they are strongly solution-oriented, such co-benefits and trade-offs (spatial) analysis need to be addressed taking into account the perspective of solving societal challenges (at different scales, from global to local). However, there still is lack of knowledge about how to assess the impacts of and the co-benefits simultaneously provided by NBS within and across different societal challenges, since existing frameworks do not cater for such complexity (Raymond *et al.* 2017) and previous studies mainly assessed (co-)benefits by making reference to single indicators or challenge areas (e.g., Maes, 2013, Bain *et al.* 2015, Rao *et al.* 2016, Mouchet *et al.* 2017). Moreover, in order to ensure the feasibility of NBS, these solutions require to be embedded within viable governance and planning frameworks due to the need for cooperation and knowledge integration of actors from different fields or sectors, the institutional context within which these actors operate, and the financial options that are available (Albert *et al.* 2019). Thus, for the development and mainstreaming of NBS in urban planning on the one hand evidence is needed to motivate, guide, and support decision-makers in decision-making processes, and on the other hand approaches supporting the development of NBS are required to be integrated into proper planning processes and instruments to guarantee their effective implementation. Below, some challenges associated to the development and mainstreaming of NBS in urban planning are outlined and briefly described. It has to be noted that these challenges are presented not necessarily in order of relevance but just randomly.

The first challenge is related to the development of methods and tools to support decision-making for NBS. Such methods and tools are aimed at substantiating evidence of their capacity and effectiveness to provide co-benefits and simultaneously address different societal challenges while contributing to human well-being, e.g., decision-making toolkits and processes that simplify and systematize the monitoring and evaluation of co-benefits in decision-support (Ürge-Vorsatz *et al.* 2014), as well as model, explore, and suggest solutions (Bell, 2012). Since the effectiveness of NBS is strictly related to the capacity to provide multiple ES, once identified the problem(s) that should be solved and potential solutions, it is essential to create/make use of scientific and spatial models to define, explore, and analyse the spatial scale of the co-benefits that such solutions can provide through the supply of multiple ES, as well as who and where are the beneficiaries. The spatial analysis and mapping of the effects of NBS on the provision of ES is essential to conduct ex-ante assessment – and provide ex-ante evidence – to inform decision-making, since makes it possible to analyse both ecological and socio-economic aspects of an intervention in a spatially-explicitly manner, as well as the beneficiaries of the services (and associated co-benefits) the interventions might yield. Different scientific models already exist and can be used to map and assess ES. However, some ES are considered as difficult to capture through scientific models and indicators, such as cultural ES (La Rosa *et al.* 2015, Cortinovis and Geneletti, 2018). In fact, cultural ES are

characterised by intangible dimension, relation with non-material values, and inherent subjectivity (Chen et al. 2012) and can be investigated through stakeholder involvement (Luederitz *et al.* 2015, Wolff *et al.* 2015, Cortinovis and Geneletti, 2018) instead of applying scientific models that are typically used with biophysical data (e.g., for regulating ES). In general, methods for mapping and assessing ES are intended to:

- portray the current situation in relation to the supply and demand of ES, in order to identify those areas characterized by *low performances* in terms of ES that are associated to a series of social and environmental issues, or societal challenges, and, consequently, affect human well-being (e.g., urban and peri-urban areas that are difficult to access or have scarce presence of facilities have *low performances* in terms of recreational services; residential areas with scarce presence of vegetation have *low performances* in terms of regulating services, such as microclimate regulation or water flow regulation);
- develop scenarios associated to the implementation of NBS aimed at addressing societal challenges (e.g., to address the impacts of climate change, permeable areas for stormwater retention can be created) and enhancing human well-being (e.g., planting a large amount of trees can support the alleviation of health problems associated to air pollution or high temperatures thanks to their ability to capture pollutants and cooling capacity) through the provision of ES (e.g., by bridging the gap between ES demand and supply for stormwater retention; by creating areas characterized by *high performances* in terms of ES supply associated to the presence of trees such as microclimate and air quality regulation); potential ecosystem disservices and options to avoid or mitigate them should be investigated and included in the analysis when developing scenarios (for ecosystem disservices see also the fourth challenge presented below).

Once scenarios based on ex-ante assessments of ES associated to NBS are implemented, cost-effectiveness assessment of NBS projects can be performed on the basis of the evidence base, so that alternative solutions can be compared considering the place-specific implications of each alternative in relation to the expectations for solutions in any particular context. It has to be noted that cost-benefit analyses alone may not adequately capture the multiple benefits over time of NBS, thus methods including integrated sustainability assessment and mapping (long-term and short-term) multiple benefits and how they change over time are required for ex-ante assessments (Xing *et al.* 2017, Raymond *et al.* 2017).

The second challenge concerns the use of performance-based planning approaches, which support better land use integration as long as performance criteria are met instead of more traditional planning approaches and regulations that are typically based on zoning, thus on segregation of land use zones (Frew *et al.* 2016). Performance-based approaches are composed of two components: “first, criteria that describe the desired end result, and second, methods to define standards used to measure the acceptable limits of impact to ensure the desired end result” (Baker *et al.* 2006). Performance-based planning approaches are therefore more suitable to foster the implementation of NBS since it uses clear standards that set acceptable environmental performances (Porter *et al.* 1988; Blackwell, 1989; Frew *et al.* 2016), and can be tailored in order to include more qualitative objectives in urban planning. Performances of urban transformation and management options in relation to such objectives can be measured and assessed by making use of appropriate data and indicators (i.e., performance-based indicators) that are typically used to map and assess ES. Performance-based planning approaches can be linked, for example, to ex-ante assessment frameworks for the evaluation of i) the suitability of any urban development resulting in land use and/or land cover change with respect to some minimum standard requirements, desired results, and/or qualitative and quantitative objectives (in terms of ES supply), and ii) the effectiveness of NSB projects to meet agreed goals or desired end results, e.g., through the selection of a set of easily measurable criteria for the ecological, social, and economic effectiveness of the interventions.

The third challenge is associated to the development of appropriate indicators that consider direct effects and associated co-benefits and that can be used to assess and compare the effectiveness of possible NBS in addressing environmental issues during the strategic environmental assessment of urban planning instruments. It is argued that planning decisions would benefit from systematic considerations of their effects on ES (e.g., Geneletti, 2011). Since many of NBS benefits and co-benefits rely on the supply of multiple ES, systematic considerations of their effects on ES can be founded on the testing and assessment of alternative actions by using such indicators so that advantages and drawbacks of the different alternatives can be highlighted. When assessing NBS, it is of great importance to take into account also long-term benefits and effects, as NBS projects often show their advantages in a longer period of time with respect to traditional solutions (Kabisch *et al.* 2016). This could help to fill the knowledge gaps that exist with regard to long-term benefits and effects of NBS, as well as their contribution to increasing the resilience of cities against foreseen environmental changes (Kabisch *et al.* 2016).

The fourth challenge regards the inclusion of potential disservices or negative externalities that may emerge when analysing, assessing, and comparing the effects of NBS interventions. Some authors (e.g., Lyytimäki, 2015, Schaubroeck, 2017, Blanco *et al.* 2019) advocate that an integrated assessment of both ES and disservices will help towards a clearer understanding about the role that nature has for humans and human well-being, and towards the formulation of more effective and innovative sustainability policies. The inclusion of ecosystem disservices valuation is therefore crucial to estimate the sustainability of NBS (Schaubroeck, 2017). If properly applied during decision-making processes concerning NBS projects, the inclusion of ecosystem disservices in the assessment phase can help to develop ad-hoc management and policy instruments that address potential solutions to avoid or manage them (e.g., long-term management options, appropriate selection of species, or compensatory measures), as well as provide information to inform decisions on alternative solutions.

The fifth challenge concerns the development of adequate measures of progress and success towards agreed goals in order to strengthen the evidence base for the benefits and co-benefits provided by NBS projects, for example through a selection of a set of easily measurable criteria for the ecological, social, and economic effectiveness of the interventions (e.g., Heink *et al.* 2015, Hobbs and Harris, 2001, Nesshöver *et al.* 2017). Many indicators have the potential to be considered as success criteria, but these will need to be clearly related to the specific *solution* goals in terms of biophysical aspects and ES (e.g., carbon sequestration, water use efficiency, pollination, microclimate regulation, cultural and recreational services), and the same applies to the economic and social spheres in terms of value, capital or investment/revenue in the system, or to the effects on health and well-being (Nesshöver *et al.* 2017). Monitoring of NBS impacts/effects over time is considered a fundamental step of NBS development and assessment phases, as it is crucial for their continuous refinement and testing. In fact, when monitoring shows that targets are not met, the community is informed and corrective measures can be taken such as revising the goals, changing planning practices, or improving the implementation of the plan or project (Ahern *et al.* 2014).

Conclusions

The promotion of NBS builds on the increasing evidence and experiences showing that natural resources can play an important and cost-effective role in addressing societal challenges and enhancing human well-being through the provision of multiple ES. These evidence and experiences are largely related to the agricultural and forestry sectors, with relatively little focus on urban areas (Munang *et al.* 2013). This paper presented five challenges associated to the development and mainstreaming of NBS in urban planning, so as to provide directions for their promotion in urban areas. Such challenges are related to the development of decision support methods and tools aimed at providing evidence of NBS effectiveness, to the use of performance-based planning approaches instead of traditional zoning approaches since NBS are strongly performance-oriented, to the development of indicators to assess and compare the effectiveness of possible NBS during the strategic environmental assessment of urban planning instruments, to the analysis and assessment of potential disservices

or negative externalities that may emerge from NBS interventions, to the development of adequate measures of progress and success towards agreed goals to monitor the effects of NBS over time and to strengthen the evidence base for their benefits and co-benefits. The main features of these challenges are introduced and discussed in order to provide insights for the integration of NBS in urban planning processes and instruments.

Acknowledgements

Research for this paper has been partly conducted for the project ReNature (Promoting research excellence in nature-based solutions for innovation, sustainable economic growth and human wellbeing in Malta) receiving funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 809988.

Abstract: Green Infrastructure (GI) multifunctionality – namely the capacity to deliver a wide range of Ecosystem Services (ES) – is one of the main GI planning principles. It is for this reason that the integration between GI and ES concepts and approaches is increasingly tested. This paper presents the outcomes of an applied research that took up the challenge of implementing GI at the local level through the landscape design of a peri-urban rural park (Chieri, Italy) conceived as a GI node. The park's project was based on the evaluation of ES, that allowed to highlight the ES performance of alternative design choices and to support the GI design towards multifunctionality. Eventually, Payment for Ecosystem Services (PES) schemes were defined in order to foster the implementation of the park's project. The research, thus: (i) puts in action a multiscale approach, translating at the local level, through landscape design, GI planning indications; (ii) promotes GI multifunctionality based on a “place-based” vision, that is through the assessment of local features, highlighting the actual area's potential to provide ES and the existing ES trade-offs; (iii) identifies PES as a tool for increasing the effectiveness of GI implementation.

Keywords: Ecosystem Services; Green Infrastructure; landscape design; peri-urban park.

Introduction

The integration of Ecosystem Service (ES) evaluation – namely both ES biophysical assessment and economic valuation (Häyhä and Franzese, 2014, Mavsar and Varela, 2014) – into spatial planning policies is today widely promoted. This integration is generally assumed to be a crucial step to address territorial transformations towards sustainable development, since the ES concept effectively connects environmental, social and economic issues (Braat and de Groot, 2012). Several recent studies addressed the question of how to operationalize ES evaluation for spatial planning and landscape planning in particular (see, among the others, Gómez-Baggethun and Barton, 2013, Von Haaren *et al.* 2016, Tammi *et al.* 2017, Hian *et al.* 2018, Lam and Conwey, 2018). To date, this is a still open and experimental issue (Lerouge *et al.* 2017).

In the last decade, the relationship between ES and landscape design has been increasingly investigated too. After the publication of the Millennium Ecosystem Assessment Report (MEA, 2005), the ES paradigm started to fertilise landscape design science (Nassauer and Opdam, 2008, Termorshuizen and Opdam, 2009). An increasing number of studies proposed ES as a conceptual framework for landscape design, to address it towards multifunctionality objectives, that is the capacity of providing at the same time environmental, social and

economic benefits (Lovell and Johnston, 2009). Performance indicators for designed landscapes based on the delivery of ES were defined (Windhager *et al.* 2010, Sustainable Sites Initiative 2015).

It is precisely this capacity of the ES concept to support *multifunctionality* that makes it a central element in the Green Infrastructure (GI) paradigm as well. Multifunctionality is actually one of the main GI planning principles (together with “connectivity”, “multi-functionality”, “integration”, “multi-scale approach” and “multi-object approach”, Hansen and Pauleit, 2014). GI has been defined as a “strategically planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services” (EC COM(2013)249). The integration between GI and ES concepts and approaches is thus increasingly studied and tested (Arcidiano *et al.* 2016, Marino *et al.* 2019). It is worth underlying that multifunctionality should not be seen as a straightforward and simplistic result of GI promotion, but as a “place-based” vision, based on the local assessment of GI environmental, social, cultural, economic and institutional context (Madureira and Andresen, 2014). This, in turn, entails the need of meeting another GI principle, that is a multi-scale approach able to link different spatial scales. The construction of an effective link between the planning and design levels is still an open issue in landscape planning policies and ecological network policies (Voghera and La Riccia, 2018).

This paper presents the outcomes of an applied research that took up the challenge of implementing GI at the local level, through the landscape planning and design of a peri-urban rural park that was conceived as a GI node. The park’s project was based on the evaluation of ES at the local scale. ES evaluation (biophysical assessment and economic valuation) was developed both for the area’s current state and for three different design scenarios, allowing to highlight the ES performance of alternative design choices and supporting the GI design towards multifunctionality. Eventually, PES schemes were implemented in order to foster the actual implementation of the park’s project.

Territorial and Institutional Context

The project area, known as *Fontaneto*, is a rural area of 100 ha close to the city of Chieri (Turin, Italy). It is a residual peri-urban zone, surrounded by residential and industrial buildings and transport infrastructures. The area, which is crossed by two minor watercourses (Rio Tepice and Rio del Vallo), is mainly characterized by an intensive agricultural activity (cereal and forage crops), that has non-negligible impacts on the nearby residential areas, due to the use of chemical plant protection products and fertilizers. Despite some punctual restoration projects developed by the Municipality, today *Fontaneto* presents a general low environmental and landscape quality. The area is mainly private and highly fragmented (439 cadastral parcels and 175 owners).

This area has been identified in the Chieri Local Ecological Network¹ as a part of a “*cuneo verde*” (green wedge). Green wedges are areas with a high density of zones with relevant ecological functionality. These areas act as important ecological corridors that penetrate the urban and peri-urban context. *Fontaneto*, in particular, is situated in the northern part of a green wedge (Figure 1) and it is a crucial transitional zone between the city and the surrounding rural landscape. In green wedges, interventions to increase ecological performance are needed in order to improve the quality and connectivity of the overall network. A Plan (“*Biciplan*”, closely connected to the Ecological Network Plan) aimed at improving the soft mobility network in Chieri highlighted the need for integration of bicycle pathways in the city and in the *Fontaneto* area as well.

¹ “Local ecological network and Biciplan of Chieri” (2016) is a study developed by Politecnico di Torino – DIST (research group: Angioletta Voghera, Luca Staricco, Stefania Guarini, Gabriella Negrini, Luigi La Riccia), on behalf of Chieri Municipality.

Figure 1. The *Fontaneto* area in the context of the Chieri Local Ecological Network (Source: *Variante strutturale n. 15 del Piano Regolatore Generale Comunale*. Urban areas are highlighted in pink, green wedges are highlighted in light green, the *Fontaneto* area is circled in yellow).

On the wave of these studies, and of a more general Municipality's effort to develop policies that reduce soil consumption, in 2019 Chieri Municipality approved a modification of its local urban plan (*Variante strutturale n. 15 del Piano Regolatore Generale Comunale*). According to this modification – that was supported by the LIFE+ project SAM4CP (<http://www.sam4cp.eu/en/>) and explicitly aimed at maintaining and enhancing ES provided by soil – some areas of *Fontaneto* that were previously classified as industrial zones and golf courses have been converted in rural areas. The Municipality aims to create in *Fontaneto* a rural-recreational park that could act as a crucial node of the local GI (here intended as the combination of the local ecological and mobility networks above-mentioned), in which sustainable agricultural areas, natural areas, and recreational areas coexist and, in the meanwhile, a more sustainable relationship between the dense city and its peri-urban rural context is promoted.

The research here presented – developed by SEACoop, in collaboration with Politecnico di Torino, on behalf of Città Metropolitana di Torino (December 2017 - July 2018) and the Chieri Municipality (October 2018 - today) – meant to support the area's transformation by developing a design vision based on *Fontaneto* environmental and landscape enhancement. To this aim, the concept of ES has been assumed as an operational paradigm to address the area's design towards the requested multifunctionality and to envisage a peri-urban park capable of delivering provisioning, regulating and cultural ES. Evaluation has been thus conceived not only as a knowledge tool but as an operational tool, able to sustain and address landscape design choices.

Ecosystem Service Evaluation for *Fontaneto* Landscape Design: Methodological Framework and Outcomes

Evaluation was carried on in relation to nine ES (Table 1). Starting from the ES classification framework provided by the Common International Classification of Ecosystem Services (CICES, V5.1, 2018, cices.eu), ES were selected according to their representativeness of the main ES classes – Provisioning, Regulation and Maintenance, and Cultural ES – and the primary functions that are currently performed by the area and envisaged by the project. In order to evaluate ES, both biophysical and economic indicators were used. Because of the site-scale of the evaluation, indicators, when possible, relied on empirical and in-situ collected data (e.g. water quality is based on the analysis of extracted soil samples, Habitat maintenance on local avifauna observation, Agriculture production on a survey of local agriculture land uses).

Ecosystem Services		Biophysical indicator	Structure	Economic indicator	Structure	Economic valuation method
PROVISIONING	Agricultural production	Amount of agricultural products	ql/ha/year	Value of agricultural products	€/ha/year	Market price
	Wood production	Volume of extracted wood	m ³ /ha/year	Value of extracted wood	€/ha/year	Market price
	Groundwater	Volume of water extracted for irrigation use	m ³ /ha/year	Value of water extracted for irrigation use	€/ha/year	Market price
REGULATION AND MAINTENANCE	Hydrogeological protection	Surface of vegetation areas acting for prevention of riverbanks erosion	ha	Value of the protective function played by riparian vegetation	€/ha/year	Replacement cost
	Habitat maintenance	Surface of areas able to maintain nursery populations and habitats	ha	Value of the ecosystem capacity to maintain nursery populations and habitats	€/ha/year	Avoided cost and Benefit transfer
	Water quality	Amount of nitrogen absorbed by soil	g/m ³ /year	Value of the water purification function played by soil	€/ha/year	Replacement cost
	Climate regulation	Amount of carbon absorbed by soil	t/ha/year	Value of carbon absorbed by soil	€/ha/year	Market price
CULTURAL	Recreation	Number of visits	Visits/year	WTP/visits	€/ha/year	Benefit transfer
	Aesthetic values	Number of visitors	Visitors/year	WTP/visitors	€/ha/year	Benefit transfer

Table 1. Biophysical and economic indicators for the evaluation of Ecosystem Services.

To make evaluation an effective tool to sustain the landscape design choices, ES evaluation has been developed as tightly connected to the design phase.

Firstly, we evaluated the baseline, namely the current provision of ES in the *Fontaneto* area. Through the application of indicators, we defined, for each ES, per unit (ha) and per year biophysical and economic values, and we applied them to the different land-uses in the area that contribute to specific ES production.

We then defined a Masterplan for *Fontaneto* aimed at improving the delivery of ES in the area and at meeting the Municipality's request for a multifunctional park where rural, naturalistic and recreational areas can coexist. The Masterplan entails three main types of landscape design interventions: (i) interventions explicitly aimed at improving the area's environmental quality, such as cultivation changes from cereals to oil and protein crops to grant a more sustainable agriculture, creation of a wetland to improve local biodiversity, and planting of riparian vegetation for hydrogeological protection; (ii) interventions to improve the area's landscape quality (here meant in terms of scenic-perceptive values), such as a planting of vegetation for the mitigation of the visual impact of buildings situated inside and nearby the area; (iii) interventions to improve the area's recreational potential, such as the creation of recreational areas and tree-lined bicycle paths.

With regard to interventions, we envisaged three different implementation scenarios: (i) in the first one (the optimum scenario) all the interventions are carried on; (ii) in the second one (the medium scenario), some landscape elements aimed at improving the area's environmental quality (e.g. wetland and riparian vegetation) and the recreational potential are not implemented; in the third one (the worst scenario) only tree-lined bicycle paths are implemented. For each scenario we evaluated the overall ES provided, applying indicators to the new envisaged land-uses. The comparison between the scenarios and the baseline, and among the three scenarios (Table 2), gives interesting insights to support the definition of the final project for the rural-recreational park.

Ecosystem Services		Scenario 1 (optimum scenario) €/year	Scenario 2 (optimum scenario) €/year	Scenario 3 (worst scenario) €/year	Baseline €/year
PROVISIONING	Agricultural production	95,105.18	96,586.88	99,620.18	101,724.37
	Wood production	139.24	119.41	87.02	87.96
	Groundwater	45.81	47.22	46.81	45.55
REGULATION AND MAINTENANCE	Hydrogeological protection	18,866.34	17,630.23	17,630.23	17,325.31
	Habitat maintenance	6,109.17	6,092.92	5,839.81	5,810.30
	Water quality	24,282.36	24,246.16	24,028.07	9,297.66
	Climate regulation	89,008.39	90,412.60	89,642.13	60,698.30
CULTURAL	Recreation	50,585.83	37,846.65	25,969.91	19,273.92
	Aesthetic values	47,886.39	27,841.64	5,283.75	1,869.97
TEV		332,028.71	300,823.71	268,147.90	216,133.34

Table 2 Evaluation outcomes: baseline and scenarios.

The TEV of ES delivered by each scenario is higher than the baseline. The envisaged interventions thus improve significantly the value of ES provided by the area, even if we consider the worst scenario. Concerning the three

scenarios, the values of ES differ consistently among them. In most cases, ES values grow from the worst to the optimum scenario (only Groundwater and Climate regulation present non-linear dynamics). Agriculture production is the only ES whose values decrease from the worst to the optimum scenario. This negative dynamic is due to the conversion of a part of the current agricultural areas to different functions (e.g. recreational functions, through bicycle paths, or environmental functions, through riparian vegetation). This trend of values catches the trade-off phenomena that can occur among ES: maximizing the delivery of all ES simultaneously is often difficult, if not impossible (Torkelboom *et al.* 2018). This is particularly true for provisioning ES (such as agriculture production) whose dynamic is usually inversely proportional to regulating and cultural ES (Braat and ten Brink, 2008). In *Fontaneto* this relationship is clear and poses issues regarding social acceptance and feasibility of the project.

Potentialities and Challenges of Payments of Ecosystem Services as a Tool for Supporting Green Infrastructure Implementation

PES can be defined as incentive mechanisms to promote the provision of ES. More specifically PES are “voluntary transactions where a well-defined ES (or a land-use likely to secure that service) is being ‘bought’ by a (minimum one) ES buyer from a (minimum one) ES provider, if and only if the ES provider secures ES provision (conditionality)” (Wunder, 2005, p. 3).

This theoretical scheme proves to be significantly more complex when applied in reality (Muradian *et al.* 2010). Every PES is necessarily a site-specific solution. This is even truer in Italy, where there is not a legal framework for ES (the legislative decree which should have regulated PES in accordance with the principles laid out by Section 70(1) of Law 221/2015, art. 70.1, is still to be enacted). Moreover, a strong tradition of “command and control” planning tools and a widespread land property fragmentation do not favour the implementation of PES in our country, that are less common² compared to other European contexts (Maztdorf *et al.* 2014). PES are currently a technical testing ground for environmental and landscape policies in Italy.

However, despite these challenges we think that PES could represent a valuable tool for implementing in *Fontaneto* the landscape interventions described above, and, more generally, for fostering the actual implementation of GI. Thanks to the main features that should characterize PES – i.e. conditionality, additionality and permanence (DEFRA, 2013) – this tool could improve the effectiveness of the design action by: (i) granting a real and long-term provisioning of ES, (ii) fostering local actor “responsibilisation”, and (iii) contributing to solving potential social conflicts linked to ES trade-offs. In *Fontaneto* PES could be used to incentive farmers to provide cultural and regulating ES, through giving up portions of arable land for creating bicycle paths, or planting and maintaining riparian and mitigation vegetation.

We thus identified possible “buyers” of ES in *Fontaneto*: the Municipality itself, other public institutions (such as the Local Health Authority), private actors that are already committed with the Municipality to pay for landscape-environmental compensations (e.g. local companies) or that could be interested in sponsoring PES. Concerning the ES “provider side”, farmers have been identified as the main potential ES providers in the area. However, due to the high fragmentation of the land properties, an Association of owners has been identified as the most suitable actor to be involved in a PES scheme that could assure a consistent management of the area.

Conclusions

This applied research aimed to link ES and GI concepts and approaches. We think that the *Fontaneto* project can be considered a valuable experience of GI implementation because of the following reasons:

² Beyond some interesting, punctual experimentation (see for instance Marino 2017).

- it puts in action a *multiscalar approach*, translating at the local level, through landscape design, planning indications concerning the local ecological and recreational network;
- it promotes *multifunctionality*, by considering the provisioning of different ES as a key criterion for the Park's design. Multifunctionality is not a "simplistic result" of the GI concept, but it is based on a "place-based" vision. The assessment of the local features highlighted the actual area's potential to provide ES and the existing ES trade-offs;
- it identifies *PES* as a tool for increasing the *effectiveness* of GI implementation. A path for activating PES schemes between the Municipality and some locale farmers has already been started. The Municipality has recently dedicated a part of the 2019 annual budget to finance PES on private rural areas. Moreover, the Municipality is currently working on the hypothesis of decreasing the rental price of public rural areas in order to incentive farmers to deliver certain ES. Several operational aspects still need to be stated (e.g. constitution of landowner association, drafting of PES contracts, definition of the monitoring processes), but the process for the activation of PES schemes in *Fontaneto* can already be seen as an innovative and experimental practice in the national framework of landscape policies.

Land development and management in post-socialist countries

Land development and management in post-socialist countries

Územní Plánování vs. Generalbebauungsplanung:
A Comparison of Planning Concepts and Practices
between the former Czechoslovakia and the German
Democratic Republic

Azmah Arzmi

Bauhaus-Universität Weimar, azmah.arzmi@uni-weimar.de

Abstract: While there is no denying that the Soviet Union had great influence over the patterns of urban growth and development of land in Central and East European countries in the 20th century, yet a qualitative comparison of how each country defined urban planning and spatial planning during their state socialist regime have not been examined in depth. The nuances in meanings would reveal local perspectives on how the planning process operated in each respective country, thus unfolding the unique trajectory path of each city based on its location and importance within the country even after the transition to post-socialism. The aim of this paper is to expose the particularities of planning practices in Czechoslovakia compared to the German Democratic Republic (GDR) and to explain the differences in urban development in strategically located cities of East Berlin and Bratislava. The first part of this paper introduces the definitions and concepts of urban planning in the Czech, Slovak and German context and how they evolve throughout the four decades of various planning and building stages during state socialism. Then it discusses the concept of spatial planning and the instruments used respectively in each country. The third part will then demonstrate how these concepts and instruments were applied in an important aspect of planning infrastructure, the nation-wide transportation network, and its influence on growth in East Berlin and Bratislava.

Keywords: comparative planning history, state socialism, infrastructure, centralised economies;

Introduction

Much of the discussions in the current discourse on post-socialist cities acknowledge the need for critical analysis of their respective history rather than orienting the research as an East and West divide (Tuvikene, Hirt, Ferenčuhová, 2017; Ferenčuhová, 2016). This is due to the fact that the cities of Central and East Europe as well as the former Soviet Union experienced diverse development pathways after the fall of socialist regimes. An overview of the presentations during the recent *Three Decades of Post-Socialist Transition* Conference in Darmstadt, May 2019, which brought academics and experts from cities all around Europe and the former Soviet Union, revealed the individual responses and measures in urban development during the transition to global capitalism that varied from each other. Indeed, authors who have studied these developments have categorized them into sub-regions, e.g. Baltic, Balkans, Central Europe, Russia and the former Soviet Union cities as distinguishable from one another (Tosics, 2005; Bohle, Greskovits, 2012). While it may be helpful to categorise these developments, researchers advocating comparative urbanism have highlighted the need to analyse cities as products of their own history rather than just results of empirical studies (Roy, 2016; Ferenčuhová, 2017). This paper aims to contribute to the discourse by analysing the

contextual meanings of urban planning in the German Democratic Republic (GDR) and Czechoslovakia, and by juxtaposing them, exposing the differences in their approaches to further understand the imprint on today's urban development. This paper is based on a discourse analysis through texts derived from architectural journals, textbooks, maps and documents from the former educational institutions and the ministries of the GDR and Czechoslovakia as well as local contemporary secondary literature. While it addresses that each region has national histories of urban planning dating back hundreds of years, the paper will focus only on the socialist regime period. The first part introduces the local definitions and concepts of urban planning, the second section touches upon the concept of spatial planning and the instruments used respectively in each country, while the final section demonstrates how these concepts and instruments were applied in an important aspect of urban planning, the transportation network, with examples in East Berlin and Bratislava.

Urbanismus and Städtebau

It is insufficient to explain the planning history of the former socialist countries without considering how planning was understood from their own perspectives. The understanding of the current usage of *Urbanismus* in Czech (or *Urbanizmus* in Slovak) can be referred to *Slovník Soudobého Urbanismu* (A Contemporary Dictionary of Urbanism) written by Jiří Hrůza (1977), a prominent Czech urban planner from Prague. He describes *Urbanismus* as “the most general expression for a set of working methods and procedures for the purposeful formation of human settlements and especially of cities.” The term *Urbanismus*, borrowed from Latin, began to be used at the end of the 19th century and at the turn of the 20th century when Prague experienced an expansion of new districts such as Vinohrady and Žižkov. Hrůza admitted that *Urbanismus* is a rather nebulous term, and was used in Czechoslovakia in its most general sense (p.266). At the time of writing, he pointed out that *Urbanismus* has more emphasis on the notion of the cultural and artistic aspects of urban planning, and not associated with the technical and economic aspects of the creation of settlements as defined by the Czech term for spatial planning, *Územní plánování* which will be discussed in the next section. Karel Maier, a Czech planning expert from the Czech Technical University, described *Urbanismus* broadly as a discipline to create and develop settlements as functional and balanced entities (Maier, 2000). What is clear between the definitions from these experts is that *Urbanismus* is about the development of an *osídlení*, a populated area or settlement, be it town, village or city. With regards to the etymology of the word *urbanismus* in the Czech or Slovak language, Hrůza mentioned that it evoked concepts of developing urban estates, or the solution of general municipalities, parks, landscapes and the whole wider territorial unity (Hrůza, 1977, p.266). In practice, the technocratic terms of *městské inženýrství* (city engineering) and *městské stavitelství* (city building) was more widely used.

In the German language, the word *Städtebau* is frequently used and loaded with complex meaning. In their book ‘*Urbanism and Dictatorship*’, Max Welch Guerra, Harald Bodenschatz and Pierro Sassi (2015) refers to *Städtebau* as the “planned, drawn and built structural form of the city” and that it is also the “processes, and production conditions that lead to the creation of an urban structure.” *Städtebau* refers to the profession as well as the science behind the aforementioned aspects (Guerra, et al., 2015). Dieter Frick, a professor of *Städtebau und Siedlungswesen* at the Technical University in Berlin provides a more precise definition, that by perceiving the city as an object, *Städtebau* is the ‘*Bauen von Stadt*,’ or building activity upon that city, such as the production, regeneration, removal of buildings, technical installations and landscaping. Apart from this aspect, *Städtebau* is also about the arrangement of buildings and their relationship and connection to each other and about the coordination and control of the building activity in that area. Moreover, Frick considered *Städtebau* as

the structural-spatial organisation of the city (Frick, 2008, p.15-20). As industrial and urban development emerged hand in hand in German-speaking countries in late 19th century onwards, the term *Städtebau* became an interdisciplinary term that was widely discussed. Renowned engineer Reinhard Baumeister (1876) and architect Josef Stübben (1890) emphasise the technical, structural and organisational aspects of the city while art historian Camillo Sitte (1889) considered the city as an object, a work of art drawn from historical patterns (Kress; Ed. Hein, 2017, p.178). As Germany underwent the *Neues Bauen* movement of housing development, the term *Siedlung* for housing estates and its relations with surrounding regions became synonymous with *Städtebau* (Frick, 2008, p.20).

A degree of uncertainty of what specifically constitutes the word *Urbanismus* enabled several adaptations throughout the existence of the Czechoslovakian state especially during the state socialist regime, depending on the socio-political and economic situations of its time. Architects who practised during the era, Emanuel Hruška and Jan Krásný wrote extensively with regards to this issue in the *Architektura ČSR* journal entitled *Tricet let urbanismu v ČSSR, Jeho teoretický vyvoj i praktické realizace* (Thirty years of *Urbanismus* in the Czechoslovak Socialist Republic, its theoretical development and practical realisation) in 1975. From 1948 to 1952, the socialist realism period, which was also referred to as the 'formalistic' era, *Urbanismus* was defined as urban development which followed the national economic plans and with formalistic tendencies. Examples are Ostrava-Poruba, "Prednádraží" in Banská Bystrica and Nova Dubnice in Slovakia. Before the overcoming of formalism, there was the period of the controlled formalistic approach in 1952-1956. At this stage, *Urbanismus* was reduced to the construction of superblocks in new housing complexes, or 'nova sidliste' on the peripheries of existing cities. These include Invalidovna in Prague, Ružinov in Kladno and Terasa in Košice. The years 1957 to 1961 was when *Urbanismus* took on a more technical term, rejecting previous flamboyant concepts of formalism as the industrialised construction industry flourished. Urban design, which was based on crane tracks and superstructure of the construction site, was embedded in *Urbanismus* at this stage. In the experimental period 1962-1966, Czechoslovak urban planners realised that *Urbanismus* could not just be confined to the idea of housing production, hence they attempted to include civic amenities in the pursuit of 'complexity' in the search of an ideal housing complex. Proposals for the largest housing estates in Prague and Bratislava, Jižní Město and Petržalka respectively, were conceived at this stage. In the late 1960s to early 1970s, as sociological issues in housing development came to the fore, *Urbanismus* expanded its definition to include a more quantitative approach with prognoses into the long-term social and economic development of cities and their increasing agglomeration. These concepts develop rapidly during the normalisation period after 1968. The socialist idea of *Urbanismus* eventually expanded as concerns about the regeneration of the inner cities appeared from mid-1970s. At this stage, *Urbanismus* became linked to a more creative and artistic aspect, while the term to characterise organizational solutions of land-use was attributed to *územní plánování* (Hruška; Krásný, 1975, pp. 152-164).

In the GDR, the focus was more on how they could use *Städtebau* to forward their agenda to provide better living conditions in comparison with West Germany. The objectives of *Städtebau* was, among others, to increase efficiency of socialist production, the territorial development should provide good working environment for labourers, improve housing conditions and to reduce the differences between the different living standards of residential areas (Lammert, 1979, pp. 20-21). From 1949 to mid-1950s the architectural form was oriented towards classicism in connection to the national construction tradition. Following the GDR architects' trip to Moscow, the 16 Principles of *Städtebau* was established in 1950, and as the GDR architect Bruno Flierl elaborated, that while it was inspired in part by the Athens Charter, it was an alternative model that was social. While the Athens Charter assumed functional differentiation as a solution to the overcrowded older cities, the 16 Principles

considered the city as a unifying entity in which the functions exist and where they should be arranged (v. Beyme, 1987). In this period, *Städtebau* was expressed in the new city centres, central plazas and great monumental thoroughfares such as the Altmarkt in Dresden and the Stalinallee in Berlin. During de-Stalinisation in the mid-1950s onwards, *Städtebau* became industrialised and rationalised with the dominance of industrial building construction. In this period, the references were made to the earlier Neues Bauen in the 1920s and the search towards a concept of a social-oriented *Städtebau* (Grönwald; Ed. Bernhardt et. al, 2012, pp. 188-189). Large housing estates began to emerge, such as Halle Neustadt and Hoyerswerda in this period, as *Städtebau* became rationalised to produce superblocks of panel buildings, generated in large spaces. Finally, during the last stage of the GDR, from mid-1970s onwards, there was much awareness on qualitative renewal of the old city centres at the same time as large *Siedlungs* of housing estates were reproduced in the outskirts of the cities such as Berlin-Marzahn and Leipzig-Grünau as part of the infamous Housing Building Program. In this period, *Städtebau* was about the transformation of old city areas into pedestrian zones and concentration of individual civic buildings while contending with the ongoing large-scale housing development (v. Beyme, 1987).

What is noticeable about *Urbanismus* in its application during the state socialist regime was the heuristic tendency in its quest for meaning. In contrast, while the idea and concept of *Städtebau* remained constant, its approach changed as urban planners in the GDR had to adopt rationalised methods from the 1950s onwards (Pretzsch, 1979, p.570). Nevertheless, for both countries, *Urbanismus* and *Städtebau* must consider and operate on the investments and regulations provided by the national economic policies, which changed every five years. To understand how cities develop in the socialist period, even though each had a distinct and individual trajectory, they generally operate as a 'synchronized instrument' based on the master plan of 'economic production and social transformation in physical space', according to Kimberly E. Zarecor in her paper '*What was So Socialist about the Socialist City?*' (2017).

Based on figures from the Warsaw International Statistics Yearbook in 1965, (Goldzamt, 1975, p.18), Czechoslovakia had a larger area to contend with (127,900 km² to GDR's 108,300 km²), as the Slovak lands were not industrialised or urbanised as Czech lands after the Second World War, hence there was more intensity in urban development and building new cities, while GDR built fewer new cities and focused more on rebuilding and restructuring their own existing cities. As we compare the 1965 population density per area between the two countries, Czechoslovakia had a higher percentage of people in the rural area (39%) and more land than the GDR (26.9%) while the GDR had a higher population density (157 people per km² compared to Czechoslovakia's 111 people per km²). Furthermore, there was an almost 10% increase in rural-urban migration in Czechoslovakia from 1950 to 1965 compared to 2% increase in the GDR during a similar period.

Taking into account Zarecor's frameworks for analysing socialist cities, she introduced the concepts of infrastructural thinking and the socialist scaffold. To put it in simple terms, the former are the decisions made based on the scale of urban infrastructure and the latter refers to the 'basic infrastructure for future growth' where the economic, social, political and environmental systems could attach and become activated (Zarecor, 2017, p.7). Thus, the cities expand but it was in a controlled and rationalised way dictated by a master plan of several levels. If these cities operate on a state master plan of the whole country or regions that determine the socialist scaffold of managing growth of labour, capital and infrastructure over time, then the concept of spatial planning is a dominant feature in former state socialist countries than urban planning alone. To comprehend how the urban actors make decisions in the development of the city is to grasp the concept of this master plan as an important intermediary sanctioned by the state and left to the actors to translate these goals in physical space.

Územní plánování and Generalbebauungsplanung

Spatial planning is rarely used in the English-speaking countries compared to the terms urban planning or city planning. This concept is mostly used in the European context. To elaborate, the definition of spatial planning, according the European Commission (1997), are methods utilised by the public sector to influence the distribution of activities in space with the aim of creating a more rational territorial organisation of land uses. The goal of spatial planning is to ensure a balance between demands for development and need to protect the environment to achieve social and economic development objectives (p.24).

There were many stages of spatial planning processes with regards to these two socialist countries. In the 1980s, Czechoslovak spatial planning journals have frequently looked to their German neighbour to evaluate the effectiveness of their own systems (Kuthan, 1984). The *Územní plán* and *Generalbebauungsplan* were important instruments for which any development decisions on cities and agglomerations take place. They were both developed in coordination with the national economic plans. Both were adaptable with accordance to changes in the five-year plans and used for short or long-term development. The plans were developed and approved by the top central organs in accordance with the general traffic planning and other sectoral planning. By the mid-1970s after three decades of centralised economic planning experience, both countries have refined their methods for effective spatial planning. From these the local councils, municipalities and architects had to develop plans for the cities, land use, urban design, concepts for the regions with allocated investments from the state planning commissions (Hrůza, 1977; Lammert, 1979; Gál & Furdik, 1984; Kadatz, 1997).

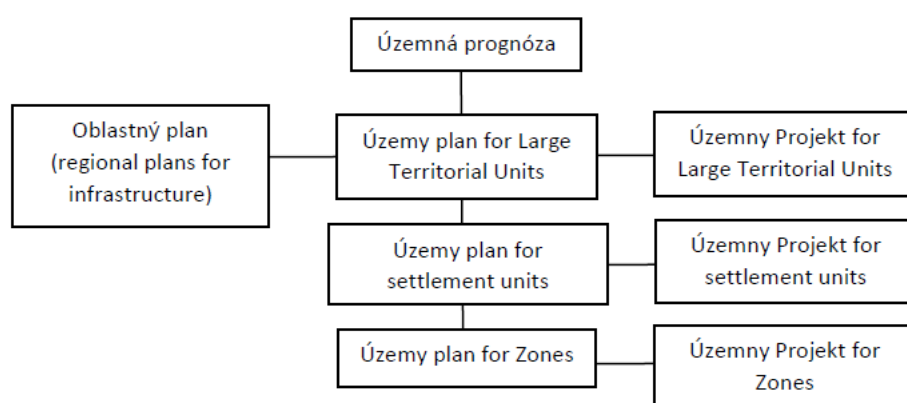

Chart 1: Simplified diagram of the hierarchy of the *Územní plán* documentation in Czechoslovakia after 1976

According to the slovik.seznam.cz official Czech-English translation, the word *území* refers to territory. Hrůza (1977) defines *území* as a territory with natural resources which creates possibilities for exploitation and rational utilization. He went on further to say that *území* does not only include areas with high population densities and controlled urbanization, but also in a relatively large rural area undergoing urbanization (p.269). Hence, *Územní plánování* means the planning of the *území*. Under the context of the Czechoslovak centralized economy, according to the textbooks from the Faculty of Architecture at the Slovak Technical University in Bratislava (1984), *územní plánování* is the development of the environment in a large territory into a uniform settlement system (Gál, Furdik, 1984, p.6). The *územní plánování* has three different stages; large territorial units, zones and

settlement units. The cities of Prague and Bratislava are each separate territories with their own agglomerations and have their own territorial development plans, the *Územný plán*. There are separate regional plans for infrastructure which must be coordinated with the *územný plán*. These documentations form the basic framework of the long-term development of the territory, including land use, social transformation, economic production, traffic planning and environmental protection. Based on the Building Act No. 50/1976, in which building regulations must be strictly bound to *územní plánování*, each *územný plán* must be accompanied by the *územná prognóza*, an economic, social and demographic forecast of the territory and the *územný projekt*, a time-based development plan for the territory (Ibid, p.26).

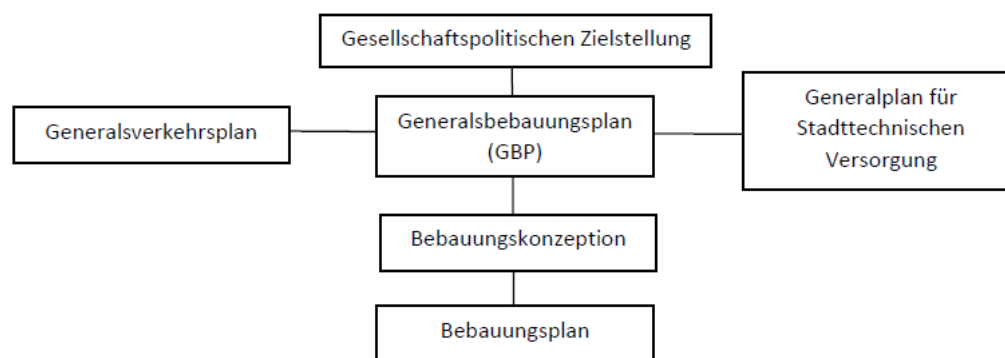

Chart 2: Simplified diagram of the hierarchy of the *Generalbebauungsplanung* documentation in the GDR in 1972

In the German context, the *Generalbebauungsplanung*, according to the Langenscheidt Routledge German-English Architecture and Construction Dictionary, means master plan whereas the *Bebauungsplan* is defined as development plan. The root word *Bebauung* means development, house-building or built-up area (Gelbrich, 2007). More specifically, for Frick the *Bebauungsplanung* should not be limited to construction of buildings according to the Building Code, but rather all the objects and corresponding procedures that are connected with the qualitative control of the building activity in the area such as land division, public spaces or green spaces. *Bebauungsplan* intended for an entire city or agglomeration is referred to as the *Generalbebauungsplan* (pp.167-168). The *Generalbebauungsplan* in the context of the GDR was introduced in 1965 and used more as an instrument for the long-term management, planning and coordination of urban development from effective traffic planning, identifying suitable residential locations and nature reserves (Kadatz, 1997; Rietdorf & Werner, 1972; Lindemann, Eds. Bodenschatz, Brake, 2017; Sommer & Weise, 1971). The *Generalbebauungsplan* had to be coordinated with the *Generalverkehrsplan*, the General Traffic Plan and *Generalplan für Stadttechnischen Versorgung*, the General Plan for Urban Technical Supplies. Each municipality or district had its own *Generalbebauungsplan* approved by the top organs and was responsible for drawing up its own *Planwerk Generalbebauungsplan*, a plan of work for development projects, under which there were *Bebauungskonzeption* and *Bebauungsplanung* (Lammert, 1979, p.232), dealing with the development and urban design of each subareas of the district, e.g. the Marzahn *Bebauungskonzeption*. For important projects such as East Berlin, the state and district planning commissions, as leading economic organs were directly involved with the development of the *Generalbebauungsplan* (Lindemann, 2017). The *Gesellschaftspolitischen Zielstellung* was a prerequisite for each *Generalbebauungsplanung* in each council of the district. This provides the comprehensive view on population growth, labour force and workplace developments, funds and

planned stages of development, planned infrastructure, recreation and environmental protection (Kadatz, 1997).

Comparing these two terminologies used in the local context, *územní plánování* has more to do with the exploitation of the territories, their rational utilisation in the distribution of settlements, infrastructure and economic production. On the other hand, *Generalbebauungsplanung* concerns itself with development and the structural spatial organisation of either rural or urban areas, akin to the *Städtebau* concept. This is not to say that territorial planning in the GDR did not exist, but the responsibility to develop the city or urban areas was not strictly bound to territorial plans as they were with the *Generalbebauungsplan*, based on sources in the 1970s (Junker, 1976) and could range up to 1:25 000 in scale (Maaß, 2006, pp.88-89). In fact, territorial planning in the GDR was directly under the State Planning Commission and had more in common with West Germany, as the system was already established before the divide (Fege & Menge, 1992).

As for the *územní plan*, the plans of the large territorial units were the most crucial derivation of the national economic plans, and they could range from smaller scales of 1:2500 depending on important projects in which the centralised regime wish to focus in detail, to large 1:200 000 of a specific territory (Gál & Furdik, 1984, p.27). The laws that bound planning activity and urban development in any village, town or city to the *územní plánování* dates back to 1949 and up to 1976 (Maier; Šlemr, 2016, pp. 164-179). The plans for settlement units could be 1:25 000 in scale while their zones up to 1:10 000. Considering these are large scales to work with and several layers of bureaucracy that projects have to go through, as they must conform to the non-negotiable plans for the wider territory, there was more room for ambiguity as they become translated and processed into *zastavovací* (building) plans from the federal ministry to the local state organs.

As we go over the problems of these methodologies discussed by practising architects and urban planners in the official professional journals during the 1970s and 1980s, the specificities of the issues that they raised in the GDR differ from that in Czechoslovakia. In the late 1970s, the GDR architects discuss the lack of clarity in the *Generalbebauungsplan*, which led to confusion when they tried to develop the *Bebauungskonzeption*. For instance, where to locate the social and retail centres and tram stops at a reasonable distance from the dwellings, green corridors, the practicality of technical installation in the area to the arrangement of spaces to reduce noise pollution (Schattel, 1977; Pretzsch, 1979). In Czechoslovakia, the problem with the *územní plánování* process that the planners and architects frequently complain about was the incoherency between the layers of *územní plán* and the national economic planning. They admitted that the long-term goals and concepts eventually got lost along the stages of the process when it came to land management and construction (Hrůza, 1977, p.272). Representatives of the local municipalities claim that there was a lack of guidance in implementing the plans into design and construction of the area, in addition to the lack of coordination between the *oblastný* and the *územní* plans (Matoušková, 1985; Zibrinová, 1988, p.23). Maier and Šlemr (2016) stated that the *územní plánování* method had more consequences in the urban development of Slovakia more than the Czech Lands. From a German perspective, Hans-Joachim Kadatz from Berlin, an expert on urban development in central and east Europe noted that there were no clear distinctions between urban and regional planning in the case of Czechoslovakia.

The reason for the bigger issues in Czechoslovakia was the rapid growth the country was facing as the state governments had to ensure that the largely agrarian Slovak lands must develop to be on par with

their Czech counterpart. This was also associated with the idea of the Slovak Affair, by increasing higher standards of living by providing jobs, housing and infrastructure in Slovakia to legitimise the existence of the regime. They saw their own *územní plánování* as an efficient way to control the development of the villages, small towns, cities in the regions. Of course, there had to be a degree of flexibility and devolution of authority to the local councils, enterprises for urban development, as long as it fulfilled the needs of the *území* plans of the larger territorial units. The regime also allowed more private housing ownership compared to the GDR, and people were allowed to build their own family houses in the countryside especially during the normalisation period (Šlemr & Maier, 2016 p.173). For instance, The proportion of private apartments in Czechoslovakia was 35.5% while in the GDR it was only 9.8% (Landmann, 2017). Moreover, when Czechoslovakia was federalised in late 1969, the Slovak Socialist Republic had its own Slovak National Council and its own ministries to develop the Slovak *území* plans with approval from the Czechoslovak central government based in Prague. Despite federalisation, laws for urban development and infrastructure were still centralised.

Transportation Networks and Subsequent Urban Development

Referring back to the concept of socialist scaffold (Zarecor, 2017), the cities that developed in the GDR and Czechoslovakia had roles to play as nodes in an integrated system. Each city or town was a component of economic production that contributed to the socialist scaffold, and the transportation networks connected these nodes, increasing the efficiency of the centralised economy. This section will discuss how the respective centralised spatial planning processes of Czechoslovakia and the GDR were instrumentalised in the construction of infrastructural networks.

Between 1950 and 1970 alone, no less than 16 new industries were established throughout Slovakia by the central government, including the chemical and engineering industries in Bratislava, Trenčín and Košice (Czech National Museum, 2018). In order to increase the efficiency and the productivity of these nodes, the connectors in the socialist scaffold had to be strengthened. Even though the Czechoslovakian state was federalised after 1969, the central government needed to reinforce control especially during normalisation as the modernisation and construction on the Prague-Brno-Bratislava highway began in the late 1960s, allowing better connections between the Czech cities and the developing cities in Slovakia (Šteis, Hulej, 1989). The highways served the booming automobile industry and increased the capacity of recreation activities as city residents have better access to the Tatra mountains and forest parks throughout Czechoslovakia, during the era of social-pacification. They also served an ideological purpose as the central regime needed to strengthen the idea of Czechoslovakia as a state within its national boundaries, to orientate itself away from the previous Austro-Hungarian Empire. Modernisation and construction of highways throughout the whole country from late 1960s until 1990 influenced the *územní plánování* of the cities, eventually establishing new housing estates along its path. The largest housing estates ever built in Czechoslovakia were fed off this highway; these are Jižní Město in Prague and Petržalka in Bratislava. The modernisation of Bratislava cannot be attributed to the socialist regime alone, as regulatory plans under the Hungarian authorities in early 1900s showed the influences of scientific and technical urban planning from German experts Baumeister, Stübbern with the artistic approach of Sitte (Moravčíková, Lovra, Pastoreková, 2017). The final version of the regulatory plan submitted by Budapest architect Antal Palóczi in 1917 before the end of the empire already showed the proposal of three bridges across the Danube, proposing an outer ring for cars bypassing traffic in the city centre (Ibid) which was also an effective strategy adopted by the socialist regime later on.

Figure 1: Sketch of the road networks from Prague and Brno to the cities in Slovakia implemented in 1970s.

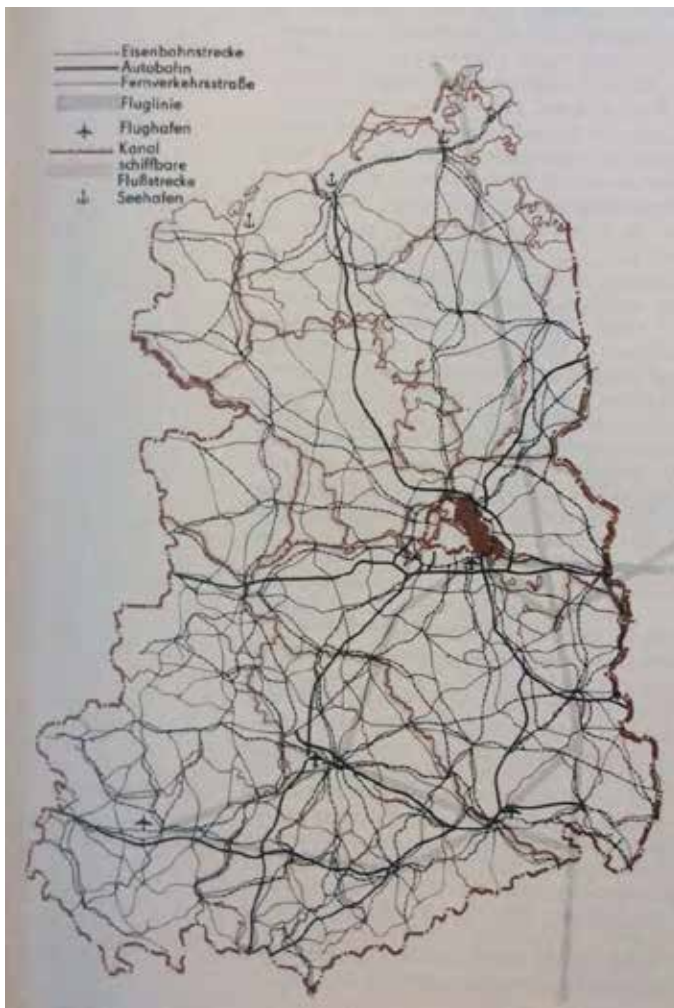

Figure 2: Transportation networks throughout the GDR. Source: Lammert, Bauakademie der DDR, 1979, p.61

In comparison to Germany, an integration of comprehensive and efficient public transport system in Berlin along with the Autobahn network was already obvious in 1926-1929 during the Weimar Republic (Bodenschatz, 2018). Hence, when the GDR was founded after the Second World War, they only had to inherit the Autobahns left by the Third Reich, which were already efficient connectors to the nodes needed to establish an effective socialist scaffold; hence, only minor adjustments were needed. The Autobahns were extended to new GDR cities such as Eisenhüttenstadt, Hoyerswerda and Halle-Neustadt and directly to Warsaw through Łódź in Poland. They also successfully extended the railway networks, in 1960s and 1970s (Lammert, 1979, p.60-61).

As we take a closer look at the development of Bratislava, the highways, roads and bridges that were constructed around the city drastically changed its urban structure. The old Jewish quarter in the old city was demolished to accommodate the road that led onto the SNP Bridge connecting the main city to Petržalka. To divert traffic from the old city quarters, the D1 highway was built, with the Lafranconi Bridge taking it through Petržalka and thus creating faster connections. The D1 was part of the Prague-Brno-Bratislava highway, and the urban planning of Bratislava focused on deconcentrating the functions of the city, also due partly to its geographical limitations. Several housing estates were developed because of the planned highways. Indeed, this resulted from the infrastructural thinking of the regime. According to the proposal for the 1984 Directional Plan of the Bratislava *územný plán*, the housing estates of Dlhé diely, Lamac, Líščie údolie as part of the housing building programme in the 8th Five-Year Plan had

to be located along the highway, supposedly because excluding these sites would ‘reduce the efficiency of transport and engineering investments’ (Hauskrecht, 1983, p.4). The intensification of traffic planning and concentrating growth along the highways was apparent in the 1963 Bratislava *územy plán* and was more prominent in the 1976 Bratislava *územy plan* (Hladký, 1978; Hollarek, 1983; Hauskrecht, 1983; Žalman, 2016). While works on the highway construction through Bratislava was given priority, public transportation such as railways and trams were placed on the backburner (Nigrin, 2018, p.61-76). Although there were plans to include trams and metro in Petržalka, the new residents who moved in the 1980s had to rely on buses instead.

Figure 7: 1968 Generalbebauungsplan showing the integration of public transportation networks with the development of new housing settlements. Source: Korn, Schweizer, Walter (1976): 9. Stadtbezirk in Berlin. In Architektur der DDR (9), p. 549

The case was different in East Berlin. The 1968 *Generalbebauungsplan* included more planned public transportation networks, detailing where the S-Bahn stations would be, incorporating them with the existing and planned Autobahn and road networks. In conjunction with the 1973 Housing Building Programme to build more flats in the city, areas were already allocated at the outskirts for Marzahn-Hellersdorf in 1969, served by several S-Bahn stops along the edge of these *Siedlungen*. With the expansion of the S-Bahn and the U-Bahn networks, setting up trams and trolleybuses, the regime paid attention to the provision of public transport infrastructure in their vision to develop East Berlin. The map showing the network of S-Bahns refer to the radius of new and existing S-Bahn stops as *Einzugsbereiche*, or 'catchment areas' and this idea of 'catchment areas' allowed suitable connecting paths to be made to areas of interest such as new housing estates, cultural institutions and schools when planning infrastructure. Even when developing the road networks in East Berlin, the GDR traffic engineers were more pragmatic in their approach with its planned *Tangentialverbindung*. East Berlin city centre was to be a compact urban area with direct road connections to the large housing estates, industrial areas and recreation areas. The *Tangentialverbindung* is the main road network consisting of a system of radial roads with tangential connections, creating a grid system effectively distributing traffic to connect individual city areas (Krenz, et al., 1969, p.38). The main transport for the residents

of the new housing estates in the 1970s were the S-Bahn connections and the *Generalverkehrsplan* was in alignment with the *Generalbebauungsplan*, in the sense that the planned new residential areas in principle should not be interrupted by main roads to eliminate disruptive crossings (Schattel, 1977, p.390).

Comparing these socialist scaffolds built between the two cities in the 1970s, the planning model for Bratislava was a more automobile-oriented city, while East Berlin was more transit-oriented. Paradoxically, despite the so-called federalisation of Czechoslovakia, the centralised system of the *územní plánování* method on a larger scale allowed major interventions on the land-use of the territories within and around the cities and their agglomerations, affecting greatly the urban developments at smaller scales. They imposed highways, bridges and main roads that circulate around the city to ensure efficiency and faster connections for the vehicles transporting and delivering goods between Prague, Brno and the rest of Slovakia. In East Berlin, the emphasis was more about the rational use of public transportation, effective traffic network around the compact city concept. Housing developments built during the normalisation periods of Czechoslovakia in 1970s-80s seem to be an afterthought of the highway and road infrastructure while in the GDR there was more

consideration of integrating the housing estates into new and existing public transit networks. An explanation for this contrast is that East and West Germany experienced a more advanced modern car-planning movement in comparison with the other Central and East European countries. After the war, both East and West Germany had already altered their urban landscapes with large motorways running through their cities in Berlin, Dresden and Halle. The turning point for the GDR was in the 1970s, when they were influenced by the intellectual discourse critical of the automobile-friendly city and its effects on the urban environment in West Germany since the 1960s (Aßman: Bernhardt, Butter, de Rudder, 2016). Central and East Europe saw the start of the great car-friendly urbanisation in the 1960s, as was evident in the *územý* plans of Prague and Bratislava compared to East Berlin in the same period. As a symbol of Western modernity, the car was largely denied until it became accepted in the 1960s and are still influential in the present day, as design stages for urban development still show signs of being automobile-oriented (Aßman: Brzosteks, 2016). Mobility was linked to modernity and it was crucial to provide the necessary infrastructures despite the restrictions and hurdles to individual car ownership (Beyer, 2011; Tuvikene, 2018).

The four decades of policies that characterised land-use planning under the state socialist central-planned economies are some of the factors which contribute to the divergence in the urban development patterns between Berlin and Bratislava today. For instance, the current planning system in Slovakia is still based on the 1976 laws, which were refined in the 1992 constitution before its independence in 1993 (Finka, 1997). The particularities of how urban planning in one country developed can only unfold in comparison with the other, and this is reflected in how they gave meaning to the concepts of urban and spatial planning.

Towards comprehensive and integrated land management practices in Albania. How can the new paradigmatic shift in land use planning and growth management foster a positive impact on local finances and the tax base? The case of Municipality of Tirana.

Kejt Dhrami¹, Fiona Imami²

Abstract: This research draws upon the array of changes that have occurred in the spatial planning system in Albania over the last decade, and examines possible impacts at local level, namely on the financial situation of local governments. The research is conducted in two inter-relational directions: firstly, it tackles the possible impact of land use changes and tools that determine the change patterns, on taxation and local budgets; and secondly, it analyses the strategies used to address urban growth, through development indicators, principles, etc. and assesses their possible influence on the tax base. These aspects are analyzed for the municipality of Tirana, which has the highest development rate and financial growth in the country; and are anchored to the current planning document in place: the General Local Territorial Plan (GLTP) of Tirana, for the period 2016-2030. The research contributes to the overall discussion on the relevance of local planning instruments, with respect to improving the tax base, the fiscal autonomy of local governances, the provision of services, the urban growth in terms of sprawl or densification, and the prioritization of investment projects. Methodologically, the research is based both on desk review of land use planning theories; current planning legislation and documents in Albania, and local finance studies; as well as sample studies of specific spatial typologies in the city of Tirana, and their development scenarios in relation to the proposed land use changes and development indicators, in terms of tax revenues. This research, albeit not exhaustive, draws conclusions on the real potential of using land development instruments to induce growth in local financial capacities, both through property tax, and other taxes that are related to land and property.

Keywords: land use change; local finances; growth management; land development indicators

1. Introduction

The majority of the world's population now lives in urban areas and depends on urban systems for housing, job opportunities, health services and all typologies of social and economic activities. Particularly in developing countries, the size of urban areas will continuously increase as cities daily blossom and expand to accommodate the new comers/residents.

In an effort to contribute to successful urban policies (both in terms of growth and investment capability), this research explores how plans, policies and development normative affect planning systems to their core: the fiscal local autonomy, in order to support the upcoming challenges of urban growth.

THE LAND BENEATH OUR CITIES - AND ALL POLICIES THAT REGULATE IT - SHAPE THE CHARACTER OF HUMAN SETTLEMENTS. THIS IS A CRITICAL AWARENESS FOR A RAPIDLY URBANIZING PLANET. LAND IS, QUITE LITERALLY, FOUNDATIONAL TO THE DEVELOPMENT OF PRODUCTIVE, SUSTAINABLE, AND EQUITABLE CITIES.

(Moody, et al,2014)

2. Context overview

This chapter introduces the main pillars of the research work in a theoretical and legislative point of view. Firstly, an overview of the main challenges faced in Albania in the last decades is presented, which highlights the main reforms that are still under way, and their impact on territorial governance, especially at local level.

Secondly, it sets the context on the relationship between land-use changes and the fiscal situation of local government units, underlining the possibility to use land-use zoning as a tool to make effective investment plans in the territory. Thirdly, it draws some conclusions on the strategies used to address urban growth in different contexts, and the way they are implemented in the Albanian legislation after the planning reform.

2.1 Albania - filling the gaps towards a comprehensive integrated approach to planning

The planning concept in Albania has changed drastically in the recent years, with a paradigmatic shift from an 'urbanist' approach in city planning, to a more comprehensive and integrated style¹. (European Commission, 1997). This constitutes an emergent need to also change the mentality of perceiving the city as a rigid division of forms and functions, as was the case in the "central planning period 1950-1990". (Toto, 2012) The idea of *building complexes* and *building blocks* functioning as compositional parts of one-another, in hierarchical way, albeit theoretically very stimulating, has long been outdated in the urban realities Albanian cities (and not only)

¹ This is referenced to the classification of the Planning Systems in Europe in 4 main traditions in accordance to the political and legislative context: (1) Land use / (2) Urbanist / (3) Regional Economic Development / (4) Comprehensive Integrated Approach). For the purpose of this comparison, the other dimension: (5) South East Europe, where Albania would fall under, is not taken into consideration. For more information see: European Commission, 1997. *The EU compendium of spatial planning systems*. Luxembourg: Office for Official Publications of the European Communities.

are facing today. Urban areas are multifunctional. They are also, in most cases, built realities, where property issues need to be met in urgency, before taking action on idealistic planning instruments. Furthermore, the change in planning systems in Albania has been introduced in parallel to several political processes, such as: the Decentralization process; the territorial administrative reform, and the ongoing Europeanization process². The issue gets more complex, when the challenge of territorial governance is accompanied by the overwhelming issue of poor local capacities, both, in human resources, and financial aspects. Indeed, it comes as no surprise that the urban context in Albania is hampered in an irreversible way, and the fact that the planning system and the instruments are changing quickly and continuously makes it almost impossible to observe and benchmark real results from the reform in the territory. (Co-PLAN, NTPA, USAID, 2015)

The General Local Territorial Plan (GLTP) is the main instrument of local planning to date, which defines the framework policies for territorial planning, as well as all proposed interventions, development scenarios, and investments for the next 15 years. The implemented zoning principle is very similar to the form-based codification system, used in the US³: the territory is divided into the so-called *structural units*, which are supposed to be manageable areas in terms of land development, divided upon given criteria. In other words, structural units are the smallest scale where the standards and land development norms are set and applied, serving thusly as a basic unit of planning and development. (Dhrami, 2018)

² In 2014, a newly elected Albanian Government defined the decentralization reform as main priorities. A territorial Administrative Reform was implemented, resulting in the amalgamation of 373 municipalities and communes (urban and rural local self-government units) into 61 consolidated municipalities. This was followed by the preparation of a new Decentralization Strategy, aiming to give more power and autonomy to local self-government units in Albania, and the preparation of a Law on Local Finances, which should address further the fiscal decentralization for Local Government Units.

³ Form-based codes are a land management instrument used in the USA that falls into the category of zoning, but also differs considerably from conventional zoning. This coding system divides the territory into different districts based on the character and intensity of land development, as well as the desired urban form. (Marshall, 2011)

Figure 1. Example of division of territories into structural units- Municipality of Fier (on the left- the whole municipal territory ; on the right, excerpt from the center)

Source: Municipality of Fier, Co-PLAN, 2015

Moreover, this planning reform also created the opportunity to expand the concept of public-private partnerships to land development, by promoting area-based development instead of rigid, profit oriented plot based development. (Allkja & Toto, 2018) Law no. 107/2014 introduced the General Local Detailed Plan as a planning instrument, bringing together 4 typologies of stakeholders (developers, landowners, the municipality, and citizens) in the development process, through the implementation of several financial instruments⁴.

In terms of development indicators, the following table summarizes the requirements on national level, to be determined for each structural unit.

Table 1. Development indicators to be defines at the level of structural units

Development indicators	Definition	Comments
Code	[Municipality_System code_Land Use Subcategory code_No.] This is a unique code for each unit	

⁴ The instruments include, but are not limited to: Transfer of Development Rights, Land Readjustment, Betterment Fees, Bonus FAR, etc.

Area	ha	
Number of inhabitants	No. of inhabitants expected to be accommodated in the unit, as regards to the carrying capacity	There is no indicated way to calculate the carrying capacity based on the typology of the structural unit and the proposed development indicators
Population density	inhabitants/ha	
Territorial system	In accordance with article 72 of DCM 686 Each structural unit should be part of one territorial system	The categories of territorial systems are: urban, infrastructural, agricultural, natural, water. This makes it impossible to have a structural unit with 2 land uses that are not part of the same system, making the zoning process more rigid (f.e. the case of adjacent agricultural and urban plots)
Land Use Category (percentage of each)	In accordance with article 77 of DCM 686 Each of them is defined according to the percentage occupied in coverage area or in built area.	The categories of land use are pre-defined into 22 main ones, followed by subcategories and functions. Among the main categories, 2 mixed ones can be found: agriculture-residential; and residential - service. Both are interpreted vaguely and overlap with the idea of distinguishing between percentages of uses in one structural unit.
Other allowed land uses	In accordance with article 77 of DCM 686, all other allowed uses should be listed	This takes into consideration land use changes that can occur during the implementation period, that do not impact the typology of the area in a thorough way, or land uses that are not covering significant percentage of the total area. Hence, the total percentage of proposed land uses does not always total to 100%
Prohibited land uses	In accordance with article 77 of DCM 686, all prohibited land uses or activities should be listed	
Conditioned land uses	In accordance with article 77 of DCM 686	
Land Use Subcategories	In accordance with article 76 of DCM 686	All subcategories and functions are listed in a detailed way in the Planning Regulation. The development indicators are defined on the basis of main categories of land use, so the subcategories and functions are more suggested, rather than obligatory
Functions	In accordance with article 77 of DCM 686	
Floor area ratio	Total built area / Total buildable plot area for each category of land use (maximum value)	This definition of FAR for each land use makes the process rigid, since it relies on the idea that an exact estimation of each land use area / percentage can be defined. This is not always the case, thus the FAR is usually defined at unit level, even though the regulation states otherwise. This indicator is calculated at plot level or area level, depending on whether the unit is subject to DLP or not.

Plot Coverage Ratio	Total ground floor area/ Total buildable plot area (in percentage), for each category of land use (maximum value)	Same as FAR.
Road Coverage Ratio	Total road area / Total unit area (minimum value)	This indicator is calculated at unit level, and it is perceived as indicative, since it is not always possible to know the exact network of proposed street area. Especially when the unit is not subjected to an DLP, this indicator is very difficult to implement.
Public Plot Coverage Ratio	Total public plot / Total unit area (minimum value)	The definition of public plot takes into consideration all properties that are of public nature, from public gardens to state-owned facilities. Hence, the indicator is not a fair measure of livability, but more of division of public and private rights.
Height	both, in meters and number of floors	
Minimum plot size		There is no national law defining minimum plot sizes for different typologies of buildings. This is the only element in the local planning documents that regulates subdivision.
Distance indicators	According to the Territorial Development Regulation (DCM 408, dated 13.05.2015)	The regulation has changed the distance norm many times in the last decade. It defines three parameters: distance from building to building, distance from plot boundaries, and distance from the road. This is one of the most defining factors of plot-based development
Green areas/inhabitant	m2/inhabitant for units belonging to the urban system	The standard for green areas used to be defined at national level (9m2/inh for all types of greenery, and 2.5m2/inh for zone level), but it was recently removed from DCM 686 with all other planning standards. It is responsibility of the local authorities now to define the minimum green areas per person
No. of parking spaces	no/inhabitant	This standard for parking used to be defined at national level (6 m2/inh) but was removed.
Proposed intervention	densification, regeneration, redevelopment, consolidation, conservation, urbanisation, etc.	Categories of intervention are defined more thoroughly by the local level. In theory this indicator should be the basis of all decisions on FAR, Coverage ratio, DLP, etc.
Spatial typology	to be defined only for the units belonging to the urban system	Categories of spatial typology are to be defined at local level. In theory this indicates many spatial characteristics of the unit, such as FAR, plot size, etc. Nevertheless, in practice the typologies are so mixed, that this serves as an indicative measure

Detailed local plan	According to article 68 of DCM 686, all units that are subject to development or redevelopment; major regeneration; major change of land use and development indicators; major public investments should be designed through a Detailed Local Plan	The DLP is a process that involves all actors in the structural unit (or the part of the structural unit where it is applied), and is approved by the mayor. If a unit is subject to DLP no building permission can be issued before the approval of the DLP.
Development instruments	By law: Bonus FAR, transfer of development rights, etc.	These instruments aim at balancing the public and private interest through new financing mechanisms. The law proposes 2 instruments but the local authorities have the right to implement as many as they see effective, as long as they mention them on their planning documents and draft detailed programs for the implementation.
Development phasing	Short term (1 year) Mid-term (1-4 years) Long term (4-10 years) Long term (+10 years) etc.	The phasing process should define development priorities according to the Capital Investment Plan and the Mid Term Budget Plan of the Municipality. Nevertheless, this correlation almost never exists.

Source: DCM 686, dated 22.11.2017 ‘For the approval of the Territorial Planning Regulation’; author’s contribution

The table shows that, while more comprehensive in scope, planning at zone level has become increasingly more rigid in Albania. This is manifested firstly in the wide array of pre-defined indicators at national level, which are not always relevant to local contexts, and moreover, reduce local autonomy in decision-making processes that are related to land management. Secondly, there is visible discrepancy between the indicators used, both within themselves, and the principles of flexibility, comprehensive approach that are stipulated in the legislation. While the new planning and development legislation⁵ brings new paradigmatic changes in the planning system, the accompanying bylaws (DCM 686 and DCM 408) are reintroducing similar concepts to the ones of the 1993 Law on Urbanistics, such as functional zoning, the ‘yellow line’ of urbanization, etc. What is even more troublesome, is the fact that indeed these new bylaws have changed repeatedly in the last 8 years, and these changes have not been favourable to the local autonomy or public interest. For example, the distance norm has been reduced and all standards that regulated public amenities, such as green areas, parking, public spaces and structures, sport terrains, etc, removed all together from the national legislation. The case of GLTP of Tirana demonstrates better than any other municipality the issues of normativity and growth management.

2.2 Land use changes and the impact on fiscal autonomy

Regardless of the geographical location, genesis or the size of a territory (urban or not), land use patterns are constantly changing in time as the result of human activities running for the best locations through demand and

⁵ Law no. 107/2014 ‘On territorial planning and development’

supply forces set out by the market. As stated above, cities are more than the sums of their built environment. In terms of territory, their character is defined in large part by land policies, ranging from planning for development to the collection of land based revenues, from new environmental challenges to the provision of affordable housing and adequate services.

Experiences in drafting general local plans, territorial development strategies, detailed or partial plans etc. have shown that land use analysis as an instrument is one of the key steps in assessing spatial and developmental impacts of urban growth. And while research has shown that urban growth and land use change analysis have to be linked to urban form and processes to lead to effective urban interventions (Longley and Masev, 2008), any urban intervention is associated with several decisions / fiscal issues.

Every day, new opportunities for good land use policies to improve the lives of urban populations expand, as these cities grow too. Responding to this (and climate challenge we must add being a very expensive proposition), comes at a difficult time when most local governments are burdened by financial stress.

From an economic perspective, land is one of the factors of production, which attracts investment and generates wealth at the same time when socially is a sensible and scarce source, thus taxes on land (or property) are the oldest and most common form of taxation. But the European and developed countries experience has shown that the basic forms of taxations are not really enough to finance all the required development. New and innovative forms of taxation and adequate and reliable land-based revenue streams will be needed to finance the delivery of urban services and supporting urban growth and expansion of our cities.

In this framework, the Municipality of Tirana, being the main growth centre of the country, is the most interesting case to study in terms of fiscal capacity, and other ways to foster urban growth and provide better services.

2.3 Growth management strategies and the approach to normativity

Traditionally, zoning and subdivision control plans have been the two main instruments embedded in most planning legislations and culture, to enable sustainable growth management. Of course, this is only one of the functions of zoning.

For example, zoning codes that include the distribution of density for permitted use areas determine a theoretical figure of the maximum population. On the other hand, subdivision control regulations affect liveability by determining the minimum size of the parcel. This, in turn, influences the phasing and the development rate of the areas. (Juergensmeyer & Roberts, 2007)

Literature on property development suggests that there are some concepts of growth management that are strongly connected to each other: carrying capacity, impact analysis and sustainable development. The origin of all these concepts is in the environmental legislation. "Carrying capacity" is used to determine the environmental criteria upon which land use decisions will be based and refers to the level at which the land in its current or natural state can develop without degrading the ecosystem. This comes as a very crucial concept in terms of attributing development rights in urban areas in Albania.

Another growth management instrument, with a more advanced approach to planning, is the Smart Code, an integrated land development ordinance, created by Duany Plater-Zyberk in 2003. Its aim is to have a more 'new urbanism' oriented legal model of city development. Essentially, it is a form-based code that incorporates Smart Growth and New Urbanism principles. This coding system divides the territory into different districts based on the character and intensity of land development, as well as the desired urban form. Zoning usually regulates only land use, and development standards (maximum building height, distances, FAR, coverage ratios, etc.). But form-based codes regulate things that are not typically part of zoning, such as the design of streets, sidewalks,

and other public spaces, which conventionally would be regulated by subdivision manuals, or public work manuals. Thus, Form based codes bring all these manuals together, in an integrated document that addresses land use, development indicators, provision of public/non-profitable services and subdivision regulations. The integration ensures that these documents are coordinated and coherent with each other. (Marshall, S., 2011).

Is this approach applicable in Albania? Following the subtle tendencies of ‘Europeanisation’ of planning traditions in EU member countries, Albania has seen some drastic changes in the way it approaches spatial (territorial) and urban planning. The level of normativity has increased, and the responsibility to establish norms and standards is shared between the central and local governments. Even though the system is supposed to be more flexible, it adopts various concepts of the post-New Urbanism planning framework, including zoning, form based codes, as explained above. (Dhrami, 2018)

It is yet to be seen, whether an integrated model such as Smart Code, or even more flexible, can be applied in the context of Albania.

Figure 2: Example of transect zoning in Handsboro Community Plan

Source: Handsboro Community Plan, 2008⁶

3. Methods

From a methodological standpoint, this study is of a comparative and empirical nature. Specific areas of distinguished typology have been extracted from the General Territorial Local Plan, Tirana 2030 and analysed accordingly. Based on the theoretical framework set out above, this study attempts to calculate, in a simplified and general way, the level of local tax revenues that may be collected by the Municipality of Tirana, based on these proposals and development indicators, as to understand the impact of the proposals on the possible fiscal autonomy of the municipality. On the other hand, the research sheds light on the growth management instruments applied and whether they are realistic or not.

⁶ Handsboro is the third existing community in Gulfport to make the SmartCode mandatory within its boundaries. Its Community Plan was adopted as an integral part of the City's SmartCode in February 2008. The Regulating Plan depicts the boundaries of the planning area, assigns the new Transect zones, and features new overlay districts such as transportation and retail corridors, density-receiving areas and neighborhood conservation districts.

This research takes into account all the limitations set out in the study, such as the lack of an accurate database on land use, lack of information on potential investments carried out in the study area as part of the plan projections, or lack of the precise indicators of monitoring the implementation of the plan. On the other hand, taking into account the complexity of both the planning and the tax burden estimates, the study is limited to the calculation of the 4 potential taxes that represent a more direct link to land use and development, which are:

- Tax on agricultural land
- Tax on Infrastructure Impact for the new buildings
- Residential property tax
- Commercial property tax

The main research question raised by the study is: How can the new paradigmatic shift in land use planning and growth management foster a positive impact on local finances and the tax base?

In order to validate this hypothesis, in an imbalanced real estate market situation with the inability to generate enough revenues and a shortage of taxpayers, the study raises a simple matrix to answer the above question. The study also tries to give an assessment of the legislative and territorial context where the respective plans are implemented, to understand how land development and the implementation of local plans directly affect the fiscal situation, and can have a greater contribution to growth management in Tirana Municipality.

Table 2 Framework of empirical research

	Area A (urban) 3 samples	Area B (periurban) 3 samples	Area C (rural) 3 samples
General Local Plan Proposals			
Area of the sub-unit			
% of land use categories			
Development indicator			
Area of agricultural land			
Area of residential urban land			
Area of commercial urban land			
proposed Built area			
Potential revenues as per taxable base			
Tax on agricultural land			
Tax on residential building			
Tax on commercial building			
Tax on Impact in Infrastructure			
Estimated total Revenues			

The selection of the case studies (or samples) has been done strategically based on the categorization of spatial typologies assessed in the TR030 Plan.

However, land value after development varies from many factors, such as distance to the centre, vicinity to main services, etc. In the same way, the reliability of various revenue sources (considering here taxes) likely will vary

with factors such as the rate of urban growth or decline, the national legal structure, etc .Therefore, this value will be generalized.

4. Tirana - from planning to economic growth

4.1 Main principles of growth management adapted in the General Local Plan of Tirana

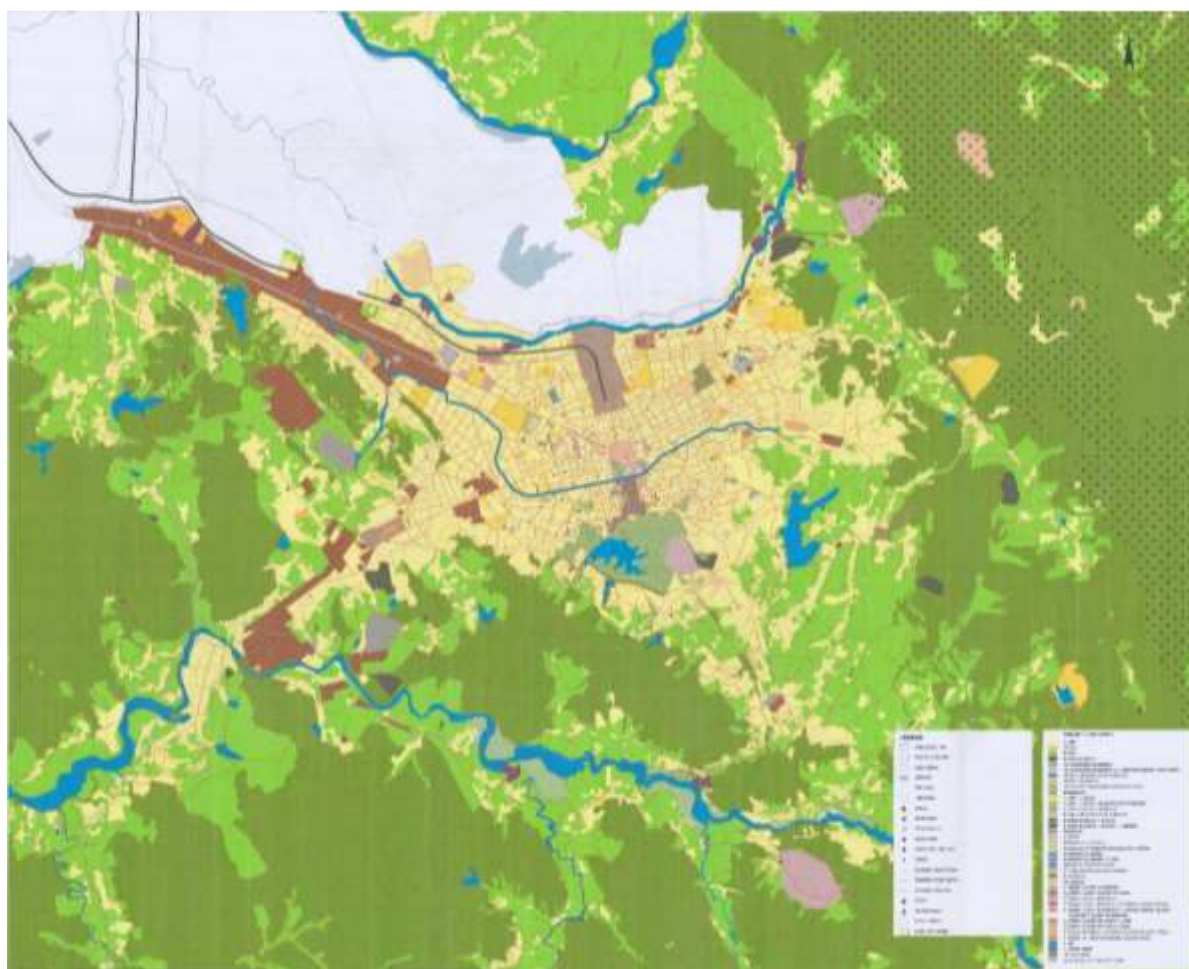

The Local Territorial Plan 'TR030' is the first designed for the municipality after the territorial reform. It was prepared by Stefano Boeri Architetti, UNLAB, IND in cooperation with the Municipality of Tirana and financed by the Ministry of Urban Development and the National Territorial Planning Agency. At present, this plan is the guiding document of territorial development policies in the Municipality of Tirana, and is implemented for the period 2016-2030.

In 2016, Tirana's overall local plan shows the future of a polycentric and kaleidoscopic metropolis, which will host in every part of it a balance between city and nature. The vision identified the ten strategic objectives that aim to direct urban development , economic and social development of Tirana in the next 15 years.

TR030 envisages the territory as a hierarchic correlation between 3 main typologies: urban, peri-urban, rural:

- a. The urban territory includes all urbanized areas, which are almost completely constructed and comprised of compact urban medium and high density urban areas where urban residential, tertiary and commercial services prevail.
- b. The suburban area includes all medium density built areas that consist of informal residential palaces, industrial and commercial buildings dispersed in different ways and the presence of the main infrastructure in the city's service.
- c. The rural territory includes all areas located outside suburban areas and include urban units (poles) and agricultural and natural areas characterized by the presence of scattered buildings with mainly agricultural and residential purpose.

Figure 3. Proposed land use at city level, Municipality of Tirana

Source: Tirana 2030, Municipality of Tirana, 2016

4.2 Fiscal autonomy in Tirana - an overview

Catchphrases such as “metropolitan areas are the engines that pull the national economy” turn out to be fairly accurate. But the same comparative advantages of metropolitan areas that draw investment also draw migrants who need jobs and housing, lead to demands for better infrastructure and social services, and result in increased congestion, environmental harm, and social problems. Roy W. Bahl, *et al.* 2013.

The structure of financial resources for municipalities can be used as an indirect indicator to assess their financial capacity, the ability to undertake investments independently and meet community service requirements. While Local Government Units (LGU) revenues in Albania are made up of its own revenues, governmental transfers and separate taxes, *local own source revenues* are essential for an efficient, effective and autonomous local government. Yet the financial performance of the municipalities in Albania remains still, while investment needs become more and more urgent. On average, for the 61 municipalities in the country, revenues from its own resources accounted for only 25.4% of total resources at the end of the first half of 2018.

The view that local governments have little capacity to deliver services (or collect revenues)⁷ is, however, too broad a generalization, after almost 20 years in decentralization process.

Tirana Municipality reports significant improvements in urban public management. And the quality of public services delivered in the metropolitan area is far better than that provided in the rest of the country. The financial resources available in the Municipality of Tirana have followed an upward trend in recent years. In 2017, the available resources were about Albanian Lek (ALL) 16.7 billion, up by about 16.2% in annual terms. This performance was largely determined by the increase in local source revenues, the increase in infrastructure impact tax and real estate tax shown in the chart below (Local Finance Portal, 2017). Namely, the transition from 600,757 ALL in 2015 to 3,466,070 ALL in 2017, taxes collected from the infrastructure impact tax, clearly demonstrates the increase of the construction activity in the Municipality of Tirana, which is directly related to the increase of the number of construction permits after the approval of the Plan.

Tax on buildings, in the other hand, reports lower incremental rhythms (1,145,184 ALL in 2015 to 1,718,480 ALL in 2017), which in comparison to the allocations provided by Impact on Infrastructure Tax, is approximately ½ less of it. Even though many may justify the potential of allocating revenues from property tax by the fact that only in June 2018 the property tax will be applied on the basis of its value, (and that before this period it is very difficult to estimate the potential of property tax in a context where data on taxpayers are still missing), this reform is not really fundamental. The property tax reform in Albania remains still much generalized, calculating the tax burden, on the basis of several macro-zones with a fixed estimation of the property values on the whole area, rather than apprising the real property value regarding the real estate market. This shift in the way this tax is calculated, has only increased the tax burden by 0.05%, thus making really small difference in terms of lump sum allocations in one hand, and not really making the differences between well-serviced and high valued properties with the lesser ones⁸.

⁷ Local revenues and taxes in Albania are regulated through the legal framework specified in Law no. 139/2015 'On Local Self-Government' and Law no. 9632, 2006, "On the Local Tax System", as amended.

⁸ It is a common evidence in the city of Tirana that within these macro-zones high rise building, new building residences, and well maintained streets, or better school provisions lie beside (sometimes just across the streets) with low rise old building, historical ones, amortized infrastructure etc.

Figure 4 Distribution of local own revenues through the years, Municipality of Tirana (respectively purple color representing the infrastructure impact tax and in yellow tax on buildings)

Source: Local Finance Portal in Albania, 2018 (www.financatvendore.al)

Though the Municipality of Tirana is one of the few municipalities in Albania that show a positive balance in terms of government dependency, the potential to further improve its performance fiscal policy has not yet been captured. The challenges of Tirana metropolitan public finances are to capture a share of the economic growth, as a consequence of new developments, that is adequate to finance the new and growing expenditure needs and to organize governance so that services can be delivered in a cost- effective way. At the same time, care must be taken to avoid over densification, over taxation and short term financial resources, which will hamper the successful implementation of the planning instrument.

All this is well-articulated in the principles of GLP TR030, but there's an evident missing of any instrument/ tool which ensures the implementation and the monitoring of these principles.

5. Empirical analysis and preliminary findings

Following is a summary of the chosen areas for study and their characteristics.

	<p>1. Building complexes of the communist period</p> <p>This typology is represented by apartment blocks, constructed by the state in the period 1945-1990. Some general characteristics of these areas are: the densification of the area after the fall of communism; good access to services, poor quality of public spaces. The typology occupies about 9% of the urban areas in Tirana.</p> <p>Structural Unit: TR371</p>
	<p>2. Historical urban tissue</p> <p>This typology is comprised of villas constructed in the early 20's and 30's, mixed with high-rise buildings, constructed after the 90's. The oldest villas date back to the ottoman period and are part of very small plots. These plots are merged eventually to make room for high-rise dwellings, which make for a lack of public space. The road network is not regular, but is well-connected with the center. This typology makes up 3% of the urban area in the city.</p> <p>Structural Unit: TR317</p>
	<p>3. Mixed central areas</p> <p>This typology represents a mix of form and function, from villas to longitudinal buildings and high rise buildings. They are characterized by a rapid densification, a quadratic road network and a good access to public services. This typology makes up 5% of the urban area in the city.</p> <p>Structural Unit: TR363</p>
	<p>4. Informal areas</p> <p>The informal typology is comprised mostly of 2-3 storey buildings, constructed after 1990. These areas usually have a quadratic road network, poor access to services, and tend</p>

to be densified in height. These areas make up 41% of the cities urban area.

Structural Unit: TR412

6. Urbanized village centers (T5)

These areas are located in administrative units around the Tirana urban center, and differ in mixing between old structures of villages and new housing. Usually have poor or medium access to public services, road system in irregular networks, and gradual densitization. Typology constitutes 3% of the residential area and 2% of the population (TR030). To represent this typology, Unit TR69, Sauk Village was selected.

7. Areas developed around rural infrastructure (T7)

This typology includes all urban areas developed along the connecting roads between small centers. They predominate an individual home, with a height of 2-3 floors, with significant deficiencies in infrastructure and public services. This typology occupies about 13% of the inhabited area (TR030). To represent this typology, Unit FA30 was selected in the Farkë administrative unit.

8. Areas developed in mountain relief (T8)

This typology refers to high-rise areas, built in recent years. Occupy about 5% of residential areas in Tirana (TR030). To represent this typology, Unit DA75 was selected in the administrative unit Dajt.

9. Area developed along main economic stripes (T9)

These are mainly industrial zones, with mixed economic

and commercial functions, extending along the Tirana-Durres interurban road. This typology occupies about 5% of urban territory (TR030). To represent this typology, Unit KA158 was selected, part of the Kashar One.

Below the main finding are shown in a conclusive table:

Unit	TR372	TR317	TR363	TR412	KA252	DA75	KA158	TR69	FA30
Code	T1	T2	T3	T4	T5	T6	T7	T8	T9
Category	urban	urban	urban	suburban	suburban	suburban	suburban	rural	rural
Typology	Communist blocks	Mixed central	Historic	Informal area	Tower buildings	Mountain areas	Economic areas	Urbanized villages	Areas along infrastructure
Area (m2)	77,100	47,200	33,300	188,400	43,300	140,900	76,300	115,900	524,700
Existing FAR	1.99	0.95	1.54	0.42	2.36	1.07	0.56	0.51	0.09
Proposed FAR	3.5	2.95	4	0.6	2.5	1.6	2.6	0.6	0.6
% of categories of land use (existing)	A (73%); AS (9%); IN (9%); S (4%); AR (5%)	A (82%); AS (7%); IN (11%)	A (73%); IN (15%); AS (12%)	A (62%); IE (22%); B (12%); IN (4%)	A (73%); B (21%); IN (6%)	A (85%); N (6%); S (5%); IN (4%)	IE+S (83%); A (9%); B (5); IN (3%)	A (73%); B (12%); S (2%); IN (12%); AS (1%)	B (92%); A (5%); IN (3%)
% e of categories of land use (proposed)	A (78%); AS (9%); IN (4%); S (5%); AR (2%)	A (89%); AS (7%); IN (4%)	A (82%); S (5%); IN (7%); AS (6%)	A (97%); IN (3%)	A (70%); B (14%); S (10); IN (6%)	A (78%); N (16%); B (4%); IN (3%)	IE+S (98%); IN (2%)	A (93%); IN (3%); AS (3%); B (1%)	B (52%); A (46%); IN (2%)
Total revenue from TII	3,428,123,476	8,574,646,667	5,896,235,846	287,841,046	23,340,400	1,141,630,688	0	109,065,810	1,148,780,819
Total revenues from tax on agriculture	0	0	0	-7,941	-1,055	2,029	-1,437	-4,450	-76,605
Total revenues from tax on residential property	3,390,254,644	10,718,308,333	6,599,066,808	359,801,308	-1,215,699,500	1,427,038,360	0	662,281,100	2,487,699,950
Total revenues from tax on commercial property	3,579,598,800	0	4,627,368,000	0	4,979,500,000	0	80,682,086,016	0	0

As it seems, in the 9 typologies studied there are different models of land use changes. Mainly, the trend has been the expansion of the residential area both in the parcel and in the densities. Five of the areas provide DLP instrument, accompanied, where appropriate, by conditional intensity instruments. This means that redevelopment and alienation of most of the existing typologies is proposed and, in some cases, of the land uses.

It is estimated that classifiable typologies such as urban areas (including historic areas, state-owned and mixed-use areas) may generate tax revenue of approximately 45,000,000,000 Lek⁹, based on plan proposal. Of these, the TII, which is only collected once, in the process of obtaining the construction permit, is estimated at about 17,899,000,000 Lek. The rest are revenues that would be generated periodically every year. These areas, at the level of interventions proposed by the local plan, mainly undergo significant densification, and a small increase in the percentage of occupied services.

Suburban areas, including informal areas in northern Tirana, and peripheral housing blocks (in Kashar and Dajti) and the Tr-Dr economic zone, may generate revenues of about 103,821,000,000 Lek in the first year, out of which 17,589,229,337 are only one time beneficial from TNI, and the rest are generated year after year in addition to the existing one. The suburban typology is considered as a predominant relative to the urban territory of the Municipality of Tirana (with about 57% of it), therefore the tax values are considerably higher.

Finally, rural areas, represented by village centers and developed areas along the roads, represent about 12% of the urban terrain of the Municipality of Tirana, and usually experience very small changes in intensity but major changes in land use: agricultural territory replaced by urban territory at 50%. Thus, the taxes generated from these areas by TII are around 218,130,000 Lek, while other periodically collected taxes amount to 3,149,981,000 Lek (additional to the existing ones). Of course, in these areas, from the conversion of agricultural land, they lose about 81,056 Lek each year.

6. Conclusions and discussions

As far as efficient investment planning and budgeting matters are concerned, drafting a realistic planning document can be considered the most important step. In the absence of proper financial analysis (Capital Investment Plan being one as such), the actual GLP for Tirana misses the linkage between its strategic objectives to foster future urban growth with its actual efforts (and possibilities) for implementation.

The empirical analysis above has shown that the building proposals of the GLP can generate a high immediate value from Impact on Infrastructure Tax (20 billion ALL). But this tax, remains a one-time tax, which partially justifies the need for investments needed for including these new buildings to the city. In the other hand, maximizing the efforts for improving the system for collecting the property tax on buildings might result in a collection of considerable budget of 184 billion ALL, each year. These values together, exceed the actual municipal budget, highly rising the opportunities for better services to its residents.

As a consequence of the above discussion, it is necessary to improve the system of asset registration, tax collection, etc., so that this potential is not untapped. Adapting new and innovative financial instruments for land development as well, remains a highly considerable solution to foster future urban growth, while ensuring public goods to the community.

⁹ 1 euro is equivalent to approximately 122 Lek

On the other hand, it is important to link the taxation (purpose, base, etc.) to territory through land use instruments and normative. The first one, with the requirement of being more flexible, might help better planning and better projections of financial resources that can be allocated from the differentiation of the tax types.

In addition, in the way the rules for structural units have been drafted, this study highlights some of gaps as follows:

- Often the proposals on land use categories (in percentage) do not really reflect the reality (the existing land use situation).
- On the other hand, the Kshp and Kshr proposals contradict the Surfaces in% estimated for Infrastructure, Education, Recreation and Similar uses as well as the greening areas specified in the passport. In any case, the document becomes speculative as far as the standard you can refer to in each case.
- With regard to the proposals, taking into account unit holding capacity, the expected population in the Municipality of Tirana for the next 15 years will increase by an average of 421,000 people, i.e. by almost 50%. This does not reflect the real growth trends of the city.

Finally, it is certainly worth mentioning that this assessment takes into account the ideal situation, where any Local Plan is implemented. This is not realistic in the long run. However, it should be borne in mind that the planning function is to predict the country's socio-economic, territorial, environmental, etc. dynamics as precisely as possible, and to precede it with instruments and orientations to enable development and increase prosperity.

Abstract: As one of the three most important location-oriented policies in urban and regional development, the location selection of new towns largely determines the strategy of urban economic development and regional economic development. In the previous study, an objective model of municipal administrative areas spatial zoning model (MAA-SZ model) is constructed based on the theory of spatial equilibrium and mathematical logic deduction, which can provide guidance for the location of new towns. This paper takes a city in the south of Heilongjiang Province as an example to verify the value and superiority of the MAA spatial zoning model in the location selection of new towns. The results show that the consistency Kappa value of the model is 77.2% when the MAA-SZ model is compared with Glaeser-Gottlieb new town location selection model new towns that has been widely used, which verifies the accuracy of the model. In addition, the spatial differentiation and DEA effectiveness of the model are higher than the contrast model. The superiority of the MAA-SZ model over the contrast model mainly lies in two aspects. Firstly, the MAA-SZ model effectively reduce the influence of some factors that can not be assigned objectively while inheriting the economic relationship among the factors of the contrast model. The MAA-SZ model makes it easier to simulate and operate, and more practical. Secondly, it effectively reduce the contradiction between development, agriculture and ecology, which is often caused by the traditional site selection of new town basing on center-urban gravitation. The MAA-SZ model solve this problem by balancing the relationship among construction, agriculture and ecological land from the macro-perspective of the MAA. Therefore, the MAA-SZ model has the characteristics of high accuracy, high balance, high effective, high spatial differentiation, and high practicality. We believe the MAA-SZ model can also provide a reference for the development of urban system.

Keywords: spatial zoning, municipal administrative area, new town.

1. Introduction

From the perspective of urban economics, new town construction is an important carrier to promote the rapid development of urbanization and the sustainable growth of regional economy. With the increasingly prominent problems of environmental pollution, traffic congestion, and the decline of quality of life in urban central areas,

new town construction has become an important way to solve urban space expansion and function optimization (Sun, 2016). As an important location-oriented industrial policy, the location of new towns has a significant impact on the layout of urban industries. The location of new towns largely determines the urban economy and is an important part of the strategy of regional economic development (Johnson, 2007). At present, most of the models used to solve the problem of new town location are based on the economic factors that attract consumers from the city. Their application is not practical enough, and there are great differences between the valuation of some economic factors and the actual situation (Nouri *et al.* 2013). At the same time, many new town location models focus on the city gravity and lack of balanced consideration from the perspective of the city, resulting in conflicts between the location of new town and the location of agricultural and ecological land (Sun, 2016). In order to solve the problems of new town location, it has become the primary task of regional economic development strategy to establish a highly practical and balanced MAA spatial zoning model to guide the new town location.

At present, the new town location selection models can be divided into five categories: agricultural location model, industrial location model, single-center new town location selection model based on the gravity of the central city, multi-center new town location model, and new town location model based on agglomeration economy. The core idea of agricultural location model (Johann, 1826) and industrial location model (Alfred, 1909) is from producers' version and aim to maximize the production profit. It selects the appropriate new town location through the producer input/output ratio. The new town area has little connection with the traditional central urban area and is relatively isolated. With the continuous deepening of the relationship between the new town and the traditional central city, a single-center new town location model focusing on the gravity of the central city based on the logical deduction between economic factors was developed. Developers determine the location of the new town according to their target income. Among them, the number of enterprises, population size and land area of the new town are endogenously generated by the gravity of the traditional central city. Chen Hongxia (Chen, 2008) started with the gravity of the central city, and aimed at the theoretical and practical problems of the new town formation and development, constructed a general endogenous theoretical model of the new town. And the mechanism of the new town development was also studied. With the development of multicenter city and urban diffusion, Krugman's multi-center new town location model was proposed. Based on the single-center new town location selection model and the principle of attraction and repulsion between enterprises, this model organically connects the new town and the traditional central city to clarify the inner structure of the economic spatial pattern of the city (including the new town and the traditional central city) (Krugman, 1993). Recently, the impact of agglomeration economy on new town location selection increase, so some new town location selection models based on agglomeration economic factors and balancing the central and suburban areas have been proposed. For example, Gottlieb and Glaeser (Glaeser and Gottlieb, 2008) pointed out that the agglomeration economic effect under spatial equilibrium between the central city and the new city is an important economic factor behind the new town location selection policy. At present, this model has been widely used in the location selection of new towns, and many meaningful results have been achieved (Minha, 2017, Liu, 2016).

Generally speaking, the existing five types of new town location selection models differ from each other due to the differences in urban structure and morphology, and all of them show shortcomings in the application practice of new town selection location. Firstly, the existing models are constructed by the logical relationship between economic factors. Some of the economic factors, such as consumer preferences and the number of urban products, can not be assigned in practice, which leads to the weak applicability of the models. Secondly, most of the existing models advocate that the location of new towns focus on the gravity of the central urban areas. It is lack of rational consideration to the relationship between the development of new towns and agricultural and ecological land from the perspective of MAA. Therefore, it aggravates the contradiction among construction, agriculture and ecological land. Thirdly, most of the existing models are based on different urban forms and structures, and their scope of application is limited.

In our previous study, the model of MAA spatial zoning was constructed by using the economic logic derivation and the objective derivation of the relationship between the model factors. The MAA-SZ model aim to study the suitability of MAA spatial development construction basing on the theory of spatial equilibrium. It is used to simulate and analyze the MAA spatial zoning and the results are compared with three existing models: urban structure model, UGB delimitation model and functional regionalization model. It is found that the average Kappa value is 81.3%, which verifies the correctness of the model (Zhao *et al.* 2018). Theoretically, it is possible to use the MAA-SZ model to solve the problem of new town location selection. In order to verify the application value of the model in the new town location selection, this paper take a city in southern Heilongjiang as an example and applies the new town location selection model to it. Meanwhile, we compared the spatial differentiation and DEA effectiveness of the MAA-SZ model and Glaeser-Gottlieb new town location selection model (Glaeser and Gottlieb, 2008). The results show that the model has advantages in solving the problem of urban new town location selection. Moreover, the model show many advantages than the traditional Glaeser-Gottlieb model, such as it is more balanced, more effective, as well its more spatial differentiation, easier value assignment, wider application scope and more convenient application.

2 Research Method and Research Area

Based on the practical problems existing in the existing model for the new town location selection, this paper starts with the introduction of the model and the research area.

2.1 Introduction of the Model

2.1.1 MAA Spatial Zoning Model

In the previous study, through data, personnel research and economic derivation, under the condition of the restriction of the main functional areas, the model of MAA spatial zoning was constructed, and the correctness of the model was verified by comparing with the existing spatial zoning model. The MAA-SZ model is used to solve the spatial differentiation of urban areas (including central and new towns), urban systems and village and town systems. The factors included in the model are: available land resources; population aggregation; economic development level; location advantage; traffic advantage; number of development zones; topography; natural disasters; available water resources; environmental capacity; ecosystem vulnerability. Among them, the factors contributing to D are: available land resources, population aggregation, economic development level, location advantages and transportation advantages; the second factor contributing to D is the number of development zones, topography and topography; the lowest factor contributing to D is natural disasters, available water resources, environmental capacity and ecosystem vulnerability. (Zhao *et al.* 2018) In order to reflect the superiority and practical value of the established model of MAA spatial zoning, this paper uses the model to further apply in the new town location. The MAA-SZ model is as follows: Formula 1.

$$D(r) = \left(\frac{L_1^2 N_1 \lambda t Y e^{(\lambda t |r - r_0|)}}{e^{\lambda t r} - 1} \right) \left(p^{x_1} (y + r_0)^{x_2} J^{x_3} \right)^{(1-\mu)} \left(\frac{\sigma - 1}{\sigma} \right)^{\mu} M_1(r)^{\left| \frac{\mu}{1-\sigma} \right|} \quad (\text{Zhao et al. 2018})$$

The weight of each factor in P value is 0.15 for natural disasters, 0.15 for topography, 0.3 for available water resources, 0.2 for environmental capacity and 0.2 for ecological vulnerability. The parameters of μ 、 t 、 x_1 、 x_2 、 x_3 、 σ are 0.5, 0.005, 0.45, 0.2, 0.35, 2 (Fujita *et al.* 1997, Fujita and Mori, 2005, Wang *et al.* 2009), respectively. (Zhao *et al.* 2019)

2.1.2 Glaeser-Gottlieb New Town Location Model

$$D = \theta N^{-\sigma} (1-t) W P^{-\beta} \quad (\text{Glaeser and Gottlieb, 2008})$$

In which, D represents the suitability utility of MAA spatial development, N represents the population, W represents the wage rate, T represents the location advantage, P represents the preference of MAA participants to the land commodity. The values of parameters θ 、 σ 、 β are 1.9, 2 and 0.5, respectively(Fujita *et al.* 1997). What we need to explain here is that because the value of P consumer preference is difficult to determine, the p value of the MAA-SZ model (the model of MAA spatial regionalization) is adopted in the simulation, that is, the preference value of the main body of the MAA.

2.2 Introduction of Research Area

The study area is located in the south of Heilongjiang Province. The main landform is low mountains and hills. The elevation is between 100 and 850 meters. The distribution of water resources and available land resources is uneven, and the difference of natural environment is significant. In 2018, urban population accounted for more than 1/2 of the total population, urban area accounted for more than 20% of the total urban area, leading industries were secondary and tertiary industries, and its GDP accounted for more than 80% of the total GDP.

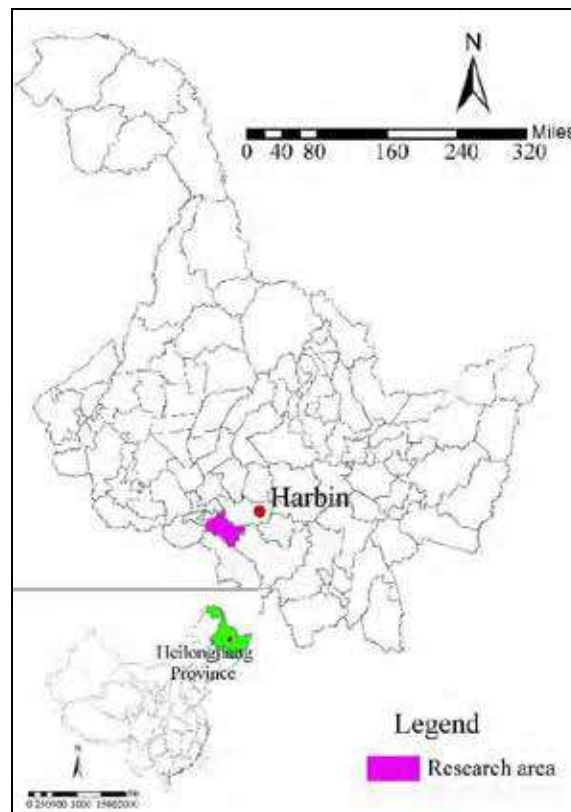

Fig. 1 Location of the research area.

3. Application and Verification of MAA Spatial Zoning Model in Location selection of New Town

Based on the current situation and research methods of the research area, the model is applied by starting with the consistency test, spatial differentiation and DEA validity of the model and the comparative model (Glaeser-Gottlieb New Town Location Model).

3.1 Consistency Test and Nonlinear Regression Analysis of MAA Spatial Zoning Model and Glaeser-Gottlieb New Town Location Model

Combining the distance factor with the old city and the local policy orientation, the new town location simulated by the MAA-SZ model is compared with the new town location simulated by Glaeser-Gottlieb model, as shown in figs. 2a and 2b. The consistency kappa value is 76.1%, and the consistency test value is high. The main reasons for the difference are the determinacy of the model factors and the restriction of the main functional areas. Especially, compared with the uncertainty of consumer preference and the quantity factor of urban products in the comparative model, the MAA-SZ model can be replaced by the factor of available water resources, topography, environmental capacity, ecosystem vulnerability, natural disasters, and the number of development zones through preliminary validation and deliberation (Zhao *et al.* 2018). As a result, the MAA-SZ model has more advantages than the comparative model in delineating new cities. Because of the limited role of the main functional area, the model can balance the relationship between development, agriculture and ecological land from a macro perspective. Compared with the comparative model, it is easier to deal with the contradiction between development, agriculture and ecology when selecting the location of the new town. In conclusion, the MAA-SZ model is more balanced than the comparative model.

By comparing the consistency kappa values of the model, the comparison model generation map and the government behavior map, the kappa values of the comparison between Figure 2a and Figure 2c of government behavior are 83.8%, and that of Figure 2B and Figure 2c of government behavior is 79.7%. Compared with the government behavior, the consistency of the model is higher than that of the comparison model, which verifies that the model is more consistent with the current situation. It further illustrates that the model has a good guiding role in the location of urban new towns.

By using the MAA-SZ model and the Glaeser-Gottlieb new town location model, the multiple non-linear regression analysis and linear regression analysis show that the R_2 value of the MAA-SZ model is 0.79 while that of the comparative model is 0.73, which proves that the MAA-SZ model is more objective than the comparative model in the actual fitting process.

As can be seen from Fig. 2a, the land on both sides of the northwest and southeast of the city is more superior, and can be used as location selection for new towns. It is suggested that urban construction land be reserved in the northwest and southeast of the city in the future. And gradually adjust the future construction land and nearby agricultural land, ecological land, population transfer and other policies. This will help to adapt the development of new towns and population changes gradually.

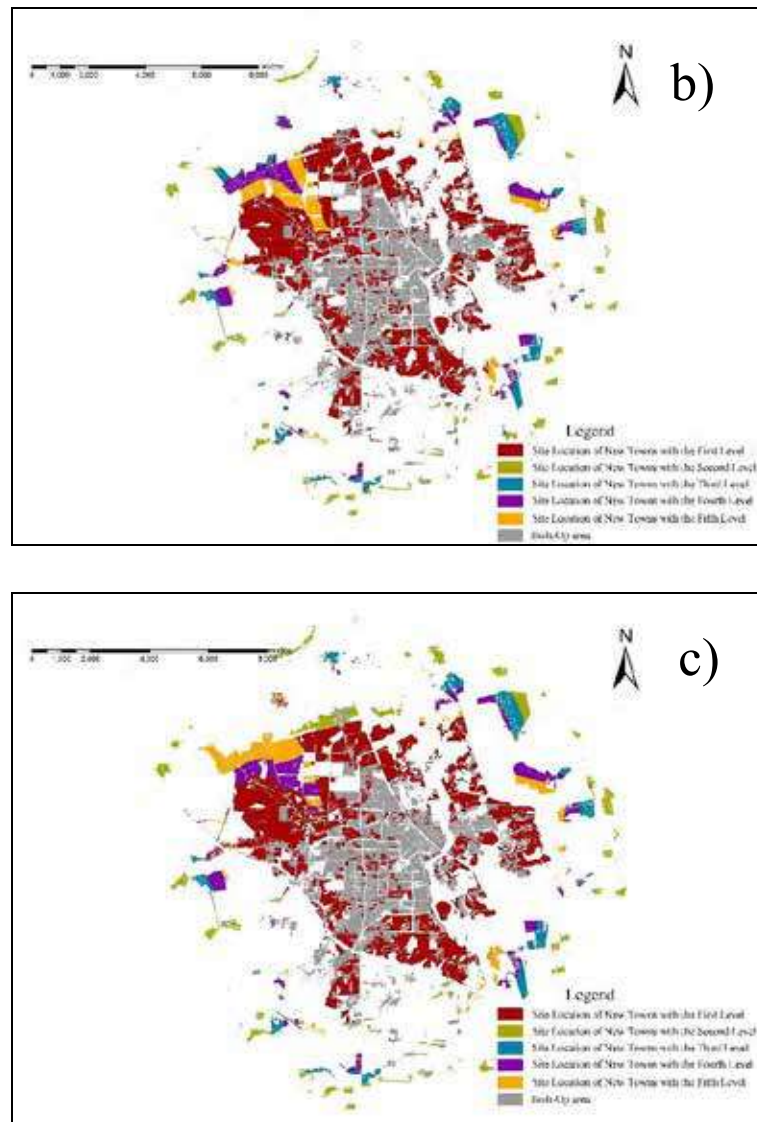

Fig. 2 Evaluation of New Town Location Selection. a) Simulation Results of the MAA-SZ model. b) Simulation Results of Glaeser-Gottlieb model. c) Government Behavior Results.

3.2 Comparison and Analysis of Spatial differentiation between MAA Spatial Zoning Model and Glaeser-Gottlieb New Town Location Model

Generally, the spatial differentiation of simulation results between two models is measured by the degree of variation of the semi-variogram of the model. Therefore, this paper tests the spatial differentiation of the two models by comparing the degree of variation of the semi-variogram of the two models. Before calculating the variation degree of the semi-variogram of the model, it is necessary to process the data with special values, analyze the spatial correlation and test the determinant coefficient of the semi-variogram and the normal distribution of the data. The processed special values are substituted into the data to test whether they belong to the normal distribution or are transformed into the normal distribution, and have good spatial correlation and the determinant coefficient of the semi-variogram. The premise of simulating the variation degree of semivariogram.

3.2.1 Special Value Processing

Geostatistical analysis requires that the data analyzed be of normal distribution, and the existence of special values will cause discontinuity of the continuous surface of variables, and then change or even conceal the

original spatial structure characteristics of semi-variogram (Li *et al.* 2014). Therefore, in this section, the domain method is first used to detect and process the special values in the simulation results of 10 models. That is to say, the values in the range of 3 times standard deviation of sample average are normal values, while the values outside this range are regarded as special values, and the normal maximum is used to replace the special value (Li *et al.* 2014).

3.2.2 Semi-Variogram Fitting

Geographic statistics is based on the theory of regional variables and the main method of semi-variogram (also known as semi-variogram function). It has been applied in urban spatial regionalization, land spatial economy and ecological pattern evolution (Zhang *et al.* 2019, Xu and Hao, 2017, Jiang 2015, Yue *et al.* 2005). In this paper, semi-variogram model is used to study the spatial differentiation significance of several models. In the semi-variogram model, the nugget value represents the quantity of random variation, reflecting the variation caused by artificial and other random factors in the experimental error. The base value represents the structural variance of spatial variation, indicating the total variation in the system. The higher the base value, the higher the total heterogeneity of the system. The nugget coefficient is the ratio of nugget value to base value, which is caused by the random part. Spatial variability accounts for the proportion of total variation in the system. The nugget coefficient < 25% indicates that the variables have strong spatial correlation, 25%~50% indicates that the spatial autocorrelation is obvious, 50%~75% indicates that the variables have medium spatial autocorrelation, and > 75% shows weak spatial autocorrelation. The variation is mainly composed of random variation (Tatem *et al.* 2002).

Statistical analysis requires the data to be normal distribution, and Kolmogorov-Smirnova normal distribution test (K-S test) is used before the spatial analysis. If $P_k-s > 0.05$, it is considered that data obey normal distribution, otherwise data conversion is needed. The results of normal distribution test show that the significance level of the MAA-SZ model $P = 0.82 > 0.05$ and the comparative model $P = 0.85 > 0.05$, that is to say, the two sample data pass the K-S test and obey the normal distribution, so there is no need for data conversion.

Based on GS+9.0 software platform, the semi-variogram formula is fitted. The semi-variogram fitting results show that the decision coefficients of the fitting functions of the MAA-SZ model and the comparative model are greater than 0.5, which are 0.91 and 0.83, respectively. It shows that the function fitting effect of the spatial differentiation of the new town location selection land in the study area is good under the Gaussian model, and the model can explain the spatial structure adequately (Table 1).

Tab. 1 Fitting result of semi-variation function

Model	Nugget	Abutment value	Nugget coefficient	Range change (m)	Coefficient of determination	Spatial differentiation model
The MAA-SZ model	0.25	1.44	17.4%	322	0.89	Gaussian
The comparative model	0.23	1.53	15.0%	243	0.82	Gaussian

3.2.3 Anisotropy analysis of semi-variogram

The variation degree of semi-variograms in the four directions of 0 (east-west), 45 (northeast-southwest), 90 (south-north), 135 (southeast-northwest) of the model and the comparative model is plotted in Figure 3. The dotted line in the graph indicates the variation degree of "semi-variance/sample variance=1", which can be used to measure the variation degree of elements in four directions. When the semi-variance/sample variance is greater than 1, the elements exist. When the semi-variance/sample variance is less than 1, the variation of elements is weak, even there is no variation.(Zhang *et al.* 2011)

The MAA-SZ model simulates the land evaluation of new towns site selection, which varies significantly in four directions. Wave-like fluctuation trends were observed in all four directions. Small peaks of variation appeared in the direction of 0° near 2876 miles and 8340 miles respectively, which may be caused by the high variation of population and economic factors in the two places above 0° from the annex. The U-shaped trough appears near 4321 miles and 9514 miles in the direction of 45° , which may be caused by the weak variation of economic and traffic factors between the above two locations in the direction of 45° and the appendages. In the 90° direction, the correlation factors of the model change relatively little, so the variation level presents a relatively stable low level state. The small variation peaks appeared at 1431 and 7521 miles in 135° direction, which may be caused by the high variation of population, location, economy and traffic factors between the two places above 135° direction and the accessory.

When the comparative model was used to simulate the land evaluation of new towns site selection, the similar variation trend was also found in four directions. However, compared with the model, the degree of variation is not that obvious. There was a significant variation near 9304 miles in the direction of 0° , which was mainly influenced by consumer preferences in that direction, and in a smaller range. There are some variations in the direction of 5° 847 miles and 12 238 miles, which are mainly influenced by the wage rate and consumer preferences in this direction. A small peak appeared in the vicinity of 5026-977 miles in the direction of 90° , which may be affected by consumer preferences, location, wage rate and population in that direction, and show great variation in this range. There are two U-shaped troughs near 4873 miles and 11373 miles in the direction of 135° , which may be caused by the weak variation of population and location factors between the two places above 135° and the appendages.

Generally speaking, the model simulates the variation of the evaluation of new town location selection in four directions, which is more obvious than the comparative model, indicating that the model has a higher degree of spatial variation, that is, the spatial differentiation is higher than the comparative model. The high-low alternation in the semi-variogram simulated by the MAA-SZ model may be attributed to the important position of economic development level, location, population and other factors in the MAA-SZ model. The high-low alternation in the semi-variogram simulated by the comparative model may be due to population, location, economic development level, consumer preferences and other factors.

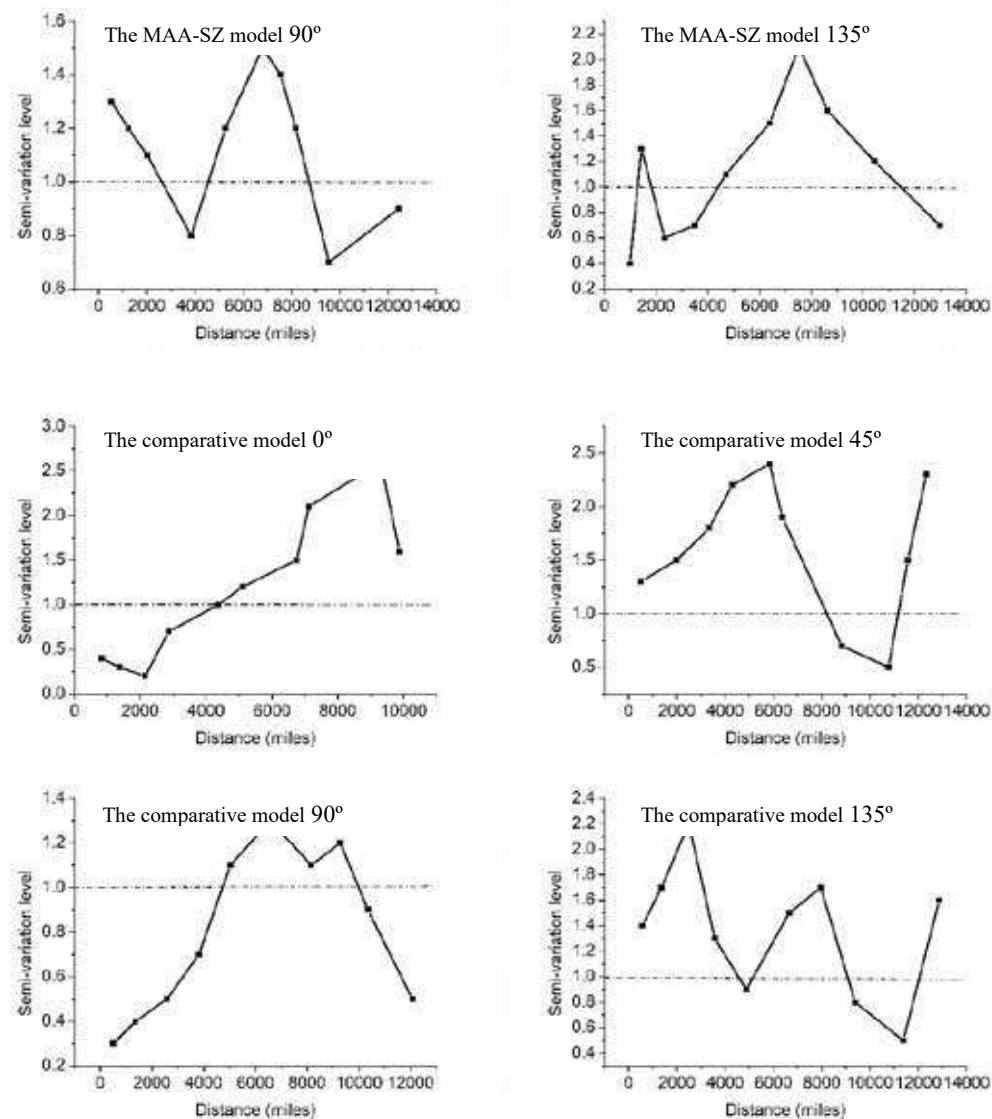

Fig. 3 The spatial differentiation of the model and the Glaeser-Gottlieb model.

3.3 Comparison and Analysis of DEA Effectiveness between MAA Spatial Zoning Model and Glaeser-Gottlieb New Town Location Model

3.3.1 DEA Model Method

DEA is a method to evaluate the relative effectiveness or benefit of the same type of decision making units (DMUs) based on the concept of relative efficiency and the multi-index input and output of the model. It is one of the commonly used methods to test the validity of the model. (Zhang *et al.* 2014) This method has been widely used in the validity test of relevant models such as urban planning and land use (Tonts *et al.* 2013, Sun *et al.* 2012). The correctness of this method has been verified in practical application. In this paper, DEA validity test method is applied to the model and the comparative model respectively, in order to verify which model is more effective. In this study, DMU refers to a block unit with a single evaluation result of the suitability utility of MAA spatial development. Among the DEA models, C2R and C2GS2 models (Li *et al.* 2017) were used more widely. Among them, C2R model reflects the comprehensive efficiency of the corresponding production state of DMU, including technology and scale efficiency; C2GS2 model reflects the technical efficiency of the corresponding production state of DMU. This paper chooses C2R model to simulate the validity of the above

four models in order to reflect the synthetical effect of the model on the suitability of urban spatial development. Its construction is as follows.

In the C₂R model, assuming that the performance of n research blocks is evaluated, and that each research block has m input indices and s output indices; suppose x_{ij} ($i = 1, 2, 3, m; J = 1, 2, 3, n$) and y_{ij} ($r = 1, 2, 3, s; J = 1, 2, 3, n$) represent the total input and output of the first type of factor and the total output of r, respectively; then the input and output of each research block can be expressed by vector X_j and Y_j . According to the evaluation idea of DEA method, a linear programming model based on input reduction and output invariance is established.

$$\begin{cases} \min \theta \\ s.t. \sum_{j=1}^n \lambda_j x_j + s^- = \theta x_{j_0} \\ \sum_{j=1}^n \lambda_j x_j - s^+ = \theta y_{j_0} \\ \theta = \frac{\sum_{i=1}^s \lambda_{ij} x_{ij}}{\sum_{i=1}^m \lambda_{ij} y_{ij}} \\ \lambda_j \geq 0, j = 1, 2, 3 \dots n \\ s^+ \geq 0, s^- \geq 0 \end{cases}$$

In the formula, θ is the efficiency index of the research block; λ_j ($j = 1, 2, 3, n$) represents the combination weight of the n research block (since the research block is equally important here, the weight is set equal); $\sum_{j=1}^n \lambda_j x_j$ and $\sum_{j=1}^n \lambda_j y_j$ are the input and output vectors of the block combined according to this weight; X_{j_0} and Y_{j_0} are the input and output vectors of the J_0 block; S^- and S^+ are the relaxation variables, representing pure excess and insufficient, respectively. In the C₂R model, θ , S^+ , S^- are the important basis for evaluating the suitability efficiency of the development of MAA.

The criteria for determining the validity of the study block are: (1) DEA is effective: when $\theta=1$, and $S^+=0$, $S^-=0$; (2) DEA is weak: when $\theta=1$, at least one input or output is greater than 0; (3) DEA is ineffective: when $\theta < 1$. (Zhang *et al.* 2014)

3.3.2 Data Resource

The MAA-SZ model involves 11 input and 1 output indices while the comparative model involves 4 input and 1 output indices. The data of population, economy and wage rate come from Heilongjiang Province's 2016 Population and Economic Statistics Yearbook; the amount of available land resources and the price of land in Heilongjiang Province come from the Heilongjiang Land and Resources Department's data of 2017; the amount of available water resources in Heilongjiang Province come from Heilongjiang Taxation Bureau's data of 2017. The data about the number of undeveloped development zones in Heilongjiang Province of 2018 was provided by the Ministry of Construction. The data of natural disasters in Heilongjiang Province in 2016 was provided by Heilongjiang Seismological Bureau. Heilongjiang Elevation and Slope Data in 2016 were provided by Heilongjiang Surveying and Mapping Bureau. The Annual environmental capacity and ecosystem vulnerability data of 2016 come from Heilongjiang Forestry Bureau. The input and output evaluation system of the MAA-SZ model and the comparative model is shown in Table 2-3.

Table 2 The Suitability Evaluation System of New Town Spatial Development of the MAA-SZ model (Zhao *et al.* 2019)

First level index	Second level index	Third level index
Input index	Available Land	Area of Available Land
	Population aggregation	Population growth rate
	Economic development level	Economic growth intensity
	Location advantage	Internal location advantage
		External location advantage
		Railway stations, expressways and main roads at all levels
	Transportation advantages	Arterial airport
		Regional airports and ports
	Number of development zones	Number of undeveloped or uncompleted development zones after adjusted by the state or government
	Topography and topography	Altitude
		Slope
	Natural disaster	Risk of floods, droughts, earthquakes and forest fires
	Available water resources	Available water resources per capita
	Environmental capacity	Individual environmental capacity bearing index
		Population density
		Gdp density per capita
		Ratio of construction land
		Cod emission intensity
		Environmental quality index
		Value of ecosystem services
		Water resources per capita
		Net income per-capita
		Proportion of urban population
		Total power consumption of industrial enterprises
		Gdpcod quantity
		Sewage treatment rate
		Government investment in environmental protection
Output index	Suitability utility of urban new town spatial development	

Table 3 Glaeser-Gottlieb model of Suitability Utility Evaluation System for New Town Spatial Development (Glaeser and Gottlieb, 2008)

First level index	Second level index
Input index	Wage rate
	Location advantage
	Population size
	Consumer preferences
Output index	Suitability utility of new town spatial development

3.3.3 Operation Result Analysis

In this study, three kinds of validity of a city in the south of Heilongjiang Province were counted (Fig. 4). First, the second-level input indices of the model and the comparative model were taken as the unit; then, the land

with the same evaluation result of the second-level input index of each model was merged into one block unit to ensure that each block had the reasonable evaluation result under the same model. The total research blocks of the MAA-SZ model is 1327, and the total research blocks of the comparative model is 1124. Under C_2R model, the number of DEA valid in the MAA-SZ model is 1115, accounting for 84% of the total; the number of DEA weak valid is 146, accounting for 11% of the total; and the number of DEA invalid is 66, accounting for 5% of the total. The effective number of DEA in the comparative model is 888, accounting for 79% of the total; the weak effective number of DEA is 90, accounting for 8% of the total; and the invalid number of DEA is 146, accounting for 13% of the total. Compared with Glaeser-Gottlieb New Town Location Model, the MAA-SZ model is more effective and less invalid.

Fig.4 DEA effectiveness of the MAA-SZ model and the Glaeser-Gottlieb model.

4 Conclusions and Discussion

4.1 The kappa value, spatial differentiation and validity of the model and the comparative model

Based on the basic idea of spatial equilibrium theory, this paper applies both the MAA-SZ model and Glaeser-Gottlieb New Town Location Model to the practical application of New Town Location under the restriction of main functions. The validity, superiority and application value of the MAA-SZ model in new town location are judged by comparing the kappa value between models, spatial differentiation and DEA validity analysis.

Compared with Glaeser-Gottlieb model, the consistency kappa value of the MAA-SZ model is 76.1%, which verifies the correctness of the MAA-SZ model. At the same time, because of the determinacy of the model factors and the restriction of the main function area, the MAA-SZ model is more accurate in the new town. Because of the limited function of the main functional area, the model is more macro-balanced. Meanwhile, the consistency kappa value between the MAA-SZ model and the government behavior map is 83.8%, while that of the comparative model and the government behavior is 79.7%, which proves that the model is more consistent with the government intention.

Nonlinear regression analysis shows that the R_2 value of the MAA-SZ model is 0.79 while that of the comparative model is 0.73, which proves that the model is more objective in the process of fitting with the actual situation.

By comparing the spatial differentiation between the MAA-SZ model and Glaeser-Gottlieb new town location model, it is found that the determinant coefficient of the semi-variogram model is 0.89 for the MAA-SZ model while that of the comparative model is 0.82. And the nugget coefficient of the MAA-SZ model is 17.4% while that of the comparative model is 15.0%. From the simulated variation map, the MAA-SZ model has a higher degree of variation, which proves that the spatial differentiation of the MAA-SZ model is higher than that of the comparative model.

The DEA validity of the MAA-SZ model and Glaeser-Gottlieb new town location model were analyzed. It is found that the number of effective DEA accounts for 84% of the total, the number of weak effective DEA accounts for 11% of the total and the number of invalid DEA accounts for 5% of the total for the MAA-SZ model. For the comparative model, the number of effective DEA accounts for 79% of the total, the number of weak effective DEA accounts for 8% of the total and the number of invalid DEA accounts for 13% of the total. It proves that the MAA-SZ model is more effective than Glaeser-Gottlieb model in DEA.

4.2 The Widespread Application of the Model and Its Enlightenment to New Town Location Model

Based on the certainty of factor selection and weight assignment, it is believed that the model has greater application generalization and inheritance, as well as wide application area.

The MAA-SZ model not only enriches the equilibrium theory, but also provides new ideas for the location of new towns. The application results show that the model can effectively and reasonably divide the development, agriculture and ecological space from the macro-equilibrium point of view, and more accurately determine the location of the new town through the development time of the MAA. It promotes the balanced and rational utilization of the macro-direction of urban land. In addition, it also provides scientific basis for the future development direction of urban system.

Generally, compared with the traditional models, the MAA-SZ model show three advantages. Firstly, the MAA-SZ model maintains the objectivity of the existing new town location model, and extends the spatial regionalization equilibrium of the existing new town location model. Briefly, the traditional new town location model advocates the balance from the central city to the new town, while the idea of the MAA-SZ model is the balance of construction, agriculture and ecological land within the city area. Secondly, the MAA-SZ model widens the scope of application of existing new town location selection model. For example, different traditional new town location models were used to meet different requirements of urban structure and morphology, while there is no limitation for the MAA-SZ model. Lastly, the MAA-SZ model facilitates the application of existing new town location model. As we know, some factors of existing new town location model can not be assigned, while the MAA-SZ model reduces the factors that can not be assigned. We believe these improvements will make the model easier to operate and practice.

Home sharing.
Short-term rentals affecting
local housing markets

Built Commons: Reclaiming the Sharing Economy

Ioana Petkova¹

¹*Royal College of Art, London, United Kingdom, ioana.petkova@network.rca.ac.uk*

Abstract: The advance of distributed computing research in the U.S. during the 1990s led to the conception of novel channels for subletting surplus space right after the burst of the U.S. housing bubble. The coincidence of the new technologies with the biggest increase in house prices (1990-2008) resulted in a new sharing culture which we know today as the “sharing economy”. This paper suggests that even if sharing platforms today are failing by exacerbating the housing crises around the globe, they could provoke other *alter-sharing* practices. The paper aims to reevaluate the sharing economy in relation to housing and in particular, its spatial implications. It looks into historical non-digital stranger-shared housing precedents and their architectures by deploying the theoretical framework of the commons as autonomous, resilient grassroots sharing networks. Finally, it explores contemporary online listing accounts looking for spatial evidence for both the effects of the sharing economy today and the potential emergence of alter-sharing practices. While regarding housing as a resource, it speculates if the pressures of its ever-growing scarcity and unaffordability could lead to the emergence of a collective political action.

Keywords: sharing economy; commons; housing; architecture

Introduction

A decade ago, as the sharing economy was just starting to gain momentum, it was initially advertised through stories of resilience and sustainability. This soon gave way to a critical wave and the realization that the practice was, among other things, disregarding employment protection legislation and exacerbating housing crises in metropolises around the globe (Slee, 2017). Recent research points to strong evidence of how short-term rentals are taking housing stock off the market and making it unaffordable through “gentrification without redevelopment” (Wachsmuth and Weisler, 2018, p.7). At the same time start-up founders and sharing advocates continue building upon the positive “feel-good” rhetoric.

The term “sharing” is very suitable for appropriation due to its lexical ambiguity – one can share a language, a meal, a room (Belk, 2010). The same could be said for the term “economy”, it can relate to both the production/consumption of goods/services, and to the careful management of resources especially in the context of today’s global housing landscape. So it is understandable that in both academia and practice there is a disagreement on what the term “sharing economy” actually means. Koen Frenken and Juliet Schor (2017) refer to this as a “definitional issue”. They argue that the sharing economy is very similar but not equivalent to other preceding practices such as second-hand economy (eBay), product-service economy (car rentals) and on-demand/gig-economy (using the

professional services of a handyman). Instead, Frenken and Schor define the phenomenon as “consumers granting each other temporary access to under-utilized physical assets (‘idle capacity’), possibly for money” (Frenken and Schor, 2017, p.5).

Both Belk and Schor and Fitzmaurice argue that stranger-sharing today was enabled through technology. For Belk the decisive development was the emergence of user generated content (Belk, 2014), while Schor and Fitzmaurice understand it as the guarantee for trust between strangers (Schor and Fitzmaurice, 2015). This paper traces how both stranger-sharing and collective content (value) generation are not new and have an analogue precedent in the face of the commons.

Theoretical Background

The commons have a long history, going back to open-field system England where the term “common” was used in relation to “common land”. Few centuries later Elinor Ostrom (1990) suggested a new definition, arguing that the common is neither private, nor public, but communal. The work focused on grassroots strategies for natural resource governance as an alternative to existing state or privatized models. Another important contribution to the debate is Antonio Negri and Michael Hardt’s (2009) definition. Here the common (singular) is the social space where the multitude arrives at a shared subjectivity, and which acts as the foundation of the emergence of the commons (plural) – the social product of collective political action. And finally, Massimo De Angelis (2017) suggests that the commons are autonomous grassroots systems for the production and governance of shared resources – both material and non-material. Drawing on the theoretical discourse described above the paper will suggest the potentiality for today’s sharing practices to transform into “commons” as a response and solution to a failing housing market.

Unfortunately, today’s sharing economy platforms have still a long way to go as they currently conceptualize sharing as distributed value. Yochai Benkler (2004) draws a direct comparison between the popular at that time distributed computing trend and the material culture of car-pooling in post-war America. Benkler suggests that today’s sharing practices are originating in projects such as SETI@Home, the distributed computing experiment of NASA as an attempt for an economical supercomputer. The incentive was working through volunteers all over the globe who participated by downloading and running a screensaver and by doing that donating their underutilized computational capacity.

Benkler (2004) explains that idle capacity is generated by specific characteristics of the shared product such as “indivisibility”, which refers to the way a product is bundled and packaged. Computational power is a good example, as it is not fully utilized all the time and this inevitably generates idle capacity. One could argue that housing has the potential to be indivisible too. And here lies one of the main conflicts of the sharing economy in relation to architecture. If the platform is conceptualized to understand sharing in such quantified ways, it proves to be problematic especially in relation to space.

The essay even goes as far as claiming that sharing is an “economically attractive modality of production” (Benkler, 2004, p.342). However, those systems have commercial value only if a certain profit threshold is crossed. Otherwise the idle capacity stays an object of “social sharing rather than market exchange” (Benkler, 2004, p.317). Looking at the house prices curve in the U.S. for the last

decades (Shiller, 2015, p.20), this statement seems to be confirmed. Positioning the two most popular platforms today, Airbnb and Couchsurfing, one can clearly see that the barter platform emerges in 1999 at a low point, while the commercialized market version Airbnb is conceived in the peak of the housing prices, just before the bubble burst.

Figure 3.1
**U.S. Home Prices, Building Costs, Population,
and Interest Rates, 1890–2014**

Figure 1 Schiller's Study of U.S. Home Prices (Shiller, 2015, p.20)

The technological developments mentioned above coincided with another major shift, one in the housing market. In the last few decades one has witnessed a steep increase in house prices, turning housing into a desirable investment asset (Monnery, 2011, Minton, 2017). The merging of soaring real estate prices and dysfunctional digital sharing platforms has marginalized the practice by reducing it to a transactional scheme. In this context idle capacity often gives way to new capacity allowing for housing units to be acquired as an investment only (Frenken and Schor, 2017). Taking housing stock off the market and exacerbating housing crises all over the world is only one side of the problem. Turning domestic interiors into staged home-themed experiences as in the documentary of Ila Bêka and Louise Lemoine (2016) reveals another dark side of the sharing economy today. The work tells the story of an Airbnb user Mark who in the pursuit of constructing the perfect host storyline, ended up giving up his marriage, home and day job. But where does all this leave us and does this mean we need to give up sharing altogether?

Research Methods

The paper argues that technology was merely the channel and not the reason for today's sharing popularity. Moreover, it claims that "sharing economies" have existed before in various analogue forms. The historical overview will construct a genealogy of stranger-shared housing and place the sharing economy within a tradition of preceding practices. It will also examine the relationship between the home and the common and how it has been actualized in space historically to then further assess today's sharing economy.

Following the historical overview, the work is going to introduce accounts of contemporary platforms through analysing online listings. The investigation will explore listings as constructed images of today's domestic condition but also as an economic marker.

Historical Overview

The following historical overview will explore a group of cases where the relationship between the home and the common was manifested differently and, essentially, formalized to a various extent. This includes the Diggers in Surrey, ca. 1649, the Oneida Community house in Oneida, New York, 1848, the Communal House of the Textile Institute in Moscow, 1931, and finally, Zollhaus in Zurich, estimated completion date 2020.

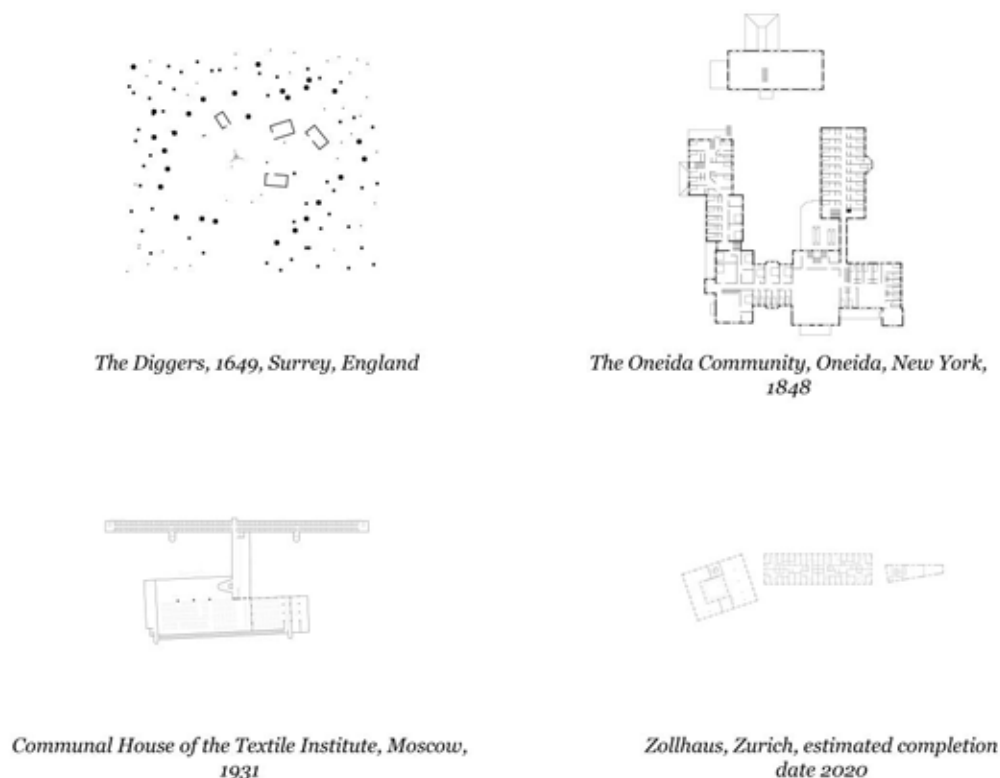

Figure 2 Historical Examples of Stranger-shared Housing

The Diggers are quite often referred to as one of the first accounts of autonomous counterculture projects. In fact, they have acquired an almost mythological status for many following counterculture

movements culminating with the SF Diggers group in San Francisco in the 1960s (Carlsson and Elliott, 2011). The story of the Diggers begins in 1649 as they settle on a piece of common land in St George's Hill, Surrey and start cultivating it. The historical background of these events was accompanied by the already on-going enclosure in England which minimized common pastures and woodlands that used to be available to all manorial tenants under the open-field system (Gurney, 2015). Other historic events of the same period included the English Civil War (1642-1651), the overthrow of the English monarchy with the execution of Charles I., and the following takeover of Oliver Cromwell (1653-1658). At the time cultivation of common land was comparable to today's squatting culture. It was a strong political statement but also a solution to an urgent necessity. The same period was marked by a famine in Northern England in 1649, and generally, food and wool production were regarded as very profitable enterprises at the time. The home on the other hand was by far not understood as something valuable. Apart from a rather wealthy urban segment of the population, it served purely utilitarian functions. Perhaps this is also the reason for the limited historical material on the architecture of the colony. John Gurney offers a brief description: "they have built them some few little hutches like calf-cribs, and there they lie anights, and follow their work adayes still with wonderful joy of heart" (Gurney, 2015, p.73). Those lines depict an agglomeration of small-scale agrarian buildings scattered through the wood. The built structures are used only as collective bedrooms and the rest is defined by the spatial condition of the landscape. The common land, which is also the site of the production of the common in this case, is also reflected in the architectural language. Borrowing the architectural vocabulary of the site of production of the common, "little hutches like calf-cribs" affirms the insignificance of the home. One could even argue that the home was inserted in the predominant condition of the common.

The Communal House of the Textile Institute in Moscow on the other hand suggests the reverse case by attempting to reproduce the common in the home. In fact, a very particular kind of common. The building dates back to 1931, a time in Soviet Russia when housing was particularly involved with reinventing the "byt" or the everyday life of the Soviet citizen (Trotskii, 1973). This political project was truly important to the extent of the state relaxing banks borrowing policies in 1929 for housing projects that addressed the question (Crawford, 2015). The common here was used to support a certain political project through architectural form. Similar to the Diggers the architectural language was borrowed from the site of collective production - the factory. But this time it was inserted into a new housing typology, one where the private spaces were minimized to "sleeping cabins", completely identical and efficiently stacked together. In that sense the Communal House of the Textile Institute has succeeded in inserting the common, in this case an externally constructed one, in the home. As Christina Crawford (2015) points out there was no place for a mid-scale familial gathering, the choice was between the individual and the "ideological family". This managerial way of dealing with domesticity had a very strong sense how architectural form could be engrained in the domestic condition and have behavioral consequences, essentially formalizing a political ideology through spatial arrangement.

The Oneida Community was founded by John Humphrey Noyes in 1848 in Oneida, New York. The specific historical context included the American Independence and the Civil War. This was a time of exploration, prospecting dreams and the utopias of Robert Owen and Charles Fourier. Having initially originated as a religious community, the Oneida were very skeptical towards both private property and marriage. They advocated for common ownership and polyamorous relationships. Their ideology

was strongly expressed in their “architecture of the complex marriage” as Dolores Hayden (1976) refers to it. The space was very carefully orchestrated especially in relation to the production and sustenance of the common. The Oneida believed in having designated spaces for specific uses (Hayden, 1976). Here too the private bedrooms were as small as possible in order to encourage social interaction. At the same time private space was superseded by Oneida’s “Victorian Sexual Revolution” as described by Hayden (1976, p.187). Besides being minimized physically the very essence of privacy was ruled out. Additionally, mid-sized living spaces were scattered along the corridors between the bedrooms to both surveil and encourage interaction. Those spaces had a function to police and sustain the community’s behavioral protocols. And finally, there were the large-scale gathering rooms, where the communards could enjoy the community’s company and the common was consumed in social terms. Those different scales of architectural interventions related to the common in different ways and constituted together an intricate strategy between space and social code. In that sense one could argue that there was a complete correspondence between the common and the home. The common has managed to permeate every aspect of the domestic and was strongly expressed in space.

The historical overview will conclude with a housing project by the Kalkbreite cooperative in Zurich. Having originated from various squats during the city’s real estate bubble in the 1990s cooperatives developed an efficient strategy to counteract real estate speculation. This happened at the time of a state-driven relaxation of the interests rates from banks allowing for cooperatives to kick-off housing projects all over the city. According to the new cooperative ownership model units were not owned in traditional sense but corresponded to shares which the members could acquire. The shareholders were paying back the loan through their rent which, independently from market prices, would go lower once the initial construction costs have been repaid (Bridger, 2016). This alternative housing micro-market is reflected in the architectural diversity of the unit mix in Kalkbreite’s project Zollhaus. The building offers great variety of flats from a studio to a 8-person unit and even some completely open floor plan units, free for the residents to spatially equip them as needed. The specific housing units are self-contained and private and there are designated large-scale gathering spaces in the building. Zollhaus has managed to counteract the market dysfunctionalities by collectively engaging in the conception and delivery of the physical space of the home. Unlike any other cases, here one can see a common which is the very subject of the commons. At the same time the common-home relationship is facilitated by the cooperative which leads us to today’s sharing practices.

The historical examples described above provide evidence that stranger-sharing is not really new. In fact, it has often been related to a socio-economically driven collective response. If the steep increase in housing prices of the past few decades has indeed led to the emergence of a new subjectivity, the following contemporary accounts will investigate how this is actualized spatially in today’s sharing economy.

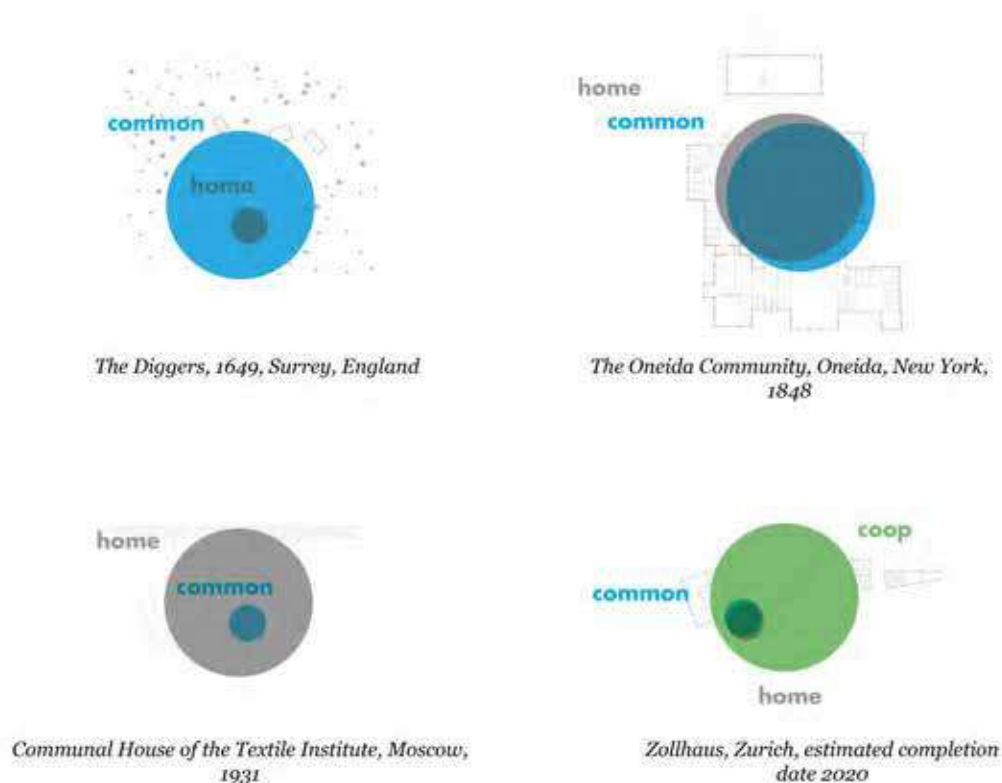

Figure 3 Common-Home Relationships in Stranger-shared Housing

Today's Home Sharing

One could perhaps draw a comparison between today's sharing practices and the pursuit of the "byt" in Soviet Russia, as the common has been conceived and managed outside the community - by the platform. How exactly does this impact the architecture?

Preliminary study in the form of online listing analysis is to explore this question further. Airbnb distinguishes between four "home types": entire place, private room, hotel room, shared room. From that one could assume that there are two different types of space occupation – parallel, when there is actual co-habitation in the same unit of guest and host, and non-parallel, when the host and guest are there at different times. The following study is going to focus on the "shared room" category, as these would be the type of listings where negotiation would be most present. The selected listings were acquired from a publicly accessible dataset of Airbnb listings provided by OpenDataSoft (<https://publi.opendatasoft.com/explore/dataset/airbnb-listings>).

Figure 4 Built vs. Shared Space – Airbnb Shared Room Listings

If one takes a closer look at those spaces, one can see that the room outline doesn't change much. What is regulating the negotiation of space is the arrangement of the furniture. The fact that the architectural envelope has been rendered absolutely obsolete, and that furniture is the main representational medium, asserts the assumption that perhaps the sharing economy was not only a result of an economic crisis but of an architectural one too. In a time when housing is treated and traded as a valuable asset, the domestic interior is the only artefact where one can trace the agency of the inhabitants. In this scenario the architectural elements constituting the typology such as walls and thresholds are almost too precious for any interventions.

A closer reading of online listings reveals various strategic uses of furniture such as surplus, scarcity, affect, utility, presence. In some of those cases the furniture is there not only to negotiate shared space but to overcome a spatial issue too like surplus or scarcity.

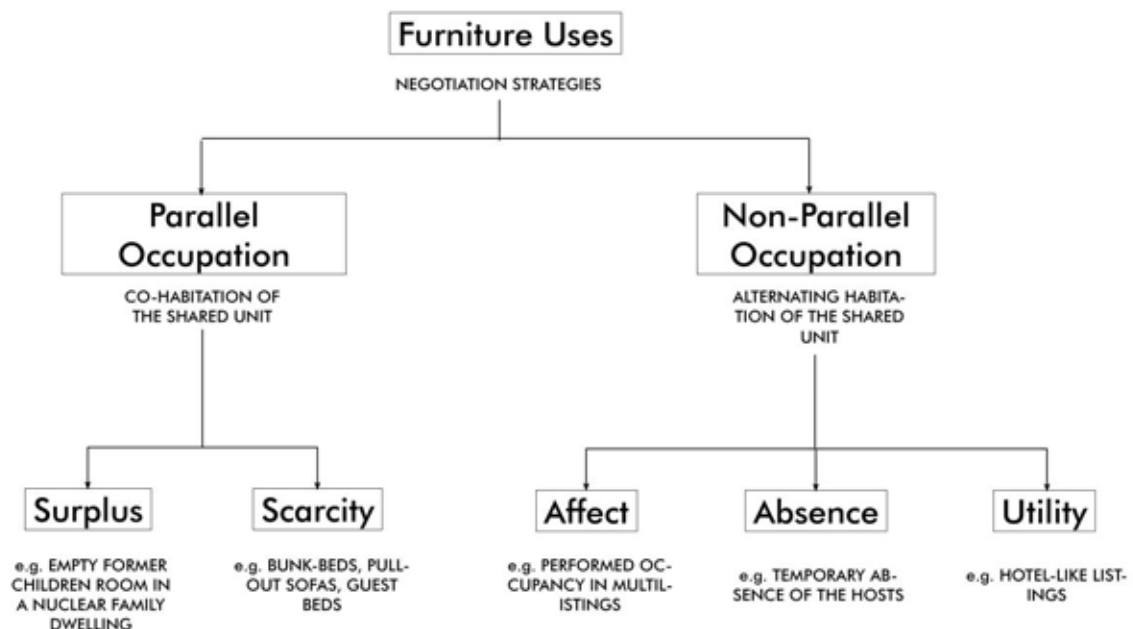

Figure 5 Sharing Negotiation Strategies Through Furniture

In a moment when housing has become so valuable, furniture is deployed not only to negotiate space with other people but also to negotiate space with a conflicting architectural design.

Conclusions

Sharing has indeed proven to have destructive effects on the accessibility of housing (Slee, 2017; Wachsmuth and Weisler, 2018) but it hasn't always been that way. Sharing economies have historically existed in other forms and successfully managed not only *not* to exacerbate market speculation but to counteract it. Without underestimating the sharing economy's negative effects, the pressures of the dysfunctional platforms and market could act as the common ground for new housing concepts to emerge. These new models could, similar to the Swiss cooperatives, have the potential to counteract market failures and create alternative economies.

There is a new generation of platforms which, having witnessed the dysfunctionalities of the existing models, has other aspirations. Notions such as networked home ownership (Doma, Strelka Institute), diverse economic transactions (Nookzy), or platform cyber currencies (Bee Token) address the question of value and how it can be retained within the community. It is perhaps simply a matter of time for those new alternatives to gain wider popularity and reclaim the otherwise conflicted practice.

Spontaneous Living Spaces – Dwellings and Settlements in Pemba (Mozambique)

A typo-morphological analysis in changing urban environments

Corinna Del Bianco¹

¹ *Director Istituto Internazionale Life Beyond Tourism,*
corinnadelbianco@lifebeyondtourism.org

PhD Politecnico di Milano, corinna.delbianco@polimi.it

Abstract: Self-construction determines large parts of the urban landscape of cities in developing countries. Self-built houses born from need, haste and limited economical resources, with formal or informal methods, are often conceived as temporary when built but then become constituent parts of the urban fabric. Loosing the character of temporariness, it becomes necessary to consider them as an integral part of the city. This research is aimed at mapping the “spontaneous living spaces” of changing urban environments, in terms of dimensions, inhabitants, used technologies, etc. identifying a stage of development and analysing the characteristics of contemporary living in contexts not designed by professionals. The results produced by this research experience can be useful for the development of policies and projects respectful of local, contemporary ways of living. Up to 2019, the research has analysed three case studies: the favela Guapira II in Sao Paulo, Brazil (2012); Pok Fu Lam neighbourhood, Hong Kong (2013) and four selected neighbourhoods in Pemba, Mozambique (2016-2018). Focusing on the evolution of architectural and urban elements that characterize self-built urbanization in Pemba (Mozambique), this paper illustrates the main evolution lines that define the relationship among the house, the city and the main settlement trends, addressing how traditional self-built architecture is evolving and creating new forms of living within the city. Architectural and urban categories, as conceived in the western tradition, such as formal/informal or planned/unplanned are not applicable in developing contexts. Thanks to a typo-morphological on-site survey on, and analysis of, 50 houses in four selected neighbourhoods, this research gives its contribution to a critical understanding of their role, creating a more conscious background on living systems in Pemba. The analysis was integrated with schemes, architectural drawings, photographs, videos and interviews to the inhabitants.

Keywords: Development, Self-built architecture, Typo-morphological survey, Pemba (Mozambique), Sub-Saharan Africa, Living Spaces

Introduction

World population is increasing and cities are exponentially growing, especially in those countries that are now facing the industrialization process. Trends report that by 2100 the 70% of people will live in cities. If these trends will verify the world will have to face new dynamics of urbanization. Self-built houses constitute the main part of the urban landscape in developing countries. Their relevance requires a deep analysis of the present typologies and the comprehension of the characters of variance and permanence from the traditional living typology. Furthermore, globalization is influencing the living typology in terms of city investments, new economies (such as tourism) and architectural functions, elements and materials. Therefore, the research recognizes the importance of self-built architecture within the urban fabric analysing the houses linkage with the street and the city dynamics, looking at the urban morphology and typologies in their bottom up and top down implementations. Understanding different cultures is becoming crucial for a deeper comprehension of cultural diversity and *home* is a concept intrinsically connected to the culture of living, connecting the private to the social life. Self-built settlements are the spontaneous answer to the spatial need of home and represent an important expression of the local culture of living. In most of the cases, the number of people moving towards cities and the speed of this phenomenon are so high that the municipalities cannot really control it. This leads to several problematics among which is housing. New urban residents answer to the housing need with self-construction, and often, coming from the countryside, import rural typologies into the urban fabric¹. The challenge of this research is to create a transversal knowledge of different cultures' way of living contributing to the cultural mapping (Pillai, 2013) of the nowadays-moving society. The research proposes tools and methodologies to:

1. contribute to the mapping of the contemporary cultural landscape;
2. increase the awareness on local cultural diversity, therefore, contribute to intercultural dialogue;
3. contribute to the cities' management in the transformation processes;
4. create the basis for the understanding of the living landscape of places (UNESCO, 2011);
5. inform designers and planners with preliminary studies on local contemporary spontaneous living.

Within this framework, since 2012, the research selected three case studies, belonging to the tropical climatic zone, in which the phenomenon was relevant. The first case study analysed a block in the *favela* Guapira II, within the area called *Jardim Filhos da Terra*², in 2013 the second case study took place in *Pok Fu Lam*, a traditional Hong Kong neighbourhood, then from 2015 the study focussed on the Mozambican coastal city of Pemba, with the survey of four selected city neighbourhoods³.

The research tries not to use the terms formal/informal, planned/unplanned as often are not fitting the contexts that have completely different interpretative categories, both one case study from the other and

¹ It is not an exception to see that self-built houses have some rural materials, characters and functions, such as hen houses, kitchen gardens etc.

² The research found its origins in 2011 during the work at Stefano Boeri Architetti for the exhibition *São Paulo Calling*, and concluded in 2013 with the author's master thesis awarded *cum laude* at the Politecnico di Milano, supervisor Stefano Boeri and co-supervisor Pier Paolo Tamburelli. The research was then published by Pacini Editore in 2014 with the name *Jardim Filhos da Terra*.

³ The case study represented the PhD research carried out at the Politecnico di Milano, Dipartimento di Architettura e Studi Urbani, supervisor Michele Ugolini and co-supervisor Michael Turner. The PhD was concluded *cum laude* in December 2018.

also from the western concept, as often there is a contamination between what is planned and what is not and what is formal and what is informal and both the categories could be used. In order to expand the point of view on the topic, in this paper the author tries to avoid these categorizations.

Figure 1 location of the three case studies developed since 2012 and located in between the tropics

Methodology

Climatic and environmental conditions are crucial in the designing of the house and neighbourhood and also in the way of living in them. Therefore, the research carried out three case studies that belong to the tropical climatic zone: Sao Paulo (Brazil), Hong Kong (China), Pemba (Mozambique). The tropical zone was chosen as it allows a quite *easy* relationship between the human and the environment⁴. Further indicators for the choice of the study cases were

1. the economic growth of the country (GDP),
2. the size of the city,
3. the speed of growth of the city.

The studied typologies of spontaneous domiciles differ consistently and highlight the different cultures of living.

⁴ The geographic zone is characterized by mainly two seasons (the humid and the dry one) with temperatures never severe and with days and night length of around 12 hours along the whole year.

In this research the survey of spaces and functions and the analysis of the houses, couples with a wider analysis of socio-economic factors, developed through a participant-observational approach, that is considered crucial instrument for mapping spontaneous cultures of living and providing guidance for policies in urban planning and for the architectural and urban design.

From the survey methodological point of view, the main references are related to the typo-morphological schools of urban and architectural analysis, both the Italian school, with Muratori's studies on Venice (Muratori, 1960) and the British school, with Conzen's work in Alnwick (Conzen, 2012). Other relevant surveys taken into account are those of Simounet in the *bidonvilles* of Algeri, the inquiry *Inquérito à Arquitectura Regional Portuguesa* on Portuguese popular architectural elements (AAP, 1988) and the studies of Bernard Rudofsky on architecture without architects. The architectural method is integrated with anthropological tools of analysis, pictures and videos to represent the diversity of cultures within the city with a synoptic picture even if with the consciousness that, as Lévi-Strauss affirms, no culture is capable of giving a true judgement on another one, and that it is only possible to give a representation of them (Lévi-Strauss, 2017).

Being aware of the complexity of the urban organism, the research tries to represent it with an analysis that is integrating the study on the urban morphology and houses typologies, with various scales of detail⁵ and various tools⁶. Furthermore, the analysis is integrating the historical reconstruction of houses and settlements development through historical maps.

Finally, in this research the interaction with the local community is crucial, as there is the need of creating a relationship of trust in order to interview the inhabitants and builders and let them open their doors to the author in order to survey the spaces and functions of their houses and the neighbourhood's dynamics. According to the context different strategies were used to get in touch with locals⁷.

Research Goals

The research is based on the idea that in order to work in developing contexts it is necessary to use context specific categories, therefore, the western categories and intervention methodologies whether should not be used or should be adapted. For this reason the research, in the framework of the *New Urban Agenda – Quito Declaration on Sustainable Cities and Human Settlements for All* – and of the *Sustainable Development Goals*, is aimed at giving its contribution to the comprehension of the urban issues related to self-built dwellings and settlements through:

1. acknowledging that popular self-built houses are a consistent part of the urban fabric of most of the changing urban environments and constitute their city landscape;

⁵ From the regional framework at various scales (1), the territorial analysis usually at the scale of 1:5000 – looking at the selected layers that create the city, such as the main streets, secondary streets, street fronts (2), the neighbourhoods analysis at 1:1000 – through the layers: green, voids/built-up, infrastructures, public/private property, community functions - (3), the blocks survey analysis at the scale of 1:500, looking at the relationships between public and private and open and closed spaces and the connection elements among them (4), the houses spaces and functions at 1:200 (5) and the photographic survey of the elements and objects within the houses (6).

⁶ Used tools, beside the traditional architectural maps and drawings, were geolocalized pictures and tracks, videos, pictures, sketches and interviews to inhabitants.

⁷ Contacting the community leaders, the Municipality, the local associations or schools.

2. studying self-built houses, linking the house to the street and city dynamics and recording urban morphology and typologies in order to recreate the bottom up and top down implementations;
3. giving to self-built architecture the dignity of being studied as any other part of the city. Therefore, to acknowledge the cultural value of self-built urbanization and architecture;
4. address challenges for alternative solutions taking into account the spatial, social, economic and environmental factors.

The results of this research will enable planners and designers operating in the analysed contexts, or in similar urban environments, new tools to comprehend the city development and therefore, to design in respect of the local urban and architectural identity in order to preserve the diversity of its cultural expressions.

Furthermore, the research could give its contribution to Municipalities, GOs and NGOs working on site, in particular the research would be useful for the improvement of living conditions and building techniques and would encourage sustainable forms of tourism and increase the awareness of the relevance of traditional constructive methods and the preservation of the urban and cultural landscape.

Three case studies

Up to today three case studies were developed, belonging to three continents (South America, Africa and Asia) and the *atlas* is still under development. Comparing them, they have similar contexts in terms of economic resources and weather, with heavy seasonal rains and droughts, but cultural differences are highly differentiating living spaces and residential neighbourhoods.

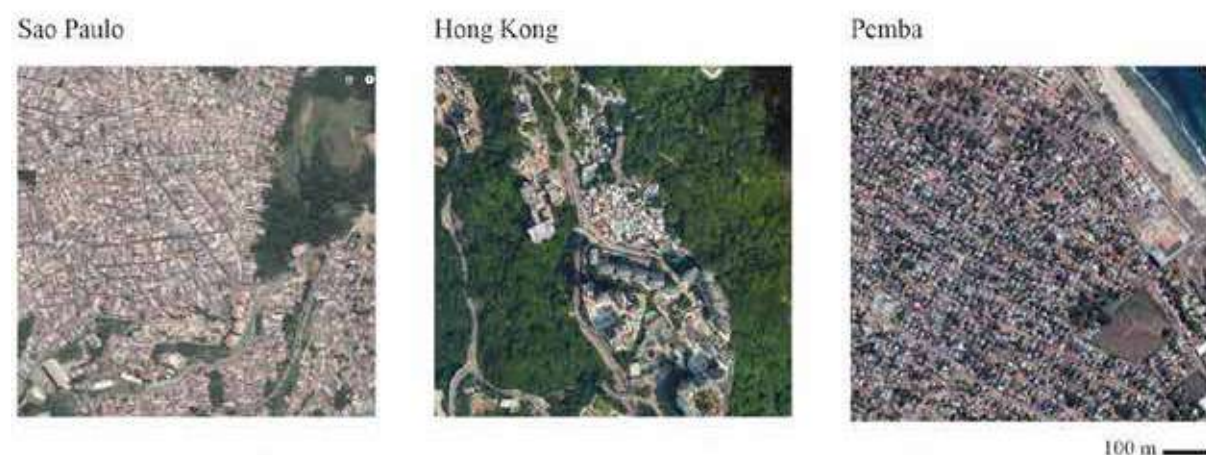

Figure 2 the three case studies: from the left the neighbourhoods of Guapira II in Sao Paulo, Pok Fu Lam in Hong Kong and Natite in Pemba. Image Google Maps 2019.

The first case study that has been developed is the one of *Jardim Filhos da Terra*, an area in the northern region of Sao Paulo where the *favela* Guapira II, born at the end of the 90s is located. The “*favela* phenomenon” in São Paulo started at the beginning of the 70s, when the city began its economic growth, and summoned labour forces from all over the country without having the tools or the time to provide

sufficient housing to all. This phenomenon became extremely critical in the mid 80s and continues to be so⁸: the city is now dealing with the problem of regularization of urban housing and it is solving the most high-risk situations. Since 2000, a new middle class is emerging and an important number of its representatives is living in *favelas*.

From a social point of view, *favelas* usually have a strong community life that is conducted in houses, bars, commercial activities, streets and community centres. From a technical point of view, beyond the lack of transportation and sanitation, residents live in highly precarious conditions since houses are often without stable foundations, ventilation and basic infrastructures.

The development of the surveyed area was carried out all at once by a group of people that acted all together, and that divided the block between Boa Vista, Planalto and Davi street, in regular and equal plots which are still recognizable by shape. Here 68 plots were surveyed.

Looking at the *favelas* constructions around the city of São Paulo, it may be observed that there is quite a diffused typology. São Paulo is a city with a harsh topography that exposes the area to landslide risks, and the predominant typology has adapted to it. Houses are gradually built upwards in rectangular plots, by using several construction materials available: reinforced masonry, concrete blocks, metal sheets etc. A multi storey typology is the prevailing in the area with two to four floors⁹. The stairs, a key feature because of the topography, are usually semi private spaces, closed by a door or a gate (with or without a key or locker), for ventilation purposes they are partly or completely open at the roof level. The sensation when entering the staircase is of disorder and noise, caused by the overlapping functions of this area. Although one can experience a sense of comfort from the dwellings, the space usually is insufficient in size for the number of occupants. The stairs distribute the floors and, if separated, the apartments. In facts, the property on each plot can be either for a single family or for multiple families. Each apartment is usually made of two to four bedrooms, one to two bathrooms (with at least one shower but never bathtubs), a kitchen, a living room and in most of the cases a garage at the street level. Each apartment is around 65 square meters.

Houses are rapidly built by the inhabitants and can be improved by the addition of several upper floors, according to the the family's needs. People build them during weekends and holidays and the materials and the workforce are provided both by the family and by the *mutirões*¹⁰.

The finishing is usually very rough even if sometimes plaster is used on the cladding. Technical equipment is usually positioned outside the walls and pavements are usually finished in concrete.

Home is a place open to everybody, with non exclusive bedrooms usage, it is a place for family and friends and the only place for being alone is the bathroom. Bathrooms are also generally very big spaces with good quality finishing. Invariably most showers do not have a base, though the floor is tiled. On the whole, each family member makes an intensive use of it taking around two showers per day. Courtyards represent the entrance to the houses and are used both for leisure activities and services.

⁸ Sao Paolo has 11 million inhabitants in its micro-metropolitan region. In this area, the Municipality counts more than 5100 informal settlements. This informality includes a variety of settlements among which the *favelas*, the *loteamentos*, the *cortiços*, the *nucleos urbanizados* and the *conjuntos habitacionais*.

⁹ In the surveyed area of Guapira II, it was possible to identify three types of housing: the most diffused is the multi storey house, then is the one consisting of one floor, finally is the wooden hut.

¹⁰ Neighbourhood solidarity groups.

They usually follow the longitudinal axis, and as they incorporate various functions tend to be very large.

In terms of public space, at the neighbourhood scale, the only present and respected is the street space that is used for various neighbourhood activities. As a consequence, there is a generalized lack of “breath” in the urban fabric.

Figure 3 one of the houses of Guapira II in 2012. Drawing by the author.

Figure 4 the street front of one of the houses of Guapira II. Photograph by the author.

Three case studies

Shifting to Asia, in Hong Kong, due to the density of the city, often the “traditional” informality phenomenon develops in rooftop communities (Canham and Wu, 2015) but this is not the case of *Pok Fu Lam*, an ancient and unique neighbourhood in Hong Kong, one of the very few historical neighbourhoods and with low-density buildings left in the city. The first residents got to the *Pok Fu Lam* area in the 1660s but it is in the 1810s that the first descriptions of the neighbourhood are findable. In between the 60s and the 80s of the 19th century, because of the British colonization, the village, went through changes especially concerning building typologies and infrastructures. In these years the area turned from a rural area to a composition of commercial, residential and agricultural compound. After the end of the Second World War the important migration from China to Hong Kong increased the neighbourhood population from 20 to 100 families.

As in the 1980s Hong Kong economy rapidly grew, as multinational, globalized commercial activities and population increased¹¹ so land price. The population kept increasing until the 2000s

¹¹ The population increased from 76900 people in 1981 to 84500 people in 1985 (ref. Record from town planning notes – Outline Zoning Plan No.: S/H10/1, February 28 1998)

when the population had a small decrease¹². High rise residential development started spreading around the neighbourhood (for example the nearby Chi Fu Garden). Up to 2006 redevelopment works were carried out but villagers still did not have a title guaranteeing them the right to live in those houses. Therefore, people were not improving their houses and the village was rapidly becoming a slum. With the title clarification in 2006, a boom in building started: in one year from 20 to 30 houses were rebuilt and mainly the typology increased both in section and plan as floors were added and the front was extended. This boom created a rapid and uncontrolled rebuilding process. After this first boom, in the middle of 2007, the land department made rectification orders with restrictions in height and in the use of rooftops¹³. For the purpose of this research in *Pok Fu Lam* ten houses were surveyed.

As Benjamin Sin Chiu Hang said in the interviews: “The area was an area of pig houses belonging to the *Hakka* main residential buildings (18 units) in the Wai Chai. As pigs were very valuable they were having the safest and therefore highest place in the village. The area is well repaired in case of typhoons, storms and landslide. These houses have an average of 100 years. Of course this is the age of the original ground floor level. Then the addition of further floors was starting during the 50s’ and the 60s’. In 1960 the British Communities developed the community to involve people in the social community life, to facilitate people to get together and improve their life quality by themselves and not by the government. The plots’ shape was so regular because land was partitioned by the owners of the *Hakka* houses for the pig houses. Within the village a company established within the community does the maintenance works. In 5 years the sewage system should be built. There are threats after the village because of the value of Hong Kong land. People stand up to be able to stay there but the Government power is very strong, CARITAS gives a help.”

Entering in Pok Fu Lam the visitor has the perception of entering in a private, closed neighbourhood. The use of the streets and alleys, mainly pietonal and characterized by small steps going up and down the hill, is semi private. Often sinks are located along the alley, and with sinks also toothbrushes, kitchen pots and dishes and other private objects and often residents wash their face and hair in these sinks or in buckets along the alley. Furthermore, as residents take off their shoes in the house, usually these are tidily left in front of the door along the street.

Here the prevailing house typology is usually made of two parts: the “wet part” (kitchen and bathroom) and the “dry part” (living room and bedroom), here these two parts are often separated by the street on which two doors stand on the two sides of the alley, one for the wet and one for the dry part. While the wet part is one floor high, the dry part of the house can be of two or three floors and adapt to the topography of the area, especially on those plots that have a transversal double entrance. Staircases or just few steps distribute the multiple floors present inside the houses, which are mainly built in concrete blocks or in PVC sheets, and roof is usually in PVC sheets.

In this context the conception of public and private space is very different, the public space also includes neighbourhoods gardens, spaces where to sit and where private chairs are left all time long.

¹² From 86000 inhabitants in 1998 to 81900 in 2001.

¹³ The information comes from Benjamin Sin Chiu Hang, team leader of the Community Development Service, Caritas Pokfulam Community Development Project, interviewed in September 2013.

Public and private deeply interact and contaminate one each other with their functions and the community life is highly affected as it is more difficult to be accepted but once physically entered the neighbourhood you are part of a community.

Pemba is a coastal city in the northern region of Cabo Delgado in Mozambique. Being located on a natural bay it was born as a harbour during the Swahili time and kept its vocation during the Portuguese colonization and up to today.

Here four neighbourhoods were selected for the analysis: Alto Gingone, Paquitequete, Chuiba and Natite. In these four 56 houses were surveyed. These neighbourhoods have different morphological and architectural features as they represent the popular living in different periods of the city expansion.

In terms of age of the settlement the first one is Paquitequete, belonging to the pre-colonial period, then Natite represents the colonial settlement, the independence period generated the neighbourhood of Alto Gingone and Chuiba represents the actual expansion¹⁴.

The four neighbourhoods have similar topographic conditions. The geographical homogeneity of the settlements was crucial to allow the comparative analysis of the house typologies, therefore, all the areas are settled on a plane area of Pemba and even though all the neighbourhoods are close to the coastline, Paquitequete, Natite and Chuiba are directly facing the sea.

The selection of the neighbourhoods also took into account the feasibility and safety of the survey operations, the disposability of community leaders to participate in the research and to create the connection with the local inhabitants. According to the statistics, Pemba is a safe environment, however the main threats documented by the *Plano de Desenvolvimento Municipal 2014-2018* (PEDM) are corruption, malaria and cholera. Generally, the population is open to dialogue with foreigners, however,

¹⁴ Paquitequete <1857, Natite 1934-1960, Alto Gingone 1960-1975, Chuiba 2000<.

the delicacy of the survey, asking people to enter in their private space and to collect information on it, needed to be introduced and prepared by locals¹⁵.

Furthermore, the choice of the neighbourhoods took into account the number and ethnicity of people living in it¹⁶. In spite of the homogeneity in the number of people, all the areas differ significantly in terms of ethnic provenance. In fact, Mozambique hosts a plurality of ethnicities and Pemba is well representing this mixture. The main ethnic groups in the four neighbourhoods are the Mwani, Macua and Maconde¹⁷.

Figure 8 prevailing ethnic groups per neighbourhood. Photographs by the author.

The house typology of Alto Gingone neighbourhood is findable in all the city neighbourhoods, and its presence is due to the fact that people have the competences for self-building it and its general construction rules are clear and diffused. Furthermore, people recognize themselves in the life-style generated by this typology, being part of their cultural identity.

Here, the house is conceived as a sequence of open and covered spaces within the plot. In most of the neighbourhoods the plot is delimited by a physical boundary that increases in thickness and material durability as the density of the area increases. The prevailing materials used for the boundaries are bamboo sticks, interlaced or simply aligned and fixed together to wooden bars with nails and cement blocks. The constructions within the courtyards are at least two: the main building and the hygienic services, such as bathroom and latrine. The main building is usually made of a wooden structure, often simply leaning on the sand or in other cases on a concrete slab of about 10 cm thick. Walls, internal and

¹⁵ The only neighbourhood in which several inhabitants refused to be part of the research was Natite, a neighbourhood that is very diversified in terms of ethnic groups, and that is a commercial area where usually foreigners pass through and in which the sense of community is not as strong as in the others. In that case some plots were not surveyed and are reported as “not surveyable” in the integrated analysis.

¹⁶ Concerning the number of inhabitants, just Chuiba differs, with a number between 4,000 and 9,000 people, while the other three neighbourhoods host between 9,000 and 22,000 people.

¹⁷ Mwani, Arab provenance, mainly of Islamic religion. Historically they were considered servants and submitted. This ethnic group was always devoted to fishing and commercial activities. Paquitequete hosts a big community of Mwani people; however, they are living also in the other neighbourhoods in family cells. Macua, is an African tribe, believing mainly in Islamic and African beliefs. Groups of these people can be found in Natite, Alto Gingone and Chuiba. This is a gentle population living in respect with nature. Both women and men wear a beauty white mask made from wood. Their society is traditionally patrilinear. Maconde, is an African tribe, they were the warriors who fought for the independence of Mozambique. Their people usually had their faces covered with tattoos, a tradition that is being lost by the latest generations. Maconde speak ChiMakonde (or Makonde language) that has Bantu origins. Their society is traditionally matrilinear. Traditionally they believe in animistic beliefs, even though many of them are now Catholic or Muslim. They are famous for their artworks in carved blackwood. In Pemba they live mainly in Alto Gingone and Natite.

external, are usually made in *pau à pique*: a local constructive technique in which two layers of bamboo sticks are filled with stones and mud. Vertical finishing is often absent and if it is present it is in *matope* (Swahili word for mud) that can be of different colours, from light brown to red. The roof is made of a wooden structure and covered in vegetal materials or in metal sheets.

Regarding the functions and their distribution within the house, the main building is used for sleeping, resting and for storage. The interiors of the building are usually distributed by a central corridor that is linking one entrance to the symmetrical one, and it is distributing four rooms of similar dimensions, two on one side and two on the other. One of these rooms, usually the one facing the street side, is used as living room, the others are used as bedrooms. The other always-present construction within the yard, is hosting the hygienic functions of bathroom and latrine. This construction is made to be moved within the yard, as there is no sewage system, therefore it is considered temporary and it is located in the furthest point from the house, on the back side of the yard. Its surrounding walls are or in bamboo, or in plastic materials, or in fabric. Often, they have no over-head covering. Waste of every type is usually buried or left at the edges of the neighbourhoods or buried in the courtyards. The courtyard is usually hosting vegetal elements, decorative and/or productive, such as a kitchen garden or fruit trees and in most cases a hen house. The type of paving inside the house embraces a wide range of varieties, from concrete with decorations, to concrete without decorations, to plastic coverings, to clean sand. Clean sand characterizes the flooring of all the surveyed courtyards, and this makes the distinction from the street paving that is usually in dirty sand. This distinction occurs also in those houses that do not have a physical plot boundary.

The openings often are obscured for privacy and security reasons. As a consequence, the interiors are usually dark and not properly ventilated. Windows can be voids within the wooden structure without obscuration or obscured by metal sheets or by fabrics. The artisanal window frames are always framed in wood and can be decorated and have a mosquito net. Doors are framed and delimited within the structure and are made of wood, industrial or handmade, or of iron. Usually the openings are symmetrical both on the street side and on the courtyard. Most of the elements of the houses are made of local materials, which make the houses environmentally friendly and cheaper. The insertion of industrial elements is today perceived as wealth recognition, but still the purchased elements, such as window or door frames, are often not properly employed (often used just as decorations or for symbolic and religious purposes). These elements are affecting the typology; today the main change is represented by PVC roofs, replacing the vegetal ones, often modify the whole structure and distribution of the house.

Among the architectural and spatial elements of the typology, two are the main ones that increase the quality of life, in its interior/exterior and public/private relationships: the courtyard and the veranda. The courtyards of the houses are empty spaces that are used for multiple purposes among which the family food production, mainly poultry and kitchen gardens. The courtyard, as it is conceived, creates the possibility of a green productive space that is a resource for families. The veranda is the architectural element that creates a powerful interaction between the public and the private space, increasing the quality of the streets through permeable street fronts. It is present in all the houses of Alto Gingone and it is deriving directly from the Swahili typology. The veranda stands on the two larger sides of the main building and it is used for several functions such as cooking, working and resting.

At the neighbourhood scale, the typology is easily aggregable and independent from the urban structure. Public space is present, respected and perceived as important by the community.

Figure 10 street front of a house in one Paquitequete neighbourhood. Photograph by the author.

Conclusions

Self-built houses are a powerful answer to the urbanization phenomenon in all the contexts as they represent the local culture of living and should be studied for the implementation of new local projects. They represent the social, economic, cultural background of a place, highlighting the intangible and tangible culture of living.

The morpho-typological surveys, accompanied by the study of the bibliographical sources, leads to context specific conclusions at the architecture and at the city scale.

Assuming the fact that some contexts cannot afford substantial public investments, it is important to plan a development that can use alternative resources such as the creativity of the local inhabitants and their productive and building capabilities.

In spite of the differences, the self-built houses of Sao Paulo, Hong Kong and Pemba represent a stage of the evolution of the local living typology mixing the rural and the urban one with a cross-fertilization process. The bottom up construction rises the possibility of improving them much easier providing information tools to the citizens, to improve their living quality.

The spontaneous characters of living relate to the local cultural identity and represent a strength for the local development and could innovate the existing urbanization models.

As Lévi-Strauss stresses, each culture has its own path of evolution inscribed in a peculiar system of criteria that determine the process (Lévi-Strauss, 2017).

It is precisely in contexts in which urbanization has not already verified, where there are no existing infrastructures of the industrial sector and where the urban culture is created almost *ex-novo*, from the rural culture, that a new concept of city can evolve and be developed.

Changing the spatial hierarchies through the implementation of the local self-built typology and enriching it with a diffuse production, the possibility of creating a new type of city is generated, in which the need of transportation, time of commuting and the related economy of scale change their meaning. A city in which the strict division between the urban and the rural does not occur and in which it is possible to get the advantages of a diffused production and of a process of urban forestry¹⁸. This would be possible only if it is intended as a natural evolution by the citizens, and this is a further reason why local typologies should be employed, so that their vernacular building knowledge is not lost.

The Jericho Gate Project: Planning Challenges and Political Struggles around a Megaproject in the Oldest City in the World

Mohammed Isayed

University of Sassari, m.isayed@studenti.uniss.it

Abstract: Starting from 1993, after decades of occupation and political conflicts, the Palestinians enjoy some form of local self-government in areas of the West Bank (areas "A"), through elected bodies like municipal councils and the National Government. Those young institutions that are in charge of urban planning, have to deal with a highly complicated set of challenges, with a very modest experience and a legacy of old and inadequate laws. In Jericho, a heritage-rich town in the Jordan Valley, the Palestinian company PADICO has recently proposed a leisure-oriented, multi-billionaire, 300 HA mega-project, called Jericho Gate (JG), including tourist and entertainment facilities, villas, hotels, resorts, a sports city, amusement and water parks, malls and other facilities. JG follows a national and regional trends of privately financed new cities that is common in the region (i.e. Rawabi), that are marketed as development and job creators, and as a tool to improve the living conditions of the Palestinians who are struggling for an independent and sovereign country. In this study we will explore and analyze how that project has been received by the different actors, in particular, the local and national government and the local public opinion, how it was presented to the population through the media and how it was debated and finally approved by the official bodies. Despite its glittering architectural envelop and its promise of economic development, the JG project arises a number of questions about the capacity of the local context to benefit from it. Will the municipality, weakened under the state of occupation, be able to handle the needs of the new temporary residents, given its modest resources and capabilities? Will this upper-class oriented project increase socio-spatial fragmentation between wealthy visitors and the local population?

Keywords: Mega Project, Conflict area, Planning challenges, Jericho- Palestine

Introduction

In the Jordan valley, almost in the lowest point, one can admire an Oasis in the desert, called “Jericho” the oldest city in the world, 8 km from the Dead Sea and from the “baptism site” in the Jordan river, 25 km from Jerusalem. It’s one of the Palestinian cities lying in area “A”, encompassing 20% of the Occupied Palestinian Territories, subdivided in Areas A, B and C based on the Oslo agreement between Palestinian and the Israeli. According to it, Palestinian can manage directly the civil and security issues in Area A. The municipal territory is surrounded by areas “C”, where the control of civil and security issues is in the Israeli hands. The area, as well as the Jordan Valley, has a very low population density due to the dry weather. Nowadays it has about 21107 inhabitants (PCBS¹, 2018), and it remains one of the few cities in area “A” that has unbuilt lands to be developed.

Starting from 1993, when the Oslo agreement was signed, and the hope of a final settlement of the Palestinian Israeli conflict was high, the economic situation of the Palestinian starts to improve. Since the 1990s, the real estate sector enjoyed an important growth, despite a slowdown during the difficult periods of the second intifada (2000-2005). After that, due in part to the high natural growth of population, the demand for new houses returned to be high. At the same time, because of limited available constructible land within area A, leading to a considerable increase of lands and houses prices, new kind of development appeared, such as the construction of entire neighborhoods and master planned cities like Rawabi, promoted by private sector investors². In the last decade, this new trend appeared in Jericho, notably in the form of the mega-project called “Jericho Gate” (JG), a 300 Ha new mixed-use development in the southern part of the city. Referred to as “a new integrated township”, by Mr Al-Sayed Ahmad, general manager of JG, in an interview on Arabian business, this large scale project will affect the economy and change the identity of the historical city. The city’s economy, primarily based on agriculture for centuries, is now possibly undertaking a transition to become a touristic city for leisure and entertainment, as the promoters of JG hope to attract more local and foreign tourists thanks to new cultural and commercial areas. Furthermore, the project boosts a large residential area of high-end second-homes addressing a clientele of Arabs coming from East Jerusalem and Israel.

This new project, completely market-driven by the private sector, are proceeding under a very weak planning system with enjoy a bad reputation as a tool of foreign ruling powers. Historically, The Palestinian Territory experienced successive occupations and was ruled by different authorities, such as the Ottoman, the British, the Jordanian and Egyptian and finally Israeli occupation that used the local planning as an instrument to control Palestinian urban development and to serve their colonial interests (Abed Alhamid, 2005). In fact, During the British Mandate (1920-48), "Master planning" approach was part of a British colonial policy aiming to control and

¹ Palestinian Central Bureau of Statistics

² Interview with Mr Issa Qassis, CEO of Palestine Mortgage and Housing Corporation on <http://www.alhayat-j.com/sooq/HayatWaSouq143.pdf>

restrict Palestinians development at the local level by issuing orders and laws that facilitated land confiscation while restricting Palestinian communities expansion and growth (Coon 1992, Khamaisi 1994). This situation continued during the Jordanian administration in the West Bank and the Egyptian administration in Gaza Strip. After 1967, the Israelis have continued to use the same planning laws and regulations, while modifying them to meet their own interests of land confiscation and control over Palestinian growth (Abed Alhadi, 1990; Coon, 1992; Khamaisi, 1994; MOLG, 2005). During all these periods, the planning system was considered a tool to confiscate Palestinian lands, to restrict development and a prelude to further expropriations and disposessions. Israel policy contributed to make it clear in the Palestinian mind that land use planning, land expropriations and settlements are three interlocking aspects of a global policy aimed at the Judaification of the territories occupied in the 1967 (Abdulhadi, 1990).

When the Palestinian national authority (PNA) took the control of civil matters on areas “A” and “B”, including the responsibility for urban planning, they inherited a system whose evolution has been greatly influenced by the previous Israeli military orders and regulations, as most of them remain applicable in the Palestinian territories (MOLG, 2005; Daoud, 2009). The planning approach and process remained centralized, not participatory, physical oriented only, with no consideration of community's developmental aspects. Thus planning efforts remained largely inefficient, time consuming and rigid, and considered as a problem rather than as a solution for most of the Palestinian cities and villages. Despite the adoption of the Physical Planning Manual in 2010 by the PNA, a new planning tool that introduces of the analysis of community needs in development and mandates some form of community participation, the new planning processes are still not consolidated and young³.

While the unprecedented scale and cost of JG may result in substantial social and economic transformations in Palestine and the historical city of Jericho, this development has not received scholarly attention to date. Most attention has been paid by local media: short articles have been published in newspapers and Palestinian TV has broadcast interviews with the developers and some stakeholders about JG. This paper aim to fill a gap in the literature on Palestine's new cities, by exploring the national ambitions manifested in the JG project, contextualizing it within the international new cities trend, and providing an overview and preliminary analysis of JG's detailed plan. We also critically examine challenges facing JG with regards to sustainability and relation with the local authorities, mainly the Jericho Municipality (JM). This paper draws on several sources for material including: JG's own promotional material, interviews and reports on different Palestinian Newspapers, official documents from the Palestinian Ministry of Local Government (MoLG) and the JM, personal interviews with JG officials and JM's staff directly involved in dealing with the project conducted in Jericho in the beginning of 2019, and documents and recommendation about JG issued during the preparation of the Jericho Master Plan⁴ of 2012-2014.

³ Interview with Tamara Erikat from Jericho Municipality in 2019).

⁴ Project funded by the Italian cooperation finalized to prepare a model of sustainable development through new Master Plan for the city of Jericho in collaboration with the university of Ferrara and JM in the period of 2012-2014.

Building to Communicate

Recent scholarship illustrates how cities are not only the medium by which the powerful express their influence, but they can also reveal the aspirations of the State and how it wishes to be seen by others (Vale 2008 [1992]). In this sense, a primary objective of many master planned cities is to construct, communicate, and normalize a particular sense of identity to the citizenry (Moser, 2012). This dynamics are already at play in another recent project in Palestine: Rawabi, a completely master planned city, the first of its kind in the West Bank. With this project, Palestinians are trying to express and send a message to the world: they are not only the bad and violent people depicted by international media, but they are also able to build modern cities and neighborhoods, improve themselves and be civilized⁵. As city building is a powerful vehicle for expressing ideology due to its highly visible and symbolic nature, the Palestinian government supports these types of economic activities and encourages them by facilitating the approval process and by providing some basic services, such as police and civil defense stations, health centers, etc.

Palestinians also construct houses to express their intention to remain in their lands and not to leave and immigrate despite the occupation, they use to do so constructing even along the cities edges far from the main infrastructures and services, this way of thinking or doing is leveraged by the developers to promote their projects saying that their efforts support the resistance against the occupation.

Building to protect vs Building to confiscate: Who build first?

The Israelis are continuing to construct housing units everywhere in areas “C” of the West Bank. From 1967 through 2017, over 200 Israeli settlements were established in the Palestinian Territories (including East Jerusalem) and their current population is almost 620,000 inhabitants (B’Tselem, 2019). Israeli settlements are visible as they surround the Palestinian cities and so are part of Palestinian’s everyday landscape, when passing by the main roads. This constant physical presence affects profoundly the Palestinian mentality, vehiculating the idea that Palestinians should build as much as possible to protect their lands from confiscation. This “rush to build first” is happening with no connection to real needs and without thinking into account minimum sustainable planning criteria. Thus, when developers are proposing such projects to the public opinion, it’s very difficult to oppose it on factual grounds or even to open an objective discussion about the real need, because of a diffused idea that building new houses means to save the land from confiscation. This message is strongly leveraged by promoters: talking about a real estate project in the Jericho governorate called ‘Moon City’, Eng. Munif Treash, CEO of the Ammar Group⁶, said that this type of projects aims to protect the Palestinian lands and to increase the population density in the Jordan valley area⁷.

⁵ Interview with the founder of Rawabi, Mr Bashar al Masri, 2015.

⁶ Amaar Group is Palestinian investment fund’s investment arm in real estate development, and was established in 2009 with a declared capital of 140 Million U.S. Dollars.

⁷ Interview on Alwatanvoice, 2014.

The approval Process

Planning of JG has been a lengthy and challenging process. Jericho's residents expressed concerns fearing that the project could come to somehow replace Jericho, serving as "a new city", that will feel like a new Dubai," as Hulileh⁸ puts it. The municipality and the Governorate, found it a big challenge to deal with such unprecedented large-scale project. In public meetings the promoter of JG, Padico, used spectacular and appealing ways to present the project, advertising it as a job creator, of capital importance for the national economy, and, of course, as a tool to protect land from Israeli confiscation. Most of the people attending these meetings were in favor of JG. In other meeting and political discussions, promoters stated that this project would increase the Palestinian population in Jordan Valley area, that because of its very low population density is threatened of be confiscated by Israeli to construct more settlements. Mohammed Abu Mohsen, director of the Finance department in the municipality, 2019, thinks that such project will create a real economic development in the city, bringing new residents from the middle and high class that will benefit local businesses, since they mostly come from outside the city. Others believe that the project will improve social cohesion among Palestinians, as different people from different part of Palestine will live close to each other, as was the case in Jericho for many years.

When the project was first proposed in 2011, the municipality was preparing a new master plan, the Jericho Master Plan (JMP) funded by the Italian cooperation, by a group of Italian and local planners in close collaboration with the Municipality and the ministry of local government (MoLG), which is responsible for approving and following the planning process. The leader of the JMP planning unit, Prof. Paolo Ceccarelli, expressed worries and perplexity about JG project. In fact, the area of JG was located outside the old Master plan, and the new master plan didn't envision to expand the city in the southern area where JG was proposed. Based on natural growth and the assessment of the actual situation, like population growth and available natural resources, primarily water, the JMP considered that there was no need for such a large expansion of the built-up area and that it was extremely difficult to guarantee its economic and environmental sustainability. Moreover, a high number of empty plots and tracts of lands inside and around the actual built-up are, accounting for about 1439 ha, were still available for infill development (JMP, 2014).

Despite the concern expressed by the JMP team, the approval process went forward with several meetings between the developer, the municipality and other stakeholders. Changes were made as the municipality asked to apply the standard building regulations mandated in the Palestinian cities, requested to allocate service areas for public use, and to avoid high density and multi-storied buildings. The detailed plan was approved by the municipality and, following the normal procedural steps through the regional committee, the supreme planning council, and a period of objection period, the project obtained the final approval on March 2015⁹.

⁹ Interview with Tamara Erikat from JM, 2019.

CHALLENGES AND SHORTCOMINGS OF A NEGOTIATED PLANNING PROCESS

JG Project: Exploration and Analysis (a flawed market background)

Figure 1: Entrance Design of the new neighborhood of JG as appeared on a Palestinian economic web site of Aliqtisadi. Source: http://www.aliqtisadi.ps/ar_page.php?id=15ad47by22729851Y15ad47b

The project is being led by Munib al-Masri's Palestinian conglomerate Padico Holding, and is aiming for a \$3 billion worth of investment by the time it is completed in 2024. It will encompass 300 Ha, 7% of the area of JM and almost the size of the existing built-up area of Jericho. When finished, it will have 1,500 villas, up to seven hotels, a water park, along with a shopping complex and a museum.

Figure 2: Location of Jericho Gate Project. Source: <http://www.jerichogate.com>

An early planning stages in 2011, Padico identified what they believed to be an important gap in the market for hotels, restaurants, and most importantly, attractions "if you want to stay there for a whole day" for short-time visitors. According to Hulileh, Jericho is visited annually by around 1

million Palestinian tourists, 1 million foreign tourists, as well as another 1.5 million crossing through to Jordan at Allenby Bridge; thus, "you need to entertain them, to take care of them."

JG is situated in the Southern part of the city, and it is advertised as strategically positioned only 50 Km from Amman, 25 Km from Jerusalem and 8 Km from Dead Sea, so theoretically located within a short car trip from large urban areas and main touristic attraction. In reality, as anyone who is familiar with this region knows, the main important travel factor here is the time and not distances, as travel time are highly uncertain because of fixed and "flying" check points, border controls and by pass roads that unpredictably affect movements time and freedom.

An unbalanced detailed planning negotiation

The detailed plan (DP) of the project was negotiated and approved by the different local, regional, national levels, after a process of meeting and adjustment characterized by external pressure by different actors in favor of the project. The approved plan comprise different land uses and some rules regarding the types of materials and shapes of buildings, all aiming at conserving a "high quality and modern" urban environment. The residential zoning is the larger one and represents 43.31% of the total area, followed by different uses like commercial, touristic and cultural. It is worth mentioning that the DP envisions the presence of 35400 m² of "aquatic elements", as this will be a big challenge for the developer given the water scarcity in the desert climate of Jericho.

Figure 3: Land uses Plan of JG, Source: JM

Figure 4: Different Land Uses of JG Project, Source: JM

All residential buildings can be no more than 3 floors high, while in the area zoned for tourist, commercial, cultural and entertainment purposes (around 26,77% of the total), 6 floors will be allowed. The exception is made the “Jericho Tower”, a multi-storied and multi-purposes iconic building (commercial, tourist and residential), that will represent the architectural identity of the project; with its 50m height, it will be by far the tallest in Jericho, a relatively horizontal city, well known in Palestinian imaginary as the cities of low heights buildings, and renewed worldwide as the “Oasis city”, with a spectacular landscape, where palms and trees cover buildings and look taller than them. The JG project is a major shift from this urban landscape.

There are also some aesthetic rules regarding the external appearance of buildings, such as the material to be used in residential buildings’ facades that have to be built from hollow blocks with plastering finishing. Nevertheless, this aesthetic became common in the area during the modern period, while the traditional construction technique in Jericho employed mud adobe and finishing. Unfortunately, the DP shows no interest in the use of mud construction techniques, which are the natural and original material used in the past in Jericho, Furthermore, any other types or material have to obtain previous approval by the owner (JG Company), other rules regarding water containers and Satellite dishes on top of houses, have to be covered and invisible.

During the preparation of JMP, Prof. Paolo Ceccarelli, in one of his letters to the mayor of Jericho, regarding some of the basic regulations for new large-scale residential estates in undeveloped areas, formulated some guidelines based on the need to adequately preserve the unique landscape of Jericho that constitutes one of its main attractions. The main concerns were regarding the height of the buildings, size of the parcels, open spaces and the adoption of sustainable architecture principles.

Analyzing the DP regulation, we can observe that JG project accepted completely or in part some of Ceccarelli's recommendations, while ignoring others (see the comparative table 1 below):

Table 1: Comparison between Detailed Plan of JG and Paolo Ceccarelli's recommendations

Criteria	DP of Jericho Gate	Paolo Ceccarelli's recommendations
Height of the buildings	3 floors for residential	Two floors
	6 floors for touristic and commercial	
	15 floors for Jericho Tower	
Size of the parcels	750 m ²	1,000 m ²
size of the buildings	Max 225 m ²	Max 200 m ²
floor space ratio	30%	20%
Building types	Not Traditional Villa with pool style	architectural tradition of the region
Building materials	traditionally used in the lower Jordan Valley	traditionally used in the lower Jordan Valley
Sustainable architecture		
Water recycling	The project will be connected to the treatment plant of JM	Must be
Water Saving	There are different water elements for tourist and houses like pools and aquatic games	Must be
Passive solar energy design	No rules, depend of the developers	Must be

Ununcertain phasing

A controversial aspect of the project is the implementation phases of the JG. To date, it is still uncertain which is the planned order, which parts of the project (housing, hotels, commercial facilities, etc...) will be implemented first and how long it will take to fully implement the project.

Figure 5: Under construction's roads. Source: <https://geomolg.ps> and: <http://www.jerichogate.com>

The high uncertainty of market demand and of the general political situation makes such predictions on the project time schedule very complicated. In the selected business model the JG main developer will only provide the main infrastructures while other developers will purchase the land and invest in the implementation of the different parts of the project. Few information have been provided by the JG company about the possible timing, apart from a generic three phases schedule as in figure 6. No agreement has been signed with official bodies engaging the company on an official phasing, and the planning law does not provide any guideline or restriction about that. In discussion I had about this issue with one of the employers of JG company, he confirmed that it depends totally on market demand and supply¹⁰.

Figure 6: Project's Phases. Source: <http://www.jerichogate.com>

Jericho Gate Project is envisaged to be developed over 10 years in three major phases as seen in figure 6. Phase one has already started and will expand until the end of 2018. Phase 2 will commence in 2019 through 2021. Phase three will commence in 2022 (Interview with Al-Sayed Ahmad from JG Project, 2016), based on the aforementioned information and the DP analysis, we can explore the contents of the three phases of the project as below:

Phase 1

Phase 1 will include the construction of the main infrastructures by the JG main company itself, the realization of the project core which includes a vast complex of hotels and villas centering around a plaza with artificial lakes, the eponymous “Jericho Gate”, a structure equal in size to

¹⁰ Interview with Omran Abu Sbeih, March 2019.

Paris' Arc de Triomphe (Hulileh, 2017), the aforementioned Jericho tower. Further touristic and aquatic areas, hotels and recreations will be implemented by other developers.

Phase 2

Phase 2 include the first residential area and other tourist and commercial zones. Once the residential area is completely built and inhabited, the total population will be of around 7600 inhabitants, (considering three floors and the media of family size 5.6 (PCBS, 2017)), almost the population of the Aqbet Jaber refugee camps, which is less than 1.5 km far. The head of license department in JM believes that the building typologies will be large villas, which means single-family houses with two floors (interview, 2019), this mean that the number of expected residents will reach a maximum of about 2600 residents.

Phase 3

Phase 3 is envisaged as completely residential area, including around 1500 plots where building up to three floors are allowed, so if full completed and inhabited it will potentially accommodate more than 25000 inhabitants (considering the media of family size 5.6 (PCBS, 2017)). This would mean duplicating the number of the city population with this phase alone. Even if larger single family dwelling are constructed, as is more probable, it can still accommodate up to 9000 residents.

Project progress

During a site visit made in March 2019, we observed works on infrastructures, like roads, water and waste water pipes and electrical/telecommunications cables are undergoing. Furthermore, villas construction in phase two has already started, while no construction for commercial or tourist purposes within phase one has yet commenced.

Since there is no external control on phasing implementation, the JG company is following markets request, so in reality implantation phases of DP are purely indicative and the administrative body of JG is changing it continuously, and so it is doing with the DP itself¹¹: some requests of changing are already being submitted to the municipality to emend the DP, requesting, for example, to reduce the water element due to the clear water scarcity or changing the number of hotels¹².

¹¹ Interview with Omran Sabaih from JG, March 2019

¹² Interview with Tamara Eriat from JM, March 2019.

Figure 7: Residential Villas construction in phase Two, Source: Mohammed Isayed, 2019

A mega Project without local agreement

Despite the formal planning process, the municipality of Jericho didn't reach any understanding with JG Company. Several meetings were held throughout the process, but without tangible results, and local request were regularly ignored or downplayed. For example, despite the municipality clearly stressed many times that it was not able to provide the needed services for the new population in JG, notably an adequate supply of drinking water, these concerns were outplayed, as the JG company assured that they were planning to supply the site with water from Mekarot¹³ and not the Jericho municipal network¹⁴. However, as no final deal or agreement have been signed with Mekarot, the municipality officials and council members fear that the municipality will be responsible for providing water and other basic services (as they are mandated by law) and that they can guarantee it only based on its availability. To protect itself, the municipality find itself forced to write it in a statement on "the site plan", an official document which the municipality issues when citizen request for a building licenses.

Moreover, as Municipality Licenses fees and other fees related to building constructions have already been paid by the JG Company, the municipality is in theory mandated by law to provide basic services. Unclear regulations and leave little leverage to the municipality to regulate a development that can potentially put a huge burden on local financial and natural scarce resources, that's why the municipality think an agreement is essential to clarify the obligations and rights of each parts for such mega project.

An alternative to the real Jericho and the worries of social segregation

"People do not like this word 'entertainment'," says Samir Hulileh (interview on Maan news, June 3, 2015) the project's chair and CEO of Padico. "They feel that it is contradicting what

¹³ Mekarot is the national water company of Israel and the country's top agency for water management.

¹⁴ Interview with Eng, Mohammed Fityani, head of water department in JM, 2019.

occupation is all about". But he adds: "There is no way that anyone can know when this conflict will end, and we believe it's a must that people should survive the conflict and survive the process until it ends. Survival does not mean that we just barely live."

About one million local visitors (Jericho SDIP¹⁵, 2018-2021) are coming to Jericho annually to enjoy the good weather in different tourist facilities (Hotels, restaurants, commercial buildings) so there is a risk that most of these tourists will be diverted to JG instead while leaving existing local businesses in the city center deserted. The new indications at the main entrance of Jericho are already tempting the visitors to go to the new development.

Figure 8: Street signage in the entrance of Jericho city in the southern part. Source Isayed, 2019.

Conclusions

JG is rising in a context where there is insufficient awareness and capacity, both on official and unofficial levels, to deal with the potential consequences of such a large development. This mega project, that can potentially transform in depth the identity and the landscape of a unique and historical city, has been handled through a very weak and immature planning system, with no obligations regarding the management of implementation, leading to continuous requests by the developer to amend the DP to adapt it to changes in market demand, with little capacity for the municipality to oppose profit-driven request of the developer. The case of JG shows in these market-driven urban mega projects, a totally new trend for Palestine, the government and the local authorities managed to play only a passive and minimal role in the decision-making process, despite the fact that this development address to a limited range of the population and have a big impacts on the rest of the it, probably a very negative ones, such as social segregation, competition over scarce natural resources, loss of job and turnover in existing city businesses, etc.

To mitigate this outcomes, the government and the municipality of Jericho should move forward to sign, as soon as possible, a solid agreement with JG company to deal with the sustainability issues of this mega-development, as it will affect the city, determining reciprocal rights and obligations in order to save what can be saved, reducing the impact on the historical city of Jericho.

The role of the local in
improving cohesion and
spatial justice

Session 17. Emerging spatialities and eu policy instruments: cases and perspectives

The *Pla de Barris*: a remarkable case of place-sensitive territorial policy

Marco Peverini¹

¹ *Politecnico di Milano, DASTU (Dipartimento di Architettura e Studi Urbani),
marco.peverini@polimi.it*

Abstract: Spatial injustices are rapidly growing and, in the wake of the so called “revenge of places that don’t matter”, there is urgent need for better territorial policies. Ranging on a wide variety of contexts, territorial policies should implement strategies that are not only place-based, but also coherent, effective and place-sensitive. Aim of the paper is to give a contribution to the debate, shedding light on one lesser-known yet remarkable case of territorial policy for social cohesion. The *Pla de Barris*, Plan of the districts of the Catalan Region implemented between 2004 and 2010, is here investigated. The research followed two main methodologies: on one side, quantitative socio-spatial analysis; on the other side the tools of policy analysis to investigate its implementation. It shows that the measure was efficient and effective in targeting spatial injustices thanks to integrated place-sensitive implementation mechanisms. A fairly balanced combination of centralized analytical apparatus, multi-level governance and involvement of the local administrations explains its success in addressing spatial injustices. There is much to learn from this experience, since this approach can make the difference in providing a coherent framework in which to develop place-sensitive interventions in deeply variable local contexts, that is the crucial point for the endurance of European Union.

Keywords: Urban regeneration; Urban governance; place-sensitive territorial policies; cohesion policies.

Introduction

Territorial inequalities are increasing all over Europe. As shown clearly by Rodriguez-Pose (2018), the more dynamic regions of Europe are leaving behind the less dynamic ones: places that ‘don’t matter’, where there is very little possibility of economic development and where a revenge going on through the ballot box. In the last decade, all over Europe, lower economic performances have turned out into anti-establishment vote, expressing the voice of big parts of the society that feel an increasing distance from where the development concentrates and consequently where the decisions are taken. These communities that don’t matter can be described as ‘peripheries’, indicating a distance from the ‘centre’ that is not only geographical but multi-dimensional (Petrillo, 2013).

In this sense, Regional Studies describe that peripheries exist on a European scale (e.g. the South and East of Europe) but also on national scale (e.g. the South of Italy, all Spain except Catalonia and Castilla, most of France except Paris, etc.). Parallely, Urban Studies focus on peripheries that exist on a metropolitan and urban scale, often referring to the district level. More recently, the importance of peripheries inside the scale of a

region has been acknowledged, for example with the notion of ‘inner areas’ (Barca, 2013) that also became an operative framework of the Italian government.

In this panorama, cohesion policies (not only European) act on different scales and with different mechanisms for targeting inequalities. On a national level, in Italy the territorial cohesion has been promoted through the investments of *Cassa del Mezzogiorno* that, stressing particularly on infrastructures as means to recover the gap between South and North, had often the effect of wasting resources and consume the trust of the people. Since the 1980s, following the importance given to the urban dimension of inequalities, cohesion policies integrated operational frameworks that targeted the cities and the regeneration of the city centres (e.g. Urban, Urban II, etc.) and of some peripheral parts considered more vulnerable, like *Programmi di Recupero Urbano* (PRU).

These regeneration programs aimed at concentrating resources where the vulnerability is concentrated, using the space as a factor that assures more efficiency and effectiveness to the measures activated. Nevertheless, these programs had a weakness: they stressed a lot on the physical restoration of the built environment, often forgetting the urban and social fabric and therefore failing in addressing the multiple dimensions of inequalities. Nowadays, in the wake of the ‘revenge of places that don’t matter’, all the levels of administration call for more efficient and effective ways to invest in the territorial cohesion, particularly regarding the response that those policies can have on the territories (Nello and Gomà, 2018).

Barcelona: a city with strong traditions of Urban Planning

The history of the urban development of Barcelona is very peculiar and is due to an accumulation of trends and events that had no comparable in Europe. During the dictatorship of Franco, the urban development was led by the interests of major real estate companies and developers that pushed for a ‘developmentist’ model. This, together with the lack of democracy and social policies, resulted in evident social and spatial segregation, and consequently to strong social mobilisation. After the death of Franco in 1975 and with the economic recession, the city - together with the entire Spain - required a deep institutional and economic restoration. From the point of view of urban development, the transition from industrial to tertiary economy followed an approach that changed completely from the ‘developmentist’ one and was described as ‘qualitative’, because it tended to target specific areas of the city with projects of requalification of the public spaces instead of savage urban development. Moreover, in the 1980s a season of big investment in the social services was inaugurated.

At the same time, as the city was nominated for the 1992 Olympic Games, a big change was on the run. From the ‘qualitative’ approach that had dominated after the dictatorship, the so called ‘Barcelona Model’ was being settled. This season was dominated by a strong, top-down, strategic planning approach that aimed at an urban development on the global city scale through big interventions: the Olympic facilities, the new downtown areas and new infrastructures – such as the famous *Ronda*, the new city Beltway. If in the previous phases the planning was led by different public bodies, the ‘Barcelona Model’ was heavily based on public-private partnerships in the form of mixed-capital companies with considerable autonomy. Thanks to this, and to the relatively good level of consensus around the measures, the transition of Barcelona from a mainly industrial city towards an important global city was rapidly accelerated.

This ‘new developmentism’ relied a lot on the attraction of capitals and on the interest and collaboration of the economic elites, but also on a completely new idea of administration. New management techniques were adopted by the Public Sector: the figure of the ‘local manager’ was appointed executive control on the administration; mixed-capital companies were created to manage autonomously special urban functions and processes; privatisation and externalisation of activities; spending review and tax reduction. The ‘Barcelona Model’ demonstrated many cracks in the ten years that followed the Olympic Games, such as the failure of the 2004 Universal Cultures’ Forum, and was highly criticized and opposed (Delgado, 2007). At the beginning of

the 2000s, Barcelona had reached a very high status in the European global cities, but it was still affected by social and spatial segregation.

A new generation of planning? The *Pla de Barris de la Generalitat*

Following this period in which Barcelona had grown a lot in terms of economic indicators but also in inequalities, a new approach was released. In 2004 the Parliament of the *Generalitat de Catalunya* [Region of Catalonia] approved the *Llei de Barris* [Law of the Districts], also known as *Pla de Barris* [Plan of the Districts] with the aim of “promoting projects of rehabilitation of those districts where major urban deficiencies are accumulated and where, as a consequence, the population that need more social attention is concentrated” (Nello, 2012) on the scale of the whole region (Figure 1).

The Law 2/2004, for the improvement of districts, villages and urban areas requiring special attention, of June 10th 2004. The norm was the first legislative text carried out and promoted by the government presided over by Pasqual Maragall. In fact, the draft bill was made public on 19 January 2004, by order of the Minister of Territorial Policy and Public Works, Joaquim Nadal, only three weeks after the new government had taken office (Nello, 2003: 25–28).

Figure 1. Map of the interventions that were funded by the Law 2/2004, between 2004 and 2010 . Source: Nello O. (2012), *Ordenar el territorio, La experinecia de Barcelona y Cataluña*. Elaboration by the author.

As visible in Table 1, the *Llei de Barris* financed between 2004 and 2010 projects in 141 districts, where more than one million people lived (at that time, the 13% of the total population of Catalonia), with a very important investment of 1.330 million Euros, of which: 693 million from European FEDER funds obtained by the Catalan Region; 513,2 million from the involved municipalities. It is based on the creation of a fund for the promotion of the ‘programme for districts and urban areas that require special attention’, provided with budgetary resources

from the government of the *Generalitat*, attached to the Ministry of Town and Country Planning and Public Works.

Number of calls	7
Number of districts	141
Total population in the 141 districts	1.005.214
Total funding	1.330 mln Euro
Funding from the <i>Generalitat</i>	693 mln Euro
Other funding (municipalities, privates, etc.)	513,2 mln Euro

Table 1. Some numbers of the Plan of the Districts. Source: *Generalitat de Catalunya. Departament de Política Territorial i Obres Públiques* [Department of Territorial Policies and Public Works].

Even if in some ways the Plan of the Districts represents a typical area-based program, a series of characteristics distinguishes this program from the mainstream of the various generations of neighbourhood programs of intervention that were released in Europe and makes it represent a very important step in the Catalan planning history (Scarnato, 2015).

Multi-level governance and inter-administrative cooperation

First of all, a big role was played by the Catalan regional government, that decided not to focus on single urban areas but to maintain the whole regional territory as a scale of intervention. Indeed, the planners acknowledged that segregation is originated also at a big scale, due to the real estate market. As explained by Oriol Nello: « due to the process of metropolitanization [sic] and the growing integration of the territory, the housing market in which the citizens and the economic operators make their decisions is not longer [sic] local, but rather has a much wider scope. Thus, segregation not only appears between districts in the same town but also – and usually, at first, between districts in the same urban area and even throughout the whole of the region» (Nello, 2009). It is here acknowledged that only from the regional scale it would be possible to distribute the necessary resources in an equal way for the districts and municipals that require interventions and services to face the concentration of vulnerability and which, due to the concentration itself, face great difficulties in providing them.

At the same time, in the mind of the planners, proximity to the field of action is essential for the success of urban policies. Their execution by higher institutional bodies (as in the French case), in the mind of the planner, could entail errors of appreciation and action which may lead to failure. The role of the *Generalitat* is therefore to promote, select and evaluate the projects, whilst the responsibility of the execution of the project lays completely on the town council concerned. In other words, the town council is the body responsible for the design and execution of the programme, having direct knowledge of problems and potential of each district, while the *Generalitat* maintained a role of mere funder and supporter, renouncing to be the protagonist. The Plan of the Districts, relying strongly on the potential of local government, fully applies the principle of subsidiarity.

The inter-administrative cooperation was considered of mayor importance and the law was designed in a way in which not only execution of the projects but also the selection process itself is conducted in cooperation. The law established an organism that is responsible for the selection and assignment of the resources: the Commission for the Administration of the Funds for the Promotion of the Districts and Urban Areas that require special attention. It is composed of 30 members, equally of representatives of the different Ministries of the *Generalitat* and municipal entities (Federation of Municipals of Catalonia and the Catalan Association of Municipals), as well as professionals of the Architects and Technical Architects professional bodies. This marked the beginning of a new era in the relationship between the *Generalitat* and local governments.

In conclusion, through the instrument of the competition the Region aimed at building a multi-level governance model. On one side, the leading role of the regional authority guarantees the coherence of the projects with the aim of social cohesion, the multi-institutional “tuning”, certain funding availability and territorial equity in the access to the funding. On the other side, the protagonist role of the municipality in promoting the project guarantees knowledge of the local situation and correspondence with the specific problems; the requirement of conspicuous co-funding ensures the “determination” of the municipality in effectively implementing the proposal.

The localisation of the interventions and resources

The plan aimed at reducing inequalities targeting specific neighbourhoods – *barrios* [districts], representing a precise administrative division of the territory that is nationwide recognized – that fall on the ‘areas of special attention’. A municipality could apply for one or more districts, making one or more applications. The application, in order to be successful, must target a district that belongs to the ‘areas of special attention’. This measure is to assure that resources go where there is actual need of it.

Anyway, there is to say, there is not a general overview of the Catalan districts that fall in the ‘areas of special attention’. The districts where to intervene are proposed by the municipalities and then examined by the same commission that is in charge of the evaluation of the projects. From an operational point of view, the Law of the Districts works in a way that is inspired to by the European programme URBAN. The proposed districts are examined by the commission through a set of quantitative parameters, as in Table 2, with a scale established by the regulations of the Law of Districts. In order to be considered an ‘area of special attention’, a district must obtain a minimum amount of points from all of the indicators in the scale. Then, a score is awarded adding the points given to the project and, based on the resulting score, the resources available in each call are distributed among the participating municipalities.

Criteria (defined by the Law 2/2004)	Shortfalls in works, facilities and services	Demographic problems	Presence of economic, social and environmental problems	Social and urban deficits and problems of local development
Objective statistical indicators (defined by the regulation of the Law of the District)	Insufficient level of conservation of buildings	Density of population	Number of people that receive assistance and non- contributory pensions	Lack of public transport
	Buildings without running water or water disposal systems	Decrease and accelerated population growth	High level of unemployment	Lack of parking spaces
	Buildings of four or more floors without a lift, designated mainly to housing	Dependent population	Lack of green areas	Low economic activity
		High percentage of immigration	Low level of education	Percentage of the population at risk of social exclusion

Table 2. The criteria and indicators individuated by the Law 2/2004 and its regulation to verify that the district of application is in the ‘areas of special attention’. Source: Nello O. (2009), *The Law of Districts. A collective commitment to social cohesion*, Generalitat de Catalunya. Elaboration by the author.

The reason for this is to assure that the targeted district is among those that actually deserve it, avoiding that resources go to places that are in a relatively good condition but where certain municipalities would like to intervene with very good projects. However, the notable aspect is that the selection is not only based on statistical evidence of the urban and social deficits of the district. Indeed, the planners thought that establishing and publishing a ranking of those districts which find themselves affected by segregation would cause the stigmatisation of those in worse conditions and, therefore, further worsen the conditions of vulnerability of the district. Therefore, they elaborated an evaluation method that took into consideration the strength of the proposal on the side of the project.

‘A plan for projects, not for problems’

As said, the analysis of the proposed context with 16 statistic parameters is done to indagate the effective state of need of the proposed district and avoid a competition based merely on the efficacy of the projects, while the evaluation of the project means to push the focus from vulnerability to planning, trying to avoid possible effects of stigmatization.

Therefore, after the initial analysis of the districts with objective indicators, there is a second stage of evaluation based on the projects presented by the municipalities. The evaluation is done through four criteria: the level of comprehensiveness of the proposed proposal; its general coherence; the level of economic commitment of the town council; the parallel execution of complementary actions. Those two evaluation criteria have the same weight in the score, aiming to generate a combined evaluation method (as in Figure 2).

Figure 2. The governance scheme and the evaluation criteria established by the regulation of the Law 2/2004. Source: Nello O. (2009), *The Law of Districts. A collective commitment to social cohesion, Generalitat de Catalunya. Elaboration by the author.*

One of the main factors for the evaluation of the process is the degree of integration of the actions included in the proposal, assumed as a fundamental device to assure the success of the project on the district. The Law establishes 8 different fields where the projects of the municipalities should intervene in the same project, for each district. The fields regard mainly 3 areas: urban design and equipment; improvement of energy, environmental and communication infrastructures; social actions that support the population. Looking at Table 3 it is possible to see that, even though the far largest part of the funding were dedicated to strictly physical interventions like public spaces, green areas, installations for collective use and accessibility (with about 2/3 of the budget), an important role has been played by the involvement of the population through social programmes (with 1/10 of the budget) and with the refurbishment of the common elements of private building (another 1/10).

Improvement of the public space and provision of green areas (paving of streets, planting of trees, lighting, creation of gardens)	44,24%
Refurbishment of the common elements of buildings (facades, drainpipes, lifts, roofing)	9,96%
Provision of installations for collective use (civic centres, centres for the elderly)	21,83%
Incorporation of communication technologies (wiring of building, establishing of wi-fi areas)	1,28%
Introduction and improvement of energy and environmental infrastructures (collection of residues, putting rubbish containers underground, establishment of recycling centres, promotion of renewable energies, water saving mechanisms)	4,74%
Promotion of gender equality in the use of urban spaces and installations (premises for women's associations, specific training activities, interventions for the improvement of women's safety);	2,13%
Development of programmes that entail social, town planning and economic improvement of the districts (actions for the support of collectives that are facing social exclusion, training programmes, dynamise commerce)	9,39%
Improvement of access and removal of architectural barriers (widening of pavement, building of ramps, putting in escalators, elimination of obstacles).	6,26%

Table 3. Fields of intervention required by the law with examples, and the weight that each field had on the fundings. Source: Generalitat de Catalunya. Departament de Política Territorial i Obres Públiques [Department of Territorial Policies and Public Works].

In addition, the law required that the applications of the municipalities should consider two collateral actions that aim at strengthening the plan:

- the creation of complementary programmes by the different Ministries of the Generalitat;
- the constitution of comprehensive follow-up mechanisms.

Regarding the first action, the complementary actions established by the Ministries of the *Generalitat* in the districts included in the programme have been of great importance. The program 'Jobs in the Districts', created by the Ministry of Employment, has led to the establishing of 81 agreements in 92 districts included under the law in order to set up training and school-work transition programmes, with a total investment of 30 million euros. Similarly: the Ministry of Health has carried out studies on public health and health care in the districts participating in the programme; the Ministry of the Environment and Housing has established specific lines of aid in the refurbishment of common elements of buildings for the 37 districts of the programme; the Ministry of the Home Affairs, Institutional Relations and Participation has contributed to the financing of the process of citizen participation in a special way in a further 14; the *Incasòl* (Catalan Land Institute) has signed agreements in order to carry out urban remodelling actions (especially the replacement of obsolete housing with new housing) in 24 districts of the programme, with an investment of about 200 Million Euros. In the effort to cover all of the substantial aspects of the life of all of the areas of intervention

The Evaluation and Follow-up Committees (one per district) include the mayor of the municipality, representatives of different areas of the town council (directly involved in the management of the district), representatives of seven ministries of the *Generalitat*: Town and Country Planning and Public Works, Environment and Housing, Governance, Social Action, Economy and Finance, Health and Employment, as well

as a representation of the Delegation of the Government in each territory. These Committees are configured to bring together all of the services of the *Generalitat* and the Municipality that are concerned with the district. The Committees are held approximately once a year per district and are not meant to substitute the daily action of the administrations, but to maintain a coordination on the action on every district and to create the basis for integrated and transversal action.

Conclusions

In conclusion, this analysis shows how this plan has represented a very important step and pioneering application of some of the precepts of the place-sensitive approach. Of course, the place-based approach with the space as a means to understand the vulnerability of the society, and the neighbourhood as a unit of investigation of the territory and of concrete intervention. But also: the importance posed on the project and its strongly integrated character; the fact that the proposal (both of the neighbourhood and of the project) has to come from the local administration, with a pro-active role of the municipality; the devices to assure the communication and coordination among different levels (vertical) and sectors (horizontal) of governance and the implementation and follow-up of the actions.

Even if, it has been admitted, the process of adaptation of the administrations to act in a more area based and less sectorial manner (in the districts of special attention and in many other fields) required a long process of adaptation, it was a very important turning point in the innovation of the governance of this kinds of plans of intervention. Concerning Barcelona, that has had a very central role (approximately one tenth of the interventions of the Law fell on the Metropolitan Area), in comparison with what had happened before in the history of the physical transformation of the city of Barcelona, a shift was made from the top-down, architecturally hard and punctual intervention of the era 1979-2004, to a softer, more integrated and co-designed intervention that has a dimension of plan. This was very important, in the wake of the huge protests and critiques that previous plans (e.g. the one related to the Culture Forum 2004) had faced.

Not all the aspects of the plan have been investigated in this paper, even though some of them are very important and would require further investigation. The first regards the housing market: even if the Law of the Districts did not include any direct measure in that field, it was very clear in the mind of the planners that bettering the conditions of those neighbourhoods, especially those that are in the city centres, would increase the value of the land and the housing prices, with possible effects of residential exclusion or expulsion. For this reason, a combined plan was designed with the *Pla d'Habitatge 2004-2010* [Housing Plan 2004-2010] that was assigned the role of avoiding speculation effects, providing measures that promoted the social role of housing. Since the value of the lands has actually increased after the interventions of the Law of the Districts, it would be very important to examine whether the Housing Plan was able to contrast possible negative effects on the side of housing.

Considering possible replications of such a pioneering experience presents some complications related to the specificity of this case. It is important to underline that the Law of the Districts was made possible in very peculiar conditions: in a national administrative system, that of Spain, that leaves heavy financial autonomy to the regional level; in the richest and more economically advanced region of Spain; after the accumulation of many experiences in urban regeneration; in a relatively stable political situation and before the financial crisis of 2007-08. Nowadays, it would be very hard to imagine such an alignment. Nevertheless, it brings a quantity of lessons that were learnt and that could be adapted to other cases and situations, wherever there are 'geographies of discontent', in order to give concrete answers to the questions posed by the 'places that don't matter'.

Acknowledgements

The paper draws on the research carried out by the author between November 2016 and February 2018 at the Observatory of Urbanization of the Autonomous University of Barcelona (UAB), with the support of prof. Francesc Muñoz Ramírez. I would like to thank him for the help and inspiration.

Thematic villages as the example of neo-endogenous local development in rural areas

Paulina Tobiasz-Lis¹

¹*University of Lodz, Department of Regional and Social Geography*

Abstract: This paper is focused on a set of activities undertaken by the local community of peripherally located Polish village and their various cultural, economic and landscape effects. The selected village of Masłomęcz (Lubelskie Voivodeship) is one of over 50 active thematic villages in Poland and well presents the problem of post-war settlement of people from various parts of the country and the long process of their adjustment to the new living environment. The paper is based on quantitative and qualitative data gathered both infield (observation, individual in-depth interviews, focus group, research walk) and along the desk research (the study of literature, documents on local development strategies). The multithreaded analysis in a local scale enabled to present the anatomy of undertaken activities in the scope of the Theory of Change framework. Thematic village of Goths in Masłomęcz presented as the example of neo-endogenous local development in rural areas of Poland is one of the 33 case studies analyzed along the Horizon 2020 Framework RELOCAL Project.

Keywords: Thematic Village, local development, rural areas, Theory of Change

Introduction

In Poland, just like in other countries, rural areas are in the time of intensive transitions. Since the beginning of the market economy in the 1990s, we observe the dynamic emergence of a multifunctional rural regime which influences new non-productive functions in local economies and new lifestyles reflected in the rural landscape. The parallel process within these transformations is the empowerment of local communities and thus reinforcement of social and territorial identity. However, it has to be stressed that these are complicated processes, difficult in view of the economic crisis of that period, bad living conditions, and a number of other phenomena, which turned out to be a serious obstacle for the real social change, based on the recovering of the cultural and territorial identity (Bukraba-Rylska 1992). In some areas, especially on peripheries this transformation was delayed, and became possible only with the acquisition of the structural funds from the EU directed to the strengthening of the social capital and to the broadly understood rural renewal (Czapiewski 2010, Fedyszak-Radziejowska 2010, Jeziorska-Biel and Psyk-Piotrowska 2012, Idziak and Wilczyński 2015).

This paper aims to focus on the idea of thematic villages, which may lead to widely understood rural renewal reflected by redefining local identity and multifunctional development in areas that are

economically and socially impoverished. Activities undertaken along the process of the local development exemplified on the case of Masłomęcz village will be reflected within the Theory of Change approach with the special attention paid on the use of local physical and human resources supported by external incentives, which resulted in a set of cultural, economic, and landscape-related changes.

Theoretical background

The classic formulation of rural development in post-war Europe was an exogenous model that put industrialisation at the centre of development. The key principles, referring to economies of scale and concentration, saw the primary function of rural areas in providing food for the expanding cities. Early models of rural renewal implemented since 1960s in Germany, focused on modernisation of the countryside and increasing the effectiveness of agricultural production, might serve as the example of exogenous approach to local development. By the late 1970s, this model was falling into disrepute. It was criticised as dependent development, reliant on continued subsidies and the policy decisions made by external stakeholders, experts and planners as well as erasing the cultural and environmental differences of rural areas. Among its side effects observed European-wide were: destruction of traditional rural landscape, depopulation and weakening of social capital. In response, a new – endogenous development approach was introduced and the strategies of rural renewal started to focus on social and cultural aspects, sustainable development and thematic villages as a tool in this process. Three fundamental aspects have summarised the endogenous development approach in a rural context: 1) the territorial instead of the sectoral frame, 2) the valorising and exploiting of local physical and human resources, and 3) the focus on “needs, capacities and perspectives of local people” (Ray 2000).

It should be mentioned, that in Poland, similarly to other post-socialist countries, new paradigms for regional and local development appeared with a delay. This was mainly due to ideological factors whose impact weakened along with the transformation and democratization of political and social structures. Within the last 30 years, social sciences in Poland are subject to theoretical and methodological revolution, manifesting primarily in the interest of culture in various contexts and dimensions (Tobiasz-Lis and Wójcik 2014).

Some authors have criticised endogenous development ideas. They argue that any locality will include a mix of exogenous and endogenous forces, and that the local level must interact with the supra-local. The critical point is how to enhance the capacity of local areas to steer these broader processes, resources and actions to their benefit. Recently, an increasing interest in governance dynamics, institutional changing and participation practices has been widely recognised, especially in peripheral and inner areas. Their development and in particular actions that promote local assets and knowledge enhancement, new possibilities of cooperation, new governance structures at different administrative levels, social innovations and participation are considered as the centre of neo-endogenous development and an essential prerequisite for its success (see further: RELOCAL Project applied under Horizon 2020 framework).

In the neo-endogenous rural development two interrelated notions are central, e.g., local resources and local control. The endogenous part refers to development along bottom-up approach that is when the search for possible resources and mechanisms focuses on the local territorial level. The “neo” part

identifies various manifestations of the supra-local and their roles in local development (Ray 2006, 279).

Taking into account the issues listed above, in the case of Masłomęcz village presented in this paper, the process of learning and adapting to the new environment started just after the II World War with the post-war resettlements of people. Based on local historical assets (impact of the territory) and developed thanks to a bottom-up initiative together with external actors' assistance (impact of social capital and relations between local and supra-local), a thematic Goth Village has been established there, which well exemplifies the neo-endogenous concept of local development.

Thematisation of space is a method, widely described to make the “place” known in the broader scale through development of thematic spaces, amusement parks, cultural events and festivals (see: Lengkeek *et al.* 1997, Boruta and Markova 2012, Blichfeldt and Halkier 2014). In a narrow sense, it is focused on selecting a leitmotif for places, events or persons, which become the basis for creating tourist products and serves mainly the marketing purposes (Idziak, 2008, Kłoczko-Gajewska 2013). In a broad sense, it is a model for the neo-endogenous development of a local community providing the basis for acquiring, creating and developing the local identity (Dmochowska-Dudek and Tobiasz-Lis 2017).

Geographical Context – the village of Masłomęcz

Masłomęcz is a small but very dispersed village of about 400 inhabitants (100 households), located in Eastern Poland in the Lubelskie Voivodeship, not far from Hrubieszów and only 8 km from the boundary with Ukraine (Figure 1). Current local economic activities are very poorly diversified, and the productive structure is still based mainly on farming, and particularly on the cultivation of wheat and sugar beets. A complex set of political, historical and demographic factors marked the contemporary character of Masłomęcz. The former multicultural society, composed of Ruthenians, Poles and Jews have undergone due to the war and numerous post-war processes, changing its structure. One of the most important among these was the resettlement of the Ukrainians from Poland to the Ukrainian Soviet Socialist Republic in the years 1945-1946 and the “Vistula” Operation in 1947, aimed at resettlement of the Ruthenian population to the western and northern regions of Poland, as well as the settlement of the Polish population, repatriated from the USSR in the years 1944-1948 and later on in the 1950s.

Figure 1. Location of Masłomęcz village

In 1977 archaeologists from the Lublin University of Maria Curie-Skłodowska started excavations in Hrubieszów Valley. Between 1977 and 2002, on one of the farming plots in Masłomęcz, they discovered a complex of Goth settlements and cemeteries from the 2nd-4th centuries. Initially distrustful of “strangers”, the residents of village slowly got used to the presence of archaeologists every summer. Their work, at first a new, unprecedented occurrence, became, as time passed, an element of the annual life cycle of the community, until then dictated only by the natural cycles, farming and family activities.

The Goth Village Association was formally established in 2010, although the local community started to be involved in the reconstruction and promotion of the cultural and historical heritage of the region in 2004, in response to the sense of loss they had after the last season of archaeological excavations in 2002. As a consequence of the idea to “bring archaeology and Goths back” to Masłomęcz, a partnership of the residents, NGOs and authorities was set up in the form of a Local Action Group “Better Tomorrow”. Their initial plan was to use the historical and cultural heritage of Goths to develop tourist attractions and services. In 2006, a wooden hut with a straw roof was constructed on a plot of land purchased by the Hrubieszów municipality, serving as a careful reconstruction in the scale of 1:2. It was a Goth hut from the 3rd-4th centuries. This structure constituted the beginning of the Goth Village, an open-air museum which is continuously developed and aims to present examples of everyday activities of ancient Goths along living history lessons, workshops and fests. Between 2007 and 2009, a few projects were realised, focusing on the historical education of the inhabitants of the village and shaping their skills in arts and crafts typical for ancient Goths. In 2009, “the Goth Squad” was established with support from archaeologists, employees of the regional museum in Hrubieszów. Nowadays, the Squad gathers about 30 persons of various age, who, after a series of trainings with professionals, reconstruct with archaeological accuracy the crafts, everyday life rituals and martial arts of the ancient Goths. This local social initiative has become a new symbol of the region.

In 2009 municipality of Hrubieszów received financial support from the Swiss Contribution Fund for the project “From a vision to modern management of the Gothania region”, whose purpose was to create a tourist brand of the entire region and to stimulate the residents in economic terms. Therefore, the Goth Village was accompanied by the establishment of two agri-tourism farms where, in addition to accommodation and a variety of services (bike and ATV rental, horse riding), one can buy and taste local products.

Methods

To design the study focused on thematisation of rural space as the way towards local development, the preliminary desk research of literature and documents have been conducted. The collection of primary data was conducted in the summer and autumn of 2018. In the beginning, a Focus Group activity was organised and conducted in Masłomęcz to gather community members, local stakeholders and experts and observe interactions between these groups of people, 16 in total. Issues addressed during the focus group activity referred to: 1) first idea of the Goth Village in Masłomęcz and its links to previous actions undertaken by the local community; 2) implementation of the idea of the Goth Village in Masłomęcz; 3) the Goth Village Association gathering local community as a tool for the development of the locality; 4) benefits acquired by the local community from the Goth Village; 5) Individuals and groups of people most intensively involved in the Goth Village; 6) formal

procedures in the course of deployment of such projects and their realization; 7) role of the municipality / county in the support for such projects and their realization; 8) role of the Local Action Groups (LAGs) in the support for the projects; 9) notions of “thematic village”; 10) future developmental priorities, improvements, visions and plans; 11) possibility to look for partners in other places (formation of a network).

Following the focus group interview, 9 in-depth individual interviews were carried out. The interviewees were: members of tourism sector (two women running agritourist farms), the local leader, leaders and members of local NGOs (firemen, Farmers’ Wives Association, Goth Village Association), mayor; town councillor responsible for the tourism sector, director of Regional Museum in Hrubieszów. The interviews were designed to take the form of a conversation guided by the researchers (Kvale and Brinkman 2009). Respondents were encouraged to talk freely on the prepared discussion points. These included questions over the mental mapping of the village surroundings as well as about interviewees’ level of involvement in the Goth Village project and a discussion of perceived strengths and weaknesses of undertaken activities. Interviewees were asked to reveal their role and specific contribution to the establishment of the Goth Village in Masłomęcz and features of their character, competences, skills enabling them to stand up to the challenge of this process. They were also encouraged to talk about characteristics and distinctive features of their local community and main changes over time due to the establishment of the Goth Village in Masłomęcz (social, economic, landscape-related). Interviewees also referred to the lessons, learnt on the basis of their experiences, associated with the work on development of the Goth Village, their overall attitude towards their place of living and plans for the future. All the interviews were recorded and transcribed to become the basis for the qualitative content analysis and inductively interpreted later on with reference to person-process-place framework.

Following the focus group activity and individual interviews, along with a research walk, the photographic documentation was collected. Finally, researchers participated in Archeologic Fest – an annual one-day festival which takes place in the Goth Village open-air museum on the last Sunday of July. This primary data was further supplemented with quantitative and qualitative data from secondary sources, including existing statistical data, to contextualise local-level findings (Census data, local chronicles, newspapers, and municipality internet site).

A broad range of collected data on thematisation of Masłomęcz village allowed to present the process of local development in a *Theory of Change (ToC)* framework. The ToC approach (Blamey and MacKenzie 2012, Connell and Kubuisch 1998) is part of a family of approaches to policy design and evaluation which emphasizes the need to clearly specify the intervention logic which underpins any “action”, in order to facilitate subsequent monitoring of the policy process in relation to a logical chain of cause and effect linkages, and evaluation of the changes achieved against the clearly specified goals. The family of approaches also includes *Realistic Evaluation* (Pawson and Tilley 2001, Pawson *et al* 2005), *Logic Models* (Kaplan and Garrett 2005) and *Theory-Based Evaluation* (Stame 2004).

Theory of Change framework, used in this research, aims to highlight the causal pathway between the “action” (intervention) focused on establishing thematic Village of Goths in Masłomęcz and the ultimate goal of local development of this rural settlement. It also considers how aspects of the wider local and national environment (economic, social, governance, policy etc.) affect the intermediate

outcomes which form the links within the causal pathways. This analysis is known as *mechanism mapping (MM)*.

Results

Baseline Theory of Change

The case study of the active thematic Goth Village in Masłomęcz well illustrates local responses to general challenges of rural areas among which the most important are declining and ageing population, problems with youth retention, limited economic and social opportunities for residents, loss of local services and higher costs of living. Thematisation of rural space of Masłomęcz village is the core process in diversifying local economic base, enhancing the quality of life, and seeking for new functions and roles of this settlement. Rural renewal reflected by multifunctional development, redefining local identity and strong place attachment in the peripherally located area that is economically and socially impoverished, has been outlined as the *long-term goal* of all practices applied in the process of thematisation of rural space in Masłomęcz.

Thematisation of rural space in Masłomęcz as a process leading to local development was possible thanks to parallel activities of:

- local self-government of the Hrubieszów commune which provided Masłomęcz community with a land parcel devoted to the future development of the open-air museum – a tourist attraction presenting cultural heritage of the village connected with the history of ancient Goths, and
- continuing assistance of leaders (archaeologists) who came back to the village after finalizing their archaeological excavations to set opportunities for economic activities related to the Goth Village in Masłomęcz by exploring and developing human and social capital of the village.

These two components of the action can be regarded as the starting points for two causal paths connected with the development of physical space of the village relating to the development of the Goth Village open-air museum - a new central place of the settlement and a tourist site of local and regional scope, setting space for social and economic activities and the growing sense of belonging – both in terms of territorial identity and social trust.

The first of these (on the left of Figure 2) comprises a chain of *intermediate outcomes*, starting from the organisational and financial backing of the Hrubieszów Community in the form of purchasing a land parcel and devoting it for the development of the Goth Village which have led to new employment possibilities, development of local products and services influencing multifunctional development of Masłomęcz. However, this chain of more economically and landscape-related outcomes is also clearly linked with those deriving from leading role of external experts (archaeologists). Innovative exploitation of territorial assets, which, in turn, leads to additional local economic activity and employment results in enhanced demographic sustainability. This set of intermediate outcomes focuses primarily on distributional aspects of spatial justice, because it concerns what may be judged fair access rights to the benefits associated with multifunctional local development of rural area.

The second chain of intermediate outcomes (right hand side of Figure 2) has a stronger procedural element, in that it is about developing human and social capital reflected in growing capabilities of drawing down resources for the benefit of the local community. It is about fair access to local development processes perceived as a pre-condition for long-term development in relation to both, quality of life in Masłomęcz as well as the position and perception of the village in the wider regional and national context.

The linking part of both chains of intermediate outcomes is the Goth Village Association having a specific potential for involving local resources and the whole community into common activities and interests. The Association runs a Goth Village open-air museum, employs staff, engages volunteers, secures funds, carries out educational programmes and becomes highly professional thanks to the engagement of external organisations – the Marie Curie-Skłodowska University of Lublin and Regional Museum in Hrubieszów. Of special significance are, in particular, such undertakings as the development of a Goth Squad uniting residents over common history, interests and activities aimed at popularisation of the historical and cultural heritage of the village.

The causal paths illustrated in Figure 2 only work on the basis of a set of *assumptions (contingencies)* of two types:

- “internal” contingencies which are specific to particular intermediate outcomes, and their links within the causal paths;
- “contextual” contingencies, which are broad underlying assumptions about the geographic, governance, policy, economic and social environment within which the case is found.

The former will be considered in this section, as part of the ToC process whilst the latter are properly considered under the mechanism mapping below. It should be stressed that although internal contingencies are certainly part of the ToC mapping process, mechanism mapping considers the effects of changes in both internal and contextual assumptions.

In the process of interviewing stakeholders there was awareness that some of the internal “contingencies” were factors which facilitated the causal path, whilst others acted as brakes on the process. In the ToC of local development activities undertaken in Masłomęcz village, six internal assumptions may be observed:

A) The basic internal assumption of the local development activities success is the authentic theme (the ancient history of the area) for developing Goth Village open-air museum, understood as a local asset of this particular settlement;

B) The mutual trust of the local community and external actors (archaeologists) enabling to use results of archaeological excavations in the village as the development asset wouldn’t be possible without the existing capability of collaboration in the local community. Leaders were needed here as the trigger to start the process, but the local community was ready to work together;

C) Leaders – in Masłomęcz, archaeologists – were the first factor to form a group and to impart adequate dynamics of implementing new ideas which seems to confirm the assumption that expert external assistance is necessary at key stages, especially by providing professional knowledge of markets and marketing. However, professional experts in Masłomęcz (archaeologists) are not perceived as “external” by the local community. After the excavations carried out for 25 years around the village, they have become “ones of us”. As a consequence, they had and still have a strong mandate to represent local community of Masłomęcz and set ideas for the development of the Goth Village open-air museum.

D) The development of the Goth Village open-air museum in Masłomęcz aims to result in new opportunities for economic activities and employment – however the choice of such activities is inevitably constrained by the assets available and the market context – necessitating some kind of smart specialisation approach.

E) The next “internal” contingency is associated with the two-folded connection between demographic stability/growth as well as multifunctional local development and the final goal of rural renewal in general. This link is contingent upon demographic and economic growth, or at least their sustainability being associated with enhanced well-being.

F) Strategic capacity of the Goth Village Association members in defining, reflecting and pursuing their aims to build up a platform for sociocultural activities in Masłomęcz as well as the learning capacity of the association, including its flexibility and adaptability to react effectively when opportunities arise (for instance, through funding programmes).

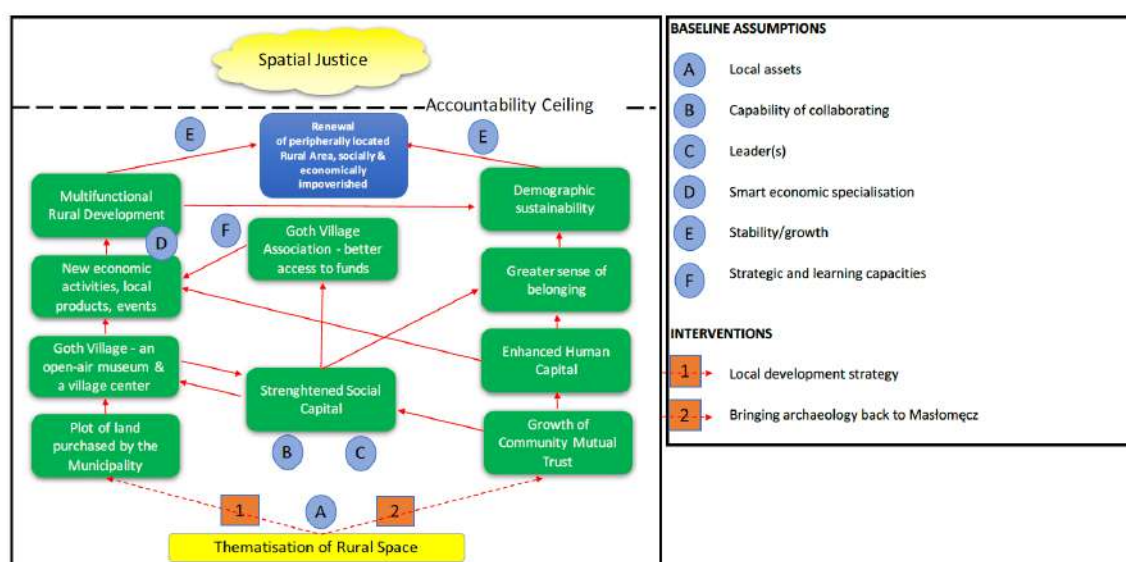

Figure 2. Baseline Theory of Change for the thematisation of rural space in Masłomęcz village, Poland

Baseline Mechanism Mapping

In essence mechanism mapping considers how a ToC map might adjust if the initial set of assumptions (both internal and external) cease to hold good. This might be associated with the intervention being

applied in a different geographic context or it may be the consequence of contextual political and social changes over time (Figure 3).

Regarding *geographical context*, it should be stressed that Masłomęcz is a small rural settlement located in the remote, easternmost part of Poland, with a complicated post-war history and suffering from outmigration, high unemployment and weak economic infrastructure, especially since the political and economic transitions of the 1990s. However, local assets associated with the natural landscape of Hrubieszów Valley and new features of cultural landscape in the Goth Village open-air museum in Masłomęcz provide the local community with opportunities for economic activity (especially tourist infrastructure) which would not be available (or at least not to the same extent) in other parts of rural areas in Lubelskie voivodeship. The second assumption considered under geographical context is that remoteness places constraints on the choice of economic activities and “styles” of doing business. Essentially entrepreneurs in this kind of environment seek ways to survive without the benefits of agglomeration. One response (particularly for those not so much growth orientated) is to develop a strong relationship with a local customer base.

The *policy context* within which activities undertaken by local community in Masłomęcz village is placed exhibits both continuity and uncertainty. Although there are potentially some big changes on the horizon (changes in EU Cohesion Policies, change of the position of Poland from beneficiary to net payer) the key policy contingency would be the continuity of the support to Eastern peripheries of Poland and rural areas and thus, Masłomęcz community by EU and national development programmes and funds.

Among *societal and market context* the demographic shrinking and ageing which characterises the rural parts of Poland was considered as serious constraint for the activities of Thematisation of rural space in Masłomęcz. Nevertheless, there was some anecdotal evidence of a “turnaround”, driven by younger, economically active residents and in-migrants. New opportunities associated with developing a common tourist offer within a wider region of “Gothania” around the Hrubieszów community might be interpreted as a response to two main inhibitors of the action which were: 1) narrow spatial influence due to peripheral location; 2) seasonal character of the Goth Village open-air museum offer. Further backing of cultural and scientific institutions result in unique offer of the Goth Village keeping it authentic and historically correct.

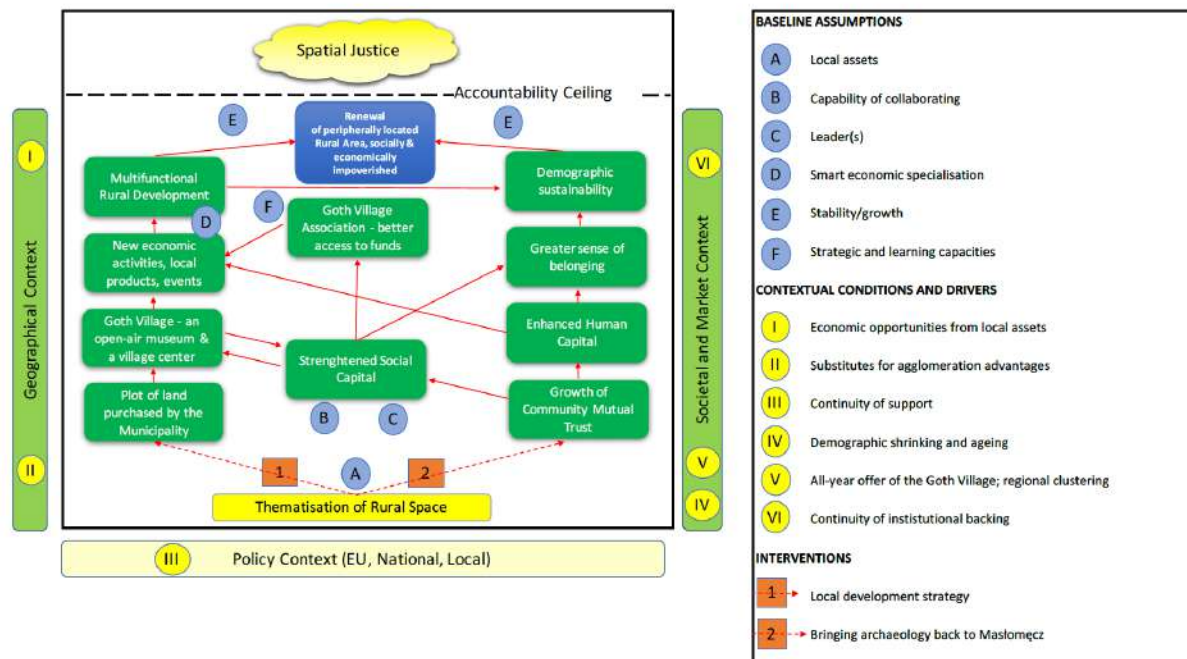

Figure 3. Baseline Mechanism Map for the thematisation of rural space in Masłomęcz village, Poland

Conclusion

Thematisation of rural space of Masłomęcz as presented in the scope of Theory of Change and mechanism mapping enabled identifying promoters and inhibitors of effectiveness in terms of local development in the remote rural areas of Poland. The main promoters influencing the scope and impact of the thematic Goth Village as a tool for local development of Masłomęcz are:

- an authentic theme for developing the thematic village (ancient history of the area);
- mutual trust of the local community and external actors (archaeologists) enabling the use of the results of archaeological excavations in the village as the development asset;
- strategic capacity of the Goth Village Association members in defining, reflecting and pursuing their aims to build up a platform for sociocultural activities in Masłomęcz;
- learning capacity of the association, including its flexibility and adaptability to react effectively when opportunities arise (for instance, through funding programmes).

Apart from these internal factors, which are related to the set-up and management of the association, further supporting factors play a role:

- organisational and conceptual support of the community of Hrubieszów, Regional Museum in Hrubieszów and Lublin University of Marie Curie-Skłodowska,
- positive influence of EU funding programmes on the strategic development of the association into a sociocultural development actor.

Regarding the main inhibitors influencing the scope and impact of the Goth Village we might conclude:

- peripheral location of Masłomęcz having impact on regional scale of the Goth Village open-air museum's influence (only within Lubelskie voivodeship);
- seasonal character of the Goth Village activities – the open-air museum is opened for organised groups (children from schools, kindergartens) and individual visitors between May and October.
- demographic crisis in rural areas (especially in peripheries) hinders generational replacement among the members of the Goth Squad involved in the action of the Goth Village open-air museum.

A Theory of Change framework has been developed for the purpose of this study retrospectively, by reading documents, talking to residents and stakeholders, as well as analysing data. Thus, it might serve as evaluation reflecting what has worked or not in order to understand the past and plan for the future activities towards local development of the village.

Friendly spaces and
mobility for ageing

ELDERLY PEDESTRIANS, AGED >65 YEARS, DURING WINTERTIME -ATTITUDES TOWARDS WALKING OUTDOORS, SAFETY EQUIPMENT AND EXPERIENCES OF FALLS. A COMPARISON WITH HEALTHY ADULTS.

Glenn Berggård

Lulea University of Technology - Department of Civil, Environmental and Natural Resources Engineering - Sweden – Lulea

glenn.berggard@ltu.se

Abstract: Pedestrians slipping and falling is a major safety problem in countries with long winters such as Sweden. According to the Swedish questionnaire-based National Traffic Safety Survey, self-reported accidents involving pedestrians without involvement of any vehicle (single-pedestrian accidents) accounted for roughly half, (1 141 962) of the total number of all road transport single accidents (2 335 017) in 1998-2000. This survey covered 23 030 people aged 1-84. Fall accidents during wintertime accounts for a large portion of all single-pedestrian accidents. An intervention study was performed from February to April among 67 healthy adults, aged 27-67, in northern Sweden, examined the obstacles for walking outdoor during wintertime, attitudes towards safety equipment, their previous experiences of outdoor falls during wintertime and the effect of using anti-slip devices on daily walking journeys and their prevention of slip and fall accidents. A intervention study has been made among elderly people, aged more than 75 years, also in northern Sweden. A questionnaire has been distributed to record their background, health status, attitudes towards different conditions to reduce outdoor walking and their usage of safety equipment. A daily travel diary was distributed during February to April 2009 to record daily walking and experiences of slipping and falling. The results from comparisons of attitudes and previously experiences of outdoor falls among the elderly persons is compared with the results from the pilot study among healthy adults.

Keywords: elderly, pedestrian, winter, slip, fall

Introduction

Pedestrians slipping and falling is a major safety problem in countries with long winters such as Sweden. According to the Swedish questionnaire-based National Traffic Safety Survey, self-reported accidents involving pedestrians without involvement of any vehicle (single-pedestrian accidents) accounted for roughly half, (1 141 962) of the total number of all road transport single accidents (2 335 017) in 1998-2000. This survey covered 23 030 people aged 1-84. Fall accidents during wintertime accounts for a large portion of all single-pedestrian accidents. The frequency of hospital visits due to severe fall injuries is higher during wintertime (about 34,000 people) than during the rest of the year (Berggård and Johansson, 2010; Eriksson and Sörensen, 2015)

Healthy adults experiences of slips and falls

A study, which focused on healthy adults in northern Sweden, examined the effect of using anti-slip devices on daily walking journeys and prevention of slip and falls. The study was limited to 67 respondents in the ages 27–67 years.

The respondents were divided into three groups: an Intervention Group, a Control Group, with similar distribution of gender and age, and a Comparison Group. Four questionnaires were distributed:

- background,
- daily diary of distance walked and occurrence of incidents or accidents reported weekly,
- detailed incident or fall report and
- experiences of using anti-slip devices for those who used these devices during the trial period.

Half of the respondents stated that they had previous experience of using anti-slip devices. In this study, 52% of the respondents used anti-slip devices. Anti-slip devices improve the walking capability during wintertime. The mean daily total walking distance among all of the respondents in this study was similar to the average walking distance according to the Swedish National Travel Survey, which is 2–3km (SIKA Statistics, 2007).

Among subjects using appropriate anti-slip devices, the average daily walking distance was found to be statistically significant longer compared to people not using anti-slip devices.

Respondents aged 45 years and above walked significantly longer distances, in mean daily total walking distance 3.21km compared to 2.48km and when using anti-slip devices 4.19km compared to 1.73km respectively. There are statistical differences between older (45-67 years of age) and younger (27-44 years of age) respondents for both the mean daily total walking distance for all respondents ($df = 1$, $F = 43.277$, $p < 0.05$) and the distance with anti-slip devices ($df = 1$, $F = 44.818$, $p < 0.05$). The elderly walk longer and use anti-slip devices more frequently. This study indicates that an increase in daily walking distance can be made without increasing the risk of slips/falls when using anti-slip devices. The study also indicates that by using appropriate anti-slip devices and having information about when and where to use them, based on their design, people avoid having slips and falls. The respondents experienced in using anti-slip devices in this study will continue to use them and will also recommend others to use anti-slip devices.

Elderly pedestrians, aged >65

In an intervention study among elderly people in Boden Municipality in North of Sweden data from a survey has been analyzed. The municipality distributed anti-slip devices to elderly citizens, aged over 65 years. Questions were asked among the elderly citizens about their ability to move, activity level and the effect of weather conditions on their mobility. Questions were also asked on using safety devices (e.g. bike helmet, safety belts in cars, ...) and number and explanations of falls during winter. The research attempted to analyze different factors that influence activity of elderly during winter conditions. In total the answers from 110 subjects were analyzed.

The structure of the questions were:

- Gender and age
- Walkability, balance and general health level
- Activity level

- Factors affecting walkability (slippery, snow, rain, wind, minus degree)
- Usage of safety devices in all modes of transport (bicycle helmet, anti-slip device, seatbelt, boat life jacket, luminous tag, ...)
- The relative importance of each type of safety devices
- Occurrence and number of fall during wintertime

An overall hypothesis was that age, health and activity level might correlate with occurrence of fall during wintertime. In a first model a regression analysis was performed with the number of fall without anti-slip device as dependent variable and age, walkability and physical activity level.

Examining first model regarding relation between the number of falls without anti-slip device with health and age factors, did not illustrate a high degree of correlation between dependent and independent variables. Among 108 subjects, 33% had experienced fall during that winter. The analysis showed that experience of fall is not an appropriate variable to be explained by age and health variables.

In a second model the attention was drawn toward the activity level. The aim was to analyze if activity level can be explained by factors such as age, balance level and walkability level. This model displays relatively higher significance ($p < 0.05$) compared to the first model.

In a third model, the aim was to test if the relation between age, activity level, and health significantly correlate with the usage of anti-slip devices. The hypothesis was that the use of anti-slip devices is significantly correlated with age group and health conditions. This model reveals weaker results. Therefore age and health do not offer a significant variance in the usage of anti-slip device. Does it suggest that usage of safety devices is independent of health and age.

Besides the three models described above, many other relations were analyzed between health and age of respondents and their usage of safety devices. The results did not show significant correlation between usage of anti-slip devices and age or walking and balance. It seems that using safety devices is an accepted norm among subjects regardless of their health conditions. A conclusion is that occurrence of fall and use of anti-slip device cannot be explained by age, walkability and balance ability with strong significance. On the other hand, the level of physical activity is indicated to correlate with age and walkability.

Discussions

A further step in this research can be to focus on the impact of gender in using safety devices. In this regard, a multi-regression model was conducted to study the impact of gender that did not generate clear interpretable results and hence is not presented in this paper.

There still is a lack of knowledge concerning pedestrians' perceptions of safety aspects related to the use of anti-slip devices during community walking. A case study aimed to explore pedestrians perceptions of walking safety, balance, slipping risk, priority for own use and subjective criteria for a well functioning anti-slip device has been made. Results indicate that both anti-slip properties and balance enabling properties of the device need to be considered for safe community walking. (Gard *et al*, 2018)

Since not everyone is not using anti-slip devices all the time the environment should be adopted to all users. We need to rethink the definition of the concept 'design for all' in the context of all weather conditions. A new integrated and multi-dimensional framework for understanding the accessible built environments for all, in all weather conditions, has to be developed. A framework should be developed by integrating three different disciplines urban design, social and behavioral studies, and the maintenance aspects (Pasupuleti and Berggård, 2014).

Issues of accessibility are more evident in the Nordic countries with long winters and where public spaces, streets and open spaces are covered with snow and ice for several months of the year. Based on preliminary findings, we can conclude that such a framework can be useful to study different environments and how people try to adapt to such changes in weather conditions by using anti-slip devices, kick sledges etc. More importantly, it reveals that the designers should take a good account of site considerations while planning for design for all in all weather conditions.

Acknowledgements

Most of the laboratory studies on walking on slippery surfaces has been made together with Agneta Larsson, Gunvor Gard and Peter Rosander. The statistical analysis of the questionnaires from the elderly pedestrians has been made by Saeed Ebrahimabadi. The study of a new framework for design for all in all weather conditions has been made by Ram Pasupuleti.

Old age-related stereotypes, inclusion and the development of ‘age appropriate’ neighbourhoods

Carlo Fabian¹

*¹University of Applied Sciences and Arts Northwestern Switzerland, School for Social Work,
carlo.fabian@fhnw.ch*

Abstract

The environment in which one lives, i.e. the neighbourhood, can have a strong impact on people's well-being and health. This also applies to older people. The number of older people increases in absolute and relative terms, especially in urban areas, while the lifestyles of older people are becoming more diverse. At the same time studies show that age-appropriate planning of living environments is often influenced by stereotypes. We investigated how 'age-appropriate' living environments are conceived, practiced and lived (based on Lefebvre) and to what extent age-related stereotypes affect these processes. The research methods were interviews and walkthroughs conducted with experts from various planning disciplines as well as with current (aged 70-80) and future (aged 50-60) older people. Furthermore, this article refers to the model “setting-approach”, to discuss the importance of participatory urban and environmental development. The findings show that negative stereotypes predominate. These stereotypes have an impact on the planning processes. In thus, older people are normally excluded from these processes. This has an impact on the quality of the neighbourhood and so this has a potential impact on well-being. For planning-related social work, this means that older people must be involved more in the design of their living environments.

Keywords

neighbourhood, stereotypes, inclusion, participation, setting-approach

Introduction

When we think about inclusive and ‘age appropriate’ living environments and neighbourhoods, three essential aspects are important.

a) In addition to the *Universal Declaration of Human Rights* (United Nations, 1948)¹, we have the *Principles for Older Persons* (United Nations, 1991)² and the concept and program of Age Friendly Cities.³ These documents are all key documents. They emphasise among other things the *participation in social and political issues* and address the *inclusion of people*. Furthermore, the “New Urban Agenda” (United Nations, 2017a) also emphasises participation as an important element of urban development.

b) A second important aspect in the context of age appropriate’ living environments and neighbourhoods is that, according to Henri Lefebvre (1991), the *city and the urban are not places, but social conditions of mutual inspiration and collective action* (see also Vogelpohl, 2015). This means that the people, the communities, the society and the interactions and dynamics between the people as well as between the people and the built are what city and urban is and not (only) the built.

c) The third relevant aspect is determined by two central concerns of social work: the *empowerment of people* and the *reduction of social inequalities* in order to contribute to social justice and to the well-being of all people. These concerns can hardly be considered independently. One focus of social work is on disadvantaged or less powerful people. These target groups often include people with disabilities, as well as children and older people. In these groups, injustices are united and accumulated for various reasons.⁴

Access to and the possibilities of using public spaces in urban contexts, i.e. neighbourhoods with all their offers and infrastructure, are of the greatest importance in connection with social inequality. The question of inclusion and exclusion very quickly arises. The focus must therefore be on the *development of appropriate neighbourhoods*. The central challenge here is how the *development processes* of neighbourhoods can be designed so that both the *result and the processes themselves* are as inclusive and equitable as possible.

Inclusion is a central concept in that it emphasises that all people should be involved, that they must be part of decisions concerning their life and be part of the community. Inclusion is more than a concept; it is an attitude and a human right. However, how can inclusion be achieved? In the context of public space, it can be argued that access to the public space is a prerequisite for inclusion. In other words: if a person does not have an access, but her or he want or need to have it (and here we are essentially talking about physical access), they are excluded. However, it is not only necessary to consider how the public space itself is used, but also the access routes etc. by whom and how. Rather, great attention must be paid to who uses the public space and who does not. One can assume that not all people use the public space in our cities, because the use is too highly thresholded. Reasons for the high threshold can be very individual. Possible examples are: Uncertainty, disorientation, poverty, special needs - physical or mental, the feeling of not having the right to use the public space. Special attention must be paid to

⁴ See for further information concerning the principles of Social Work: <https://www.ifsw.org/what-is-social-work/global-definition-of-social-work/>

these aspects. This applies in particular to all people who, for various reasons, are already less integrated in society, i.e. who are "weaker" in this sense.

In the following, one such vulnerable group, older adults, will be described in more detail based on a concrete project. Although older adults have the same rights as adults, they are often stigmatised or even discriminated against because of many stereotypes and prejudices (see for a comprehensive overview Ayalon & Tesch-Römer, 2018).

Neighbourhoods, the setting-approach and stereotypes

There is a clear link between the place and environment of older people and their quality of life and well-being (Petersen & Minnery, 2013). This means that the quality of the living space must not only be high, but also suitable for the people who live and work there. On the other hand Wolf & Mahaffey say (2016, p. 59): "Design and Planning professionals have long been influenced by the belief in physically and spatially deterministic power over people and the environment, a belief that their representations of space become space." (c.f. Buse, Nettleton, Martin, & Twigg, 2016) Based on these statements, the decisive question is how such places and environments are planned, developed and implemented. Even more decisive is who has the power of decision and who is involved in these processes.

In addition, a look at the Ottawa Charter of Health Promotion (World Health Organization, 1986) and the setting approach advocated there, is important when considering the link between the environment and the health or well-being of people. Following the setting approach, health is to be established and maintained in people's everyday lives. A setting is a social context in which people spend time in their everyday lives and which has an influence on their health. This social context is relatively permanent and subjectively conscious of its members. It expresses itself through formal organisation (e.g. company, school, kindergarten), regional situation (e.g. municipality, district, neighbourhood), equal life situation (e.g. pensioners), common values or preferences (e.g. religion, sexual orientation) or through a combination of these characteristics (Rosenbrock & Hartung, 2012, p. 497). People therefore pursue their everyday activities in the settings, are committed and involved. Context-related, organisational and personal factors interact and influence health (c.f. Fabian, Drilling, Niermann, & Schnur, 2017). The setting approach thus makes it clear that in different areas of life and different social systems there are different conditions that influence health and should therefore be taken into account for health-promoting measures (Sterdt & Walter, 2012). The model by Kilian, Geene and Philippi (2004) shows the connections between behavioural and relational orientation as well as participation, but also empowerment in the setting approach (Kooperationsverbund Gesundheitliche Chancengleichheit, 2015, p. 15). The core strategies of the setting approach are the inclusion and participation of all relevant actors, process orientation, the development of integrated concepts and the inclusion of interventions that influence both individual behaviour and structural conditions within the setting (Sterdt & Walter, 2012).

If this is not done, the context conditions will not be (enough) suitable for the people in this setting, in our case the neighbourhood, and thus it has a less good impact on the well-being of the people, or in the worst case even a negative impact.

In the coming years, the number of people aged 60 and over will increase significantly (United Nations, 2015, 2017b). At the same time, older people will become more and more diverse. The lifestyle of people over the age of 65 is changing towards more activity and engagement, especially in sport, access to modern technologies, sexuality, education, fashion, etc. In this age group, new needs and desires will emerge that can draw on potentials, resources, values and lifestyles and competences, time, finances or health (Jopp, Rott, & Oswald, 2008; Santoni et al., 2015).

Stereotypes are «...schemas that we have for people of various kinds» (Gilovich, Keltner, & Nisbett, 2006, p. 18). Due to stereotypes, we tend to judge people on the basis of a particular criterion (or fewer criteria) such as gender, nationality or age, and to attribute characteristics to them (Aronson, Wilson, & Akert, 2014). Such schemes are important in everyday life, but they can also be wrong and lead to wrong judgements about people (Gilovich et al., 2006). Research shows that there are many age-related stereotypes - mostly negative ones (c.f. Australian Human Rights Commission, 2013), e.g. declining competence; less energetic, motivated or creative; less productive; less technologically-savvy; less favourably. There are also positive stereotypes (e.g. more reliable, loyal, stable and dependable), however “These positive images of ageing may not be sufficient to prevent discrimination based on stereotypes.” (Abrams & Swift, 2012, p. 4)

The rising relevance of the neighbourhood

The number of older people without family networks and social support through the family, will increase because of changing family structures, longer life expectancy and differentiated lifestyles (Siebel, 2007). Peer groups other than family-based ones will be of particular importance, while the neighbourhood as a reference framework and as a place of everyday life will provide the social arena for the formation of these peer groups. Despite the increasing relevance of social proximity, the spatial dimension of ageing has not yet been thoroughly addressed by research – except when dealing with a specific architectural project for “housing for the elderly” (eg. Petersen & Minnery, 2013; Peterson & Warburton, 2012). Concepts such as the “age-friendly city” (World Health Organisation, 2007), which support active ageing facilitated through the promotion of the core indicators of health, participation and safety, focus on the city as a whole (c.f. Mouleart & Garon, 2016; c.f. Fabian et al., 2019, accepted).

The production of space

Place and neighbourhood are relevant dimensions for the wellbeing of older people and the opportunity to age in place. Day (2008, p. ii) points out that several different types of environmental inequalities can occur. One is through insufficient access for older people to decision-making processes affecting the local environment (c.f. Walsh, Scharf, & Keating, 2017). According to Lefebvre urban spaces are not places, but social relations that are constituted by the interplay of collective action and reciprocal inspiration (Vogelpohl, 2015). In this context Henri Lefebvre’s theory of *the production of space* (1991) is a key contribution to the relational spatial development perspective. In his urban theory, Lefebvre states that space is a product of the dynamics between everyday practices and perceptions of people (*spatial practice*), cognitive concepts or theories of space (*representations of space*) and the spatially imaginary (*spaces of representation*). The production of space “is composed of three dialectically mutually co-constituting spheres or facets: conceived space, perceived space, and lived space” (Pierce & Martin, 2015, pp. 1282; c.f. Fabian et al., 2019, accepted).

Research question, design and methods

This research project focuses on the question of how 'age-appropriate' living environments are conceived, practiced and lived and to what extent age-related stereotypes impact on these processes.

A case study approach was adopted and an interpretative perspective of lifeworld research was applied for data collection and analysis. The starting points for the two cases (both in Switzerland) were an intergenerational project to promote physical activity and a new city square. For both cases, semi-structured interviews and walkthroughs were conducted with experts as well as with older people. A total of 11 experts in both cases, from the fields of urban planning, landscape architecture, science, product development and social work were interviewed. A total of 10 interviews (usually supplemented with commented walks) were conducted with older people. In addition, two world cafés with older people and two reflexive workshops with older people and planners took place (c.f. Fabian et al., 2019, accepted).

Results

From the point of view of older people

The older people interviewed describe relatively similarly a few central forms of everyday practices in the neighbourhood. A frequent practice is walking in the neighbourhood, which is also associated with sitting down and even reading. Walking and sitting down is sometimes linked with observing changes in the neighbourhood and a form of 'being involved'. This means that older people feel that they are part of life, of society, or of what is going on, they feel to be included. In addition, drinking coffee, eating out, attending appointments and events in the neighbourhood were often mentioned. All these activities generally have an important social function in the sense of encounter and exchange - they express a social practice. Some, while for one person, being able to use public transport to shop elsewhere in the city was more important, mentioned the importance of being able to shop near home. As soon as physical problems limit the use of public transport, the neighbourhood becomes increasingly important. Referring to her walks in the neighbourhood, one interviewee said that she was grateful that service workers took older people out into the fresh air: «And the neighbourhood itself is very important for this. Because taking wheelchairs onto the tram that is nevertheless a big task.» (70+/4) The neighbourhood is often seen as an important place for recreation, allowing walks and outdoor activities, as well as a place for 'being involved', to get out of the immediate surroundings and for social exchange (c.f. Fabian et al., 2019, accepted).

From the point of view of the experts

In the context of 'age-appropriate' planning and development projects, the interviewed experts often describe older people as a homogeneous and fragile group. Although different needs and requirements are attributed to older people with regard to the neighbourhood, these differentiated age images are hardly included in the planning and development of 'age-appropriate' living spaces. As soon as planning and development are involved, this contradiction between one-sided, stereotypical and differentiated age images is resolved in favour of uniform planning. Wheelchair accessibility and barrier free design in particular is considered to be of central importance.

In planning processes, however, older people are not only seen and characterized as people with physical limitations, but sometimes also as people «who are somewhat older, who also tend towards dementia.» This view of older people as a fragile group in turn finds its way into planning-related measures.

It appears that age is often associated with functional limitations. In particular, topics such as balance problems, walking difficulties and health problems are often mentioned in connection with the idea of old age and ageing. These age-related stereotypes in the form of ascribed needs materialise in age-related aspects of planning and the subsequent realisation of construction projects. Here the existence of (age-appropriate) seating is considered as one of the most important planning element for the planning and development of age-appropriate living spaces.

Although in both case studies older people are consistently described as homogeneous and fragile, with exceptions, and rarely as a diverse group, the notion of age usually remains diffuse. The term 'age-appropriate' also remains diffuse. On the one hand, places that have certain planning elements (see above) are described as 'age-appropriate'. On the other hand, characteristics such as wheelchair accessible, obstacle-free, barrier-free, paved, easy to understand, quiet, safe, green planted, shady, etc. are subsumed under 'age-appropriate': «...the almost stricter requirements are the ones we have for handicapped accessible constructions. This has nothing to do with age. There we have strict guidelines, which concern handicapped fairness, and if you keep to these, you are, like, automatically also age-friendly.» (c.f. Fabian et al., 2019, accepted).

Participation

In both cases older people were only marginally included in the development processes. Certain age images or stereotypes of the experts play a central role: «I never had the feeling that they wanted to have a big say in things». This expert also said that if you let too many people have a say, nothing actually comes out in the end...because everyone blocks everyone else.” Another expert said: «One could of course have involved even more older people, but that is of course still difficult, probably to find the right people, who also have the ability - I don't know.» and «I clearly mean, an old person sees it differently, but you also have to have the person who can really bring it to the point». Another expert said: «Yes, we had an event where we presented the project...When you talk to older people, you also have to transmit relatively simple messages, let's say, so that you are understood...and the feedback we received was relatively simple. In that sense we actually got confirmation that we were on the right track.» (c.f. Fabian et al., 2019, accepted).

Conclusions

Results show that there are many age-related stereotypes. Most of them are negative - in that, we classify people purely based on their age and see them e.g. as not very interested in anything, stupid, satisfied with little or indifferent. These stereotypes have a very strong influence on our perceptions, thinking and acting, including planning and design. A second consideration is that although older people are seen as one big group, looking at our society, we see great diversity among older people. This means that older people have different economic opportunities, health resources and challenges, interests and lifestyles and much more. Each individual has different needs and opportunities in many areas, including their living environment and neighbourhood. What we see is a contradiction: On the one hand,

we see the generalized stereotypes - this is a misleading image of old age. On the other hand, we see diversity in old age. This is a more appropriate image. The challenge is how to develop age-appropriate and diverse neighbourhoods with this rather misinformed image of older people.

A finding from the research project is that planners often say that old people do not want to be involved in planning processes or that they have difficulties to express what they want. The consequence is that older people are not asked at all right from the beginning. This excludes older people from having the opportunity to be involved in the planning of their own living environment from the very beginning. Such an attitude actively excludes many older people. In the end, planners do not know what good solutions look like (Fabian et al., 2019, accepted). This exclusion of older people is in itself unacceptable and in the end ageist. In addition, with regard to the setting approach, it is evident that this hardly leads to the development of the best solutions for the older people concerned.

What we have learned so far from our research is that if we want to design our neighbourhoods so that they suit a range of older people, we need to know what needs and opportunities they have. To do so we have to include older people in the planning and design processes. We must acknowledge that they are the experts of their lives, needs and opportunities. We must not only offer them the opportunity to participate, but we should also strive to provide methods and frameworks that they want and can participate in. We have to focus on the persons themselves and not on the problems, deficits or weaknesses associated with young or old age. Finally, participation, or more generally the inclusion of certain population groups, is not only a human right. Participation is also a question of values and attitudes and only lastly a question of methods (c.f. Fabian & Huber, 2019; Fabian et al., 2019, accepted).

Alternatively, as it says in the New Urban Agenda: "Adopt sustainable, people-centred, age- and gender-responsive and integrated approaches to urban and territorial development by implementing policies, strategies, capacity development and actions at all levels, based on fundamental drivers of change,..." (UN, 2017) Whereby also here the choice of the word "age responsive" has to be questioned. An alternative term would be "age sensitive".

Talking about age-appropriate developments, participation is a central concept. Participation includes social and political aspects among other things, and address the inclusion of people (c.f. United Nations, 1948, 1991, 2017a; World Health Organisation, 2007). However, participation goes beyond that. Participation include a theoretical concept, social values and working methods. Central elements are: information, collaboration (co-development, co-creation), taking part in decisions (design, realization) and co-responsibility (c.f. Fabian & Huber, 2019).

Four central recommendations can be noted: First, social work (and others) must advocate for a differentiated look at older people. The focus may not be only on problems and limitations, but above all, on the potentials and resources of older people. Second, training and sensitising of planners and other professionals regarding stereotypes and ageism is needed. Third, the local focus in developing (all) age-appropriate neighbourhoods is crucial. Fourth, research and evaluations with a focus on output and outcome must be done.

Friendly and accessible public spaces: the Venetian case

Abstract: The population of Venice is falling drastically and its people are ageing steadily and living a unique existence as regards the town's morphology. Venice has no car traffic and thus urban accessibility for elderly people is neither straightforward nor always safe. The reasons which make it difficult to live in the historic centre are bound up with its specific features: its town framework is made up of 120 islands linked together by bridges, alleyways and *fondamenta* canal side streets frequently free of rails, all of which are accessible primarily on foot as the public ferry service cannot link up all its urban spaces and areas. In the light of this, it is important to enable elderly people to get out into open spaces for both health reasons and in relation to the passage of the seasons as well as for socialising. This research work enquires into the physical barriers in the town which can make moving around its open spaces difficult, the various technical and architectural solutions which have been adopted over the years to improve public transport and urban policies designed for an age-friendly town.

Keywords: age-friendly cities; urban accessibility; Venice; elderly people

Age-friendly and accessible cities: the Venetian case

The United Nations' population scenarios forecast world population growth to over 9 billion by 2050 with an over-60s segment increasingly significantly all around the world, with the exception of Africa. "The number of older persons in the world is projected to be 1.4 billion in 2030 and 2.1 billion in 2050, and could rise to 3.1 billion in 2100. Over the next few decades, a further increase in the population of older persons is almost inevitable" (United Nations New York, 2017). In this context Italy has one of the oldest populations in the world and forecasts for 2065 confirm this trend with a percentage of over-65s which will rise to 32.6%, an increase of 10% over 2015¹. The future holds an ageing population, then, and an ability to cope with this is a must, above all in urban decision making and urban planning terms.

Specifically we must orient ourselves to what the World Health Organisation defines Active Ageing (WHO, 2002) which takes the form of a process in which health, participation and safety opportunities are optimised to improve quality of life for the ageing.

¹ <http://www4.istat.it/it/anziani/popolazione-e-famiglie> (Date of access: 19/05/2019)

The backdrop to this action may be the towns, given that it is in these that half the world's population lives. "More older people are also living in cities. The proportion of the older adult population residing in cities in developed countries matches that of younger age groups at about 80%, and will rise at the same pace" (WHO, 2007).

Age-friendly cities must be the future, then, in which the urban, social and physical space will be designed to foster urban and architectural scale life styles. The essential characteristics of age-friendly cities relate to external spaces and buildings, transport, housing, inclusion, participation in social life, communication, information, health services, public support services and also the potential for employment. In particular, on the subject of the outdoor environment, WHO project consultations highlight that elderly people and those interacting significantly with them focus attention on a vast range of urban landscape and built environment characteristics which contribute to solidarity to elderly people. Recurring themes in cities all around the world are living standards and safety, which take the concrete form of practices such as: a pleasant and clean environment, green spaces, somewhere to rest, age-friendly pavements, accessibility, a secure environment and age-friendly buildings.

The majority of these characteristics might seem specific to Venice, a town whose morphology and life organisation are exceptional, moreover if compared with other cities. Inherently traffic free, Venice's transport is slow and takes place primarily on foot: here people meet in its alleyways and chat in the squares and this favours social contact, nurtures neighbourhood relationships and limits isolation, above all for the elderly and those living alone. The data regarding the resident population in the historic centre of Venice shows the over-65s accounting for 31%² - above the national average - while the number of residents has been drastically dropping over the last ten years. Thus whilst, on one hand, the town centre is depopulating, on the other it is increasingly the elderly who lead their everyday lives in it. Despite its 'positive' urban space characteristics, the lagoon city is, in actual fact, not an easy one for the elderly as there are a great many architectural barriers, and because the absence of pavements and roads with traffic is offset by over 430 bridges linking the 120 islands making up the historic centre (Figure 1). These bridges, built over the centuries and each different from the next by shape and materials used, are an impassable constraint for people with motor disabilities using wheelchairs and also for those whose ability to move around is reduced. Originally built without side barriers at a time when the town's life was changing and, in particular, as the use of horses was diminishing, these are, for the most part, without handrails. Those in stone and brick - the majority - comprise no end hand rail to support people by their very conformation and this makes them challenging both up and down, especially in adverse weather conditions.

² Data from Venice town council dating to 31/12/2018 from sestieri San Marco, Castello, Sant'Elena, Cannaregio, Dorsoduro, San Polo, Santa Croce and Giudecca. Accessible on the following link: <https://www.comune.venezia.it/it/content/classi-det-2018> (Date of access: 19/05/2019)

Figure 1. View of the Venetian *insule* (islands) and their over 430 bridges (highlighted in red).

Venice and the slow mobility paradox, from urban obstacles to action to overcome them

To gain an understanding of the current accessibility situation in Venice the authors carried out research whose objective was to capture the situation in the lagoon and collect information on and describe the great deal of work done on it over the years (Tatano, 2018). This first phase was then followed by a further two, one linked to scientific study³ of the ramps used to solve the bridge accessibility problem and the other to outline certain accessible itinerary hypotheses for people with limited motor capacity. In this third phase, in particular, all the town centre's bridges and differences in pavement level were mapped for the purposes of outlining a knowledge base on Venetian accessibility and understanding how accessible the town really was. Given the complexity and variability of the town's solutions, some routes were totally accessible and others 'elderly person friendly'. Focusing attention on the elderly, then, the situation is relatively positive, although a range of action remains to be done to guarantee independent movement to this segment of the population. In actual fact, even before the 2004 Piano per l'Eliminazione delle Barriere Architettoniche (PEBA) 55% of the bridges were normally equipped with a sort of handrail (iron railings with an easy to grip rail for the elderly at the top), as shown in Figure 2.

³ The research was funded by the European Social Fund and enabled the various types of existing ramps to be assessed scientifically.

Figure 2. Map of Venice's *insule* highlighting (in blue) bridges with handrails.

If, on the other hand, both action to place handrails on walls (Figure 3) and action taken to make bridges accessible to the disabled in wheelchairs (Figure 4) are considered, the percentage of bridges accessible to the elderly rises to 85%.

Figure 3. Map of Venice's *insule* highlighting (in light blue) bridges with added handrails.

The data thus shows that almost all Venice's bridges are 'elderly friendly'. If we consider only fully accessible bridges (Figure 4), however, the percentage drops drastically to 8% and this shows how

much work still remains to be done in the town in the light, furthermore, of the fact that not all elderly people are independent in their movements and that many are obliged to use wheelchairs outside.

Figure 4. Map of Venice's *insule* highlighting (in yellow) bridges with access ramps.

In addition to pedestrian access routes (overland routes) there are water-based routes used by public ferries (very few people have private boats, especially motor boats). Such services do not link up all urban spaces, however, which can be reached on foot for all purposes and in any weather conditions, although this can involve a series of urban 'obstacles' represented, above all, by bridges but also by steps and differences in ground level along them.

Both of these have been made more accessible over the years, equipping boat services and implementing a range of work to ensure access to some bridges and improving the user friendliness of the majority of these.

Over the last twenty years the town council has undertaken a range of work, regarding new ramps and handrails where these were not present, in particular. The rails on Venetian bridges, added over the centuries for the purposes of guaranteeing safety and avoiding people falling into the water, are made of various materials: wood, brick and iron. Brick walls, in contrast with iron railings (Figure 5, left), do not enable people to grip them for support and thus these have been equipped with new handrails (Figure 5, right) to facilitate use both up and down and providing a fundamentally important support⁴. This work increased the percentage of bridges accessible to the elderly by approximately 30%.

⁴ In conjunction with the board of cultural heritage, Venice town council drew up specific guidelines for the positioning of handrails on bridges with brick walls (Comune di Venezia, 2016).

Figure 5. (Left) Example of a bridge with an iron rail. The top of the rail is used as a support by the elderly both up and down the steps as it allows for good grip. (Right) Example of a bridge with a brick wall and added handrails on both sides.

More tangible and complex work - above all architecturally speaking - relates, on the other hand, to the addition of ramps on bridges of various types and gradients, incorporated into the structure of the bridge or added to it to ensure removal if required (Figure 6). In addition to linear 8% gradient ramps, facilitated step ramps have also been used in Venice (Figure 7), an ‘alternative technical solution’ (Comune di Venezia, 2011) in which linear gradients have been replaced by a series of elongated, sloping steps linked by a chamfer or a triangular profile instead of a riser. This type of ramp is less elderly friendly, however, as it does not allow for full step stability, but as these ramps are generally positioned to one side of a pre-existing bridge, people can choose the method they prefer (either ramp or steps).

Figure 6. Ponte delle Sechere, an example of a fully accessible bridge. In this case the bridge has been equipped with both handrail on its brick wall (left) and a facilitated step ramp.

Figure 7. Example of facilitated step made up of two units (gradient 14% - 6%) and a triangular chamfer (gradient about 42%). Average step gradient is 13.4%.

There are also temporary linear ramps put in on some bridges for the Venice marathon which, although they remain in place for much longer than is required for the race itself, are removed for several months.

Lastly, certain small steep gradient ramps were installed on Ponte Contarini in 2017 to facilitate passage with shopping trolleys. This is an experiment designed to help people using trolleys and carts.

These latter are used on a daily basis by the elderly to carry their shopping and avoid carrying heavy bags by hand and also to lean on, as a support (in the same way as a walking frame).

It is not only Venice's bridges, however, which act as barriers and the urban space itself is full of obstacles, such as small differences in height in the various parts of the town or unfenced off canal sides which can lead to people falling into the water, especially the sight impaired and the blind. Since 2017, to cope with the former type of obstacle (generally just a few steps), the town council has been building low gradient ramps (Figure 8) to connect up alleyways, *fondamenta* and squares at different heights. These ramps are being built in brick and covered in trachyte and Istrian stone, like the existing pavement, and only a few of these have handrails.

Figure 8. Ramp with a gradient of 5% to get over a pavement height difference between two alleyways.

The issue of canal side streets with no railings is a more complex one. These rarely have walls, although their traditional design makes for good visibility thanks to the colour contrast between the grey trachyte pavement and the pale coloured Istrian stone edge. Tactile pavements for the visually impaired have been used only in certain parts of the town to highlight dangers (the Piazzale Roma bus terminal and ferry services stops) and gates have been restored at landing quays. Acting on all the town's *fondamenta* and alleyways directly facing onto the water is impossible, as it would radically modify the very nature of Venice.

Old people's homes in the town centre

In this unique and, at the same time, complex urban system, the 2018 data shows that two out of every five elderly people live alone⁵, mainly as a result of the death of a spouse. To enable everyone - including those who are no longer independent - to remain in their home town, the town council generally has to supply home care and provide services to make urban spaces more user friendly. Using open spaces and green areas contributes to the wellbeing of the elderly, maintaining their sense of the seasons and the passage of time and combating isolation and the loss of autonomy and social relations. Keeping elderly people in their own social contexts without isolating them is to be preferred, therefore (Iacomoni, 2009), but it is not always possible as a result of a lack of home care services and opportune home technological solutions. Furthermore, elderly, non-independent people need care and spaces suitable to their physical and illness related needs. Thus when necessary, the elderly tend to be grouped into residential complexes, old people's homes and care homes, with attempts being made to keep people in the nearest building to their home area.

In Venice, too, a range of buildings have been adapted for use by independent and non-independent elderly people and, in some cases, Alzheimer's sufferers. The care homes, old people's homes and communities for elderly people in the town centre include some which are large (such as Residenza San Lorenzo in Castello with 180 beds⁶) and smaller ones (such as the two communities in Dorsoduro which host 4 people each at most). So that elderly people will not live in isolation and alienation, residences for elderly people must enable the latter to keep up their contacts with the outside world and thus be suitably situated in the urban fabric and a direct extension of it. To this end, Residenza Zitelle on Giudecca island⁷ is a virtuous example of incorporation into the urban context: in a project designed to renovate a 1930s building, access to the alleyways was restored and an urban courtyard was added, including spaces open to the whole district (urban vegetable gardens, day centre, meeting room, medical and assistance services, boules court, etc.). The Zitelle *insula* itself (Figure 9) - the site of this building - is linked to the rest of the town by a public ferry service and to the Giudecca's other *insule* via 'elderly friendly' bridges (all the Giudecca's bridges have handrails or accessible ramps). This enables the elderly people in the residence to go out for a walk and avoids them feeling isolated from the rest of the urban context.

Conclusions

Via an analysis of the de facto state of Venice’s accessibility we have seen that, in a town as complex as this from a town planning perspective, it is possible to create an age-friendly itinerary network thanks to the intelligent use of architectural solutions. The example of Venice and the solutions adopted to resolve its various ‘physical barriers’ can be a useful reference point for other towns with important historical heritage. The paradox is that while, on one hand, the town promotes projects designed to foster an increase in its accessible trajectories and thus the user friendliness of its public spaces for people with reduced motor capacities (physical action), on the other hand it has begun to adopt ‘protection’ systems for certain spaces which previously acted as public, meeting and sharing spaces from uncontrolled tourism⁸, closing them off and limiting their use as is now occurring for many small alleyways ending at the canals. And, to an even greater extent, it is closing itself off to protect itself from potential tourism, adding anti-bomb barriers in Piazzale Roma and at the foot of Ponte della Costituzione⁹.

⁸ An example is the recent Regolamento di Polizia e Sicurezza Urbana, approved on 16/05/2019 by the town council, whose 82 articles set out a series of behavioural rules for the town (<https://live.comune.venezia.it/it/approvazione-regolamento-polizia-urbana-venezia-16-maggio-2019>, date of access: 20/05/2019).

⁹ The flower pot barriers at the foot of Ponte della Costituzione, on the traffic access side of Piazzale Roma, were located there in 2011 after a car drove over it as a prank and got as far as Campo San Geremia.

At the same time, the private housing spaces which traditionally extended into the courtyards and alleyways are no longer used as shared spaces as they, too, are 'occupied' by large numbers of tourists: everyday living spaces tend increasingly to be confined to within the four walls of the home while open spaces now under siege from huge scale tourism no longer guarantee co-existence between residents and tourists. 'Physical' accessibility, then, cannot effectively guarantee the creation of an age-friendly town if the town loses its uniqueness and is transformed into a straightforward tourist destination. What is needed is thus no longer solely physical action but governance policies to reactivate these features.

What has been described makes clear that Venice is now facing three conflicting phenomena: a falling resident population in the historic centre, its progressive ageing and a huge surge in mass tourism. As a result of this latter factor, whilst physically accessible to the elderly, the town is actually closing off to them, obstructing the resident population in its use of public spaces and generating a certain aversion to visitors from residents (especially the elderly). For a town to be truly age-friendly, then, co-ordinated initiatives of a physical and managerial nature are required. On one hand urban spaces must be adapted via planning and technological action with accessibility in mind. On the other, public space creation for the community is required, with the latter understood as a physical space but also an activity incubator, especially devoted to the elderly in order to foster active ageing in harmony with local communities and the town.

Abstract: In the current panorama of many cities, difficulties associated with public transportation and with public space, limit the access of the elderly, also creating difficulties for other age groups. One of the objectives of the project is to carry out a review of the literature on mobility and accessibility characteristics of the elderly. Another is to develop a methodology for diagnosis of age friendly spaces, analysing the area and the population affected. The MOBI-AGE project intends to use two case studies, Coimbra and Porto. This article is a first attempt to identify the main characteristics and main indicators of the mobility of the elderly and the quality of the public space, whose optimization can contribute to an accessible city for all.

Keywords: age-friendly cities, elderly urban mobility, accessibility, central historical spaces, public space.

Introduction

Some paradigms related to the mobility of goods and people have been changing, especially since some of the factors that interfere with mobility patterns, such as age, have changed. In fact, the demographic pyramid is changing, the elderly population is increasing and, consequently, mobility patterns have also changed in the last decades. If up to now the quantitative of this (elderly) population could be considered balanced with that of the younger population, it is found that it is expanding worldwide, and in many countries the number of people over 65 exceeds the number of persons under 18 years of age. This population, with some restrictions in terms of personal mobility, does not always have easy access to urban spaces and to components of the transportation system.

The analysis of the aging index, which is shown in the following chart (Figure 1), also shows the strong aging trend of the population of Portugal, with some prominence for the municipalities of Coimbra and Oporto.

Figure 1- Evolution of the index of aging according to the Census (ratio-%) (Source: PORDATA)

The urban centers concentrate a good part of the population aged in the cities, which generally inhabits the oldest buildings. By definition and in most of these cities, it is in these areas that historical monuments and other factors of tourist attraction are located. Senior tourism is also a consequence of the general aging of the population and has been increasing. This scenario means that urban centers, especially historic centers, are places where more seniors are concentrated in comparison with other areas of the city, whether residents or visitors. In these areas, neither the urban public space nor the transport system are adequately adapted to the access and mobility needs of this age group.

Seniors have specific travel needs that can affect their mode of transportation choices. In order to encourage the maintenance of activity and the adoption of sustainable travel practices during aging, it is crucial to understand what factors influence the mobility of the elderly. In addition, it is necessary to understand which indicators characterize the accessibility of the elderly to the city's public spaces and to the collective transportation system. This article aims to consider these two issues (accessibility and mobility) and develops a framework of factors related to their impact among the elderly.

Thus, the MOBI-AGE project (supported by the FCT-MIT Portugal funding program, referred to in the acknowledgments) aims to develop a literature review focused on the themes of urban aging, healthy aging, active aging and elderly mobility and accessibility. In addition, and through two case studies, one in Coimbra and another in Porto, emphasizes the adequacy of the urban space and the transportation system to the needs of the older population. At this stage and from the literature review, it was possible to identify the main factors that contribute to an accessible city for all or an age-friendly city.

After this introductory chapter, the MOBI-AGE project is presented and, following, a review of the literature on urbanistic barriers in urban areas. In the first place, the factors that characterize the mobility of the elderly are discussed, exploring the relationship between their personal characteristics and their travel patterns, their movement through public transportation, and also the urban design and its impacts on the pedestrian mode. Next, the methodology is presented, namely emphasizing the factors that characterize the accessibility of the elderly to the city public spaces and to the collective transport system are synthesized. It is also characterized the accessibility to the network of transport

and communication infrastructures and the location of activities of interest for the elderly. Then, ways of acting are suggested. Finally, a chapter is presented with some conclusions.

The MOBI-AGE Project

The MOBI-AGE project is an exploratory project whose objectives are to review the literature on the mobility and accessibility of the elderly in the transportation system, the suitability of the urban space at the level of the urban design and infrastructures of paths and the accessibility to the pedestrian paths, both public buildings and access points of the transport system. Using some information from this review, two case studies (selected areas of urban rehabilitation areas) will be analyzed, one in the historical center of Coimbra and another in the historical center of Porto.

These studies aim to identify needs and failures that limit the mobility and accessibility of the elderly population. This process goes beyond cabinet work and also aims to create social innovation by holding participatory and dynamic collaboration sessions with this population, assessing more precisely needs and aspirations. The review of the literature will contribute to the preparation of the queries, to be applied in these case studies.

As a final goal, the project intends to elaborate a methodology for the diagnosis and classification of historical central spaces as to their suitability in terms of mobility and accessibility for the elderly population. This methodology should inform the future development of interactive information platforms for end users of the space, both residents and visitors, that will allow them to find solutions to their travel needs.

Characteristics of Mobility Of The Elderly In The Urban Environment - Literature Review

Introduction

We consider it important to evaluate the impacts of the built environment and transportation systems on the mobility and accessibility of the elderly. During the study, there was a need to differentiate between mobility and accessibility because, since they are different concepts, they require different approaches. Mobility is able to travel without limits, have information about travel options, know how to use them, use them and have the means to pay them [1]. Accessibility is a term that describes the greater or lesser ease with which people access goods and services, facilitated either by well-organized transport systems and that move people efficiently as more activities are achieved by these people, also benefiting from quality of infrastructure [2].

Thus, this literature review began, in the first part, to study the theme of elderly mobility, addressing the relationship between the characteristics of the elderly and their travel choices, followed by a study on the needs and barriers of the elderly population in the use of public transport and, finally, an analysis of the impact of urban design in the pedestrian mode, especially the elderly. In the second part, the theme of the accessibility of the elderly to the urban space was studied, analyzing the favorable and inhibiting characteristics of the transport and communications infrastructure network, access to the public space and the transportation system, also identifying the places of interest for the population.

The characteristics of the elderly and their travel choices

For men and women who fail to drive, alternative means of transportation become a necessity. However, the effective use of alternative transport is relatively low [3]. Therefore, a good understanding of the travel patterns, needs and factors influencing the mobility of the elderly is needed to design an improved access to public transport and, in general, a life of active aging while maintaining economic and social participation, as well as the quality of life.

Depending on the age group, the population has characteristics that may influence their mobility. In order to understand how the elderly move and identify mobility patterns, it was considered important to analyse, in a general way, the relationship between their characteristics and their travel options and the choice of mode of transportation.

People tend to slow down walking with advancing age [4]. The study [4] concluded that while young adults (25-34 years) walk at an estimated velocity of 1.25m/s, the elderly (65 years or more) walk at an estimated velocity of 0.96m / s.

As people get older, they are making fewer and fewer trips, with shorter duration and less distance. This phenomenon is more pronounced in the female population. Characteristics such as being single, having poor health conditions, low educational level or low income are also negatively associated with the mobility of the elderly population.

Women are more dependent on walking, cycling and public transport, while men use the car more often. Possession of a valid driving license is positively related to mobility in general and to the frequency of travel and, of course, the likelihood of traveling by private car. Older, high-income people tend to use less collective transportation.

The elderly in collective transport

Collective transportation can allow autonomous journeys for those who cannot or do not choose to drive. When older adults (60 years of age or older) have inadequate access to the transport system, they tend to experience low levels of physical activity, reduced independence and high health risks [5]. Strengthening the mobility capacity of older people should be seen as an integral part of efforts to promote the overall development of society, especially in the transport sector [6]. From the point of view of social and economic quality of life, public transport services should be increasingly friends with the elderly to ensure that older people can maximize mobility and access to the opportunities they need to access [7]. Next, some of the travel characteristics that are positively related to the use of collective transportation by the elderly are presented.

Also the integration of transport in certain buildings, a subject still under-explored, can allow a varied set of solutions. Buildings can be excellent supports for transport systems, allowing not only the use of the public space by atriums related to the street and urban structure, but also the greater articulation of the pedestrian circulation channels with the other sectors of the transport system, allowing greater comfort (in relation to the type of climate) and accessibility of the pedestrian, in particular of the elderly [8].

An urban space suitable for pedestrians also has a positive connection with the probability of an elderly person making a collective transport trip. Older people prefer to travel by bus due to cheaper travel fares and taxi fares due to greater accessibility. Older people tend to avoid rush hour and prefer to travel during other times of the day. The density of bus stops encourages the population in question to use public transport more frequently [8].

The impact of urban design in pedestrian mode

Pedestrian mode is a critical component of a transportation system. In addition to driving, it is the most popular mode of transport compared to other modes of transport, such as public transport or taxi [9]. Walking is often necessary even when using a car or public transport [10]. Adults aged 65 years and over resort to this mode of transport on a substantial part of their journeys, around 9% [9], and for most of the elderly almost all journeys begin and end by walking [11]. Thus, knowledge about the characteristics of urban design that can facilitate an active lifestyle can allow the development of a system of decision support for public health, land use and transport policies [12].

Older people prefer neighbourhoods with safe and continuous walks, with aesthetic pleasant and several pedestrian paths to make the movement easier and pleasant. The existence of street lighting and the possibility of perceiving that there is little traffic are essential aspects to your sense of security. The presence of slopes and microclimatic conditions (sunlight, ventilation, humidity) influence the travel choices of elderly people who prefer mild temperatures and low humidity to opt for active mobility.

Concerning the sense of security, the elderly feel more motivated to walk if there are other people on the street, whether walking, running or cycling, or the presence of a police or security. As for the time of day, the elderly prefer to go hiking early in the morning. On the contrary, large crowds, people who cause disturbances or individuals to ask for money can be considered obstacles.

The elderly population takes into account the characteristics of the urban environment when deciding to walk and is more likely to do so if the pedestrian path is quiet, clean and maintain. The presence of parks, gardens, trees and shadows, places to rest, eat or use the bathroom, variety of views and activities and accessibility to public transport are also decisive characteristics. In addition, the existence of ramps on sidewalks, as well as the presence of handrails in the presence of stairs or steps, signposted walkways and routes with low pedestrian traffic (one way), are factors that influence the walk of the elderly. In contrast, the existence of abandoned or under construction houses, garbage, inadequate lighting, fallen trees or branches, poorly lit plant walkways with unexpected interruptions forcing individuals to walk on the road with vehicles have been identified as inhibitors of use of the pedestrian mode by the elderly.

In addition to its role in optimizing pedestrian circulation, it is also up to the urban design to promote interfaces (creation and strategic location), adequate modes of transport and accessibility that are complementary to the pedestrian mode, favouring access to public transport in pedestrian areas and location of shelters and stops in a suitable way [8].

The accessibility of the elderly to the urban space

Accessibility is one of the crucial components to be considered in cities that are favorable to the elderly [13]. Accessibility refers to the possibility for citizens to achieve the goods and services they need, as well as all other activities [9].

In order to increase urban accessibility for the elderly, it is fundamental to think of both the infrastructure network (transport and communications) and the location of activities of interest [14]. Intervening in these two elements means improving urban accessibility for all groups, making physical limitations more easily accommodated [15].

Transport and communications infrastructure network

The concept of accessibility is related to the way people achieve the desired activities through transport systems [2], [9]. Systems that are efficient and allow people to reach a greater number of locations per unit of time are viewed positively [9].

The public transport system should be fully accessible to all citizens. Limited access to collective and private transport has often been identified as one of the main factors contributing to the social isolation and economic poverty of certain groups. Older people are often identified as being socially excluded because of the difficulties associated with journeys away from their homes, to access services and facilities, especially for non-car drivers.

Barriers related to the feeling of low personal safety, difficulties in carrying heavy loads, few bus stops, long distances on foot, low population density, poorly designed and/or poorly maintained bus stops, a low ergonomic vehicle design, pedestrian infrastructure in poor condition, difficulty getting on or off the bus, parking cars at bus stops, insufficient time for crossing in traffic lights and crossings in dangerous places, have serious implications for the elderly users in terms of security perception, use and comfort. The elderly population favours, on the contrary, factors such as punctuality and little waiting time, cleanliness, the existence of bathrooms, low travel costs, safe driving and seats available.

Location of activities of interest

Accessibility is also related to user use and satisfaction of public areas [13]. There is thus a need to identify the destinations that are of interest to the elderly, as they have different needs and interests in relation to younger age groups. It has been found that having nearby destinations such as restaurants, libraries, pharmacies, grocery stores, hospitals, banks and various stores, within a range of action easily reachable on foot or by public transport can contribute substantially to the accessibility of the elderly to the public space.

Methodology of Intervention

Summary of indicators to consider

After this review of the literature, it is possible to make a synthesis identifying the main indicators of an inclusive and friendly city of the elderly, while being of benefit to all other age groups. The

distinction between the concepts of mobility and accessibility was fundamental in this process in order to better identify the factors associated with the way the elderly perceive and use public transport and the public space in general. With regard to the mobility of the elderly, we sought to understand the mobility patterns, their movement through collective transportation, identifying barriers and needs in the use of these modes and how to promote the improvement of the transportation system. In the case of accessibility, they assessed their difficulties in accessing the transport system and public places, emphasizing the importance of good urban design in this process.

Barriers associated with pedestrian access to stops and low population density were identified as main barriers to the use of collective transportation. The characteristics of urban space positively related to the use of public transport have to do with well-designed and maintained infrastructures, as well as with high population density and jobs. Other barriers are the long distances to walk, service availability, stocking and waiting times. On the other hand, the high density of collective shuttles, frequency during off-peak periods, clear information on routes and waiting times, cheap travel fares and punctuality are positively related to the use of public transportation. Vehicle-related barriers such as difficulties in carrying heavy loads and entering or leaving the vehicle (lack of ramps) were also identified. Vehicles with access ramps, shelters at the stations and comfortable and available seating, as well as cleaning, are seen as characteristics that attract the elderly to public transportation. Finally, the barriers encountered in relation to personal safety were speed and volume of traffic, insufficient crossing time in traffic lights, crossings in dangerous places, inappropriate behaviour of other passengers, improper parking at bus stops and high crime rate in the neighbourhood. Positive indicators are measures of calm, speed reduction and presence of police or security.

In terms of urban design, many barriers related to the mobility and accessibility of the elderly, such as empty houses and abandoned lots, garbage and pollution, were also identified. In contrast, the characteristics favorable to the elderly are a well-maintained built space, the presence of parks, gardens, trees and shade, places to rest, eat or use the bathroom, a quiet and peaceful environment, buildings or statues of personal significance or historic and clean. We have identified barriers related to the state of the rides, such as trees or fallen branches, walks covered with weeds and / or damaged. The characteristics of the walks positively related to the mobility and the accessibility of the elderly are continuity and good connections to the rest of the network, with ramps, illumination in the crossings, pedestrian paths and adequate pavement, the presence of connections in escalators or elevators to overcome differences of way to allow continuous paths and also the existence of handrails in the presence of stairs or steps. Identifying neighborhood characteristics related to older people's sense of security found barriers such as criminal activity, slow or inadequate police response to crime, inadequate lighting, the presence of windowless walls, connections through parks and large crowds. On the other hand, the public lighting, the presence of police or security, the traffic lights with sufficient passage time and the presence of people were identified as positive aspects. Finally, we found that the lack of access to places of interest was negatively related to the mobility and accessibility of the elderly. Instead, having access to public spaces that integrate older people with younger people, families with children and tourists, parks, public transportation, health facilities, pharmacies, restaurants, libraries, grocery stores, banks and stores were seen as positive features.

Sizing principles

On the basis of the conclusions obtained from this review of the literature, namely the identification of barriers and characteristics that promote active mobility and the accessibility of the elderly to public spaces and the transport system, it was possible to define, from the outset, some design principles that can be useful to propose a first set of actions in favour of a city that is friendly to the elderly, listed with available and applicable legislation.

This process is still under development.

Conclusions

This literature review allowed to identify the main characteristics and possible indicators of suitable cities and spaces for the elderly, to be applied in the case studies. This study was vital to understand the barriers and preferences of the elderly on the use of public transportation and public space in general, as well as identify their perception of accessibility and usability in relation to their interests and needs. In the next phase, we will identify the direct relationship between the identified characteristics and the indicators that we intend to quantify and evaluate, which will be crucial in the next stage of the project, also contributing to the preparation of the form, namely inquiry, to be applied in our studies case - within the selected focus groups.

The definition of these indicators is crucial for our main objective, to contribute to the creation of a diagnostic methodology that will lead to recommendations for the rehabilitation of the historic centers of the cities of Coimbra and Oporto (illustrative of centers with high proportions of elderly, residents or visitors) in areas that are friendly to the elderly. In addition to contributing to the development of a methodology for the diagnosis and classification of historic urban centers - and consequent recommendations for urban design and reformulation of the public transport system - it is hoped that this methodology could constitute a decision support system in the future development of interactive information platforms.

Abstract: It is worldwide acknowledged that the rapidly rising share of older people places a challenge to public policies at different scales. International and national guidelines have been underlying both the need to promote a more active ageing and the importance of creating the necessary means for decision makers and other relevant actors to work together (the governance mechanisms) to implement local active ageing policies. How are local governments and other actors conceptualizing active ageing? What are their priorities? What governance mechanisms are used to implement such policies? These are some of the questions that this paper addresses in the context of a southern European country: Portugal. Mixed methods were used to address the issue at stake. First, a study at the national level was developed by applying questionnaires to local stakeholders in order to map local active ageing policies. Second, a case study approach involving interviews in two NUTS III regions was conducted to understand the governance mechanisms. Findings confirm the 'passive organization type' in which European politico-territorial studies tend to place Portugal, as there are gaps in the way policies are formulated, implemented and evaluated, as well as a lack of coordination at various levels.

Keywords: Active ageing, Local policies, Governance, stakeholders, population ageing

1. Introduction

Population in developed countries is rapidly ageing and an increased number of older people is expected to live longer. Amongst the EU member-states, Portugal is already the fourth most aged country, in which approximately 21% of the population is more than 65 yo (EUROSTAT, 2017). Even though this phenomenon results from several positive societal factors, it also creates many individual and collective challenges. Up until the transition to this century, debates and policies on population ageing envisaged mainly the physical and psychological deterioration of the elderly along with the need to provide a range of services capable of coping with such limitations. This perspective was somewhat linked to Cumming and Henry (1961) disengagement theory, which postulates ageing as something inevitable that results in a decreased interaction between the older person and the respective community.

From the 90s onwards, a new representation of older people gradually emerged (Caldas and Thomaz, 2010), mainly influenced by two aspects. Firstly, ageing as a market segment of millions of people. A new image of the elderly – active, consumer, and participant – captured the attention, not only of marketers but also of decision-makers. Secondly, expectations towards public policies increased as older people became more demanding due mainly to the growth of literacy rates. Accordingly, seniors

began to fight for their economic, social and cultural rights in order to be an active voice in decisions that concern them (Naue and Kroll, 2010; ONU, 2002).

At a public policy level, a more efficient answer to the ageing phenomenon relies on a multi-scale intervention, i.e., involving various public entities at local, regional and central levels – whole of government approach – in close collaboration with other stakeholders – whole of society approach. The challenges posed by this cooperation should be taken into account by policy makers in the elaboration and implementation of policies to promote active ageing.

The World Health Organization (WHO), the Organization for Economic Co-operation and Development (OECD) and the European Commission (EC) concomitantly refer to active ageing as a process not only of individual responsibility but also of collective responsibility, implying productive activities, be they economic or social, without putting aside the physical and mental well-being (José and Teixeira, 2014).

Accordingly, national and EU policies seek to overcome the social imbalances resulting from an ageing society, such as the pension system, social security, and restrictive measures harmful to the interests of retired citizens (Pereira, 2011). However, if we take into account that each place has a specific cultural pattern which influences its political culture and social practices, one may argue for the nuclear importance of the "local level" in the process of designing a plurality of policies in society. Being a crucial element in the central government/society dialogue (Ruivo, 1990), local government and local stakeholders must thus act as key players in fostering active ageing. According to the Age Platform Europe (2011), they are in the best position to meet the needs and challenges facing the older population, as they are at the forefront of capitalising on opportunities for active ageing. These local or even regional actors are linked to education, health, sports, transportation or even employment policies that will emphasize good active ageing practices.

The design and implementation of policies aimed at improving the living conditions of the population depends on the involvement of several actors, be they public or private, such as local governments, non-profit organizations, among others (Bárrios and Fernandes, 2014). From the few studies focused on this subject, it is worth mentioning the works published by Barbosa (2015), which compares Portugal and Sweden with regard to local initiatives focusing on population ageing, and Bárrios (2017), which seeks to identify and analyse policies and political support for ageing, taking into account the characteristics and needs of the older population. It is possible to conclude from these studies that local governments, endowed with skills and resources, play a key role in improving the conditions of older people, since there is, in fact, a role of greater proximity to the citizens, accompanied by a greater capacity to mobilise the remaining local stakeholders.

This paper attempts to contribute to the research developed with respect to local public policies supporting active ageing in the Portuguese context, seeking to answer the following questions: how do local governments and the other local stakeholders conceptualise active ageing? What are the priorities underpinning the promotion of active ageing (e.g., urban design, healthy lifestyles, social and financial support)? How are policies of active ageing designed and implemented and through which governance mechanisms?

2. Methods

In order to answer to the questions above listed, a mixed-methods approach, combining qualitative and quantitative methods and analyses, was applied.

In a first phase, so as to obtain a broad picture of the local policies implemented in Portugal, a self-administered questionnaire was created and sent via an online platform to several key actors working in the following institutions: Local Government (LG); the charity institution of Santa Casa da Misericórdia (SCM); Community Care Units (CCU) and Senior Universities (SU). These actors and institutions were chosen due to their nuclear role in capitalizing opportunities for active ageing, thus being perceived as proxies of the most salient dimensions- social, health and educational- involved in this process.

The goals of this phase were twofold: to understand if the actors were aware of different concepts and notions related to active ageing and to map the ongoing and future initiatives developed within this context, from a multi-level perspective.

The applied questionnaire comprised three sections. In the first one, participants had to identify key concepts of active ageing and respective source of knowledge. In the second one, participants had to rate in a Likert scale (1- highest priority to 5- lowest priority) the degree of priority concerning a set of strategies that the Local Council should adopt to face the challenges posed by an ageing population. In the third section, participants had to identify implemented policies, cooperating entities and, in those cases, the main outcomes.

482 answers were collected, among which 162 were complete and 320 incomplete. In the end, and after a detailed analysis, 153 answers were included: Local Government (n= 96); Community Care Units (n=24); Santa Casa da Misericórdia (n=23) Senior Universities (n= 10), which geographical distribution is presented in Figures 1, 2, 3 and 4.

Figure 1 – Response distribution- Local Government

Figure 2 – Response distribution- Santa Casa da Misericórdia

Figure 3 – Response distribution- Community Care Units Figure 4 – Response distribution- Senior Universities

After the questionnaires' analysis, key actors from Aveiro and Coimbra- the 2 more representative regions in the previous phase- were contacted to explore some additional information through semi-structured interviews. More specifically, we intended to further explore two aspects: (i) the process of elaboration and implementation of active ageing-related policies at a local level and (ii) the ways in which the actors work and interact with local, regional and national entities in this process.

Eight interviews were conducted following a script divided in three sections. The first section focused mainly on the challenges that active ageing may pose to the local power and local policy definition and implementation. In the second part, the goal was to analyse the extent of the horizontal cooperation between the several entities involved, exploring if and how the policies were being coordinated with a wider network of institutions that also promoted active ageing. Finally, and drawing on a multilevel perspective, we intended to explore the inter-connection between policies defined at a local level and other government levels, namely regional, central and European. From the eight interviews conducted, five were with LG actors and three with actors from SCM, one CCU and one SU.

A descriptive analysis with a software (SPSS) was conducted on the data collected through questionnaire whereas the interviews were transcribed and subjected to a content analysis.

3. Results and Discussion

(i) Concepts and perspectives by key-actors

The analysis of the answers to the first section of the questionnaire, where participants had to identify key concepts of active ageing and respective source of knowledge, shows that “active ageing” and “healthy ageing” were the most familiar concepts for more than 90% of the participants. On the other hand, 50% participants from CCU and 43% from SCM did not know the concept “productive ageing”. One could attribute these results to the fact that, in both entities, almost 50% of the participants were

not in high rank coordination positions, hence not being responsible for the organization. Still, an analysis of the answers of the participants which were the heads of SCM and CCU shows that only half were aware of the concept.

A more adequate interpretation is that the actors of these two particular entities of services provision related to Health and Charity deal mostly with older people in more vulnerable positions, thus not recognizing immediately their potential as active members of society. The opposite is true for the actors working at LG and SU, whose familiarity with the concept, may be due to the fact that they are closer to active older people, thus having a more positive view on their potential contribution to society. In what regards the concepts of “healthy cities” and “aged-friendly cities”, the LG actors are the ones showing a higher degree of familiarity with the concept, probably due to their role in elaborating and putting these concepts into practices and policies.

The link between knowledge of a specific concept and proximity to the entities’ reality and actors’ position within the institution is also corroborated by the analysis of the knowledge sources. In what concerns the concept of “productive ageing”, results indicate an association between knowledge of the concept and working in entities that value and envision related practices. As such, SU actors indicate that they were informed of its existence in classes, which is coherent with the entire mission of the entity whereas LG actors refer that the information on the concepts and related actions are transmitted via institution or via European guidelines.

The relatively low percentage of actors from SCM and CCU learned about this concept by themselves, with only 10 % indicating that it was via institution. As for SCM, only 10 % were informed of the concept of “productive ageing” via institution.

In what refers to the perspectives more valued by these entities, it is important to highlight that, for LG actors, the matters concerning public spaces and urban design barriers are perceived as of low priority. This may mean that there are already measures being implemented to tackle this issue and/ or that there is a more urgent concern towards the promotion of individual practices related to healthier lifestyles and leisure activities. On the other hand, there is a major concern from SCM actors regarding public space design. This may be explained by the fact that this entity deals with more dependent older people, which may also influence the high percentage of SCM actors that devalue the contribution of older people to decision-making processes.

For the CCU actors, who also contact with a population with a higher level of dependence, the less valued perspective is also the one concerning the contribution of older people to decision-making processes as opposed to the high priority attributed to the implementation of a good transport system that may prevent social isolation.

Differently, actors from SU, in line with the ones from LG, value less the Public Space design and more the involvement of older people in decision-making processes. These choices reflect, respectively, the type of population that they are used to deal with who tends to be more active on physical and cognitive aspects.

(ii) Implemented initiatives

After mapping the knowledge of concepts and the perspectives held by key actors, the implemented initiatives were identified and analysed in order to have a representation of what is currently undergoing in the Portuguese territory. As shown in Figure 5 below, the majority of the initiatives are elaborated and implemented by LG, unsurprisingly given the specificities of the Portuguese culture and political tradition. Social action is the field with more initiatives, being these related to policies which promote support and benefits, particularly financial ones. Health- related initiatives appear in second place, referring to events that promote health education and sports.

Figure 5 – Absolute Frequencies of implemented initiatives by area

On a related note, it is worth mentioning that, at the local level, many initiatives and policies are elaborated and implemented through a system of networks, as is evidenced by the number of local partnerships. LG (cfr. Figure 6) is the most prolific entity in establishing partnerships, namely through “Rede Social”, which is defined as “a planning and execution device of participatory public policies and an instrument that promotes synergies and a coherent action towards an active social state” (IESE, 2012:7).

Figure 6 – Absolute Frequencies of Partnerships with local actors and LG

Even though the added value of these networks, their large majority are still at a local level, thus lacking a coordination with national entities, and, what is more, a systematic assessment of the results.

The aspects outlined so far on the process of policy-making and underlying governance mechanisms were corroborated by the data collected through the interviews. A fundamental aspect relates to the perceived positive role played by networks established at a local level, such as “Rede Social” and CLAS (platform of debate, at local level, focused on the participation, representation and collaboration between public organisations and private social initiatives”(Law- Decree no.115/2006, 2006). The work developed by these two networks is viewed by our interviewees as crucial for promoting active ageing practices, particularly due to their ability in motivating local entities to work together for a joint cause. Intermunicipal Communities (IC) and Supra- Council Platforms(SCP), the latter partaking “ Rede Social” are also viewed in a positive way, given their role in optimizing the planning and management of financial and social resources.

However, it should be noticed that most of the interviews were conducted in Aveiro IC which has addressed, in recent years, the optimization of several aspects concerning the process of active ageing. Accordingly, in what refers to the formulation and implementation of policies, LG actors from Aveiro Region are the ones most concerned with consulting the population in order to identify existing problems and define measures that can tackle citizens’ specific needs. This is not the case for other regions in Portugal, where still prevails a weak culture of formulating and implementing local policies for active ageing.

On a related note, one of the most salient problems identified in our study is the lack of an efficient multi-level cooperation. This is particularly true for the relation between local government and intermediary and central instances, especially in what refers to the clear definition of roles and inherent responsibilities. Without specific guidelines on the matter of ageing provided from the central power, there is a disparity between regions, given that most of the initiatives rely on local contextual features, such as demographic and financial aspects.

According to Matos (2013), improvement of multi-level cooperation may result from connecting CLAS and PSC (NUT III), at a council level, to Social Security Institute, at a national level, that, in turn, could respond directly to the central power. This model enables the formal conditions to articulate different levels of power, either between actors as well as policies and instruments.

Only the interviewees from Aveiro Region mention this cooperation, agreeing on the relevant work conducted by the CLAS and PSC. However, the connection between PSC and central government is still perceived as inefficient.

Another important result of the present study refers to the perception held by LG actors on two main gaps: the lack of financial support to develop more initiatives and the insufficient legislation concerning what they can and should do within the context of policy and practices development. Although the interviewees from Aveiro region show a higher level of knowledge of national and European policies on ageing, especially of the ones that were already in course, overall, those are not widely known. What is more, it appears that the organizational structure of LG entities is lacking venues and means to inform their employees on European guidelines and to apply systematically to communitarian initiatives and funding.

4. Conclusions

The definition and implementation of active ageing-related policies requires a broader view on the multidimensional nature of the ageing process. True, political agents are increasingly thinking and debating the pervasive issues of population ageing. However, as argued by Walker and Maltby (2012), even though "active ageing" is widely promoted by the EC, this does not automatically translate into devising and designing policies to be implemented. The results of our study shed some light on some of the strengths and shortcomings of this process as it is perceived by the key actors who partake it.

In what concerns the design of policies and the development of initiatives, one of the most salient issue is the lack of a clear cooperation between levels of power, which is viewed as fundamental to approach some of the challenges posed by an ageing population. This is also a key-element put forth by Ferrão (2015), who posits the importance of multilevel governance to public policy design and implementation while defending that it can only be efficient as much as the needs, priorities and capacities of private and public actors are taken into account.

This consideration is aligned with the view on the importance of consulting the local population on a regular basis so as to have an informed insight into specific concerns, needs and limitations. Another salient theme of our data was the role of networking for more efficient governance mechanisms. This process is perceived as paramount to design and implement active ageing policies and initiatives; as ageing is a concept that encompasses many areas, it is an added value to devise joint (network) measures. Local governance mechanisms play herein a crucial role by enabling a network of partnerships between local entities, ranging from third sector institutions, public and private providers, academic institutions and civil society. On this regard, "Rede Social" is a strong lever to aggregate and get the local agents in constant cooperation. However, the absence of a multilevel view (encompassing the central level) limit the scope of the initiatives, which are mainly focused on the promotion of healthy lifestyles and leisure and occupation activities, as there are no guidelines from the central government that may serve as a guide to local government. As for the intermediate

structures, namely at the level of the IC, the interviewees identified the need for these structures to consolidate their role as places for debate and sharing, for policy implementation, for clarification and, above all, for monitoring what is at stake.

The results obtained with this study allowed a deeper understanding about what is being outlined at the local level regarding active ageing whilst identifying some of the inherent mechanisms of the decision-making policies process. Firstly, it was possible to identify the areas in which the entities were most involved, namely the promotion of healthy lifestyles and occupational and leisure initiatives, with a very strong commitment on the part of local governments in the area of social security and financial benefits. Secondly, it showed the prominence of a culture of decision-making in network, based mostly in the Rede Social. Finally, it corroborated some concerns express by research on governance within the Portuguese context, specifically regarding the lack of guidance from the central administration on these matters, as well as the low interconnection between the different governance levels. In this context, it was possible to observe that an intermediate level of governance may be the key to these issues, with the CIM and the CPS holding the potential to foster debate and common practices among the various municipalities in a region.

On a final note, it is important to mention two main limitations of this study, that may be tackled in further research. The first one refers to the sample size, which was relatively small, hence not allowing a generalization of the conclusions. The other one relates to the importance to combine our approach with (i) a mapping of these policies in the Portuguese territory, in order to understand the different geographical contexts (coastal / inland or rural / urban) and (ii) the extension of the study to other regions of the Portuguese territory so as to explore if these findings are context-dependent or if they reflect a more national-based reality. Finally, it would also be of great value to compare the differences and similarities between the Portuguese context and other European countries, especially in what concerns the degree up to different countries align their policies with European guidelines or lack thereof.

EU urban strategies 2014-2020: exploring the functional area approach

Carlotta Fioretti¹, Martina Pertoldi²

¹European Commission, Joint Research Centre (JRC), Seville, Spain, carlotta.fioretti@ec.europa.eu

²European Commission, Joint Research Centre (JRC), Seville, Spain, martina.pertoldi@ec.europa.eu

Abstract: There is a vast literature that has investigated processes of spatial reconfiguration, contributing to the emerging of a "new urban question" that not only reframes traditional urban issues but also challenges our understanding of what are cities today. At the same time, the "European city model" still persists, particularly regarding the institutional role of cities, increasingly considered as relevant policy actors. This "urban paradox" gives new emphasis on the urban regional scale and urgently calls for connecting the two dimensions, both in terms of dynamics on the ground and policy formulation. The paper addresses the topic by focusing on the functional area approach promoted by the EU Regional Policy discourse discussing how it shapes and legitimates new spatial configurations, with implications for urban analysis and policy approaches. The paper is based on the analysis of a database gathering nearly 1000 strategies for Sustainable Urban Development funded by EU in 2014-2020, with a significant number of functional areas. Interestingly, functional areas as a strategic approach do not only apply to metropolitan areas, big cities and FUAs. On the contrary, it has been used for different type of territories, beyond metropolitan areas, and suggests the need for better understanding what kind of spatialities and territorial arrangements they contribute to shape.

Keywords: EU urban policy; sustainable urban development; functional urban areas; strategic planning

Narratives on emerging spatial forms¹

There is a vast literature that has investigated processes of spatial reconfiguration of urban areas in the past 30 years (Sourel and Youn, 2009, Brenner, 2014). Once that the nineteenth century model of city as described by the Chicago School has clearly become outdated, literature has been engaged in finding new narratives and terms able to describe the new spatial forms urbanization was assuming. However, according to Soja (2011) a sort of inertia has prevented contemporary urban scholars from going beyond a traditional division between (dense) urban and (low-density) suburban, and such dualistic model has been reiterated by the majority of them.

¹ Neither the European Commission nor any person acting on behalf of the Commission is responsible for the use which might be made of the following information. The views expressed in this publication are the sole responsibility of the author and do not necessarily reflect the views of the European Commission.

On the contrary, what characterises the contemporary urban form is an erosion of the boundary between urban and suburban, with a convergence in the density levels, and the upsurge of an "expansive, polynucleated, densely networked, information-intensive, and increasingly globalized city region" (Soja, 2011, p.7). In such new urban form, it is not possible to distinguish between a centre and a periphery, and on the contrary it is found a "polycentric network of urban agglomerations where relatively high densities are found throughout the urbanized region" (*ibidem*). Even if in the words of Soja it is impossible to generalise, still there are some elements that characterizes regional urbanization:

- Processes of decentralization and recentralization, leading to the emergence of new unstable "inner cities", with new concentration of immigrants which lead to an unprecedented cultural and economic heterogeneity of the population, and growing conflict between domestic and immigrant populations.
- Increasingly dense and demographically as well as economically differentiated suburbs, characterised by new and heterogeneous way of life, more like what the urban used to be. Expulsion of some urban functions in peri-urban context capable of generating new centres.

City-regionalism can be seen as a powerful narrative which spans beyond spatial disciplines as planning or urban studies. The narrative has in fact lead to a spatial turns in economics. According to Soja (2017, p.198) if regions were seen in the past as purely "places where things happens" now they are seen as "powerful driving forces in themselves energizing regional worlds of production, consumption and creativity, while at the same time shaping the globalization of capital, labor and culture".

However, Morgan (2015) warns on the risks of adopting a narrow frame of this narrative, and seeing city-regions purely as vehicles for economic growth. On the contrary a broader perspective on regional urbanization can lead to address city-regions as strategic planning spaces to address sustainable urban development.

Along this line, Soja (2017) recommends on the one side to adopt a critical interpretation on the generative force of regional development. On the other side to recognize the negative effects of regional urbanisation, which implies higher densities and in turn means more strain on public services, worsening of environmental and health conditions, increasing social polarisation and spatial inequalities. What is important to stress, it that all those externalities together cannot be seen nor responded to as a simple extension of the metropolitan model, but must be reframed as a new urban question.

Secchi (2010; 2012) talks also about the new urban question, underling how historically, to a radical change in the structure of economy and society has also corresponded the emergence of an urban question. The present urban question can be defined on the basis of growing urbanization and spatial redistribution of the world's population, and it entails issues of climate change, right to mobility and increasing economic, cultural and spatial polarization. In relation to all these aspects, Secchi underlines the role of space and of spatial relations, and it concludes affirming how spatial capital should be intended as a central independent category for social and economic institutional organization.

Building on the tradition of Italian territorial political economy, Le Galès (2018) argues that contemporary urbanisation process can be explained only in relation to social and political transformation. According to him, it is true that we are witnessing some dramatic changes in the nature of cities but is not possible to generalize trends at global level, neither to identify as unique factor at stake macro-economic forces. In particular, for what concerns European cities, the traditional urban system has been proven stable over time, with some internal differentiations (p.232):

- A certain number of metro regions on the periphery of Europe (southern Europe, Northern England, Eastern Europe) are facing acute difficulties.
- Middle-sized middle-income metro regions are also struggling.
- High-income metro-regions are becoming more distinctive.

In Le Galès view, even if under threat, metro-regions are in a favourable position in respect to states, considering that through urban policy they can foster national economic growth, tackle social problems, face issues of sustainable development or climate change. In the 90's, political dimension was central to the flourishing of European middle-sized metropolises. Strategic projects and planning strategies were collective projects where urban elites sustained the representation of cities as a whole. The point is then to assess the capacity to govern of today's urbanised regions.

Impacts on the statistic definition of a city

As a consequence to the upsurge of new urban forms, the need of finding new statistical definition of what can be considered a city, as well as new ways of classifying urban areas emerged. In the EU, Eurostat launched a legislative initiative called 'Tercet' aimed at integrating the classification of territorial units for statistics based on population thresholds known as NUTS (Regulation (EC) No 1059/2003) with a classification based on territorial typologies which better qualitative defines the nature of territorial areas. In particular, at local level the definition of city (Dijkstra and Poelman, 2012) is based on the method developed by EC and OECD called Degree of Urbanization (DEGURBA). This method is computed using maps of built-up area and population density obtained from satellite images and national censuses. Moreover, it has been adopted the typology of Functional Urban Area (FUA) which identifies densely populated urban areas (cities) and adjacent municipalities with high levels (at least 15% of the employed population) of commuting towards the densely populated centres (commuting zones) (figure 1). At regional level, the typology of metropolitan region is introduced, which refers to one or an aggregation of (NUTS 3) region(s) in which at least 50% of the population live in Functional Urban Areas of at least 250.000 inhabitants.

Figure 1 From left to right: Urban centre, city, commuting zone and functional urban area. Source: REGIO GIS

If NUTS classification mirrors largely the administrative structure of the Member States, the territorial typologies introduced with Tercet regulation are on the contrary purely based on density and on a functional understanding of cities, allowing for individuating urban areas across administrative boundaries.

The importance of Functional Urban Areas can be illustrated by the size of the “spatial mismatch”: substantially a larger number of people live in the functional urban areas of European cities than in the core city (European Commission and UN-HABITAT, 2016, Lavalle *et al.* 2017). In the case of Milan, if the urban centre that corresponds to the municipality of Milan counts with 1,242,123 inhabitants (2011 national census), the City has 3,139,394 inhabitants, and the FUA counts with 4,138,424 inhabitants. That means that the population living

outside the municipal boundaries but gravitating around the Milan FUA is 133% larger than the one living in the core urban area.

In the case of many urban areas across the EU sustainable urban development would need to be coordinated across the whole functional urban area, although, in many cases cooperation between municipalities is weak or not existing at all. This is why the concept of Functional Urban Area beyond its statistical significance started entering the policy discourse in the EU.

New spatialities in the EU urban discourse

Traditionally two separate discourses have been developed within the EU policy frameworks and regulations (Atkinson, 2001). On the one side the *urban policy discourse* which since the early Urban Communications of the '90s has been focused on reversing the internal decay of cities, and in particular on the issue of deprived neighbourhoods. On the other side, *the spatial or territorial policy discourse* which during the same years was carried on by the European Spatial Development Perspective (ESDP) which has its roots in traditional regional development policy and pushed for the achievement of a balanced and polycentric development of European urban areas within a framework of competition and cooperation (Informal Council of Ministers responsible for Spatial Planning, 1999).

The urban discourse was more centred on social cohesion and had as main operational counterparts area-based initiatives (e.g. URBAN Community Initiative) intended as integrated response to the decline of districts within cities. This kind of approach, that is to say integrated, holistic, participated has characterised what has been defined as the EU approach to urban policy, in other words the "Acquis Urbain" (European Commission, 2009). The ESDP on the other side assigned priority to market processes and set the bases for a spatial agenda. Its basic goals were: economic and social cohesion, sustainable development and balanced competitiveness of the European territory (Atkinson, 2001). The ESDP also triggered the first reflections about the relationship between urban and rural areas.

In the first decade of the 2000s these two separate discourses started to converge. In particular, in 2007 the informal Meeting of Ministers responsible for Urban Development and Territorial Cohesion was held in Leipzig, Germany. During the meeting two important documents were approved: the Leipzig Charter, setting common principles and strategies for urban development policy throughout the EU (Informal Meeting of Ministers responsible for Urban Policy, 2007); and the Territorial Agenda, aimed at providing strategic orientations for a polycentric and balanced territorial development in the EU (Informal Meeting of Ministers responsible for Urban Development and Territorial Cohesion, 2007). According to González Medina and Fedeli (2015) the joint launch of the two agendas proved a growing link between the urban and the territorial dimension of EU policies in the framework of the Cohesion Policy. It is in fact in the same years that the EU supported urban actions were mainstreamed in the EU regional policy, in the sense that they stopped being separate Community Initiatives, and started to be part of the Operational Programmes funded through the European Investment and Structural Funds (ESIF). Moreover in 2012, DG REGIO changed his name and became explicitly the Directorate General of the European Commission both for Regional and Urban Policy. This happened in line with the Toledo Declaration of 2010 (Informal Meeting of Ministers of Housing and Urban Development, 2010) which stated that urban development should be integral part of the concept of territorial cohesion (González Medina and Fedeli, 2015).

The converging of the two perspectives influenced the way in which the urban dimension of the EU policy has been conceived, and a growing attention was put to the spatial and territorial development of EU cities and city-regions. The EU urban discourse shifted from being solely linked with the regeneration of neighbourhoods, to

embrace more broadly the objective of *sustainable urban development*; deprived neighbourhoods were inserted into wider territorial frameworks and strategies encouraged crossing administrative boundaries.

The discourse on functional areas has started permeating programmatic documents. The Territorial agenda 2020 (Informal Meeting of Ministers responsible for Spatial Planning and Territorial Development, 2011, p.6) states that "the cooperation and networking of cities could contribute to smart development of city regions at varying scales in the long run. *Cities should, where appropriate look beyond their administrative borders and focus on functional regions*, including their peri-urban neighbourhoods". At the same time, the Urban Agenda for the EU (Informal Meeting of EU Ministers Responsible for Urban Matters, 2016, p. 4): "acknowledges the polycentric structure of Europe and the diversity (social, economic, territorial, cultural and historical) of Urban Areas across the EU. Furthermore, the Urban Agenda for the EU acknowledges the importance of Urban Areas of all sizes and contexts in the further development of the European Union. *A growing number of urban challenges are of a local nature, but require a wider territorial solution (including urban-rural linkages) and cooperation within functional urban areas*. At the same time, urban solutions have the potential to lead to wider territorial benefits. *Urban Authorities therefore need to cooperate within their functional areas and with their surrounding regions, connecting and reinforcing territorial and urban policies*".

Themes with spatial connotation, that were previously discussed strictly in the territorial discourse, entered also the urban one, implying an acknowledgement of the emergence of new spatialities in the EU, of the erosion of the boundaries between urban and rural, of the upsurge of urban areas across administrative boundaries and defined by density and functional relations.

From the operational viewpoint, this turn has been reflected in the 2014-2020 framework for urban policy. During this programming period, mainstreaming was further consolidated and the investment in urban areas through integrated strategies of Sustainable Urban Development (SUD) becomes compulsory (5% of ERDF earmarked for SUD in each Member State). Moreover, special emphasis has been put on the importance of urban-rural linkages and on the functional area approach and new tools has been promoted such as the integrated territorial investment (ITI) to implement strategies on the level of functional urban areas.

This correspondence between political orientation and policy praxis makes even stronger the stress on the functional urban area concept, which is not seen only as a spatial category, but becomes also a strategic one. In 2014-2020 framework in fact, urban areas targeted by SUD are not defined by administrative boundaries, but are defined by strategies themselves (Balducci, 2014). Paraphrasing Morgan (2015) the EU emphasis on functional urban areas seems to legitimate these new spatial configurations as strategic planning spaces to address sustainable urban development.

How this new opportunity has been received by Member States remains to be investigated. In particular, the analysis of SUD strategies addressing functional areas will help to disentangle the implications of this approach in terms of policymaking.

Analysis of SUD strategies addressing functional areas in 2014-2020

In the following three paragraphs an analysis of the Sustainable Urban Development strategies addressing functional areas during the 2014-2020 programming period is discussed. The analysis is the outcome of an ongoing research project called URBADDEV "Support knowledge management of EU measures in Integrated Urban and Territorial development" run by the Joint Research Centre of the European Commission and entrusted by DG REGIO. The project has two main outputs:

- The creation of knowledge base on urban and territorial strategies supported by EU provisions called STRAT-Board.
- The drafting of a Handbook on Sustainable Urban Development strategies.

STRAT-Board is also an online webtool available at <https://urban.jrc.ec.europa.eu/strat-board/>. It visualises almost 1,000 urban and territorial strategies currently implemented across Europe. The strategies can be explored at different geographical levels: European, national and regional. Different aspects of the strategies are presented, such as territorial focus, size of population targeted, thematic focus, funding arrangements, governance structure and implementation mechanism. Data used for STRAT-Board were partially derived by a previous study (EPRC, 2017), and mainly based on a survey addressing Managing Authorities across the 28 Member States, run between February and December 2018.

In addition, the Handbook on Sustainable Urban Development strategies, currently under drafting, is largely based on a mixed methodology which entails a quantitative analysis of STRAT-board data, literature review and a selected number of case studies analysed in respect to methodological challenges tackled during the implementation of strategies.

First of all, the STRAT-Board database provides an overview of the territorial focus of 849 Sustainable Urban Development (SUD) strategies that have been funded by the 2014-2020 Cohesion Policy programming period.

Figure 2 Distribution of strategies per territorial focus (n = 849)

Figure 1 show that the majority of SUD strategies focus on cities (45%), followed by neighbourhoods (31%), functional urban areas or metropolitan areas (20%), a network of cities (4%), and a portion of territory with specific features such as a park, an archaeological zone, or an island (0.4%). In other words even if traditional target areas for EU SUD persist (cities and neighbourhoods), at the same times a growing attention to new spatialities across administrative boundaries can be witnessed, implying the emergence of a functional area approach. Put differently, the functional area approach identifies a space – usually different from administrative boundaries - in which a specific territorial interdependence (or function) occurs, and may need to be governed jointly. Adopting this broad definition of functional area, the joint consideration of the latter three categories of territorial focus², even if smaller in respect to the other two, becomes to be relevant.

² For most analyses that follow, the three latter categories of territorial focus are merged into one called "functional area (multiple municipalities)".

When looking at the territorial focus per Member State (see figure 3), it shows that the functional area approach can be found throughout all macro-regions, with the exception of a few countries. However some differentiations emerge when looking into more details. In some countries like the Czech Republic, Estonia, Croatia, Poland and Slovakia strategies focus exclusively on functional urban areas. In other countries like Austria, Belgium, Greece, France, Italy, Sweden and UK, the focus on functional urban areas is relevant but not exclusive, and coexists with other territorial focuses.

Figure 3 Map of SUD strategies in Europe per territorial focus.

The importance of the functional area approach becomes evident when looking at funding. Overall, the largest share of ESIF funding is invested into functional urban areas, which absorb 51.1% of the total funding (corresponding to 8.3 billion EUR). Cities are the second category absorbing 35.2% of ESIF investment (5.6 billion EUR), while neighbourhoods receive 13.3% of it (2.1 billion EUR).

As figure 4 shows, the majority of the investment in functional areas is in less developed regions, where the share of EU funding is highest (70%). This is interesting because it shows that this "new" type of territorial focus -although applied to a lower number of strategies- is the one receiving most ESIF investment.

Figure 4 Distribution of ESIF funding per territorial focus and type of region

In fact, strategies with the largest ESIF budgets (more than 100 million EUR) targeting functional areas are exclusively located in less developed regions of EU13 countries (Poland, Czech Republic, Croatia). On the other side, in EU15 countries there are a quite relevant number of strategies addressing functional areas with small ESIF budgets, probably mirroring the size of the population targeted (figure 5). For example in France, 50% of the strategies with a ESIF budget of less than 5 Million EUR address a functional area, while in Italy this is 33%. In fact, in France and Italy, many strategies are targeting functional territories formed by conurbations or networks of small towns with a population of few thousand of inhabitants. In those cases, the functional link is often thematic, such as a common touristic strategy. By pooling resources and establishing inter-municipal cooperation these small towns are able to form a critical mass. This sheds light on the nature of "functional area" category used for SUD policy, and makes clear that the functional area approach can be used for different type of territories, beyond metropolitan areas.

Figure 5 Map of strategies targeting functional urban areas with largest and smallest ESIF contribution

Passing then to analyse the thematic focus of strategies, it is possible to look at the thematic objectives (TO)³ more frequently addressed through the functional area approach. Data shows that strategies targeting functional urban areas address more TO4, that is to say "supporting the shift towards a low-carbon economy in all sectors" while strategies targeting neighbourhoods address largely TO9 "Promoting social inclusion, combating poverty and any discrimination" (respectively 209 and 217 out of 266). Moreover, a focus on transport (TO7) is almost exclusively addressed in functional urban areas.

These thematic priorities are confirmed when looking at key words characterising strategies. In particular the first two key words for functional urban areas are "mobility" (76% of the sample) and "energy" (52%). Quite interestingly even if "spatial planning" is not highly selected, there are other key words concerning spatial issues which are often recurrent, as for example public spaces (43%) and abandoned spaces (39%). Social issues (social inclusion, housing, disadvantaged neighbourhoods) are still important for functional areas but less than

³ In the 2014-2020 programming period, the European Structural and Investment Funds, in particular the European Regional Development Fund (ERDF), the European Social Fund (ESF) and the Cohesion Fund, will support 11 investment priorities, also known as thematic objectives. At the same time, the first four objectives constitute key priorities for the ERDF, and a significant part of the investment will focus on these areas (between 50% and 80%, depending on the region's level of development). More information can be found [here: https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32013R1303&from=EN](https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32013R1303&from=EN)

in the overall sample of strategies, while "entrepreneurship" and "jobs and skills" are both especially addressed in functional urban areas.

Figure 6 First 11 key words for functional urban areas, with percentage of use for functional urban areas strategies, and for all strategies.

On the other side, it surprises that the key word "urban-rural linkages" has been selected only in the 8% of cases while it would be ideally linked with wider territorial scopes. It is also true that, although supported by EU policy orientations and regulations, it remains a theme difficult to be addressed by urban strategies. Moreover, two important key words characterising the new urban question as emerges in the literature as well as in EU policy documents, that is to say "climate adaptation" and "migration", are hardly ever found across functional urban areas strategies (resp. in the 11% and 0% of cases).

Concluding it seems that the functional area approach is currently used to face more traditional physical or infrastructural issues as well as economic/job related issues. Social themes traditionally associated with core cities/districts, such as social inclusion, housing or deprived neighbourhood are entering also the discourse of functional urban areas to greater or lesser extent. On the other side, most up-to-date themes, which probably require also more innovative solutions, struggle to enter the mainstreamed policy-making.

Challenges in the implementation of the functional area approach

Considering the relative novelty of the functional area approach, it is no surprise that putting it into place can be challenging for bodies designing and implementing SUD strategies. A review of main existing studies (e.g. EPRC, 2017) and resources on current SUD development allows highlighting some of the major challenges of the functional area approach in SUD.

The first challenge when designing a strategy concerns the fact that in many cases the perimeter of the functional area is not given in advance but it is established specifically for the development of the SUD strategy. The establishment of the perimeter should be based on data evidence, but it depends not only on the territorial characteristics of the area, but also on the objective of the strategy, as well as on the relationships among the local actors.

This is why the perimeter of the strategic functional areas in SUD seldom corresponds to the one of the statistical FUAs as defined by OECD/EC methodology. This becomes evident through spatial analysis. When superposing the two type of areas, it emerges that only in half of the cases there is a significant overlap between the two (meaning that more of the 66% of the strategic functional area overlap with the statistical FUA). Almost never the perimeter coincides perfectly, but in the majority of cases (for example in France, Italy, Poland, Czech Republic) the strategic area is smaller than the statistical one. Only in a few cases (in Croatia, Belgium and England) the strategic area is larger than the statistical. Moreover there are many cases (for example in Greece, Spain, Austria and France) where the strategic functional areas do not correspond at all with the statistical FUAs.

Functional areas in SUD can be defined through criteria that are decided at national, regional or local level. Arguably, to ensure optimal strategic planning, when the perimeter is defined at national or regional level (in compliance or not with existing framework) some adaptability is required, to allow better adjusting to local realities.

An example comes from Poland where the territorial scope of SUD strategies is defined on the basis of national guidelines that set socio-economic criteria to delimit urban functional areas around regional capital cities. However, there is some flexibility as the Lublin SUD strategy follows the same criteria but they were revised locally to include other municipalities on the basis of important functional links with the regional capital. Another example is that of the Italian Region of Veneto where the regional Managing Authority has defined five eligible FUAs following an adapted version of the OECD/EC methodology, but then the specific target area for the SUD strategies has been defined at local level with more flexibility⁴.

Figure 7 Areas targeted by five strategies in Veneto compared to the FUAs

Key to a successful delineation of boundaries is to have access to data that allows for determining the appropriate indicators and criteria on the basis of which the area will be defined. Especially when the functional area is explicitly or uniquely defined by the strategy, it is difficult to retrieve comparable and homogeneous data

⁴ To these five strategies another one was added which does not target any Veneto's FUA, and it covers the area of Asolano-Castellana-Montebellunese.

across multiple municipalities. Being able to identify the appropriate indicators, it is not only important for what concerns the delineation of the functional area, but it is also extremely relevant in the phase of designing and monitoring the strategy. In order to collect and harmonize data, administrations have established partnerships with local universities and/or research institutes. In Brno, for example, the collaboration with the local university allowed to develop an evidence-based method to delimitate the targeted area. The delimitation was based on analyses of spatial arrangements and the intensity of spatial (functional) relations, using five main indicators: commuting to work; commuting to schools; migrations flows; public transport accessibility; and individual transport accessibility. As a result, the Brno Metropolitan Area (BMA) was defined with a perimeter rather similar to the one established by the OECD-EC definition of FUA. The BMA became a relevant scale for territorial analysis and since 2014 a series of investigation, data collection and production concerned the wider territorial area.

The implementation of the SUD strategy also served as an important trigger for the establishment of inter-municipal cooperation previously lacking. It was a test bed for implementing organizational integration, in the sense of a common coordinated approach of engagement of the stakeholders of the territory based on the partnership principle. The process was not exempt from challenges that could hinder the cooperation (scale imbalances among municipalities, contradictory priorities as emerging from diverse territories, conflicts among decision makers); nonetheless, it seems particularly relevant that the functional area approach has been internalized by other processes, becoming a catalyst for innovative institutional metropolitan cooperation (Feřtřová, 2018).

As the case of Brno highlights, when there is a lack of a common institutional framework, the consensus and cooperation among different public administrations becomes even more crucial, while clearly also more challenging. Territorial integration requires the creation of governance systems that enable policy coherence in spatially and economically homogenous, but politically fragmented, areas. The choice of how to proceed can be different according to the previous experience in terms of territorial cooperation. For example in Poland, central government guidance stipulated two possible models for cooperation: to form an association of municipalities, or to reach formal agreement between municipalities. Some smaller municipalities that have limited experience of working together have opted for formal agreements, but some larger municipalities where there is already experience with similar initiatives have opted for the association model.

Governance arrangements become even more complex when strategies involve actions on multiple scales. In many cases in France, even when the strategy looks at a metropolitan area or at a large agglomeration, often the interventions are targeting neighbourhoods within that area.

In addition, there can be a problem of political legitimation and responsibility with respect to the new territorial dimension, which can be even more substantial in case of power imbalances among the municipalities that constitute the functional area.

In order to promote and support territorial integration, new bodies have emerged in a number of Member States, or existing bodies have taken on new roles. These bodies may facilitate collaboration between different localities, take on responsibilities for management and implementation, or have advisory capacities.

Coherent functional area planning approach requires the establishment of shared governance process that enables dynamic interaction across spatial scales, policy issues, land-use functions, and a wide range of stakeholders.

Conclusions

Cities in Europe have changed. A trend towards regionalisation has involved also European cities, and a new urban question has arisen. Even if the European city model has proven to be quite stable, at the same time the capacity to govern of the new urban configurations cannot be taken for granted.

The EU urban policy discourse seems to have acknowledged the emergence of new spatialities. One of main signal is the emphasis that has been put on the new territorial typology of functional urban areas. Born as a statistical categorisation, the concept has entered also the policy discourse, and today it is used to indicate strategic planning spaces to promote Sustainable Urban Development.

That has been reflected also in the implementation of SUD strategies during the 2014-2020 programming period. The analysis shows, in fact, a growing trend towards developing strategic frameworks for wider territorial areas, across administrative boundaries. At the same time the analysis also shows that in those cases it is not correct to talk about strategies applied to Functional Urban Areas as intended in the statistical definition. The areas targeted by the strategies in the majority of cases does not overlap with FUAs, in some cases they concerns conurbation of small-medium sized towns outside metropolitan regions, in some cases twin cities. It is then more appropriate to talk of a *functional area approach* intended as a space – usually different from administrative boundaries - in which a specific territorial interdependence (or function) occurs, and may need to be governed jointly.

The implications of adopting this new approach to EU supported policy-making are relevant. In particular, it entails the need of establishing new governance systems, across administrative boundaries and scales, triggering cooperation processes among municipalities often in the absence of pre-existing institutional frameworks. To this respect there are various practices across the EU. What seems to be still far to be reached, is the potentiality of using these new strategic planning spaces to tackle the most impellent emerging urban questions. The questions tackled so far are more traditional physical or infrastructural issues as well as economic/job related issues, while most up-to-date themes, which probably require also more innovative solutions, struggle to be considered.

Concluding, the analysis shows that the functional area approach could become a new paradigm for EU supported policy making, even if it is not yet. While the statistical definition is clear, what is intended with the functional area approach in strategic terms is still not commonly shared across the EU. A thicker debate around it should be promoted, acknowledging the variabilities that the discourse could assume in the various countries, and individuating more clearly the pillars characterising such an approach.

Acknowledgements

This publication is largely based on the project URBADDEV "Support knowledge management of EU measures in Integrated Urban and Territorial development" run by the Joint Research Centre of the European Commission and entrusted by DG REGIO. The authors thank for their contribution all the members of the project, and in particular Sjoerdje Van Heerden for the analysis of the STRAT-Board database and Mario Alberto Marin Herrera for the spatial analysis of territorial coverage.

How to connect freight logistics, persons mobility, and spatial planning in and between urban regions? Perspectives from different European urban nodes on TEN-T corridors

Raymond Linssen¹, Martijn De Bruijn², Ricardo Poppeliers³ and Jos Arts⁴

Abstract: European urban nodes are vital for the effectiveness of the European core transport network (TEN-T), for passengers and freight transport. Yet, this role also comes with challenges regarding liveability, a battle for space with other functions in densely populated and growing urban nodes. Effective solutions should be designed at the level of the *functional urban area* of freight and logistics which exist at a different spatial scale from a passenger transport perspective, as examples of Vienna and Rotterdam illustrate. Urban nodes that are stimulating multi-modality ambitions and solutions should include freight and logistics. Regional opportunities for transit oriented development (TOD) could be combined with potential freight hubs, logistics oriented development (LOD). Initiatives can be taken within the urban nodes as well as on the corridor between the urban nodes, as is illustrated by several examples (Venlo (NL) and Lauterbourg (FR)) that relieve spatial and transport pressure in Rotterdam respectively Strasbourg. European tools and funding exist that could support urban nodes in dealing with these complex challenges and investment needs, both from transport and regional policy. An analysis of the STRAT-Board database shows that ESI funds are used by the majority of urban nodes for investments in mobility and infrastructure..

Keywords: Integrated planning and governance; TEN-T corridors and urban nodes; freight transport and logistics; functional urban areas

1. Introduction

European urban nodes are vital for the effectiveness of the European core transport network (TEN-T), as they are the origin and/or destination of most long-distance transport flows, for both passengers and freight. They host major multimodal transport hubs, and are crucial regarding the interface of long distance and last-mile delivery. At the same time, urban nodes play a major role in the transition of Europe's transport system as expressed in the European Commission's Transport White Paper (COM, 2011) aiming at limiting transport emissions and improving accessibility and liveability in cities. European urban nodes are the major arenas where public and private parties and society should join forces to cope with several trends and challenges. Stimulating electric mobility and zero emission transport and other innovative technical solutions will not be enough to deal with the challenges described above.

In order to further explore the role and challenges of urban nodes that are part of the TEN-T network, the European Commission launched a call under Horizon 2020. This paper builds on the mid-term results of a project that was set up under this call: the project *Vital Nodes* (<https://vitalnodes.eu>).

Main objectives of the Vital Nodes project are:

- a) Delivering validated recommendations for a more effective and sustainable integration of all 88 urban nodes into the TEN-T corridors focusing on freight and logistics;
- b) Establishing a long-lasting European expert network for safeguarding long-term continuity in knowledge and implementation (Vital Nodes Consortium, 2017). *Vital Nodes* has brought existing networks together and has been working on ensuring long-term engagement and recommendations for research and funding needs as well as input to TEN-T and CEF guidelines (EC 1315, 2013).

Vital Nodes combines bottom-up knowledge and experience through personalised city workshops with data gathering and policy analysis. This has given the project a unique view on the challenges urban nodes face linked to their position in the TEN-T network.

This paper will explore these challenges, deepen two aspects of these challenges – *functional urban area* (FUA) and European instruments – illustrated by two urban nodes cases and conclude with some lessons learned.

2. Trends and challenges of urban nodes

The Vital Nodes project conducted numerous workshops throughout Europe in 2018 and 2019, in which local, regional and national professionals in spatial and transport came together. Several (local) trends and challenges in the field of (freight) transport and logistics have been identified (Linden, van der, and Linssen, 2018):

- Growing urbanization and densification in many European cities and urban regions, e.g. in Vienna, Budapest, Rotterdam and Strasbourg.
- An increasing number of cities is aiming for low-emission transport policies and stimulating sustainable transport modes, expressed in a local or regional sustainable urban mobility plan (SUMP). Inspiring example is Vienna's STEP 2025 (Vienna City Administration, 2014).
- Development of micro and midi hubs for last-mile freight deliveries in urban regions (e.g. in Vienna, Mannheim and Strasbourg).
- Conflicting transport flows between freight and logistics and person transport, mainly on ring roads and river crossings in e.g. Vienna and Mannheim.
- Risk of 'logistics sprawl' by ad-hoc planning of XXL warehouses in urban regions and along corridors.
- Growing demand of flexibility in freight transport and logistics.

Aggregating the above mentioned challenges a few elements come back as crucial for success. First, the awareness that transport and logistics chains are much larger than the administrative border of the city and have very different stakeholders in comparison with passenger transport. Second, at the level of the urban node transport interests often conflict with environmental and spatial planning interests, leading to more and more complicated, expensive and time-consuming decision-making processes. As

a consequence, public actors need a different type of governance at a different scale, looking beyond administrative (city) boundaries. Good examples and funding opportunities exist but could be better exploited.

3. Exploring the *functional urban area*: definitions, urban nodes typology and examples

When focusing on the spatial and network implications for freight flows, stakeholders need to look at a different spatial scale, beyond administrative boundaries: the *functional urban area* (FUA). This is deviating from the *Daily Urban System* (DUS) level, based on labour market and persons transport flows, which is common practice among most urban regions. So far freight and logistics have been quite underexposed among urban and regional planners. Investments in freight logistics are mainly privately driven whereas investments in persons transport (roads, public transport, bicycle routes, etc.) are public. Within urban areas people and freight often share the same road and rail infrastructure, often resulting in bottlenecks e.g. at river crossings and urban ring roads.

Defining the functional urban area is complex. A few examples illustrate this complexity:

3.1 OECD and EC definition

The Organisation for Economic Co-operation and Development (OECD) and the European Commission (EC) have jointly developed a methodology to define *functional urban areas* (FUAs) in a consistent way across countries. Using population density and travel-to-work flows as key information, a FUA consists of a densely inhabited city and of a surrounding area (commuting zone) whose labour market is highly integrated with the city (OECD 2013). The ultimate aim of the OECD-EC approach to FUAs is to create a harmonised definition of cities and their areas of influence for international comparisons as well as for policy analysis on topics related to urban development. According to the OECD “the definition of urban areas in OECD countries uses population density to identify urban cores and travel-to-work flows to identify the hinterlands whose labour market is highly integrated with the cores” (<http://www.oecd.org/cfe/regional-policy/Definition-of-Functional-Urban-Areas-for-the-OECD-metropolitan-database.pdf>).

3.2 Outside Europe

Further exploration of the FUA outside Europe – for example the case of Ecuador – can be found in: http://www.ub.edu/irea/working_papers/2017/201705.pdf. Concluding: There is a large diversity of names for such urban areas (Metropolitan areas, functional regions, urban zones, conurbations, urban regions, large urban areas, metropolis, etc.) which illustrates the complexity of the phenomenon.

The Florida Department of Administration states as the core: “Functional Classification is the assignment of roadways into systems according to the character of service they provide in relation to the total roadway network” (<https://www.fdot.gov/statistics/hwysys/cubfc.shtm>).

3.3 Definition in TEN-T guidelines

Urban Nodes are a constitutive element of the Trans-European Transport Network (TEN-T) and foster the integration of the network into urban circumstances like spatial structure, economy and regional development.

According to regulation 1315/2013 of the EU, article 3 (p), "urban node means an **urban area** where the transport infrastructure of the trans-European transport network, such as ports including passenger terminals, airports, railway stations, logistic platforms and freight terminals located in and around an urban area, is connected with other parts of that infrastructure and with the infrastructure for regional and local traffic" (EC 1315, 2013).

3.4 Typology of urban nodes

Vital Nodes has formulated a typology to identify and to cluster challenges and potential solutions in dialogue with urban nodes more effectively and efficiently. This typology helps to define the function of an area for TEN-T (and vice versa: how does TEN-T influence the functional area?).

Criteria have been described as follows:

- Cross border function. In case of a cross border node, is it multi-modal or uni-modal?
- Sea port: In case of a sea port node, is it a gateway or a regional hub?
- Inland function. In case of an inland node, is it a small or a big node (threshold is 1 million inhabitants or more)?
- Relation of the node (logistics FUA) and the Corridor: Urban (inbound focused on local consumption) versus Transit (outbound focused on production and transit of goods).
- Is the urban node located in a developed or in a cohesion region?
- Is the urban node centric or poly-centric? In other words, does the node serve multiple urban areas or only one urban area?

3.5 Examples of Rotterdam and Vienna

To illustrate the way how this typology could work out in practice, two examples will be discussed: Rotterdam and Vienna. Table 1 shows the different characteristics of these urban nodes in their functionality of an urban node. Rotterdam as a gateway sea port mainly dealing with outbound-oriented production and transit to the hinterland. Vienna as a big (more than 1 million inhabitants in the metropolitan area) multi-modal inland and cross-border node.

Table 1: Urban nodes typology, examples of Rotterdam and Vienna. Source: Poppeliers *et al.* 2018

	Cross – border: multi or unimodal	Sea: Gateway / regional hub	inland: size: small / big (1 mln inhabitants or more)	Relation of the node (logistics FUA) and the Corridor: inbound / consumption versus outbound / production and transit	Developed or cohesion region	Centric or poly centric
Vienna	Multi-modal		Inland, big	Inbound/consumption	Developed	Centric
Rotterdam		Gateway		Outbound/production and transit	Developed	Polycentric

The (indicative) functional areas for the urban nodes Rotterdam and Vienna illustrate the potential emerging spatiality when focusing on a freight and logistics perspective.

Example Rotterdam

Figure 1: the indicative functional urban area of Rotterdam

The functional urban area of Rotterdam (NL) extends along the multi-modal corridor towards the German Rhein/Ruhr area, passing smaller towns and cities (figure 1). Venlo, on the Dutch-German

border, is one of these towns playing an important function for the corridor. Venlo's inland tri-modal terminal (along the river Meuse, railway and highway) functions as an inland terminal for Rotterdam, thereby having a place in the functional area from a freight perspective. From a point of view from network and spatial dimensions the location of freight / distribution centers influences the impact in a functional area. Therefore the regional authorities (within the functional area) as well as the TEN-T (EC and national authority) all have a role and responsibility in realizing objectives including sustainability and energy transition, liveability (safety, noise, clean air), accessibility and connectivity. A sustainable logistics plan on the level of a functional area should include objectives and governance models to realize those objectives.

Example Vienna

Figure 2: the indicative functional urban area of Vienna

Example of a centric, inland and inbound-oriented urban node is the Austrian capital Vienna. At this moment the city has approximately 1.75 million inhabitants and in the coming years Vienna's population is growing fast, with 40,000 inhabitants per year. The number of inhabitants is expected to increase to 2 million citizens in 2030, while the metropolitan region is expected to be home and workplace for over 3 million people (Vienna City Administration, 2014). Vienna's functional urban area extends to the Slovakian capital of Bratislava, 60 km to the east (figure 2).

On basis of both examples we can conclude that both poly-centric and monocentric urban regions are dealing with growing population, urbanization and increasing transport flows of persons and freight/logistics, resulting in a real challenge of space. There is need for mixed land uses and attention for socio-economic relations to maintain a liveable city. This relates to both central city and peri-urban areas, urging for multi-level governance and integrated planning at the level of both DUS (persons transport) and FUA (freight flows). There is need for a combination of TEN-T related goals and SUMP objectives, as promoted by the Commission in the 2013 Urban Mobility Package (UMP). These joint goals open the perspective for forward-looking practices and integrated approaches, which both enhance transport solutions and stimulate synergies with other urban functions (Balázs *et al.*,

2016). Regarding the complexity of the challenges, there is no ‘silver bullet’ (CEDR *et al.*, 2018; Broesi *et al.*, 2018).

3.6 Towards logistics oriented development

Urban regions that are stimulating multi-modality ambitions and solutions should include freight and logistics. Too often SUMP’s are limited to passenger transport solutions, so this scope should be widened to include freight solutions beyond the last-mile as well. Regional opportunities for transit oriented development (TOD) could be combined with potential freight hubs, logistic oriented development (LOD). This regional strategy will only work when municipalities are not mutually competing and when stakeholders do not only focus on the local (city) level, but include the regional (DUS) and corridor (FUA) levels as well. E.g. by researching and monitoring the impact of freight transport flows in the urban node by developments on the corridor and by developing and deploying integrated measures on corridor level and local/regional level.

The Rastatt tunnel accident in August 2017 illustrated the need for widening the scope of the TEN-T corridor and emphasizing the joint FUA of Strasbourg (FR) and Mannheim (DE). Lowering of railway tracks during tunnel construction works led to closing down all passengers and freight railway traffic between Karlsruhe (DE) and Basel (CH) for almost two months (Interregional Alliance for the Rhine-Alpine Corridor, 2018). Investing in upgrading an alternative railroad on the (French) west bank of the Rhine will contribute to overall network resilience on the broader Rhine Alpine corridor.

Besides, these investments could relieve the city of Strasbourg from bottlenecks and allow liveability improvement solutions as diverting the A35 highway, now situated in the central city. After this diversion the current urban highway will be downgraded and integrated into the urban fabric. Besides the *Port Autonome de Strasbourg* opened a new tri-modal container terminal near the town of Lauterbourg on the river Rhine, 60 kilometers north of Strasbourg, last year. This terminal will relieve the city of Strasbourg from many freight trucks that no longer have to cross the city. Zooming in and out from city level to FUA level helps to identify (potential) solutions for urban bottlenecks at the wider scale of the TEN-T corridor including the comprehensive network, not only ‘on’ TEN-T core corridors and within urban nodes. Strasbourg is a good example of an inspiring multi-level and multi-actor approach in a dynamic cross-border region. In several other urban nodes (potential) bottlenecks occur at road and railway river bridges where local, regional and international transport for passengers and freight transport meet. For example in Vienna, Budapest, Mannheim and Hamburg. In case of renovation or renewal of these river crossings – an enormous challenge in the coming decades – specific attention must be paid to a broader regional approach on the impact of bridge closures and the impact on transport, also in socio-economic terms.

Initiatives between urban nodes, elsewhere on the multi-modal corridor are at least as much important as investments within the core urban nodes. Especially in poly-nuclear urban regions as the Randstad, Flanders, Rhein/Ruhr and Rhein/Neckar regions initiatives may take place outside the ‘official’ core urban nodes. Investments in inland terminals and tri-modal terminals can be found in Venlo, Nijmegen and Duisburg, all on the Rhine Alpine corridor but in between the official urban nodes of Rotterdam, Antwerp, Düsseldorf and Cologne.

4. Potential European tools

In this complex world of urban and regional development (housing, working, leisure and liveability), multimodal infrastructure and multi-level governance there is no ‘silver bullet’ by means of a ‘one size fits all solution’. Neither will existing European instruments (funding and non-funding) be fully equipped to stimulate a better relation between urban nodes and the TEN-T network, between urban nodes and their wider FUA. However, several tools and programmes exist that can be used by urban nodes to fund projects and improve their policy towards dealing with being an urban node on the TEN-T network.

In table 2 several European tools that already could be used have been summarized. Besides a funding programme specifically designed for infrastructure investments (Connecting Europe Facility (CEF)) and knowledge exchange programmes for European cities as CIVITAS to support better mobility planning several other European instruments exist within the policy field of regional development that could play a role in tackling the interrelated challenges the urban nodes face. These instruments are rarely mentioned in European transport policy documents at first sight.

Table 2: Overview of (potential) instruments for urban nodes

Connecting Europe Facility (CEF)	The Connecting Europe Facility (CEF) for Transport is the funding instrument to realize European transport infrastructure policy. It aims at supporting investments in building new transport infrastructure in Europe or rehabilitating and upgrading the existing one. CEF Transport focuses on cross-border projects and projects aiming at removing bottlenecks or bridging missing links in various sections of the Core Network and on the Comprehensive Network (http://ec.europa.eu/transport/infrastructure/tentec/tentec-portal/site/maps_upload/tent_modes/EU_A0Landscape2019_freight.png), as well as for horizontal priorities such as traffic management systems.
Cohesion Fund	The Cohesion Fund is aimed at Member States whose Gross National Income (GNI) per inhabitant is less than 90% of the EU average. It aims to reduce economic and social disparities and to promote sustainable development. Infrastructure and green infrastructure can be financed by this fund.
European Regional Development Fund (ERDF)	The ERDF aims to strengthen economic and social cohesion in the European Union by correcting imbalances between its regions. The ERDF focuses its investments on several key priority areas. The four main priorities are Innovation and research, The digital agenda, Support for small and medium-sized enterprises (SMEs), The low-carbon economy. Investments in sustainable urban mobility fall into this fourth topic. In this fund 5% should be spent on sustainable urban development.

Sustainable urban mobility plan (SUMP)	A SUMP is a strategic plan designed to satisfy the mobility needs of people and businesses in cities and their surroundings for a better quality of life. It builds on existing planning practices and takes due consideration of integration, participation, and evaluation principles.
Integrated Territorial Investments (ITI)	This tool has been created by the Common Provisions Regulations to facilitate cities (and other authorities) to combine different European funding programmes (e.g. ERDF and Cohesion fund) to implement one integrated strategy. Often this is used to implement an Integrated Sustainable Urban Development Strategy.
Urbact network	A European Programme, funded by the EDRF, that brings cities together in action networks. Through joint projects and exchanges they learn from each other and find the best way forward to implement Integrated sustainable urban development.
Urban Innovative actions (UIA)	A European programme that funds highly innovative urban projects which would be too risky for regular ERDF funding.
Urban Development Network (UDN)	A network led by the Commission to exchange knowledge with and between European cities about the use of European funds for the implementation of <i>Integrated sustainable urban development (ISUD)</i> strategies.
TAIEX-REGIO PEER 2 PEER	TAIEX-REGIO PEER 2 PEER is designed to share expertise between bodies that manage funding under the European Regional Development Fund (ERDF) and the Cohesion Fund. It helps public officials involved in the management of these funds to exchange knowledge, good practice and practical solutions to concrete problems thus improving their administrative capacity and ensuring better results for the EU investments.

This overview does not pretend to be complete but gives an idea of the possibilities for urban nodes to use European (funding) instruments for addressing their particular challenges. For a selection of these funding opportunities and instruments we have used available databases to check whether urban nodes already make use of these possibilities. We have used the STRAT-Board database (EC, 2019) to check which of the 88 urban nodes that have an integrated sustainable urban development strategy use *European Structural and Investment Funds* (ESIF) funding for transport related investments. STRAT-Board lists all sub-regional ESIF funded strategies in Europe, although the detail of information per strategy can vary. It typically includes the territorial focus of the strategy, the population covered, the funds used, the total ESIF contribution, the thematic objectives included and the type of implementation mechanism (priority axis, *Integrated Territorial Investments* (ITI) or programme). Investments in infrastructure were to be programmed under thematic objective 7, while investments in

urban mobility were part of thematic object 4: low-carbon economy. If an urban node has a strategy which uses investments from either thematic objective 4 or thematic objective 7, or both, we have considered that the strategy includes investments in transport. Even though this might be a slight overestimation since investments in thematic objective 4 not necessarily include investments in urban mobility.

The findings are that 65 of the 88 urban nodes have an *Integrated sustainable urban development* (ISUD) strategy. 58 of these strategies include investments in transport. Almost all of these 58 urban nodes invest in urban mobility, except two. These two, both in the Czech Republic, only invest in infrastructure. Nine urban nodes both include urban mobility and infrastructure investments. With the exception of Naples, they are all situated in the Eastern Member States. Some urban nodes that only received funding for urban mobility were nevertheless part of a larger programme that did include investments in infrastructure. Here, we touch again on the issue of functional territories. Speaking of which, 23 urban nodes designed their strategies at FUA level, 18 at city level, 14 at neighborhood level and 3 as city-network. Concerning the implementation mechanism chosen, more than half (36) of the urban nodes which invest in urban mobility and transport use ITI, 16 use a priority axis and 5 are part of a dedicated operational programme. In addition to regular ERDF funding, urban nodes could also apply for Urban Innovative Actions in the field of mobility. Of the 88 urban nodes only Toulouse was one of the winners of the UIA call on sustainable mobility.

To get an indication whether urban nodes use European programmes to exchange knowledge on mobility and infrastructure we checked the Urbact website for participants in the Urbact networks on urban mobility and transport. Twelve out of the 88 urban nodes have participated in such networks.

Even though discussions on transport and mobility are often framed around the use of CEF funding or the implementation of a SUMP, when we look at available data, three-quarters of the urban nodes also have an ISUD strategy in place for which they receive European regional funding. And the vast majority of these nodes invest in sustainable urban mobility and/or infrastructure. Mixed sources of funding is a reality for urban nodes that should be better taken into account in the policy discourse at European level and could be further facilitated.

5. Conclusions

Freight and logistics are the ‘new kid on the block’ for urban regions’ challenge on how to coordinate spatial and transport planning. This means additional complexity to urban development, regional planning practice and multimodal corridor development. Ignoring this complexity may result in a longer-lasting lack of linkages between urban nodes and the TEN-T network. Until now, most European initiatives concerning integrating professionals in spatial planning and mobility planning focused on passenger transport and last-mile freight delivery at local and metropolitan level (*daily urban system*). A focus on the *daily urban system* does not fully match with current relations and transport flows in freight and logistics. Outcomes of the Vital Nodes project show that – from a freight and logistics point of view – the *functional urban area* of several urban nodes extends the commuter hinterland thereby connecting neighboring urban nodes (Strasbourg-Mannheim, Vienna-Bratislava) or reaching out to important non-urban nodes, such as Venlo for the urban node Rotterdam.

Attention for the corridor from a spatial point of view has been very limited so far and stakeholders from different silos – corridor development, freight/logistics, and spatial/urban planning – do rarely meet nor speak a common language. Bringing in the freight and logistics perspective on urban and regional development – as has been done in the Vital Nodes project – has made clear the *functional urban area* is a new emerging spatiality that needs to be further explored.

A careful mix of interventions – regarding network, spatial and institutional dimensions, keeping in mind the typology of the urban node – seems to be the way forward to strengthen the relation between the urban node (local and regional level) and the TEN-T corridor level. Regarding the use of European funding instruments, many urban nodes already use regional funding for mobility and infrastructure investments as part of an integrated urban development strategy. More than a quarter of the urban nodes have designed their ISUD strategies at FUA level. Further exchanging experiences about coordinated planning approaches across Europe is indispensable to mutually achieve added value for an efficient and sustainable transport system and vital urban regions.

That's why we should rethink our planning and elaborate on an integrated approach that connects the worlds of infrastructure, mobility, freight and logistics with the world of urban and regional spatial development. An approach in which there is attention for 'soft' measures and innovations, addressing the multiplicity of the challenges by integrating different spatial scales, sectors, modalities and stakeholders. Multi-level governance is key.

Session 17. Emerging spatialities and eu policy instruments: cases and perspectives

The *Pla de Barris*: a remarkable case of place-sensitive territorial policy

Marco Peverini¹

¹ *Politecnico di Milano, DASTU (Dipartimento di Architettura e Studi Urbani),
marco.peverini@polimi.it*

Abstract: Spatial injustices are rapidly growing and, in the wake of the so called “revenge of places that don’t matter”, there is urgent need for better territorial policies. Ranging on a wide variety of contexts, territorial policies should implement strategies that are not only place-based, but also coherent, effective and place-sensitive. Aim of the paper is to give a contribution to the debate, shedding light on one lesser-known yet remarkable case of territorial policy for social cohesion. The *Pla de Barris*, Plan of the districts of the Catalan Region implemented between 2004 and 2010, is here investigated. The research followed two main methodologies: on one side, quantitative socio-spatial analysis; on the other side the tools of policy analysis to investigate its implementation. It shows that the measure was efficient and effective in targeting spatial injustices thanks to integrated place-sensitive implementation mechanisms. A fairly balanced combination of centralized analytical apparatus, multi-level governance and involvement of the local administrations explains its success in addressing spatial injustices. There is much to learn from this experience, since this approach can make the difference in providing a coherent framework in which to develop place-sensitive interventions in deeply variable local contexts, that is the crucial point for the endurance of European Union.

Keywords: Urban regeneration; Urban governance; place-sensitive territorial policies; cohesion policies.

Introduction

Territorial inequalities are increasing all over Europe. As shown clearly by Rodriguez-Pose (2018), the more dynamic regions of Europe are leaving behind the less dynamic ones: places that ‘don’t matter’, where there is very little possibility of economic development and where a revenge going on through the ballot box. In the last decade, all over Europe, lower economic performances have turned out into anti-establishment vote, expressing the voice of big parts of the society that feel an increasing distance from where the development concentrates and consequently where the decisions are taken. These communities that don’t matter can be described as ‘peripheries’, indicating a distance from the ‘centre’ that is not only geographical but multi-dimensional (Petrillo, 2013).

In this sense, Regional Studies describe that peripheries exist on a European scale (e.g. the South and East of Europe) but also on national scale (e.g. the South of Italy, all Spain except Catalonia and Castilla, most of France except Paris, etc.). Parallely, Urban Studies focus on peripheries that exist on a metropolitan and urban scale, often referring to the district level. More recently, the importance of peripheries inside the scale of a

region has been acknowledged, for example with the notion of ‘inner areas’ (Barca, 2013) that also became an operative framework of the Italian government.

In this panorama, cohesion policies (not only European) act on different scales and with different mechanisms for targeting inequalities. On a national level, in Italy the territorial cohesion has been promoted through the investments of *Cassa del Mezzogiorno* that, stressing particularly on infrastructures as means to recover the gap between South and North, had often the effect of wasting resources and consume the trust of the people. Since the 1980s, following the importance given to the urban dimension of inequalities, cohesion policies integrated operational frameworks that targeted the cities and the regeneration of the city centres (e.g. Urban, Urban II, etc.) and of some peripheral parts considered more vulnerable, like *Programmi di Recupero Urbano* (PRU).

These regeneration programs aimed at concentrating resources where the vulnerability is concentrated, using the space as a factor that assures more efficiency and effectiveness to the measures activated. Nevertheless, these programs had a weakness: they stressed a lot on the physical restoration of the built environment, often forgetting the urban and social fabric and therefore failing in addressing the multiple dimensions of inequalities. Nowadays, in the wake of the ‘revenge of places that don’t matter’, all the levels of administration call for more efficient and effective ways to invest in the territorial cohesion, particularly regarding the response that those policies can have on the territories (Nello and Gomà, 2018).

Barcelona: a city with strong traditions of Urban Planning

The history of the urban development of Barcelona is very peculiar and is due to an accumulation of trends and events that had no comparable in Europe. During the dictatorship of Franco, the urban development was led by the interests of major real estate companies and developers that pushed for a ‘developmentist’ model. This, together with the lack of democracy and social policies, resulted in evident social and spatial segregation, and consequently to strong social mobilisation. After the death of Franco in 1975 and with the economic recession, the city - together with the entire Spain - required a deep institutional and economic restoration. From the point of view of urban development, the transition from industrial to tertiary economy followed an approach that changed completely from the ‘developmentist’ one and was described as ‘qualitative’, because it tended to target specific areas of the city with projects of requalification of the public spaces instead of savage urban development. Moreover, in the 1980s a season of big investment in the social services was inaugurated.

At the same time, as the city was nominated for the 1992 Olympic Games, a big change was on the run. From the ‘qualitative’ approach that had dominated after the dictatorship, the so called ‘Barcelona Model’ was being settled. This season was dominated by a strong, top-down, strategic planning approach that aimed at an urban development on the global city scale through big interventions: the Olympic facilities, the new downtown areas and new infrastructures – such as the famous *Ronda*, the new city Beltway. If in the previous phases the planning was led by different public bodies, the ‘Barcelona Model’ was heavily based on public-private partnerships in the form of mixed-capital companies with considerable autonomy. Thanks to this, and to the relatively good level of consensus around the measures, the transition of Barcelona from a mainly industrial city towards an important global city was rapidly accelerated.

This ‘new developmentism’ relied a lot on the attraction of capitals and on the interest and collaboration of the economic elites, but also on a completely new idea of administration. New management techniques were adopted by the Public Sector: the figure of the ‘local manager’ was appointed executive control on the administration; mixed-capital companies were created to manage autonomously special urban functions and processes; privatisation and externalisation of activities; spending review and tax reduction. The ‘Barcelona Model’ demonstrated many cracks in the ten years that followed the Olympic Games, such as the failure of the 2004 Universal Cultures’ Forum, and was highly criticized and opposed (Delgado, 2007). At the beginning of

the 2000s, Barcelona had reached a very high status in the European global cities, but it was still affected by social and spatial segregation.

A new generation of planning? The *Pla de Barris de la Generalitat*

Following this period in which Barcelona had grown a lot in terms of economic indicators but also in inequalities, a new approach was released. In 2004 the Parliament of the *Generalitat de Catalunya* [Region of Catalonia] approved the *Llei de Barris* [Law of the Districts], also known as *Pla de Barris* [Plan of the Districts] with the aim of “promoting projects of rehabilitation of those districts where major urban deficiencies are accumulated and where, as a consequence, the population that need more social attention is concentrated” (Nello, 2012) on the scale of the whole region (Figure 1).

The Law 2/2004, for the improvement of districts, villages and urban areas requiring special attention, of June 10th 2004. The norm was the first legislative text carried out and promoted by the government presided over by Pasqual Maragall. In fact, the draft bill was made public on 19 January 2004, by order of the Minister of Territorial Policy and Public Works, Joaquim Nadal, only three weeks after the new government had taken office (Nello, 2003: 25–28).

Figure 1. Map of the interventions that were funded by the Law 2/2004, between 2004 and 2010 . Source: Nello O. (2012), *Ordenar el territorio, La experinecia de Barcelona y Cataluña*. Elaboration by the author.

As visible in Table 1, the *Llei de Barris* financed between 2004 and 2010 projects in 141 districts, where more than one million people lived (at that time, the 13% of the total population of Catalonia), with a very important investment of 1.330 million Euros, of which: 693 million from European FEDER funds obtained by the Catalan Region; 513,2 million from the involved municipalities. It is based on the creation of a fund for the promotion of the ‘programme for districts and urban areas that require special attention’, provided with budgetary resources

from the government of the *Generalitat*, attached to the Ministry of Town and Country Planning and Public Works.

Number of calls	7
Number of districts	141
Total population in the 141 districts	1.005.214
Total funding	1.330 mln Euro
Funding from the <i>Generalitat</i>	693 mln Euro
Other funding (municipalities, privates, etc.)	513,2 mln Euro

Table 1. Some numbers of the Plan of the Districts. Source: Generalitat de Catalunya. Departament de Política Territorial i Obres Públiques [Department of Territorial Policies and Public Works].

Even if in some ways the Plan of the Districts represents a typical area-based program, a series of characteristics distinguishes this program from the mainstream of the various generations of neighbourhood programs of intervention that were released in Europe and makes it represent a very important step in the Catalan planning history (Scarnato, 2015).

Multi-level governance and inter-administrative cooperation

First of all, a big role was played by the Catalan regional government, that decided not to focus on single urban areas but to maintain the whole regional territory as a scale of intervention. Indeed, the planners acknowledged that segregation is originated also at a big scale, due to the real estate market. As explained by Oriol Nello: « due to the process of metropolitanization [sic] and the growing integration of the territory, the housing market in which the citizens and the economic operators make their decisions is not longer [sic] local, but rather has a much wider scope. Thus, segregation not only appears between districts in the same town but also – and usually, at first, between districts in the same urban area and even throughout the whole of the region» (Nello, 2009). It is here acknowledged that only from the regional scale it would be possible to distribute the necessary resources in an equal way for the districts and municipals that require interventions and services to face the concentration of vulnerability and which, due to the concentration itself, face great difficulties in providing them.

At the same time, in the mind of the planners, proximity to the field of action is essential for the success of urban policies. Their execution by higher institutional bodies (as in the French case), in the mind of the planner, could entail errors of appreciation and action which may lead to failure. The role of the *Generalitat* is therefore to promote, select and evaluate the projects, whilst the responsibility of the execution of the project lays completely on the town council concerned. In other words, the town council is the body responsible for the design and execution of the programme, having direct knowledge of problems and potential of each district, while the *Generalitat* maintained a role of mere funder and supporter, renouncing to be the protagonist. The Plan of the Districts, relying strongly on the potential of local government, fully applies the principle of subsidiarity.

The inter-administrative cooperation was considered of mayor importance and the law was designed in a way in which not only execution of the projects but also the selection process itself is conducted in cooperation. The law established an organism that is responsible for the selection and assignment of the resources: the Commission for the Administration of the Funds for the Promotion of the Districts and Urban Areas that require special attention. It is composed of 30 members, equally of representatives of the different Ministries of the *Generalitat* and municipal entities (Federation of Municipals of Catalonia and the Catalan Association of Municipals), as well as professionals of the Architects and Technical Architects professional bodies. This marked the beginning of a new era in the relationship between the *Generalitat* and local governments.

In conclusion, through the instrument of the competition the Region aimed at building a multi-level governance model. On one side, the leading role of the regional authority guarantees the coherence of the projects with the aim of social cohesion, the multi-institutional “tuning”, certain funding availability and territorial equity in the access to the funding. On the other side, the protagonist role of the municipality in promoting the project guarantees knowledge of the local situation and correspondence with the specific problems; the requirement of conspicuous co-funding ensures the “determination” of the municipality in effectively implementing the proposal.

The localisation of the interventions and resources

The plan aimed at reducing inequalities targeting specific neighbourhoods – *barrios* [districts], representing a precise administrative division of the territory that is nationwide recognized – that fall on the ‘areas of special attention’. A municipality could apply for one or more districts, making one or more applications. The application, in order to be successful, must target a district that belongs to the ‘areas of special attention’. This measure is to assure that resources go where there is actual need of it.

Anyway, there is to say, there is not a general overview of the Catalan districts that fall in the ‘areas of special attention’. The districts where to intervene are proposed by the municipalities and then examined by the same commission that is in charge of the evaluation of the projects. From an operational point of view, the Law of the Districts works in a way that is inspired to by the European programme URBAN. The proposed districts are examined by the commission through a set of quantitative parameters, as in Table 2, with a scale established by the regulations of the Law of Districts. In order to be considered an ‘area of special attention’, a district must obtain a minimum amount of points from all of the indicators in the scale. Then, a score is awarded adding the points given to the project and, based on the resulting score, the resources available in each call are distributed among the participating municipalities.

Criteria (defined by the Law 2/2004)	Shortfalls in works, facilities and services	Demographic problems	Presence of economic, social and environmental problems	Social and urban deficits and problems of local development
Objective statistical indicators (defined by the regulation of the Law of the District)	Insufficient level of conservation of buildings	Density of population	Number of people that receive assistance and non- contributory pensions	Lack of public transport
	Buildings without running water or water disposal systems	Decrease and accelerated population growth	High level of unemployment	Lack of parking spaces
	Buildings of four or more floors without a lift, designated mainly to housing	Dependent population	Lack of green areas	Low economic activity
		High percentage of immigration	Low level of education	Percentage of the population at risk of social exclusion

Table 2. The criteria and indicators individuated by the Law 2/2004 and its regulation to verify that the district of application is in the ‘areas of special attention’. Source: Nello O. (2009), *The Law of Districts. A collective commitment to social cohesion*, Generalitat de Catalunya. Elaboration by the author.

The reason for this is to assure that the targeted district is among those that actually deserve it, avoiding that resources go to places that are in a relatively good condition but where certain municipalities would like to intervene with very good projects. However, the notable aspect is that the selection is not only based on statistical evidence of the urban and social deficits of the district. Indeed, the planners thought that establishing and publishing a ranking of those districts which find themselves affected by segregation would cause the stigmatisation of those in worse conditions and, therefore, further worsen the conditions of vulnerability of the district. Therefore, they elaborated an evaluation method that took into consideration the strength of the proposal on the side of the project.

‘A plan for projects, not for problems’

As said, the analysis of the proposed context with 16 statistic parameters is done to indagate the effective state of need of the proposed district and avoid a competition based merely on the efficacy of the projects, while the evaluation of the project means to push the focus from vulnerability to planning, trying to avoid possible effects of stigmatization.

Therefore, after the initial analysis of the districts with objective indicators, there is a second stage of evaluation based on the projects presented by the municipalities. The evaluation is done through four criteria: the level of comprehensiveness of the proposed proposal; its general coherence; the level of economic commitment of the town council; the parallel execution of complementary actions. Those two evaluation criteria have the same weight in the score, aiming to generate a combined evaluation method (as in Figure 2).

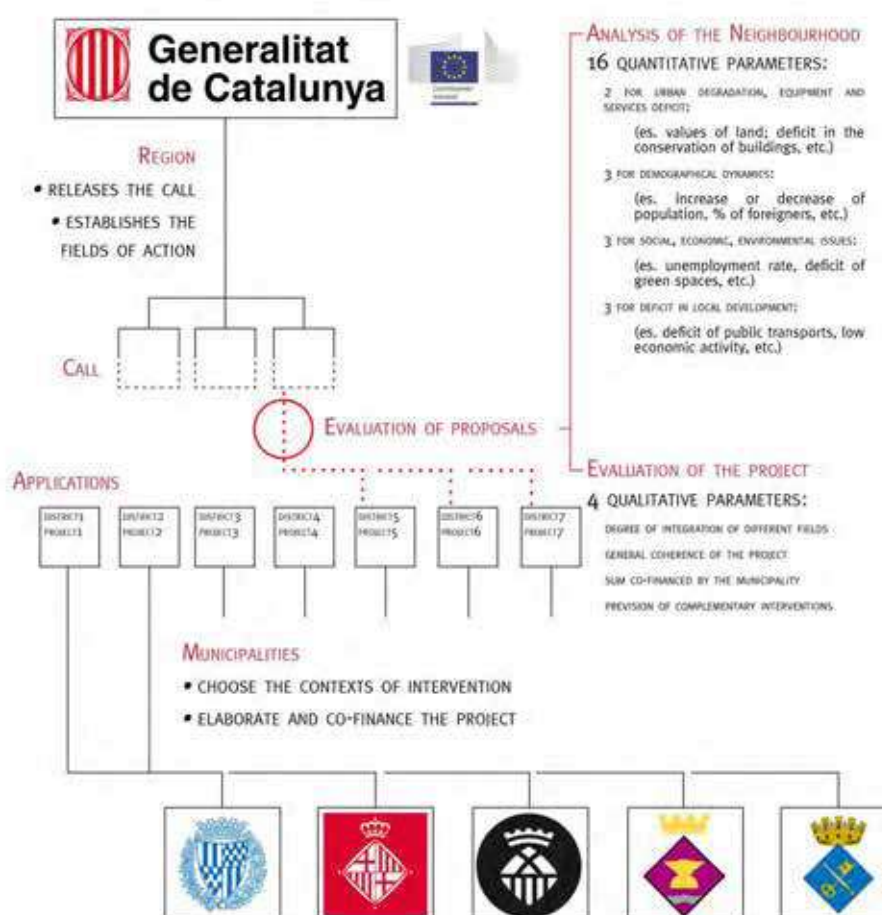

Figure 2. The governance scheme and the evaluation criteria established by the regulation of the Law 2/2004. Source: Nello O. (2009), *The Law of Districts. A collective commitment to social cohesion, Generalitat de Catalunya. Elaboration by the author.*

One of the main factors for the evaluation of the process is the degree of integration of the actions included in the proposal, assumed as a fundamental device to assure the success of the project on the district. The Law establishes 8 different fields where the projects of the municipalities should intervene in the same project, for each district. The fields regard mainly 3 areas: urban design and equipment; improvement of energy, environmental and communication infrastructures; social actions that support the population. Looking at Table 3 it is possible to see that, even though the far largest part of the funding were dedicated to strictly physical interventions like public spaces, green areas, installations for collective use and accessibility (with about 2/3 of the budget), an important role has been played by the involvement of the population through social programmes (with 1/10 of the budget) and with the refurbishment of the common elements of private building (another 1/10).

Improvement of the public space and provision of green areas (paving of streets, planting of trees, lighting, creation of gardens)	44,24%
Refurbishment of the common elements of buildings (facades, drainpipes, lifts, roofing)	9,96%
Provision of installations for collective use (civic centres, centres for the elderly)	21,83%
Incorporation of communication technologies (wiring of building, establishing of wi-fi areas)	1,28%
Introduction and improvement of energy and environmental infrastructures (collection of residues, putting rubbish containers underground, establishment of recycling centres, promotion of renewable energies, water saving mechanisms)	4,74%
Promotion of gender equality in the use of urban spaces and installations (premises for women's associations, specific training activities, interventions for the improvement of women's safety);	2,13%
Development of programmes that entail social, town planning and economic improvement of the districts (actions for the support of collectives that are facing social exclusion, training programmes, dynamise commerce)	9,39%
Improvement of access and removal of architectural barriers (widening of pavement, building of ramps, putting in escalators, elimination of obstacles).	6,26%

Table 3. Fields of intervention required by the law with examples, and the weight that each field had on the fundings. Source: Generalitat de Catalunya. Departament de Política Territorial i Obres Públiques [Department of Territorial Policies and Public Works].

In addition, the law required that the applications of the municipalities should consider two collateral actions that aim at strengthening the plan:

- the creation of complementary programmes by the different Ministries of the Generalitat;
- the constitution of comprehensive follow-up mechanisms.

Regarding the first action, the complementary actions established by the Ministries of the *Generalitat* in the districts included in the programme have been of great importance. The program 'Jobs in the Districts', created by the Ministry of Employment, has led to the establishing of 81 agreements in 92 districts included under the law in order to set up training and school-work transition programmes, with a total investment of 30 million euros. Similarly: the Ministry of Health has carried out studies on public health and health care in the districts participating in the programme; the Ministry of the Environment and Housing has established specific lines of aid in the refurbishment of common elements of buildings for the 37 districts of the programme; the Ministry of the Home Affairs, Institutional Relations and Participation has contributed to the financing of the process of citizen participation in a special way in a further 14; the *Incasòl* (Catalan Land Institute) has signed agreements in order to carry out urban remodelling actions (especially the replacement of obsolete housing with new housing) in 24 districts of the programme, with an investment of about 200 Million Euros. In the effort to cover all of the substantial aspects of the life of all of the areas of intervention

The Evaluation and Follow-up Committees (one per district) include the mayor of the municipality, representatives of different areas of the town council (directly involved in the management of the district), representatives of seven ministries of the *Generalitat*: Town and Country Planning and Public Works, Environment and Housing, Governance, Social Action, Economy and Finance, Health and Employment, as well

as a representation of the Delegation of the Government in each territory. These Committees are configured to bring together all of the services of the *Generalitat* and the Municipality that are concerned with the district. The Committees are held approximately once a year per district and are not meant to substitute the daily action of the administrations, but to maintain a coordination on the action on every district and to create the basis for integrated and transversal action.

Conclusions

In conclusion, this analysis shows how this plan has represented a very important step and pioneering application of some of the precepts of the place-sensitive approach. Of course, the place-based approach with the space as a means to understand the vulnerability of the society, and the neighbourhood as a unit of investigation of the territory and of concrete intervention. But also: the importance posed on the project and its strongly integrated character; the fact that the proposal (both of the neighbourhood and of the project) has to come from the local administration, with a pro-active role of the municipality; the devices to assure the communication and coordination among different levels (vertical) and sectors (horizontal) of governance and the implementation and follow-up of the actions.

Even if, it has been admitted, the process of adaptation of the administrations to act in a more area based and less sectorial manner (in the districts of special attention and in many other fields) required a long process of adaptation, it was a very important turning point in the innovation of the governance of this kinds of plans of intervention. Concerning Barcelona, that has had a very central role (approximately one tenth of the interventions of the Law fell on the Metropolitan Area), in comparison with what had happened before in the history of the physical transformation of the city of Barcelona, a shift was made from the top-down, architecturally hard and punctual intervention of the era 1979-2004, to a softer, more integrated and co-designed intervention that has a dimension of plan. This was very important, in the wake of the huge protests and critiques that previous plans (e.g. the one related to the Culture Forum 2004) had faced.

Not all the aspects of the plan have been investigated in this paper, even though some of them are very important and would require further investigation. The first regards the housing market: even if the Law of the Districts did not include any direct measure in that field, it was very clear in the mind of the planners that bettering the conditions of those neighbourhoods, especially those that are in the city centres, would increase the value of the land and the housing prices, with possible effects of residential exclusion or expulsion. For this reason, a combined plan was designed with the *Pla d'Habitatge 2004-2010* [Housing Plan 2004-2010] that was assigned the role of avoiding speculation effects, providing measures that promoted the social role of housing. Since the value of the lands has actually increased after the interventions of the Law of the Districts, it would be very important to examine whether the Housing Plan was able to contrast possible negative effects on the side of housing.

Considering possible replications of such a pioneering experience presents some complications related to the specificity of this case. It is important to underline that the Law of the Districts was made possible in very peculiar conditions: in a national administrative system, that of Spain, that leaves heavy financial autonomy to the regional level; in the richest and more economically advanced region of Spain; after the accumulation of many experiences in urban regeneration; in a relatively stable political situation and before the financial crisis of 2007-08. Nowadays, it would be very hard to imagine such an alignment. Nevertheless, it brings a quantity of lessons that were learnt and that could be adapted to other cases and situations, wherever there are 'geographies of discontent', in order to give concrete answers to the questions posed by the 'places that don't matter'.

Acknowledgements

The paper draws on the research carried out by the author between November 2016 and February 2018 at the Observatory of Urbanization of the Autonomous University of Barcelona (UAB), with the support of prof. Francesc Muñoz Ramírez. I would like to thank him for the help and inspiration.

Facing migrants exclusionary
urban policies

Landing

How practices of temporary hospitality challenge urban spaces and policies

Martina Bovo¹

¹*Politecnico di Milano, DASTU, martinabovo@polimi.it*

Abstract: Within the broad issue of migration, the paper discusses the conditions of intersection between the short temporality of the phenomenon and the longer temporality of urban spaces and policies. Along the migrant trajectory, the work particularly focuses on migrants' *landing*, or *first arrival*. The research therefore addresses migrant populations who have a "temporary" perspective in their use of the territory and who cannot access certain urban services and opportunities. The paper considers the case of Milan and assuming the background of existing policies, the work draws on a qualitative observation of Milanese first reception, with specific attention to hospitality "practices", broadly defined as unexpected uses of space, non-institutional actions, and unplanned answers by the Municipality. The observation unveils a general incapacity to structurally deal with the temporariness of migrants' condition, often resulting in "exceptional" reception spaces and emergency-based policies; on the other hand, some actors and practices seem to provide a deeper understanding of certain conditions, suggesting new points of view on first reception issues and highlighting alternative paths. The work argues the urgency of a renewed and more complex definition of the temporary condition of migrant populations, and the relevance of existing practices as a starting point for discussion.

Keywords: migration; landing; first reception; Milan

Introduction

The paper draws on an ongoing PhD research, carried out in the course of Urban Planning Design and Policy at Politecnico di Milano (Italy), that investigates the interaction between migrant populations, territories of arrival and urban policy, with a particular focus on the dimension of first arrival, or *landing*.¹ Assuming as a background this work, the following paper aims at investigating its initial hypothesis.

¹ The term *landing* is used to refer to the first moment of arrival on a territory (*primo arrivo e prima accoglienza* in Italian), and to differentiate it from the following settlement processes.

The PhD work starts from a broad consideration of how socio-economic changes, spaces and institutions develop at different speeds and how this challenges a lot the ordinary forms of urban governance and planning, which often resist to such changes rather than triggering or supporting them (Balducci, 2019).² The research assumes as a fieldwork that of recent migration flows around the Mediterranean Sea and specifically focuses on the phase of migrants' landing, intended as a first moment of arrival in a territory, and on hospitality experiences, intended as the reactions of the city, in its different dimensions, to such phenomenon. Landing of migrants is understood as a complex dimension of encounter between the short temporality of arriving populations and the longer one of the urban environment. Many, and well-known, stories of hospitality reveal the incapacity of city's spaces and institutions to support the presence of migrants, but some experiences represent inverse reactions, able to support the changes brought about by arriving populations. The PhD research therefore questions under which conditions the latter experiences are possible and what they may tell to urban and territorial governance.

Within such framework, the present contribution more deeply discusses the reason why the dimension of landing is chosen, arguing that landing may be regarded as a relevant point of observation, not only to investigate the field of migration studies and hospitality, but also to open up the debate on broader governance and planning issues.

The paper is organized as follows: a first section introduces the literature background on migration and urban studies, pointing out the need to better define the debate on migrants' first arrival as an independent topic; it follows a tentative definition of *landing* from a theoretical and empirical perspective, with reference to some experiences of hospitality in Milan and Europe; the fourth section aims at investigating how the developed observations may challenge some current categories of urban planning and governance, beyond the field of first arrival and reception; finally, some preliminary conclusions are drawn.

Urban studies, migration and landing

State of the art

Whilst the theme of migration and the city has old roots, in the last years its relevance for European and Mediterranean countries has clearly increased (Saunders, 2012); researches have addressed it through diverse fields, among them sociology, anthropology, economics, law and urban studies.

Literature dealing with the relation between migration and the territory identifies two parallel dimensions: on the one hand, global networks, flows and national policies, and on the other, a rather *local* scale, where municipalities, inhabitants and local policies *react*, developing everyday experiences of hospitality. The crucial dimension to understand tools and processes of territorialization appears to be the local one, which looks both at the dynamics occurring in city

² The work is still on-going and was shortly presented in a seminar at Politecnico di Milano, in January 2019.

districts and in smaller towns (Balbo, ed., 2015; Caponio, 2006). Urban studies have further built a rich framework around the territorial dimension of migration, focusing on immigrants and populations who are settling - or already settled - in urban areas. Within this long-term perspective, literature describes the processes of territorialization of immigrants (Tosi, 1998; Lanzani and Vitali, 2003; Blockland and Savage, 2008) and discusses the tools of urban policies towards the multiethnic city (Crosta, 2010; Lo Piccolo, 2013; Briata, 2014).

In a different way, the will to focus on the temporary dimension of landing implies to assume the mentioned studies as a background, and to shift the gaze from the notion of *im*-migrants to that of migrants, who interact with the territory in a clear perspective of mobility (Tarrius, 1993). The theme of landing, regarded as a temporary condition that migrants undergo before settling down, raises diverse questions: the French anthropologist Agier started the ‘Babels Research Program’, revolving around the concept of the city as a border and investigating “what migrants do to the city and what cities do to migrants” (Agier, 2016). More recently, the issue of first arrival has been addressed within studies of social policies related to first reception systems. But, while different research fields (anthropology, sociology, law) on migration start addressing this temporary dimension, urban studies still struggle in considering it as a subject by itself, so that the territorialization processes and tools of first landing still remain a rather unexplored field. The transitory nature of migrants makes more evident the reason of this gap: urban studies and policy are asked to deal with populations who are not - yet - territorialized and settled, but already using intensively urban spaces.

The outlined framework underlines the lack, in the discipline of urban studies, of a structured debate on the dimension of migrant’s first arrival and of a deep investigation on its implications for urban planning. Nevertheless, the nature of the recent migratory flows, the structural character of such phenomenon and its impacts on urban territories, are only some of the reasons why it seems urgent to investigate landing as an independent and relevant topic.

Looking for a definition

Methodological notes

The work presented explores the term *landing* both from a theoretical perspective and through references to empirical cases. The first part aims at exploring the notion of landing, it clarifies some risks and limits of its use and it finally outlines a possible definition to work with. Subsequently, the paper more directly addresses existing experiences of migrants’ first arrival and reception, so to build a more concrete framework of reference. In this case, the work is mainly drawn from a qualitative research developed within a Master Thesis in Architecture (Bovo and Lippi, 2017) on Milanese first reception system, that collects and maps the main reception centers, through official data and interviews, field visits and direct observations; some further references are made to experiences collected through interviews and recent literature on the theme.

The contribution thus reports specific case studies and it is part of a research which will probably include a field work, nevertheless the presented paper is mainly the result of an attempt to build up a theoretical approach and to set the framework for further research activities.

Landing as a point of observation

Defining a theoretical framework

The choice to assume the perspective of landing poses some questions on its possible implications and requires therefore a better definition of what is meant by *landing* and by assuming this dimension as a point of observation.

The term refers to the moment of first arrival in a certain territory, the use of the word *land-ing*, aims at explicitly addressing the act of reaching land and start interacting with it, before having a clear perspective of future plans and uses. Such notion therefore refers to a limited timeframe which may vary according to the contexts, it addresses populations that start building a relation with lands and territories that start being used by them. As regards the timeframe, it is interesting to notice that migration is defined as a movement (or a series of movements) from a country of usual residence to a different country, for a period of *at least one year*, i.e. 12 months of permanence out of the land of origin, in one or more different places³. Although such definition is very general, the question arises how may be addressed those people who live in a foreign land (for less than or) before a whole year passes by. Landing populations instead may be defined as those groups observed in the moment of arrival and orientation, before settlement in a certain territory; with or without a long-term perspective of permanence, they approach land with some initial *competences of use* of the territory, personal networks or knowledge of the place, and they start building a temporary relation with space. A third consideration refers to the landing territories, which may be easily defined as all those places where people arrive, this raises the question how much such territories are - already - usable and able to support the presence of populations who are present but not settled. The relation between landing migrants and the territory may therefore be defined as a *temporary* one, since it refers to an initial moment when migrants don't have a perspective of permanence. Nevertheless, whereas each

³ Eurostat: "As stated in Article 2.1(a), (b), (c) of Regulation 862/2007, immigrants who have been residing (or who are expected to reside) in the territory of an EU Member State for a period of at least 12 months are enumerated, as are emigrants living abroad for more than 12 months. Therefore, data collected by Eurostat concern migration for a period of 12 months or longer : migrants therefore include people who have migrated for a period of one year or more as well as persons who have migrated on a permanent basis" available at <https://ec.europa.eu/eurostat/statistics-explained/pdfscache/1275.pdf>. United Nations Department of Economic and Social Affairs: "While there is no formal legal definition of an international migrant, most experts agree that an international migrant is someone who changes his or her country of usual residence, irrespective of the reason for migration or legal status. Generally, a distinction is made between short-term or temporary migration, covering movements with a duration between three and 12 months, and long-term or permanent migration, referring to a change of country of residence for a duration of one year or more" available at <https://refugeesmigrants.un.org/definitions>.

individual may relate to space in a temporary perspective, the presence of such populations are for cities more and more structural, as La Cecla writes, migrants are special inhabitants, “dwellers with an individual impermanence and a collective permanence” (La Cecla, 1999).

When talking about landing it is also necessary to take distance from understanding it as a predetermined condition of precariousness and rather define it as a field of observation of trajectories which may differ a lot among them. Although sharing the moment of arrival, people indeed may experience very different conditions: among the migrants recently landed in Europe, some had networks and economic resources to rely on in the arrival country which limited their precariousness soon after arrival, some entered the reception system, some did not, some others after many years are still living in very precarious conditions (Tosi, 2018). Thus, landing may refer to an analytical framework, but cannot be linked to a fixed condition of precariousness, which may not only, and not necessarily, depend on the migratory seniority.

In conclusion, from a theoretical perspective, landing is here regarded as an analytical lens which addresses the relation between temporary populations and the space and aims at investigating how such relation is built, particularly questioning what kind of *capital(s) of use* people shall have to use the territory and how the latter can support their presence.

Landing practices

Observing populations, spaces, services and actors

Within the outlined theoretical approach, the following paragraph explores the term of landing with reference to some existing practices⁴. The cases are mainly drawn from the Milanese reality of first arrival and reception, between 2015 and 2016⁵, and from some other European experiences reported in literature; the observations mainly addresses the theme of migrants as landing populations and the reaction of the city in terms of space, services and actors involved.

The interviews to migrants and social workers around the system of first reception reveal a very diversified mosaic of situations, nevertheless some shared needs may be outlined. Within the first days of arrival, migrants seek very basic services, such as a night shelter, medical and legal assistance, nutrition and acquisition of certain information; the essential nature of such demands makes it easily sharable by a wide target. Even if still deeply uncertain of the possibility to settle in the city, migrants often express some further, and complementary, needs, regarding education and information, recreational activities, worship, food's and clothes' purchase and transport; the consideration of the

⁴ The term *practice* is here used in a broad way, to give account of the variety of the cases and experiences reported.

⁵ The city of Milan around 2015 underwent a dramatic change since it rapidly turned from a transit to a destination place. In the years before 2015, less than 1% of the migrants transiting would ask for asylum and spend more than a week in the city; in 2015 this changed and most of the people reaching the city started also asking for asylum there.

complementary needs clearly outlines the complexity of migrants' presence, in a phase which is instead often concerned as merely and continuously "of emergency". It also emerges that in the relation with the territory such needs encounter often strong constraints both in terms of time and space, due to a range of different reasons. The temporal limit is evident in the figure itself of the asylum seeker, a condition which juridically forces the person to undergo a period of wait before getting a status recognized and, in some way, prevents the chance to assume a long-time perspective of permanence. Strong time restrictions are also often imposed by the reception system itself, many facilities indeed have strict opening and closing times, requiring hosts to enter and exit the center according to given timetables. The relation with the urban environment in terms of spaces also presents quite evident limitations. Initially the use of urban spaces is constrained simply because people are new to the city and need orientation to places and services. Often underestimated by institutional reception, this need was broadly addressed in Milan by smaller associations who, especially around 2015, provided a lot of orientation services to support a very first degree of usability of the city for migrants arriving in Milan Central Station. The NPO CambioPasso realized a project of signage in different languages to lead migrants from the Station to information points; similarly, operators of different associations grouped together to provide a *mobile hub* service with the aim to orient newly arrived people to "move throughout the urban tissue, rather than only to first reception facilities" (Spada and Valentino, 2018). The spatial limitation is also linked to the reception centers, which result often very isolated from the rest of the territory; in some cases the isolation is due to a physical distance to urban and central areas, in some others to the lack of any connection to the surroundings because of the concentration of all services within the reception centers, and in most cases the access to such structures is very much controlled. In regards to the spatial constraints in the use of the city, it is interesting to underline the importance for migrants of some *not-mediated* (immediate) urban spaces, as green areas, open sport fields, public libraries and shopping malls, which for their nature overcome the spatial limitations in the use of the city. Thus, the temporary nature of migrants' relation to space leads to certain temporal and spatial constraints; in this sense it seems significant to understand better how this relation is built and how the city opposes to, or supports, the presence of landing populations.

The reaction of the city is here explored starting from the measures put in place by the institutions, in terms of first reception facilities, and they are considered within three main dimensions, the spaces, the services and the actors. As regards the firsts, the system of Milanese first reception between 2015 and 2016 provided 18 facilities scattered within the city, which were supposed to host migrants waiting for their status to be recognized. The spaces were of five typologies: former barracks, disused schools, reception facilities, big-sized structures and small-sized spaces normally devoted to other services; they would host from 50 to 500 people and the space was organized in the attempt to fit the new function to the existing structure, in case of large amount of people sport halls or common spaces were also arranged as dormitories, in some cases tents were placed in the outdoor courts. Especially in big structures, which were the majority, the rigidity of the space was clearly opposing to the flexibility and temporality of the hosts' presence, in other words, far from being a plural kind of space (Crosta, 2010), the reception facilities work as fixed boxes to adapt to. These experiences show how the planned spaces of reception are conceived as merely temporary and precarious solutions, and struggle in dealing with populations who may be individually temporary but represent a collective structural presence. Still within the spatial dimension, the case of the French city of Grande-Synthe suggests an alternative approach, recently discussed by some authors (Agier *et al.*, 2018). At the

entrance of the border city, migrants willing to pass the border to England occupied a tent settlement and reached in the winter of 2015 the amount of 5000 presences; in March 2016, the mayor of the town, opposed by the National government, chose to invest together with some associations in the construction of a humanitarian camp, bettering off as possible the conditions of the previous “jungle”. By doing so, the mayor showed to have recognized and accepted the temporal nature of the settlement, but also imagined for it a project of a rather permanent kind. These are just few examples of spatial answer to reception, but they already reveal some issues that the temporary nature of landing populations poses, and they challenge the more conventional understanding of reception spaces.

The second dimension considered is that of the services and is again addressed starting from the Milanese case. Institutions managing first reception facilities are required to provide basic services, such as dormitories and canteens, and in some cases also legal or medical assistance, language courses or clothes delivery; being conceived as a temporary stage, the system of first reception indeed has much lower management requirements than the ones of the so-called second reception. In most cases the services provided are all delivered within the reception center, so that the host ends up sleeping, eating, following language courses and getting clothes in the same structure, accessing services exclusively targeting migrants; when the reception center only offers a night recovery migrants are forced to use other available facilities as public showers, canteens or daily centers. Such system presents advantages in terms of management and space organization, but it also prevents migrants to start using the urban environment in an autonomous way, it reduces the chances for them to start building a personal social capital out of the center and strongly limits the opportunities of encounter and interaction between local residents and migrants. The question arises whether reception services should all be so concentrated and polarized within the reception facilities, and if reception measures should be addressing in such exclusionary way landing populations and not also other inhabitants of the city. A different reality is that of some services that often play an interesting role, probably mostly unexpected; it is the case of public libraries, which rather belong to more ordinary services of the city but also meet some of those complementary needs of landing migrants, who spend time in these places to access the internet, read or watch movies in their own languages, or learn Italian; public libraries thus are spaces of compresence of ordinary and reception services. With a similar aim, the NPO CambioPasso built a small experimental project of clothes’ delivery within existing second-hand shops in the neighbourhood around the reception facility, so that while getting their clothes, asylum seekers could also start getting in touch with other community of reference, out of the reception center. The latter examples suggest the opportunity to think of more integrated services able to trigger interactions between existing reception activities and other ordinary urban services.

A third aspect worth considering is that of the actors involved in the management and within the planned system of first reception. In Italy the Prefectures and the Municipalities are in charge of the public first reception facilities and through public call they outsource the management to third sector institutions; there are further associations who play a relevant role in the reception, even if not directly involved in the institutional system. What is interesting, and not only characterizing the Milanese case, is that on the side of the mentioned organizations, there are not-formalized figures who played a crucial role in the support of landing migrants. In Milan the clearest example is that of the Eritrean and Ethiopian community of the neighbourhood of Porta Venezia; between 2013 and 2015 resident immigrants provided help and accommodation to a large number of migrants coming from Northern

Africa and arriving at Milan Central Station (Naga, 2016). More recently, some Milanese associations are working on a project to enhance and recognize the crucial role that existing foreign communities might have in supporting the presence of landing migrants in the city. These cases challenge the notion of the actors of reception and the way current policy defines them.

The different experiences showcase some of the well-known obstacles in dealing with temporary migrants populations, but also some of the alternative answers that the city is already giving to better support them; such practices are here divided into the three dimension of spaces, services and actors, but it is worth underlining how much the three are linked to each other and how each of them rises shared issues. Whereas the mentioned cases obviously build a very partial picture of the huge reality of first arrival and reception, in some way they also reveal the specificity of the landing dimension and the importance of considering it as able to challenge some conventional answers currently given to the presence of temporary migrants.

Beyond reception

Reflecting on the challenges for urban planning and policy

The given definition of landing and the observation of the mentioned experiences certainly raise issues on migrants' arrival and reception but may also open up the discussion on themes that more broadly tackle the city and are here introduced as still open questions.

The understanding of migrants as complex temporary populations and with a constrained relation to the city - in space and time-, recalls the presence of other temporary populations already inhabiting certain urban territories. Although undergoing very different conditions, tourists, students, workers, the relatives of hospitalized people (Pasqui, 2008) are other temporary populations who more and more are establishing a structural presence in the contemporary city and who also build a limited relation with the urban environment. Such consideration does not aim at comparing the conditions of these people, but rather at triggering a broader discussion on how the city does and should answer to these temporary and structural populations.

Secondly, the spatial dimension of reception introduces the design theme of the relation between temporary and permanent. As seen, the structures of reception may be defined as "extraterritorial" spaces, that oppose a sort of physical inertia to the quickly changing needs of landing migrants; thus, as seen, the spatial project seems to be incapable to provide a structured answer to temporary populations. On the other hand, there are experiences which try to work within a more elastic notion of temporary and permanent, as a way to effectively respond to landing migrants' presence; these cases underline the need for a broader definition of permanent and temporary. In this sense it is interesting to recall the recent project of Mehrotra on Ephemeral Urbanism, by looking through very different cases of temporary settlements, Mehrotra argues that the arising distinction between permanent and temporary should not be conceived as a binary but should rather activate a broader understanding of permanence. In this sense, one of the clearest example refers to the Hindu festivity of Kumbh Mela, which every three years gathers millions of people - in 2007 they were 16 million - for only 45 days; here what makes such temporary settlement successful is the fact of being

organized, in terms of management and space, as if it were permanent, i.e. by following rules very similar to those of long-term settlements (Mehrotra, 2016).

Some similar considerations may be carried out when considering the dimension of services: whereas most of those addressing landing populations are spatially concentrated and strictly targeted, the cases of public libraries and second-hand shops represent examples of reception services distributed on the territory and integrated to more ordinary facilities. This introduces two main topics, currently debated in literature: the first regards the possibility to conceive integrated spaces of services as open to a wide (and unexpected) target, in particular it is questioned the extremely specialized nature of certain services, as the traditional social services that often end up resulting exclusionary themselves. Secondly, it is raised the issue of the access threshold of many public facilities especially for non-conventional city inhabitants. The case of newly arrived migrants highlights the different degree of recognition required to access a wide range of services, from the zero degree of public showers, to the documents asked to enter sanitary and social structures, to the higher requirements needed to access services like housing. Also in this case the lens of landing triggers questions that seem to go beyond the dimension of migrants' arrival and hospitality.

The fourth theme is that of the actors, in particular underling the presence and relevance of non-formalized actors in the management of reception. As seen, some local associations recognized their role, but the question is whether also institutions would be capable of recognizing it and, in general, enhancing the value of unplanned and unpredictable figures. Such latent capacity of reacting to changes is well described by Lanzara as a *negative capacity*, i.e. the ability of certain people to provide an effective answer to unexpected needs and thus playing the role of *informal* institutions in changing context (Lanzara, 1993). In order to be able to leave some space to the negative capacity of certain actors, policies should probably accept to have, at times, a *looser* attitude, open to possible latent resources, especially when facing unclear and undefined phenomena. Also the notion of policies' *looseness* may be encountered in some current literature on urban governance and public action.

The mentioned issues remain clearly open questions, nevertheless it is meaningful that they are raised starting from the discussion on landing and that they are themes which go beyond the dimension of migrants' arrival and reception. This reveals the relevance of landing as a field of observation on dynamics that more and more structurally are challenging the contemporary city.

Conclusive remarks

Starting from the above arguments some preliminary conclusive remarks may be outlined. The dimension of landing should be conceived as a mere analytical lens to look through, without implying any predetermined definition of arrival as a fixed and unique condition of precariousness among migrants. Assuming such perspective, landing practices not only reveal relevant issues in the debate on migrants' arrival and reception but are also representative for the discussion on broader topics in the field of urban studies. Thus, in order to address the issue of landing in a broad and elastic way, it seems reasonable to work in an in-between space, which chooses as study field that of migration but

also “keep an eye” on other languages, references and tools, which may in some cases provide clearer definitions of shared problems and critical nodes.

To conclude with a representative image of the concept of landing as presented in the paper, going back to its origin might be of use. In the nautical world indeed there is a type of sailing chart, the pilot book, used specifically by sailors in the moment of landing; such tool is representative for two reasons, on the one hand, because the pilot book specifically addresses sailors who are approaching land, on the other since it provides them with useful information on how to successfully make use of the unknown coast, turning it more readable and ready to use. Similarly, the research argues the need for urban studies to recognize and address the dimension of landing populations and to question the current usability of cities, in order to investigate how this challenges some categories of urban planning and policy.

Urban inclusion of refugees and vulnerable migrants in Portugal

Sílvia Leiria Viegas¹

¹ FCT scholarship holder (SFRH/BPD/118022/2016 – FSE/POCH), postdoctoral researcher with the Centre for Social Studies of the University of Coimbra (CCArq/CES-UC) and member of the Group of Socio-Territorial, Urban and Local Action Studies of the Lisbon School of Architecture of the Lisbon University (Gestual/FA-UL), silviaviegas@ces.uc.pt

Abstract: I will focus on my on-going post-doctoral research *INSEhRE 21. Socio-spatial and housing inclusion of refugees in contemporary Europe: Lessons from the African diaspora in Portugal* (2017-2023). The purpose is to situate the investigation and to discuss its further developments and alignments from a critical and operational standpoint. I will present my theoretical approach based on the key-concepts of ‘the production of space’ and ‘the right to the city’, ‘governmentality’ and ‘multicultural tolerance’. Also, I will refer to the main policies, practices and paradoxes of today’s Portuguese context concerning urban inclusion and cultural inheritances in general and, in particular, for refugees and/or vulnerable migrants moving to the Lisbon Metropolitan Area. Moreover, I will mention the government’s trend of sending these refugees to rural areas and small/medium-size cities, whilst pointing out the crucial role of digital networks in preserving social bonds and building citizenship. As for grass-roots initiatives, I will present the project *Refugi.Arte em Marvila*, boosted by the architectural Cooperative Working with the 99%, and the projects *Orquídea Silvestre* and *Tayybeh*, both spearheaded by the Association Family of Refugees, with different levels of action and effects. I will conclude with a short cross-checked theoretical-empirical analysis.

Keywords: INSEhRE 21; *Refugi.Arte em Marvila*; *Orquídea Silvestre*; *Tayybeh*.

Introduction

My paper cross-checks and analyses the information gathered for my individual post-doctoral research project entitled *INSEhRE 21. Socio-spatial and housing inclusion of refugees in contemporary Europe: Lessons from the African diaspora in Portugal*, during about the first two years of scientific activity, bearing in mind that the project was launched in early 2017 and is estimated to be concluded in 2023 (Viegas, 2016). Against this backdrop, the article focuses on the major political trends and dynamics currently formulated around the subject of socio-spatial and housing inclusion, including of refugees and vulnerable migrants, in Portugal, particularly in the Lisbon Metropolitan Area, all the while confronting dominant approaches with three initiatives boosted by organisations of the civil society (hopefully!) countering exclusionary processes. My purpose here is two-fold: (1) to situate the on-going investigation; and, (2) to discuss its future steps and to determine some indispensable adjustments from a reflexive, critical and operative point of view.

For this initial phase of my research I adopted an exploratory and qualitative methodological approach, based on an interdisciplinary, although architectural-rooted, bibliographical review, theoretical and of empirical studies. Also based on fieldwork, including direct observations in particular neighbourhoods of the Lisbon Metropolitan Area and semi-structured interviews to privileged actors: grass-root communities, representatives of the state and immigrants from the Middle East and Africa. Furthermore, I participated in a myriad of national and international initiatives debating and informing of the urban and access to housing situation in Portugal and Europe, and in activities related to refugees, forced migrations and border regimes. Moreover, I started the production of an iconographic roadmap consisting of photographs and maps. For presenting my preliminary achievements I structured this article as follows: (1) the first section dedicated to (re)examining today's major policies, paradigms and contradictions concerning (a) urban and housing issues, (b) cultural inheritances (and material heritages) and (c) the socio-spatial inclusion of refugees and vulnerable migrants in the Lisbon Metropolitan Area. At the same time pointing de-concentration strategies to rural areas and small/medium-size cities of Portugal, with digital social networks playing a determinant function in the building of (a complete form of) citizenship; and, (2) a second section referring to the grass-root projects *Refugi.Arte em Marvila*, *Orquídea Silvestre* and *Tayybeh*, these initiatives emphasising both structural difficulties and small and/or local scale opportunities and accomplishments.

Framework

I will now present the theoretical and empirical framework of the research project *INSEhRE 21. Socio-spatial and housing inclusion of refugees in contemporary Europe: Lessons from the African diaspora in Portugal*. Lefebvre's ([1968] 2009; [1974] 2000) well-known publications of 'the production of space' and 'the right to the city' structure my thoughts specially regarding spatial practices and their materialisations, and the building of (a complete form of) citizenship, as collectively they contextualise and differentiate the production of spaces of representation, i.e. commodifiable, with exchange value, from the production of representational spaces, i.e. with use value. At the same time, these two concepts underline ideas of (over)power, control and discrimination, as illuminated by Foucault ([1977/1978] 2008) and Žižek's (1997) words of 'governmentality' and 'multicultural tolerance', since they point to paradoxical processes of acceptance-rejection and of 'racism with distance'. Together, these notions provide a critical conceptual lens for the analysis of socio-spatial inclusion in general terms and for refugees in particular, as they help deconstructing assorted aspects of the question all the while suggesting specific levels and types of action. I presented a draft of this theoretical-methodological essay – *Spaces of Inclusion in Contemporary Europe* –, at the Association of European Schools of Planning (AESOP) Annual Congress' 17 (Viegas, 2017a).

It is, thus, with this analytical tools that I started looking at the problem of the socio-spatial and housing inclusion of refugees in contemporary Europe, specifically in Portugal, also having as reference the reception of migrants moving from Portuguese-speaking African countries since the emancipation of Guinea (1973), and Angola, Mozambique, São Tomé e Príncipe and Cape Vert (1975). This two-fold orientation favours a deeper analysis of the subjects here under scrutiny – access to space and housing, benefits of urbanisation and the building of (a complete form of) citizenship –, bearing in mind issues (once again) linked to relations of power, such as those accompanying post-colonial and economic matters, discrimination practices, and its physical

expression and consequences. In effect, by adopting a historical-geographical view I provide a privileged starting point for the analysis of the current narratives, policies and practices of the Portuguese government regarding the urban inclusion of refugees in light of the state's principal responses to the urban and housing inclusion of other populations in need, for example African migrants and their descendants, over approximately the last forty years. My article for the Journal *Espaços Vividos, Espaços Construídos (EVEC)* (Viegas, 2018a) opens the discussion around this connection while creating an elementary referential of analysis concerning refugee camps and targeted housing *versus* self/co-produced and rationalised spaces, also launching an investigation bridge to what recently became the New Generation of Housing Policies' political goal and conjectures.

Specifically regarding refugees, the so called 2015 migrants crisis and with it, the European Relocation and/or Resettlement Programmes, introduced new dynamics and challenges to the Portuguese government and the non-state system, this including central and/or local structures activated for the reception and integration of the newcomers. From the Lisbon City Hall to the Plataforma de Acolhimento de Refugiados (PAR) and/or several religious congregations (Serviço Jesuíta aos Refugiados, etc.), numerous were the actors involved in the uncontrolled process of receiving these refugees in a country structurally unprepared for this task, even if the official narratives were, as they still are, of extraordinary openness and support for the cause and persons. Hence, the results of this operation depend(ed) of the room of manoeuvre, capacity of action and primary intentions of those involved in the process, such as technicians, civil society, church members, etc. Also from the limited capacity of response of the Foreigners and Borders Service (SEF). At the same time, the High Commissioner for Migrations (ACM) assumed its important institutional role with enthusiastic support for the integration of refugees and new assistance structures were created, e.g. the Support Centre for the Integration of Refugees (NAIR). What is more, former refugees residing in Portugal created grass-roots associations adopting an exemplary role of care leaders, specifically in the Lisbon Metropolitan Area that received the majority of refugees: according to an interview with a technician (9th April 2019), the Temporary Reception Centre for Refugees (CATR) of the municipality of Lisbon received close to 250 individuals since 2016, out of a total of 1,520 refugees coming with the European Relocation Programme (ACM, 2017:6); In its turn, the Refugee Reception Centre (CAR) of Bobadela, located in a periphery of Lisbon, managed by the Portuguese Refugee Council (CPR), oversaw more than 500 spontaneous asylum seekers in January 2019. Here the infrastructure is saturated and, at the same time, many migrants face extraordinary difficulties as are not legally eligible for obtaining the refugee status (Poulet, 2019).

Urban inclusion

Concerning urban and housing inclusion in general and, in particular, for refugees and vulnerable migrants moving to the Lisbon Metropolitan Area, I will shortly refer to the primary policies, practices and paradoxes of today's Portuguese context as follows: (1) starting with a bird's-eye view on the main exclusionary paradigms, namely the urban renewal processes, some resettlements and forced evictions of those inhabiting in other's property; (2) moving to the topic of cultural inheritances and the building of an ideal(ised) urban society and space, while cross-checking this subject with those of housing struggles; (3) finishing with the government's present-day trend of sending the refugees to rural areas and small/medium-size cities, while stressing the role of digital

networks in preserving family and/or social bonds and building citizenship. In this context, I will firstly refer to the access to adequate housing by middle-income and low-income populations of different cultural and/or ethnic backgrounds, taking into account the transformation of the urban society in progress. Secondly, I will speak of the normative narratives sustaining the contemporary western world's common perception of cultural heritage(s) and material inheritances, all the while supporting the forging of an ideal(ised) urban society and space. Finally, I will refer to the dynamic urban-rural whilst emphasising the attractive features of the benefits of urbanisation, even under difficult conditions.

Exclusionary paradigms in Portugal, particularly in the Lisbon Metropolitan Area, such as urban renewal operations, resettlements and forced evictions, tend to be followed by resistance performances and/or the counter-actions of those denouncing and fighting against dominant interventions and their fierce effects. The dynamics are tangled demanding for an operative and emphatic line of action based on strong political responses that are, on the one hand, capable of analysing the major tendencies of the actual forces in charge, all the while anticipating new neoliberal-driven outcomes and, on the other hand, strong enough to listen and include the revindications of those in need. Currently, in Portugal, the Socialist Government in power is rehearsing a New Generation of Housing Policies, with different programmes, purposes and beneficiaries. At the same time, the parliament discusses versions for a New Housing Law, all proposed by left-wing parties. It is, in fact, an extraordinary political moment regarding housing issues in Portugal. Nonetheless, despite all inclusive narratives and ideological intentions, great paradoxical exclusionary movements tend to consolidate since they reproduce a myriad of socio-spatial inequalities intrinsic to the prevailing neo-liberal system. Yet, both the reading of the main examples and contradictions, and the recent political actions attached, are important to frame the refugee's urban and housing current and awaited status, for being aware of common problems and possible solutions, as recently explored in the article called *Access to housing by all and for all? Paradigms and paradoxes of the Portuguese actuality* (Viegas, 2019a in press).

Cultural inheritances (and material heritages) are also important entrances for conceptualising refugees' conditions, as they provide us with a broader perception of the western world's common self-representations, social and spatial. In fact, these inheritances tend to stress the production of political spaces for the building of 'strategic-oriented' new legacies all the while neglecting or rejecting the production of social spaces based on everyday life practices, these general occurring according to particular necessities, cultures and/or habits. Even (or especially) if these routines support ground-breaking narratives of unique heritage(s) (Viegas, 2019b). Given this worldwide tendency and the very specific Portuguese political moment concerning the access to adequate housing, I question: (1) Which plan is Portugal adopting for the transformation of its ideal urban society and space, and for this matter, how is the country responding to the 2015-onwards (very much) complex European migration issues? Moreover, (2) what spaces are being forged for the deprived communities, particularly in the Lisbon Metropolitan Area? And, (3) what characteristics differ refugees from other migrants and/or social groups in need? As far as I understood (Viegas, 2018b), we are witnessing controversial dynamics as, in general terms, the official narratives of inclusion and openness do not counterbalance the dominant exclusionary logics. What is more, political messages on the subject of refugees do not focus on housing issues as a primary choice albeit, paradoxically, they emphasise the role of the migrants as users-consumers in major urban centres, such as Lisbon.

Small/medium-size cities and rural areas became the principal alternative for distributing and receiving these refugees and numerous were the actors involved in the processes of having the migrants around the country. Yet, difficulties regarding this strategy were manifest, namely the isolation amongst family members, including parents, siblings and/or adult sons, and related communities – much of this partially filled by the use of social networks on digital platforms by closed groups –, lack of opportunities and great dependency of the host institutions and their technicians, including regarding jobs and housing opportunities. Some were supplied for the same entity, as will remain for a long time. In its turn, in Lisbon, access to housing problems amongst refugees are now emerging or becoming visible, particularly after the conclusion of the initial 18 months of institutional and financial support, as guaranteed by the European programmes. These occur because many refugees have problems with learning the Portuguese, something considered by them as the ‘key’ of integration. Accordingly, employment opportunities amongst the formal sectors are very limited, and with short earnings. Due to cultural and/or religious aspects, many women do not usually work outside home, hence the families that depend on the mens’ income now have to adapt. Complexifying these situations are the neo-liberal market-driven urban tendencies and their urban paradigms of the city renewal, rehousing and forced evictions, by all means interfering in refugees’ daily lives, some also being targeted with racism and/or xenophobia. Given all these difficulties half of these refugees illegally left the country, some going to the northern European countries, as Germany, while others returned to their original at war and/or devastated African or Middle-East countries.

Grass-root initiatives

Regarding the initiatives boosted by organisations of the civil society (hopefully, not surely) countering exclusionary urban policies, I will concisely present three case studies as they were explored in my field work: (1) the project *Refugi.Arte em Marvila*, supported by the architectural Cooperative Working with the 99%, an art-based inclusive shelter for refugees, economic migrants and low-income residents planned for a municipal under-used heritage facility in Marvila (Lisbon), the Marquês de Abrantes Palace; and the projects (2) *Orquídea Silvestre*, and (3) *Tayybeh* both promoted by the Association Family of Refugees, started by Syrian refugees in Portugal. The first project is an ecovillage and a multicultural community space to be built in the country side of Portugal. The second project is an entrepreneurship that seeks to promote inclusion through the celebration of Syrian cuisine in eastern Lisbon. Collectively, these three case studies provide an overview of the dynamics created around the building of innovative (re)settlements by (and for) refugees and migrants, in the capital and in rural areas, as together they sustain the importance of forging ground-breaking approaches based on, and promoting, a complete form of socio-spatial emancipation. They also stress the great value of civil society, e.g. the local people, refugees or migrants, in promoting inclusionary processes.

Refugi.Arte em Marvila, was conceived in 2017, so as to help with the revitalisation of the low income Marvila Street and surrounding areas, namely the housing neighbourhoods and the disused industrial areas near the river, through the rehabilitation of the Marquês de Abrantes Palace, as marked in Figure 1. It was also thought to empower local communities, vulnerable migrants and refugees, all the while promoting spaces of encounter between these actors as a strategy for curbing down segregationist and/or xenophobic tendencies. The long term presence of the Cooperative Working with the 99% in Marvila Street for two participatory experiences in the neighbourhood

(2014-2017), co-financed through the Municipal Programme for Neighbourhoods and Priority Intervention Zones (BipZip), enabled the building of trust with local residents. Together with a multidisciplinary team they actively participated in and appropriated the shaping of this art-based inclusive shelter-to-be. However, despite the recent international recognition of the project by the International Centre for Migration Policy Development (ICMPD), United cities and Local Governments (UCLG) and UN-Habitat, under the scope of the Mediterranean City to City Project (MC2CM), as reported by Cabannes *et al.* (2018), it has not been launched. On the one hand, the funding request for the implementation of this project (Viegas, 2017b) was denied by the municipality. On the other hand, the City Council prepared a master project for the district with European funding, overlapping local interests and intentions.

Figure 1. Marvila Street and surrounding areas (Viegas, 2017).

Orquídea Silvestre, was launched in mid-2018, and is an ecovillage and a multicultural community space(-to-be) built in the country side of Portugal. The original location was a 134 hectares rural land situated in Aljustrel called Morgado, as marked in Figure 2. Currently the project is considering another placement in Crato, at the barragem das Nascentes, in a close dialogue with the festival Waking Life. The Association Family of Refugees wants to promote inclusion for refugees and migrants, whilst repopulating and revitalising the interior of Alentejo, at the same time communicating and interacting with local people. The first phase of the project concerns the pioneering stage and includes finding access to sustainable infrastructures (e.g. energy and water supply, Syrian vernacular housing – earthen domes, etc.) and food self-sufficiency for 5 persons (refugees and activists) through the use of local resources and the engagement in everyday life activities. The second phase of the project, extended to accommodate 12 persons, considers the diversification and amplification of rural routines aiming at the economic sustainability. The last phase, for 24 persons, targets new forms of entrepreneurship such as ecotourism. The success and timings of this project depends on the capacity of action and the room of manoeuvre of the

Association Family of Refugees taking into account legal and funding difficulties, among others, as well as the involvement of potential partners, such as government agencies, private institutions, etc.

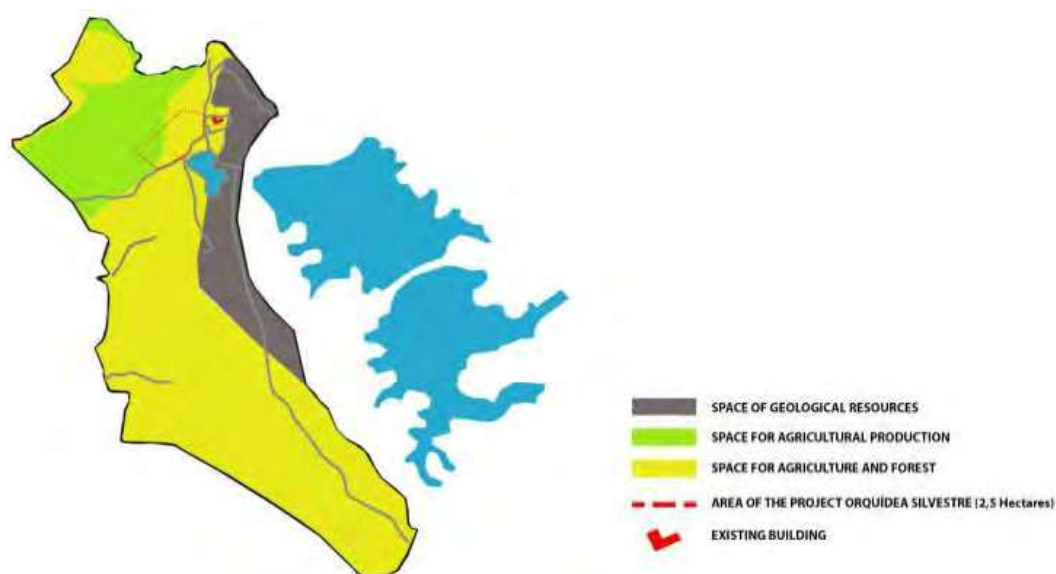

Figure 2. Morgado in Aljustrel, unscaled (Viegas and Velasco, 2018).

Tayybeh was launched in 2017, first as a catering service and later (in early 2019) evolving to a restaurant. The name is Syrian and means both delicious and kind. The project began as a start-up aiming to support Syrian refugee women to create (self-)employment opportunities and, at the same time, to present the Syrian cuisine and culture to the Portuguese society (Figure 3). During the first and second phases of the process, Ramia Abdalghani, with her husband Alaa Ghunim, invested personal time, material and financial resources to develop this entrepreneurship, also to assure the continuity of the project independently of the lack of institutional support and funds. As a caterer, *Tayybeh* served numerous events, some cultural and academy related. Presently the restaurant is established in Moscavide, a consolidated medium and/or low-income housing neighbourhood in eastern Lisbon, bordering the highly expensive urban area Parque das Nações, with its workers and inhabitants. The restaurant was mostly decorated through exchanging services with other start-ups identified online. Take away and oriental cooking school are additional services provided or in preparation. Albeit these refugees' many personal difficulties, *Tayybeh* is functioning being a fine example of emancipation associated to strong dynamics of socio-spatial inclusion trough food, with its recent large media coverage being important for its success along with the quality of the service (Viegas 2019c).

Figure 3. Alaa, Ramia and their co-workers at the restaurant *Tayybeh* (Viegas, 2019).

Analysis and future steps

The article situates the project *INSEhRE 21. Socio-spatial and housing inclusion of refugees in contemporary Europe: Lessons from the African diaspora in Portugal* as I identify the dominant narratives and the production of political spaces associated to the access to urban space and/or housing for, and by, several sociocultural and economic strata. Future steps of the study must necessarily focus on a more profound exploration and analysis of the refugees' contemporary conditions. Besides, from another point of view, I emphasise the participation of civil society regarding the refugees' problems through the presentation of three case-studies of emancipatory practices or efforts. Those must be accompanied and others should be identified. These cases will contribute to interpret the Portuguese 'urban question', bearing in mind both political and grass-roots approaches, also discussing operational aspects. Given this framework, emancipation *versus* dependency patterns amongst these migrants are crucial dimensions concerning the right to the city, since the access to urban benefits (housing, employment, health, etc.) is not, *per se*, the path for the co-building of (a complete form of) citizenship. Here, the role of digital networks could be further explored taking into account the denoted urban-rural dynamics. These could be examined as particularities of the system, since each group of actors and geography have specific routines, to contrast with activities in the Lisbon Metropolitan Area.

From a much more specific point of view, case studies as the project *Refugi.Arte em Marvila* contribute to a broader perception of the role of architects, with other technicians, as privileged mediators between local actors and the political arena, taking into account different strategies – top-down and bottom up – for achieving the same goal, *i.e.* socio-spatial and housing inclusion of refugees in the Lisbon Metropolitan Area. Also, *Refugi.Arte em Marvila* underlines polarised understandings of the use of cultural heritages under the political umbrella of inclusion. As for *Tayybeh*, since it is located in a particular eastern part of Lisbon, it may provide relevant information regarding the socio-spatial and cultural dynamics built around the initiative, as well as inform about small scale interventions penetrating the society. In its turn, the project *Orquídea Silvestre* follows the strategy of the Portuguese government regarding the repopulation of small/medium-size cities and rural areas, even if these decentralisation trends do not follow global movements for the large cities. This case study could be exemplary for analysing the reception of self-empowered refugees and vulnerable migrants in specific rural areas, also for comprehending the difficulties attached and the ways to overpass them. The construction of rural housing – e.g. earthen domes of the Syrian-type –, different from the Portuguese, and the building of infrastructures are also of interest for the project *INSEhRE 21*.

Learning loops in the public realm. Enabling social learning in communities to tackle the challenges of cities in transition

Transposition of Advocacy Experience as Triple-Loop Social Learning in Albania: Fighting HPPs in Protected Areas from the Vjosa River Basin to the Canyons of Osumi

Abstract: This paper traces the learning experiences of communities, living near protected areas, taking to the Administrative Court, in view of a lack of environmental crime law that would render these cases penal procedures, government decisions awarding the right to build hydropower plants to several national and international companies. We focus on the first four such administrative lawsuits in Albania, arguing against the construction of HPPs in the protected areas of the Vjosa river basin, the Valbona Valley National Park, the Seta river, and the Canyons of Osumi, from 2016 to 2018. Based on Brown et al.'s definition of triple-learning loops as a process transformative of decision-making paradigms and of the learning process itself (2015, pg. 1685), we demonstrate how the fight to protect national parks, biomonuments and dependent livelihoods, accompanied by social media campaigns and protests, have informed practices of participatory social learning (Brown 2015, 1686). We break down the dynamics of the multi-level and multi-agency approaches of these claims, to denote and explain the role of multiple social actors opposing the lack of compliance with environmental legislation on protected areas. We, ultimately, argue that the switch in feedback loops has acted as a catalyst for sustained behavioural change, and rendered possible the transposition of advocacy practices across different communities.

Keywords: triple learning loops; protected areas; environmental law; adaptability; Albania

Introduction

Since 2008, one of the main priorities of the Albanian government has been the exploitation of water resources in the country. First and foremost, the idea for the exploitation of water resources in Albania is based on the wrong conviction that given how the per capita water use in the country is among the highest in Europe this resource is endurable and associated benefits are permanent. Thus, the Albanian government focused on the massive development of hydropower plants (HPPs) of different sizes and types. These efforts however, have been accompanied by an indiscriminate action to exploit all water resources, independently of their ecological and biological values and approved permits for HPP constructions have been awarded independently of their social and environmental impacts. This way “[t]o date there are around 500 hydropower plants in Albania that are either operative, under construction, or planned. Of these, 105 are located in protected areas. Such power plants have had a significant impact on local biodiversity (Gjoka, 2018).” The lack of transparency that surrounded the processes of concessions the government made to private, foreign and in-country companies contributed to a widely chaotic misinformation process that made for a powerless citizen. At present, 95% of

Albania's electrical consumption needs are covered by production from hydro sources (Ministry of Infrastructure).

However, the implementation of such policies is not backed up by any significant, or meaningful study, on water resources in Albania and any proof that the production capacities of existing and proposed HPPs would eventually outweigh the permanent destruction of the natural ecosystems where they were built or are planned (Revista Monitor, 2013). The case is even more so when it comes to HPPs built in protected areas (PA). More to this point, several environmental NGOs and activists in Albania and elsewhere argued against these measures. The various privately-owned HPPs have brought about significant alterations to the Albanian landscape. The most prominent biologists in Albania saw themselves improvising as activists and arguing in favor of protecting the flora and fauna (Miho 2015a; Miho 2015b; Miho 2015c).

More specifically, just to briefly reference the average drop in annual rainfalls, the Albanian Institute of Statistics (INSTAT) reports, net domestic production of electricity decreased by 36.6% in 2017, with "public hydro plants decreas[ing production] by 42.7% and independent and concessionaire power producers decreased [production] by 21.3%" (INSTAT). The contrary was true a year later, to be fair. According to the same data gathering and interpretation process, in 2018, a good year given the rise in 89% gross domestic production of electricity, "public hydro plants contributed 68.4%, while independent hydropower plants realized 31.6% of the net domestic electricity production" (INSTAT).

As studies on the impact of HPPs, small and medium, that have sprung everywhere are beginning to be carried out either by Albanian biologists and scientists, or international bodies concerned with the environment it is obvious that the abovementioned premise does not hold true. While Albania might have a high water resource per capita in general, the relatively low and fluctuating productivity of HPPs when compared to their environmental impact does not always justify their presence.

Furthermore, the indiscriminate construction of HPPs has forever altered the landscape of the livelihoods of the communities that reside near them. While often advertised as one of the last unexploited European gems, local eco-tourism has suffered, especially in the case of touristic initiatives relying on the Valbona river PA, as we will show later on in this paper.

The current government came into power in 2013 with the promise they would halt the ferocious HPP development, but this did not prove to be the case and personal and corruptive interests have since often prevailed. Then again, the Albanian government is paying lip service to European integration strategies aiming at supporting and developing sustainable tourism, increasing environmental quality and contributing to 'blue growth', such as the EU Strategy for the Adriatic and Ionian Region (EUSAIR).

The situation escalated to the point that an assessment study, titled 'Identification of water related conflicts linked to hydropower project in Albania' (Qendro, 2017) carried out as a joint effort of several main environmentally focused think tanks and NGOs operating in Albania in 2017 showed the dire consequences of the clashes between communities threatened by the construction of HPPs and state authorities. More specifically, between 2012 and 2016, 34 people were arrested, among whom protesting the Cernaleva HPP three women and one minor, while six casualties were recorded overall.

Meanwhile, the negative impact of HPPs on ecosystems and the communities left without water became the subject of several journalist denouncements both at home and abroad. Among the most outrageous examples, the Rapuni 1 and 2 projects built in the Shebenik-Jablenica national park registered the desertification of much of the protected area and failed local mini businesses relying on water mills (Qendro, 2017).

Community Organization and Knowledge Transfer

This section of the paper traces the learning experiences of communities, living near protected areas, taking to Administrative Court, in view of a lack of environmental crime law that would render these cases penal procedures, government decisions awarding the right to build hydropower plants to several national and international companies. We focus on the first four such administrative lawsuits in Albania, arguing against the construction of HPPs in protected areas and more precisely those of Poçëm in the Vjosa river basin, the Valbona Valley National Park, the Seta river in the Dibër Municipality, and in the Canyons of Osumi, from 2016 to 2018. We demonstrate how the fight to protect national parks, biomonuments and dependent livelihoods, accompanied by social media campaigns and protests, have informed practices of participatory social learning (Brown et al. 2015, 1686).

The most sensational case of an HPP being built on a river while highly disrupting its ecosystem was that of the HPP planned in Poçëm, in the Vjosa river, one of the few existing wild rivers in Europe. The plans for Poçëm made the round of the news and of the European community of environmentalists, whom organized and staged several protests in Tirana, in front of governmental buildings. What gave protesters a leg up in this fight was the successful association of Vjosa with the ‘Blue Heart of Europe’ area of which the river is part, tracing the beginning of the river as the Aoos in Greece and making casual references to the mythologies the latter is tied to. Biologists, nature conservationists and both traditional and social media jumped on the branding. Although within national parks from Slovenia to Greece a total of 1,003 HPPs were estimated to exist in 2018, while 188 were being built and 2,798 were planned (Morris, 2018), the argument that the dam in Poçëm would forever alter the landscape of Vjosa caught up. Poçëm’s case altered the landscape of protests organized by small and poor communities, which often were paid fleeting attention by traditional media, but never received any support from outside civil society organizations (CSOs) and/or environmental actors. The community protest in Poçëm benefitted from visual materials and strategic protest tools, such as people chaining themselves to block nearby national roads (Koha Jonë, 2016). Another peculiarity of the protests in favour of the preservation of the Vjosa River was the public stance against the governmental decision on the part of five Mayors, belonging to the Përmet, Tepelenë, Memaliaj, Mallakastër and Selenicë Municipalities, who argued against the Environmental Impact Assessment that informed such decision, in February 2017 (BIRN, 2017).

Thus, Poçëm marked the first instance of a community, 37 individuals supported by three national NGOs, taking the state to court, and more precisely sued the now former Ministry of Energy and Industry, the now former Ministry of Environment and the National Environmental Agency, over the approval of an HPP permit. The sensationalism had turned into excitement and hope and the materialization of the protest into a court case, the first of its kind. CSOs felt more compelled and secure enough to speak up and insisted on the government’s obligations to several international agreements, such as the Bern Convention (ecoalbania, 2018). On 2 may 2017, via Decision no. 1813 (ecoalbania, 2017), the Administrative Court of First Instance of Tirana found the approval of the HPP permit on Poçëm to be invalid and stated that the expenses incurred by the plaintiff were to be covered by the indicted parties. More precisely, the decision of the Court stated that the developer did not fulfill his duty, and did not inform the general public on the public hearing, according to conditions specified in point 6 of DCM no. 247, date 30.04.2014, ‘On the definition of rules, requirements for informing procedures and the involvement of the general public in environmental decision-making processes’. The latter states that the developer must notify and inform the public via audiovisual media channels, printed local and national media, given the national character of the HPP project, the placement of informative tables at the place where the project is to be developed, and making available material concerning the public hearing at the offices of the Local Government Unit (ecoalbania, 2017).

Although the victory of the community impeding the construction of an HPP in Poçëm was historical and ground-breaking, the practice of building HPPs in protected areas did not stop there. Another, more sensationalist, case was that of the HPP permits approved on the Valbona river.

“In January 2016, local people in Valbona Valley National Park learned of the plans to build as many as 14 hydropower plants along 30km of Valbona River, 8 of them wholly within the National Park. The procedure and content of the projects’ environmental impact assessments demonstrate non-transparent decision making, disregard for local communities’ well-being and indifference towards high conservation value ecosystems, including a complete disregard of the fact that the development is occurring in a protected area” (Toka, 2018).

Here the Valbona community benefitted from a relatively long, taking into account the history of the nation, and stable operations of eco-tourism. The Valbona community had been attracting tourists from all over the world as one of two most popular mountain destination, together with Theth, and had been advertised internationally by big international actors acting in the country, such as The Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ) Albania, which supported the development of the Peaks of the Balkans trail. Needless to say, the Valbona community protests made use of the momentum built by the protests still occurring with regard to the Poçëm HPP and representatives of the cultural community in Albania, who had supported the electoral campaign of the ruling party or the Prime Minister himself given his role in the cultural promotion of the country abroad, voiced their stance against the HPPs. A series of events and actions were organized by different stakeholders, among which the most popular proved to be two concerts: one organized in Valbona, which attracted Albanians from all over the country and from Kosovo as well, and another one in Tirana in the city center. Protest supporting the conservation of the Valbona River were also held in New York. The concerts were played by internationally renowned figures. The events were accompanied by some ongoing fund-raising that goes toward the legal battle.

The court case regarding Valbona proved to be a harsher battle, accompanied by some outrageous court standings. First and foremost, the suing community, the Valbona community, at a certain time was not even recognized as a lawful representative of the region by the Administrative Court of First Instance of Tirana. The first lawsuit “was thrown out by the court after 14 hearings and 5 months,” as the Court stating that the government makes decision with the best interest of the citizen in mind. The plaintiff argued that their rights to free speech and “right to information, involvement in decision making and judicial recourse in development decisions with environmental impacts,” (Toka, 2018) deriving from the Aarhus Convention of which Albania is a signatory, were not respected. The case is still being processed, while the construction company, or the HPP company, is sporadically working on the project, excavating and permanently altering the environment. Conversely, the developer Gener-2 and their subsidiary company Dragobia Energy have taken to court one of the main organizers of the protest over damages on their image. The Toka NGO, as the leader of the lawsuits and any other organization against the HPPs in Valbona, nevertheless states that the experience so far has been overall a positive one. “The battle so far has been notable in helping to change the national perception of protected areas and National Parks, from distrusted, ‘mysterious’ zones created by the government to limit the rights of inhabitants to national treasures belonging to the people” (Toka, 2018).

In 2015, the National Territorial Council, part of the National Territorial Planning Agency, released a permit for the construction of four HPPs onto the Seta River, to the HydroSeta Power company. Given how the area is protected by Albanian law, and more precisely via Decision of the Council of Ministers no. 676, date 20.12.2002, “On the provision of protected natural areas” and Law no. 112/2012 “On the integrated management of water resources”, inhabitants of the area brought their claim to court asking for the partial annulment of the concession contract concerning the construction of the last HPP, SETA 4. The inhabitants claimed that this particular HPP would impact two, out of four, canyons which are within the protected area. While the inhabitants of the area argued that the deviation of the water resources would impact PAs and decimate the trout population, the representative of the former Ministry of Infrastructure and Energy argued that given how the HPP would not be built on PAs or biomonuments the plaintiff’s claim had no grounds. The inhabitants of Çidhën faced the state in court since 27 July 2017 and during 17 months they participated in a total of 20 judicial sessions. In August 2017 the police prosecuted 20 inhabitants that tried to block construction

in the area. In December 2018, the Administrative Court of First Instance definitely dismissed the plaintiff's claims and although the case was presided by a judge, "the decision was taken by a majority of votes" (Curri, 2018).

Nevertheless, a last case arguing for the protection of PAs, was still won by a community taking on the role of the plaintiff. A concession to the HEC Bigas and Veleshnje company, to build two HPPs in the Bigas watershed, in the Canyons of the Osumi River was kept secret for years, from 2013 to 2018 to be precise, until the case was uncovered by one of the top media channels in the country. Following the highly unpopular news, and how the Canyons of Osumi have become one of the main touristic attractions in the country, highly advertised via celebrities and high-level politicians, and hence a meaningful generator of revenues for the areas, adjacent communities, touristic operators and the general public started protesting the decision both in the streets and online. In a very successful first, the construction permit given to the developer was found to be irregular by the Ministry of Tourism and Environment and the Ministry of Infrastructure and Energy (MIE). More precisely, the MIE announced on 15.02.2018 that the administrative act concerning this case's Environmental Impact Assessment was null. Ultimately, the developer would sue the government on the rescission of the permit to no avail.

Figure 1. Map of hydropower plants in protected areas throughout Albania (source: exit.al)

A successful series of community protests was that of the inhabitants of Zagoria. The Albanian branch of the Dutch giant, Shell, had signed another silent contract with the National Agency of Natural Resources, representing the former Ministry of Energy and Industry, to drill in four different blocks in Albania via DCM 350, date 12.6.2018, "On the approval of the contract dividing production on the research, development and production of hydrocarbons in the soil, in Albania, Block 4, between the Ministry of Infrastructure and Energy, represented by the National Agency for Natural Resources and Shell Upstream Albania B.V.". When the Dutch

company announced community hearings, as per Law no. 10281, date 20.05.2010, “On concessions”, protests ensured. The popularity of the region, deriving not just from its touristic destination status but from the fact that one of the most popular bottled waters comes from Zagoria and is named after the region, social media followed up with online petitions and denouncing the nature of the arrangement. Ultimately, unable to conduct public hearings with the communities and overwhelmed by the pressure coming from public opinion, Shell Upstream Albania declared it was giving up its search for oil in Zagoria.

Indeed, the transformation of the overall situation regarding translated into such pressure for the next Minister of Infrastructure and Energy, after the restructuring of the Ministry and the government even more widely, that in February 2019 she declared that she would freeze works on the two HPPs that were to be built in Gramsh, near the Holta Canyon, another very popular tourist spot (Spasić, 2019). The declaration did come after protests were organized by inhabitants of Gramsh and villages near the Holta Canyon. In a first, the Minister also stated that she would investigate 182 licenses issued to build a total of 440 HPPs (Spasić, 2019), and backed her statement with the fact that the damages these SHPPs would cause outweigh the economic gain they generate (Spasić, 2019).

What had occurred at a national level, thanks to social media, traditional media and journalists that were willing to challenge the status quo of silent deals, agreed upon away from the public eye, was participatory social learning which had translated these actions into “knowledge exchange, adaptive management and local leadership, together with recognition of informal or tacit knowledge systems that extend beyond conventional scientific knowledge (Nazarea 2006 in Brown 2015, 1686).” Participatory social learning allows for “[p]luralistic approaches to knowledge development can provide an important enabler for engagement of civil society in sustainability planning if they can incorporate longer time horizons, adaptability and feedbacks, integrated approaches, and systems thinking (Burch et al. 2014 in Brown 2015, 1686).”

As Löf explains in his paper, *Exploring Adaptability Through Learning Layers and Learning Loops*, the need of small communities, that depend on water resources and rely on protected areas statuses in various locales throughout Albania to sustain their livelihoods, to adapt and react against a situation always in their disfavor led to various learning loops (2010). Social learning with relation to environmental protection and conservation has also been the subject of relatively recent studies (e.g. Keen and Mahanty 2006; Maarleveld and Dabgbégnon 1999; Pahl-Wostl et al. 2008; Stagl 2007; Wals 2007 in Löf 2010, pg. 534).

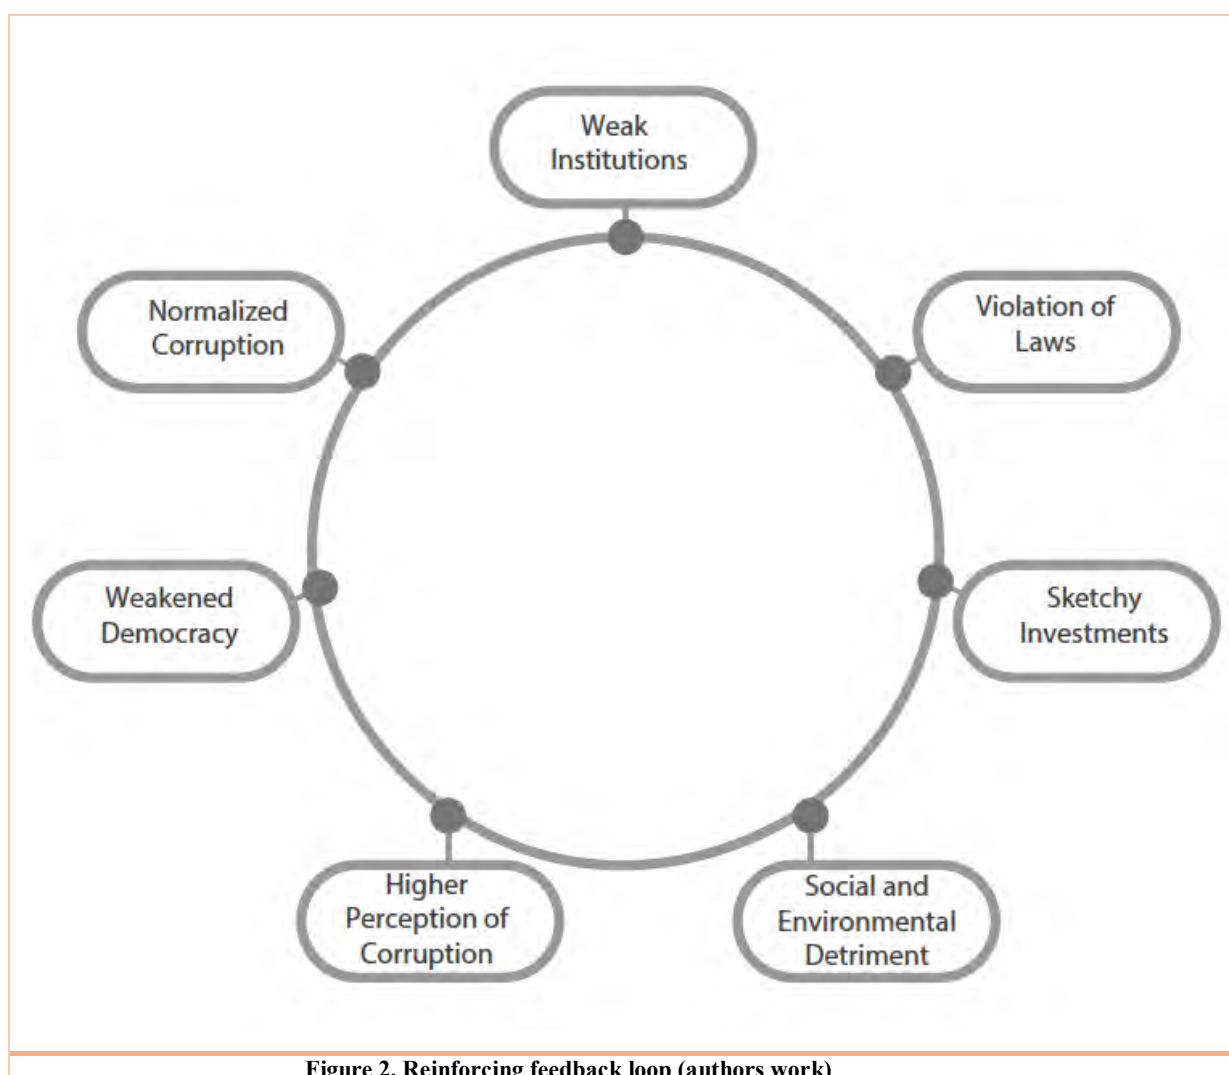

“Social learning has for instance been applied to denote individual learning in a social context; learning by social aggregates (Stagl 2007); or synonymously with participatory processes, co-management and collaborative governance (Mostert et al. 2007). The latter conceptualization emphasises that multiple-loop (group-layer) learning does not come automatically but requires deliberate and strategic efforts. (Löf 2010, pg. 534).”

Transformation of Feedback and New Learning Loops

Based on Brown et al.’s definition of triple-learning loops as a process transformative of decision-making paradigms and of the learning process itself (2015, pg. 1685), we demonstrate how the fight to protect national parks, biomonuments and dependent livelihoods, accompanied by social media campaigns and protests, have informed practices of participatory social learning (Brown 2015, 1686). We, further, argue that these communities have been able to turn a self-reinforcing feedback loop, one where economic laws undermine national and international environmental legislation contributing to the mismanagement of national natural resources for over a decade, to a balancing one, where implementation of environmental legislation is equated to higher community awareness and organization. Employing Löf’s distinction of governance versus government and governing (2010, pg. 534), we break down the dynamics of the multi-level and multi-agency

approaches of these claims, to denote and explain the role of multiple social actors opposing the lack of compliance with environmental legislation on protected areas.

For years, and more precisely since the communist regime in Albania, HPPs were built in PAs altering the livelihoods of the communities living near them and making use of protected resources. Caught in a negative feedback loop where corruption weakened democracy and left no space for governance, Albanian citizens kept quiet. Switching to a double-learning loop would have meant that the citizens in the communities of Osum, Vjosa, Seta and Valbona would have had to put up with the at least one of the elements represented in the loop diagram in Figure 2, - ultimately, an impossible task if they wanted to achieve social and environmental justice.

In the previous section of the paper, we have shown how communities, together with other key actors, were able to switch to a balancing loop (Drutman, 2015), in which corruptive practices of economic legislation were countered by pro-active communities arguing in favour of the rightful application of national environmental legislation, thus, bringing the democratic system in Albania to a new stable system.

To better support the claim of this paper, that is to say that the learning loops in Albania represent a case of triple-loop learning rather than a double-loop one, it is worth shortly focusing on the distinction between the two.

As Petersen points out, landscape conservation has usually made use of single-loop learning processes, where problem solving was directed by the desired achievement, with new strategies being continually envisioned and

implemented after initial failures (2014, pg. 784). Nevertheless, this kind of learning loop only led extremely low successful percentages, and it led to even less operational changes (Petersen 2014, pg. 784). In other respects, double-loop learning requires the identification, development and integration of new behavioral changes, “as informed by the new values and frames, into group norms and relationships so that it becomes the new normal (Putnam 2014).” While Brown et al. provide the best definition of a triple-loop learning process:

“Triple-loop learning takes actors beyond pre-existing structures by challenging existing decision paradigms and the contexts which frame the decision-making process, including underlying principles and norms (Maarleveld and Dabgbegnon 1999; Pahl-Wostl 2009). Full triple-loop learning may therefore be conceptualised as learning about the learning process itself and how this process can be further enhanced to tackle new challenges and opportunities (Brown et al. 2015, 1686).”

In short, the differences between the different learning loops that have wanted to specify in this paper, with regards to the events that have taken place in Albania following the approval of HPPs in nationally protected parks, is also presented by Löf, in his publication with the *Environmental Education Research* journal:

“*Single-loop* learning refers to ad hoc or routine learning, simply responding to errors by making smaller adjustments. *Double-loop* learning refers to actively trying to change protocols and organisational norms in response to detected errors (Argyris and Schön 1978). *Triple-loop* learning entails fundamental change of the entire mental model the governance or management process is based on (Keen and Mahanty 2006 in Löf 2010, pg. 533, authors’ emphases).”

In this paper, we, ultimately, argue that the switch in feedback loops has acted as a catalyst for sustained behavioural change, and made possible the transposition of advocacy practices across different communities in Albania. We have focused on these learning loops as they challenge the status quo and disrupt the correlation between poverty, inequality and environmental degradation. Most importantly, we hope this paper serves as a reminder that environmental and social justice are deeply interwoven and that changes with regards to adaptability and governance call for:

“[b]alancing short term needs with longer-term requirements for sustainability while managing multiple uses, accounting for legacy issues, and integrating the dynamic and complex relationships between human and nature through space and time requires a more complex and integrative approach than is normally used in biodiversity conservation and natural resource management (Thiault et al. 2017, pg. 448).”

We also aimed to show in this paper, that the approach toward the protection of national parks and connected livelihoods employed “[m]ulti-modal (direct, deliberative), multi-level (local, urban, national) and multi-user (policy, [activist], research) learning loops (JPI Urban Europe)”, not only as the Looper project distinguishes in general, but also as has become general knowledge when dealing with conservation efforts and/or water management (Petersen 2014, pg. 782; Balazs 2014, pg. 99).

Conclusions

HPPs, be them small or medium, in a time of technological acceleration most often cannot catch up with their own temporalities, - the multiple timelines that include needs for approvals, public hearings feasibility studies, and the upkeep - and the social and political worlds, - often small and already having achieved self-sustainability, just like the ones we have presented in this paper, - where they would be of relevance are already obsolete. The role of the technical/engineering expert becomes irrelevant and the role of the nature conservationist takes crucial importance. The false image these failed megaprojects projected as a necessary

modernity were not only met by a knowledgeable public, but one that was willing to learn and do more. At a time of a new climatic regime, the vision of relying for energy production on the exploitation and alteration of small and medium HPPs proves unsustainable. Drawing from UNFCCC data, rainfall in Albania is expected to decrease by approximately 14.37% by 2080 and by more than 18% by 2100, while becoming more unpredictable throughout the year (Gjoka, Hoxha and Bashmili, 2018, 107-8). The overview of the exploitation of water resources in Albania, as a top-down process regulated by central government deepening financial strains for local communities, presents us with what Bruno Latour hypothesizes, “the explosion of inequalities and the denial of climate change are one and the same phenomenon (2018, p. 1-2).”

This paper is instrumental in the way it gives out an accurate account of the learning loops through which communities around Albania, living near protected areas and living off of them, passed in an organic manner with on-the-spot organization, guided by the principle of law. The social learning lesson we draw from the above cases is that it is precisely the triple-loop learning that which makes for long-term structural change (Balazs 2014, pg. 100). Furthermore, it is imperative to demonstrate, as this paper does, that these communities shook things up and completely transformed the feedback loop that the news and top-down development approaches dictated daily via the news. These communities were successful in gaining national and international visibility and went from marginalized groups to efficient governing bodies. They transformed a negative feedback loop, one where corruptive practices weakened democracy and public institutions, into a positive feedback loop, one in which governance and adaptability determine the fate of communities and the environment, and the kind of development they seek. The first four cases of citizens taking the state to court over nature conservation marked the forming of a new public, proactive, international, collaborative, engaged and engaging, and a shift from passive to active citizenry. A culture about water, biodiversity, the protection and conservation of ecosystems as values to be upheld not as commodities to be fought upon, and about the support and promotion that remote populations, which perform this kind of work, deserve was set. “[S]ocial learning provides a link between procedural and distributive justice; to the extent that it changes water management institutions (Balazs 2014, pg. 99).”

What this paper ultimately demonstrates is that communities are willing and able to contribute to effective governance even in a developing and problematic context such as that of Albania. However, what is lacking in the latter is the use of online platforms and other traditional methods, such as traditional community planning and design workshops, to effectuate policies. These tools were, however, only employed to resist top-down, environmentally exploitative policies. To conclude, we would very briefly state that the current state of development and planning policies should shift focus from ‘sustainability’ to inclusive development, which “focus[es] on social wellbeing and protecting the ecosystem services of nature through redefining political priorities, especially in the context of the Anthropocene (Pouw and Gupta, 2016, 104).”

Learning loops in the public realm. Enabling social learning in communities to tackle the challenges of cities in transition.

A participatory approach to Societal Cost Benefit Analysis (SCBA) as a way to start the debate on transforming residential subdivisions

Abstract: Residential subdivisions remain the preferred living environment for the majority of the people living in Flanders. But, this mode of living comes at a high societal cost. These costs are paid by society as a whole, whereas the advantages are only experienced by the residents (De Decker, 2011). In Flanders, there is an ongoing debate on how to reduce these costs since the sixties (Anselin, 1967; Braem, 1967; Strauven, 1980). In spite of this debate, the subdivision of open land continues at a rate of 6 ha each day (De Decker *et al.*, 2010). Our hypothesis is that a societal cost-benefit analysis (SCBA) could benefit a more informed debate. A SCBA analyses the costs and benefits of (spatial) scenarios (ECORYS, 2008, p. 15) and relies on heuristics to translate these costs and benefits, in a transparent way, to a number of (monetary) values. As such a SCBA allows to include perspectives from multiple sectors (e.g. planning, ecology, heritage, mobility) and supports a strategic debate among policy makers. The conducting of a comprehensive SCBA is a complex process. We particularly propose to use SCBA as a dynamic and participatory instrument, that evolves along with the debate. As such, it would no longer only be a decision-support tool for policy makers, but also a capacity building tool that helps participants to reflect over the impact of their current (spatial) behavior and over how to reduce the societal cost of this behavior. In the paper, we will discuss how the participatory SCBA supports the definition of values, the composition of the value framework and the construction of the publics.

Keywords: participatory societal cost benefit analysis; dynamic instrument; value framework; constructing publics

Introduction

Residential subdivisions are the preferred living environment for the majority of inhabitants of Flanders for reasons of privacy, presence of green and overall quietness (studiedienst Vlaamse Regering, 2016). But, this low-density and uniform mode of living comes at a high cost, because it is causing inefficient services, congestion, low biodiversity, car-dependency, social isolation... (Johnson, 2001; Holden, 2004; Vestergaard, 2006; De Decker *et al.*, 2010). These costs are paid by society as a whole, whereas the advantages are only experienced by the residents (De Decker, 2011). Already since the sixties there have been a public debate that discusses the societal costs of low-density subdivisions, in particular the (negative) impact of increasing spatial dispersion (Anselin, 1967, Braem, 1967, Strauven, 1980).

Recently this debate has been gaining renewed attention in Flanders, triggered by the approval of the Spatial Policy Plan for Flanders (white paper) in November 2016. The plan sets a clear ambition to reduce the costs of dispersed urbanization as it claims a ‘net-development-stop’ by 2040 (Ruimte Vlaanderen, 2016). From that moment onwards, the net amount of built surface can no longer increase. A new residential subdivision can only be developed if one of equal size is removed.

In spite of this renewed attention, the subdivision of open land continues at a rate of 6 hectares per day in Flanders (De Decker *et al.*, 2010). With each new subdivision, the costs for society increase (Vermeiren *et al.*, 2019). The task of designers and policy makers to initiate this debate with inhabitants of residential subdivisions is difficult and sensitive because people like their way of living. The hypothesis of this research is that this can take place in a more constructive and informed way (ECORYS, 2008). One way to do this would be to make the costs and benefits of alternative modes of deploying explicit. Therefore, we propose to introduce a so-called ‘participatory Societal Cost Benefit Analysis (participatory SCBA).

In this paper we will first describe the methodology of the participatory SCBA, then sketch the context of the cases in which we will test this method and finally discuss how the participatory SCBA supports the definition of values, the composition of a value framework and the construction of the publics; three conditions to make the debate on the future of residential subdivisions more constructive and informed.

Methodology

The aim of the research is to develop an operational framework that will support the use of a participatory SCBA to come to a constructive and informed debate among actors involved in residential subdivisions (residents, local policy makers, local organizations) on the societal costs of their mode of living and possible tradeoffs between individual and collective costs and benefits. The development of such operational framework requires an iterative process that invites both researchers and residential actors to test tools and approaches and to reflect over experiments and findings. The proposal is therefor to adopt the method of action research (Wicks and Reason, 2009). More specifically, the proposal is to develop the operational framework in two cases: an urbanized neighborhood in the city of Hasselt and a residential subdivision in the municipality of Diepenbeek. The process in the case in Diepenbeek has not been started, therefor we will only discuss the case in Hasselt.

Participatory SCBA

A societal cost benefit analysis (SCBA) is a method to analyze the societal costs and the societal benefits of (spatial) scenarios (ECORYS, 2008, p. 15). It relies on heuristics to translate these costs and benefits, in a transparent way, to a limited number of (monetary) values. As such a SCBA allows including perspectives from multiple sectors (e.g. planning, ecology, heritage, mobility) and supports a strategic debate among policy makers on, for instance, retrofitting strategies.

Conducting a comprehensive SCBA is a complex process. The estimation of the costs and benefits of a scenario implies an insight in the impact of this scenario on the spatial behavior of all relevant actors, today and in the years to come. Practice has demonstrated that “the quantification of only a part of the impact of a scenario can already provide additional insight for policy making. Even the mere adoption of the mode of thinking of an SCBA can already contribute to the success of projects in the social domain” (ECORYS, 2008, p. 13)

Scholars therefore propose to use SCBA as a dynamic instrument which evolves along with the debate (ECORYS, 2008). The more data are available, the more nuanced the estimations will be, and the more interesting the SCBA becomes as a decision support tool. Interpreted as such, conducting an SCBA is, in fact, a collective learning process (Albrechts, 2004) during which all the involved actors incrementally explore and agree upon how to quantify the impact of spatial scenarios. The learning potential of this process increases from the moment that not

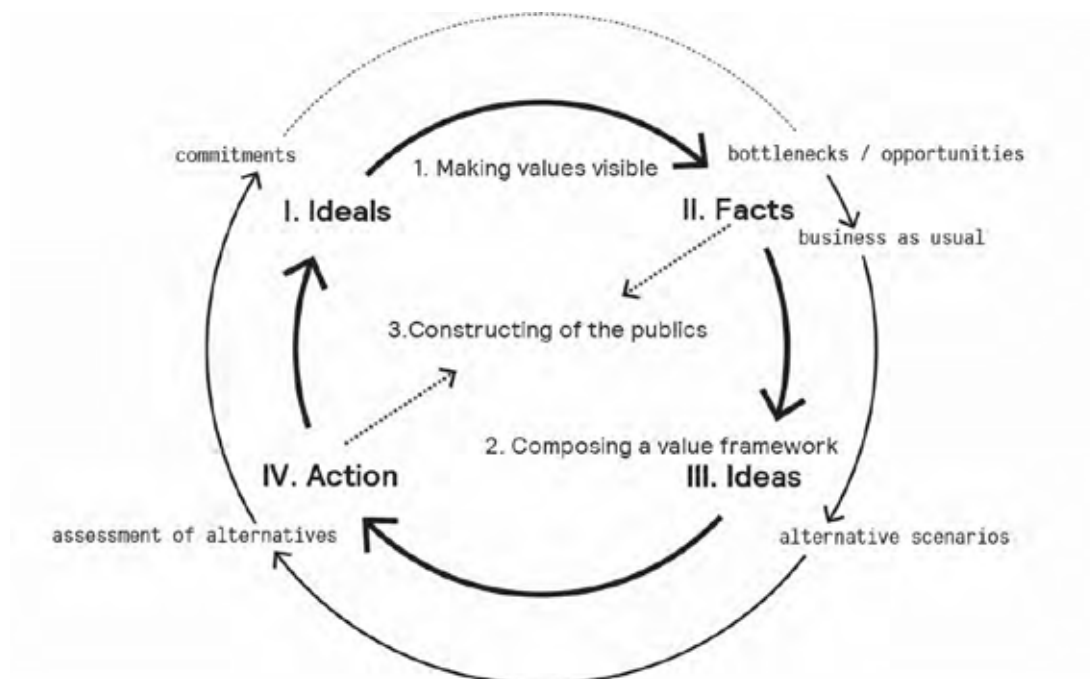

only policy makers, but also developers, residents, non-profit organizations... are invited to participate. In the words of Horelli (2002) this would turn an SCBA into an ‘enabling tool’ that supports ‘communicative transactions’ between all actors involved in a spatial transformation process.

There are examples of research where local stakeholders are consulted in the process of a monetary assessment with the aim to implement local knowledge in order to develop alternatives that are more adapted to the local context and have higher chances to be accepted by the local community (Carolus *et al.*, 2018, Sager, 1979). In this research, however, the aim is not only to add the participative or deliberative aspect in to the assessment in order to make better informed decisions (Carnoye and Lopes, 2015), but to implement the assessment aspect in the participatory process to make the debate on societal costs and benefits of dispersed modes of dwelling more articulated in order to give form to a more constructive and informed debate.

Our hypothesis is that a participatory SCBA can make the debate more constructive and informed in three ways:

1. *Making values visible*: In the first stage of the participatory SCBA, the ideals, the participants are asked to define “what should be”. When the participants formulate an answer to this question, it will reveal their values. (Brown and Lambert, 2013). Values and ideals are closely related: when people express what their ideal neighborhood should look like, they say what they value (safety, green, accessibility ...). These values will be used as a framework to assess the cost and benefits of the alternative scenarios during the process. The debate on the societal costs of residential subdivisions often stops on confused communication. We use the same words but we give it another interpretation, for instance, sustainability: for one person it means a well-insulated house, while for others it means to live close by public transportation. SCBA can help to make these values more concrete by translating them in measurable indicators and let people talk the same language.
2. *Composing a value framework*: a second reason for the roughness of the debate, is the mixture of highly individual and universal arguments. SCBA can help to prioritize the arguments and by doing so, defining a value framework: a hierarchy of values. This is an essential condition for the process of tradeoffs between individual and collective values. In the participatory process is the SCBA used to make the implicit process of defining a value framework explicit in an early stage of the research by bringing the definition of the values in the debate. Not only for the participants, but also for the action researcher who is as much a part as the process as the participants are. As researchers, we are all subject to social mindsets (by our own knowledge and how we act upon it) in which the framework is defined (Swann, 2002) and we have to be clear about the values that inform our everyday practices and our research stance (McNiff, 2017).
3. *Constructing of the publics*: The public is a concept from the pragmatist Dewey and is defined by him as “the public consists of all those who are affected by the indirect consequences of transactions to such an extent that it is deemed necessary to have those consequences systematically cared for” (Dewey, 1954). Publics originate in response to issues related to the specific context in which they are experienced and multiple publics can come from a single issue (DiSalvo, 2009). In the stage of the ‘Facts’, the participants define the bottlenecks and opportunities of the neighborhood and thus define which issues there are at stake. When one alternative scenario is tested in a real place in the neighborhood, this will also have an effect on the daily life of people who were not involved in the process yet and new publics will be constructed.

Defined in this way, a participatory SCBA is no longer only a decision support tool for policy makers, but also a capacity-building tool that helps participants to reflect on the impact of their current (spatial) behavior and how to reduce the societal cost of this behavior. Applied to residential subdivisions, to conduct a participatory SCBA would imply to initiate a process during which a diversity of actors, linked to a particular residential subdivision, collectively assesses alternative futures for this subdivision.

By going through this process of collective learning, the stakeholders will gain insight in the societal impact of their dispersed mode of living and take action on this situation in order to come to a social spatial change through spatial interventions (DiSalvo, 2009).

Context

Figure 2: situation cases in Belgium

The research will take place in two cases studies both situated in the eastern part of Belgium, in the province of Limburg (Figure 2). The context of the cases is different in order to test the possibility of transformation strategies on multiple levels: from the level of the subdivision to the level of the region. The later would allow us to examine the potential trade-offs between municipalities in decision-making on where and how to build or to remove built space. In this paper, we focus on the level of the subdivision and more specific the Heilig-Hartwijk in Hasselt.

Case Heilig-Hartwijk in Hasselt

Figure 3: location Heilig-Hartwijk

The Heilig-Hartwijk is located close to the city center of a Hasselt, the capital of the province of Limburg (Figure 3). The neighborhood is surrounded by a railway station in the south, a larger ring road in the west and north part and a former industrial site (in transformation to a residential area) and a smaller ring road in the east part. The morphology of the neighborhood is diverse: detached-houses, row houses, apartment blocks... and services that go beyond the scope of the neighborhood (three schools, a mosque, a church, a sports center, SME's ...). The process of the Heilig-Hartwijk is part of a bigger project "Werken aan Wijken" (Dutch for Building on Neighborhoods) and is formalized in a contract between the Hasselt University and the city of Hasselt to conduct participatory processes in three different neighborhoods. The aim is to organize a collective learning process during which the policy makers, the city administration, key stakeholders, the developers, designers and inhabitants together learn how to coop with the tensions between societal and individual agendas. In this neighborhood we particularly work on the tension between the ambition of the city to densify this neighborhood (located close to a public transport hub) and the fear of the residents that this densification will reduce the livability of their neighborhood caused by increased car traffic and reduced open space.

Before the participatory process was started, there were already two groups of citizens active in the neighborhood: "*Achter het Lijmfabriek*" (Dutch for "behind the glue factory") and the group we named "*The Parents*". *Achter Het Lijmfabriek* originated in a reaction to the difficult communication with the city. They want the city to guarantee the livability of their neighborhood, until then they will fight against every new urban project in their neighborhood. Their strategy is formal: they organize public debates, submit appeals, ask formal questions about projects... Their main values are safety, mobility (in specific car accessibility) and authenticity. Although they were only recently established (end of 2017), they already have a large number of followers of mainly older inhabitants who have lived in the neighborhood for quite some time and have seen 'their' neighborhood change at a high speed.

The Parents are formed by the parent committees of the schools in the neighborhood and the neighborhood committee of one specific street. They are not all parents of young children, but their normative framework is defined by the place of the children within the neighborhood: they are concerned about sustainability, quality of life, safety... They have consciously chosen to live close to the city center because it aligns with their values. The future transformation that they see, depends more on the global tendency towards a sustainable lifestyle in a livable city and depends less on the ideology to conserve the existing characteristics of the neighborhood. They are organized in a more informal way.

Besides these two groups of citizens, there are also the groups we named "*The Church*", "*The Lost Souls*", the politicians and the experts. The Church is a diverse group of people who still attend the mass, the people that live in the direct surroundings and the ones that are interested in thinking about a new function for it (as the church will be available soon due to the decrease of people attending the mass). They have a shared concern: keep the church as a meeting place for the neighborhood. Finding a new function for the church is part of the participatory process, but follows its own methodology and plays a smaller role in this research. The Lost Souls are the ones that are not represented (yet) in the participatory process: the future inhabitants, the visitors, the ones that do not have the time or need to participate ... The politicians are the alderman and the mayor of the city. The experts are the people that define the process by content and approach: the city administration of several departments (mobility, spatial planning, communication, culture...), the researchers and the design team.

Discussion

The research is still in an early stage: we are half way the process. However, it is possible to describe to what extend our participatory SCBA, as defined in our operational framework, may support to make values visible, to compose a value framework and to construct publics.

Making values visible

The participants reveal their values in the first stage of the participatory SCBA when they express what their ideal neighborhood should look like. This process of defining values continues the second stage, when we collect the facts because their values define which facts the participants want to talk about and which fact they do not want to talk about. The interaction between expressing the ideal neighborhood in the first stage and collecting the facts in the second stage results in a more precise definition of their values.

Already from the start, the process in the Heilig-Hartwijk was value-driven as the representatives of 'Achter Het Lijmfabriek' were very explicit about their values. By dividing the participants in different groups, we tried to let all the participants look at the neighborhood from different perspectives (visitors, children, inhabitant ...) in order to let them bring their own values to the table and define what a livable neighborhood means to them. The different values were defined in general terms and therefore did not lead to tensions between the different groups of participants. When the process continued, it became clear that the participants do have a different interpretation of the same generic values: some participants value green space because the current green space disappears as the neighborhood is becoming denser (and they are against it) while others value green space because it improves the livability of the neighborhood. We also observed that, after every meeting, participants narrowed down their arguments to one central value in order to make their case: they only talk about the livability of the neighborhood in terms of "how easy can I park my car in front of my house?". The SCBA helped, each time, to re-introduce alternative values and open up the process again.

Composing a value framework

In the third stage of the process, the Ideas, will the participants define alternative scenarios for the transformation of their neighborhood. The next step is to choose which alternative scenario will be used for the test set-up, in the Action stage. In order to make this choice, they have to take all their values in consideration and prioritize them, thus composing a value framework.

In the Heilig-Hartwijk it was difficult to prioritize the values because some groups will only talk about one value. And they only use the value framework (or in some cases only one value) for the assessment. The participants did not take it one step further and used it to make tradeoffs between benefits and costs. Although we tried to do this exercise, the participants only define alternatives that apply the costs to the ones that are not (yet) involved in the process without any tradeoff beneficiary for the community. They want, for instance, to ban unwanted traffic out their neighborhood by literally let them pay when they still drive through the neighborhood and it is less prior to them if a new or bigger public space is implemented in the alternative scenario.

Constructing publics

The constructing of publics is related to the stage of the Facts, when the different groups define the bottlenecks and opportunities or the issues that are present in the neighborhood. But also in the Action stage, when we will create a test setup of the chosen alternative scenario for at least one month in an actual location in the neighborhood and intervene in the daily life of the participants but also, and even more important, in that of The Lost Souls.

Achter Het Lijmfabriek is a public that was already formed before the participation process, in reaction to the difficult communication with the local policy. The Parents share a same value framework; however, they are still in the process of constructing a public. The participatory SCBA can help The Parents to define their public by making their value framework explicit and in doing so, increase their impact in the process.

As researcher we try to facilitate the creation of these alliances. That is why, for instance, we will try to elicit the different value frameworks of Achter Het Lijmfabriek, The Parents but also The Lost Souls, during the test setup. When the issue is identified and articulated, it can help the public to be formed (DiSalvo, 2009). By doing so, the

participatory SCBA is used to facilitate the constructing of different publics. The researcher as facilitator of the constructing of a public is essential to emphasize: we can only facilitate a public by an action, the action of the formation of a public is a task of its own (DiSalvo, 2009).

When the different publics use their value framework to assess the test setup and define which cost and benefits are for whom, it establishes how they and the other publics are affected (Sager, 1979) which can trigger the discussion on tradeoffs and take the debate to the level of the societal costs and benefits.

Conclusion

We started from the hypothesis that a participatory SCBA could benefit a more constructive and informed debate on societal costs of a dispersed modes of living in three ways: making values visible, composing a value framework and constructing publics. We have developed an operational framework for the participatory SCBA that departs from the principle of collective learning for transformational change (Brown and Lambert, 2013) and tested this framework it in the Heilig-Hartwijk in Hasselt.

These are the findings of this first test:

1. Making values visible: we used a collective approach to define the values of the participants in the first stage (Ideals) of the process. The Participatory SCBA indeed helps to define the values, but at the same time makes clear that the interpretation of the values can change throughout the process: they can become vaguer, the meaning can change... People are not trained to elicit their values and apparently do not have a clear image of their ideal living environment and thus this will require some help (of designers).
2. Composing a value framework: The participatory SCBA enables to make the different value frameworks explicit already in the beginning of the process but the participants of the Heilig-Hartwijk case did not use it to make tradeoffs up till now. We observed that after every meeting participants narrow down their arguments to one central value in order to make their case. The participatory SCBA helps to re-introduce alternative values and open up the process again.
3. Constructing publics: the participatory SCBA facilitates the construction of different publics in two ways: it helps existing publics to become more organized to increase their voice in the participatory process and it can lead to the formation of new publics if the consequences are experienced in a concrete action. These are '*light publics*': they exist during the action but disappear afterwards (Soenen, 2006)

Evidence-based urban developmental: beyond the urban anecdotes

The need of going beyond anecdotal knowledge in urban planning

Building a sustainable city is a complex task. Planners regularly become trapped in the tension between broad international or national aims for sustainable development and local, negotiated, agreements on what a professional is being asked to deliver. That's because professional behavior and decision-making are based on service to clients or citizens, with only a very general sense of responsibility for economic and social impact on a wider scale. On top of that, the established development- and construction industries with their traditional professional territories and divisions of labor also limit more holistic ways of working with sustainable urban development (Cooper and Symes 2009).

In the contemporary debate, transdisciplinary approaches (Harris et al 2010), new ways of co-production of knowledge (Polk 2015), often with the framework of multi stakeholder partnerships that involves universities as well as municipalities and private companies (Trencher et al. 2013; Trencher et al. 2014), preferably organized as urban living labs (Marvin et al. 2018) are presented as ways out from such traps. However, transdisciplinary co-productions of knowledge also visualize the disparity between theoretical research-based knowledge about sustainable urban development, often combined with normative visions (see Bradley and Hedrén 2014) versus experiential practice-based knowledge, emerging from the daily work with these issues as a planner or an urban developer.

The complex and wicked global problems related to sustainable urban development we face today, is the best argument for the need of transdisciplinary co-production. Nevertheless, it also demonstrates how different forms of knowledge can become one of the biggest obstacles to solving those challenges. On a theoretical and conceptual level, we all agree what ought to be done, but an informant at a Swedish planning department said: *"This will not help me tomorrow, when I'm back at my office to must deliver a detailed development plan..."*. Back at the offices, planners much serve clients, citizens and politicians, with other priorities and perspectives, and they will again be trapped into conflicts.

In this paper, we present an attempt to support the urban planner and his colleagues, in the daily struggle with challenges of translating and transforming e.g. the global Agenda 2030 goals, into the messy reality of building, and re-building, planning and re-planning cities. Instead of establishing those conflicts between long-term visions versus short time deliverables, as a sign of neo-liberal planning discourses (Taşan-Kok and Baeten 2011), we would like to offer suggestions of how such conflicts could be managed. This approach of evidence urban development will help professional planners, real-estate developers and other urban professionals to better navigate through this "messy reality" of sustainable urban

Full paper for AESOP conference 2019

development. By systematically combining four forms of evidence - professional, organizational, scientific and stakeholder evidence - we think that professional practitioners could better navigate the stormy waters of sustainable urban development.

How to combine different – and conflicting – forms of evidence

In this paper thus, we present an approach – evidence-based urban development – with the attempt to support all who daily struggle with the challenge of translating ideas, goals and visions to transform contemporary cities into more sustainable versions.

Evidence-based urban planning should be understood as a systematic way of working with co-production of knowledge, questioning the modernistic idea that scientific knowledge is “better” and more true than other kinds of knowledge, and at the same time avoiding the relativistic pitfall of “every opinion is as good as another”. Some knowledge or perspectives are better, and stronger, than others. However, instead of proposing that professional planners should rely more on research, or that researchers must work closer to practice, or that citizens' voices must be stronger, we will argue that research, professional experiences, organizations and stakeholders each produce different kinds of “true” evidences. The task is to combine various forms of evidence in a way where they support each other instead of coming into conflict. That done, we will have a better ground for making professional decisions with the aim of supporting a more sustainable urban development.

How to make better use of available knowledge

Evidence-based urban planning was formulated as a response to assignment from a real-estate company in Gothenburg, which involves both of us. The real-estate company owns a large housing stock in two socio-economic vulnerable areas in Gothenburg, the second largest city in Sweden. The areas were dominated by large-scale rental houses. The unemployment rate was high in the area, and because of that, there was a high rate of low-income households. From time to time, gang-violence and other forms of crime affected both areas. On the other hand, the building blocks were surrounded by green spaces, parks, and recreation areas, which created nice environments, and most of the residents liked to live in the area. When we started the project, we faced a complex web of anecdotes about the means and ends of urban development, narratives and prejudice about certain areas in the city (the poor ones with many immigrants), socio-economic statistics, demands from the real-estate companies, worries from the tenants and others living in the neighbourhood and so forth. To cut a long story short: we faced just about everything that makes sustainable urban planning a wicked problem.

To find a way forward, we needed a systematic approach to acknowledge the wickedness of the situation. We needed a systematic way to acknowledge all perspectives but avoid grading them as “better” or “weaker”, and avoid the dichotomy between research versus practice-based knowledge. We also look for a better way to handle stakeholder participation, and make sure that opinions from those who lived and worked in the area were treated as knowledge with high relevance for the planning process, instead of being reduced to opinions. We developed evidence-based planning as the answer to those challenges. Our inspiration was the concept of evidence-based management (Barends and Rousseau 2018), which is an approach to professional decision making, which also could be understood as a

Full paper for AESOP conference 2019

process of making judgements for actions. Barends and Rousseau argued that this could be done in ways that produced better foundations for decisions, judgments and actions, if we worked more systematic with knowledge acquisition.

At first, practical (and often messy) issues must be translated into answerable questions. Then we need to systematic search for four kinds of evidence: scientific, professional, organizational and stakeholder evidence. By using the somehow complicated concept “evidence”, we would like to emphasize that we are not talking about perspectives, or opinions but different kinds of knowledge that each. However, all those different forms of evidence must be critically judge in relation trustworthiness and relevance for answering the questions. Different forms of evidence must also be weight and pulling together (Barends and Rousseau 2018). This could be understood a process where professionals make they apply a frame to a field of experience. This frame enables them to highlight certain features of the situation, including certain worries that as symptomatic and relevant for a specific situation/problem. At the same time, they must ignore, or select out, certain other features and worries of the situation, as noisy and irrelevant. In the end, professionals bind together the salient features of the situation, including the relevant worries, into a pattern which is coherent and graspable (Schön 1983).

The outcomes from these process – the evidences – must then be applied and incorporated into decisions-making processes, which always are tangled and embedded in organizational structures and practices, like job instructions, decision procedures, chain of commands, budgeting and routines for accounting and measuring results. All these create different forms of path-dependency, which influence the incorporations of evidence into decision-making processes (Barends and Rousseau 2018). Professional descension-making always take place within a certain community of practice, which affects how evidence could be applied (Lave and Wenger 1991; Wenger 1998). Among the members of a community of practice, there are always a variation of understating of the work and what to do. Different ways of understanding the same kind of work – like urban planning – exists side by side within organizations which also affects how individuals consider and use different forms of evidence (Sandberg 2000).

To conclude, we do not apprehend evidence as something that could be applied straightforward on professional practices to improve them. Evidence is the total sum of all knowledge, both focal as well as tacit, both individual as organizational, both professional as well as lay knowledge, that could help us make better outcomes of professional work. What will be regarded as evidence depends on how we translate practical issues into questions that could be answered. *How* we understand something also affects which questions we formulate, which means that we always risk being trapped into our own understandings. To overcome this, being one of the main goals with evidence-based practice, we must constantly evaluate the outcome of our decisions. Learning is the core of all evidence-based practice, but learning is dependent on a systematic approach to problems. Evidence- based planning offer such systematic approach. In the next part, we will illustrate how to work systematically through the four forms of evidence: organizational, professional, scientific and stakeholder.

Organizational evidence: how to make better use of organizational knowledge

Organizations produce lots of data and knowledge. Another source of data is from both the members in an organization as well as the users or clients. It could be both 'hard' numbers and statistics, as well as 'soft' data such as perceptions of organizational norms and cultures. When we talk about organizational evidence, we will highlight that knowledge about urban development always are tied to one (or several) organizational context. We will use figure 1 as an illustration.

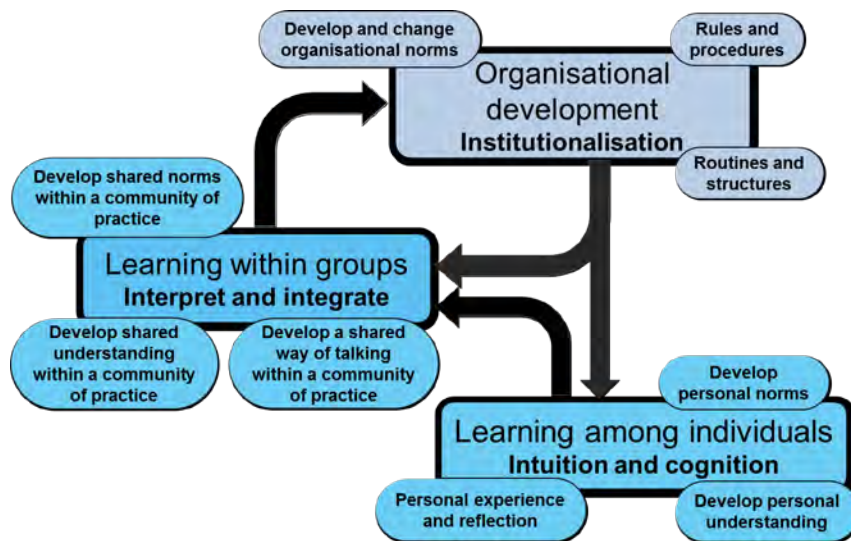

Figure 1: three levels of learning. After Crossan, Lane and White, 1990

Crossan, Lane and White (1990) claimed that an organization contains three different forms of learning

When we worked with organizational evidence with the real-estate company owning a great number of publicly-owned flats in the outskirts of Gothenburg city, we systematically tried to translate practical issues and problems – into answerable questions. One method was 'walkshops'. We walked around with representative from all organizations involved in the management of the area where the housing company's stock were situated. This visualised lots of interactions between the private company and the public partners. One was the management of public areas, like green space, bike lanes and parking lots. The ownership of public areas was divided between the municipality and the real-estate company, and consequently, the attendance differ. Those who lived in the area did not know where the borders were. They just saw how some public areas were managed in a different way compared to others, which was a long standing source of complaint from the tenants. As a first step in the developmental work, representatives from the real-estate company and the municipality walk around the area and developed a joint agreement about attendance.

At first, this seems like a very trivial thing to talk about. However, this walk and the discussion revealed lots of organizational evidence that explained why things were as they were.

Full paper for AESOP conference 2019

Administrative borders were in fact knowledge borders between the private company and the municipality. The development of a joint agreement for maintenance of public spaces triggered a process of collaborative learning. If we return to figure 1 above, this collaborative learning takes place on group level, and manifests as shared understanding (about how to maintain public spaces in the same way) and development of shared norms (in this case, what was a preferred level of attendance of green space, bike lanes and so on). However, as the figure illustrates, if the learning only takes places on the second or first level, and not affect changes on the organizational level, developmental processes will probably slow down. The concept of organizational evidence will highlight that organizational structures could effectively block a learning process. If we return to figure 1, this example illustrates a process when learning take place on all three levels. The individual, who had learned a certain way of managing the area, depend on which origination they belong to. Through the 'walkshops' they developed shared knowledge, and shared norms around how the area could be managed. This resulted in new routines for out-door management – learning on the organizational level.

The governance of knowledge production in intra-organizational collaboration is dependent on good network governance. At the same time, knowledge and information is one of the tools for carry out network governance. Intra-organizational collaboration that led to an increased capability among those organizations who collaborate are dependent on learning on all three levels (see figure 1). Nevertheless, power structures could hamper those learning processes. Here, we would like to differ between three forms of power. The first one: open power is the when an actor openly exert power. In this case, it could be if one of the parts decide not to listen, which obviously hamper processes of learning. Hidden power manifests through actors capability to exclude perspectives and ways of acting. Hidden power could be subtle ways of affect processes of naming and framing, with the aim to exclude or ignore aspects of a problem in favour to other. This is close to the concept of governmentality, which describes processes where the power is hidden in our own understanding of what is "normal". (Dean 2010).

In urban planning, those three forms of power manifests in several ways in processes of naming and framing, where some ways to understand a problem – and select solutions – become excluded. Sometimes by referring to regulations, without questioning the regulation. Other times through more subtle forms of governmentality, for example when we fail to questioned the modernistic idea that people who live in a city of course own a car and therefore must have access to parking lots. When we talk about organizational evidence, we will highlight – and at the same time put into question – the fact that organizational structures, norms, routines etc (illustrated in the third level in figure 1) always affects which knowledge are relevant for a certain organization. If we strive for an urban development based on knowledge, we must take into consideration that organizational structures affect the use of knowledge. Of course, we could criticize this. However, ignoring it mean that we also ignore structures that limits the use of knowledge, to then become surprised when some knowledge become ignored by actors in an urban planning process.

Professional evidence: how to make better use of professional experience

In his studies of how professionals handle complex working tasks, Donald Schön argued that town planning as a profession differ from other professions in that respect that a planner

Full paper for AESOP conference 2019

never could rely only on previous experiences but must always be prepared to handle unique challenges (Schön 1983). A town planner could, as best, develop some rules of thumbs, or a set-up of strategies that could be applied onto a new planning project. According to Schön, professional problem solving is also based on judgements, and therefore, problem settings could be judgements about problem situations that also contains prescriptions of desirable directions for action. Based on a broad range of case studies on how professionals work, Schön understood professional problem solving as a process of naming and framing.

In the introduction, we describe professional competence in urban planning as an ability to “tame” wicked problems to make them enough well-defined to become possible to solve. Hoppe’s (2011) distinction between structured, moderately structured, and unstructured (or wicked) problems could help us to formulate more nuanced approaches to wicked problems (see figure 2)

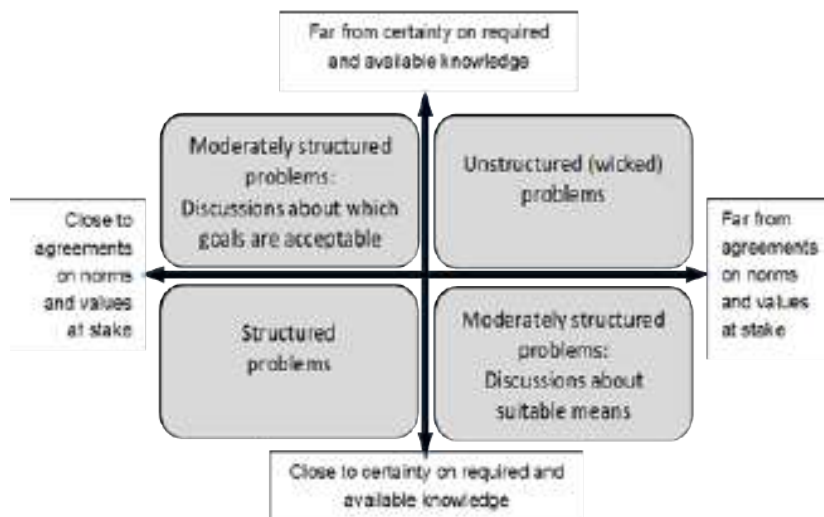

Figure 2 – Four types of problem structures (after Hoppe 2011, p. 73)

Often, the organizational every day practices dominates of what Argyris and Schön (1978) once labelled as single-loop learning. Ellström (2001) use the concept adaptive learning, for describing a situation where there is an agreement of the ends and means for a working task, how it should be done and what results should be archived. Transferred to urban planning, adaptive learning take places were a newcomer to a municipal planning department is told how a certain planning process should be done and which outcomes are preferred. The opposite, double-loop learning (Argyris & Schön 1978) or creative learning (Ellerström 2001) implies an open situation where means, ends and methods are questioned. Sustainable urban development needs (lot of) double loop and creative learning, not at least because of the fact that a waste majority of unsustainable urban development is the results of established practices, where professionals serves clients in the same way as they always do (Cooper and Symes 2009; Brown et al 2010; Polk 2015). Learning must therefore take place on several levels within an organization to accomplish long-lasting changes.

Full paper for AESOP conference 2019

If we connect the model in figure 2 with the distinction between the two basic forms of professional learning: single-loop/adaptive versus double-loop/developmental learning, following picture emerge if we have a structured problem, task, methods and results are given, according to Ellströms definitions. On the other hand, wicked problems could be the source for creative learning and innovations. If we return to Donald Schöns description of professional problem solving as a process of naming and framing, another picture emerges if innovations are dependent on the ability to develop new ways of naming and framing, then a first step may be to make structured problems more wicked by adding on new perspectives and uncertainties. If we have structured problems too hard, by ignoring to many aspects of a wicked problems, then we may hindrance the ability to innovate. Naming and framing – and professional problem-solving – could be understood as a movement between open and closing processes of naming and framing. Opening a problem means that we add on new perspectives – and may risk that a structured problem become less structured. By closing a process of naming and farming, we ignore one or several parts of a problem, which make less wicked and more structured, and then easier to solve in an efficient way.

Professionals seldom act in a such structured way, because practice are messy and unstructured. To a large extend, professionals relay on previous experience and rule-of-thumbs. Even if Schön argued that urban planners (at least in his case) found it harder to rely on established practices – planning, as every practice, become routine. With professional evidence, we include all this tacit, embodied, practice based, situated knowledge, we use, more or less deliberately, to carry out our work. If we return to figure 1, professional evidence grows at the first and second level, among individuals and groups. Professional evidence could come into conflict with organizational evidence, e.g. when personal and tacit knowledge are ignored by the organization. But, as both Argyris and Schön and Ellström illustrated with the concept of single-loop learning/adaptive learning – professional habits and tacit knowledge could be a hindrance for learning. Professional evidence – “what works” could be either an asset or a hindrance in processes of urban development. Professional evidence, as well as organizational evidence, sometimes need to be challenged.

In the work with the real-estate company, professional evidence always emerged in discussion about what could be done or not. Professional evidence are often presented as anecdotes or stories, told we the more and less open purpose to presents a truth. In other case, professional evidence was used as a way of challenge and problematize how things were done and organised. Frequently, professional evidence emerged more and less accidental in conversations. Because of its tacit character professional evidence are not regularly expressed and talked about, because of it is not considered as evidence. We tried to come around this through interview with key person both on managerial level as well among janitors, gardeners, service staff and others. Based on this, we gain a rich material with different perspectives on what out to be done. With other words; we gain a broad variety of ways of naming and framing how the real-estate company should carry out the work in this specific neighbourhood, based on previous professional experience on what works.

Scientific evidence: how to make better use of scientific knowledge

The main source of scientific evidence is literature, like textbooks, course materials, reports or articles published din academic journals. To reach scientific evidence, one must first access

Full paper for AESOP conference 2019

and learn to understand and decode academic papers. Scientific texts have high demands of clarity. Scientific clarity is reached with specific uses of concepts and words and references to previous research and relevant theories. However, the demands of scientific clarity often result in texts that people outside of academia find hard to read, understand and apply. Scientific clarity often ends up in practical obscurities, which is why research often become hard to apply “straight off the bat”.

One reason to this (which is often neglected) is that scientific problem-formulation is also a process of naming and framing. However, scientific ways of naming and framing problems regularly create boundaries between research-based knowledge versus other forms of knowledge (or in this case “evidence”). Knowledge boundaries between scientific evidence versus organizational and professional evidence is well-known. Transdisciplinary research (Brown et al 2010) or different forms of co-production (Polk 2015) often organize in Living Labs (Marvin et al 2018) are often seen as the best way to overcome this divide. However, those discussions also tend to forget (or ignore) that scientific evidence is the product of day-to-day work among practitioners – named “researchers” – who work in specific organizational and professional contexts – named “university departments”, “research centres”, and so on. (Latour & Woolgar 1986). Doing research is a professional practice among other practices, like doing urban planning.

Another reason that naming and framing of scientific problems differs processes of naming is because scientist must consider previous research, established concepts and theories and last, but not least, on-going debates within a certain research fields, when they formulate a problem. Besides being a member of a local community of practice, researchers also belongs to epistemic communities, which unites by shared ontological, methodological and epistemological perspectives on a phenomena or question, like conditions for sustainable urban development. Because of the boundaries between scientific versus practice based knowledge, which steam from different conditions of how to name and frame problems, just simply apply scientific knowledge may not help professional planners in their daily practice. For research knowledge to be spread and have an impact, researchers find allies outside the university in the form of knowledge brokers, who support the translations of scientific knowledge into professional practice (Callon 1984). However, research knowledge must be translated to find ways to overcome boundaries between scientific evidence versus professional evidence.

Despite those borders, several studies have shown that professionals from other fields often use scientific evidence as a way of making better professional decisions (Weiss 1980; Lundgren and Sundqvist 2000; Rickinson 2005). However, they use scientific evidence in an ad-hoc manner, based on current needs and situations. In general, scientific evidence seem to be used in four ways (Nutley et al. 2007), which is illustrated in figure 3.

Full paper for AESOP conference 2019

Figure 3 – Four ways of using scientific evidence (after Nutley et al, 2007 p. 51)

If we return to figure 2 above, we could assume that scientific evidence is used in a more instrumental way if a professional practitioner faces a structured problem. An instrumental use may probably occur, as a result of a single-loop/adaptive learning situation, were the problem is well named and framed. On the other hand, conceptual use of scientific knowledge could be a way of turning a well-structured problem into a more wicked one, which in turn could open for double-loop/creative learning.

In the work with the real-estate company, we begin using scientific knowledge in a conceptual way. There is a broad and varied range of literature about socio economic deprived neighbourhood, which we could draw some conclusions from, together with contemporary research about urban planning. However, we struggled to find research that were relevant for this specific area, so we had to design our own studies, and used our own capability as researcher to develop scientific evidence relevant for this specific developmental process. In this case we used UN Habitats five principles for sustainable neighbourhood planning (UN Habitat 2014) when we design our own pilot-studies and validating the results. Usually, it is not common that people with a PhD-degree work as planners. If that is the case, there is often not time or resources for them to conduct their own research in relation to a planning process. The common situation is that professionals must make their own judgement about the relevance and truthfulness of scientific evidence in relation to their own practice.

Studies of how professionals used scientific facts (Weiss 1980; Lundgren and Sundqvist 2000; Rickinson 2005) showed that professionals prefer scientific evidence that are aligned with how they already name and frame different tasks. In other words, scientific evidence that support professional and organizational evidence seem to have a better chance of being used and referred to. On the opposite, scientific evidence that come into conflict with established practices – i.e. with professional evidence – are seldom used. This point to the main argument for using scientific evidence, i.e as a way of challenging both professional and organizational knowledge. However, as Callon (1984) stated, research need to find its allies to be spread and used. Therefore, scientific evidence much finds ways of connecting with professional as well as organizational evidence, in order to become useful. Here, it is important to be aware of why we bring in scientific evidence in a developmental process. Are we striving for conceptual or instrumental use of scientific evidence? Are we looking for supporting the solution of a well-defined (tamed) problem, or would we like to open for new perspectives and make things more complicated with the intention to pay the way for more creative and innovative learning?

Above, we described evidence-based urban planning could be understood as a systematic way of “opening” problems, by adding-on evidences with the aim to visualize the complexity

Full paper for AESOP conference 2019

of a planning problem. If we return to figure 2, scientific fact could be used as a way of challenging knowledge, and make a structured problem more wicked, and at the same time open for creative and double-loop learning. But we also argue that planning problem must be “closed”, through processes of naming and framing. One way is actively ignoring aspects of wicked problems in order to tame them and make them possible to handle in professional situation, in relations to clients (Cooper and Symes 2009). This process of opening and closing could be moments back and forth along the arrow in figure 3. Structured problems could be opened (and become more wicked) using scientific facts in a more conceptual way. Using scientific problems in a conceptual way also opens for processes of creative learning. In reverse, if we want to use scientific problems in an instrumental way, we need a structured and well-defined problem. Those kinds of problems emerge from a process of naming and framing, which ignores aspects as noisy and irrelevant. According to Barends and Rousseau (2018), this is how practical issues are translated into answerable questions. Scientific evidence could be used as a tool for those translations, by highlighting what is relevant. In the work with the real-estate company, we used the UN Habitats (2014) five principles for neighbourhood planning for highlighting what the company should focus on, if they want to develop their housing stock into more sustainable ones. We also used the five principles as guides when we construct our own studies for gathering scientific evidence that could support the real-estate companies own decision making process. We also used the five principles as challenge established ideas among employees from the company about neighbourhood development. This example illustrates that scientific evidence could be used both in a conceptual as well as instrumental ways.

Stakeholder evidence: how to make better use of the user’s perspective

According to Barends and Rousseau (2018) stakeholders are different actors who, in the context of this chapter and book, are influenced or affected by a change in an urban environment of some kind. Stakeholder evidence is about understanding what is perceived as important from an everyday-life perspective, for inhabitants, associations or companies: what values are there, how is a place perceived, what are the local networks that make society work?

Previously, we discussed how urban organization has shifted *from government to governance*, i.e. from clear hierarchical governance based on well-defined political goals and with outlined and predictable roles to a more network-based and market-driven way of producing or developing city districts. The Danish organizational and public sector researchers Boch Waldorff, Söderkvist Kristensen & Vind Ebbesen (2014) argues that it is not *only* so that society is governed by the scratch of new public management, where everything is to be procured at the lowest price and where citizens are made into customers who will “trade” welfare services (see also Tahvilzadeh 2015). More traditional and bureaucratic governance models are in play at the same time and, in line with the governance ideals, another kind of logic has been merged into the game - “new public governance”. By the occurrence of the model presented in this chapter, we argue that urban dialogues are levelled with other necessary knowledges for urban development processes.

Through the dialogue we can question and reflect on basic assumptions for *how it is* in the world, in society, a city district. In or case, there are many ready-made ideas and descriptions,

Full paper for AESOP conference 2019

“black poetry” if you will (Ristilampi 1994). Beyond the urban anecdotes: what is covered in the news about suburbia is not exactly the complete picture. A good dialogue will instead produce stakeholder evidence, stories about the everyday life lived in a place. A dialogue emerges in several steps. If we use a metaphor, you can talk about the “evolution” of dialogue, in which the first step is about creating a “melting pot”, in which we try to make each other aware of the different perspectives and approaches we are sporting. In the next step, we must challenge each other's performances. Here, we need both to defend and question our own and others' views. It goes without saying that this is a process that creates uncertainty and instability. Being challenged and questionable can often be perceived as unpleasant. Here different types of evidence are placed against each other. Here, one must strive for both dare to stand for their own experience and knowledge while being open to questioning them. It's no easy process. Such dialogue requires a safe environment and it takes time. It also requires endurance of those who participate. Here, a “broker” can fill an important function by being the one who keeps the process together (Gustafsson, Norström and Fioretos 2015).

In order to move forward, the group must begin to search for a new common understanding. Since a dialogue in itself is a meeting of different competencies regarding urban life – the everyday-life perspective, the professional perspective(s), various political perspectives etc. – a contextual framework is needed. A linguistic common ground, where different forms of metaphors can fill an important function. This allows you to reach the final stage of the process: a new common performance. Group members share a common partial silent understanding. An example could be a project group that brings together different stakeholders and where time is spent on the joint dialogue. If the dialogue succeeds in getting through all the steps and achieving a new common understanding, you have also developed a new common knowledge.

The common knowledge has emerged by helping the different participants translate their own experiences and professional skills in such a way that others understand it. In the model we've discussed and argued for in this chapter, stakeholder evidence is *equally important* as any of the other evidences. Urban dialogues can be discussed from several different standpoints, methodological and political, but for us it is inevitable. To work evidence-based with urban development is to *always* do a dialogue, regardless of scope and style. Without the knowledge from local inhabitants, business and associations, you simply won't get the full knowledge circle.

In the work with the real-estate company, we conducted two workshops, one in each district, as open houses where inhabitants and others could drop by to answer a semi-structured questionnaire alongside the assignment to pinpoint the spatial experiences of the districts in question. Around 90 participants attended per workshop and the key messages concerned housing – apartment size and standard as well as form of tenure – and lack of general services in and maintenance for the public places.

Conclusions and ways forward

So, let us return to the workshop. Would the scene be different if the participants had worked more evidence-based? In one way no, because there would still be conflicts and tensions

Full paper for AESOP conference 2019

between how the participants would talk and approached the issue for the workshop: how to build sustainable cities. However, if the participants had worked more evidence-based, that had open acknowledge the different perspectives, and worked them through. At first, they should organise at least four workshops, one around each evidence, were they should use different forms of evidence for opening and closing questions.

The four forms of evidence should be treated as outcomes of knowledge from four different kinds of practices: professional practices, research as a practice, organizational practices, and living experience as a practice, here referred to as stakeholder evidence. Those outcomes would be used to translating practical issues and problems into answerable questions. Of course, depending on which evidence we use, the questions would be different as well as the proposed answers. Naming and framing a specific urban developmental process from a stakeholder perspective will result in different questions compare to naming and framing the same process from a professional perspective. Of course, there will be conflicts and tensions between those different questions, and our approach of evidence urban planning will not solve the tensions. However, by acknowledge them, we think that we could make better decisions in urban planning, were we are aware of what we win and maybe lose.

Urban development is a wicked problem. Adding on dimensions of sustainability make it even more wicked. Urban planners are squished between the wickedness of sustainable urban planning and demands from construction companies, politicians, citizens and so on to plan and construct cities in a way that are economic viable and results in neighbourhoods that are both social and ecological sustainable. That is a very complex professional task, least to say. However, we seldom talk and acknowledge its complexity as something we had to live with. In the contemporary urban debate, there is a tendency to relay on one form of evidence, like scientific evidence that refer to dominating discourses as a way of explaining failures in urban development (Tasan-Kok and Beaten 2011) and see the development of new planning discourses as necessary (Rydin 2013). Transdisciplinary approaches to urban development, (Harris et al 2010), Co-production (Polk 2015) and different forms of experimental urban planning and experimental governance (Marvin et al 2018) are proposed as a way forward. At the same time, results from urban research may not help those professionals who find themselves trapped between conflicting demands (Cooper and Symes 2009).

We will see evidence-based urban planning first and foremost as way of organising a systematic conversation which acknowledge the fact that sustainable urban planning must rely on different and conflicting form of knowledge. Instead of being content with that “it is complex”, we would like to offer a systematic way of navigating over the stormy water of sustainable urban development.

Learning loops in the public realm. Enabling social learning in communities to tackle the challenges of cities in transition

Co-creation a way of supporting development of neighbourhood-level transport innovations

Nadine Haufe¹, Astrid Großmann²

¹TU Wien, Institute of Spatial Planning – Research Unit Sociology, nadine.haufe@tuwien.ac.at

²URBANISTA, Urban Development, Urban Research and Participation, grossmann@urbanista.de

Abstract: Co-creation is a much discussed concept in the fields of urban planning, architecture, urban design and many more. In the HORIZON 2020 project SUNRISE, co-creation is the key concept to develop, implement, assess and facilitate learning about new ways to address common mobility challenges at the neighbourhood level. Towards this aim, six SUNRISE cities (Bremen, Budapest, Jerusalem, Malmö, Southend on Sea, Thessaloniki) foster co-creation processes with the explicit mandate to implement innovative solutions for and with their residents, and other stakeholders. The SUNRISE action neighbourhoods combine a blend of proven online and face-to-face co-creation methods, tools and techniques to bring together citizens, policy-makers and other stakeholders to learn from each other and to address urban challenges in neighbourhoods in transitions. This contribution gives an overview of various methods for co-identification and co-development of sustainable mobility solutions at the neighbourhood level, and discusses the advantages and disadvantages of online and offline tools.

Keywords: co-creation; participation; mobility solutions; online and offline participation methods

Introduction

Today's urban challenges are complex: population growth, climate change, new technologies and many more create new challenges for urban development. The development of solutions requires integrative and holistic approaches. Participation, empowerment and social learning make it possible to integrate the needs and requirements of local stakeholders into urban planning and are often seen as a good lever to solve urban challenges.

Citizens and urban policy makers are experimenting with new collaborative approaches like co-creation to tackle persistent urban issues, such as climate change adaptation, quality of life, and urban inequalities. In search for more effective action plans, citizens, public institutions, private sector, and knowledge institutions are increasingly teaming up in formal and informal networks (Puerari 2018:1). Participation is an essential component of co-creation. In the HORIZON 2020 project SUNRISE,

participation is one of the key aspects to co-develop, co-implement, co-assess and facilitate learning about new ways to address common mobility challenges at the neighbourhood level. Towards this aim, six SUNRISE cities (Bremen, Budapest, Jerusalem, Malmö, Southend on Sea, Thessaloniki) foster co-creative participation processes with the explicit mandate to implement innovative solutions for and with their residents, and other stakeholders.. The SUNRISE action neighbourhoods combine a blend of proven online and face-to-face participation techniques to bring together citizens, stakeholders and policy-makers to learn from each other and to address urban challenges in neighbourhoods and cities in transitions.

This contribution gives an overview of various participation methods for co-identification and co-development of sustainable mobility solutions at the neighbourhood level, and discusses the advantages and disadvantages of online and offline participation tools. Main questions are: How can these tools enhance the co-creation processes? To what extent can these tools help people, communities and policy-makers to 'learn' about the problems or to develop solutions on the neighbourhood level?

Co-Creation

People and their cities are engaging in new ways. In some cities, anyone with a smart phone can report graffiti or a pothole directly to the right city department. Others participate in change labs that engage people from problem definition all the way to finding solutions. All of these activities are part of a process called co-creation (Leading Cities 2014:1). Originally conceived as a business strategy for identifying new forms of customer engagement, co-creation is currently used in several sectors, such as marketing, public service management, design, innovation, urban and regional planning (Lund 2017: 32). Given this diversity of application contexts, it is therefore perhaps not surprising that the concept does not have one clear definition.

In the field of urban development/ urban planning, the research group Leading Cities (2014: 3) comprehensively defined co-creation as “the active flow of information and ideas among five sectors of society: government, academia, business, non-profits and citizens (...) which allows for participation, engagement, and empowerment in, developing policy, creating programs, improving services, and tackling systemic change with each dimension of society represented from the beginning.

The combination of the following two definitions from the literature describes SUNRISE’s notion of co-creation:

- Co-creation refers to a process that brings together different parties, e.g. a company and a group of customers, to jointly produce a mutually valued outcome (Prahalad & Ramaswamy, 2004).
- In a co-creation approach, heterogeneous actors collaborate to produce knowledge, instruments, technology, artefacts, policy, know-how, etc. (JPI Urban Europe 2016: 52).

Participation – The Basis of Co-Creation

The central aspects of “co-creation” – the term for creating something together as a team – are therefore idea generation and cooperation. In order to develop new solutions in accordance with urban challenges, the co-creation approach focuses on the cooperation of transdisciplinary actors who jointly address challenges in a "process of creation" (Dübner et al. 2018: 142).

Participation is an essential component of co-creation and a much-discussed concept in the field of urban planning, urban design and other fields. For government leaders, agencies and developers, public participation allows them to collect and provide information about community needs, identify attitudes and opinions, generate new ideas, allow for smoother implementation, and build constituency support. However, for citizens and community organizations, co-creation can offer opportunities to gain representation and be heard, exercise political rights and influence policy decisions (Leading Cities 2014: 4). Participation is also a big challenge because it requires an actor to yield some of its power to another actor. Often this transfer is from the city administration to residents or other interested actors. The shift of power and the subsequent renegotiations of power relations are a core ingredient of every participation process. All persons in key positions in a participation process need to be aware of the shift of power and its ramifications (Arnstein 1969: 216).

The extent of opportunities for and rights of participation in a particular process of co-development and co-decision depends on several factors. On the one hand, the degree to which the interests of citizens can be taken into account depends on the type of process involved (formal or informal), and from the willingness of decision-makers in politics, the administration and business (the urban stakeholders). On the other hand, the chosen method also determines largely the level of influence of citizens' or stakeholders' interests.

Against this background, the influence of citizens in and through participation processes can be distinguished in three steps: information, consultation and decision-influencing (simplified distinction according to Arnstein 1969; Arbter et al. 2007: 9):

- **Information:** Informative methods ensure that stakeholders and interested actors are informed about a project and its likely effects; informative methods offer little scope of influencing the decisions taken. Public meetings aimed exclusively at informing, and providing opportunities to inspect official documents, are examples of this approach.
- **Consultation:** Consultative methods provide stakeholders and interested actors with an opportunity to comment on suggestions plans or decisions, and to table their ideas, which are to be taken into account at the decision stage. Suitable for co-design processes, consultative methods need openness to differing views and alternatives. Suggestions and advice to be taken into account by local decision-makers are the outcome of such methods.
- **Co-decision:** The furthest reaching form of participation methods are joint decisions in order to find an agreed solution. This is the level all participation activities in SUNRISE were striving for. Here stakeholders and interested actors have the opportunity to influence a decision, a project and the details of its implementation. Such methods require the integration of persons from politics, administration, and other stakeholders in the process. The scope

ranges from cooperatively developing suggestions all the way to the participants having extensive powers to decide.

In SUNRISE, we strive for the third step, decision-influencing, or co-decision to meet the expectations of a co-creation process with stakeholder and resident involvement. Information, however, must accompany all participation processes in their entire duration for reasons of transparency, visibility and to keep interested stakeholders involved.

Methods and Tools for Co-Creation

There is a wide range of different kinds of participation tools, methods and technologies in the practice in different countries and cultural contexts. Depending on the goals of the participation process and the groups to be integrated, different methods are suitable for co-creation on the neighbourhood-level. In order to achieve different objectives and address several target groups it is useful to apply a mix of methods. A good mix consists of different, complementary methods that further the goal of co-learning, co-creation and commitment building.

The best applicable method of a particular participation process depends on many factors, including the objectives, the target groups, the personnel, financial and time resources as well as the embedding in the political-administrative system (Senatsverwaltung Berlin 2011: 92 & 160).

Differences among participatory processes result from the number of participants and from the regulation of access. In principle, a process may be aimed to the general public, and thus to all interested actors, to reach as many people as possible. A process may, however, also refer to a selection of representatives of different interest groups or to all those directly affected by a particular topic or the subject-matter of the participatory procedure. For the selection of the method, the following questions are relevant (Nanz & Fritsche 2012: 25):

- Is the number of participants limited by any given factors?
- Are there special hard-to-reach groups that need to be integrated in a specific way?
- Are specific methods particularly suitable for those certain parts of groups?

The SUNRISE mission is to develop, implement, assess and facilitate co-learning about new, collaborative ways to address common urban mobility challenges at the neighbourhood level. Towards this aim, the SUNRISE action neighbourhoods combine a blend of proven online and face-to-face participation methods, tools and techniques (e.g. citizen advisory committee, dialogue centre tool, field trips, focus groups, message board, mobile stand, opinion survey, public meeting etc.) to bring together citizens, stakeholders and policy-makers to learn from each other and create new mobility solutions.

Online Methods and Tools for Co-Development Mobility Solutions

In the face of the trend towards digitization, the consensus that successful urban solutions shall collectively be conceived and developed as a societal task is becoming increasingly present (Sørensen & Torfing, 2016). As we cannot elude the digitization of our built surroundings and everyday lives, we can make use of technology in a way that cities become more liveable for the individual and address overarching goals such as sustainability and resilience. In addition to a variety of conventional and innovative participation methods, digital tools create options for integrating local actors into decision-making and implementation processes relevant to urban development (Dübner et al. 2018:141).

Online tools have the potential to include some target groups that might be hard to approach with offline methods that are place-bound or take an amount of time. For such groups, online tools are suitable, as they may participate from home or via mobile phones. However, not all target groups have access to internet at home or on their mobile phones, or prefer to participate face-to-face. Furthermore, online literacy of target groups varies greatly: online tools may be difficult to understand for people who do not regularly work with them. A further problem is that many online tools, like crowdsourcing of ideas or mapping tools, have the disadvantage that we do not know exactly who participated and require a continuous moderation of the online platform to sort out meaningful contribution (Franta et al. 2017: 46).

In SUNRISE, mainly city-specific SUNRISE websites were used as an online tool for stakeholder information and involvement. The city-specific websites in SUNRISE are used as virtual information centres, where all information publication material is made available. Furthermore, a web-based mapping forum was implemented into the website, which allows collecting mobility-related issues, needs and ideas. The objective of this forum was the collection of geo-referenced problems, needs and ideas, which are subsequently rated by users. The following core functionalities were implemented:

- Submit ideas: Users are able to submit new innovative ideas for public transport;
- View ideas: All users are able to view ideas;
- Rate ideas: Users are able to rate existing ideas;
- Comment ideas: Users are able to comment on and discuss existing ideas.

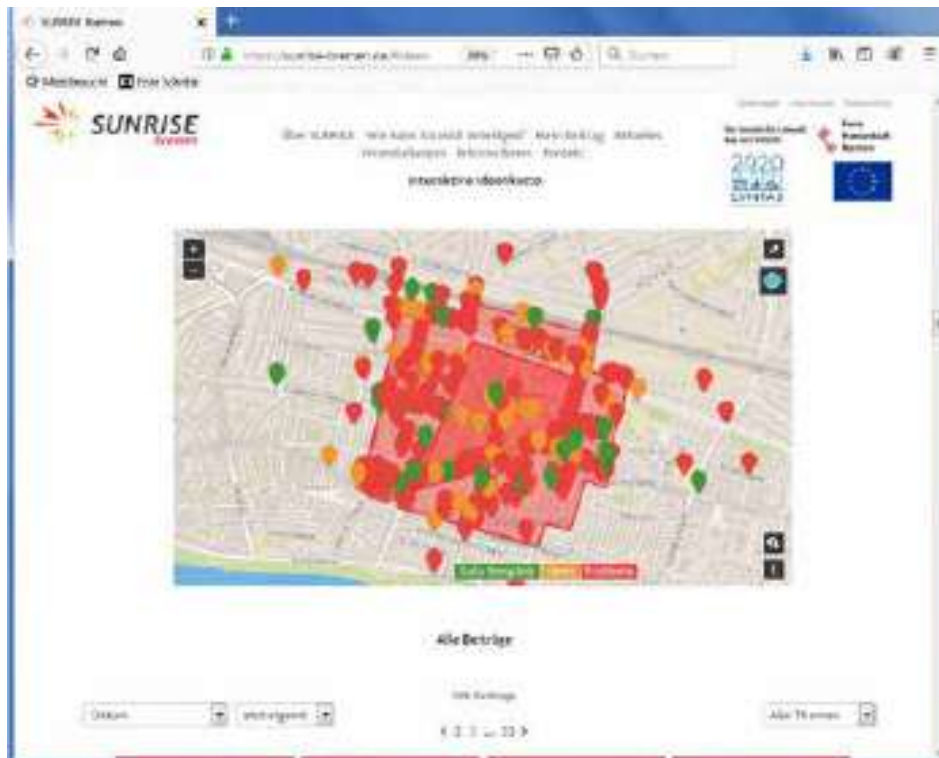

Figure 1: Website-based mapping tool Bremen (www.sunrise-bremen.de)

The online mapping tool offers the following advantages for the co-development of mobility solutions:

- Many people can share their needs and ideas:
- The functionalities of rating and commenting the ideas enable collaboration, learning and (further) development of ideas;
- A process of developing mobility solutions is possible because the tool has been permanently implemented on the homepage.

Disadvantages for the co-development of mobility solutions of online mapping tools are:

- Only people with high web-affinity are reached; some (often senior) people do not use the internet;
- It is not possible to trace who the participants are or to ensure that different stakeholders participate.

Offline Methods and Tools for Co-Development Mobility Solutions

Co-creation does not take place in a vacuum, but always occurs within socio-spatial contexts. Spaces and places are the relevant conditions that facilitate the interaction and access between actors that bring innovative ideas and resources and are also catalysts of interactive learning and innovation. Creating the physical (and mental) spaces for learning and experimenting is a necessary condition for fundamental change. Spaces and places facilitate visionary collaborations for making and learning together through co-creation practices. They enable collaborating actors to systematically and deliberately explore solutions across sectorial boundaries. Moreover, they constitute interventions within socio-spatial contexts themselves (Puerari et al. 2018:6). Spaces and places of co-creation are found to affect their socio-spatial environment, e.g., by providing meeting places, creating visibility for local sustainability issues, or by becoming “vehicles for innovation in urban planning processes” (Scholl et al. 2016: 89) .

For this reason, the SUNRISE cities also use a wide range of different kinds of offline participations methods for co-identification and co-planning of sustainable mobility solutions in the neighbourhood. On the one hand the cities used methods like mobile stands, opinion surveys, public meetings etc., aimed at the general public, and thus to all interested actors, to reach as many people as possible.

Figure 2: Mobile Stand in Törökör (Budapest)

The participation methods aimed at the general public offer the following advantages for the co-development of mobility solutions:

- Many people can share their needs and ideas;
- It is clear who the participants are and it can be ensured that different stakeholders participate;

- Depending on the method, tools and techniques, collaboration is also possible;

Possible disadvantages for the co-development of mobility solutions of offline methods for the general public are:

- Due to the mostly temporary nature of methods, the possibilities of a process for developing mobility solutions and learning from each other are limited.

On the other hand, the SUNRISE cities also use participatory methods for co-creation referring to a selection of representatives of different interest groups or to those directly affected by a particular topic (e.g. citizen advisory committee, workshops, focus groups, field trips for blind people etc.).

Figure 3: Workshop with councillor members in Southend-on-Sea

The participation methods referring to a selection of representatives of different interest groups offer the following advantages for the co-development of mobility solutions:

- Due to the small number of participants, intensive cooperation is possible;
- If the method is used repeatedly, a process of developing mobility solutions and learning from each other is possible.

Possible disadvantages for the co-development of mobility solutions of the offline methods for specific groups or stakeholders are:

- Due to the limited number of participants, not all stakeholders may be involved.

Conclusion

Co-creation is a new form of urban planning with the municipality, private organizations and individual citizens. In the literature Co-creation benefits are associated with improving processes of idea generation, decision-making and promoting co-operation and creativity. In addition, co-creation positively impacts on improving users' satisfaction and building trust or loyalty over the long-term. Especially when urban planning ideas are co-developed and tested already in the early stages, the projects are more likely to proceed smoothly, in a good spirit and are not in danger of being delayed or halted as a result of political or social resistance. There is also a possibility of minimizing economic risks as there is no need to make costly changes afterwards, if it is noticed that something went wrong in the planning stage (Oksman et al. 2014: 189)

Participation is a central aspect of co-creation, but every participation method, tool or technique is socially selective. No participation process attracts all people in the same way. This leads to certain social groups being over- or under-represented in the processes, depending on the format, the invitation policy, the setting and the structure. For those reasons, digital participation alone does not work: Only physical meetings enable dynamic face-to-face discussions and therefore, community building and networking.

Online tools have the potential to include some target groups that might be hard to approach with offline methods that are place-bound or take an amount of time. For such groups, online tools are suitable, as they may participate from home or via mobile phones. Moreover, during offline events further participatory tools and settings can reach target groups which are excluded from online discussions. Thus, what has been a crowd-sourced online need to be discussed offline and vice versa in a continuous process. All in all, online and offline dialogue should coexist in co-creation processes.

Abstract: The public realm is a place where urban stakeholders interact and come into conflict. The aim of this paper is to present the LOOPER participatory co-creation methodology and platform developed in the Learning Loops in the Public Realm (LOOPER) project to demonstrate ‘learning loops’ i.e. new ways of decision-making which bring together citizens, stakeholders and policy-makers to iteratively learn how to address urban challenges. The methodology and platform are demonstrated in three Living Labs with different spatial, cultural and thematic contexts. The main issues being solved are traffic and mobility in Brussels; traffic and green space in Manchester; and air and noise pollution in Verona. The paper will discuss the overall approach and methodology developed in the LOOPER project to support finding solutions to urban problems in a participatory co-creation process, and its broader implications for living lab approaches to urban transformation. Some interim findings emerge in the context of three main social science strands: social learning and collective intelligence; local government and participatory co-governance; and the co-design/co-production process in the urban environment. Work in progress from the LOOPER Living Labs demonstrates these wider themes in the light of front-line experience.

Keywords: co-creation; traffic safety; air pollution

Introduction

The public realm is a place where urban stakeholders interact and come into conflict. Urban areas are coming under increased pressure caused by urbanisation that results in increased competition for the limited available space. Well-developed mobility systems are especially important for urban areas to function. Nevertheless, mobility often has negative external effects such as congestion, injuries and fatalities, greenhouse gas emissions, and noise and air pollution. In recent years, urban and mobility planners have therefore moved towards sustainable urban mobility instead of trying to satisfy the ever-increasing demand for road traffic.

Stakeholder involvement is a key aspect of sustainable mobility as it can reveal new values and knowledge, increases support for the outcome, and facilitates implementation (Banister, 2008; Larson and Lach, 2008). However, involving stakeholders in transport planning is far from straightforward as it challenges the often-used expert-led and top-down model (Booth and Richardson, 2001). Nevertheless, as urban problems are becoming more complex and citizens more vocal, policy-makers are turning towards new governance approaches like co-creation to involve citizens and stakeholders in finding solutions to urban problems (Puerari et al., 2018).

Co-creation is an umbrella term for a wide range of participatory and open-design processes that have been widely used in urban planning and design. In co-creation, stakeholders are often frequently involved throughout a planning process and are given influence in the decision-making process (Sarzynski, 2015). Co-creation in urban planning has rarely been applied, therefore we have little knowledge about the benefits of such approach to transport planning and the tools that can facilitate such a participatory approach. LOOPER adopts the broad model of the urban living lab as an approach that enables solutions to be co-produced and explicitly learnt from in specific places (Evans and Karvonen, 2011).

Methodology

Planning and implementation to improve public space can be enhanced through co-creation. In the three LOOPER Living Labs in Brussels, Manchester, and Verona, co-creation has been used in the full planning cycle. A loop starts with collective debate on topical issues, then frames the problem and collects data. The platform visualizes the data and enables the co-design and evaluation of solutions. The selected solutions are then implemented, and the results are monitored with a second loop learning from the first. The LOOPER prototype platform integrates online and offline tools to facilitate learning in each stage of the co-creation process.

The LOOPER methodology is illustrated in Figure 1 The LOOPER methodology. Each Living Lab will go through a full co-creation process twice during the duration of the LOOPER project.

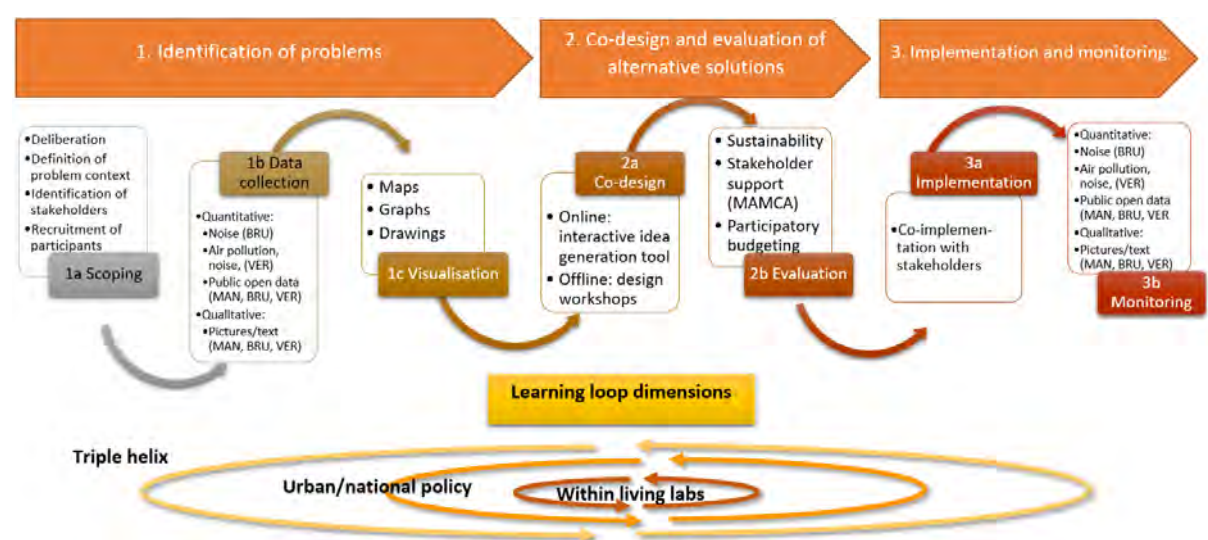

Figure 1 The LOOPER methodology

The main stages of the LOOPER methodology are as follows:

1. **Identification of problems and opportunities:** The aim is to identify the problems of a local community through a three-step process. This stage can be framed positively, referring to opportunities rather than problems:

- 1a. **Scoping:** The affected communities and the context of the problems will be identified. The problems are framed in a way to enable the tangible aspects to be identified through data.
- 1b. **Data collection:** Data to identify the scope, location and type of problems is collected with the participation of stakeholders via participatory sensing, via public databases and through face-to-face discussions.
- 1c. **Visualisation:** Visualisations of collected data are published on the LOOPER online platform and discussed at local workshops.
2. **Co-design and evaluation of alternative solutions:** The aim of this stage is to assess the problems identified in the previous stage, co-design and evaluate solutions, and select the solution(s) that will be implemented.
 - 2a. **Co-design:** Participants engage in qualitative and interactive online and face-to-face deliberation activities to propose solutions. Participants co-create alternative scenarios, explore new synergies in design or policy and define pathways for action.
 - 2b. **Evaluation:** After the co-design stage a more standardized method like a multi-criteria analysis is used to appraise the sustainability of alternatives and the Multi-Actor Multi-Criteria Analysis (MAMCA) is applied to identify stakeholders' preferences.
3. **Implementation and monitoring:** Based on the results of Stage 2, stakeholders implement a range of solutions and monitor their efficiency, using the same or comparable data used for the problem definition (Stage 1).
 - 3a. **Implementation** in the living labs involves citizens and stakeholders through their voluntary contribution.
 - 3b. **Monitoring:** Monitoring the impact of co-designed solutions uses the same set of tools as in Stage 1. This may involve participants through participatory sensing and open data or through other qualitative means of appraisal like reconducting interviews.

Theoretical context

Behind the LOOPER is a theoretical framework which combines three strands of social science:

- Social Learning theory, systems cybernetics and a 'collective local intelligence'
- Local government and democratic public participation
- Civic co-design and co-production in the public realm

This section is a brief review of these themes: there follows an interim review of the LOOPER experience (in progress at the time of writing).

Social learning & collective intelligence

Organizational learning theory is at the centre of the LOOPER concept and framework (Argyris and Schon, 1995). This applied the concept of reflexive feedback to organizations and institutions. It also reflects parallel ideas from second-order cybernetics and 'critical systems heuristics' (Churchman, 1996). Starting from a traditional view of learning as 'gathering facts', organization studies began to look at a 'Mode 2' 'double-loop'

type of learning. Mode 2 brings up not only information for direct problem-solving, but wider contextual knowledge and deeper values and goals as well.

The learning agenda has also expanded from the learning of information ('know-what'), towards learning active skills ('know-how'), social/emotional/networking intelligence ('know-who'), and cultural or ethical intelligence ('know-why'). This applies to individuals in the education system, but also to organizations and institutions, and increasingly to communities or social networks. This then applies to the LOOPER objective of '*learning loops in the public realm*':

- Learning of '**what**': Is there informational or technical content (which might be provided or signposted)?
- Learning of '**how**': Are there skills or techniques (with training or capacity building)?
- Learning of '**who**': Can policymakers / professionals learn how the community works: and can the community learn how policy works? The community can learn to self-organize, build capacity, mobilize action; the policy system can learn to innovate and adapt. Is there mutual learning between them?
- Learning of '**why**': policymakers may need to learn that mobilizing grass-roots activity can empower the community and lead toward a more harmonious society.

Social or collective intelligence is then the logical result of social learning. There is no single version or definition, but a practical starting point is with Gardner's 'multiple intelligences' (Gardner, 1983). In many walks of life, it is accepted that 'intelligence' is much more than technical problem-solving. 'Emotional intelligence' is now essential in business and management; cultural intelligence is vital in media and creative arts; ethical intelligence helps to manage business risks. The combination of all these is framed with the 'synergetics' framework for mapping the *collective urban intelligence* (Miles and Ravetz, 2016; Ravetz, 2017).

Organization change and learning is at the centre of the LOOPER concept, and this also calls on 'systems cybernetics' concepts of reflexive feedback to organizations and institutions. In practical terms this refers to a policy cycle which learns from experience, makes effective decisions, and evaluates the feedback and improves and adapts.

The challenge here is that large organizations, public or private or civic, are continuously asked to 'learn' and 'innovate'. However, in a large organization there are many layers. Training is delivered on specific items such as procurement or equal opportunities, but for the organization structure itself it is not easy to identify the more distributed type of learning, and the typical reality is one of barriers, gaps, inertia, 'workshop fatigue', and resistance to change and innovation. Most large organizations would already have some kind of management or monitoring system for learning, innovation, service improvement, and/or productivity and cost saving. Some of these methods are focused on citizen and community participation, and social innovation/cohesion/enterprise, e.g. 'Social Return on Investment'.

Government, citizen Participation and co-governance

Drawing from theories of democratic public participation (Ravetz, 1999), a cognitive or knowledge-based system of governance incorporates cybernetic feedback cycles of information and influence. In a complex society, decision structures tend to centralize and institutionalize, removing the 'decision point' from the 'impact point' for many sets of stakeholders. The result is often less effective and less equitable decisions, particularly where redistributive effects are concerned. Hence a stronger information feedback cycle will tend to

enable more effective and equitable decisions, with direct communication flows between stakeholders, project teams, programme managers and policy-makers.

Such participation processes can be seen in successive stages, as in the well-known ‘ladder of participation’ (Arnstein, 1969) which charts a range from ‘manipulation’, where information is rationed for specific purposes, to ‘consultation’, ‘dialogue’ and ‘legitimation’, where information is shared and used to form collaborative agendas. In ‘delegation’ and ‘citizen power’, not only information and control of agendas, but economic resources are transferred and devolved.

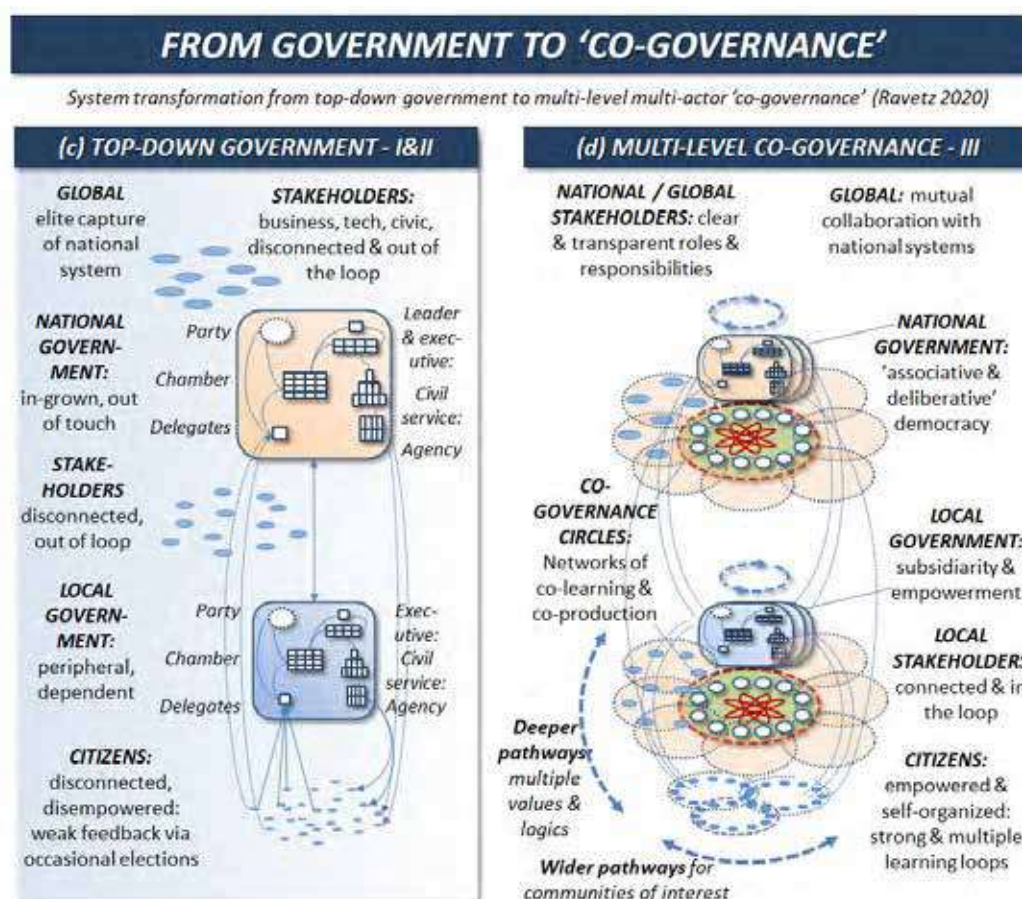

Figure 2 From government to 'co-governance'

From this cybernetic view of participation, a government of representative democracy in fixed units seems quite unsuited to these complex, overlapping, multi-layered dynamics. Moreover, the internal structures of decision-making also seem quite archaic. The diagram at Figure 2 shows, on the left a **(C)**, a typical parliamentary democracy (e.g. UK), with the local government as a smaller replica of the national level.

There are strong reasons for a complex series of checks and balances, but the overall system configuration shows a lack of feedback channels, with inefficiencies piling up, ingrown and self-serving institutions, and a 'democratic deficit' or lack of engagement with stakeholders. As a result, the needs of cities and neighbourhoods go unmet, resources are wasted, and citizens are alienated. Moreover, results on the ground include urban sprawl, car dependency, rising inequality and destruction of local assets.

Alternative thinking starts with the principle of the round table and its cognitive system properties, of collaboration, co-learning, and co-production. A round table configuration allows formal government units to sit alongside other stakeholders, both formal and informal, as sketched on the right at **(D)**. Overall there is potential

for a more responsive structure with higher levels of *collective political intelligence* – a roundtable or circle of so-called ‘co-governance’, i.e. collaborative and co-produced modes of decision-making.

The model shown above is a hybrid partnership based on networking and collaborative relations, not to replace formal decision-making structures but to enhance them. It works best with multi-level inter-connections, horizontally or vertically between the formal units of cities or districts, to allow for problems and opportunities which do not fit in formal units. The central circle can have any number of special interest or project circles attached, all linked by a common platform for information sharing, co-learning and co-production. It promotes ‘associational’ or ‘deliberative’ forms of democracy, which looks for the balance of formal and informal interests, where citizens, neighbourhoods or whole cities can be empowered and self-organized.

Living Labs

The three LOOPER Living Labs have different spatial, cultural and thematic contexts. The Brussels LOOPER Living Lab is situated in Helmet, a neighbourhood with many traffic safety problems within the municipality of Schaerbeek in the north of the Brussels Capital Region. Its location was selected after consulting local and regional governments as well as NGOs in the area. The living lab was set up in February 2018 and will run until June 2020. The lab is run by the Mobility, Logistics and Automotive Technology Research Centre (MOBI) at the Vrije Universiteit Brussel and BRAL, a Brussels citizen NGO.

The Manchester LOOPER Living Lab is situated in the Brunswick neighbourhood, a former social housing estate close to the city centre that is undergoing regeneration. The neighbourhood has a diverse population and is bordered by major roads on three sides. The Manchester Living Lab explores five interconnected issues: air quality, traffic safety, security, community spaces and greening. The University of Manchester is the coordinator of the Living Lab but works in cooperation with the social housing organisation S4B.

The Verona LOOPER Living Lab is located in the south of the city of Verona. The borders of Verona South are delimited by train tracks, roads, and a river. Air pollution in the area is a problem as it exceeds limit values imposed by EU laws. This problem is partly caused by the city’s location in the Po Valley but is exacerbated by the emissions of old heating plants as well as mobility related emissions. The Verona LOOPER Living Lab officially started in December of 2017. The lab is run by IUAV University of Venice with the cooperation of environmental NGO Legambiente and the City of Verona.

Results problem identification

The scoping of problems to be addressed in the LOOPER Living Labs was done together with local stakeholders and citizens. Living Lab organisers used their knowledge of the area but also had meetings with stakeholders such as local authorities and schools. Emphasis was put on engaging residents in the project and suggest ideas for the Living Lab. This was done via workshops, neighbourhood events, local newspapers, and posters and leaflets. These outreach events resulted in the selection of traffic safety, greening and traffic calming, and air quality as the topic of respectively the Brussels, Manchester, and Verona LOOPER Living Lab.

Each Living Lab developed a plan to collect data on the identified problem. The Labs had an online geotagging application developed by IUAV at their disposal through which residents could identify places in the neighbourhood that they found especially good or bad regarding the identified problem (see Figure 3). In Brussels, residents collected data on traffic speed and traffic volumes. The Manchester Living Lab collected data with residents on air quality using mobile Airbeam sensors and data from the fixed government air quality sensing station. Primary data was also collected on existing green infrastructure in target intervention areas using observation and geographic information systems (GIS) mapping. Resident preferences and notes on the local area were collected using the online geotagging application and, where residents were either unable or unwilling to use the app, through offline consultation using maps and photos that were then uploaded to the

online platform. In Verona, residents collected data on air pollution by using mobile (low-cost) and fixed (official body) sensors as well as data on noise pollution using stationary noise boxes built with a smartphone, an app and a calibrated microphone. Furthermore, in Verona qualitative data about perception and appreciation of urban spaces were collected using the online geotagging application.

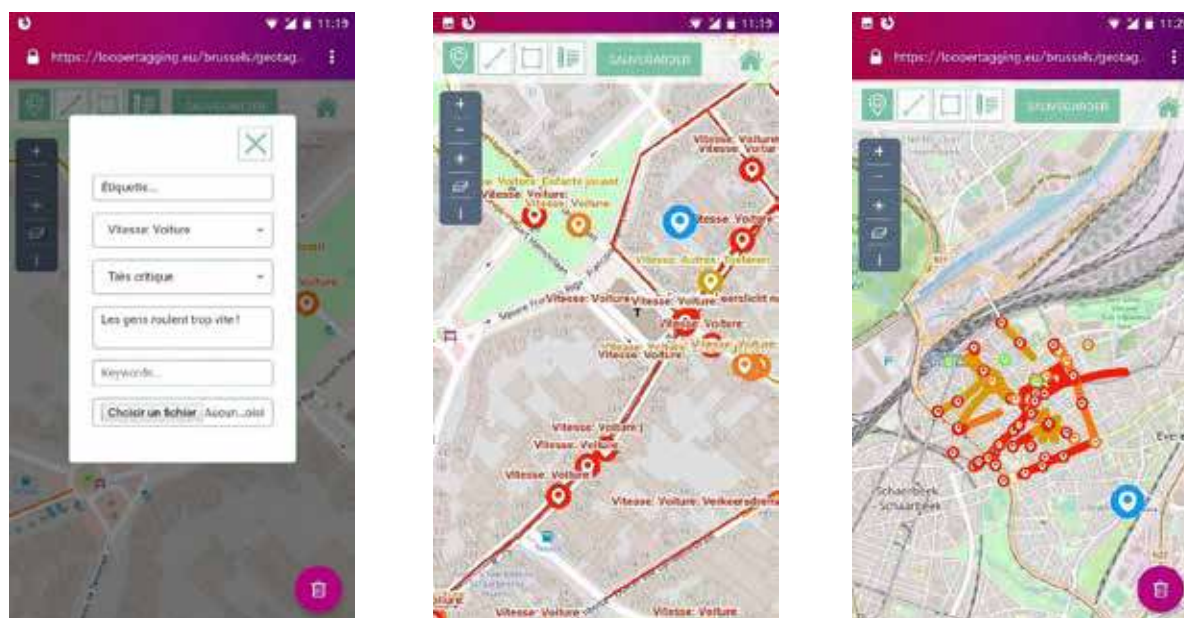

Figure 3 Screenshots of the LOOPER geotagging application

The collected data was visualised on each respective local LOOPER platforms, which is a website in the local languages used as a communication channel towards citizens as well as providing a data collection, visualisation and idea generation platform for the whole co-creation process. In Brussels, the platform showed the results of the speed measurements and traffic counts. The collected data showed that one in three cars go over the speed limit of 30 km/h and that majority of road users were either on foot or in a car. In Manchester, air quality was visualised to show the concentrations along main roads and around a local primary school. In Verona, the collected air quality data was displayed on the LOOPER platform (see Figure 4).

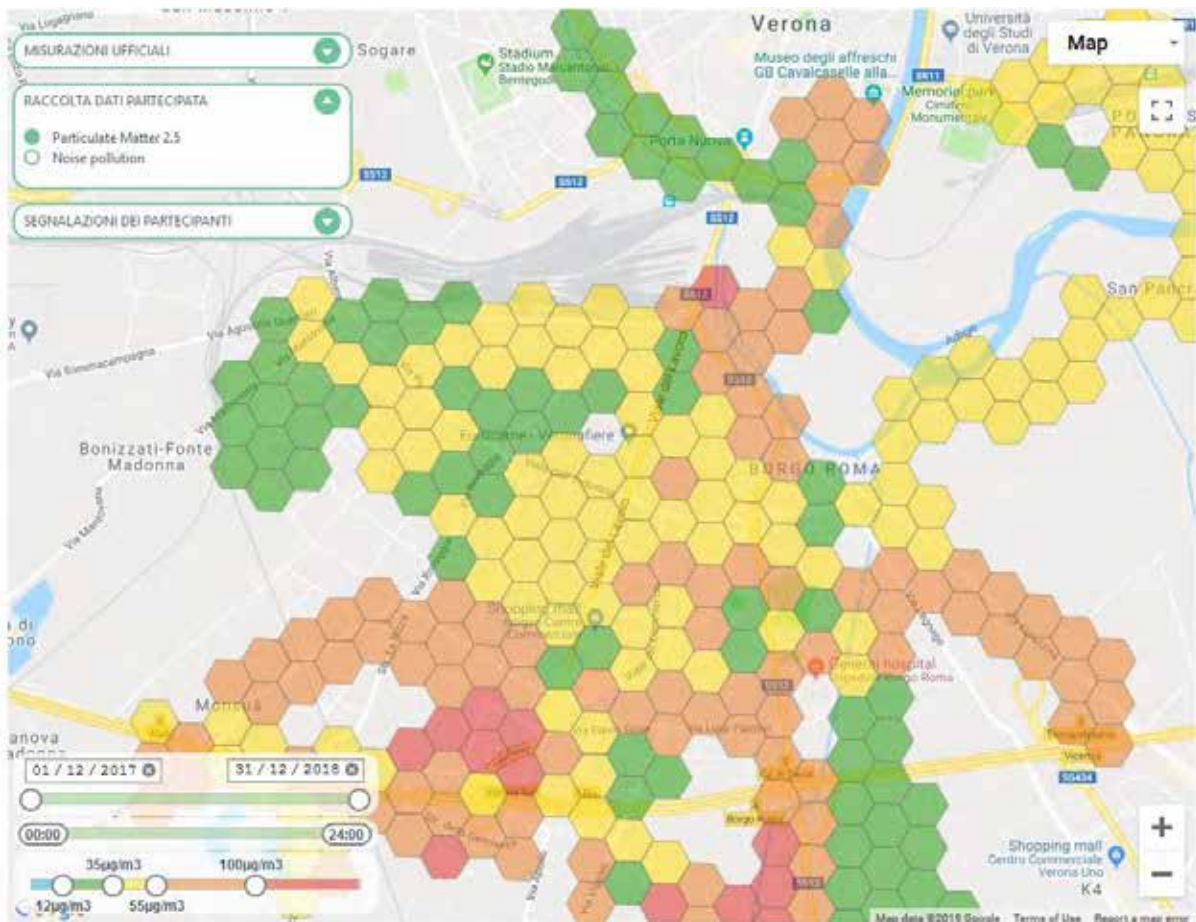

Figure 4 Data visualisation of air pollution in Verona on the LOOPER platform

In Verona, both qualitative and quantitative data were collected and displayed on the LOOPER platform. Figure 4 shows crowdsensed particulate matter (PM) 2.5 data, collected with mobile low-cost devices. The data from Verona showed that the spread of PM2.5 was almost homogeneous across a larger area, and mitigation solutions were needed across the whole Verona South area.

The data in Figure 4 shows how data collected throughout a one-year period give a homogeneous picture of the PM typical distribution. However, variations and peaks of particulate matter levels can only be seen on larger scales. This low difference of values inside on a regional scale can also be found when considering data collected in a shorter period of time. Figure 5 shows that even when considering the period with the highest levels of air pollution in Verona (a ten-day frame between January and February 2018), the collected data show no differences within close-by areas. Nevertheless, this campaign demonstrated that in some periods of the year, air pollution levels in the city are quite high and that some mitigation solutions and policies are needed.

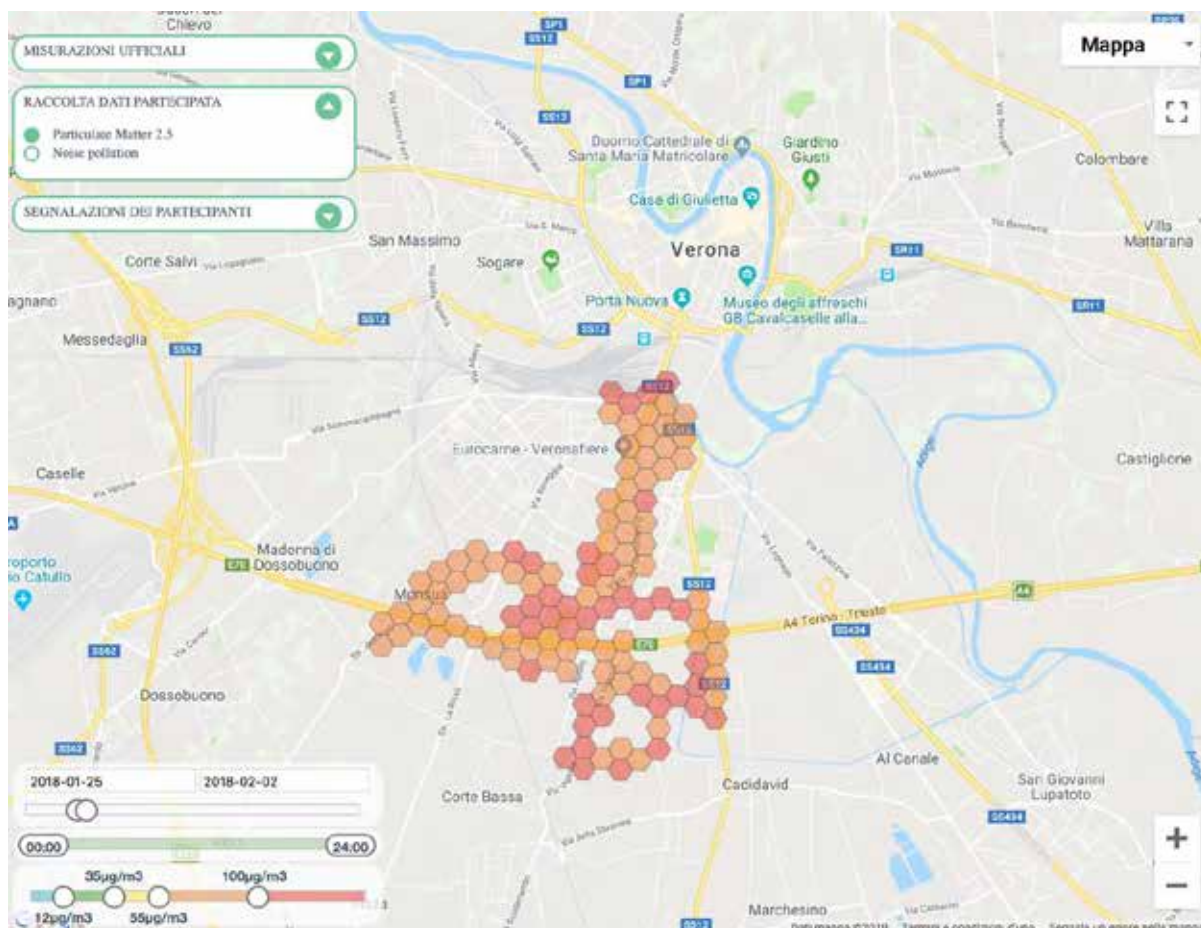

Figure 5 Data visualisation of period with highest levels of air pollution in Verona

Participants also collected data on noise pollution. Noise boxes positioned around Verona Sud showed that noise levels were close to or just over legal limits. This helped raise awareness on diseases caused by high noise levels which usually are considered as less important compared to air pollution.

Results co-design and implementation of alternative solutions

Each LOOPER Living Lab held workshops with residents and stakeholders to present and explain the collected data and to start the second stage of the LOOPER co-creation methodology: the co-design and evaluation of alternative solutions. Using their local knowledge, residents could submit solutions to the problem identified in the previous stage via the local LOOPER platforms where an idea generation tool was set up as well as through face-to-face co-design workshops (see Figure 6).

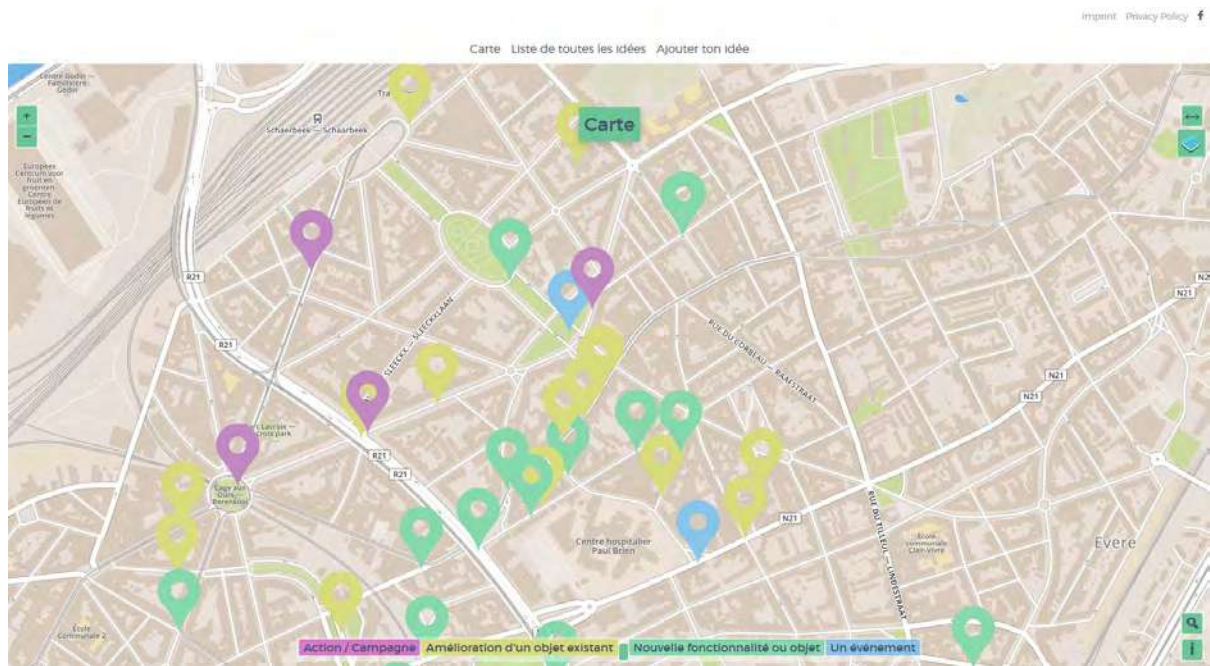

Figure 6 Location of possible solutions submitted by residents to the Brussels LOOPER platform

In the Brussels Living Lab, 43 ideas/solutions were suggested by residents. The co-designed solutions included changes in the infrastructure, awareness campaigns, and stricter enforcement of traffic laws. In the first co-design workshop, residents discussed, merged and rewrote ideas submitted via the platform and then decided on their five favourite solutions. Then, the impact of the proposed options on sustainability (MCA) and their stakeholder support (MAMCA) was evaluated. The sustainability MCA showed that none of the co-designed solutions would have a negative impact on the sustainability of the neighbourhood. Moreover, the MAMCA showed that none of the stakeholders (municipality; public transport operator; regional ministry of mobility; local cycling association; citizens) would be negatively impacted by the co-designed solutions. Residents then decided during a second co-design workshop that the solution to be implemented would be an awareness campaign for the presence of children in the streets.

In the Manchester LOOPER Living Lab, 36 ideas/solutions were proposed by residents, focusing on two specific roads and two neighbourhood wide issues (green spaces and street spaces). Overall, solutions responded to a desire to enhance the appearance and experience of the neighbourhood. On Brunswick Street three sets of ideas were proposed to address the problems of speeding traffic, lack of greenery and lack of connectivity / poor wayfinding. Specific proposals included 20mph speed limit plus a range of horizontal and perceptual traffic calming features, adding trees, shrubs and planters onto the pavement and other public spaces, adding hanging baskets and/or ivy screens and hedges in front of houses and other private spaces, and extending design elements from Brunswick Park and signposting entry into the Park from Brunswick. Wadeson Rd runs to Medlock Primary School and ideas included turning Wadeson Rd into a School Street (meaning closing down the road to non-essential residential traffic during school entry and collection). This included park and stride with neighbouring shop car parks, whereby parents could park nearby and walk the final part of the journey. Turning Wadeson Rd into a painted street and mitigating air pollution inside the schoolyard by planting hedges around school were also suggested. In terms of wider neighbourhood greening, suggestions focused on adding elements to make existing greenspace more interesting, such as wildflower meadows, woodlands, benches, play equipment, community activities, and green belt / active transport routes. There were also proposals to create citizen-led small green spaces: creating orchards with fruit trees and grapevines managed by neighbours. Finally, there were proposals to improve street spaces across the neighbourhood. These included improved

signage, connecting with design elements in the new Brunswick Park, adding benches and campaigning to prevent staff and students from the neighbouring University of Manchester to park in the neighbourhood. The MAMCA workshop was very effective in enabling the key stakeholders to rank ideas in terms of feasibility, cost and impact. This led to a desire to focus on Brunswick St, which was seen to be the most problematic element of the neighbourhood and thus the element that would produce the greatest benefits from targeted improvements. There is considerable interest in whether greening and general public realm enhancements could create a perceptual traffic calming effect. Treatments around the school were seen too complex due to existing initiatives focusing specifically on schools and air quality, while neighbourhood wide treatments were seen to be rather too diffuse to generate significant impact in a project of this scale.

In Verona, 34 ideas/solutions were proposed by residents. These possible mitigation solutions included: street closures to create calm and less noisy aggregation spaces; implementation of 30km/h zones to make neighbourhood spaces more quiet and secure; street closure during enter/exit school hours to allow children to reach school on their own; implementation of cycle lanes to have a more homogeneous network to boost the use of bicycles and to connect existing greenspaces; implementation of trees and greenings around the area of Verona Sud to make spaces more appealing and less polluted; introduction of green noise barriers on the main highway sides as it cuts through the area dividing it. The MAMCA was supported by a preliminary selection of sustainable solutions with policymakers and council employees that participated at Living Lab meetings, and the sustainability of the proposed options was evaluated while ideas were proposed. Indeed, the MAMCA was done considering the various stakeholders, and results showed that the proposed ideas could be implemented with no negative impact on stakeholders. After the MAMCA, three ideas were implemented as they had the highest, and most consistent, evaluation score for each stakeholder. The three ideas that have been implemented, and are being monitored as this paper is written, are: street closures in one part of the neighbourhood as a pilot case to propose it around the rest of the of the area; crosswalk islands near schools to be re-proposed in other school areas; and street closures at entry/exit hours to have safer spaces for children.

Results of implementation and monitoring

The last stage of the LOOPER co-creation methodology includes the implementation of (a) co-designed solution(s) (see Figure 7) and the monitoring of their impacts. Due to differences in timing between the LOOPER Living Labs, so far only the Verona Living Lab has implemented some of the proposed solutions (i.e. street closure, crossing islands for pedestrians), and started to monitor the effect of the co-design process (while writing this paper the data collected during the monitoring campaign are still to be analysed). To monitor the co-design process, the monitoring campaign is taking place using the same monitors positioned in the same locations from the 2018 campaign. This is done in order to have data as much comparable as possible, with the aim of having stronger results to support the whole process and do what is best to transform the situation.

In Brussels, an awareness campaign using temporary road paintings made by children will be implemented in June 2019. Speed measurements will be done before and after the implementation to see whether the solution has had an impact on the speed of cars.

In Manchester, a set of interventions focusing on Brunswick Street will be implemented between June and July 2019, with traffic speeds, resident perceptions and preferences, and car drivers' perceptions and preferences being monitored to assess the effectiveness of the overall treatment of the street and satisfaction with each specific intervention.

Figure 7 Examples of a to be implemented co-designed idea in Brussels and of an implemented idea in Verona

Discussion and conclusion

The LOOPER living labs have applied and investigated a number of aspects of co-creation that can be useful for other co-creation initiatives. The application and usefulness of online and offline tools, the combination of co-creation with analytical evaluation methods such as the MCA and the MAMCA, and the role of co-creation in social learning are the three most important aspects being explored.

Co-design is usually facilitated by a professional, who might choose a certain approach, and within that various methods or tools to spark creativity and keep a process of reiterative questioning, refining, reflection going. Scenario or prototypes can be built and reviewed. While co-design as an approach asserts users to be capable experts of their own experiences, they must still be supported through tools that allow them to express themselves (Voorberg et al., 2015). In LOOPER we have used a combination of offline and online tools. One of the learnings from the living labs is that online tools should have a low entry threshold in terms of previous knowledge of similar tools and in terms of access (e.g. need to register). Moreover, online participation tools can but do not always replace offline participation. A combination of online and offline participation is therefore necessary to involve as many people as possible.

In Brussels, the online idea generation tool was used by more citizens than the LOOPER geotagging tool, most likely because no account creation was necessary for the online idea generation tool and submitting an idea was a rather straightforward exercise. However, in Manchester the online idea generation tool was not used by citizens. It is unclear whether this is because of disinterest in the project or because the citizens lack digital skills to use the tool. No direct discussion between citizens, however, took place online in the three Living Labs. Whereas lively discussions about traffic safety and air quality took place during physical meetings, this was not the case online. Citizens used the online idea generation tool to submit ideas and view ideas of others but did not use the commenting function.

In addition to the online tools, we organised face-to-face meetings with citizens. These meetings served as a way to present the project to citizens, to get a debate started between citizens about the problems that the living lab would address, and to get citizens involved in finding solutions for the problems identified in the living lab. Moreover, these physical meetings allowed for the participation of those that were not able or did not wish to participate online. In Brussels, 25 people submitted ideas and 8 residents came to the two co-design workshops. In Manchester, more than 40 residents were engaged, primarily through meetings with 10 community

organisations and participation in 11 community events. In Verona, 33 ideas were submitted via the platform and around 50 residents came in total to the three co-design workshops.

In Brussels and Verona, most participants were already engaged in the topic of the Living Labs and had a relatively high educational background. In Manchester, resident engagement took place through existing community groups that showed considerable enthusiasm for the goals of the project to respond to citizen concerns and improve the local area. The Living Lab coordinators also visited citizens as part of the neighbourhood liaison role performed by partner organisation S4B in order to get input on what the problems are in the neighbourhood and how they could be solved. There was less appetite from residents to be involved in monitoring, as they felt they already knew there were problems that required attention, and less enthusiasm to engage with digital technology. This may have reflected the demographic and socio-economic make-up of the area and raises questions concerning the most effective ways to engage hard to reach groups with digital technology.

Another novelty of our approach is the integration of multi-criteria analysis and the multi-actor multi-criteria analysis with co-creation. While co-creation is a loosely structured, bottom-up method, MCA and MAMCA are very structured and can be perceived as complicated. Nevertheless, the potential added value of using MCA and MAMCA for evaluation is to show to what extent the co-designed ideas are sustainable taking into account 16 criteria of economic, social and environmental sustainability (Keseru et al., 2016); and to determine to what extent they would be supported by a wider range of stakeholders (e.g. public transport operator, police, municipality) beyond the citizens' group. This is a vital precondition for effective upscaling, as the solutions that are tested in the living labs must be feasible and practicable if they are to be adopted more widely by other organisations, places or policy makers. As Voytenko et al. (2016, p. 49) argue, "the degree to which ULLs [urban living labs] are able to stimulate broader changes beyond their institutional and spatial boundaries is directly related to the exact composition and structure of ULL partnerships, which determines which actors are included and the collective rules of experimentation." The LOOPER approach ensures that the stakeholders responsible for upscaling solutions are involved in the design and operationalisation of the living labs and their solutions.

The MAMCA and the MCA was only carried out fully in Brussels, as the method was perceived as time-consuming and requiring a lot of stakeholder input in the other living labs. That said, the process of engaging stakeholders through a value mapping process in advance of the MAMCA workshop proved to be exceptionally effective in ensuring stakeholder participation. In the second loop we will investigate how the burden on the analyst and the stakeholders can be alleviated. The role of the second learning loop will also be critical in determining how effectively local evidence concerning solutions is translated into more general insights (Hodson et al., Forthcoming).

The results in the LOOPER Living Labs show that reality is messy and unpredictable. The learning loop cycle may go around several times, especially at the co-design stage (Voorberg et al., 2015). The search for funding or the political process could be at the centre of the picture, more than any co-design options: a road safety/traffic congestion problem may be controversial, where different groups (e.g. residents / businesses) have different views and look for different data to support them. The design of traffic calming is quite technical and expensive, and the engineers might need time to learn how to do community participation and co-design. When the official approval is given for funding and traffic management, there may be 3-4 design stages, from sketch to outline to detail, each needing participation, from both a core group and a wider community, which is costly to organize. Meanwhile there are social innovations which might be quicker and cheaper, working in parallel, but where the effects are difficult to monitor. However, even if funding is difficult and little is achieved on the ground, there may be a positive effect on community capacity building.

A further issue is that of systemic scale and hierarchy. For instance, the problem of traffic pollution and noise can be framed at different levels, and the problem/response learning loops may be co-created at different levels, each with different interaction opportunities between policy, professionals and the community. All this should not suggest the problems are so complex and controversial, that nothing can be done. It does suggest a role for creative social entrepreneurs/community planners or mentors, who can bring together the different groups, navigate through uncertainty, coordinate the right level of technical/scientific evidence, and help in the co-creation of useful responses.

This paper is drawn from a project at mid-point, so any conclusions are very preliminary and subject to further feedback. We can summarise the main experiences and their implications for other Urban Living Labs so far:

- Practical interventions in the LOOPER Living Labs need to be fitted or ‘embedded’ around the realities of urban planning development, which is often very complex, slow-moving and in many cases controversial with different sections of the community, and/or the local government. With hindsight, the Living Labs could start on two parallel consultations, both with the community and policy-makers.
- Following that, issues of power and organizational dynamics cannot be ignored in a technically enhanced urban monitoring and policy development: i.e. the technology can enhance the political participation process, not to replace it.
- Citizen monitoring should include for both sides of the digital / non-digital divide, and it may be that non-digital offline methods are more effective, if the conditions for ‘embedding’ can be met.
- Evaluation methods need to be fitted to the reality of community and organization working, where the dynamics of projects are often messy, contingent, complex and unpredictable.

All these are themes for further debate and practice, in the evolving interface of policy participation, digital or non-digital learning loops, and the overall potential for ‘*collective local intelligence*’. The findings presented in this paper will be used to further improve the second co-creation loop in the LOOPER Living Labs.

Abstract: This paper illustrates methods, technologies and tools used and developed to support a co-creation method for the transformation of the urban environment, developed and tested in the framework of the Verona case from the LOOPER project. The LOOPER project (Learning Loops in the Public Realm), is an European Research Project co-funded under the JPI Urban Europe program. Other two cities are involved: Brussels, working on traffic related issues; Manchester, working on quality of spaces. Co-creation brings together participatory sensing, co-design and other activities to activate a participatory process. The LOOPER co-creation methodology, in the way it is applied at the Verona case study, is therefore based on working with the stakeholders since the first steps of the project, meaning that participatory sensing is grounded on the scoping and monitoring of urban issues done by citizens, enabling them to gain better result thanks to the knowledges obtained in the beginning. To support this process different technologies are used: passive sensors for NO₂; noise boxes; PM2.5 portable sensors; user-friendly visualisation dashboard to collect and visualise data. These methods and technologies have been used to improve co-creation to ideate and design urban transformation facing some issues in the city of Verona Sud.

Keywords: Co-creation, Co-design, Participatory sensing, Learning Loop

Introduction

The transformation of the urban environment is a complex process that involves many stakeholders, different topics and many personal or institutional interests. The consequences of this complexity are the slowing down of the transformation process and the rising of conflicts and frictions between citizens and public administration. But another aspect that influence on the scant implementation of urban transformation is the intricate and farraginous cluster of norms and regulatory plans supposed to facilitate and coordinate the management of the city development, but on the contrary, because of their top-down approach, they entrap many potential small and local urban transformation in the name of a unitary and coordinate approach at urban problems.

There is therefore the necessity of new strategies and approaches at urban problems to stimulate and facilitate the ideation and then the implementation of urban transformations to improve the quality of targeted and local urban places (e.g. a street, a small neighbourhood) through a sort of a bottom-up approach in terms of planning scale: the transformation of single urban places can contribute in the development and transformation of the whole city. On the other hand, to avoid conflicts but moreover to adopt adequate and well-chosen solutions, there is also the necessity of plan these transformations through a co-creation process based itself on a bottom-up approach. It is not a simple task and some conditions are necessities. “The fundamental precondition for the implementation of a bottom-up approach is the existence of a ‘bottom level’, which for urban planning corresponds to the existence of a community that has certain needs, problems and expectations, that are different from other communities, and is also willing to participate in planning procedures in order to influence them” (Pissourios, 2014). Another condition is the necessity to involve in the bottom-up process also city institutions with the role of evaluating feasibility of solutions in order to avoid difficulties “in translating a bottom-up procedure of urban intervention into legislation” (Pissourios, 2014).

In this theoretical context, the LOOPER project was ideated with the aim of developing and testing a reliable and adaptive strategy based on the double bottom-up approach, supported by an innovative multi-step co-creation process to improve the transformation of the urban environment. LOOPER (Learning Loops in the Public Realm) is a project co-founded under the JPI Urban Europe program and it works with three pilot cases, to be compared and evaluated, located in Belgium (Brussel), United Kingdom (Manchester) and Italy (Verona). The partners involved are: Vrije Universiteit Brussel, BRAL Citizens association of Brussel; University of Manchester; S4B (Brunswick Regeneration PFI); Click and Links; University Iuav of Venice; Comune di Verona; Legambiente Verona. In this paper the Italian case is used to better explain how the participatory sensing within the co-creation process can improve the transformation of the urban environment.

As abovementioned the Italian application is located in Verona, in North Italy, and more specifically in the area of Verona Sud (Figure 1), that is divided from the historical part of the city by the Adige river and the former freight yard, configuring it as a completely distinguishable and separated area of the city. Its development started at the end of the XIX century, with the completion of the first neighbourhood in the early twentieth century. Up to 1949 the industry grew in the area, occupying the central part of it, and the Z.A.I. (Industrial Agricultural Zone) was established.

Figure 1 - Verona location in North-East part of Italy and Verona Sud borders

The main issues that influence this area are air quality and noise pollution, mainly caused by heavy traffic, industries, old buildings' heating plants. The presence of this kind of issues lead to the creation of multiple neighbourhood and citizens associations which are interested in solving these problems. The strong willingness of the groups in protesting resulted in a conflictual relationship with policymakers and the public administration of the city (Condotta *et al.*, 2017). In this framework the LOOPER project applies its co-creation methodology to

solve the conflicts raised between the parties in order to find new shared mitigation solution to improve the urban environment.

LOOPER multi-step co-creation process

The LOOPER co-creation is a multi-step process based on a bottom-up approach. To create the condition of having a consistent and prepared “bottom level” - and therefore get a successful co-creation process – the strategy is to apply the methodology of the Learning Loop within Urban Living Labs (ULLs).

The Learning Loop (or single/double-loop learning) concept was firstly developed by Argyris and Schön (1995). Single-loop learning is an organisational learning process, meaning that people, organisation or groups modify their behaviour and actions according to how reached outcomes differ from the expected outcomes. The single-loop learning is therefor based on the idea that people change their actions, or behaviours, to avoid mistakes. The implemented version of the single-loop learning is the double-loop learning, which expands the idea of the single-loop by having people to correct not only their actions, but also the underlying causes - i.e. organisational norms, policies - behind the problematic action.

In LOOPER a double-loop learning is used as participants, and stakeholders, are called to consider not only about their actions, but also the framework in which they are working. As this leads to a deeper understanding of the pattern in which they are working, it also allows a better decision-making process within every operation. Double-loop learning also introduces organisational learning in the framework: participants and stakeholders are called to examine the underlying assumptions behind the actions to learn from possible incorrect methods.

Another important concept within the project is that of Urban Living Lab, an evolution of the Living Lab concept that is a user-centered open-innovation ecosystem (Von Hippel, 1986; Chesbrough, 2003; Almirall and Wareham, 2011) which integrates research and innovation processes (Bilgram *et al.*, 2008) within a public-private-people partnership (Pallot, 2010).

The implementation of the learning loop and ULL concepts within the co-creation process takes place by filling three sequential planning stages which are conducted inside ULLs (Figure 2): 1. Identification of problems; 2. Co-design and evaluation of alternative solutions; 3. Implementation and monitoring. After finishing the three-stage process another loop starts by going back at the identification of problems; this triggers a “learning loop” as during the second loop stakeholders already have acquired knowledge and information as a base for it.

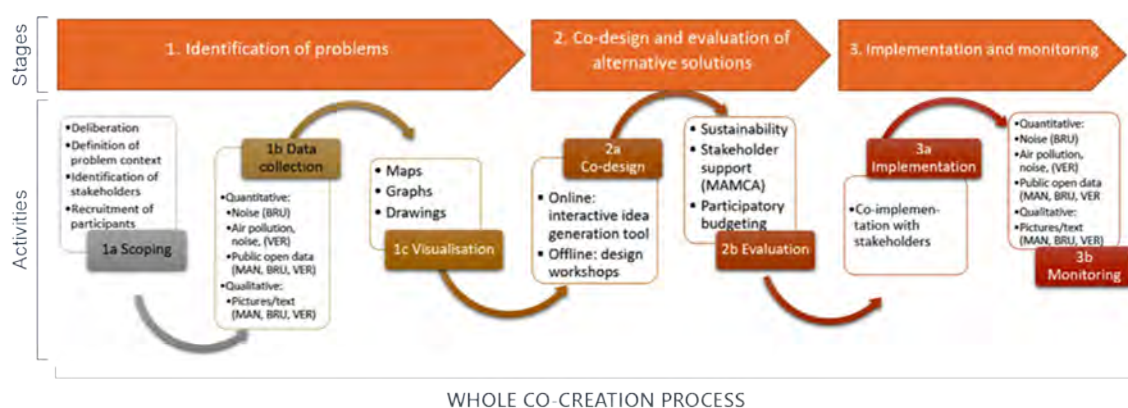

Figure 2 - LOOPER co-creation process

The learning side of the co-creation process

In the framework of the multi-step co-creation process, the LOOPER method activates a three “learning stages” process inside ULLs, each of which takes place during every learning loop (Figure 3).

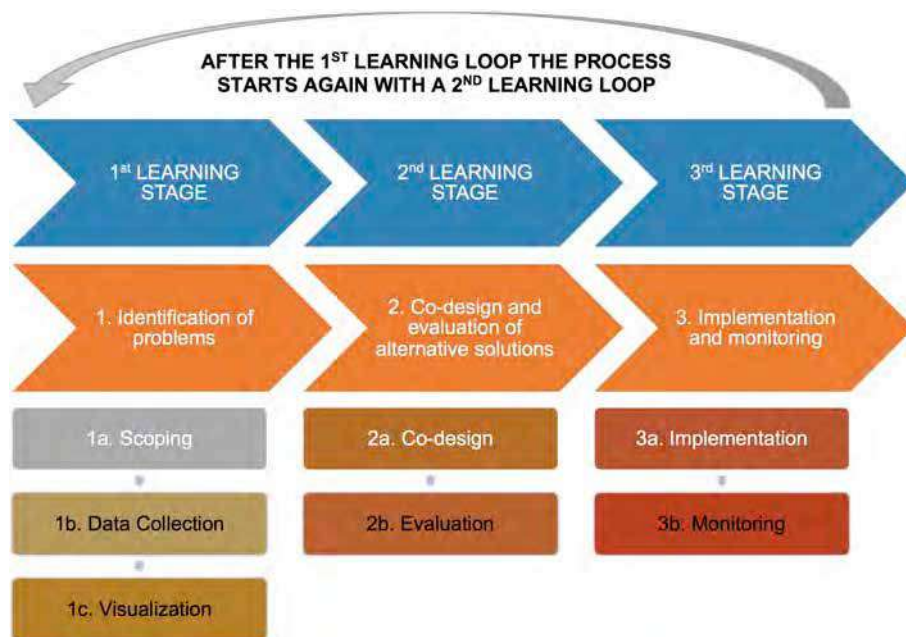

Figure 3 - Learning stages inside the framework of the LOOPER co-creation process

Each learning stage can be matched to one of the co-creation process' stages, which will be better explained later on. The first learning stage is meant to create awareness about urban issues and about the status of the problems through some consciousness activities. This first type of learning starts by focusing on the scoping of issues, done during the ULL meetings which are organized together with all stakeholders. During these meetings participants start to learn what others perceive as issues, which matters are real or perceived, and which of the issues are most relevant. The learning later moves toward applying what was learnt previously to organize the data collection activity which uses a crowd-sourcing approach. As soon as the data collection is completed, the visualization adds other skills and knowledge to the learning as participants are called to analyse the data they collected by using the online interactive geo-platform that shows every collected data with a user-friendly approach.

The second learning stage covers the activities of co-design of possible urban mitigation solutions and the evaluation of which are worth to be implemented. During the co-design activity participants are asked to propose possible solutions to solve urban issues. This co-design activity is done by having within the participants both citizens and policymakers, this allows to have an open dialogue on which proposed solutions are feasible, effective and sustainable. Moving forward to the evaluation, each of the solutions considered to be feasible, effective and sustainable by participants are assessed by using the MAMCA (Multi-Actor Multi-Criteria Analysis).

The third learning stage seeks to implement the selected solutions into the urban environment, with a second data collection to monitor if there are any effects after the implementation. During this stage participants - both citizens and policymakers - assess the results of their activities and, in this way, they increase their knowledge and awareness on possible transformation and mitigation measure to approach urban issues. At the end of this stage another loop begins, allowing to have even more learning as it starts from a more advanced knowledge base.

Furthermore, the co-creation process based on the ULLs and the learning loop methodology, which is applied in the framework of the LOOPER project, does not only aim at giving knowledge to participants, it also has the intent, or pedagogical ambition, of transforming the most common negative feelings of anger and protest, which usually citizens have towards policymakers, into positive energies of proposition and participation. This is a very important point of the process as usually these negative feeling stem from a low knowledge which citizens have when talking about urban issues, leading to a form of inertia when improvement measures are applied by public administrations.

The “participatory sensing”

The learning side of the co-creation process, that we have described in the previous paragraph, play therefore a relevant role in creating the necessary conditions for implementing an effective bottom-up approach. Another strategy to enhance the bottom-up approach is to embrace a “participatory sensing” approach within the first stage of the learning loop; this is what we have done while applying the LOOPER method at the Verona experience.

The participatory sensing concept can therefore be found in the whole first stage of the co-creation process as it is a collective way of gathering knowledge while perceiving and interpreting the urban space that surrounds the community itself. The process gets called “participatory sensing” (Figure 4) and aims to *collectively involve* (participatory) the community in *observing, measuring and interpreting* (sensing) the urban criticalities and the data collected to reach the design of possible ideas to transform the urban environment. From the scheme in Figure 4 it is possible to see how – under the umbrella of participatory sensing – the sum of the activities of the first stage of the project actually built the “bottom level” which is necessary to have a well-functioning bottom-up approach. Indeed, it is possible to reach good, and useful, results with a bottom-up approach only if citizens are given the tools to empower themselves.

To give a more complete explanation we can say that each of the activities done during the first stage give some knowledge which allows to develop participatory sensing within a community, that later on improves the co-creation process. During the scoping of issues activity citizens are able to collectively interpret and create a framework in which to work, and this collective choosing allows a feeling of involvement without which it would not be possible to trigger a bottom-up approach. During the monitoring activity the participatory sensing gets empowered as citizens are called to collectively monitor what they previously decided to scope, and this is the first active on the ground work that they are called to make. During this activity the participatory sensing reaches its peak. Moving towards the visualisation, citizens are called to interpret the data they collected about the issue they chose.

Figure 4 - Participatory Sensing concept applied at the first stage of the LOOPER process

First Stage of the LOOPER co-creation process: identification of problems.

As we here will focus on the participatory sensing and how it can improve the transformation of the urban environment, it is necessary to deeper explain the first learning loop experience of the LOOPER project and how it has hence been applied and customized at the Verona case. The loop started in November 2017 and will end in September 2019, going throughout the stages of 1. Identification of problems, 2. Co-design and evaluation of alternative solutions and 3. Implementing and monitoring. The general aim of the first stage was to identify, in practical detail, the problems of a local community through a three-step process. But within these activities the word “problem” started to include the idea of “opportunities”, and possible pathways to go forward.

The scoping activity - which means the setting of the framework of issues for the pilot case - took place between November 2017 and February 2018. Throughout this activity period, it was possible to determine which where the urban issues to be considered. During the scoping activity (Figure 5), following the broad priorities of the whole Lab setup, the focus was onto particular interventions which could solve problems - or gather opportunities - of specific interest to the community. Particular attention was given to the possible causes and effects. The problems found were later framed in order to allow the collection of data to quantify/qualify the issues chosen to be addressed: air quality and noise pollution.

Figure 5 - ULL scoping activity

Going through the problem scoping activity, a co-operative data collection planning started as it was based on the idea of a participatory sensing activity. As the problems and opportunities were selected, the data to be used as indicator of the selected urban issues were identified with the help of participants. Participants – but above all, citizens – were trained on the various aspects related to the measuring of data related to a specific issue and decided the locations on where to position the sensors available within the framework of the project (Figure 6). It was, in fact, chosen with participants where to position the sensors and when to undertake the monitoring campaign for the data collection. The sensors available for the data collection were both official ones - i.e. mobile stations – provided by the Environmental Prevention and Protection Agency of the Veneto Region (ARPAV) which is the official body in charge of the measurements, to gather more accurate data to be used as control group, and low-cost ones - i.e. noise boxes, AirBeam for PM2.5, Air Monitor for NO2, geotagging tool for qualitative data – for the crowdsourcing activity (Figure 7).

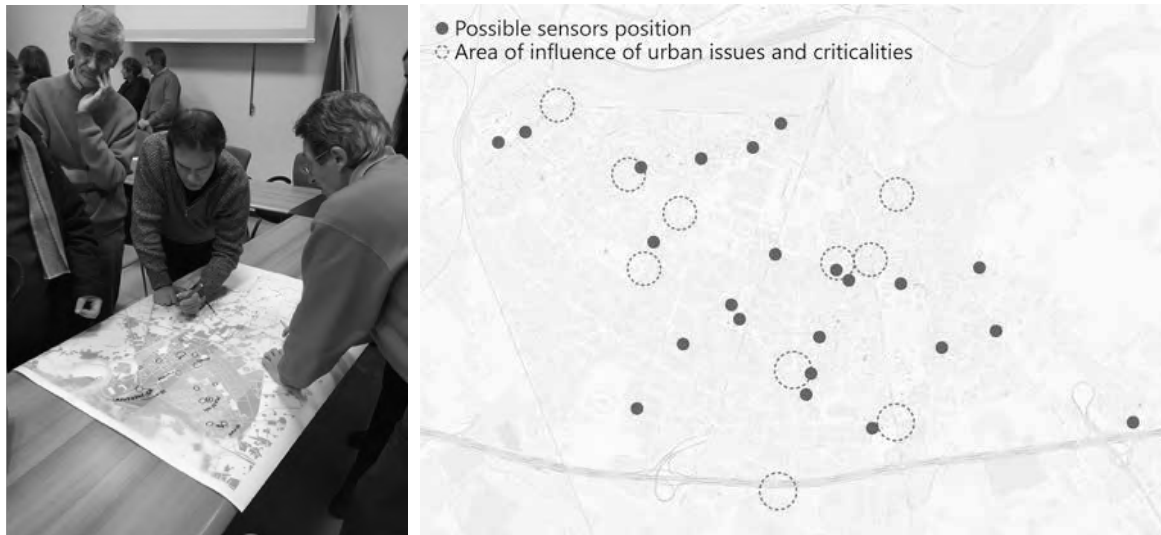

Figure 6 - ULL scoping activity and sensor position

Figure 7 - Noise box, Air Monitor and AirBeam

Considering the crucial importance of where and when the monitoring campaign would take place, the Verona ULL dedicated three meetings in this decisional process and this was done by also thinking at the second monitoring campaign and not only to the first one, and both citizens and policymakers participated and collaborated with the aim of finding a solution which could suit the needs and wills of every stakeholder participating in the project. In Figure 6 it is possible to see the locations chosen by participants where to position some sensors, from places chosen within participant houses or public buildings, and where these possible positions overlapped with the criticalities found before.

After the process of scoping of urban matters, and of questioning on where to position sensors, it was evaluated which places were suitable to position the mobile stations given by ARPAV, and which locations could be used to position the low-cost passive sensors for air pollution. During this activity participants were helped by giving them the tools which were necessary to choose wisely, i.e. knowledge about the issues found during the scoping, competences on sensors and on laws that regulate air and noise monitoring, expertise of council-employees on the feasible space to position mobile stations. The first monitoring campaign took place between February 2018 and April 2018.

Subsequently, the visualisation of the data collected - which was between June 2018 and September 2018 - was made possible by using web-GIS tools, together with other media supports such as audio, image or video. The results of the first cooperative data collection campaign can be found at verona.looperproject.eu/visualizzazione/.

The results of the visualisation activity are publicly shared information which were discussed within the ULL by local stakeholders and that were analysed in terms of thresholds, targets, priorities, opportunities. To better clarify, air quality data were matched to official risk categories. Social data such as greenspaces were to be prioritised for action. An assessment/evaluation process decided e.g. which problems to work on, by who, with what resources, in which timescale, in which location.

Tools to support the participatory sensing

As the whole co-operative data collection activity is one of the most important activities to reach a complete participatory sensing process here the tools used are explained in detail.

The tools used between February 2018 and April 2018 were:

- Mobile stations from ARPAV (official body in charge of controlling the environmental situation in Italy) which could collect data of: NO; NO₂; NO_x; PM10.
- Passive sensors from ARPAV which could collect NO₂ data from a wider range of places as these are low-cost sensors which need no electricity.
- Noise boxes made up from a low-cost Android smartphone, the OpeNoise app from ARPA Piemonte, a waterproof box and a microphone to be assembled.
- NO₂ low cost sensors made with an Arduino board to which a set of other components, including the actual NO₂ sensor, need to be embedded.
- PM2.5 low cost sensors which work with a light scattering method with a continuous data collection to find out people exposition to the pollutant.
- A geotagging web app to collect qualitative data about traffic, urban green spaces and any other issue and/or good practice to be found in the area.

The final result was that of a complementary set of tools which gave a more complete understanding of the situation of the project area. This more complete view also helped in realigning the perception that participants had with the actual situation of the spaces they live in. The two main tools which helped in overtaking this discrepancy were the AirBeam - which monitored the PM2.5 - and the noise boxes - which monitored sound levels in dB(A) - as these are the most untrusted data among those collected by the official body.

The AirBeam is a tool which can be used to get instantaneous data of the exposure of a person to PM2.5, it has been developed by HabitatMap which is a non-profit environmental health justice organization whose goal is to raise awareness about the impact the environment has on human health. The big difference between an AirBeam device and an official device relays in how data are collected, indeed the AirBeam measure PM2.5 using a light scattering method; air is sucked in a sensing chamber wherein a LED bulb scatters off particles in the airstream, is registered by a detector and converted into a measurement that estimates the number of the particles in the air (Figure 8).

This device is a crowdsensing one as it works via Bluetooth and sends data to the AirCasting Android app, developed by HabitatMap, every second. The app then maps and graphs the data in real time on the smartphone. At the end of each measuring session all of the collected data are sent to the AirCasting server and there gets crowdsourced with data collected from all the other devices to create a map showing where PM2.5 concentrations are highest and lowest. The device can be considered as a low-cost one as the price is of \$ 249,00 for a single device, this though excludes the cost of an android smartphone with internet connection which is a mandatory requirement for it to function. If the smartphone needs to be bought, it is still possible to keep the total price of the sensor under € 350,00.

Figure 8 - Air Beam tool

The other tool mainly used for the participatory sensing was the noise box. The noise box sensors are sound level meter apparatus provided by an android smartphone, a lavalier microphone and a waterproof enclosure (Figure 9). These are used to collect a data every 10 minutes, but the time laps period can be modified by the user. As the device is calibrated with an official class 1 level meter it is possible to compare the data collected by it with the official ones. To compare the data is it necessary to work on the raw data to obtain the weekly day and night data, as required by law.

The sound level meter software used for the Sound Level Meter apparatus is the OpeNoise Android app developed by Arpa Piemonte. The App allows the user to store the A weighted equivalent level in a .txt file. In the .txt file is it also possible to store the third octave band log. In the settings, it is possible to calibrate the microphone and to change the time step of the logging in a range which goes from one second to one hour. As per the AirBeam sensor, an Android smartphone is mandatory and the price of the apparatus depends on the type of hardware chosen but it can be less than € 150,00.

Figure 9 - Noise Box kit

Interactive map for data co-visualisation

To enable the co-visualisation, the visualisation tool needs to be as user-friendly as possible. For this reason the number of different subjects to whom the information is addressed has led to the design of a simplified interface strongly oriented to reduce cognitive overload. To do so a first classification of collected data and information to be displayed was done by distinguishing institutional (high-accuracy datasets) from those collected in a participatory way (high temporal and spatial resolution but medium-low accuracy). This first aspect determined the structure of the layer panel in four different sections: institutional/official data, participatory sensing, stakeholders feedback and report, public databases (in Figure 10 only three sections are shown as data from public

databases are to be uploaded as the paper is written). Again to avoid cognitive overload, layers are shown one at a time; map controls only include the base layer selection (natural or road map) and the zoom level; click event fires the details info-box but double-click is not provided; mouse-over event (only non-touch devices) shows the label of the map feature. As for the type of collected data, there are three specific cases: vector georeferenced data (points, lines or areas) mostly collected with a mobile-friendly geo-tagging tool; data series related to static monitoring points ("measuring spot") coming from continuous measurement campaigns carried out using static sensors; GPS point tracks with scattered measurement campaigns carried out with mobile sensors and data loggers.

Vector georeferenced data are qualitative data with a quantitative field that is the level of relative importance (rating) of the phenomenon reported using a 5-classes scale; therefore we chosen a graphical representation with a rating-based colour ramp (from green to red to cases ranging from optimal to the most critical). The data series collected with static sensors are instead related to the location of the measuring box; for those points, users can view firstly the campaigns list and then, with a second click, look at the details of the specific campaign (Figure 11). Lastly, GPS tracks with measurements are the only data that must be treated as whole area coverage, therefore the visualization technique is based on a hexagonal mesh made in 4 different size levels, from 25m to 250m and a dynamic calculation of average values carried out per single cell (Figure 10, Figure 13). In any case the complexity does not affect user interface that provides intuitive and effective 4-dimensional (x, y, time, value) browsing functions (see the widget at the bottom left of Figure 10).

As for the interaction design, the features of quantitative data collected with low-cost sensors in participatory mode required the insertion of a special panel to allow user to choose the thresholds and defining custom intervals between optimal and critical situations; in this way it was possible to show both accurate official data and less accurate data relating to the same phenomenon avoiding direct quantitative ratio of measures that cannot be properly compared due to the different sensing systems.

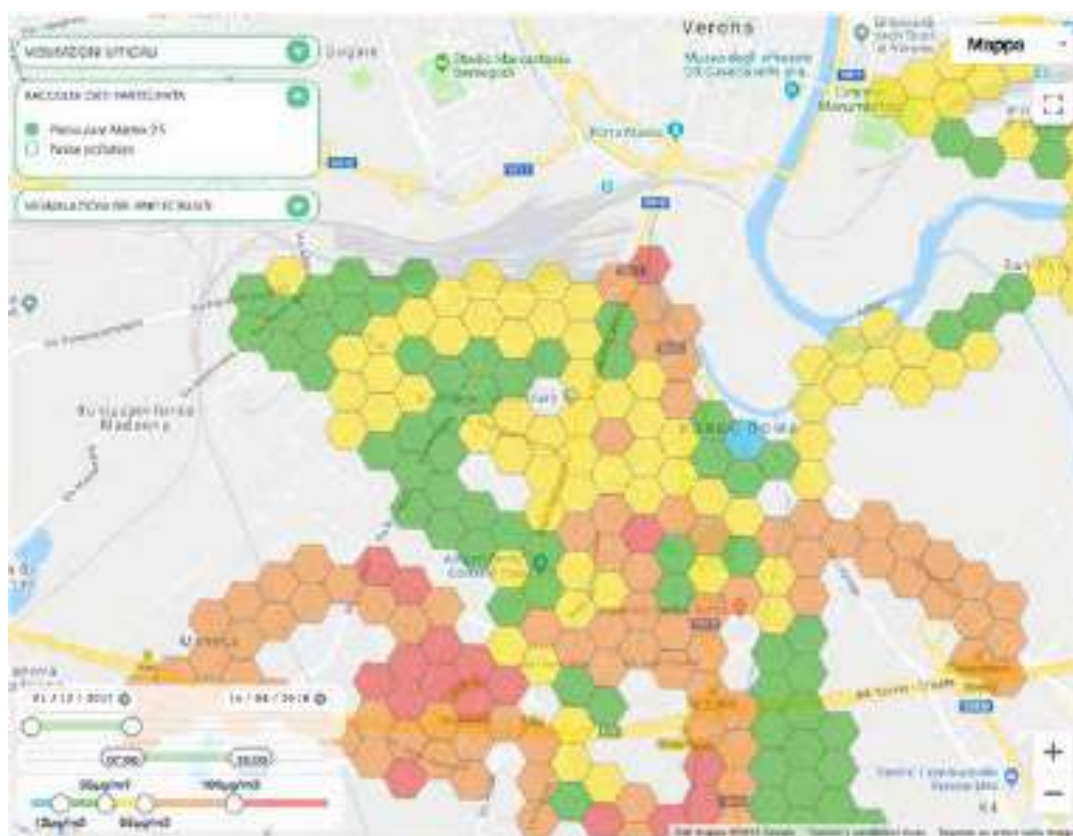

Figure 10 - Co-visualisation platform screenshot

Participatory sensing improvements in co-creation

To comprehend how the participatory sensing actually improved the co-creation process, it is necessary to understand how citizens were empowered by the co-operative data collection. It allowed them to better “sense” urban issues and to have the right tools to interpret (sense) official data.

Comparison of official data and participatory sensing data

The distrust that citizens feel towards policymakers and official bodies when talking about environment, is mostly raised by the lack of knowledge they have about both the tools used to collect data and the way these sensors work. Because of this it is of extreme importance to use participatory sensing when applying a co-creation bottom-up approach.

When talking about PM2.5 and PM10 data analysis the first thing to keep in mind is that data collected with official bodies sensors consist on the weighting of a tampon which was exposed for 24 hours to a certain volume of air controlled by using a pump, meaning that a single data in a specific position is given for each day. This means that a single data will be given for each day of the campaign (Figure 11). The way in which these data are then approached, from a law perspective, is of counting how many days are over the daily limit value of $50 \mu\text{g}/\text{m}^3$ during the year – if it is more than 35 days there are sanctions - and if the annual limit of $40 \mu\text{g}/\text{m}^3$ has been exceeded – again if this is the case there are sanctions.

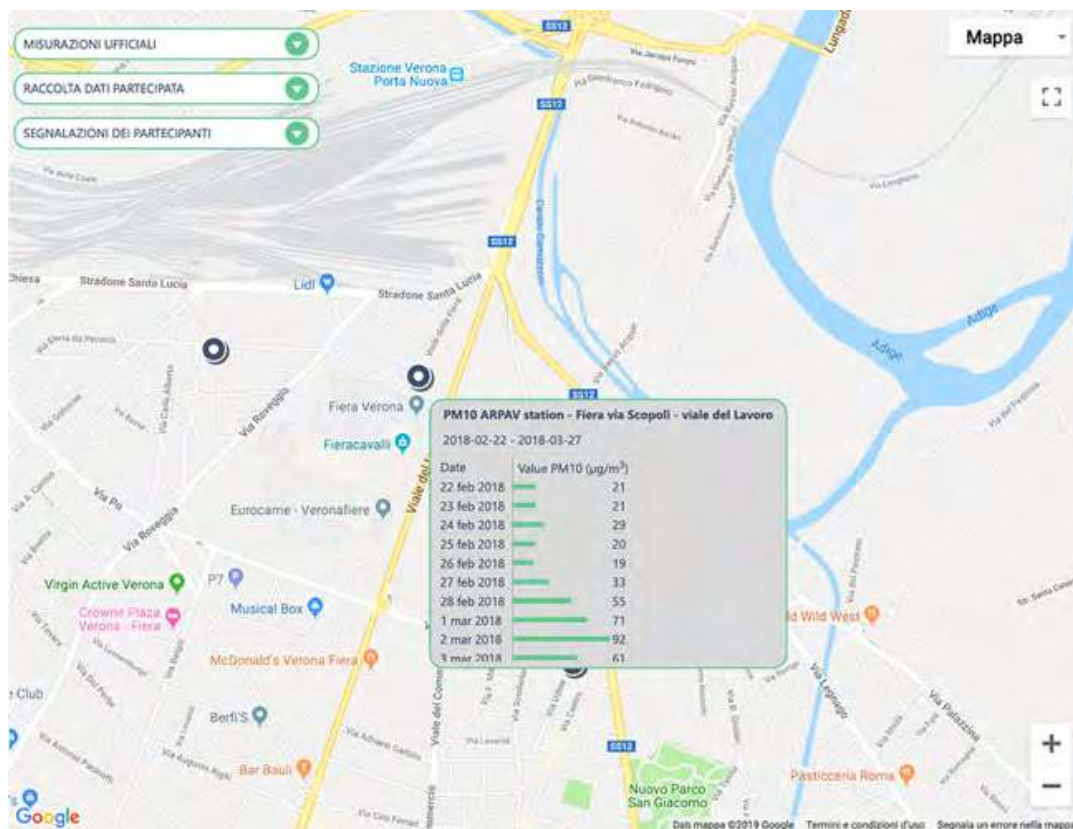

Figure 11 - Visualisation of static monitoring point

AirBeam data, on the other hand, are rather different as the sensor is meant to show the instantaneous exposure to PM that the person is facing, meaning that multiple data are collected within a one second timeframe and the method with which are collected is that of the light scattering.

The data then are not comparable with the ones obtained with the official sensors, even if the AirBeam is positioned in a specific spot for 24 hours, as the collection method is different. The main problem with the data collection done with the light scattering method is that high levels of humidity (>80%) have a negative impact on the accuracy of the sensor. Therefore, the AirBeam sensor has the main purpose of showing, mostly on a larger scale, the PM levels to which people are exposed during the day (Figure 13), rather than functioning as control group for official sensors.

For the participatory sensing, anyhow, the AirBeam was an important tool to raise awareness and trust when talking about official data. This because one of the reasons of distrust that citizens had towards ARPAV was because they thought that the fixed stations for PM were positioned away from the most polluted parts of the city. To overcome this misunderstanding, it was shown to citizens how homogeneous was the spread of PM on a large scale by showing them the daily data of all the fixed stations in the area of Verona. The graph in Figure 12 shows that there are small variations between ARPAV fixed stations, and that the changes in peaks and lows are due mainly to atmospheric conditions - i.e. rain, low pressure - within the day, and not to their position.

Figure 12 - Measurements of PM10 with ARPAV fixed stations

Citizens wanted to use the data collected with the AirBeams to refute this concept. After they were called to visualise the complex of the data, they found that changes could be found only on larger scales, and that variations happened in an homogeneous way as higher values could not be found close to the lowest ones (Figure 13).

As the comparison of data was done between official and participatory sensing data, it was possible to start to overcome the distrust that citizens usually have towards policymakers in order to strengthen the bottom-up process and the co-creation method.

Figure 13 - Measurements of PM2.5 with AirBeam

During ULL meetings, moreover, it was found that urban noise pollution is a less recognized issue by citizen compared to other air pollutants, such as PM10, as cause of the increased risk of running into serious diseases. Furthermore, it was not recognised that a constant background of high noise drastically lowers life quality. Indeed, the World Health organization considers noise pollution as a one of the causes of “annoyance, effects on sleep, cardiovascular and metabolic effects, adverse birth outcomes, cognitive impairment, mental health, quality of life and well-being, hearing impairment and tinnitus and any other relevant health outcome”. (World Health Organization, 2018)

The use of low-cost sensors for noise measurement has made possible to obtain both an extended picture of the noise levels distributed in the territory and to train citizens on the importance of noise monitoring and the need to accurately position sensors in such a way to obtain the most accurate results (Ruggeri *et al.*, 2018). Within the meetings of the working groups, the noise from vehicular traffic was identified as the main responsible for urban noise pollution. Later on, sensors were positioned close-by to critical infrastructures nodes which could be compared with Class IV area, which limits are 65 dB (A) in the daytime period (6:00 AM to 10:00 PM) and 55 dB (A) for the night period. These law values should be detected with a sound meter level placed near a façade facing the street with a microphone placed one meter from it, and the data collection should last at least one week, as it must consider the daily variations of urban traffic.

Noise boxes were used to monitor different locations distributed within the pilot area (Figure 14). The graph in Figure 15 shows the results of the survey of a typical week distinguished by day and night period, in comparison with law limits. The use of low-cost sensors, though, is not meant to quantitatively define noise levels, but is needed to identify criticalities to be investigated more accurately, i.e. by using class 1 instruments, and to raise awareness towards the possible dangers which are now less considered.

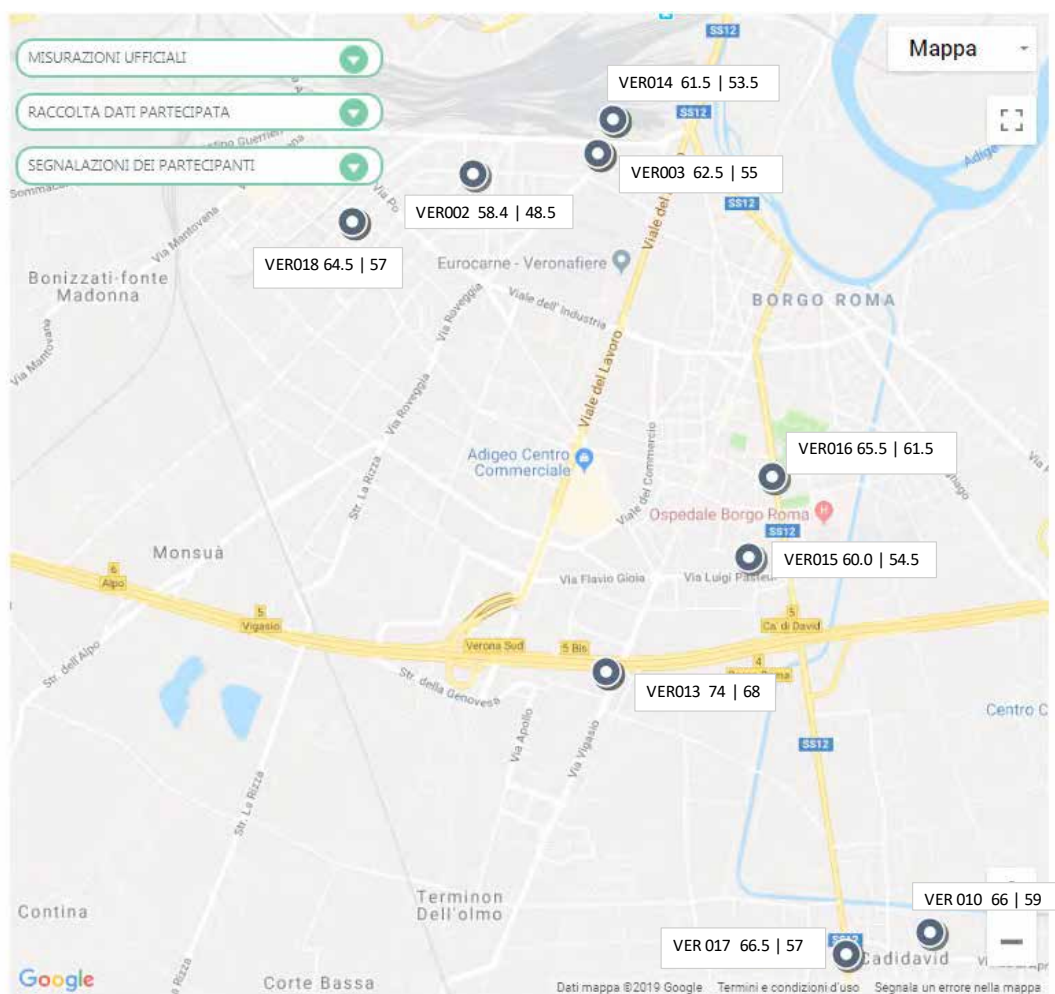

Figure 14 - Noise boxes locations and measurements

Figure 15 - Weekly noise day and night data compared with law limits

Second Stage of the LOOPER co-creation process: Co-design and evaluation of alternative solutions.

The co-design activity took place in October 2018, after an initial moment of visualisation of data with participants and policymakers (co-visualization). This activity was focused on how to respond to the problems investigated, and how to take advantage from the opportunities detected. This second stage involves co-design and evaluation of which options to implement. The main issue with the co-design activity was the creation of an iterative loop, i.e. from concept, to sketch, to outline, to detail as each of these need some form of participation and cooperation between experts, citizens, public stakeholders and policymakers.

During the co-design activity participants were engaged in qualitative and interactive online and face-to-face deliberation activities to propose a range of solutions. When going practical, co-design turned also be an iterative process as it went down many cycles to pass from concept to detail. It also involved a preliminary contrast between the community and experts/policymakers, that then turned to be an empowering dialogue between the parties. The activities which took place during this stage included the ideation of possible mitigation solutions, the designing of the ideas and understanding how to make their ideas real. During the ideation activity participants were called to generate creative divergent visions, ideas, synergies and possibilities. After this activity they moved to the design activity during which the iterative process started to move from a vision to a concept, then to an outline. During this activity the relationship between experts (researchers and policymakers) and community became very important. The last activity of this second stage was that of understanding how to transform in feasible solutions what was proposed until that point.

The process of collection of possible solutions took place both online, with the help of a co-design tool that could be found on the website (Figure 16), and offline, during the workshops. During the offline activity (face-to-face meetings) participants included not only citizens, but also policymakers and council-employees, and this create an even more interesting moment of sharing and discussing to propose better mitigation, but feasible, solutions as experts from the City Council were participating. Ideas produced offline have also been integrated on the online tool, which was used both as a way of proposing ideas for people who could not participate at meetings, and as a storage of possible solutions to keep participants informed.

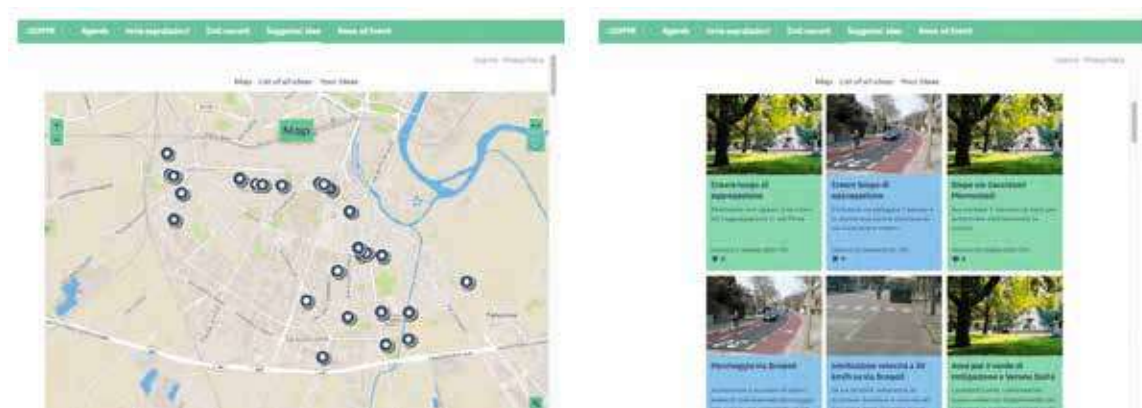

Figure 16 - Screenshot of the co-design tool on the website

In the evaluation of options phase then, the positives/negatives (costs/benefits) aspect of each solution were compared in order to prioritize the list of solutions proposed. One of the most important criteria which were considered was the cost/funding or feasibility, this because when working with a real environment it has to be taken into account if the solution can actually be implemented in a certain place, and if there is enough founding to implement and maintain it.

After the evaluation of the possible proposed ideas, the MAMCA, Multi-Criteria Multi-Actor Analysis (Macharis *et al.*, 2010), was applied in order to gather confirmation on the chosen ideas to be implemented. As the area of

the Verona Sud is quite wide and the proposed ideas where to be implemented in different location, it was needed to group and generalise the ideas to be able to apply the MAMCA. This was because the MAMCA method evaluates, and compares, different solutions among which to choose the one to implement in a specific location. As the MAMCA is a multi-actor analysis the different group of stakeholder who were taken into account are citizens, Legambiente (an NGO which is active in environment related issues) and the City Council. All of these stakeholders where the ones who actively participated until this point in the process. The ending result of the MAMCA was then that of confirming that the ideas chosen for the implementation during the last face-to-face meeting with the stakeholders, where the most feasible ones to implement.

Third stage of the Looper co-creation process: Implementation and monitoring.

This last stage started in December 2018 and is still going on. It includes the implementation of the best options - produced inside ULLs during the co-design activity - and the monitoring feedback of the results/effects obtained by the implementation of these solutions in the real context.

In the area of Verona Sud the implementation activity is seeing some physical actions on the ground, as the mitigation solutions asked by participants were: 30km/h areas around schools with streets closure at entering/exit school hours; closure of some streets to create a gathering space for residents; positioning of a crosswalk islands to allow a more secure environment in front of a primary school (Figure 17). As the implementation actually had a first part - December 2018 to January 2019 – of organisation, the solutions were officially implemented from February 2019. This allows to have the solutions in place during the second co-operative data collection campaign in order to monitor if there are any changes in comparison with the situation monitored in the same period the previous year.

Figure 17 - Positioned crosswalk island

The monitoring and feedback activity done during this third stage has the aim to check what results, impacts, outputs and outcomes can be obtained after the implementation of the chosen solutions. To do so, where possible, the impact of the implemented co-designed solutions is monitored with the same set of tools as in the first stage and with the input of stakeholders through participatory sensing and open data. As the data collection campaign is taking place as we are writing this paper, data will be later analysed to be uploaded on the online platform for further discussion with participants. These information will then go towards feedback for the next round of problem scoping and co-design. Further activities will then include: monitoring of the ‘before & after’ results; evaluation of the implications, e.g. did the co-design work, can it be improved; feedback into the next round, and/or the policy system.

Conclusions

In the paper we have emphasized the importance of bottom-up approaches to improve the implementation and effectiveness of urban transformation introducing also two levels of bottom-up approaches. The first level refers to stakeholders involved in the process, including therefore also citizens and local communities in the decision making. The second is related to the methodology of implementation of the urban transformation that, in this approach, is done by the sum of small-scale local transformation to generate an overall city improvement.

On the other hand, we have also argued that to support this double bottom-up process is essential the existence of the “bottom level”. This means the existence both of a group of stakeholders prepared and fit for the co-creation activities and also the identification in the city of the places suitable for that purposes. The participatory sensing method that we presented in the paper, understood both as “involvement” and “interpretation”, is a strategy to create the “bottom levels” required. The Looper project provided the occasion and the scientific environment to develop and experiment this theory but also to test the tools adopted in the project to activate the participatory sensing.

The pilot study of Verona produced on one hand promising results in the first (problem identification) and second (co-design) stages of the co-creation process; however, on the other hand, picked out some difficulties in the third stage in relation to implementation of measures produced in the co-design activities. In fact, although the direct involvement and participation of the City administration that supported the initiative and endorses the project goals, we run into difficulties in putting into action the ideas produced during the co-design activities. The issues found during the third stage were expected by researchers, this due to the difficulties for city administrations to allocate new budget in a short period of time and to the norms and regulations that limit the possibilities of rapidly execute – even temporarily – any innovative and/or alternative solution.

Despite the practical issues from the third stage, it can be seen how the co-creation process experienced within LOOPER was proven reliable to enhance a double bottom-up approach which allows stakeholders to open a more efficient round table to scope issues which are closer to citizens, and to propose possible solutions, to be discussed with policymakers, to improve the transformation of the urban environment.

Planning and biodiversity

Soil ecosystem services assessment to support land use planning - applications in Italy and a reflection for the future

Francesca Assennato¹, Andrea Strollo¹, Marco d'Antona¹, Paolo De Fioravante¹, Alice Cavalli¹, Michele Munafò¹

¹ISPRA, francesca.assennato@isprambiente.it

Abstract: The ecosystem services assessment (ESA) has an increasing visibility and more recently soil-related ecosystem services are under attention. Loss of agriculture and natural soil due to land consumption is one of the main causes of degradation of soil and loss of ecosystem functions. Decisions upon land use and cover at local scale are the arena to effectively foster soil ecosystem services provision. While there is some coherence in global and national ESA, the experience in land use planning is still fragmented. The discussion moves from the experience of national ESA in Italy, measuring variations in eleven soil-related ecosystem services (carbon storage and sequestration, habitat quality, crop production, timber production, pollination, hydrological cycle regulation, fresh water availability, water purification, erosion protection, microclimate regulation, particulate and ozone removal) related to 2012-2017 land consumption changes. The aim is to highlight the barriers and opportunities for integration in land use planning, and to provide critical suggestions around the potential role of ecosystem service knowledge at different levels. Results point out potentials of the ESA in representation of soil functions, together with methodological and procedural uncertainty that makes ESA potentially prone to improper uses and misleading results, in the absence of a common framework for application.

Keywords: land consumption, soil functions, ecosystem services, land use planning

Introduction

The attention towards the land consumption issue has increased in the last decade, particularly at European level with the Thematic Strategy for Soil Protection (European Commission, 2006; European Commission, 2011). Loss of agriculture and natural soil due to land consumption is recognized as one of the main causes of degradation of soil and loss of ecosystem functions. The Roadmap to a Resource Efficient Europe (COM (2011) 571) proposes, by 2020, EU policies to consider their impacts on land use, with the aim to achieve 'no net land take' by 2050. European Commission has prepared the 'Guidelines on best practice to limit, mitigate or compensate soil sealing' (SWD(2012) 101 final/2) and in 2013 the publication 'Hard surfaces, hidden costs- Searching for alternatives to land take and soil sealing' as well.

Those documents, underlying the relevance of the environmental problem, recognized the urbanisation and the conversion of land for development as a major threat in Europe, together with the hidden economic dimension and the explicit connection with soil ecosystem vital functions, from providing the basis for farmland and forests, and our food, textile and timber production, to filtering water, reducing the frequency and risk of flooding and drought, supporting biodiversity, and helping to regulate the local and global climate.

In Italy, soil suffered artificialization and degradation phenomena at unsustainable rates, with soil consumption continuously increasing despite scientific, media and legislative attention. The relevance of land consumption in Italy, made it one of the main challenges for spatial planning and land management to achieve a more efficient, sustainable and durable use of natural resources. In the last years, land consumption increased without a direct correlation to demographic growth (Indovina, 2009), mainly driven by demand for industrial, commercial infrastructures and transportation (ISPRA, 2018).

Decisions upon land use and cover are the arena to address land consumption limitation, thus the local scale is the proper one to effectively foster soil ecosystem services provision. In this context the ESA is a challenge to be undertaken by planners (De Groot *et al.* 2010), who has too long ignored to consider the benefits that the natural environment provides to human well-being. The question is what analytical framework can be usefully applied for this purpose. There are different ways to evaluate the dimensions of ES, in terms stocks of resources, potential or actual dimension of functions, potential or actual fluxes of services or benefits. The choice of the classification system to be adopted depends on the purpose, i. e. if the ecosystem services analysis focus on ecological systems or socio-economic ones (La Notte *et al.* 2017). The evaluation of the “benefits that people obtain from ecosystem” (MEA, 2005) can be used by the public administration as an incentive to limit land consumption and urban sprawl. It must be pointed out that the monetary evaluation of ecosystem services has the main risk of underestimating the natural resource values and can generate a trade based on compensation, with evident unequal effects on people and inefficient protection of the environment.

Since 2016, ISPRA produces the evaluation of the biophysical and economic loss of the main ecosystem services resulting from the increase in land consumption. In this vision, the economic evaluation is proposed at the national level to reveal the importance of those functions to humans. The purpose of evaluation should be to associate a value to the soil as a resource – with a unit of measure easily comprehensible by everyone – in order to motivate the public opinion to avoid its uncontrolled urbanization. This approach is necessarily different from the one devoted to assessing benefits in the national economic accounts, to be compared to other forms of capital and services, that follows more socio-economic purposes.

The objective of protecting soil functions in spatial planning make it necessary, from our point of view, to prioritize biophysical based approaches, in order to assure a close connection to soil functions in the evaluation of related services and benefits. More, there is a need for criteria of evaluation homogeneous within territories, to ensure a balance between local needs and practices and the protection of soil functions, also addressing trade-off between different services. There is also a need to identify priority services, as the regulating ones, often on the background of economic evaluations because of the difficulties in assessment of non-market values and in modelling of complex biophysical functions. In conclusion, the ESA in land use planning non necessarily includes the economic evaluation but must include a biophysical assessment of soil functions at the proper scale, that can be different between services evaluated.

Soil-related ecosystem services and assessment approaches

The Ecosystem Services Assessment (ESA) was created to encourage the consideration of the value of nature in decision-making and policy-making processes, and, consequently, can highlight the soil value and support planning towards more conscious and balanced choices. Nevertheless, although there is a growing interest on the institutions side, remains a lack of shared reference both in methodologies and in practical application of the ESA, particularly as far as territorial and urban planning are concerned.

Costanza *et al.* (1997) defines ecosystem services (ES) as the *benefits human population derive, directly or indirectly, from ecosystem functions*, estimating the economic value of 17 ES for 16 biomes. Considering an ecosystem as a dynamic complex of organisms, communities and the abiotic environment, interacting as a functional unit the Millenium Ecosystem Assessment (MEA) describes *the benefits people obtain from ecosystems* as ES, classified in four different groups, such as provision, regulation, cultural and support (MEA, 2005, TEEB - Kumar, 2010).

In recent years, these categories have been substantially modified both by the European Environment Agency, within the International Classification of Ecosystem Services reached the 5th version (CICES V5.1 - Haines-Young and Potschin, 2018), both from the TEEB (De Groot *et al.* 2010). In the CICES the ESs are defined as the contributions that ecosystems bring to human well-being and distinct from the goods and benefits that people subsequently draw from them. It is thus useful to

clarify between ecological phenomena (functions), their direct and indirect contribution to human well-being (services) and the welfare gains they generate (benefits).

In particular CICES, as TEEB classification, does not include supporting services, identified as habitat category not as services, which is necessary to highlight the importance of ecosystems as habitat providers for biodiversity but includes the category of regulating and maintenance services (La Notte *et al.* 2017, EU Commission, 2014).

The European Commission established a program on Mapping and Assessment of Ecosystems and their Services – MAES in response to Biodiversity Strategy by 2020 (see Target 2, Action 5). This specific action aims to provide a knowledge base on ecosystems and their services in Europe. A coherent analytical framework as well as common typologies of ecosystems for mapping and a typology of ES for accounting have been developed.

The fifth technical report (MAES, 2018) provides an integrated analytical framework and set of indicators for mapping and assessing the condition of ecosystems in the EU. A specific report on Soil ecosystems, as an output of the Pilot working group within MAES, to which ISPRA contributed, has been published by Deltares in March 2018 in support of the implementation of the EU Soil Thematic Strategy (Van der Meulen and Maring, 2018).

Recently, the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services has developed an analysis on the health status of biodiversity and the services that ecosystems offer (IPBES, 2019), in terms of Nature's Contributing to People, largely consistent with CICES V5.1 and with the importance of the basic functions of ecosystems at different scales.

National ESA for Italy

The evaluation of the biophysical and economic loss of the main ecosystem services resulting from the increase in land consumption is produced by ISPRA each year, since 2016. The experience of national assessment of ES variations related to 2012-2017 land consumption changes in Italy (ISPRA, 2018), is associated to eleven soil-related ES selected from the vast series of services associated to soil functions by international classification (Dominati *et al.* 2010, Van der Meulen *et al.* 2018).

In this national application ES are analysed with the specific aim to highlight the effects, in both biophysical and economic terms, of land consumption occurred in Italy in the period considered, offering an opportunity to evaluate the effects of landscape transformation. This evaluation, based on available data at the national level, must be integrated for further advance with information on soil functions, agricultural actual practices, data from forestry inventory, climate and water balances at river basin level, etc.

Table 1: Soil ecosystem services considered in the ESA for Italy

Regulation and maintenance	carbon storage and sequestration
	habitat quality
	pollination
	hydrological cycle regulation
	water purification
	erosion control
	microclimate regulation
	particulate and ozone removal
Provisioning	crop production
	timber production
	freshwater availability

For the development of analytical framework, results of experiences carried out by projects at different scales were considered, such as LIFE SAM4CP, SOILCONSWEB, LIFE MGN, SOS4LIFE, together with a constant comparison on

methodologies with the scientific community, as the one launched for the 2018 edition of the Report on land consumption, which involved 7 Italian universities and research centers (University of Urbino, University of Molise, University of Rome Sapienza, University of Padua, Federico II University of Naples, CNR Florence, CREA of Arezzo) and 2 regional agencies for environmental protection (Puglia and Veneto) in addition to ISPRA.

In this work we define land consumption as the replacement of a non-artificial land cover to an artificial land cover, both permanent and non-permanent. The study of each ES is based on the national land consumption map for Italy for the two reference years 2012 and 2017 with a very high resolution (10m spatial resolution). Maps are developed by ISPRA by photointerpretation of very high-resolution images and semiautomatic classification of high-resolution remote sensing images RapidEye, Sentinel-1 and Sentinel-2, and are appropriate to detect land consumption, both for the urban densification and for the sprawling phenomena, from national to local level.

Results in terms of biophysical dimension are described in following paragraph, together with some methodological element useful to understand the potential use of results in planning processes. Full methodology is available in the annex to 2018 edition of the Report on land consumption, territorial dynamics and ecosystem services (Assennato *et al.* 2018).

Results in terms of economic loss produced by soil consumption between 2012 and 2017 in Italy is calculated for each service flow, with a reference to a minimum and maximum value, in order to take account of the uncertainties. Variations in regulating and maintenance ES provision, that represent most of the losses, are shown in Table 2. It must be pointed out that this evaluation includes only a part of services provided by soil, thus the “hidden costs” (European Commission, 2013) can be much higher than those represented.

Table 2: Variation in the flow of regulating and maintenance ecosystem services due to the soil consumption between 2012 and 2017 in Italy. Source: ISPRA processing

Regulation & Maintenance Ecosystem Services	Minimum value of service loss[€/year]	Maximum value of service loss[€/year]
Carbon sequestration	102.056	538.898
Pollination	4.109.804	5.487.373
Regulation of local climate/temperature	2.251.732	9.006.928
Removal of particulate and ozone	950.980	2.938.569
Water flow regulation	1.535.630.715	1.789.521.660
Control of erosion	10.521.848	112.385.949
Water purification	226.033	60.297.780
Total	1.553.793.168	1.980.177.157

Carbon storage and sequestration

This service contributes to climate regulation at global level and plays a key role in climate change mitigation and adaptation. Intergovernmental Panel on Climate Change (IPCC) identifies five main carbon pools: living biomass, as above ground biomass (stem, stump, branches etc.) and below ground biomass (roots), dead organic matter, as dead wood (non-living biomass not contained in the litter) and litter (non-living biomass with a small diameter) and soil organic matter, which includes organic carbon in mineral and organic soils up to 30 cm. Degradated or sealed soil are not able to store carbon, which is emitted in the atmosphere.

The Carbon Storage and Sequestration model adopted provides a map that links land use/land cover codifications with the sum of the carbon values of those five natural pools. Reference values for living biomass for the forest land use categories are obtained from the biomass volumes (stock and growing) charts published by the Italian Forest Inventory (“*Inventario Nazionale delle Foreste e dei Serbatoi Forestali di Carbonio*” - INFC) and other sources related to living biomass in permanent crops (Canaveira *et al.* 2018), and calculated through coefficients derived from scientific literature (IPCC, 2006). The soil carbon pool is assessed using the new Soil Organic Carbon map produced as an Italian contribution to the Global

Soil Partnership/FAO Initiative (CREA, 2018), with resolution of 1 Km. Some values (continuous urban fabric, port areas, dumpsites and building sites) were forced to zero.

Figure 1: Variation in the flow of regulating and maintenance ecosystem services due to the soil consumption between 2012 and 2017 in Italy. Carbon storage (t/ha) Source: ISPRA processing

Pollination

Crop and wild plants productivity rely on pollination. Over the past few decades, pollinator insects have declined in Europe, both in abundance and diversity, and their decline has raised much attention because animal pollination is essential for wild plant communities. The main drivers of the decline include land-use changes which cause habitat fragmentation, pollution (due to pesticides), loss of biodiversity and increasing of alien species, pathogens and climate change (Martin *et al.* 2019). The assessment of the spatial distribution of pollination services has become a policy priority in Europe with the EU biodiversity strategy (EC, 2011). In this study 50 pollinator species were considered, and input data was determined through a bibliographic research. Output data are two indexes (0-1) which represent the pollinator potential presence and their ability to reach croplands.

Habitat quality

A primary goal of conservation is biodiversity protection, including the range of genes, species, populations, habitats, and ecosystems. The habitat quality service considers biodiversity as the base of the production of ecosystem services. It considers the provision of different essential habitats for the life of any species and the preservation of biodiversity. It represents one of the main reference values in the evaluation of the ecosystem state of soils. For the evaluation the Habitat Quality model of InVEST suite of models (Integrated Valuation of Ecosystem Services and Trade-offs, Natural Capital Project) (AA. VV. 2015) was used. This model considers the ability of the habitat to sustain animal and plant life forms; the impact of threats on different habitats; the sensitivity of each individual habitat to be influenced by different types of threats and distance of the habitats from its sources of alteration. Biophysical results are represented in form of an indicator (0-1) of habitat quality for each pixel.

Figure 2: Variation in the flow of regulating and maintenance ecosystem services due to the soil consumption between 2012 and 2017 in Italy. Habitat quality (adim). Source: ISPRA processing

Hydrological cycle management

The infiltration of water in soil is one of the main elements of the regulation of hydrological cycle, in terms of surface runoff regulation, and is directly affected by soil consumption. This study is based on an evaluation of water balance related to different scenarios of land use and land cover, in order to evaluate the consequences due to land consumption (Assennato *et al.* 2018). In the figure 3 the values from maximum to minimum variation in water infiltration between 2012 and 2018 is illustrated.

Figure 3: Variation in the flow of regulating and maintenance ecosystem services due to the soil consumption between 2012 and 2017 in Italy. Hydrological cycle management (adim). Source: ISPRA processing

The water budget components at monthly temporal scale for the whole national territory is calculated by an automatic GIS-based procedure named BIGBANG version 1.0, produced by ISPRA (Braca and Ducci, 2017), working on a 1km grid, using precipitation and temperature data mediated for the period considered (2012-2017) and information on the soil's hydraulic and geological characteristics and the different scenario on land cover and use obtained from ISPRA 20 m resolution grid map of soil consumption (ISPRA, 2018).

Erosion control

The magnitude of erosion depends on many factors, including different land use/land cover conditions. The variation of the retention capacity through the comparison between the steady state of land use/cover and soil properties and a different scenario, can be considered as an indicator of the ecosystem service change in biophysical terms. The SDR "*Sediment Delivery Ratio*" InVEST model (AA.VV.,2015) represents the avoided soil loss, expressed in tons/hectar, by the current land use compared to bare soil, weighted by the SDR factor. The figure 3 shows the geographical distribution erosion control loss in terms of sediment retention in tons/ha.

Figure 3: Variation in the flow of regulating and maintenance ecosystem services due to the soil consumption between 2012 and 2017 in Italy. Erosion control (t/ha) Source: ISPRA processing

Microclimate

The expansion of artificial areas influences the energy exchange process between the earth and the atmosphere, having significant effects on local climate in urban areas. The urban heat island phenomenon increases the need for summer cooling (Lai X. *et al.* 2018) and results in a higher energy request. Urbanization can cause a temperature increment between 1 and 3 °C. It can be estimated An average increasing of 0,6 °C of temperature in urban area every 20 ha of more urbanization, 0,9 °C in summer can be estimated, leading to an increasing of 0.04 °C produced by the increasing in urban density estimated in 0,081 ha/km²..

Water purification

Ecosystems such as forests and wetlands contribute considerably to improving the quality of water resources. Vegetation and soil can absorb and therefore remove pollutants and water nutrients and reduce their speed in order to regulate their infiltration into the soil (Elmqvist *et al.* 2010). Water infiltrated in soil undergoes a process of "purification" through biochemical processes carried out from the mineral part of the soil, and even more from its biological components. The purifying capacity is function of soil properties (cationic exchange capacity, organic matter, the reaction (pH) and its depth) and is linked to climate, management practices, and inputs of nutrient and pollutant load in water. This service is evaluated using purification capacity information (selected layers from JRC map of soil properties for Italy) as indicator (0-1) of service provided by soil.

Particulate and ozone removal

Currently, exposure to air pollutants is the main environmental risk factor in Europe (EEA, 2014), thus the improvement of air quality has an important role among the ecosystem regulatory services (Manes *et al.* 2012). In this context, the highest number of deaths is estimated for Italy premature from atmospheric pollutants (8,440; EEA, 2015). The estimation is carried out using the pollutant removal level for each ecosystem following classification for Italian territory (Blasi *et al.* 2016; Capotorti *et al.* 2015). Pollutant removal estimation is obtained from a 10 Italian metropolitan areas research (Manes *et al.* 2016) which evaluate concentrations of PM₁₀ and O₃ through the AMS-MINNI model on air quality (Mircea *et al.* 2014).

An overview of potentials and limits of the ESA from experiences at local level

Loss of agriculture and natural soil due to land consumption is driven the most by decisions upon land use and cover at local scale. Thus, spatial planning is the arena to effectively foster soil ecosystem services provision. The practical application at the local scale of ESA in planning is still fragmented and only few cases provide an operative application in planning tool. The existing experience of ESA in Italy was analysed based on a comparative analysis of local scale application of ESA within projects LIFE SAM4CP, SOILCONSWEB, LIFE MGN, SOS4LIFE and the most recent SOIL4Life, together with other experiences analysed within the development of the national analytical framework. This comparison points out potentials and limits of the ESA and offering a contribution towards an effective application of this innovative and powerful evaluation methodology. Considerations come from experience of planning in different contexts (Municipalities of Bruino, Chieri, None Settimo Torinese from LIFE SAM4CP, San Lazzaro di Savena and Forli from SOS4life, Rome from SAM4CP and SOIL4life, Romano di Lombardia).

For the purpose of limiting land consumption, local land use planning is the final tool to address. The difficulty comes from the need to consider the actual biophysical land cover instead of the land use destinations. A second difficulty is how to address excessive and unrealized forecasts of land consumption or unworkable compensation. In some of the experiences analysed the evaluation of ES was referred to land use destinations. In this condition the actual reduction of ES produced by land consumption is masked by reduction of transformations for the future, as compared to the present prevision of plan, or balanced by only potential improvements of the environmental conditions, obtaining a virtual, not effective balance in ecosystem services provision.

The scale of application is also a matter. In the available experiences different ESA methodologies were used on different "evaluation objects", from the national level to the scale of the single transformation intervention (a few dozen square meters). The great flexibility of the instrument allows a multiscale application, but it should be verified at different levels for appropriate inputs and proper use of results. It must be emphasized that the ESA at local level loses much of its effectiveness if it does not find an adequate regional reference, in terms of availability of data and references for the selection of ESs. At the scale of single transformation ESA should be limited to a qualitative assessment linked to the eventual quantification on a higher scale, because of the little significance to draw conclusions on biophysical balances carried out on an excessively reduced scale. This is particularly valid for some services, i.e. the Habitat Quality Service or Pollination, for which the minimum dimensions must be comparable to the biophysical "distances" considered in the analysis. More in general regulatory services, such as hydrological cycle management, sediment retention and filtration of contaminants, must be referred to hydrological basin or sub-basin scale.

Experiences of ESA in Strategic environmental assessment (SEA) procedures are still very limited. High complex application as ESA rarely is practicable in local planning, without methodological reference and data at higher scale. From experience analysed emerged that ESA clashes with the Italian practice of proceeding with non-general variants of the urban planning instruments, which in most cases limit the environmental assessment to the variant areas only, making not effective with the evaluation of effects i.e. on ecological networks or the protection from hydrogeological risk. Moreover, partial revision lead in most cases to the absence of an effective participation in SEA, not foreseen by the norm for small transformations. As evidenced by the case of Romano di Lombardia, in which the participation was cared of particularly, ESA results was of great interest for the citizen, who were able to use scientific results to build their positions on transformation priorities.

It must be said that, as in many public-decision contests, there is still an under-representation of soil natural values, functions and ecosystem services. Among the institutional actors obligatorily foreseen by the planning conference, with the exception of environmental agencies and some "lucky" regional cases, these issues are not well represented. The development of planning support tools will help to tackle this problem, providing sets of indicators (as the one produced by ISPRA) or tools for the direct evaluation on selected areas, such as the one developed by the LIFE project SAM4CP (Simulsoil & Playsoil). A guideline for the evaluation of the soil component in the SEA process, to be more inclusive of the quality of the soils and the ecosystem services offered by them, is currently under study by SNPA (National environmental protection agencies network)..

Some methodological barriers emerged from the experience. Majority of biophysical methods are quite complex and there is a need for information and support to professionals and local administrations for their correct use. The given flexibility of open tools with direct access to data and the possibility of using local values, represents a further vulnerability of the results, which the user is not always able to evaluate. There are some criticalities also on the analytical side. The multi-criteria analysis with the identification of synthetic “multi-service” indexes must be further discussed. It represents an opportunity, in terms of communicative strength, however it represents a risk of inconsistency of the results as well as of loss of information on individual services. As emerged from some of the cases analysed, the multiservice index mask trade-offs and negative effects on “critical services” with benefits on other less strategic services (such as in some cases the services from agricultural land in comparison with those from urban green). Furthermore, the use of normalization parameters makes this type of representations not comparable (in space and time) and not useful for scenario analysis.

Another criticality comes from the identification of usage thresholds for ecosystem, that is a very sensitive topic under debate. In some of the analysed cases, thresholds applied to multi service index have been used to exclude a part of the project/plan from the evaluation and, consequently, excluding mitigation and compensation too. In those cases, the mechanism lead to an underestimation the effects whose extent cannot be known. It is therefore essential to identify the different services and related biophysical indicators coherently, to be analysed and compared separately to verify the consistency of the conclusions. The selection of which SEs to consider and how to treat the tradeoffs between the different services should not be left to the individual local experience but should always complement the local participatory choice with an adequate indication from a higher level. It is always better to consider all the possible SEs initially, only after the analysis, if possible, exclude those that are not pertinent (Cortinovis and Geneletti, 2017). In this choice, a major attention must be paid to “urban ecosystem services”, because the proposed application of new technological solutions (eg vertical woods or green roofs or drainage systems) must be verifies in terms of its ecological effectiveness.

Money or not money? The economic evaluation is one of the most critical issues in ESA. The introduction of economic terms risks to open to a possible exchange market of non-renewable natural resources (Pileri et al 2018 in ISPRA 2018). With a view to strong sustainability, we must consider ESA as a tool to make the intrinsic value of the resources that benefit human beings even more evident, tangible and clear, considering the economic parameters only as indicators for scenario comparison, not for exchanges. There are several technical questions in economic ESA, related to market vs social costs, to the evaluation of actual or potential flow, or stocks of resources, and to the evaluation of offer and demand of services. The evaluation of actual services is not always useful for the planning purpose, potential services would be more appropriate to compare different scenarios. For the purpose of planning, the choice of economic value to be consider is critical. The evaluation via a direct expression of the local population, is not always able to adequately represent the need for protection of collective or global interest on natural resources. The effort of translation into money is critical for its natural outcome of translation in economic compensation. Compensation means the restitution elsewhere of the destroyed environmental values without therefore resulting in a modification of the impacts of the transformative project. It has long been perceived as the canonical “way out” of environmental negotiation, however in practice it turned into the main element of the negotiation. In this condition, the use of economic value from ESA can be a complete misusing of results. The value of the actual service flow is not representative of the entire value of the resource and should not be used as a measure of a compensation. For a correct determination, it would be necessary to evaluate the amount of stock of consumed resources, but this is far from present evaluations capabilities.

The need for a common framework for application.

This first comparison allows to observe that ESA is an effective reading tool, able to integrate the different topics involved in territorial transformation analysis and, more, it is scalable at the different levels. It is also able to represent and summarize the values of soil and naturalness, and the costs associated with their loss, in a language suitable for discussion within planning processes and for the public. However, it remains a still “young” tool, whose applications can vary a lot in terms of methodology, scale and subject of investigation, and in terms of final use.

The complexity of this tool is thus related to the methodological, procedural, regulatory and political side. In the absence of a more solid methodological and procedural reference to be used in the decision-making process, its application is potentially subject to improper uses or misleading of results.

Having as a target the zero net consumption of land, it must be underlined that the sole inclusion of ESA, even in the presence of a common methodological reference, cannot be enough to protect Italian soil from further aggression without an upstream, quantifiable and not circumvented, limitation of consumption.

Spatial Planning in view of new challenges: Land take and some evidence from Greece

Elisavet Thoidou¹, Dimitris Foutakis²

Abstract: The growing interest in natural resources and ecosystem services has led to increasing attention to land as a natural resource. Land degradation has been included among the key environmental degradation problems all over the planet and land take is a key causal factor. Sustainable land management is required in order that land degradation be controlled. The role of spatial planning in sustainable land management has been accentuated, due to its close relationship with land use change and rapid urbanization. From the viewpoint of sustainable development, a turning point for land gaining significant importance on a global scale has been the Rio+20 Summit, 2012, in which the aim for a “land-degradation neutral world” was expressed, leading to efforts towards the minimization of land degradation. In the context of the EU environmental policy, land take and soil protection have been highlighted from the viewpoint of ecosystem services and the strategies for conservation of biodiversity. The case of Greece is interesting in this regard, since spatial planning is influenced by the EU context while at the same time patterns of territorial organization in the country are characterized by increasing land take. Based on the above, this paper examines the way land take becomes apparent as an environmental concern as well as a spatial planning task. It also focuses on the case of Greece and examines how spatial planning is capable of addressing relevant challenges and utilizing the EU policies' framework. It endeavours to highlight challenges emerging not only to addressing land-related issues but also to transforming the approach of spatial planning towards land resilience.

Keywords land degradation, land take, Greek spatial planning, ecosystem services

Introduction

Spatial planning is closely related to land management, since it is on a territorial basis that it endeavours to organize human activities, with land use plans being the most important planning instruments at the local level. Spatial planning addresses land-related issues in a normative way through land use regulation, or in a strategic way through the setting of policy objectives for territorial development. The relationship between spatial planning and the environment influences the content of spatial planning and, in particular, the way it addresses land-related issues. This relationship has led to increasing environmental concerns in the context of spatial planning including the recognition of land as a natural resource. Since the 1990s, the sustainable development agenda has posed significant challenges for spatial planning. Among these, land-related issues have a key role in promoting

environmental protection and socio-economic development. This is, for instance, the case with policy objectives set by the European Spatial Development Perspective document (EC, 1999) for the protection of environmentally sensitive areas as well as for soil protection. The sustainability agenda has highlighted various land-related challenges faced by spatial planning, as for example the problem of urban sprawl that led to the adoption of alternative policy options such as the compact city model as well as land recycling practices that seek to reduce land take. Recently, the importance of land in relation to spatial planning has been emphasized in the risk management framework, in particular in the context of climate-related risks, as for instance is the case with the risk of flooding that led to the adoption of measures aimed at reducing soil sealing such as green infrastructure.'

The growing interest in land as a natural resource in the context of the ecosystem services approach highlights the relationship between land and spatial planning and even more so the potentialities of spatial planning for tackling land degradation. The aim for a "land-degradation neutral world" was expressed in the UN Rio+20 Summit in 2012, involving two key policy directions: sustainable management of land in order that degradation be slowed down, and increasing the restoration rate of degraded land so that the two trends can converge for the minimization of land degradation (Barbut and Alexander, 2016). "Life on land" constitutes one out of 17 Sustainable Development Goals (SDGs) of the "Sustainable Development Agenda 2030" adopted by UN member states in 2015. This is the SDG 15 "Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss" (UNDESA, 2019).

Awareness of land degradation is becoming evident at the European level, with land occupying a significant position in environmental issues addressed by the EU environmental policy. Since the mid-2000s, land and soil have been addressed not only by the EU statistical and monitoring systems but also by EU policy agendas, above all the sustainable development strategy, which provides useful tools for addressing land take. The EU has adopted the objective of promoting a "land degradation neutral world" in the context of sustainable development decided upon in the RIO+ Summit (Official Journal of the European Communities, 2013). The 7th Environment Action Programme places emphasis on natural capital and highlights the importance of land as a resource. It stresses that "the degradation, fragmentation and unsustainable use of land in the Union is jeopardising the provision of several key ecosystem services". Among others, it recommends that "Environmental considerations including water protection and biodiversity conservation should be integrated into planning decisions relating to land use, so that they are made more sustainable, with a view to making progress towards the objective of 'no net land take', by 2050" (Official Journal of the European Communities, 2013, p. 180). This is important especially for countries like Greece, in which land-related issues have started to be recognized.

In seeking to explore contemporary challenges spatial planning is faced with, this paper focuses on those which are land-related, and land take in particular. The second part following this introduction examines the issue of land take and briefly presents the relevant EU framework. In the third part, the paper refers to the case of Greece and seeks to identify options for addressing land take that derive from the EU policy context. Concluding remarks highlight the significance of land take as a parameter of land degradation as well as the relevant role of spatial planning.

Land degradation, land take and spatial planning

Land degradation has become one of the most worrying issues regarding the environment (Oliveira, Tobias and Hersperger, 2018). It is considered “one of the major forms of environmental degradation all over the world” having an adverse impact on ecosystems’ capacities to provide goods and services (Smiraglia *et al.*, 2014). Land degradation has negative impacts on human and ecological systems (Stavi and Lal, 2014). Various causes such as climate variability, soil quality, and land management are involved in the complex process of land degradation (Smiraglia *et al.*, 2014). This process includes “soil degradation and the capacity of land areas to support water resources, biodiversity and primary productivity” (EUROSTAT, 2018). The fact that land is a finite resource (Sonderegger *et al.*, 2017, p. 9) combined with the fact that fertile soils are not a renewable natural resource triggers this process. Land degradation, which usually appears in the form of land take, land fragmentation, and soil sealing, severely affects ecosystems and threatens ecosystem services (BIO by Deloitte, 2014). Land use and land cover changes are key drivers of land degradation. In this respect, the role of urbanization seems to be crucial, despite the fact that urban areas occupy a relatively low percentage of the earth’s surface, as it “affects land change elsewhere through the transformation of urban-rural linkages” (Lambin *et al.*, 2001, p. 265).

Land take describes both the process and the result of land use and land cover change, which is largely caused by the processes of urbanization. According to the European Environment Agency (EEA, 2019) land take “looks at the change in the amount of agricultural, forest and other semi-natural and natural land taken by urban and other artificial land development. It includes areas sealed by construction and urban infrastructure, as well as urban green areas, and sport and leisure facilities”.

Following Boschetti (2016, pp. 51-55), land-related challenges faced by land management and spatial planning go beyond mere land management rules, regulations and techniques, and concern not only land take that is linked to the urbanization process but all land transformations, including also “undeveloped lands (agricultural, green, open lands)”. For instance, as Rojo *et al.* (2014) note, despite the potentialities of peri-urban agrarian ecosystems in relation to ecosystem services, they have been rather neglected by spatial planning.

As regards the policies capable of addressing land degradation, it can be argued that the various sectoral policies that address land-related issues such as those for agriculture, forests, and transportation lack a holistic approach. Therefore, sustainable land management is needed so as to address land degradation in an integrated manner (Barbut and Alexander, 2016). Efforts to achieve land protection and restoration should focus on addressing land use and land cover change, which mainly concerns spatial planning (Oliveira, Tobias and Hersperger, 2018).

Despite the fact that such an approach has not been widely implemented or is yet at an initial stage, it is being promoted by various policy contexts. For EU member states in particular, several EU policy frameworks, strategic guidelines and statistical and monitoring systems promote actions and measures towards combating land degradation. Since 2006, the “Thematic Strategy for Soil Protection” (CEC, 2006) has stressed land-related issues and acknowledged the fact that “there is little public awareness of the importance of soil protection”. In 2011, the “Roadmap to a Resource Efficient Europe” (EC, 2011) which is orientated towards a green economy in the context of the “Europe 2020” strategy, noted that “more than 1,000 km² are subject to 'land take' every year for housing, industry, roads or

recreational purposes. About half of this surface is actually 'sealed'." Land and soil constitute one out of seven issues addressed in the chapter "Natural Capital and Ecosystem Services" of this Roadmap and are included in the vision set for 2050 which among others provides that "All resources are sustainably managed, from raw materials to energy, water, air, land and soil." One out of the eighteen milestones adopted by this Roadmap refers to land and soil: "By 2020, EU policies take into account their direct and indirect impact on land use in the EU and globally, and the rate of land take is on track with an aim to achieve no net land take by 2050; soil erosion is reduced and the soil organic matter increased, with remedial work on contaminated sites well underway" (EC, 2011).

Table 1. Interlinks between sectors and resources (Land and Soil), and EU policy Initiatives

SECTOR / POLICY	LAND	SOILS
Energy	Reduce land take for biofuels	Prevent soil damage by SO ₂ and NO _x emissions
	Optimize energy infrastructure	Mitigate soil impacts of new infrastructure / Energy solutions
		Preserve peatlands
Food	Optimize land use to reconcile with other uses	Reverse soil loss
	Use taken fertile land for agriculture	Restore organic matter content in soils
	Reduce land take (e.g. via optimal animal protein intake)	Prevent soil damage by SO ₂ and NO _x emissions
		Avoid pollution from fertilizers and pesticides
Buildings	Avoid additional land take (e.g. for urban sprawl)	Avoid urban sprawl on fertile soil
	Remediate contaminated sites	Minimize soil sealing
Mobility	Minimize impacts of transport infrastructure on land fragmentation	Minimize impacts of transport infrastructure on land sealing
EU policy initiatives	Communication on land use (2014)	Guidelines on best practice to limit, mitigate or compensate soil sealing
	Communication on LULUCF in the EU climate change commitments (2011) ¹	

Direct relationship with spatial planning

Source: EC, 2011 (Annex: Resource efficiency – the interlinks between sectors and resources, and EU policy initiatives, p. 24) (own elaboration)

¹ An EU Regulation on the integration of land use, land use change and forestry (LULUCF) into the EU's 2030 climate and energy framework was adopted on May 2018. (See: Official Journal of the European Union, 2018).

Promoting strategic objectives and meeting commitments to land and soil protection is not always an easy task. Constraints derive from already established practices that implement EU policies, such as those for grey infrastructure. At the same time, synergies can be found between sectoral policies and land protection as seen in Table 1 above.

Several Community policies such as those on agriculture, regional development, transport and research address issues related to soil (CEC, 2006). In practice, soil protection is promoted by EU funding instruments such as those of cohesion policy. A case in point is the investment priority “Protecting and restoring biodiversity and soil and promoting ecosystem services, including through Natura 2000, and green infrastructure” which is promoted by the European Regional Development Fund within the thematic objective “(6) Preserving and protecting the environment and promoting resource efficiency” (EC, 2015).

Land as a natural resource is being addressed in the framework of the environmental policy of the EU. Despite the fact that a Europe-wide spatial planning policy does not exist, the EU framework significantly influences spatial planning of member states in terms of planning regulations and guidelines, which is above all the case with the 2001 Directive on Strategic Environmental Assessment (SEA). As Treville (2011, p. 6) argues, SEA “has the potential to be an effective tool for preserving land consumption”. Moreover, land-related issues are addressed through the development of scientific tools and research including the monitoring, mapping and developing of statistics as well as through conceptual elaboration and empirical investigation (see, for example, EUROSTAT, 2018, JRC, 2015). This is the case with the indicators for monitoring the UN SDGs and, in particular, the SDG 15 “Life on land” that is based on three sub-themes: “ecosystem status”, “land degradation”, and “biodiversity”. This is also the case regarding the CORINE Land Cover inventory for the monitoring of land cover all over Europe. Parallel frameworks such as the 2007 INSPIRE Directive on access and interoperability of spatial data, the 2007 Directive on the assessment and management of flood risks, and the 2011 Strategy for Biodiversity promote land-related issues. Thus, it can be assumed several tools for addressing land take can be utilized, as in the case of Greece that is presented below.

Land take and spatial planning in Greece

Land cover by artificial surfaces in Greece was 3.4% of total land surface in 2015 and 2.9% in 2009, which corresponds to an increase of 17.3% (4.4 and 4.1 for EU aggregate, respectively), while the capital region of Attiki shows the greater percentage of land cover by artificial surfaces (20.5 and 20.6 respectively for the same years) (Thoidou, 2017a, EUROSTAT, 2017). Among the various land cover categories, agricultural land has been mostly affected by land take in the period 2006-2012. The same is true for the EU28 average as well as for the average of the 39 countries for which the European Environment Agency provides land cover data (EEA39). However, the pattern of the relative contribution of land cover categories for uptake by urban and other artificial land development in Greece is quite different, as seen in Table 2 below.

As regards the contribution of the various types of human activities to the total annual land take in the country, the highest figure is for construction at 37.3% of the total, above the EU28 and the EEA39 averages. Land take by transport and infrastructures is also above the EU28 and the EEA39 averages, while land take by housing, services and recreation, as well as land take by industrial and commercial

sites are below the EU28 and the EEA39 averages. Land take by mines, quarries and dump sites is similar to the two averages, as seen in Table 3 below.

Table 2. Relative contribution of land-cover categories to uptake by urban and other artificial land development % (land take/year 2006 – 2012)

Land-cover category / Country	Arable Land & Permanent Crops	Pastures & Mixed agricultural areas	Forests and transitional woodland	Natural grassland, heathland, sclerophyllous vegetation	Open space with little or no vegetation	Wetlands	Water bodies	Total land take
Greece	33.5	30.8	7.3	27.3	0.3	0.0	0.7	100.0
EU 28	51.9	25.9	14.4	6.0	0.3	0.6	0.9	100.0
EEA39	46.2	26.7	16.3	7.2	2.1	0.6	0.9	100.0

Source: EEA 2017b (own elaboration)

Table 3. Annual land take by several types of human activity % (land take/year 2006-2012)

Types of human activity / Country	Land uptake by housing, services and recreation	Land uptake by industrial and commercial sites	Land uptake by transport and infrastructures	Land uptake by mines, quarries and dump sites	Land uptake by construction	Total
Greece	11.6	17.9	11.2	21.9	37.3	100.0
EU28	32.5	19.1	6.8	24.0	17.6	100.0
EEA39	18.7	22.1	6.4	21.0	31.9	100.0

Source EEA 2017a (own elaboration)

It seems that land take in Greece is caused by various activities that fall within the competence of different policies. It is essential to mention that soil is protected under environmental law as well as in the context of various sectoral policies albeit not without difficulties (Charalabidou, 2017). In their report on the best practices for limiting soil sealing or mitigating its effects, Prokop *et al.* (2011) noticed that detailed information about measures aiming to reduce land take and soil sealing was not available for Greece.

As already stressed, the role of spatial planning is crucial for addressing both, the causes and impacts of land take. Widespread unauthorized land development has led to the urbanization of large areas without prior planning as well as to the continuous expansion of out-of-plan areas dealt with by ad hoc legislation (EC, 2000, pp. 21-22, Thoidou, 2017a).

On a strategic level, in 2017 the Greek Government endorsed eight national priorities to promote the incorporation of the 2030 Agenda and into the national framework. As referred to in the “Voluntary National Review on the Implementation of the 2030 Agenda for Sustainable Development” (General Secretariat of the Government, 2014), the main national priority linked to the so-called environmental SDGs (11 “Sustainable cities and communities” and 15 “Life on land”) is “the protection and sustainable management of natural capital as a base for social prosperity and transition to a low-carbon economy.” In relation to SDG 11, and more particularly in the context of the provision made for “Inclusive, safe, resilient and sustainable cities”, urbanization is considered a driving force for land use change. In the same context, the following sustainability challenges are stressed: “the extension of urban activities beyond designated urban zones, the building and housing construction in certain cases without prior adequate planning and building permits especially in coastal areas as well as the need to increase communal and green spaces in city centres.” Among the priorities and measures selected, the following can be mentioned with regard to spatial planning: the already established “spatial planning framework system [...] setting the strategic guidelines for compact cities”, the combat of “unauthorized construction and uncontrolled urban sprawl”, and the “completion of the National Cadastre to cover the whole land territory of the country by 2020” (General Secretariat of the Government, 2014, pp. 62-63).

Quite recently, concerns regarding land-related issues have been expressed by the strategic plans at the metropolitan level. Worth noting is the emphasis placed by the new Strategic Spatial Plan for the metropolitan area of Athens–Attiki on the conservation of biodiversity, the protection of fertile agricultural land, combating urban sprawl and promoting the compact city model (Greek Government Gazette, 2014a). The contribution of this strategic plan is crucial not only for setting the overall context at the metropolitan level, but also for enforcing the implementation of new directions and measures by means of the detailed land use plans, which is not always easy to achieve through specialized instruments.

The European framework has seriously influenced the content and rationale of spatial planning in Greece, above all through the principles of sustainable development, which have been incorporated into the legislation and rhetoric of urban and regional planning. Moreover, the EU cohesion policy mainstreams environmental objectives into projects and programmes financed by Structural Funds (see among others Thoidou, 2017b). The implementation of the INSPIRE Directive has supported the prominence given to land-related concerns.

As Ludlow *et al.* (2013) note for the case of Greece, spatial data and methods have been taken into account by spatial plans in recent years while the utilization of digital platforms such as the one for electronic urban planning is expected to support the planning process. They argue that, despite the pressures to prioritize economic criteria due to the economic crisis, the pursuit of sustainable development remained important for spatial planning in Greece. The new “Special Inspectorate for Building and Energy” is considered a good practice since among others “it uses satellite photos of different periods to identify urban sprawl and land take, and penalizes illegal acts.” Soil quality and appropriateness of ground conditions are examined by the geological studies carried out in the context of land use plans (Ludlow *et al.*, 2013).

Evidence regarding the role of spatial planning in various environmental issues can be drawn from specific frameworks such as the National Strategy for Biodiversity (Greek Government Gazette, 2014b), as well as the report on the State of the Environment (EC, 2017).

In the document on the National Strategy for biodiversity, the growing urbanization and housing development, the development of industrial and tourist uses as well as land use change that affects natural systems, are all evaluated against the pressures placed on the species of flora and fauna of Greece. In this context it is concluded that urban sprawl and housing development together with uncontrolled urbanization which is triggered by the still allowed out-of-plan building and the accompanying infrastructural projects cause intense artificialization of land. Among others, from the viewpoint of spatial planning, delays and shortcomings in the revision of the spatial planning legislative context are considered to be among the key drivers of the loss of biodiversity, not to mention the non-application of existing legislative rules. This is, for instance, the case of the above-mentioned widespread unplanned land development. Consequently, several of the general targets set by the National Strategy for Biodiversity in Greece identify among others specific targets, which are directly related to spatial planning, as seen in Table 4 below.

Table 4. National Biodiversity Strategy in Greece: General and specific targets related to spatial planning

General Targets (selection)	Specific Targets (selection)
2. Conservation of national natural capital and ecosystem restoration	2.2 Restoration of important species and habitat types
3. Organization and operation of a National System of Protected Areas Protected Areas and enhancement of benefits from their management	3.3 Design, and possible integration, of ecological corridors of special designation status and their effective management
5. Enhancing the synergies among the main sectoral policies for the conservation of biodiversity	5.1 Effective integration of biodiversity conservation at all levels of spatial planning
6. Conservation of landscape diversity	6.1 Completion of integration of conservation landscape diversity policy into all sectoral policies. 6.2 Maintaining landscape diversity both inside and outside of protected areas. 6.3 Conservation of unique landscapes.
13. Appreciation of ecosystem services and the promotion of the value of Greek biodiversity	13.3 Promotion, establishment and maintenance of natural green infrastructure

Source: Ministry of Environment, Energy & Climate Change, 2014 (Table D1: Summary table of the general and specific targets of the National Biodiversity Strategy, pp. 92-97) (own elaboration)

Worth noting is that this strategy recommends the update and implementation of the National Action Plan against Desertification which was drafted in 2001 in the context of the relevant UN Convention. In the same direction, the report on the State of the Environment in Greece refers to shortcomings in sustainable land management as well as its coordination with sectoral policies. The

causes for biodiversity loss, it is noted, can be found in the way various policies such as those for agriculture, fisheries, forests, and tourism are applied, as well as in the prevailing consumption patterns (EC, 2017). In terms of funding, the above-mentioned investment priority on protecting and restoring biodiversity and soil is promoted by the Operational Programme on the Environment in the context of the EU cohesion policy 2014-2020 for Greece. However, it mostly addresses issues that concern protected areas, without making reference to spatial planning.

Concluding remarks

The increasing interest in land as a natural resource has accentuated the importance of land take as a process that causes land degradation and as a policy target that seeks to control this problem. This interest has also accentuated the role of spatial planning and has raised new challenges which highlight not only the need for detailed planning tools in the context of regulatory land use planning, but also for a renewed way of thinking in spatial planning that is a matter of both regulatory and strategic spatial planning.

It seems that the role of spatial planning in the conservation of biodiversity and more particularly in land and soil protection has started to be recognized in Greece, especially within the context of the implementation of EU policies. Even though the various strategies and reports do not proceed with detailed recommendations about new planning objectives, methods and practices, concerns for land degradation have started to appear in relevant rhetoric and practice. This might be a challenge and a driver for transformation of the rational of spatial planning itself towards a land-resilient approach

Spatial tensions:
urban microgeographies
for changing cities

*Motionless Movement: The Brazilian urban crisis
from the creation of the Ministry of Cities to the great
protests of 2013*

Roberto Andrés¹

¹Urbanist, professor at Universidade Federal de Minas Gerais, editor of *Piseagrama* magazine and PHD student at Universidade de São Paulo. robertoandres@gmail.com

Abstract: This article aims to investigate the period between the creation of the Ministry of Cities in 2003 and the great protests of June 2013 in Brazil. It looks for the connections between the greatest set of riots in the recent history of the country and the accentuation of the urban crisis, with special focus on the role (potential and real) of public policies in the transformation of cities. My main hypotheses are that, despite the economic growth and poverty reduction that took place in the period, some of the historical urban problems were accentuated; that the urban reform agenda built for years by popular movements, culminating in the creation of the Ministry of Cities, could, if implemented, have dealt with the structural problems of Brazilian cities; and that this mismatch between project and achievement contributed in a relevant way to bubble up the cauldron that exploded in June 2013.

Keywords: Brazilian cities; urban mobility; housing; urban policies.

Introduction

For thunder to form, we need clouds in the sky. In addition to water droplets, storm clouds carry inside them ice crystals, which bump into each other as the air turbulently moves around. The movement and the friction create an electrical field that turns the cloud into a large battery. The high voltage ionizes the air in the surroundings and forms the path of plasma that carries the electric discharge to the ground. None of this is possible if the sky is blue.

When the big rallies of June 2013 broke out in Brazil, a lot of people saw lightning in blue skies. Using the parameters offered by hegemonic social meteorology, they would ask: if the economy was doing just fine, if there was full employment, if poverty had been reduced considerably in the previous decade, if the political class was reasonably well evaluated in polls, if our international image took off – then why suddenly millions of people in fury paralyzed hundreds of cities in just a few days?

Still in the midst of the thunderstorm, literary and social critic Roberto Schwarcz (2013) summed up this mismatch: “In two weeks, the country that was believed to be working, that had knocked out inflation, included the excluded, put an end to extreme poverty, and become an international example was replaced by another country, a very worse one, in which public transport, education and health are a disaster and in which the political class is a shame, not to mention corruption. Which of the two versions is correct?”

Some would say that the sky hadn't been that blue. People that were part of the social movements that helped organize the protests as well as independent analysts on the left came to demonstrate that Brazilian

society was quite mobilized; that the number of strikes had reached record highs in 2012; that many protests against high bus fares had taken place and been successful in previous years; that the social inclusion of the previous decade had disregarded key aspects such as urban displacement, pollution, quality of life, public spaces; that it was increasingly evident that World Cup spending would not contribute to healing the social and urban woes of the country.

In short, according to such analysts there was already plenty of raining and thundering here and there, and only those insulated in bureaucratic offices would not see it. One month after the marches, a collection of articles published in the book *Rebel Cities* (Maricato *et al.* 2013) sought to demonstrate what were the elements which, in their interaction, transformed the streets of Brazilian cities into explosive batteries: deteriorating urban life, exorbitant fares and precarious urban transport services, the resilience of poor public health and education, the eviction of thousands of people from their homes, rent inflation etc.

Also in the heat of June, philosopher Marcos Nobre (2013a) published his *Shock of Democracy: reasons for the upheaval*, in which he demonstrates how the mass rallies marked the end of a political pact which, for good or for worse, had organized Brazilian society during the New Republic, the democratic period that began with the end of the military dictatorship in the late 1980s. For the author, “the protests show that the functioning of the [political] system is in disarray with the streets. Society attained a degree of pluralism of positions and political trends that is not reflected in the shapeless mass of political parties.” Another philosopher, Paulo Arantes (2013), recalled the centrality of public transport fares for contemporary life in Brazil, stating that “through the tenuous thread of the fare the entire system is challenged – from the displacement of the labour force towards places of exploitation to the violence of the segregated city that marches towards ecological collapse”.

These and other analyses offered relevant interpretations of the social crisis that the country was experiencing, and some of them will be taken up later in this article, but it is possible to say that nobody had predicted protests of such magnitude. As stated by Marcelo Freixo (2013), a left-wing politician who had counted on a great social mobilization around his candidacy for the municipality of Rio de Janeiro in the previous year, “not even the most optimistic militants could have expected to see so many people in the streets and such desire for change in the air”. As the sociologist Leo Lynce (2013) put it, “we were all, without exception, taken by surprise, including those who called the protests”.

It was evident that Brazilian society had become organized on many fronts, and movements such as Movimento Passe Livre (MPL) and the Popular Committees against the World Cup Impacts (COPACs) pointed to an increase in protests, but still it remains difficult to explain how some scattered clouds suddenly became one of the biggest storms the country had ever experienced. Most experts classified the protests as “spontaneous” in news coverage, opinion articles, academic essays, books and documentaries. But as British sociologist Colin Barker (2014) puts it, when analysts use the term “spontaneous” to define a social manifestation, what they usually mean is that they do not quite know what is happening.

This article seeks to address the relationship between the intensification of the Brazilian urban crisis during the country’s period of greatest economic prosperity and the protests of June 2013, which ended up closing such period. It also seeks to propose the hypothesis that the hegemonic tools used to measure social life, which emphatically concentrate on the economy, account to an analytical myopia that suppresses concrete and urgent problems linked to urban issues such as mobility, public services, housing and the quality of public spaces – in short, the whole agenda of what is commonly called “right to the city” – which, sooner or later, have to emerge in some way.

Economy x Urbanity

In a recent article, former Minister of Education (in charge from 2005 to 2012), former mayor of São Paulo (in charge from 2013 to 2016) and the Workers' Party presidential candidate in the elections of 2018, Fernando Haddad (2017), asked the following question: “How to explain the explosion of discontent that took place in June 2013, expressed in the largest wave of protests since the democratic transition? Unemployment was still low; inflation, although under pressure, was at a bearable level and still below wage increases; public services continued to expand, and so did the rights provided for in the Constitution”.

The questions posed by Haddad four years after the demonstrations still point to thunderstorms in blue skies – or at least in skies with very few clouds. The country was undergoing a transition, ending a cycle of economic growth with poverty reduction to enter, from the middle of 2014 onwards, one of the biggest economic recessions in its history.

There are several ways of narrating this transition, and they depend on to the point from which to stand in the political spectrum. For political scientist André Singer (2018), for instance, Dilma Rousseff's first government (from 2011 to 2014) made progressive economic choices that confronted the marked rentism of Brazilian society. Such choices aimed at favouring the productive matrix. Rousseff was, however, betrayed by the industrial bourgeoisie, became unable to sustain the main pillar (low interest rates) of her plan and saw her “new economic matrix” die before reaping its fruits. According to economist Monica de Bolle (2016), inversely, the Federal Government made a series of maladaptive actions. It sought to reduce interest rates and devalue the exchange in a biased manner, increasingly using public resources to (i) induce private investments, through tax exemption (ii) control inflation, by holding back public utility charges. Not only did the plan fail, it also caused great fiscal deterioration.

A more nuanced version of the story is told by economist Laura Carvalho (2018), who uses the image of a waltz in order to analyse the Brazilian economy in the 21st century: one step to the front, one step to the side, one step back. The step forward would have been given in the second term of Lula's government (from 2007 to 2010), when the country took advantage of the favourable international context of high commodity prices to increase public investment and credit, boosting the economy and generating what Carvalho called “milagrinho brasileiro”, “Brazil's little miracle” – a reference to the so-called “Brazilian Miracle” of the military dictatorship, when the country's GDP grew on average 10% per year between 1968 and 1973 .

In the 2007-2010 “milagrinho”, the GDP grew at an average annual rate of 4.5%, inflation at 4.7%, public investment at 27.1%, and total investment at 9.1% (CARVALHO, 2018). For Carvalho, what made this virtuous path collapse was mainly the change in the nature of public spending: while during Lula's second term public investments preponderated, Rousseff's administration reduced investments to the extent that it amplified tax exemptions for businesses. The leading role was shifted towards private investment, which however narrowed – not because entrepreneurs staged a boycott, as proposed by Singer (2018), but because of a lack of demand and stock accumulation in companies. Without the previous inductive investments and with indebted households, the economy stagnated: one step to the side. The step back, in the author's view, would have been given with the fiscal adjustment that came in 2015, which in fact was unable to save the country from one of its largest economic recessions.

In spite of the differences in perspective between the authors mentioned, there is something in common between them: the idea that things were going well and then got distorted by a change of course. In any case, Haddad is right when he argues that in 2013 the country still had full employment and inflation was at a “bearable level” and below wage adjustments. GDP grew on average 2.3% between 2011 and 2014, and annual inflation was at 6.2% (CARVALHO, 2018). Such economic indicators would not fare badly in most places, let alone for a period that followed the 2008 economic crisis and a major economic downturn in countries such as Italy, Spain and Greece.

The question remains: if the economic indicators were still satisfactory and yet the country witnessed one of its largest strings of protests, are we not looking for the wrong indicators? What would happen if we were to add to the analytical history of the period indicators that rarely appear in public debate, but which tell a lot about the life of a predominantly urban society, such as time spent in traffic; the cost of public transport fares; health problems caused by air pollution; deaths and health problems generated by traffic accidents; the quality of public spaces and housing? Would the sky remain blue?

A brief history of urban politics in Brazil

To answer that question, we will briefly review the formation of Brazilian cities. Along with the industrialization that intensified in the middle of the 20th century, Brazil experienced an intense phenomenon of urbanization. According to data from IBGE, the Brazilian Institute of Geography and Statistics, the country saw its urban population increase almost sevenfold in 40 years, from about 12 million people (which represented 31.24% of the total population) in 1940 to more than 81 million people (67.59% of the total population) in 1980.

This great urban growth occurred within a specific process of peripheral capitalism, well dissected by sociologist Francisco de Oliveira (2013). For the author, the modernization of Brazil did not happen *despite* the maintenance of backward sectors, but *in dependence* on them. In the case of cities, the formation of new so-called “informal neighbourhoods” – which occupied idle land in the urban fringes, had self-construction as a predominant building method, and lacked services and public infrastructure – was the main form of growth absorption and served well the scheme of capital accumulation, since the costs of housing and public services did not need to be included in wages and taxes.

The great precariousness of urban peripheries was only to start being remedied with the resumption of democracy in the mid-1980s. Essential items such as pavement, water and electricity supply services were finally almost universalised in recent years. Still, most of the territory in Brazilian cities is still flooded with problems, ranging from poverty to lack of public spaces, from exacerbated violence to extreme urban immobility.

As the military dictatorship agonized, the Urban Reform Movement grew, bringing together popular and professional segments to propose an agenda of social and spatial justice for Brazilian cities (ROLNIK, 2018). The Urban Reform Movement was very active in the process of drafting the new Constitution in 1988, and managed to include two articles related to policies for cities in the letter. These articles were then regulated through an Act, known as the City Statute, promulgated in 2001. The Statute was to be seen as an international reference for progressive normative frameworks, establishing advanced instruments that aimed at the reduction of socio-spatial inequality and the improvement of the quality of life in Brazilian cities. When the coalition led by the Workers' Party won the elections in 2002, the Movement had yet another victory: the creation of the Ministry of Cities. The appointed minister was Olívio Dutra, who had been the mayor of Porto Alegre when the city implemented its well-known participatory budget, and he brought with him leading experts in the struggle for urban reform.

It is worth recalling the level of chaos and inequality in Brazilian cities at the beginning of the 21st century, a result of decades of authoritarianism and neglect. Such a context is well described by Erminia Maricato (2005), a professor at the University of São Paulo who was then appointed Executive Secretary of the Ministry of Cities: "Chaos in collective transport; the decay of public regulation; growth of favelas at levels unheard of; lack of housing alternatives [...]; pollution of rivers, streams, lakes and beaches for lack of sanitation; civil war numbers in deaths related to drug traffic; environmentally fragile areas destroyed by the illegal occupation of riversides, hills, dunes, mangroves and water sources".

In this context, the Ministry of Cities came to "occupy an institutional void that is inexplicable for a massively urbanized country which has had in the past 50 years one of the largest urbanization rates in the world" (MARICATO, 2005). It came with a promise to heal historical ills in Brazilian cities and to promote social and spatial justice, supported by a progressive normative framework – the City Statute – and structured by a broad participatory process, organized in periodical Cities Conferences that branched into states and counties.

The promise, however, was not fulfilled. On the contrary, as Maricato pointed out in an article written some years later, "life in Brazilian cities has worsened a lot in the last years of the past decade" (MARICATO, 2013). The indicators that I propose to analyse would confirm such an assertion: increased time in traffic, costly bus fares, traffic accidents, air pollution, etc. How did this happen? How could a promise that seemed about to be fulfilled become its reverse?

The Ministry of Cities was led by Olívio Dutra and the team linked to the Urban Reform Movement only until 2005, when the Lula administration faced a political crisis and traded the control of the Ministry with a conservative party (ironically named Progressive Party), led by politicians who made their careers during the military dictatorship. It is thus possible to say that the urban agenda never really became a central agenda of the Workers' Party government. Even during the short period in which historical figures of the Urban Reform struggle had a say in the Ministry of Cities, little got off the paper. That period, it must be said, coincided with the fiscal austerity policies of the first Lula administration, and federal government investments shrunk 4,5% per year on average at the time (CARVALHO, 2018). Even if there were good ideas, they got little investment.

Starting in 2006, the federal government's economic policy changed, with a strong emphasis on public investment and a "developmentalist drive" (MARICATO, 2014). As soon as public funds began to flow, policies such as the housing program Minha Casa Minha Vida (MCMV) or the infrastructural Growth Acceleration Program (PAC), in addition to tax exemptions for automobiles, were implemented with a large volume of resources. They shared, however, almost nothing with the directives and regulatory frameworks achieved in previous decades. As Maricato (2014) put it, "we see a paradox. When the Brazilian state finally resumed investment in housing, sanitation and, to a lesser extent, urban transport [...] living conditions worsen radically." In this article I discuss two elements of this paradox: housing and urban mobility.

Housing

It seems to be a consensus amongst urbanists that the MCMV program, which emerged in 2009 in response to the global crisis of 2008, was a policy intended to fight the economic recession, but not the housing deficit. Still according to Maricato (2014), the launch of MCMV in March 2009 mostly ignored the guidelines of the National Housing Plan, which had been developed by the same government. The logic of the program encouraged developers to build in the urban fringes, producing new neighbourhoods devoid of urbanity (ROLNIK, 2018). As can be appreciated in an extensive survey on the theme (WHITAKER, 2012), entire neighbourhoods emerged on the edges of cities, generating stigma, monotonous landscapes, and segregated territories: devoid of transportation, basic social services and commerce.

As the MCMV imposed a "planned socio-spatial segregation", a term coined by the architect André Luiz Prado (2017) in a study on housing estates on urban edges, it also had a major impact on escalating rents and real estate prices. It is pointed out by Ana Paula Ribeiro, Guilherme Boulos and Natalia Szermeta (2014), that although the MCMV reached the goal of building more than one million houses in 2009 and 2010, the housing deficit grew by astonishing 1, 5 million units in the same period. In a later review, Raquel Rolnik (2018) points out that "the MCMV has built more than 4 million housing units in seven years, but has

produced little effect on reducing housing needs. Research shows that the housing deficit has grown over the same period: from 5.8 million to 6.2 million units".

According to the authors, such a contradiction resulted from a lack of regulation combined with the excessive incentives given to construction companies, which were providing for a market with huge credit facility whilst receiving subsidized loans from the National Development Bank (BNDES). These companies started to acquire more and more land and thus to control urban growth streams, speculating whenever possible and inflating property prices across entire regions. From 2008 to 2013, rents in São Paulo rose 195%. "Thus grew the housing deficit, shaped by an explosion in the cost of rents, even in the urban peripheries" (BOULOS *et al.*, 2014).

As pointed out by Maricato (2013), "the heart of the urban reform agenda, the land reform, was neglected." This is true, and it is curious that this and other issues have continued to occupy the debates in the Cities Conferences – participatory spaces created by the first team of the Ministry of Cities. It seems that the participatory processes, which had a historical momentum in the governments of the Workers Party, had different degrees of incidence in the policies actually carried out. Larger programs with voluminous resources, such as MCMV and PAC, "ran outside" the participatory guidelines, along with other "armoured areas", as Anna Luiza Salles and Rosângela Dias (2013) pointed out.

Public policy researcher Sônia Fleury (2013) perceived a very direct relationship between such a "mobilizing yet at the same time centralising" model and the dissatisfaction revealed in the rallies of June 2013: "We created a democratic mechanism in 1988 that allowed society to have a very deliberative and participatory form of control over the State. And we kept activating it all the time – there have never been as many conferences in Brazilian history as during the Lula years. At the same time, however, the real power of decision was very far from such participatory spaces, and that gap kept growing. The organisation of the mega-events disclosed [...] how the decision-making process and the definition of [...] where the resources would go happened between the government and businessmen. This contradiction had to surface at some point. "

Urban mobility

Another policy designed to battle economic recession was the tax relief for cars, called "IPI Zero", as of 2009. The Brazilian car fleet had grown almost 50% from 2000 to 2008 – an increase of about 10 million units in nine years. Large and medium-sized cities were filled with cars, and air pollution and noise, accidents, and slow traffic intensified. With IPI Zero, between 2009 and 2012 another 10 million cars and 6 million motorcycles were registered. Deaths in traffic jumped from 28,995 in 2000 to 44,812 in 2012, according to data from the Ministry of Health.

Health problems and deaths caused by air pollution also burgeoned. According to a study published by the Health and Sustainability Institute (SALDIVA *et al.*, 2017), coordinated by USP professor Paulo Saldiva, the total number of deaths caused by air pollution in São Paulo (11,200 in 2015) is higher than the number of deaths caused by traffic accidents (7,867), breast cancer (3,620), or AIDS (2,922).

According to the study, inhaling the air of the city of São Paulo for two hours is tantamount to smoking a cigarette. Diseases such as arrhythmia, heart attack and stroke represent 80% of the effects of air pollution, which is also a proven cause of lung and bladder cancers and is linked to half the cases of pneumonia in children. According to estimates by Saldiva (2012), a 10% reduction in air pollution in São Paulo could avoid the death of more than 100,000 people in 20 years and save around R\$20 billion in health treatment costs.

Collective transportation was strongly impacted by a car-oriented policy. The exponential growth in the number of automobiles and motorcycles meant that many users gave up public transport – which increased traffic

sluggishness. Compensation however was made not with an improvement of the service (attractive fares, fleet improvement, exclusive corridors), but with disproportionate fare increases and precariousness. From January 2000 to December 2012, inflation rose 125%, but bus fares in the main Brazilian cities increased in average 192% (RIBEIRO *et al.* 2013).

Correspondingly, the average travelling time in collective transport also increased. In Belo Horizonte, the sixth largest city in the country, the average time spent in bus travels went from 42 minutes in 2002 to 62 minutes in 2012 (COSTA, 2012). Such an increase is a result of slower traffic, but also of a reduction in supply – a common adjustment made by bus operators in order to keep their profit margins even with fewer users –, a situation that is more critical in peripheral neighbourhoods, where the supply has never been sufficient to begin with.

The result is a vicious cycle explained in a chart drawn up by engineers and economists at IPEA, the Institute of Applied Economic Research (Ribeiro *et al.* 2013). Such cycle is based on both the lack of investments in urban public transport and the incentives for the use of automobiles – which take the form of tax exemptions or road building and works. This leads to a reduced demand for collective transportation and the migration to individual motorized modes; which results in an economic and financial imbalance in public transport systems; which, in turn, is compensated by precarious supply and raising fares – feeding back the cycle.

These problems could have been faced with policies such as the ones proposed in the 2004 National Urban Development Plan as the basis for the 2005 Cities Conference. The document endorsed a regulatory reform in urban collective transport, aiming at "the adoption of transparent rules and the accurate assignment of responsibilities between public and private agents" (DUTRA *et al.*, 2004). The proposed regulation would structure municipal concessions, and aimed to "include in the contracts tools for efficiency control as well as for the participation of users in the evaluation of services." The creation of a consistent source of subsidy for urban public transport and of an industrial policy for the sector would also be proposed later in 2014 by a group of activists and technicians which included one of the members of Olívio Dutra's former team, economist João Luiz da Silva Dias (DIAS *et all.* 2014).

Without policies aimed at regulation, subsidy and incentive, collective transport followed its spiral of precariousness and overprice. Within a structure of land immobility, this path stretches towards the unbearable, as described by Bruno Cava (2013): "There are millions of vehicles crowded with resigned people and lost looks in the dead-time of daily transportation. We sit or stand, in any case compressed into the mass of similarly tormented mates. We wake up early to face this *via-crucis* and at the end of the day we just want it to end soon and to get home and take a shower so that we can start it all over again the next day. "

Even though public works based on individual motor transport did not enter the official discourse, the guidelines established by the Cities Conferences or the priorities defined by the National Urban Mobility Law, they were heavily present in Brazilian cities in recent decades. Such works were carried out with municipal, state and federal funding. They found their way into programs such as the Growth Acceleration Program (PAC) for Mobility, which would often include works that privileged individual transport within large-scale projects such as the BRTs (Bus Rapid Transit: exclusive bus corridors with prepayment stations). An exhaustive study of the impact of road works on aggravating the crisis of urban mobility in Brazilian cities remains to be done. However, decades of research, especially in North America and Europe, have shown that increasing the supply of space for cars does not result in improved traffic, as new roads tend to saturate in less than ten years (DURANTON and TURNER, 2010).

While they do not improve traffic, viaducts, trenches and highways work very well to create urban scars, degrading pedestrian life and entire neighbourhoods, as Jane Jacobs (2009) has already pointed out in her studies of American cities in the 1950s. There is a heavy burden of violence and authoritarianism in such works, which is well demonstrated by psychoanalyst Tales Ab'Saber (2015) in an analysis of the construction of

the “Minhocão” elevated highway in São Paulo: “Minhocão and the entire road complex that came along with it brought about an urban and mental catastrophe, with grim social effects, a ferocious cultural degradation and the overall imposition of a poorer life. It constituted a veritable conservative device, with profound biopolitical implications over the life in the city to come. A total spectacle, inside out. Only a real dictatorship could have built something like that. It is the living document of the real force of authoritarian desire. ”

For the author, “only a real dictatorship could have built something like that”, but the great works of engineering – from elevated highways to hydroelectric plants –, seem to have smoothly transited from the imaginary of the military dictatorship to that of Brazilian democratic governments. It should be remembered, for instance, that the series of viaducts built in Belo Horizonte, justified in the context of the implementation of a BRT system and the World Cup, was financed by the Mobility PAC program – against the principles of “prioritizing collective transport over individual transport” provided for in regulatory frameworks that were conquered with great struggle. The works dislodged slums, split neighbourhoods, cut hundreds of trees, and made pedestrian life more barren (ANDRÉS, 2016).

At the rallies of June 2013, Luiz Felipe Aniceto de Almeida, a 22-year-old attendant, and Douglas Henrique de Oliveira, a 21-year-old student, lost their lives in one of such viaducts, in the northern part of the city. They were fleeing police shots and bombs and fell from the structure, which “did not provide for pedestrians,” as the construction engineer would later argue.

When, during the 2014 World Cup, just a few kilometres ahead one of the recently built viaducts collapsed, killing two people and injuring twenty-three (*a total spectacle, inside out*), our long history of aberration and violence only showed a more public face. What we saw on television was the product that perhaps best symbolized the enormous gap between the decades-long desires, constructions and efforts to implement urban policies that would promote social and environmental justice, and the conciliatory and regressive *realpolitik* in which the heirs of the dictatorship and hungry contractors dictate urban transformations: the debris of tons of concrete and steel, overpaid and, what is more, evidently useless, since a year after the disaster the traffic in that spot proved not to differ from other parts of the highway where the viaducts still stood (ANDRÉS, 2016).

Conclusion

The urban issues summarized here are only the tip of an iceberg of problems and impacts of economic activities that are not taken into the accounts of hegemonic indicators. The economy may continue to grow, we may control inflation and reach full employment, but life will be worse if that comes with an increase of time lost in traffic, accidents that kill lives, health problems originating from air pollution, rent pressure etc. If people are removed from their homes to give space to dubious infrastructural works, if cities lose trees and public spaces, if the grey of the highways degrades pedestrian life, if urban displacement becomes increasingly unviable, are better wages and full employment enough?

By posing questions along these lines, a number of economists have started to question the hegemonic methods and indicators used by Economics. This is not a trivial matter: the economy occupies a significant place in public debate, functioning at the same time as both the compass and rudder of governments. As early as the 1930s, none other than John Maynard Keynes (1961) considered that “the ideas of economists and political philosophers, both when they are right and when they are wrong, are more powerful than is commonly understood. Indeed, the world is ruled by little else”.

The economist Kate Raworth (2017) soundly recalls that “economics is the mother tongue of public policy, the language of public life, and the mindset that shapes society”. She argues that relevant changes in the economics approach are necessary if we are to seek a future with less inequality and the preservation of environmental

conditions on the planet. The author suggests that "GDP is a cuckoo in the economic nest", in reference to birds that lay their eggs to be hatched in the nests of others. She argues that GDP, the main metric in economics, was not created alongside with the discipline, but was introduced less than 100 years ago, occupying a space that was open due to the absence of concrete, measurable targets.

Not a few economists have criticized the use of GDP as the predominant metric for measuring progress. A report signed by Amartya Sen, Joseph Stiglitz and Jean Paul Fitoussi (2009) proposed a "shift emphasis from measuring economic production to measuring people's well-being ". Economist Ladislau Dowbor (2019) argues that "GDP measures the flow of money, not the attainment of ends." The classic example is that natural disasters and airplane crashes increase GDP, as they generate demand for environmental cleaning services, insurance activation, etc.

Raworth (2017) wrote an entire book on changes in the economics approach. Her main point would be to replace GDP, a linear and simplifying metric, with a donut – a graph in which two rings make up a space of action in which to 1) provide for the universalization of access to goods and resources and 2) guarantee the preservation of living conditions on the planet. "Below the inner ring – the social foundation – lie critical human deprivations such as hunger and illiteracy. Beyond the outer ring – the ecological ceiling – lies critical planetary degradation such as climate change and biodiversity loss. Between those two rings is the Donut itself, the space in which we can meet the needs of all within the means of the planet. "

A design of the donut proposed by the author that addressed elements related to city life could provide us with much more accurate indicators of social life. If it were for instance to be applied to the period of greatest economic and social development in the country's recent history, which Laura Carvalho (2018) called "the little miracle", we would probably realize that the miracle was not that miraculous. We would have a graph in which the thunderous growth of deaths due to traffic accidents and air pollution, time lost in traffic, and the worsening quality of urban life would become evident. We would also see the environmental impacts caused by a certain ideal of development that marked that same period, such as emissions growth and water contamination.

An exercise like this is yet to be done and is meant to be a step in my ongoing research. In any case, simply envisioning an alternative form of visual measurement of economic and social progress allows us to return to the debate at the beginning of this article. Had there been a graphical system of indicators that took into consideration the elements discussed above, would the analysts of June 2013 still see thunders in a blue sky? Or would they see the storm clouds, heavy and dense from the accumulation of the massive energy of years of urban and environmental pressure?

Marcos Nobre (2013b) identifies the period of Brazilian democratization as a period marked by clashes with a conservative political system of locks and brakes that aims to immobilize social transformation and the penetration of democratic and progressive forces. The presence of such a system engendered a social and political dynamic in the past decades that he describes as "*immobility in motion*".

Conversely, it would be possible to understand the dynamics of Brazilian cities in the period here discussed as a *motionless movement*. The very large public employment of resources and the substantive growth of access to goods had effects that reduced or even nullified possible emancipatory and life improving results. Huge real estate investment resulted in an escalation of the housing deficit; the boom of the liberating dream of automobiles resulted in increased transit time; the unprecedented intensification of participatory instances had no real impact on decision-making; hosting the World Cup only left a burden of more urban inequality and elitist stadiums.

Fear and segregation: anxiety beyond the gated communities. The Costa Rican case.

Karla Barrantes Chaves¹

¹*Bartlett School of Planning-University College London, karla.chaves.16@ucl.ac.uk*

Abstract: Fear of crime is a constant concern in Latin America. In Costa Rica, those feeling seems to be changing the urbanisation patterns; giving way to gated communities. However, those developments might be increasing feelings of exclusion and anxiety instead of reducing crime. In the last 25 years, the gated communities have been rising; as a result, the traditional neighbourhoods have to coexist with these new developments. This paper aims to explore the effects of gated communities in the distribution of fear in their peripheries, mainly those regarding tensions between outside – inside. The research is taking place within the Greater Metropolitan Area of Costa Rica. Eight open neighbourhoods were selected, using the poverty indicator basic unfulfilled needs (NBI). In each case was carried out a walking interview with some members of the community; those walks were tracked with a GPS and recorded. Additionally, there were focus groups, observations and interviews. Some preliminary results suggest significant residential segregation between the neighbourhoods and the gated communities. It seems the fortification is more than a physical barrier; there is no room for sharing, which causes misconceptions and fears towards other people.

Keywords: Fear of crime, gated communities, Costa Rica, residential segregation.

Introduction

Safety is an important concern in most of the Latin American people. This region holds the highest rates of homicides worldwide (Chioda, 2016). Also, the fear discourse has been part of the political rhetoric from the 1990s, fuelling people anxiety even more (Huhn, 2017). As a result, more than 61% of Latin Americans agree to the increase the repressive measures such as zero-tolerance policies (Latinobarometro, 2016). Those punitive practices have been imported mainly from the United States. However, many countries also have reproduced from that country the model of gated communities, considered for many people a sort of ‘shelters’ against criminality.

Although high inequality has characterised Latin America, most of the countries started a reduction in their figures at the beginning of the century. However, Costa Rica has shown the opposite trend; this country moved from being one of the most equitable towards ranges similar to the average. In 2016 the Gini coefficient was 0.521, without any significant change since 2011 (Programa Estado de la Nacion, 2017).

Central America is also one of the most violent areas in the world; however, it is not homogeneous in their figures, then countries such as Costa Rica, Panamá and Nicaragua have lower rates of homicides than the rest. The overall victimisation rate in Costa Rica has diminished from 2008 (INEC, 2015); however, gated communities have been proliferating because they are seen for many people as security providers. This trend has started to fragment the city, physically and socially, creating isolated places

into the urban fabric. As a result, paradoxically, those developments might be increasing the fears towards their peripheries in turn.

This paper is part of an ongoing PhD research, which explores the distribution of fear outside of gated communities within the Great Metropolitan Area of Costa Rica. This work is focused on the possible tensions produced by gated communities over the surrounding neighbourhoods. The data were collected mainly through walking interviews and focus groups, in eight neighbourhoods beside gated communities. The initial findings suggest a deep residential segregation and exclusion feelings in most of the cases. The results also suggest that pre-existing fears are fuelled by the isolated landscape and the uncertainty about who lives behind those walls.

Fear of crime beyond the walls

Fear of crime has profound impacts on quality of life. Those emotions might affect social cohesion and experience in the city. This feeling is defined by Ferraro and LaGrange (1987, p.72) as ‘a negative emotional reaction to crime or the symbols associated with crime’. However, fear of crime is a complex phenomenon, which involves different dimensions and factors such as incomes level, gender, education, race, age and attach to the neighbourhood (Gray et al. 2011). In this regard, the built environment might have a significant role in the perception of fear.

Some authors have suggested the manipulation of physical space to prevent crime. Newman (1973) through his concept Defensive Spaces, points out that buildings’ configuration and urban design can help to surveillance, as well as community control is the only efficient tool for assuring safety in neighbourhoods. According to his view, the community becomes a guardian encouraging territoriality feelings. Besides, the Situation Prevention Thesis (Clarke, 1983; Crawford, 1998) supports the idea of reducing the opportunities for crime through informal community vigilance, the introduction of barriers, use of Closed-circuit television (CCTV), as well as any physical alteration. In both cases, the presence of strangers is avoided; the neighbourhood is under community control.

On the other hand, those territorial controls seem to affect the permeability of the city. Minton (2009) holds the idea that the ‘Defensive Spaces’ are the reason why gated communities and cul de sac have been spread along the United States and Britain since 1970. She argues that those measures make strangers be seen as a source of danger. In like manner, Sennett (2018) claims that edges are tense rather than friendly places of exchange, he mentions that turning walls in membranes allows the interchange inside-outside, stimulating ‘neighbours who mix casually’ (p. 223); for instance, buying food. This measure makes contact less confrontational; it could be the first step to debunk misconceptions about ‘the others’.

The tension between the absence or presence of unfamiliar people affects the dynamism of the city. Jacobs (1961) highlights the importance of bringing different type of people altogether. Actually, she points out that a successful city is that in which a person feels safe among strangers. Furthermore, Sennett (2018) points out that preconceptions towards strangers just because ‘they are incomprehensibly strange’ degrades the ethical character of the city’ (p.126). He holds that the experience of living in a diverse group has the power of reducing the feeling of insecurity and frustration because there is no clear image of who is the enemy.

Barriers of differentiation

Latin America cities have imported the concept of gated communities from anglo-saxon countries. Those residential developments arise in the United States in the early 1980s (Blakely and Snyder, 1997), later in Latin American cities during the 1990s (Castells, 1999). Although the United States has had an important role spreading those developments, gated communities have expanded rapidly in urbanising countries, 'they were simply part of the surreal economic and spatial transformation that engulfed so many countries in the last two decades of the 20th century' (Webster et al. 2002). This growth could be explained as an answer to social conflict and violence in cities; however, these developments also reflect new lifestyles emerging under the globalisation process (Coy and Pöhler, 2002). Under this perspective, the developers of gated communities' see themselves as providing both security and social familiarity' (Blakely and Snyder, 1997). However, Blakely and Snyder (1997) argue that those fences represent more than physical barriers, they are a reflection of tensions between particular aspirations based on fear and defence of privileges, with the principles of community responsibility.

Criminality causes concern among most of the Latin American people, around 88% express any fear about being a victim of delinquency, in Costa Rica, this figure is 86% (Corporación Latinobarometro, 2016). Consequently, demands for 'iron fist' to address this issue seems to be deeply attached to Latin America culture. In this regard, Costa Rica occupies the second place in Latin America with the highest percentage of people claiming for this measure, while the average is 61%, in Costa Rica reaches the 78% (Corporación Latinobarometro, 2016). Against this background, populism punitive seems to be used in the political discourse, exacerbating the fear of crime (Huhn, 2017). According to Huhn (2017) in Central America, those elements intensify each other, fuelling pre-existing fears and hence, justifying more repressive measures. The fear discourse in Costa Rica might be included in political rhetoric since the 1990s and reproduced by some media (Fonseca and Sandoval, 2006; Huhn, 2012). The spread of fear has also changed the urbanisation patterns, raising the number of gated communities within the country.

Gated Communities in Costa Rica

Costa Rica has had a significant increase in the number of gated communities. In that country, most of those developments have been created under the condominium scheme, an ownership system which has individual dwellings or units within a shared land with common areas. From 1990 to 2017, the rise of the built area under this category increases from 5,2% to 25,2% (Programa Estado de la Nación, 2018). Although this figure does not mean that all those developments are walled, it is an important sign of the current trend. A report from the United Nations Development Programme (UNDP) in Costa Rica highlights that the widespread of unsafety feelings have altered people behaviour 'They live in a condominium rather than open spaces, put razor wire around what was once an open garden.' (PNUD-Costa Rica, 2005, p. 4). Carrion (2008) mentions that in Latin America safety policies in residential areas have increased the barriers of differentiation; paradoxically, rising the segregation and creating exclusion spaces. This situation is also present in the Latin America suburbs, where poor and rich are next to each other but separated by a wall (Roitman and Phelps, 2011). In Costa Rica, due to a green belt around the Greater Metropolitan Area (GMA), the gated communities seem to be mostly concentrated in the urban region; nevertheless, there are also cases of gated communities in rural areas. Pujol et al. (2011) suggest that within GMA, those places where gated communities are located, the social segregation has climbed steadily. In Costa Rica, the planning system has different rules for open residential developments and gated communities. Historically the open neighbourhoods have

transferred to the local government land for public parks and streets; on the contrary, most local governments allow to gated communities to keep the entire property for themselves. This situation seems to provoke a reduction in the number of public spaces per inhabitant; therefore, the decline of areas for sharing within the city. With this in mind, the traditional open neighbourhoods have to coexist with the new gated communities daily. Those neighbourhoods are very diverse; they may be either low or high incomes. Many authors have suggested an association between fear of crime and income inequalities (Franklin et al. 2008; Wilkinson and Pickett, 2009; Vieno et al. 2013), where those areas more unequal reveal a higher level of anxiety.

Methods

The research is based on eight study cases; they are neighbourhoods beside gated communities. Those cases are located within the GMA of Costa Rica. This area concentrates more than half of the country's population, despite it is just 3,83% of the Costa Rican territory (OUGAM, 2018).

The neighbourhoods were also selected according to their unfulfilled needs, called by the National Institute of Statistics and Census (INEC) as *Necesidades Básica Insatisfechas* (NBI). The NBI is a tool to measure poverty, which was gotten from the Costa Rica census data from 2011. It is based on four needs: housing, educational level, health and access to goods and services. When a dwelling holds the four NBI, it means that it has the highest level of poverty. The eight cases have different levels of unfulfilled needs, from communities without any NBI (0 NBI) to neighbourhoods with the highest level of poverty (4 NBI). Those places were chosen using Geographic Information Systems (GIS) with the census cartography; the first random selection was polished with aerial images and then reassessed in the field.

The data collection was made from June to December 2018; the following techniques were used:

- Walking interviews
- Focus Group with adults and teenagers
- In depth-Interviews
- Observations

In each neighbourhood was carried out a walking interview with some members of the community, according to with the method suggested by Evans and Jones (2011), those walks were tracked with a Global Positioning System (GPS) and synchronised with an audio recorder. It was carried out also one focus group per each study case. Additionally, there were observations in each neighbourhood and some complementary in depth-interviews. These initial findings are based mainly on the walking interviews and focus groups.

Initial Findings

Residential segregation

Most of the participants mentioned that they did not know people from the gated community. However, those from the communities with high incomes indicated to have met them at some point. In seven of the eight cases, there was no connection between the gated community's residents and the community organisation, the only exception was the wealthiest neighbourhood, where people from the gated community were part of the community board. This overall residential segregation was also expressed by the teenagers, who despite having an extensive network of friendships beyond their neighbourhood, they did not have friends within the gated communities nearby.

Walls and preconceptions

As a result of residential segregation, people created their own concept about people from the gated community. Those ideas also fuel anxiety and tensions; there is a general feeling that those people do not care about the community because maybe they belong to another town. The level of incomes of those people also causes concern among neighbours; for instance, many participants think they are wealthy people, which is an issue for their neighbourhoods because those developments might function as a magnet for criminality, therefore, it could affect the safety of the surrounding communities. Other people believe that maybe they are involved in illegal business; hence their neighbourhoods are under threat, mainly their young people who are vulnerable and easy to recruit. On the other hand, those communities where the neighbours at least have met somebody from the gated community they assume they are just working people from middle to upper middle class. In this regard, beyond the physical barriers between neighbourhoods and gated communities, those prejudgments might be increasing some pre-existing fears.

Overwhelming growth, involuntary enclosure.

As has been noted, gated communities in Costa Rica are expanding quickly. Within GMA they are embedded into the urban fabric, next to established neighbourhoods. In those cases where the growth is notorious, the neighbours expressed their overwhelming towards this situation. To illustrate this point, those neighbourhoods surrounded by at least four gated communities larger than one hectare, manifested to feel 'wrapped' by those developments. This sort of involuntary enclosure seems to rise the exclusion feelings and fuel resentments. That frustration obeys mainly to the sensation that their community has been taken by strangers who live in their own fortifications. In the absence of spaces for sharing and mixing, as Sennett (2018) refers, the anxiety towards strangers is even more significant.

The edges

The edges between gated communities and neighbourhoods were mostly walls. The only exception was the wealthiest neighbourhood, in that case, the perimeter was permeable but keeping the restrictions of access. In most cases, those walls were associated to feelings of fear; they were described as isolated places, therefore, a convenient area for crimes such as muggings, drugs traffic, abductions, sexual abuses, among others. Due to the gated communities nearby were larger than nine hectares -in six of the cases, many neighbours were forced to walk along their edges to take the bus; actually, many bus stops were located just next to the wall. This situation provoked them a considerable anxiety, especially during the night.

Planning issues

A common complaint was the lack of contribution from gated communities to the neighbouring areas. Especially regarding the supply of public spaces such as parks and streets. In addition, they pointed out how the significant surface covered by those developments makes difficult the communication among neighbourhoods. Pujol et al. (2011) have mentioned how those gated communities have risen the drawbacks in the Costa Rican road system, which also has affected the traffic congestion. In general, those neighbourhoods where the amount of gated communities is growing faster, there is a discontent towards the local government's controls and regulations.

Final thoughts

The tensions from the outside to inside seems to be fuelled by feelings of exclusion. The residential segregation has provoked fears towards the unknown; people from gated communities are seen as

strangers who belongs to somewhere else. However, those differences seem not being present in the wealthiest community, where the gated community's edges were soft, and people from there were involved in communal issues. In this case, apparently, the levels of trust in both directions worked differently than the rest.

The local governments in Costa Rica have not reacted quickly to control the size, edges and configuration of gated communities, as well as an eventual supply of public spaces. As a result, there are 'islands' of dwellings embedded into the city, without any permeability towards the rest of the urban fabric.

The spread of gated communities in Latin America has been varied; this work aims to contribute to give more views to that discussion, mainly from Central America, which is also diverse. This work also seeks to offer another angle of observing the fear, from the other side of the wall.

Acknowledgements

My deep gratitude to the communities involved in this research.

Lofts districts in Milan. Overlapping tensions between uses and regulations. Instruments for urban and architectural design

Stefano D'Armento¹

¹Politecnico di Milano, stefano.darmento@polimi.it

Abstract: The topic of conversion of industrial buildings and compounds into lofts got very little attention in the Italian case, represented mainly by the city of Milan. The gray areas of national and local regulations allowed the unplanned emergence of entire multi-functional enclosed districts within the city, built from the ruins of former industrial plants. Due to the inherent flexibility of industrial buildings, with spaces that can be divided horizontally and vertically in modules which can be joined and split, lofts allow for the coexistence of diverse uses. Officially listed as workshops, these units host housing, commerce, small manufacturing, one next to the other or even in the same unit. Lofts developments may represent a case of overlapping tensions, of uses and practices and at the same time a possible way to use architectural and urban design to address several issues about the contemporary city, as the flexibility of uses and urban manufacturing. The contribution aims first to quantify the phenomenon in the city of Milan through a map of loft developments and then present one of the most critical cases, showing the tensions produced in these environments between the different uses, formal and informal, legal and illegal.

Keywords: loft, industrial heritage, reuse, flexibility

Introduction

In this paper, I will cover a somewhat ignored piece of knowledge in the chapter of the transformation of former industrial areas in Milan. The conversion of industrial buildings and compounds into lofts has been widely studied in foreign countries, starting with Zukin's seminal work "Loft Living" in 1982, until the more recent "City as Loft" of Baum and Christiansee (2013). In Italy though, even in Milan, where the loft phenomenon is quite huge, the topic has been usually moved to the background, just mentioned and rarely deepened.

In the first part, I will provide a brief international background to the topic of loft conversions. In the second, the phenomenon of loft conversions in Milan will be set in the general process of post-industrial transformation of the city. Then the loftscape of Milan will be described and analyzed. The current situation of loft developments in Milan will be depicted and quantified. A paragraph on methodology in this section will explain how data were found and processed. Finally, a significant loft compound in Milan will be studied. According to the purpose of the session the paper is presented in, the focus will be on the tensions between the many paradoxes of lofts (Zukin in Vv.Aa., 1990) and all the tensions that these paradoxes engender both at an architectural and urban scale.

The emergence of the loft phenomenon

What we can consider as the ancestors of the lofts are already found in Paris at the turn of the 19th Century, where young and not affluent artists started to rent the upper floors of buildings. Artists found appropriate for their purpose what was an uncomfortable location for most people. The interior space was normally distributed on two floors, the upper one, with skylights which let plenty of natural light getting inside, was used as a studio and the lower one usually as a bedroom.

However, it is in New York City where loft lifestyle as we intend it was born and spread in the second half of the 20th Century. First artists started to rent abandoned spaces in industrial buildings for cheap, in a period when industries already started to move outside of Lower Manhattan to more convenient locations for logistic and land prices. Those artists started a new way of living: in huge open spaces, displaying materials and features that until then were not associated with residential habits. The space of their lofts was able to combine home and work, public and private, a workshop and a gallery, remarking the difference in the notions of house and home (Nicolin in Vv.Aa., 1990).

The appropriation of these spaces for purposes other than industrial production meant the construction of new significances also for all the objects related to industry and production and the activities previously hosted in those buildings, a domestication of the industrial beauty (Polazzi, 2007). This appropriation of industrial spaces and change of values was possible because the original use was terminated, since "only people who do not know the steam and sweat of a real factory can find industrial space romantic or interesting" (Zukin in Vv.Aa., 1990, p. 21).

The conversions started a conflict between artists and the municipality of New York since all the occupations were illegal. The first measure was taken in 1964: the City Planning Commission rezoned some sections of SoHo allowing only artists to work and live there, officially recognizing the value of art production for the collectivity and the City (Celant in Vv.Aa., 1990 and Sussman, 2017).

After the first colonization by artists, this new way of living began to be fashionable and started soon to attract also nonartists and got the attention of the real estate market which immediately made of the loft a commercial product, thus starting processes of progressive gentrification of the affected areas. The appeal to a broader public was possible thanks mainly to two changes occurred in the Sixties. The first is an opening of the public administration to a limited change in the zoning regulation and the possibility to make legal living in such spaces, with the aforementioned 1964 rezoning. The second one is the emergence of new habits of consumption of the middle class, open to new different and more articulated models of living (Polazzi, 2002). Affluent people, not related to the world of arts, started to be eager to buy or rent industrial spaces to turn into their homes, and contemporarily landlords began to raise rents, which became not affordable for the same artists who benefitted from low prices at first. In 1982 the Loft Law, for protection of loft tenants, was promulgated by the State of New York. In most cases gentrification meant the end of urban manufacture and mixed uses, even contradicting the basic features of the first lofts developments such as the promotion of mixed-use and the benefit of the transformation of abandoned areas. Indeed public funding directed to this last one gets substantially lost in the moment this transformation favours a more affluent part of the population.

Lofts started then to expand in Northern America and western Europe, finding their ideal setting in cities with two characteristics: a certain amount of old industrial abandoned buildings and a lively cultural environment (Zukin, 1982).

The transformation of industrial areas in Milan

In the 1970s of the 20th Century, the profound reorganization of the industry also hit Italy and its leading industrial city, Milan. Relocation of industries in the outskirts of the city or even farther happened simultaneously with the processes of tertiarization and suburbanization leading to a progressive expulsion of functions as housing and industry from more central areas.

Within this economic context, the 1980 City Plan tries to contain tertiarization and to retain industries in the city boundaries, not allowing modifications to the zoning regulation. The impossibility of governing economic and societal dynamics happening at a broader scale with an urban regulation freezing the land uses resulted in the 7 million square meters of abandoned industrial areas (Figure 1) the city of Milan had to deal with in the next years and, to some extent, still now (Mocarelli, 2011).

Figure 1. Abandoned industrial areas (marked in black) in the City of Milan at the beginning of 2000s. DiAP, Politecnico di Milano (Morandi 2001).

When it became clear that it was impossible to retain the industry in the city with the purple spots¹ (Secchi, 1984) the first attempts to direct the transformation of the areas were set up by the city in 1988, starting thus a season of large scale urban projects, known as Plans of Urban Recovery (PRU) and Integrated Intervention Plans (PII).

At the same time, at the end of the 1980s, the word loft started to enter in the common language and to become fashionable, with the first conversions of relatively small industrial buildings in central areas of the city or in the Navigli (the canals of Milan) district by people involved professionally in the world of the fashion industry and design, willing to import the American loft lifestyle.

¹ In Italian urban planning purple has usually been the colour identifying industrial areas. In his famous piece of 1984, Italian architect and urban planner Bernardo Secchi reflects on a change in the situation, stating that is not possible anymore to think to retain industries just fixating those purple spots, *macchie viola* in the original Italian, on paper in the City Plans.

Loftscape of Milan

Every city has a different and peculiar loft landscape, an effective expression I will contract to loftscape, a product of the very characteristics of the land market and built environment of the same city (Podmore, 2002).

In the collective imaginary lofts are located in an industrial heritage context (Janetti in Ufficio Studio Gabetti, 2010). However, this is just the more familiar image of the loft we have. The real situation is much more complicated. The term loft can define two kinds of different products, and we can find these categories both in the real estate market and in everyday use:

- 1) Lofts by regulation. The first type is a loft defined on a regulatory point of view. Although there is not, at least in Italy, any law or even somewhat legal definition of a loft, this category represents the regulatory status of what is typically called loft. Indeed the word loft usually indicates any unit not officially registered as housing but used as such, or for mixed activities. There is then a difference between the official (regulatory) function of the unit, function certified at the cadastre and in the official urban planning documents, and its actual daily use. The most common case is the registration as a C/3, cadastre code for a workshop;
- 2) Lofts by morphology. The second meaning refers instead only to a morphological or typological issue. Often, indeed, a unit officially registered as a house may be defined as a loft due to its architectural characteristics, as its being a nonpartitioned open space, with a free internal layout, or for the presence of huge skylights or windows, and more generally its industrial-like look.

There are then lofts defined as such only by the first or only by the second category and others, most of them, which are included in both. After specifying the possible meanings of the term loft, we can analyze the loftscape of the city of Milan, which is composed of two main categories of conversions of former buildings and units into lofts:

- micro transformation: conversions of single units of modest dimension, mainly former warehouses or workshops part of other buildings, primarily residential, scattered all around the city in the inner courtyards of the old fabric and the 19th-century city;
- large-medium transformations: conversions of entire former industrial buildings or compounds that stopped their monofunctional activity and production and turned into lofts villages.

Microtransformations are very difficult to map and to count, due to their very nature. The phenomenon is vast and widespread all around the city, but no official data are available neither it seems to be possible to map it effectively. Within this category, we find two main products defined as lofts:

1. Standard apartments renovated with loft-like features like being open space or duplex. They are lofts only by morphology, in the real estate market language;

2. Reuse with mixed or mainly residential use, with or without change of use, of shops at the street level, offices, workshops, and garages, mainly in the inner courtyards of the buildings, attic spaces and also basements. All of these conversions present peculiar architectural features which make them lofts by morphology. If a change of land use did not occur, then they are lofts also by regulation.

Medium-large transformations are the ones we will deal with now on in this writing and could be subdivided into three categories:

3. Reuse of buildings and areas on a gradual and progressive basis through actions of subtraction, addition, and modification of the existing (lofts by regulation and by morphology);
4. Demolition of the old industrial buildings and new construction of residential buildings recalling the industrial morphology of the previous ones or, if that was not significant, inventing a new industrial-like look (lofts by morphology);
5. Demolition of the old industrial buildings and new construction of buildings completely different by morphology that could be registered as commercial units without any change of land use (lofts by regulation) or as residential units after a change of land use but with architectural characteristics of lofts as mezzanines and big windows. (lofts by morphology).

As we can see, loft is a word that can define multiple situations, from a living, legal, morphological, or typological point of view. It is a word as flexible as the product it describes. What it becomes clear is also the normalization of the loft product (Multiplicity Lab, 2007), which became another among various real estate market proposals.

Lofts compounds in Milan are many and compose quite a heterogeneous loftscape. Medium-large transformations amount to 86 areas varying in the number of units between 5 and 500 and in surface area between 1.100 and 85.000 square meters for a total of approximately 700.000 square meters. Most of them, and this is a distinctive trait of Milanese loftscape compared for instance to the New York one, develops mainly horizontally rather than vertically. Ackermann (1991) subdivides industrial buildings into two types: multiple floors and big sheds. The first includes, as the same name says, buildings characterized by a vertical subdivision into multiple floors. They are very common in Manhattan, where industries did not have space to expand horizontally, and early technological developments allowed for vertical growth. These buildings are readily convertible into "common" city residential or commercial buildings, with one or more dwelling for each floor. The conversion is usually a matter of internal redistribution and the creation of spaces. The second ones instead, taking their name from the typical industrial roofs, develops horizontally, reaching a limited height, generally of just one floor (considering that the height of a floor for industrial use is significant, often exceeding ten meters). These kinds of industrial facilities, when converted to other uses resemble more a village than a building. A little town within the city, with row units, internal open-air streets, the outcome of a process of subtraction, cut and addition of volumes.

Furthermore, as we can see in Figure 2 another unique characteristic of the Milanese loftscape is that most of the most significant converted areas are not in very central locations but peripheral areas of the city. Milan is quite compact as a city and distances are not so huge. The adjective peripheral here

defines what is outside the very city center, recognizable as the Zone 1, delimited by the circle of the former Spanish Walls. Industrial areas developed outside the historical center and when conversions started these locations were not central and not regarded as fashionable. One for all, the Navigli area of via Tortona, which also due to the loft conversions is nowadays an active and vibrant part of the city, devoted to the industry of fashion and design. In any case, the centrality of location does not seem to count as a plus for the appeal of conversions in Milan, which instead involved half peripheral and even very peripheral locations, not so well linked by public transit with the center of the city. The loftscape of Milan is indeed characterized by significant peripheral developments. The limited size of the city should be, of course, taken into account when making these considerations.

Figure 2. Lofts compounds (marked in black) in the City of Milan in 2018, with city center in red perimeter. Elaboration of the author.

The creative environment, instead, did play a major role in importing the loft-living style and spread the loft culture around the city. The very beginning of the phenomenon, as mentioned before, started in the Navigli area thanks to a few pioneers linked to the world of fashion. With the expansion in the last decades of the reputation of Milan as a world fashion and design capital, these two sectors kept gaining importance in the economy of the city. Some of the districts renowned for the heavy presence of creative industry-related activities are also the ones with a massive presence of lofts: such as the aforementioned Navigli, or Lambrate or Mecenate.

Tucidide 56

The loft complex Tucidide56 (via Tucidide 56 the address of the building complex) stands where once was the productive site of Richard-Ginori, famous pottery producer where the renowned architect Giò Ponti used to work as art director. It is located in the eastern outskirts of the city, beyond the railway belt, in an area where the urban fabric remained quite compact and still the separation between the city and the agricultural land is perceivable.

Tucidide56 is the second biggest loft development per surface with 57.000 square meters and the one with most units, over 500, a proper urban village, with streets (Figure 3), common spaces and services. The factory, built during the first decades of the 20th Century, was characterized by some art-deco architectural elements and ornaments.

Figure 3. A street inside Tucidide56 area, result of the operation of subtraction and cut of a former warehouse.

The compound is very peculiar due to its size but also for the composition of the property of the area. The development started in the early 2000s as a sale operation. The units were sold to privates by the new landlord of the whole area, who bought it from a prominent and controversial real estate company. The landlord was in charge of the facades and the common spaces while the interiors were delivered not finished so that buyers could personalize them. Year after year a certain number of units was put on the market until the economic crisis of the second half of the 2000s. With the crisis, the redevelopment operation changed from sales to rent, which became more profitable at that time. The landlord and developer became then also the manager of the complex, building, renting, and managing the newly constructed units.

Lofts for rent are very different from lofts for sale (Hemnett and Whitelegg, 2007). The lofts made for the specific purpose of being rented are oriented toward ultimately another market than the ones for sale. They can be smaller, and the quality of the finish can be rougher and cheaper, with no personalization from the developer, which aims to extract the maximum rent at the minimum cost. This issue also reflects on more mediocre environmental performances of the buildings.

Nowadays in the area, there are over 550 units, of which around 200 properties of private citizens and the rest property of the developing company that rents them. Land use was changed in most of the privately owned lofts, mainly used as family homes. Some of them have been put on the temporary rent market. They usually are quite spacious and with outer spaces, gardens or terraces, with double heights and all the features that characterize lofts in the common imaginary.

The units for rent are over 350, and still growing in number as long there are other old hangars to be transformed. The average surface is of 76 square meters, far from what is the typical image of a huge loft space and a lot of them are even mini-lofts of 30 square meters. All of them are listed in the building registry as commercial units, but they host a permanent population of an average of 1,2 persons per unit.

The 55% of the lofts are used only as housing, 30% as house-studio and 15% for office or deposit. The population is evenly divided between males and females, 60% of the inhabitants are singles, and 20% are foreigners. The 82% of the holders of the rental contract own a VAT number, which makes them autonomous workers or entrepreneurs. The 28% of the occupants work in creative professions,

intending as such jobs in visual production, communication, design, show-business as photographers, designers, architects, musicians, dancers, artists of many kinds, and so on.

The peculiar and heterogeneous mix of inhabitants and activities gave life to a lively environment. Of course there are condo-living like issues and problems, but there is also a community spirit, with social events, a dedicated social media page, and it fosters continuous contacts among different people involved in the world of arts or small manufacture, giving the opportunity for easily starting collaborations.

Lofts as a place of conflict

As we saw, illegality played a major role in the history of lofts. The whole story began thanks to a few rule breakers willing to pay the price of relative discomfort for having other advantages, as cheaper rents for bigger spaces in central locations on the island of Manhattan. When they became too many to be ignored, public administration had to intervene, some way even endorsing them, recognizing their role and the importance of art production in the economy of the City (Sussman, 2017). The biggest change lofts brought along was about land use. They forced the city of New York to revise the zoning regulation; they brought back a way of living that was typical of cities in the past (living and working spaces together, mixed). Separation of functions and zoning, heavily promoted by the Modern Movement, had their right reasons in hygiene: due to the very unhealthy conditions of cities back then a strict separation of functions was a necessary and effective way to avoid or diminish sanitary risks.

Lofts are the place of multiple conflicts. The word conflict, recalling the Latin etymology and use, which acceptance is both collision and encounter, divergence and medley. Conflicts both at an architectural and at an urban scale, regarding little things of the daily life of inhabitants and concerning crucial issues related to the functioning of the city, urban planning, regulation, and taxation. There is a conflict between their legal situation which is different from the actual daily use; a gap between what is *de jure* and what is *de facto*. The conflict between living and working, and among various kinds of activities one next to the other. The conflict between public and private, mixed in the same space, inside each unit, and inside the whole compound, canceling any form of zoning.

Furthermore, local and national regulations on urban planning and taxation produce different types of conflict in each different city. Again, loftscape is different from one city to another, not only according to the local cultural environment and economy but also to local regulations.

In Milan, but what follows could be generalized in the case of Italy, for instance, building lofts has been a way to avoid and bypass a series of prohibitions and limitations, introducing residential functions where it was not allowed. This is possible thanks to the grey areas of the law, especially about the place of residence a person is allowed to declare. It is possible indeed to declare the place of residence in a non-residential unit, as long as this is suitable for a living. Suitability consists in having a furnished kitchen, bathroom, and bedroom, the basic requirements controlled by the inspector, who does not check the land use or cadastre registration code of the unit, but only the fact that the applicant is living there. This situation engenders two main issues.

The first one is about the relation with the city. Many people live and are allowed to live and use the public services of the surroundings, services for which they or the developer never paid and contributed to build or create if any change of land use was done. In this way, lofts' inhabitants use city public services in a parasitic way (Pareglio and Vitillo 2013). Furthermore in this way the developer achieved to accumulate most of the urban rent, more than it would have been able to if he paid a land use change, leaving the public administration to more costs to sustain and less income.

Then there is also a second issue related to taxation. People living and using commercial units as housing are subjected to commercial taxation and pay for commercial utilities, but they can put this costs into the VAT subject that officially use the unit, which in this way result as an asset useful for the business of the VAT subject, being thus deductible from taxes. In this way, although there is not real tax evasion, a sort of tax avoidance occurs, and an implicit pact is established between developers and users, both gaining and taking advantage of this blurry situation.

However, on the other side, lofts compounds brought quite an innovation in the city. They responded to a demand which was not met by traditional forms of living providing new typologies and managed to create art-professionals friendly environments. Indeed they got much appreciation in the real estate market. The most diverse activities live one next to the other. There is the web designer with the bedroom on the mezzanine and the studio/living room downstairs, on the ground floor. The neighbor is a young couple of professional, only sleeping there while working in the center of the city. Next to them an artisanal pastamakers laboratory. On the second floor instead, there is a group of four university students, a small independent recording firm and a musician. Structural flexibility of the modules allows for merging and splitting the units according to the needs (Figure 5).

Figure 4. Scheme of a big shed industrial building transformation into lofts

They have been innovative also for construction management. The old buildings, especially of course in extended areas, have been transformed gradually, but in the meanwhile, they have been started to be inhabited. People were living there already during the construction, basically in a worksite. A flexible schedule of construction allows minimizig the risks connected to sale or rent market and prevent a failure of the operation.

Additionally, in many cases, they preserved the minor industrial heritage that would have been otherwise lost. In this case, preservation was not regulated by any law or institutional body since buildings were not officially protected and may have been torn down as well, but the general industrial look and their feature were an integral part of the product that was going to be sold, representing its main competitive advantage. Preservation then coexists with the needs of real estate development, with some interesting outcomes.

The paradox of lofts is more evident when looking at lofts compounds next to PRU or PII areas (Figure 6). The first ones, despite standing on, or beyond, the border between legal and illegal, created a vibrant and vital urban context, in the form of urban villages, recovering abandoned buildings and allowing for some innovation in the way of living and working of people, responding to existing needs otherwise unheard.

Figure 5. Aerial view of Distillerie lofts compound and PRU Pompeo Leoni. Elaboration of the author on Google Maps image.

On the other hand, PRU and PII are often made of speculative buildings, and although they officially comply with regulations they did not provide any innovation and in many cases, they also did not provide either for enough public services, or for quality space or even mixed functions (Doni, 2008). Opposed to loft compounds, the failure risk was higher in this kind of developments, and traces of this issue are still unsolved in the city, for instance in the Porta Vittoria development.

City as loft?

The loft, or better, the concept it embodies, may be seen as a symbol of flexibility, until the point of imagining it as a primary architectural and urban planning tool for the entire city (Baum and Christiansee 2013). Lofts indeed anticipated many issues we are facing in the last years, and they managed to be a successful market product thanks to their overall flexibility of uses and layouts, matching with the need of a changing and more flexible society.

Zoning is being progressively abandoned, and land use change is becoming easier. Are we going toward a city where every function may be put everywhere, and all of them can coexist in a very limited or nearby space, as already happening in lofts? Is this the end of land use regulation? Is this a way to foster a possible return of manufacture to the city centers? From these points of view reflecting on lofts make us think about the future of the city more in general.

Yet there are some issues to be considered. One is about how landlords and developers will get away with capturing all the urban rent in case of a total liberalization of land use change. The other is about taxation, to be solved at State level, on the different levels of taxation according to the use. Another issue is about the quality of the land remediation that nowadays can be made different according to the planned land use.

Lofts may be considered as the first outposts of a contemporary way of living and making our cities, but they are still an issue to deal with. Near past and current policies have gradually reduced zoning

and liberalized land use changes, going toward an acceptance of the loft model. In other cases, such in New York City, a specific body, the Loft Board, has been created to deal with the topic but also in this case it seems like laws and regulations just come ex-post to regulate what already exists and has already been done.

Methodology

The content of this paper is based on an extensive literature review of the loft phenomenon on international sources cited in the references. The Italian part of the literature is mainly about the conversion of the industrial areas in Milan, where a few paragraphs about lofts can be found. A GIS database of the loftscape of Milan has been developed with data coming from several different sources. First of all from personal knowledge of loft compounds, afterward through a real estate websites survey for rent and sale of lofts, allowing to discover other converted areas. Further additions of areas came through the comparison of maps identifying former industrial areas with actual Google Earth tools, to see what kind of transformation occurred in these areas. Eventually, all the recognized areas have been checked through the Agenzia delle Entrate website (State Revenue Agency) in order to find out the number of single units declared to exist in the area and their category of registration at the cadastre, whether productive or residential or others. This operation allowed to find out if areas are composed of lofts by law or lofts by morphology. A final check through on-site surveys when possible or at least a google street-view analysis has been made for all the areas.

The work here presented achieves to map in detail the loftscape of Milan for the first time, although of course there is the possibility of some developments missing and it should be constantly updated in the future. The database set up provides a sound base of knowledge for any further consideration and thought on the topic.

In regard of the compound Tucidide56 the analysis is partly qualitative, coming from direct observation of the place over a long period and hugely quantitative with data coming from a census I conducted in the area on behalf of the landlord.

Conclusions

In this paper, the topic of conversion of former industrial areas into lofts in the city of Milan has been presented and developed. The topic has been contextualized into the more general phenomenon of conversions, giving a historical background going back to the very beginning of the phenomenon in New York City in the 1960s and then to the industrial transformation of Milan.

Within the frame of the transformation of the industrial areas of Milan, a process already much studied, lofts conversions always found a very little space in the debate, although this paper shows that it is not at all a marginal phenomenon and it deserves at least the same attention that has been given to in other cities.

After a better definition and description of the loftscape of Milan in all its variations, I proceeded with mapping and quantifying the phenomenon of lofts compounds in the city, showing how widespread and diverse it is.

The general description of the phenomenon in Milan is followed by a presentation of a case study of one of the largest converted areas, Tucidide56. The case of Tucidide56 allowed for a better

understanding and explaining of peculiar dynamics occurring in this kind of developments and the problems and opportunities arising from them, which are discussed in the following chapter about conflicts and tensions. In this chapter, lofts and especially lofts compounds are presented as a place of conflict, intending this word both as divergence and encounter. The problems and issues arising in lofts compounds are discussed. Also, the benefits, mainly about the innovations in living and working that this model engendered, are considered. Lofts are a possible useful urban and architectural design tool for the city that changes, thanks to their overall flexibility. In any case, they are a good cause for reflection about the contemporary meaning of land use and the organization of space on the architectural and urban scale.

Design experimentation in a context of cultural division: the case of Ahmedabad

Giovanni Gualdrini¹

¹*Politecnico di Milano, giovanni.gualdrini@mail.polimi.it*

Abstract: The essay “Design experimentation in a context of cultural division” aims at investigating the context of social segregation visible in the city of Ahmedabad (capital of Gujarat, India), caused by the violent strife between Muslim and Hindu communities culminated in the riots of 2002. Social segregation within a city requires a reflection on possible places where design solutions could help in creating meeting spaces. The article tries to understand the reasons for these social frictions, wondering whether urban space has changed as a result of these tensions by answering the need for privacy of the two communities. After studying three areas in different border conditions between Muslims and Hindus, the study identifies in the ‘disputed areas’ places suitable to investigate social and architectural strategies. The work suggests a strategic solution with the aim to transform the contact points from barriers to spaces of relationship between the two communities. Starting from the fragile relationships and issues in the areas of intervention, this project firstly tries to meet the basic needs of the population with an infrastructural proposal. In a second communitarian layer, it suggests to foster the exchange of craft traditions through the construction of meeting spaces such as workshops and cultural centers.

Keywords: religious conflict, disputed borders, meeting spaces

The cultural background: Ahmedabad and the reasons for a disputed territory.

The concept of *border*, as well as the processes and issues related to the political and social divisions of cities, represents an increasingly central theme in the contemporary debate. We live in places that change rapidly, mutate in the form of urban fabric and in the uses that the inhabitants make of public spaces (Zanini, 1997). In particular, some developing country show how processes and forms of integration between different cultures and traditions undermine the paradigms of urban space. The story tells of many *divided cities* (disputed) in which the separation has assumed an emblematic role in the lives of the inhabitants and in the forms of construction (or destruction) of the urban contexts (Calame, Charlesworth, 2012). This text is about a city, Ahmedabad, located in the heart of India, in the state of Gujarat, and latent tensions (Cerruti, et al, 2017), which marked its identity and urban tissue. Faces, at the same time, a decisive question for the urban project: How architecture can intervene in disputed places, in areas marked by tensions linked to religious beliefs and to the different established ethnicities and traditions that often collide?

The journey to discover the Indian Territory and, in particular the context of Ahmedabad, commenced at CEPT University¹; thanks to some exchanges between teachers and students over the last few years, research and project exercises have been carried out to reflect on the conditions of these places and on the answers that architecture can and must provide.

The critical reflection on the nature of the border in the heart of the traditional city of Ahmedabad was born downstream of a research conducted by the author² on the opposition and tensions generated by the coexistence of Hindu and Muslim communities in the city. A complex coexistence, marked by violent riots and tensions, is still readable today in the construction process and in the architectural language of the city (Naipaul, 1978). In particular, the objective of the research is to seize the link between the uses of the urban space and the architectural expressions connected to it. It is an innovative look that no longer puts the conflict in the center of the architecture project but defines and proposes places of sharing, such as flexible pavilions and cultural spaces, devoted to welcome and foster cultural, social and human integration of the involved communities. The innovative challenge of this work focuses on two fundamental aspects: on one side, the profound knowledge of the Indian context, through a precise detection of the reasons that have fueled the conflict and the clash over the years; on the other side, the possibility of using the architectural project as an operative *site-specific* intervention tool. Through punctual projects and flexible organization are proposed fluid spaces, able to adapt to the needs of different cults, traditions and customs. The designed pavilions constitute *simple* spatial devices, from the point of view of materials and involved architectonic forms, but strategically *complex* because they are hosting specific activities, mixing Hindu and Muslim traditions to construct spaces where to rebuilt community relations. The described scenario can be considered an emblematic case study for the definition of a methodology of intervention “sensitive to the territory”, in particular in developing countries, marked by rapid social and urban changes, where the space, abandoning the common rules of the project, is transformed in a flexible design tool, capable to adapt its form to different wishes and able to respect the cyclicity of the time and uses.

Ahmedabad: A politically emblematic city

The city of Ahmedabad appears emblematic for the cyclical tensions that have been generated by the opposition of the Muslim and Hindu communities. From its origins this capital attracted communities of different backgrounds, fascinated by the commercial importance of Ahmedabad within important merchant routes. The possible tensions, which could arise from the contrasts of different cultures, were mitigated by a flexible administrative structure that ensured the individual communities of traders and craftsmen to define their own internal rules, having to respect a few collective norms (Doshi, 2003). The governmental structure of Ahmedabad delineated on an urban scale a federal system within which the different cultures could take part.³

The economic and cultural blossoming of the city coincided with the Mughal Dominion (1573-1758), which went into crisis due to a series of famines and attacks, flowing into the Marathas domain,

¹The context of Ahmedabad is particularly prolific for urban studies because of the location of the CEPT School of Architecture founded in 1962 by B. V. Doshi (graduated Pritzker Prize 2018), center of Excellence in teaching and training of architects and urban planners.

² The present contribution originates from the research work carried out by the author in the master thesis entitled: "Sewing Ahmedabad's Wounds: Design experimentation in a Context of cultural Division", Supervisor: Prof. Giulia Setti (Politecnico di Milano), Co-Supervisor: Prof. Sachin Soni (CEPT University). The thesis discussed in July 2018 describes and interprets the religious and political divisions present in the context of Ahmedabad, both through a historical reconstruction of the main events that have marked its identity, and through a project experimentation that will be summarized below.

³ This administrative system was defined only during the Moghul domain, in which Ahmedabad reached its maximum splendor. It was only during this period that the Hindu community was able to enter the city, gaining an important role at the commercial level.

opening up to an uncertain period characterized by continual looting and crises ⁴ (Yagnik, Sheth, 2011). From 1817, under British rule, Ahmedabad developed a thriving industrial production focused on cotton processing. If in major centres, such as Delhi and Mumbai, this economy was promoted by the British rule, in Ahmedabad the industry was born by investments of wealthy local Indian families, highlighting the independence of individual communities from the central power⁵ (Tripathi, Mehta, 1978).

The independence from the English domain, that enjoyed the entrepreneurs, defined a fertile ground for the first independence movements. Gandhi, who arrived in Ahmedabad in 1915, tried to unify the Indian population against colonial rule, putting in direct relationship entrepreneurial families and working families. The first steps of the nationalist movement focused on some policies aimed at improving the housing and educational conditions of workers' families (Bremar, Shah, 2004).

These initiatives proved successful even after the independence of 1947. The bloody conflicts, following the formation of Pakistan, had much more content outcomes in Ahmedabad, thanks to policies in favor of lower classes mitigating tensions. In the years following independence, the Nehru government focused its policies on the industrialization of the country with the aim to create a modern nation free from the caste divisions of the society (Torri, 2007). With the death of Nehru (1964), many of the secular and socialist ideals of the Congress came into crisis by reaffirming the political role of religious divisions, which were further highlighted by the failure of the government's social policies⁶. The lack of funds for the new non-specialised working masses and the failure of the industries led to the flowing of the majority of workers into the informal market. The breakup of social policies and the rise in unemployment also led to the complete breakdown of the integration processes presented up to that time. Social policies, in fact, ensured a systematic entry into the world of work, allowing a gradual transition from the communitarian original condition to the identification in their working class (Bremar, 2002). In the informal economy, the original community became the only social factor guaranteeing the possibility of employment and, therefore, of livelihood (Weiner, 1978). The socio-economic context led to the decline of secular Nehru's thought, opening up to Hindu nationalism. The Muslim community became the scapegoat, believed to be guilty of the economic and social crisis. This led to the facing of Muslim and Hindu communities in the riots of 1969, 1985, 1992 and, in the most bloody of 2002 (Spodek, 2011).

During these conflicts in Ahmedabad there was a complete crystallization of the social panorama that saw the gradual disappearance of areas in which there was a strong cultural mix, growing up more and more monocultural quarters. If Ahmedabad, in the years following independence, had an urban fabric divided into macro-areas in which resided social classes with different beliefs, following the conclusion of the conflicts, the city was divided sharply into two parts: on one side, the Muslim city consists of four small ghetto towns (Juhapura, Shah Alam, Ramol and Vatva), on the other a large portion of urban fabric is inhabited with a Hindu majority (Mahadevia, Desai, Vyas, 2014).

Types of border in the urban fabric of Ahmedabad

The research carried out in this fragmented and conflictual context focused on the nature of urban forms, to understand whether they reflected the condition of "divided identity" like the ones of Ahmedabad.

In the urban tissue of Ahmedabad, three border areas between Muslim and Hindu communities were chosen to represent emblematic conditions that were different and capable of constituting useful

⁴The passage from the Moghul domain to that Marathas coincided with the transformation of the urban planning. If up to the Moghul domain the Ahmedabad plant was planned according to large radial axes that allowed a rational expansion of the city, during Marathas domination the urban structure underwent an informal drift, leading to an unregulated thickening of the fortified nucleus.

⁵ The Division of labor in the industries followed the social structure, where the different tasks were organized according to the caste of provenance; in addition, the organisation of work did not follow Western taylorization but defined non-competitive rules encouraging individual industries to cooperate.

⁶The return to community ideals was due to the many failures of policies promoted by the Nehru government, such as the failure to eliminate illiteracy or the failure in the redistribution of agricultural and industrial wealth, still in the hands of noble families who were part of the conservative fringe of Congress.

samples to investigate the structure of the conflict along the border. It should be pointed out that the border is not always determined in a physical way, but it often appears more like a mental construction of the inhabitants. These points of passage mark a state of danger that leads inhabitants to avoid boundaries, abandoning these spaces. It is important to understand the nature of the boundary and its identity, based not only on the physical structure of these remarkable points, but also on the use that the inhabitants make of these places and their social composition (Jaffrelot, Gayer, 2012). The three areas chosen for the design experimentation are represented by different characters: one is placed within the new expansion areas on the west of Ahmedabad, a second within the industrial areas and a third within the historical walled nucleus (the so-called Old City).

Figure. 1 Shrinand Nagar Road: A contested border in the areas of new urban sprawl, Ahmedabad. Image by Giovanni Gualdrini.

Among the newly expanding areas, Shrinand Nagar Road was chosen, a road along which there is a clear passage from the Muslim ghetto, the district of Juhapura, to a district – Vejalpur – with predominant Hindu dominance. Juhapura accommodates about 240,000 Muslims, representing about three quarters of the total population of Islamic origin of Ahmedabad⁷. Because of this social conformation this neighborhood has grown as an autonomous city itself (Desai, 2008). The boundaries of these two quarters clearly show a stark division not only by a religious point of view but, above all, present a different economic status of the inhabitants.

These conditions appear clearly in the different residential typologies, in fact, the area with a richer Hindu majority, has high walls of enclosure to protect the gated communities, whilst the Muslim quarter has a more informal structure and recovers traditional forms by placing commercial activities on the front to safeguard the residential areas behind them. (Figure. 1)

The second focus is on the industrial area east to the railway line that has been the scene of the bloodiest riots between the two communities, as inhabited by a heterogeneous working population who has been severely affected by the failure of the cotton mills (Das, Agarwal, Joshi, 2003). This area was chosen to study a neighborhood between Saragpur Bridge and Anil Sarch Road presenting a *Hindu enclave* within a Muslim quarter. The Hindu community strongly shows the need to protect itself from the other through a high enclosure wall and relates to the rest of the city through a single entrance. In correspondence to the main entrance, and along the road axis, there are mainly butcher's shops and commercial activities belonging to the Muslim community. The Hindu community, which traditionally does not consume meat, avoids going along this path preferring alternative routes. (Figure. 2)

⁷ The total population of Ahmedabad is around 7 million inhabitants. (Office of the Registrar General & Census Commissioner, India, Census 2011)

Figure. 2 Saragpur Bridge and Anil Sarch Road: A boundary in industrial areas, Ahmedabad. Image by Giovanni Gualdrini.

The historical nucleus of Ahmedabad: a sedimented system of cultural cohesion

It seemed fundamental, to understand the reasons of separation and conflict, to start from the heart of the Old City of Ahmedabad, specifically from the study of a road axis, Dariyapur Rd, in the fortified historical nucleus. Here in addition to the characters described in the previous two cases, the transition point between the two communities is controlled by a police station. The district of Dariyapur was chosen as the key place of the research and design experimentation because, since the times of independence, it was one of the areas mostly affected by the riots, housing Hindu and Muslim communities both employed in cotton Mills (Varshney, 2002). (Figure 3)

In addition to these aspects, Ahmedabad's historical nucleus, unlike the other areas of the city, is emblematic as it encompasses urban forms and settlement strategies that are useful for two different communities to coexist. The high density⁸ and heterogeneous population have led to the definition of a complex settlement organization that can show different urban layouts taken in more recent urban extensions.

The original structure of the walled nucleus of the city was organized according to a radial road system useful for the gradual settlement of new communities.

The structure of the urban tissue followed a clear hierarchical order passing from wide streets to increasingly narrow roads, where there were placed separate activities. This simple criterion has been instrumental in setting up a heterogeneous population.

From market areas there was access to residential areas showing a gradual transition between public spaces and private areas. Looking at the distribution of the commercial and religious activities of the two communities within the district of Dariyapur, it is possible to catch a clear separation of the two groups and different modalities of aggregation of the corresponding public spaces. If the collective areas in the Muslim quarter orbit around the mosque, the Hindu communities, differently, clearly divide the intercommunity meeting places (the markets) from those belonging to the individual communities. Unlike the mosque, the Hindu temple is closely linked to the inhabitants of the single *enclave* (Jain, 1975), not constituting an institutional collective center⁹.

⁸ Within the historical nucleus one reaches a population density of 800 inhabitants per square hectare. (Ministry of Foreign Affairs. Ministry of Urban Development and Indian French Embassy, 2001)

⁹ Inside, the mosque hosts more complex functions, such as Koranic schools, and plays an important role at the urban scale.

Fig. 3 The Dariyapur Road police station: a controlled border, Ahmedabad. Image by Giovanni Gualdrini.

On the contrary, the main mosque stands in the middle of the Muslim ward at the intersection of the road axes. The *enclaves* of the individual Muslim communities, unlike the Hindu settlements, do not have a mosque inside and are distributed along the axes without defining a clear distinction between residential and commercial areas¹⁰.

Analyzing the individual neighborhoods (Hindu and Muslim) it is visible how the places of worship are able to build the urban form of the settlement. (Figure 4)

Studying the structure of the road network there is a different organization of the two neighborhoods: the wards with a Hindu dominance usually have the main route placed along the perimeter of the settlement, while, on the contrary, areas with Muslim majority gravitate around a center connected with radial axes to the outer perimeter. This organization is further underlined by the different positioning of the commercial areas. If the perimeter of Hindu settlements was further marked by the presence of commercial activities, differently Muslim quarters have shops in the central area and near the entrances. Hindu settlements then concentrate the public activities along the perimeter protecting within the *enclaves* the single communities (Raman, 2012).

The visible differences in the Muslim and Hindu quarters are motivated by the historical-political development of the city. Muslim wards originally formed a self-standing area belonging to prominent personalities of which the sultan was surrounded. These areas, called *Puras*, constituted independent settlements, presenting an orthogonal urban organization according to two central axes, at which intersection were placed institutional buildings as mosques and noble palaces. The Hindu community settled, within the walled nucleus of Ahmedabad, only during the Mughal domination. Because of the constant tensions with the Islamic community (Theodore, 1866), Hindu neighborhoods were structured according to more introvert systems trying to protect the residential areas.

Enclaves belonging to individual communities, called *Pol* in *Gujarati*, constitute the basic element of the urban structure. The organization of these residential units appears common in both the Muslim and Hindu communities showing the same joints. The *Pol* has a dense perimeter defined by blind facades or commercial activities. Within it, the road network follows a hierarchical order by gradually giving access to more intimate places. Through a sequence of interior spaces to the pole, it is possible to access the temple and the common square, called *Chowk*, around which the community life orbits.

¹⁰ The different locations of commercial establishments within the neighbourhood can be justified by the activities traditionally linked to the different communities; the Muslim ones were specialised in handicraft activities, which allowed a mixed use of the neighborhood where the shop was often associated with the dwelling. On the contrary, the Hindu communities were specialized in the sale and for this reason they preferred a clearest separation between store and dwelling.

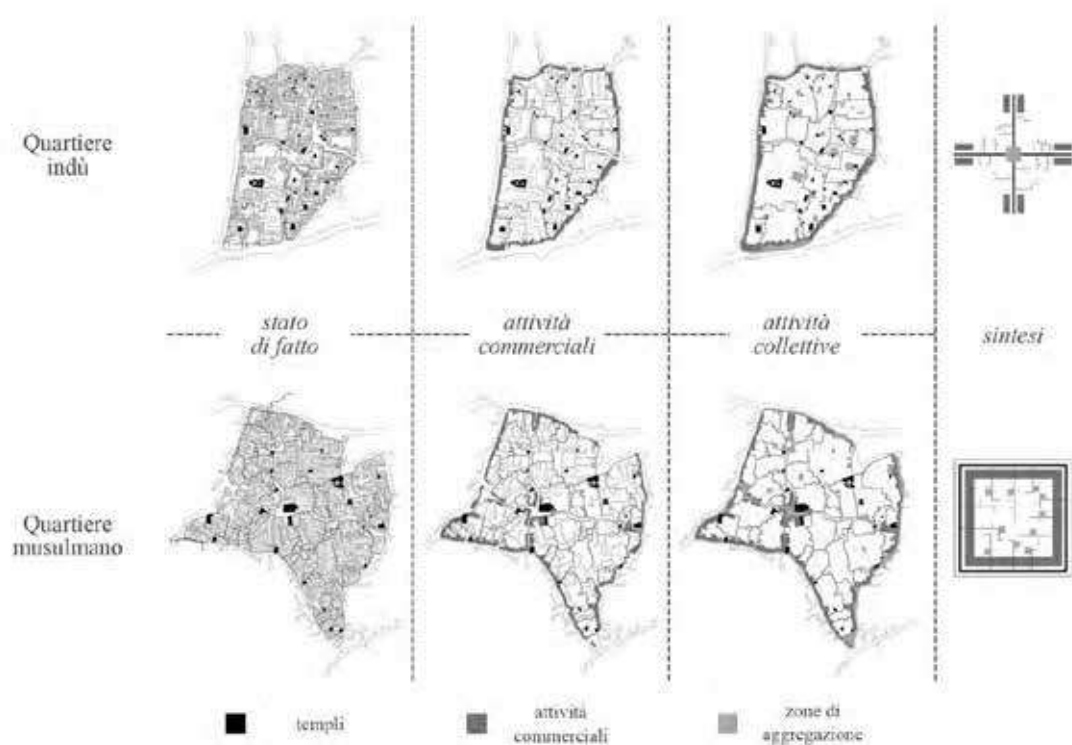

Figure. 4 differences in the structure of the Muslim and Hindu quarters. Image by Giovanni Gualdrini.

The structure of the border: the example of Dariyapur Road

Observing the crossing point present on *Dariyapur Road*, the activities are repeated on both road fronts; the points for *rickshaw's* drivers are at a short distance on both sides of the border and drivers follow specific routes to avoid crossing areas belonging to the other religious community.

An interesting feature in the border of *Dariyapur Road* is the specialization of the two communities in separate activities. In Ahmedabad, as in other Indian contexts, it is common to find ways in which same goods are produced and sold. This condition shows the specialization of the communities in the same profession (Davis, 2006). The Hindu community of *Dariyapur* owns most of the shops and laboratories specializing in the sale and production of drums such as *Dhol* and *Tabla*, percussion instruments used in both Muslim and Hindu religious processions. On the other hand in the Muslim ward there is a strong specialization in weaving and sewing of fabrics and clothes. Until 90s, *Daryapur* constituted an important production center for *Khol* and *Chindi*. These fabrics, produced from the waste of cotton mills, represented a cheap product, also accessible by poor classes.

The present specialization allows to define a channel within which the two communities manage to interact. In fact, the Community division of labour allows Hindu groups to frequent the Muslim quarter to buy colorful fabrics and prints, crafts in which the Islamic communities are specialized. In turn, the Muslim communities go to the Hindu quarters to buy drums to be used during the religious anniversaries (Jain, 2011).

In addition to these relationships of pure commercial interdependence, the growing process of urbanization that the Indian metropolises are experiencing contributes to the creation of new places in which communities of different origins and religions interact. Public transport stops and some infrastructures, such as drinking water delivery points, become a meeting point for communities, constituting fundamental urban nodes (Krishna, et al 2014).

Experimental strategies in Cultural division contexts: A flexible approach

The design in disputed areas underlines a basic question: what design tools can operate in a context of such strong social segregation as that represented in Indian society? The different types of relationships in the area under study have been chosen as key elements on which to define a possible project strategy capable to lead to the integration between the two communities.

Five areas located at different points along the border have been identified along the *Dariyapur* Road. In the Muslim area, east of the police station, which defines its margin, lies the Islamic elementary School of *Daryapur* characterized by a large void and a courtyard now used as a playground. The other four areas consist in residual spaces, urban vacuums, of small dimensions, mainly occupied by buildings in a state of ruin. Thanks to the presence of these empty spaces, which are inserted on both sides of the boundary, the project proposes a unitary system, able to establish reciprocal relations between these places through the presence of activities of support to the school and the population of the two communities.

The project promotes and studies the possibility to define places of encounter and sharing capable of intercepting collective interests, favoring the creation of a dialogue and integration process. The research proposes an approach defined in different strategic levels with the aim to define a sequence of relation spaces similar to those observed and described in Ahmedabad. The design strategy work on different layers like an infrastructural level and another more connected with the local community activities. This last one, in turn, is divided in different temporal phases to better interact with the different users of the place. (Figure 5)

From an infrastructural point of view, the project develops a system able to offer essential water resources for the daily life of the two communities. With the aim of responding to the arid climate and the difficulty to access public drinkable water¹¹, the five pavilions include the function to filter and make the rain water drinkable¹². The project ideally recovers the traditional place of the *Puyau* 'Water hall'¹³ (*parab* in Gujarati), imagining a system that makes drinkable water usable in the two pavilions adjacent to the border in order to define a new collective centrality.

On the basis of the commercial and functional relationships, caused by the division of work by the caste of belonging, the pavilions welcome open craft laboratories in which they will be taught and promoted activities typical of both Islamic and Hindus community, defining new cultural exchange points.

The design scenario foresees that the new introduced facilities interact with the elementary School of *Daryapur*, offering laboratorial spaces linked to the context and to the different needs of the children. In particular, in the Muslim ward, the proposed pavilion hosts a workshop for music activities, while in the Hindu dominance area are located dyeing laboratories and fabrics weaving. Inside the pavilion, which stands as the terminal of the system in the Hindu ward, is designed a Theatre as main space of relation for the communities. The proposed theatrical activity wants to resume the idea behind the places created in the industrial quarters during the Gandhian independence riots, which sought to unify the entire working population without distinction of creed or caste.

(Self Employed Woman Association)¹⁴ which played an essential role in offering professional alternatives based on crafts to workers affected by the crisis of industrial production (Bhatt, 2006).

The program foreseen in the project combines different activities adapting to the needs of the inhabitants that are changing during the day: the school laboratories, linked to the handicraft, are

¹¹Only 30% of the population has direct access, from home, to sources of drinking water, while the rest of the inhabitants often have to cover, on foot, distances higher than the kilometer for the water supply (Office of the Registrar General & Census Commissioner, India, Census 2011).

¹² The infrastructural character of the pavilions is evident in the recycling of meteoric waters. This system was taken over by the project of the Mass Design Group for the Gheskio Coleric Centre (<https://massdesigngroup.org/work/design/gheskio-cholera-treatment-center>).

¹³ The ' *Puyau* water hall ', *parab* in Gujarati, were sources of drinking water built by traders to offer refreshment to travellers. The same fountains had an important value in the city and were built in memory of the ancestors of the family.

¹⁴ One of the few associations that tried to define common lines between the different communities was the Self Employed Association Women Association (SEWA). This group formed by the detachment of some members from the Textile Labour Association (TLA), focused its efforts on improving women's working conditions.

The SEWA brought together communities of different religions and castes, such as the Muslim and Hindu, trying to provide tools to the different communities to be more palatable in the world of work. These initiatives indirectly created the pretext for bringing about inter-community relations.

transformed into places of vocational training, while the pavilions, like the Theatre and the musical one, become studio classrooms and neighborhood libraries.

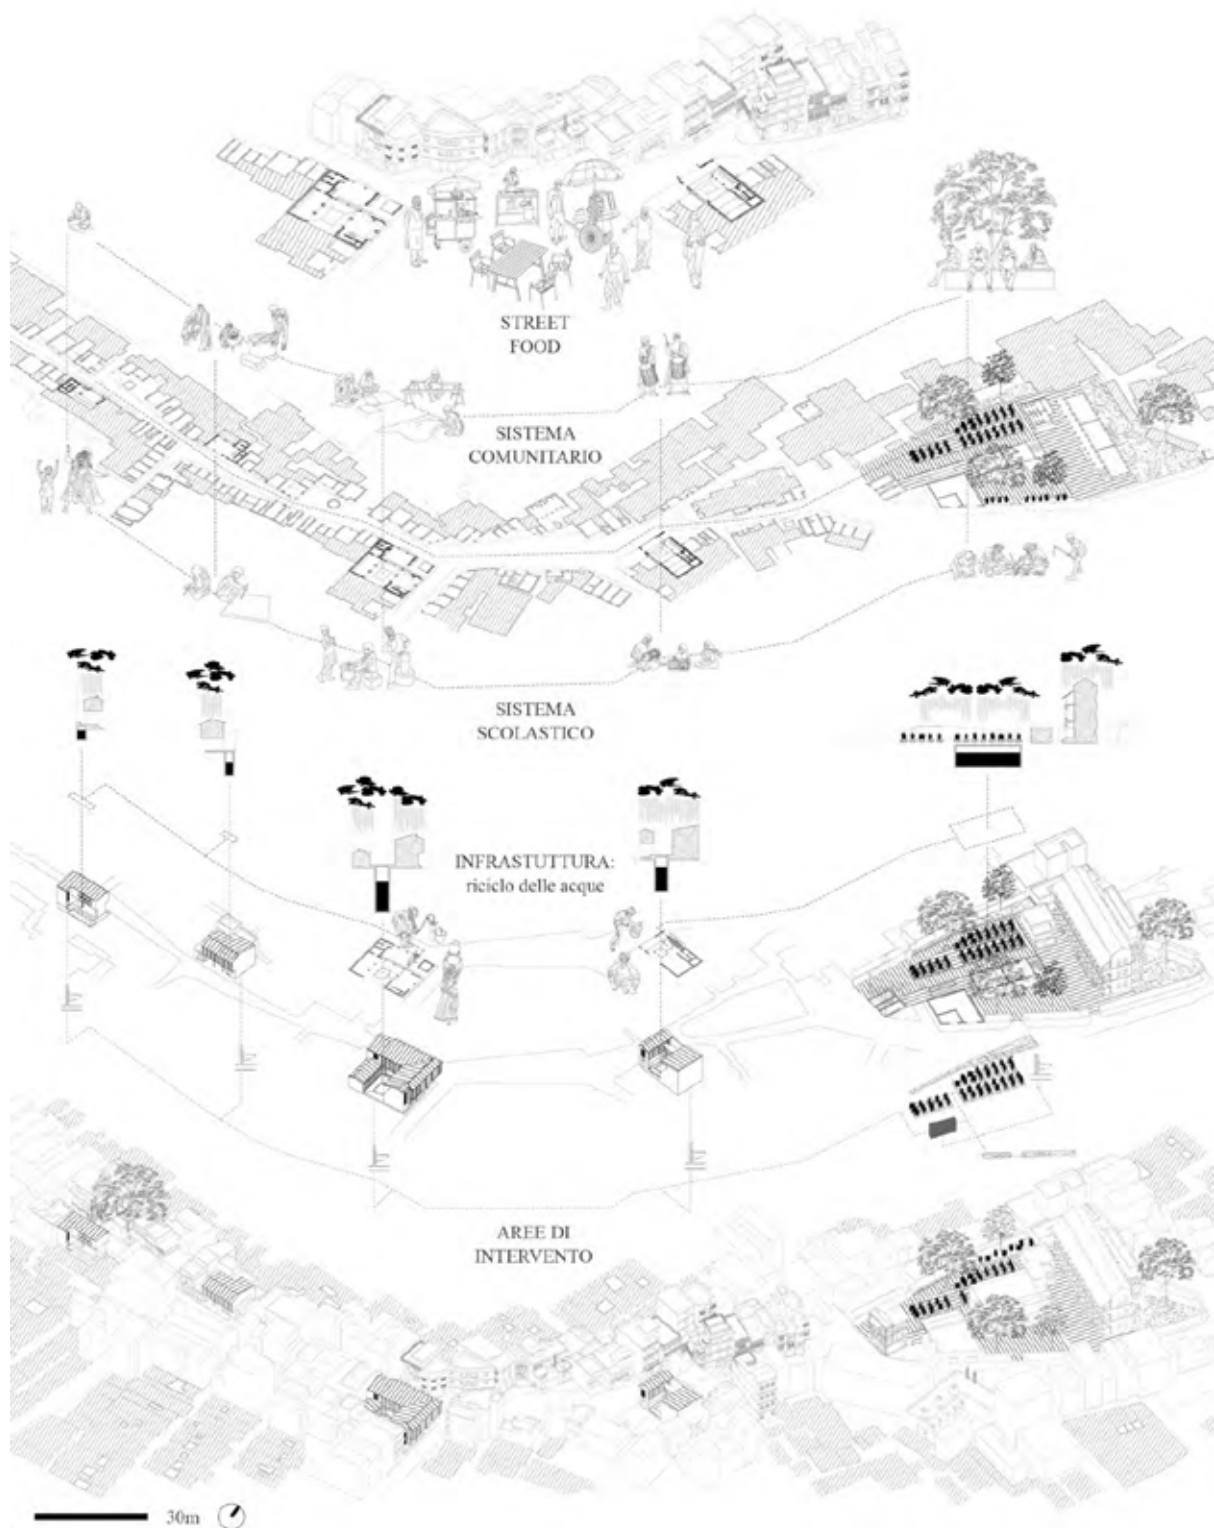

Figure. 5 Social strategies and architectural choices to transform the disputed boundaries into meeting places. Image by Giovanni Gualdrini.

The stratification of several activities within a single architectural and urban space, as envisaged in this design experimentation, is a typical characteristic of traditional Indian public spaces changing their scopes during the day. For these reasons the project works on different temporal phases: at different times, correspond different activities and uses.

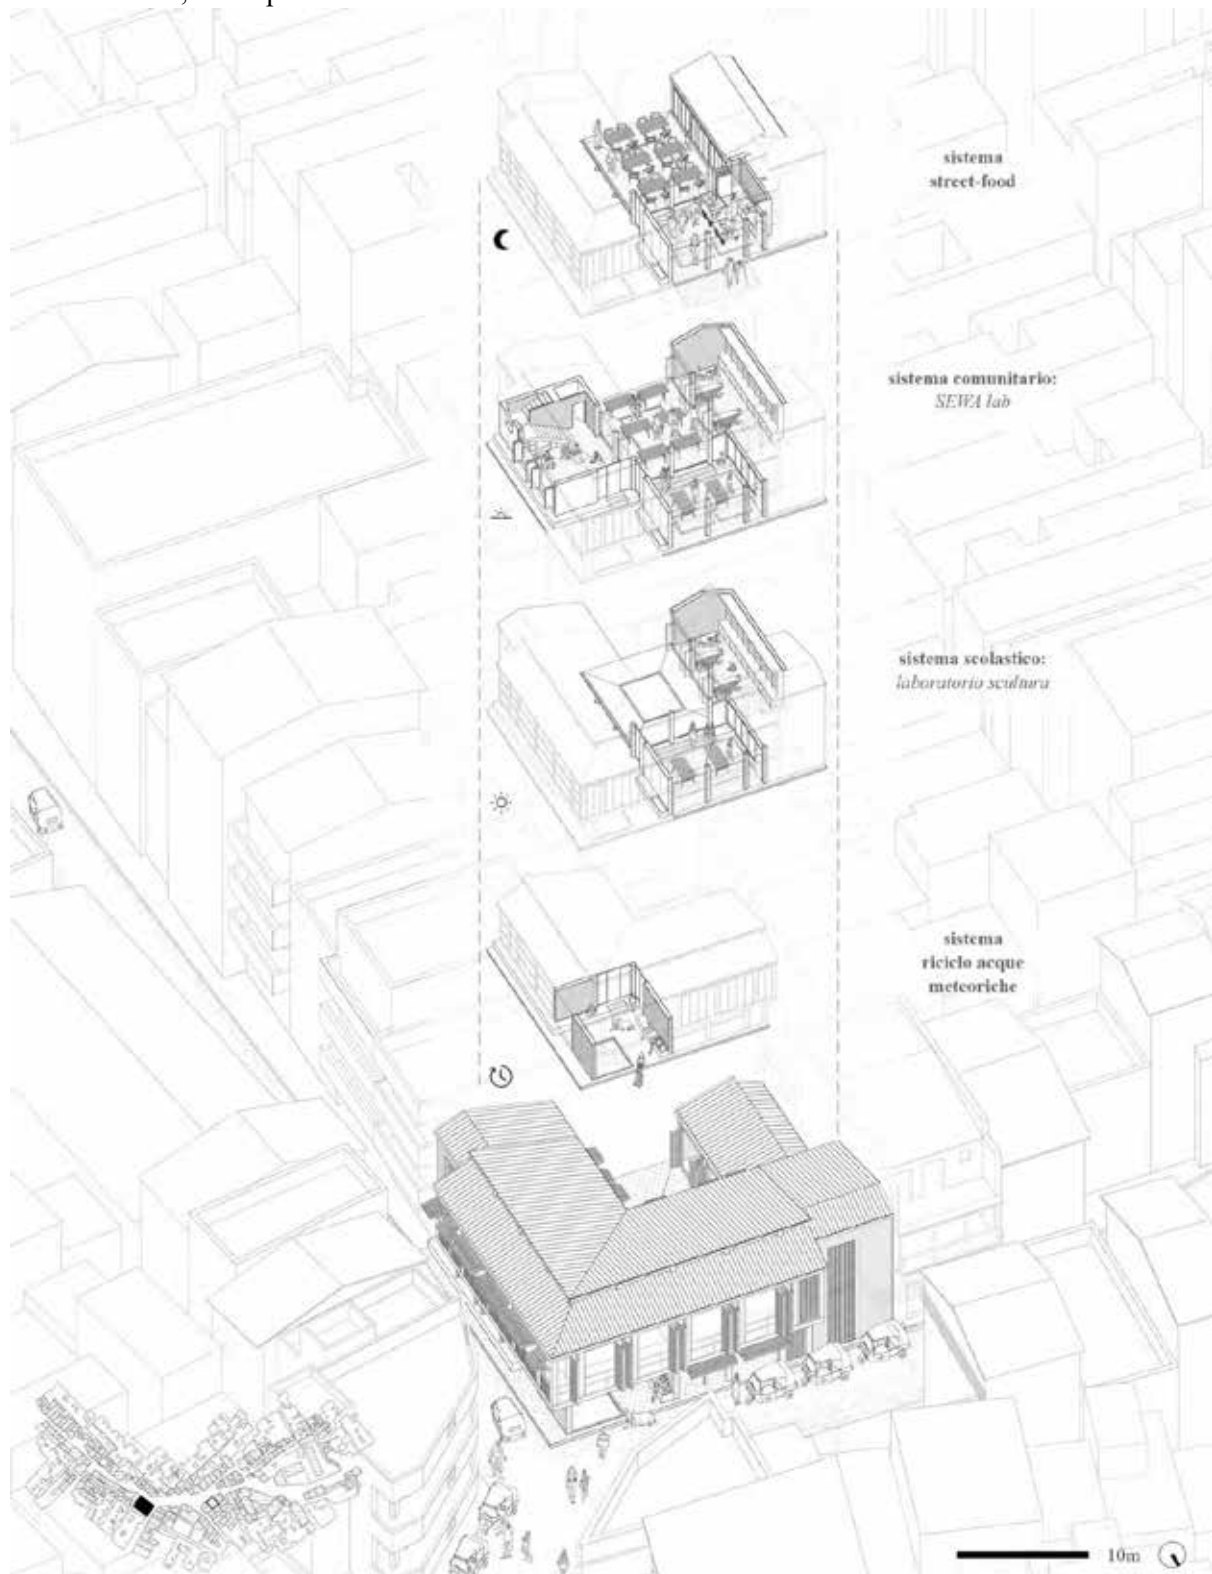

Figure. 6 Design scenarios: The Weaving pavilion and its transformations during the course of the day. Image by Giovanni Gualdrini.

When the elementary school close the project enters in the living of its function, the pavilions are open to the whole community offering spaces for the vocational and cultural training. The introduction of training spaces is inspired by the Gandhian Association SEWA.

As a matter of fact, observing *Maneck Chowk* during the course of the day, the commercial and religious heart of the historical nucleus of Ahmedabad, are visible several changes of use over a single day. During the early hours of the morning this space is a place of pasture and foraging of the sacred cows of the city. With the passing of the day, business activities gradually open and the central area welcomes parking spaces. The clearest and fascinating change takes place during the evening hours: on the fronts bordering of the square there are restaurants that transform the central area into an open-air restaurant in the mode of a street-food. Overuse is a fundamental feature of the Indian public space, managing to intercept the most diverse categories of users. Similarly to *Maneck Chowk*, the pavilions designed along the *Dariyapur* border open on the street front, welcoming informal dining spaces, to define places of sharing for the two communities.

Starting from the boundary and the relations present in the Territory: functional flexibility and transformation of the architectural structure

The continuous change of activity within the pavilions corresponds to a transformation of the planimetric organization, made possible thanks to the use of mobile panels. The flexibility of public (and private) space has been revived by traditional merchant houses, called *haveli*, which have an internal organization capable of adapting to different functions.

The traditional houses are articulated around a central patio, called *Chowk* (which can be traced back to the idea of a common patio), which overlook 'functional' spaces such as the kitchen, the votive chapel and the water room. Depending on the needs, the main domestic activities can expand within the *chowk*, which can become a place of prayer, a dining room or a reception space (Ray, 2008).

The project of the five pavilions incorporates this solution, articulating the ground floor in a central patio around which are overlooking the main spaces that can expand their activities in the same *chowk* or in the street space, virtual extension of domestic Indian public space. (Figure 6)

The extension on the road extremes the concept of flexibility presented in the traditional house, in fact, the traditional central patio, in fact, divides the house into two blocks presenting a more private and a more public area adjacent to the road, consisting of a portico called *otla*. The adjoining domestic spaces to this portico are places of representation, filter spaces to better protect the innermost parts of the house. As has emerged in the description of the structure of the city, the urban fabric, to better accommodate populations of different origins, determines net transitions defining areas clearly belonging to the individual communities.

The dwelling, placed in a semi-public context, is the only element in antithesis compared to this unwritten rule by defining a labile transition with the road where the public and domestic space merge. The structure of the pavilions incorporates the relationship between the atrium and the public space, presenting a threshold-diaphragm adjacent to the road able to completely transform the relationship between the patio itself and the exterior. Thanks to this device the pavilion can open completely to the community guaranteeing a complete use of the inner court. (Figure 7)

The project strategies described in this text are the result of a thorough research on the territory of Ahmedabad, aimed at understanding the wounds and imbalances that led to the conflict between the Muslim and Hindu communities (Howe, 2011). A careful study of the conflict must include in itself both the general causes that have led at national level to the escalation of tensions, and the local motivations that have moved the individual city communities. Only through the knowledge of these factors the project can be addressed to such a divided context, giving up the ambition to immediately resolve a problem, but opening up to a process destined to take time and breath.

The design proposal – albeit partially utopian – wishes to indicate a possible vision of the architectural project which is able to emphasize the need to operate for minute interventions in the disputed places of the city of Ahmedabad. If in large Asian metropolises we often see extensive and impose urban interventions, which cause the displacement of many inhabitants (Desai, 2011), the proposed intervention strategy shows how punctual interventions on the territory are the most careful way towards the birth of an interreligious identity, by grabbing how a pavilion or the construction of a simple infrastructure can give a new birth to forgotten places.

Resisting gentrification. Socio-spatial dynamics of three work places in Brussels.

Verena Lenna¹, Luis Antonio Martin Sanchez²

¹IUAV+ KU Leuven, verenalenna@hotmail.com

²Politecnico di Torino, luis.martin8911@gmail.com

Abstract: An association working around the production of a biannual parade. A polyvalent organisation operating at the crossroads of culture and economy. A cooperative for entrepreneurs and precarious workers. The three of them being situated in some of the poorest neighbourhoods of Brussels and implying the renovation of former productive sheds. Their contribution looks crucial to bring back work in the city and in those areas that have been mostly affected by the deindustrialization processes started by the end of the 60s. While in the long term they may engender a gentrification process, the three of them are aware of this risk. Despite not defining themselves as social operators, they nevertheless could allow to resist it, by embedding in the local urban fabric, reshaping and renewing urbanity, although in very different ways and as part of very different strategies, in the case here observed mostly centred on redefining the relationship between work and life. Based on a research-by-design exercise, the paper will explore under which conditions new forms of working, a new approach to productivity and the related spatial dynamics could counterbalance potential gentrifying effects related to the improvement of problematic parts of the city.

Keywords: work-and-life, gentrification, governance, urban ecosystems

Introduction

The contents of this paper are based on the exercise of design developed in occasion of the workshop *Designing Brussels Ecosystems*, organised by Metrolab Brussels¹. The workshop explored the concept of urban ecosystem, looking at the condition of the Brussels Capital Region (BCR) through four lenses: agriculture, density, work and circularity. Together with other participants, we have been involved in the group dealing with topic of work². Three case studies were proposed, supposedly juxtaposed to the concept of third places. Purpose of the

¹ Metrolab Brussels is a transdisciplinary and inter-university laboratory for applied and critical urban research, funded by the Brussels Capital Region through the ERDF program 2014-2020. The workshop was held between the 28th of January and the 8th of February 2019. The results and reflections of the workshop will be published by Metrolab by the end 2019.

² We deem that exercise meaningful in relation to the topic of the urban tensions dealt with in the occasion of this special session. It is rather a beginning of potential future researches on how a new approach to the life-work balance and productivity can affect contemporary urban ecosystems and the related tensions. Given the short amount of time we had, it was not possible to enlarge our theoretical understanding of the themes; in that sense, the contents of this paper would need further inquiries. We rather used design as an envisioning practice, researching on the local socio-spatial potentials and prospecting how the tension between processes

two weeks was to explore the related urban ecosystems, in either descriptive or designerly terms. Three examples of urban renovation concerning different vacant spaces of production, transformed –at different stages- by three different actors: Recyclart, an organisation assembling cultural and creative production with work based insertion programs; Zinneke, a centre of artistic production, operating at the scale of the city; Smart LaVallée, a cooperative having the mission to support on many different levels the small scale entrepreneurial activities, free-lance and other precarious working conditions.

Being situated in different spots along the post-industrial corridor of Brussels, where the concentrations of poverty, unemployment and of the youngest and immigrant individuals coincide, these cases have the potential to engender gentrification processes. On the other hand, the kind of urban ecologies possibly generated by these initiatives could in fact contribute to resist gentrification, under specific conditions that the design exercise allowed to explore in projective terms. How could a project of renovation improve the living conditions of a neighbourhood, at the same time resisting gentrification and the collateral expulsion and privatisation processes? This paper would like to reflect on this sort of tension, thus further elaborating on the design-based scenarios developed in occasion of the workshop. A tension ultimately solvable –we argue- at the level of governance and ownership approach of the concerned assets, in relation to which design is called to play a crucial role.

We will first describe the three cases into detail. For each of them we identified a core concept, which seem to be coherently at work both at a spatial and at an operational level. But how do they actually relate to the concept of third places? To question that framework, in relation to the workshop purposes and starting assumptions, will allow to critically seize their pertinence as case studies and their *modus operandi*, thus identifying the aspects around which to intervene as designers. Moving from the architectural to the urban scale, in all the three cases the leading actors are aware of their spatial and urban impact of the activities they organise. In one case, Zinneke, they have an explicit agenda concerning the neighbourhood where the building is situated, and that agenda concerns in fact the very governance and use of the building. In other words, Zinneke seems interested in what we could describe as an ecosystemic approach to the organisation of their environment and their activities, which goes beyond the walls of the building and involves the larger ecology in which they embed. It is by referring to this case that our group decided to develop a design proposal, given the clarity and pertinence of their approach in relation to the workshop purposes. By analysing the local potentials -morphology, existing programs and actors, vacancies, unexplored synergies and other local and non-local potentials-, we imagined how temporary uses and long-term strategies could result in a lively urban environment, sustained by the engagement of the local communities around a different approach to work and productivity, from the individual to the collective level.

The thesis we suggest here, further elaborating on the results of our designerly explorations, is that these urban renovations interventions could in fact represent an occasion to resist gentrification only when triggering the appropriation by the locals and recognizing their role in their way of functioning. In this perspective, the morphology of the building and surrounding neighbourhood would have to serve the interweaving of the pre-existent and the new, the community based and the regional scales, the vacant and the occupied, the individual and the collective. In the cases here observed, possibly happening because of a different approach to the work-life balance, performed in between the individual and the collective. This would also mean the implementation of a different approach to the use of resources -in this case vacant plots and buildings and pre-existing local initiatives- based on patterns of exchange, coexistence and collaboration, care and responsibility. Not necessarily without conflicts. If one of the consequences of the dispossession of the city and the expulsions provoked by increasing privatisations is the loss of urbanity (Sassen, 2015), the urban ecosystems designed during the Metrolab workshop allow to imagine how urbanity could be in fact recreated and reclaimed: on the

of improvement and expulsion could be dealt with. So in fact, the paper brings a research by design-based contribution to the theme of the Special Session.

grounds of a community based approach to work and productivity, reinventing the individual within the collective realm.

A magnet, a bubble, a project of doors.

The three initiatives described in the following lines are expression of a different approach to work and work conditions, experimenting around emancipation, the expression of the self and new forms of protection. The spaces they shape reflect and make possible those attitudes.

Recyclart is a polyvalent centre, assembling cultural and artistic production, an atelier for the production of wood and metal artefacts called Fabrik and a restaurant. The cultural centre was established in 1997, by occupying the railway station La Chappelle, one of the secondary railway stations of Brussels, rarely used. For twenty years the site has hosted a variety of cultural programs and artistic projects, developed in collaboration with the Region. As a result, this neglected part of the city could enjoy a vibrant atmosphere, which contributed to keep under control episodes of criminality, while offering some form of support to fragile individuals relying on the solidarity and sympathy of the artists and organisers. As explained during the visit of the site, today the whole area surrounding the railways shows the signs of gentrification and the land values have risen. Not far from La Chappelle Station, Bar Recyclart is a restaurant where fragile and problematic individuals –because of their income, life path, education, health issues, etc- have the chance to take part to programs of work based insertion. Work, in other words as the first step towards their emancipation. Similar programs are also hosted at Fabrik, another initiative of Recyclart. Situated not very far from the station and the restaurant, people there can learn how to craft metal and wood, realising commissioned objects or their own creations. After more than twenty years of successful artistic and cultural production, at the beginning of 2018, SNCB and Infrabel, the companies responsible for the functioning and the management of the station, announce Recyclart will have to quit the place, for safety issues related to the renovation works of La Chappelle. After the mobilisation of civil society and the intervention of a few politicians, a new site has been identified in the municipality of Molenbeek, big enough to concentrate the different parts of the Recyclart program: a former typography in Rue de Manchester, composed by a few buildings disposed around a courtyard. Both the morphology of the building and the new location will redefine the conditions of accessibility, both in terms of space and of public. The capacity of Recyclart to work as a magnet, by attracting people from any part of the city, will be tested in the new location: a centre of artistic production and emancipation operating in a municipality severely affected by the end of the industrial productivity, for many reasons stigmatised.

Figure 1. The new site of Recyclart, in the dense urban fabric of Molenbeek.

The establishment of LaVallée as a co-working space in Brussels has been possible thanks to the initiative of Smart, one of the biggest cooperatives in Europe providing not only a co-working space, but also training programs, juridical, and financial assistance to entrepreneurs of the creative industry. While maintaining friendly relationships with the neighbourhood, LaVallée is introvert, working as a bubble of protection but also encounter and exchange, offering spaces and an the possibility of an alternative welfare to flexible and precarious workers, otherwise often working in isolation. The building occupied by LaVallée is a former industrial laundry whose spaces are distributed around two main courtyards. Different kinds of spaces foster daily interactions and encounter: the kitchen, relaxing sofas for a coffee and a break, courtyards, terraces. The atmospheres are often domestic, mixed with different kinds of working spaces: from the small individual rooms to the larger co-working spaces. All of them customised and appropriated according to the needs of the designers and artists. Other bigger spaces are used to organise events, by the workers of LaVallée as well as by external users. Among others, the European Union, their delegates and politicians often enjoying the rawness of post-industrial, non-formal spaces. The assemblage of different publics and situations triggers the emergence of collaborations and allows to share not only the costs, but also the expertise.

Figure 2. Space and spatial appropriations at LaVallée.

Zinneke asbl is an organisation working mostly around the artistic production of the biennial Zinneke Parade, established in 2000, as part of the initiatives organised for Brussels as European Capital of Culture. In addition to that however Zinneke hosts other projects, such as *Atelier Metal*, for the training of those interested in the realisation of metal artefacts, especially large scale objects. Or *Matos*, for the recollection and the recycling of waste materials. Zinneke is an initiative celebrating solidarity and cultural diversity and triggers the use of the public space for the expression of collective and individual selves. The Parade is made of more or less twenty performances, interpreting a main theme and realised by artists and creatives in collaboration with local actors. Each performance is called *zinnode*. The activities and practices leading to the realisation of the *zinnodes* are realised occupying the spaces available in the concerned neighbourhoods and involving the local actors. In this way, different parts of the city are re-activated though all the whole process of realisation. After a long time of nomadism, during which Zinneke occupied different available buildings in the city, the organisation finally managed to occupy a former imprimerie in the Masui neighbourhood, in Schaerbeek, in the framework of a

FEDER³ project. At present Zinneke has the project to transform the imprimerie in a polyvalent space, hosting not only the activities related to the production of the Parade and the mentioned other initiatives, but also any kind of event or regular program organised by any other actor in the neighbourhood or in the Region. The transformation of the building is conceived as a pilot project under many respects: the renovation should make possible the reuse and recycling of existing materials and structures, possibly in collaboration with other initiatives in the city, while respecting the existing structures. But most importantly, the re-organisation of the spaces should on the one hand increase the accessibility of the building, allowing other actors in the neighbourhood to use it; related to that, on the other hand, it should make possible the coexistence of different practices, with their compatible and incompatible aspects. The articulation of the needs of different actors within the same building is a matter of rhythms and choreographies, in time and space and requires what at Zinneke has been defined as a project of doors.

Figure 3. Section of the former imprimerie, where Zinneke is located.

Individuals, beyond individualism: emancipatory approaches to work.

Concerning our group, purpose of the workshop was to question the notion of third place in relation to work dynamics. Taking advantage of the reflexive opportunity of this paper, we believe it would be first necessary to frame the meaningfulness of the proposed cases. How do the three cases position themselves in a global city such as Brussels? What do they represent in relation to the work market characterised by a polarisation of highly skilled and low skilled? The three situations here considered at present do not represent neither classic, nor prevailing work domains. Nevertheless, they could indeed have the potential to address a variety of individuals, from the highly educated or strongly experienced, ready to take the risk of an entrepreneurial condition. To the low skilled or fragile individuals, to which the opportunities of a manual job or service related position could look more appealing to increase their capacities and start new work paths. Though at this moment these initiatives may be still marginal, they indeed represent an innovative approach to work, not very far from that in

³ Fonds européen de développement régional

fact presented at the design biennale of Saint Etienne, in 2017, *Working Promesse – Les Mutations du travail*. What was showcased was the possibility for individuals to reclaim themselves through their work activities, thus moving from a condition of dispossession of the self (Castel & Haroche, 2001) and hyper-fragmentation of their work capacities –the atomisation of work (Berardi, 2004) – to a condition where they reclaim authorship and try to conquer back their capacities of doing, meaningfully. The mentality of the do-it-by –yourself, as a result of the insufficiency of what is being provided –by both publicly and privately organised services, welfare and administrations- but also as an occasion of empowerment and joyful experiencing of life and leisure⁴. At the same time, increasingly often the re-appropriation of the self happens through the collaboration and cooperation with others. Group works, platforms, cooperatives, different forms of co-working promote encounter and collaboration as ways of overcoming isolation and learning from other people experiences. This is for example part of the mission of Smart, as an organisation looking to promote alternative structures of welfare⁵, but also interested in offering the spaces and the situations required for such encounters, for the building of solidarity networks. And this brings us to discuss the spatial conditions supporting such reconceptualization of work, as something we were supposed to directly address in the framework of the Metrolab workshop.

While the workshop proposed to question the notion of third places, the three cases rather suggest a reflection on the work-life balance, *potentially* related to the concept of third places, evoking the relational conditions of third places, but not fully coinciding with them. Third places have been defined in fact as those places where we do not either live, nor work, but where we rather can have leisure activities, make new acquaintances, where conversation and verbal and non-verbal exchanges are a main activity (Oldenburg, 1989). Examples of third places are churches and universities, restaurants, bars and coffee- shops, community centres, barbers, malls and markets, among many others. What may be confusing is the fact that indeed third places are increasingly being used to perform work activities –as shown in Saint Etienne- and they could indeed serve the increasing need for flexibility of people’s daily schedules, as well as the need for networking and inspiration, in some cases. Blurring the distinction between leisure time and work time, as many scholars pointed out in terms of labour exploitation, affecting in particular the workers of the cultural sector and creative industries. While this issue cannot be properly treated in the space of this paper, we simply point out the difficulty to fully recognise the three cases identified by the workshop as examples of third places. Especially when observed under the lens of the people who work there –not the clients or the occasional visitors. Recyclart is indeed also a restaurant and a cultural centre, but not for the employees hired as part of work based insertion programs: the way they perform their work in such a place is not very different than in other restaurant. Similarly, for the individuals crafting metal and wood objects at Fabrik, the space in which they work is an atelier, quite traditionally organised, where they are supposed to go every day, for a given number of hours, to perform what can still be recognised as work, not leisure, though leaving space to their creativity and interpretation.

On the other hand, what emerged as a common element in the three case is an emancipatory approach to work, though realised in different ways. Specifically, we observed a common attention to the work-life balance, not necessarily meant in term of rhythm, between the working hours and the time for the private life. Rather meant as redefinition of what work could mean in the life strategy of an individual –as a person and later collectively: in terms of self-expression, of emancipation, of claiming back opportunities and the capacity to contribute to the making of the world. In other words: not work as opposed to life, rather work as life.

And indeed such an approach could lead to the emergence of a third dimension: in between more mono-oriented, traditional working and living environments, in between the need for sheer productivity and the need

⁴ However, that is not always the case and a difference should be stressed between the engagement and urgency for gardening and the efforts made to claim back a housing unit or a squatting initiative.

⁵ Before the establishment of the welfare state regimes, cooperatives allowed workers to build solidarities and to organise primordial forms of welfare.

for the re-appropriation of the self. In between the competitiveness of the market and the need of self-expression. In the case of LaVallée for example, the appropriation of the space and of the work environment is somehow paramount and facilities, the supports and spaces are provided on purpose in a neutral condition, so that the new users could create their ideal setting. At Zinneke, artists and creatives have the possibility to reinterpret and recycle materials, while combining competences and ideas. Similarly, in the case of Fabrik, where in addition to what asked by the clients –mostly small-scale productions, which leave a lot of space to interpretation-, workers are invited to experiment new creations. At LaVallée and Zinneke a sense of a domestic environment often characterizes these working spaces: recreated by the very concerned individuals, looking for a comfortable atmosphere, fostering cooperation and exchange, allowing to reach the state of mind that leads to new ideas and innovations. Which is why a couple of sofas are just behind a cluster of desks and spaces are sometimes left unstructured, not furnished. Only basic supports are being provided, to use Habraken's words (Habraken, 1972). Something similar will probably happen in the new venue of Fabrik, big enough to combine the cultural and artistic production with the work trainings and insertion programs, and the restaurant. The courtyard promises hybridisations and exchanges, mixing users and activities, visitors and inhabitants, potentially from any corner of Brussels.

At the core of our case studies, overall, we observed some kind of emancipatory understanding of work, meant as an activity, which could and should lead to a re-appropriation of the self. In that direction, the spatial conditions realised inside the building promote individual creativity, but also exchange and collaboration, thus empowering the concerned individuals, allowing to learn from each other experiences or simply to build some sense of solidarity and mutualisation of resources. A way of resisting post-fordist processes of fragmentation. Necessarily such an approach has implications which cannot be contained within the walls of the building where is experimented.

While the emergence of a third form of spatiality -not for leisure but indeed allowing the interweaving of work-oriented and domestic atmospheres- can be easily observed in the interiors of the buildings, part of it seems to be manifested also exteriorly, though the distinction between interior and exterior is arguable in these cases. When looking at the urban impact, the spatial-urban attitude of each of the cases seems to be a continuation of the same philosophy expressed in the interiors. So the protective approach of Smart LaVallée, as a cooperative, is somehow mirrored in a spatial attitude that while being aware of the context where it operates, does not look to proactively fuel any relationship with it. "We have occasional relations with our neighbourhoods. At the same time we are not social workers, our mission is not to improve the neighbourhood. But we are open and welcoming and we do our best to maintain good relationships"⁶. In the case of Recyclart, both the cultural centre and the atelier of Fabrik have an impact in the surrounding neighbourhoods, more or less evident. The cultural centre -especially during the years of the most successful activities- engendered a lively atmosphere, making possible to keep under control the marginalisation and the stigmatisation of an otherwise isolated part of the city. Fabrik, on the other hand, is a well-known place for the realisation of few pieces or small-scale artefacts, fulfilling the most diverse and specific needs and local inhabitants maintain a friendly relation with the workers. What will happen once the new venue in Molenbeek will be conquered and transformed is an open question: though a certain level of interaction with the local inhabitants is foreseen as part of their grounding strategy. Finally, in the case of Zinneke, the governance of the building is supposed to be a neighbourhood affair, though not in the closest future. But the way the building is being reorganised and reconceived goes in the direction of allowing the appropriation by the local community. It would be a forced statement to say the three initiatives intentionally invest on the ecological continuity of the interiors towards the exteriors. As previously mentioned, it is rather a matter of attitude, of actors, aware of their impact, having different degrees of intentionality and willingness to interact with the surroundings. And the nature of their activities necessarily

⁶ From the conversation with one of the managers which accompanied us during the visit at LaVallée.

results in more or less extrovert patterns. In the case of LaVallée exchanges with the surroundings are occasional and supportive, but not essential to the functioning of the platform. In the case of Recyclart, they are the by-product of their activities, especially the cultural production. Zinneke is perhaps the only case to which such a statement could indeed apply and the continuity between the interior of the building and its surroundings is a relevant part of their medium-long term vision. The clarity of intentions and the spatial implications of their plans made their case more promising to the eyes of a group of architects and designers investigating their work re-interpretation and the related urban ecosystems.

While the spatial pattern of post-fordism is about fragmentation –of time and space- and delocalisation leading to individualism, isolation, *désaffiliation*, as Castel defined it (Castel & Haroche, 2001), what would be the spatial implications of an approach to work and productivity based on exchange and collaboration? Which kind of city could support or would derive from such a different approach to productivity, centred on the re-appropriation of the self, on the empowerment of the individual, beyond individualisms? How would neighbourhoods transform? And in particular, at the moment of shifting our views from the architectural scale to the surrounding neighbourhoods, as previously mentioned it was unavoidable to think about the risk of gentrification processes that the development of these initiatives could trigger. Happening in some of the poorest neighbourhoods of the city⁷, it is plausible to think that, as a result of a renewed productive ecosystem, land values could also rise, especially when considering that the surrounding neighbourhoods are already showcasing episodes of gentrification. Land values along the canal are in fact already increasing and a growing number of investors is being attracted by that area, after the way has been paved in the past years by the public administration policies and projects meant to improve the living conditions and indeed attract investments (Dessouroux et al., 2016) A risk especially tangible when considering that the core business of Recyclart and Zinneke is about arts and cultural production. And LaVallée is at the very least making room to creative businesses, potentially more attractive to well educated, middle class individuals with the capacities and the resources to stand some margin of entrepreneurial risk. While this could be in the future the prevailing direction in order to have an occupation –for anybody, independently from education and social status- it is clear the improvements directly and indirectly generated in those neighbourhoods will provoke the rise of land value. Instead of avoiding the improvements and investments, how to make sure the value being produced could be kept in the hands of the concerned communities?

A project of doors.

Also in consideration of the short amount of time, our group decided to focus on the spatial and ecological implications of one of the cases: the project of doors of Zinneke. Rather than simply describing existing dynamics, we opted for a design exercise as a means to imagine which kind of ecosystem could be generated by a different approach to work, productivity and -in particular in the case of Zinneke- the use of resources. It allowed to show how existing potentials and resources could be reinvented within an ecosystemic approach and how space could play an important role –among other things- in establishing an empowering governance for the concerned communities.

The project of doors described by the members of Zinneke was defined as such to stress the relevance of doors as devices allowing the coexistence within the same building and at the same time of activities implying very different needs, in terms of safety, self-expression of the involved individuals, logistics, scale, externalities and more. Within a similar perspective, the door is a device allowing to deal with the compatibilities and

⁷ Data can be verified at <http://monitoringdesquartiers.brussels/>. Number of scholars and researches have shown the concentration of poverty and the socio spatial segregation characterising the central neighbourhoods of the BCR. In particular, since the 80s, the work of Christian Kesteloot (Kesteloot, 1986, 1998; Kesteloot & Loopmans, 2009; Wayens et al., 2010)

incompatibilities of activities. To merge or to divide spaces, to regulate accessibility and to have the control on safety or privacy issues. To create gradients and atmospheres, to transform spaces intervening on their porosity and flexibility, according to changing needs and desires. In these terms, a project of doors would allow different activities not simply to coexist, but also to establish collaborations, while respecting each-other's boundaries and different needs. More ambitiously, it would also make possible the appropriation of the building by local and non-local actors, who could enjoy the use and the access to the building without interfering with the need for privacy or safety of other departments. The aspiration of Zinneke however, goes beyond use and accessibility: an effective project of doors should also imply a shared governance, which also means a shared responsibility and shared care. Appropriation and accessibility would hence imply the responsabilisation and the engagement of the concerned users, which should hence acquire the capacities to do so. A project of doors would thus become the occasion for individuals and collectives to increase their awareness and expertise concerning the governance of their resources, thus empowering them and ideally creating the conditions to recognise their contribution to the liveability of a place. And their power to decide about it.

While the project of doors the people of Zinneke describe is supposed to concern primarily the former *imprimerie*, at the moment of addressing the impact of Zinneke initiative at the neighbourhood level and within an ecosystemic perspective, we intuitively started to explore the possibility that the project of doors could in fact concern the whole neighbourhood. What if the concept could be extended to the whole neighbourhood, as a continuation of the work environment created within the building walls? What if the idea of a shared governance could be enlarged to other buildings, vacant plots and other assets in the neighbourhood? This would imply local actors to gradually appropriate not only the former *imprimerie*, but in fact the whole neighbourhood. Empowering them by means of increasing their expertise and capacities to govern them, thus ideally allowing to resist processes of expulsion and privatisation potentially deriving from gentrification. As previously mentioned: the idea would be not to avoid the improvement of living conditions in a given neighbourhood, rather to enable the local actors on the one hand to take part to the realisation of those improvements, on the other hand, beyond participation, to appropriate and have a voice in the governance of those improvements. As Henry George (George, 1883) and Ebenezer Howard (Howard, 1902) pointed out in the past, the problem with privatisation and speculation is the appropriation by very few individuals of the values and the assets produced by a whole community.

The building of Zinneke is situated in a somehow mixed neighbourhood, belonging to a fine grain piece of city, in between the monumental dimensions of the *projet Manhattan*⁸ to the south and, to the north, the more recent sheds of a productive area which begins right on the back of Zinneke's courtyard. A few blocks away, to the north-west, the Senne Canal hosts industrial and logistic activities. To the east, the railway lines heading to the station of Bruxelles Nord. Outside of the *imprimerie*, Place Masui is mostly occupied by cars and their circulation. The old urban fabric mixes residential units, shops, bars and a certain number of car repair activities, occasionally perceived as invasive. Vacancy is relevant and concerns both buildings and small plots. Not far from Zinneke, the final segment of a linear park, *Parc de la Senne*, is being realised. The park partially follows the trajectory of the vaulted river and for this reason is delimited by the back walls of former productive buildings, as well as the backyards of recent residential buildings, some vacant land and the bigger, the non-accessible perimeters of productive and commercial sheds. In similar conditions, the challenge is to engender a lively environment, avoiding the risk of a nicely paved corridor.

⁸ The *Projet Manhattan* was conceived and partially realised between the 60s and the 70s. It was supposed to provide office and related facilities to the companies and institutions increasingly investing in the Brussels agglomeration as global city. The big glossy towers, the large sidewalks, the functionalistic approach would have provided the allure of a modern business district. The project is infamously known for having been realised thanks to the eviction of thousands of inhabitants, most of whom were never relocated (Clerfayt, Houtart, Rigaux, & Al., 1975).

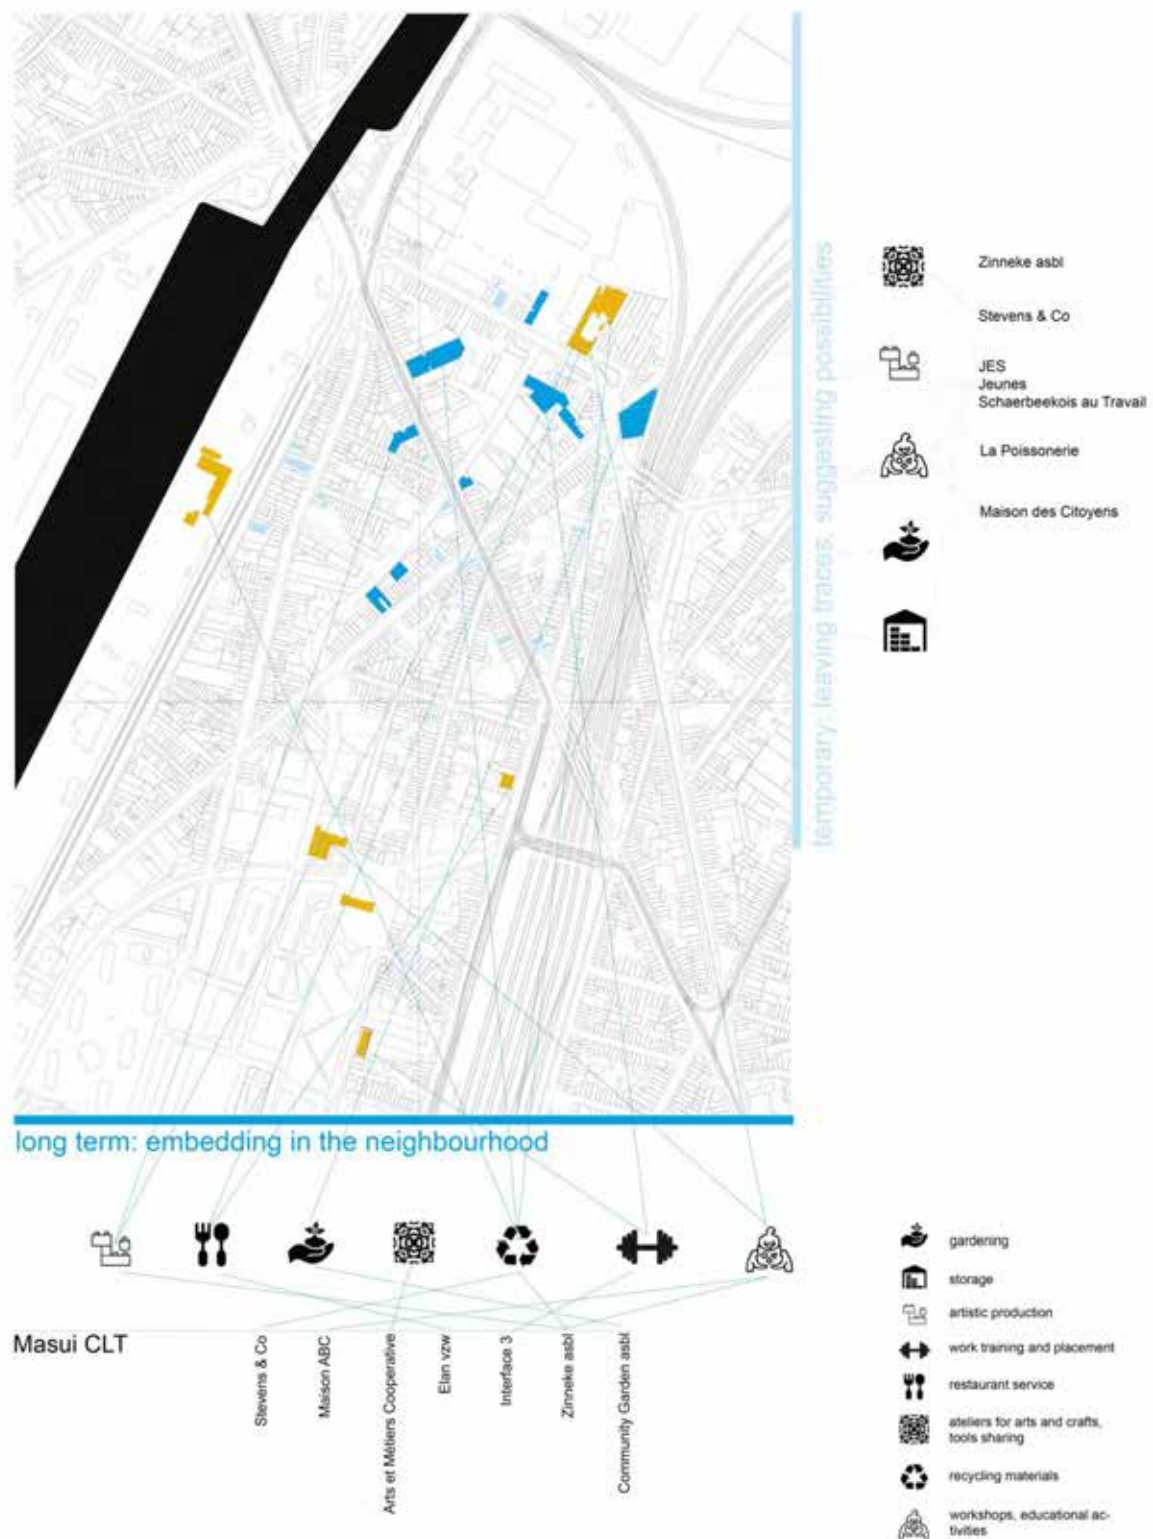

Figure 4. A project of doors. The configuration of short term and long term occupations in the area of Masui, leading to a neighbourhood governance.

The design exercise allowed to imagine which kind of ecosystem could respond to a work approach based on collaboration and sharing, of rights, but also responsibilities, centred on rebalancing work and life, of individuals and collectives, as embryonically experimented within the walls of the *imprimerie*. We explored how existing actors and spatial potentials could support the emergence of such an ecosystem. We tried to suggest in which way space could be reshaped and reprogrammed –at an urban and at an architectural level– thus allowing the coexistence and hybridisation of different activities, as a whole making possible a sustainable governance of resources, in this case meant as the socio-spatial assets of the whole neighbourhood.

Referring to the *modus operandi* at Zinneke, we identified three actions that we used as programs for specific parts of the neighbourhood, based on the mapping of their socio-spatial possibilities. To negotiate, to perform, to invade: these the three actions, three examples of a longer lists of patterns and attitudes we identified, emerging in the Zinneke environment. To negotiate time and space, for example, given the limitations of the built space and the compatibilities and incompatibilities of different activities: to negotiate is about building exchange and encounter. To perform is about the expression of the self –individual or collective–, the making, the experimentation on the existing resources, implying the capacity to risk, to innovate, to take the time to do so and inventing the required, *ad-hoc* collaborations. To invade, sometimes disturbing, out of necessity, provoking conflict but also encounter, of different activities and different users; it is about the need for more space, but also the hybridisation and the production of unavoidable externalities, such as noises, pollution. Each of the three actions worked as instructions at the origin of three different narratives that we tested in different parts of the city, exploring what a project of doors could do in each of them, in consideration of the provided occasions and potentials. We explored negotiation along *Parc de la Senne*, imagining how an alternative market could be organised involving local ateliers and community kitchen gardens, not only to sell their products and provide their services, but also to trigger the implication and the interest of the local inhabitants for the neighbourhood activities and the concerned spaces. The act of performing has been interpreted in the space of Place Masui, imagining how artistic events could bring new life to the square, working across the walls of the *imprimerie*, redefining the transition from one to the other, allowing local inhabitants to appropriate the public and the collective dimensions thus engendered. Finally, the canal banks are invaded by unusual activities such as promenades and festive events thus allowing the locals to appropriate this part of the city, opening to the potential collaborations and work insertion programs for example involving the existent metal recycling factory and the activities of Zinneke.

Through these narratives, the urban ecosystem of a whole neighbourhood is reshaped. At the core, a different system of values concerning work and the environment that could support it, centred on the empowerment of the individual as part of a community endeavour. Individuals in fact –meant as people or initiatives– are encouraged to experiment because immersed in a collaborative ecosystem, which could provide support and ideas. The work life balance is hence reconceived starting from the very definition of work and its meaning in relation to an individual's life and path of emancipation, beyond sheer productivity. The collateral aspect of the implementation of such an approach to work and the related ecosystem is a shared governance of resources and assets that are supposed to serve the concerned actors and users in different ways. For that reason, they need to be preserved, so that their activities and their living environment could also continue to exist in the long term. In other words, to re-appropriate the self through the doing, by contributing to the making of the world necessarily implies to have access and to govern the required resources: transforming the self implies the transformation of the world. This would imply the re-appropriation of neighbourhoods otherwise neglected or privatised, under the pretext of fuelling and supporting community centred forms of productivity.

Operatively, we imagined a combination of temporary uses and long term strategies and purposes. This would allow to combine permanent and non-permanent programs; people and collectives will thus have the chance to gradually become familiar with existing resources and to transform them while remaining open to the needs of the neighbourhood and adapting where necessary. In other words, it could engender a more resilient ecosystem, without losing the opportunity to determine some priorities and guiding directions.

Among others for example, a long-term goal could be the establishment of a neighbourhood based Community Land Trust (CLT), with the purpose of resisting gentrification and sustaining an aware and capable governance of resources, because based on the concrete needs and the competencies of the concerned communities. While their implication in the improvement of their living environment should be sufficient to recognise their right to stay and to govern the resources and assets they contribute to produce and valorise -literally and symbolically- with their daily activities, in fact this is not always the case. Processes of financialisation of the city and privatisation –as previously mentioned- simply concentrate such value in the hands of few investors and result in the expulsion of those who cannot afford the rising living costs of their neighbourhood. In the long term, our scenario suggested an empowering form of governance would have to recognise the role and the implication of the concerned communities, as in the case of the ecosystem we imagined, designed around their spatial and. The model of Community Land Trust currently being experimented in Brussels (Lenna, 2019) –though for the moment concerning only the residential function- would allow to retain the plus value generated by potential improvements at the advantage of the whole community.

Conclusion

As a result of such an emancipatory approach to work, conceived *as* life, centred on the individuals and their capacities of doing and exploring resources, overcoming fragmentation and alienation, on the one hand the living conditions of a neighbourhood would improve. On the other hand, the concerned communities –local and non-local, occasional users and inhabitants, administrative actors- would be empowered, on the base of their competences and capacity to govern the local resources: the resources they need for their life strategies. The model of the CLT here suggested is just one among many other possible models allowing to recognise the power to decide of those communities, thus retaining the value collectively produced.

The role of design, meant as a process of co-creation, is fundamental for the emergence of such an ecosystem at least on two interconnected levels: for the design of the systems and for the design of the spaces. On a strategic level, it would allow the involved actors to become aware of the resources and to imagine how to synergize them at best, which programs to enact, both temporarily and in the long term, adapting through the time, contributing to the resilience of the city. Concerning spaces, the challenge is the realisation of the conditions fostering encounter, exchange and collaboration, the coexistence of compatible and incompatible activities. Design in other words, would be fundamental for the establishing a horizontal form of governance, necessarily based on the appreciation of the environmental complexity that a new balance between life and work demands. From the architectural to the urban scale, allowing the individual to meet and to expand into the collective dimension, while expressing the self and his capacity to contribute to the making of the world. At the conclusion of our design exercise, we realised that the concept of a project of doors could possibly be applied also to the other two cases, the door being meant as a device allowing a certain flexibility, easily adaptable to the specificities of other neighbourhoods. The project of doors could hence be read rather as an approach: a concept about the need for porosity and the possibility to regulate it, for the coexistence of uses and the flexibility of spaces; for the intersection of scales and actors. An approach looking at the city as an environment where work and life intersect by definition engendering urbanity, inherently capable of resisting to the forms of existential alienation and dispossession of the city currently being enacted.

Acknowledgements

We would like to acknowledge Metrolab for the opportunity of researching around the theme of urban ecosystems and our group colleagues for the exchanges and conversations emerged during the design process, about work, life and joy.

17. Spatial tensions: urban microgeographies for changing cities

Urban Crisis Storytelling: idioms and forms of city's equilibrium integrating the uncertainty

Martina Pietropaoli

Università degli Studi Roma Tre, martina.pietropaoli@gmail.com

Abstract: I will present two years of experience as a PhD researcher on the thesis “European city: Fundamentals and images of its Crisis”. I made an anthology of narrations accompanying projects “for”, “against”, “between” crisis. How do these tells make urban government frameworks pass from the paradigm of “finality” to the paradigm of “intentionality”? Mixing functional rationality (biological sciences) and intentional rationality (social sciences), Urban Studies create the condition to reshape equilibrium. From the consciousness that the total outcome doesn't satisfy everyone's interest, negative externalities are something to be controlled. Like Odysseus binds himself to not hear the Mermaids, reducing the field of action, we reduce the unpredictability. The problem of operationalization of the concept of crisis reveals the contraposition of two genealogies of thoughts; the one considered dominant and the other in objection. If we give the attribute of “feminine” to the genealogy of thought in opposition, we find some important concepts: empathy, contradiction, anachronism, otherness, cosmogony. Recognising the historical genealogies of this thought I want discuss the lexicon of the tension between patriarchal language and a feminine way of access to reality. How does the triad work/efficacy/example change? May this manage European city in order to integrate the uncertainty?

Keywords: crisis; feminine; European city; storytelling

Introduction Starting from the call of this Session I will discuss three main themes: the concept of crisis, intended as discontinuity transformation; the storytelling potential of the discipline of Urban Studies; the concept on gender, in a double sense of literary genre and in a biological/cultural sense. I will put the emphasis on some misguided words expressing transformation, to propose tension problem roots. Is it true that cities does never stop to change? From what distance we look at the urban? I propose the perspective of ‘micro’ not as a dimensional topic but as something to do with emancipation. These reflections I propose are inspired by my PhD activities (still in progress) for nearly two years. For my research project “European city: Fundamentals and images of its Crisis” I am carrying on an anthology of narratives about the presumed aspects of “urban crisis” at the beginning of this century. My review of discourses on the presumed urban crisis as a complex construct (not yet well framed in in Europe) leads to consider vocabularies showing their mutual conflict. How can these rhetoric and speeches define the two horizons separating something *before* and something *after*? My work has both an historical/geographical value and an anachronistic approach (in a positive sense). Effective verb *krino* (from the ancient greek “to separate”, “to decide”) is that part of the human experience that sets out the fundamental issue of something we could say as: *While a human being is transforming his world human being is transforming himself*. I will discuss this one-to-one condition to propose a concept of ‘tension’ and to wonder

about its geographical and economic scalability. Is micro-geography a good point of observation for changing cities? Is this a dimensional size?

Is it enough European? Starting from the rhetoric of the crisis, the purpose of my PhD dissertation would be to point out some aspects of the relationship between project and community, between civilisation and measure of the space, between the idea of city and practices. At the beginning of my research project the majority of my interlocutors observed that:

- European city doesn't exist!
- 'Urban crisis' hasn't been univocally defined in European geographical context

Unlike in other contexts (for example in America Latina, as a political crisis; or in North America, as recession) the association between 'urban' and 'crisis' has many different declinations (economic crisis, resources crisis, refugees crisis) often well mixed in a general 'crisis of values'. This general feeling is a good starting point to examine the cultural devices of transformation. So I took different 'urban' projects (simply meaning for 'urban' ones assuming the pre-existence of the city as a matter) and look at the corresponding storytelling (involving one of the various concepts of crisis), plotted by different narrators. My Questions is: With what extent are the narratives of the crisis functional to the reformulation of the practices and of the frame of government actions? And so: In which cases did the narration allow to configure a change and when, instead, was it misleading?

I could have chose to do a transoceanic comparison or to focalise on a casa study (as Rome, Barcelona or Madrid) or to chose and compare different sensitive contexts (such as Cipro, or post-Brexit Ireland, or Athens). But what I am doing is to conduct small case studies with a mixed method and heterogeneity of the sources (photography, spaces, interviews, kinds of spaces). This investigation of different discourses uses historical reconstructions, with references to Carlo Ginzburg and Alessandro Portelli; biographies of cases, in the manner of Arturo Lanzani and Pierluigi Crosta. This may appear like an heuristic method but I have been naturally been brought to the hypothesis that the essence of European city is mainly a device of translation (Leciejewicz, 2000), indeed the world 'crisis' arises when an intentional action is transforming something, understanding the rules of the living.

In European *forma mentis* a presumed equilibrium of urban coexistence is always built through *an effort of translation: from a culture to another, from a city to another*. European modern culture was born in the literary entourages and the Myth of Europa is migrant and tells of a rapture.

Figure 1 Palazzo Farnese, Caprarola (Italy), Sala del Mappamondo o delle Carte Geografiche and Figure 2 Antonio Carracci, *Il ratto di Europa* [credits, M. Pietropaoli].

If “European city” or “European culture” don’t exist, what is shaping urban relationships are plural “European cities and European cultures”. Right in in this proliferation of the use of the lemma ‘crisis’ I see a reaction to the dogma of identity, mainly underlying a patriarchal thought. This must be considered not a weakness, not a ‘crisis of values’, but an impulse to define the authenticity of timeless values put into practice in the democratic coexistence. Is the project of democratic city (and has it always been) a project of redemption for human being? Does the lexicon of crisis make arises an ‘objection thought’? How this words are opposing or collaborating or weave a complementarity with the ‘dominant thought’? Does this emerging vocabulary belong to a feminine genealogy of thought?

The feminine as a culture of emancipation through project What I propose with this paper is to give the attribute of ‘feminine’ to the genealogy of thought in opposition to the dogma of ‘unique identity’. It points out some important concepts: empathy, contradiction, anachronism, otherness, cosmopolitanism; and the capacity to lead this transformation one-to-one between giving form to the world and the knowledge of being. ‘Feminine’ attribution is intended as *feminine way to access to reality* and not only as cause for women’s right (Buttarelli, 2017). This is not a way to reclaim the separation of gender identity but to “unravel” it; it is necessary to deconstruct the narrow gender affiliation built in the context of socio-political, historical creations (Villani, 2018). The Reclaim and Rebranding feminism is the so-called Third wave of feminism. I consider this reclaim activism one of the references of my research. I will not dwell on these aspects of gender activism because I don’t want to give the Gender Study tag to my investigation.

My contribution concerns mainly the theoretical part of my research work with a multidisciplinary approach. I will discuss some idioms. I believe that this perspective could offer some coordinates to draw an idea of ‘tension’ able to rediscover a design culture integrating conflicts, contradictions, uncertainty. In the following paragraphs I will claim a systematisation of this approach coming to the definition of three spatial tensions:

1. **Part One: The possibility of becoming-woman or the concept of *work*** about the “becoming-body” of the city as a “becoming-woman” of the city;
2. **Part Two: The possibility of making space or the concept of *efficacy*** about the concept of authority is changes in a society drawing its storytelling on a dimension of permanent crisis;
3. **Part Three: The possibility of becoming-urban or the concept of *example*** about how an emerging lexicon is refunding Urban Studies not only in the performativity of the vocabulary but radically conditioning the possibility of urban narratives (in politics, policies, practices fields) as a literary genre.

I will use humanistic fields’ tools (semiotics, philosophy, anthropology) to sustain my arguments. The starting and final point is the concept of ‘tension’ as opportunity for urban planning and design practices (as invitation by the curators of this Session of Aesop 2019). The question underlying these themes is that urban government frameworks are wondering how to integrate the paradigm of “finality” with the paradigm of “intentionality”.

Over recent years, Roman Departments of Architecture has been marked by the presence of distinguished philosophers, invited to introduce Academic Years; to give a direction to research priorities, to provoke a questioning of design categories. Giorgio Agamben has celebrated with *Costruire abitare* speech the inauguration of PhD Courses (7th of December 2018, Sapienza University, Rome) and Carlo Olmo gave a *lectio magistralis* with the title *Segmenti e bastoncini* (14th of December 2018, Roma Tre University, Rome) and another for a cycle of open lessons about Europe, *L’Europa vista dai tetti del Birkbeck College* (March 2019, Roma Tre University). In Italy this presence is not new, since Massimo Cacciari has been the catalyst for several disciplinary and political debates, with a multi-media relevance. This quest for a philosophical assumptions of the relationship between “standard and form” (Olmo, in the second conference) shows a permanent conflict. The “common destiny” expressed by the syntagm ‘public space’ is in crisis (Olmo, 2018). This can be the latent tension informing all the other tensions.

In the next paragraph I will discuss the problematic pact between *mots et choses* bringing it to the view of the possible integration of a genealogy of thought properly feminine within a large *corpus* of morphologies of human living structures. The way these structures consolidated their trajectory can be assumed as a predominantly patriarchal way of

access to reality. Annarosa Buttarelli (2017) emphasizes the presence of two big mechanisms of repression: the civil war (in the wake of Nicole Loraux and Marija Gimbutas), the sexual contract (in the wake of Carole Pateman). I propose, with Buttarelli, this double and interconnected substratum as a generative matrix to be freed up from a masculine empowerment:

- the unconscious repression of the origins of democracy, buried deep in a lasting subjection
- the freedom from a monosex and chained history

And I add a third critical issue:

- European City as a thematic field in which an emerging feminine vocabulary expresses thoughts liberating the patriarchal matrix.

Agamben offered a reflection of the sense of *arché*, reclaiming this attitude to investigate this root. Olmo (2018) invokes the distinction between the use of “visual tools and narratives as a support for instrumentalized governance functions” and “the impartiality that this function should practice and conserve”. The “definition of the democratic form of the contemporary city” (id.) is passing from the report about the present possibility of a feminine government authority; not only in by woman or for woman.

Part One: the possibility of becoming-woman or the concept of *work* Last year I wondered how to recognize in the additive culture of ‘zoning’ some interesting trace of *transition* culture (Pietropaoli, 2018). I tried to show “how urbanism, mediating between a geography of the supply and a geography of the demand, organises a discourse on diversity which can help the individual story-telling to escape from the single frequency of the *Égal*.” (id.). I proposed to see in urban government thought some intuitions of Deleuzian coordinates with a decolonising attitude (id.).

“Negotiation of an urban fact cannot fall in a dichotomous dimension (be/not be): the challenge is to construct discourses on the future of the urban, that are able to contain the minute stories of the becoming-minor; that make order, rarefying.” (id.)

I adopted from Deleuzian categories both the concepts of becoming-minor and rarefaction. While a “general theory of urban facts”, in Aldo Rossi’s *L’architettura della città* (2011), is a way to express the permanent essence of the ‘immobile stage’. Aldo Rossi wants to affirm “the values of architecture in the city’s study” (id.). Collective and private elements are confused in the city, “small beings looking for their accommodation, a small environment suitable for the general environment” (id.). Paraphrasing Rossi, architecture as an inherent fact of civilisation is a permanent stage of a theatre; it is necessary to:

- create a favourable environment for life
- express an esthetical intentionality
- make readable the stratification of memory and self-awareness of the city itself.

While Aldo Rossi shows that the “the city grows on itself” (id.), he trusts on the possibility of the universality and readability of architecture. He calls on a particular attention in the study of permanences. I think that this milestone signs a misunderstanding yet operational, leading the way for the concept of ‘assemblage’.

In the current time, some discourses use the word ‘assemblage’ trying to challenge the determinism of zoning approach, Sixties season of urban standards openly had declared the trust on urban fact as a dispositive of socio-cultural articulation, providing norms for society. Federica Giardini (2017) proposes a review of the massive success of this English acquisition of the French word *agencement*, pointing out that “this notion is both a point of precipitation of the transformations of the politician and an indication of a return of the materialistic approach” (id.). In Italian *agencement*/assemblage is translated as *concatenamento*, giving the accent on this figure of continuous chain (Deleuze and Guattari, 2017). Giardini shows that the “spatiality of the chain” gives relevance to the question of the “unforeseen

development” (Giardini, 2017). She grabs the point of the problem of the “provisional composition of strengths” (id.). For urban planning the problem today is the knowledge of the dynamics, more than the mastery of balanced forms. We are back to the concept of tension. If we immerse further in Deleuze and Guattari’s *milles plateaux* (2017), we find in the *Traité de nomadologie : la machine de guerre* (chapter 12) the figure of the “transhumant”: “to follow the flow of matter is wandering, roaming”. And they evoke the figure of the artisan as a *phylum macchinico*, “who is determined to follow a material flow” that “cannot only be followed” (ibidem). This transhumant figures are made of concentric circles, different from the practice of nomadism and itinerancy. Therefore the material has its own life (flowing) and to follow its dynamism means is a sort of encirclement.

European Urban scholar is accustomed to esteem the figure of the flaneur as positive way of re-mapping the world, while participating to life. I want to stress the aspect that this non-finalisation of the wandering is a typical ‘feminine’ attribution. In the same way it’s a woman attribute the accent on the non-action, in opposition to an active way. Man acts, builds, and transforms, interrupts the infinity of the woman experience of the continuous (of which he has no experience).

This value of inactivity in ‘space realm’ has his own correspondence in ‘time realm’; the aesthetics of the *ephemeral*. If the non-permanence in space has the value of making a free presence exist, non-permanence in time has the power of dissolve the traces of an action shaping the world. In the first figure the perception of the subject is moving and the scene is immobile. You can trace a map of this experience. In the second the thought is able to shape reality only for a meanwhile. A female lightness of the action is less ambitious and permanent but has a form, a tension, and a trajectory. What’s the problem? And why we need a reclaim of feminine way to reality? I see to forms of these concepts of equivocal appropriation by patriarchal *forma mentis*:

- mapping is a properly colonial action (Anderson, , attributed to the feminine/post-colonial experience of the suspension of the judgement)
- the figure of transhumant has a cyclical (as in woman experience) and circular way but the risk is to confuse it with a vicious cycle.

I come back to ‘permanence’ concept of Aldo Rossi, to reveal the misunderstanding I anticipated. The problem of an unforeseen development for Giardini (2017), in search of a renunciation of permanence, lead European design culture fall into a dichotomous opposition. To follow the stream of material and impermanence of this material is free. But according to my opinion these categories can be re-appropriated by an effort of re-configuration that see in ‘assemblage’ just a more casual way of zoning.

Giardini (id.) points out that the ‘assemblage’ weakens the effectiveness of the vertical playset approach; in the “spatiality of the chain” (id.) geographical scales are not Chinese boxes. Inter-connections are not only vertical, as in Actor Network Theory. The problematic effect of this ‘non vertical’ feature is that words linked to the culture of *agencement* are flatted to a one-dimensional aspect. And what’s the paradox? Without a vertical reference, territorial scale becomes a generic scale. So these adjectives, associated to design devices, give to project an inability to recognize its efficacy. Process/procedural, relationship/relational, participation/participated. Here are some evidences of how the tension of reality is frozen in a presumed horizontal playset. Horizontal has the generic value of a non-territorial-scale tag, good intentions often unsuccessful, a false friend of emancipation. These may be forms of “salvage capital” (Tsing, 2015) which appropriates itself of emerging awareness born in the local frictions. Often this “salvage capital” re-uses positive expertise to conquer again the freedom of local cultures. Tsing also claims that is not possible to scale-up any adjectives and frame of sense.

The problem of reshaping a world full of layers and objects is not new. “The basis of the current concept of city is the idea that it does not therefore fulfil the physical representation of a rigorous concept, but rather it’s the effect of the sum of countless historical experiences, of an inexhaustible process of shaping, involving, more or less directly, all the citizens, with their daily behaviour” (de Seta, 2010). As well as Rossi, de Seta conceives the city as a big artifact. What happens if the typological configuration is not a standard for project *efficacy*? De Seta (id.) points out the classical

difference between *civitas* (the complex of people shaping their living together with architectures and rules) and *urbs* (the physical construction, as a result of the way of living). These are often categories conceived as in opposition. Nothing newer than the opposition between Antigone and Creonte. What can be radically new (or radically reconquered) is considering the multiple physicality of the city as an activator of a multiple subjectivity. The problem of multiple points of view has been taken on with thought of *plurality*, by de-colonisation thought. Considering that another way of being is always possible in a feminine scenery. While cosmogony observes and accepts, cosmopolitan culture collects and juxtaposes differences (Buttarelli, 2017). Patterns, imagination, narrative, expectations compose a lexicon for a project that can observe but also tags used by politics and policies for a unique identity. Cosmopolitan government just accepts and recomposes differences without continuing the observation.

Another form of “salvage capital” can be the people-for-people paradigm: just a mutual appropriation through an instrumental knowledge and acceptance of the difference of the Other (Pietropaoli, 2018). “What is the work of genius if it is not the work he produces?” is the question posed by Massimo Carboni (2017) in *Il genio è senza opera*. The title is taken by an ancient Chinese expression. I take the three words “work, efficacy and example” from his essay. Carboni starts questioning about how in art the performativity of life became more important than the subjectivity of the kantian *genius* expressing an idea (id.). I will treat the problem of efficacy and example – closely related topics – in the next paragraphs. Now I want to end this paragraph with an accent on the becoming-body. The effectiveness of urban narratives outlines an idea of city no longer as the sum of decisions, but as becoming a woman, understood as becoming-body (Pietropaoli, 2018). Becoming-woman gives to the materiality of reality the character of a fold (Deleuze), of a push toward the multiplicity. This plural presence of objects is to be intended as a ‘work’ that is the result of Deleuzian practices of emancipation. I am proposing that the impartiality to which Olmo referred must be intended as a discourse on the urban body, different from the organic and medical metaphors of functionalism. This becoming-body is a field of a cosmogony of which dynamics are tensions to be read. This becoming-body could substitute the category of work.

Part Two: The possibility of making space or the concept of efficacy This dynamics reveals hidden theories of urban government based on the integration between masculine and feminine genealogies of thought. The index of this passage is the proliferation of the word crisis instead of the word equilibrium. What is breaking the wall of order? Stories. In this part of my essay I want to discuss about the possibility of histories and stories to exist; this touches the classical opposition of *logos* vs. city of stone. One of the questions underlying the use of the concept of tension is: does *logos* gives an order or get out of order? There’s a beautiful scene of the documentary about Donna Haraway (Terranova, 2016) where she’s playing with her dog (Figure 3). It’s a serious play, because they are making a contest for dog and masters of dogs, of those with obstacles. The sequence shows how the intimate understanding between these two creatures is made by experience and exercise. They have some common rules, a pact, and a common way of living. I see in this attitude to dispose bodies to a common discipline something important about tension. They feel empathy. They keep attention on gestures.

The importance of the exercise of gesture is something not so trendy in the current urban design composition. In a world overloaded with signs we are often embarrassed by giving an unique gesture to the use of an object. Narratives on ‘spontaneous’ and ‘informal’ are very successful. As happened in the case of impermanence, these are two adjectives taken from feminine realm but are exploited by patriarchal *forma mentis*. The culture of the ‘residual’, the basis of the concept of regeneration, starts from the recognition of a missing gesture. There are no gestures using a building, a park, a... Whatever object in the city. This generality of the concept reminds us what I still told about non-territorial-scale. These objects can be not only abandoned but also misutilised. The consubstantial presence of these objects ‘within’ the city reveals the unavoidable coexistence of life and death in urban becoming-body. But urban ‘death’ doesn’t coincides with a lack, a void, an organic decomposition. Architectural organism sometimes are still void (as a square space) or are made by a complex texture of organic and, often, inorganic materials. So the lack is an absence of intention or the presumed inefficacy of the intention using that part of the urban body.

In *Karman*, Giorgio Agamben (2017) treats the topic of gesture, starting from the origins of the concepts of cause, fault, will. “The laborious grafting of the concept of will on that of power” (Agamben, 2017) is fulfilled in Christian theology, with philosophers Agostino and Anselmo. The verbs “I can”, “I want”, “I must” are void of significance and “Possibility contingency, necessity” are articulation of the ontological thinkability (ibidem). Agamben shows how the ancient man has power and the “Christian man is a wanting being”. Proper of the ancient word is also the difference between *skopos* and *telos* (purpose and finality), with a preference on finality. Because “the *skopos* doesn’t depend from us but from the destiny” (id.).

Figure 3 Donna Haraway and her dog, photogram from the movie by Terranova, F., 2016, *Donna Haraway: Story Telling for Earthly Survival* [1h 30m].

I think that this tension between purpose and not-finalisation is some other material for the misunderstanding path I am proposing. This accent of ‘something lacking’ and the way Donna Haraway performs the efficacy of her relationship with her dog offers an image to a kind of social contract more based on ‘community’ realm than in ‘society’ one. In the documentary Haraway calls this relationship “a lifetime commitment”. This is not a question of metric-scale; society doesn’t contain community as something smaller. Efficacy gesture is something to cultivate between relationship and purposes. Efficiency is different from efficacy (Buttarelli, 2017). The efficiency is a different paradigm that prefers *telos* than *scopos* and common destiny is taken for granted. Instead if we choose efficacy, common destiny is something to conquer from time to time.

It reminds Cristina Bianchetti’s expression in *Tensioni urbane* (Cerruti But, Kërçuku, Setti, Vassallo, 2017, p.140): “pragmatic attitude that does not surrender to general theories”. Nevertheless this approach of urbanism in the same book is defined as ‘weak’ by Paola Viganò (chapter *Verso un’idea di Urbanistica debole*). This is the problem of considering opposition thought as something weaker (because proper of women), by convention. The strength of efficacy can be shown by considering philosophical and grammatical problems as a scenery to be integrated in case studies. The strength of efficacy can be reclaimed by women to be offered to everybody. This brings us to the final paragraph. Two sexes: the one strong, the other weak. An human being: primarily bad.

Part Three: The possibility of becoming-urban or the concept of *example* I will end my argumentation with a reflection about responsibility of Urban Studies scholars. A recent work by Patrizia Gabellini has the title of *Le mutazioni dell’urbanistica. Principi, tecniche, competenze* (2018). She reviews a large number of words, as an emerging field of urban government actions. Assuming any alternative way of thinking as an opposite ‘weaker’ thought is something very insidious. This lexical emancipation has no sense if the narratives on crisis and mutation assume this dominant-man-thought as a reference for human action. Marcel Gauchet (2018) denounces the end of male domination: “To women the gift of life” and to men the posses of society. Based on the possibility of tradition of values, men power takes the the family domain as the “basic cell on which the common existence was based” (id.). According to Gauchet, the dissolution of family gives a new assessment to society, made of individuals. This is the end of the male domination: the paternalism in matter of exercise of the authority has become a scarecrow (id.). In the second paragraph about efficacy, I still discussed the passage from society to community topics. The relevant step of Gauchet argumentation is a consideration about the dimension of the public sphere; he shows how this sphere had its cognitive

fundamental in the “results of science”, because that kind of objectivity was “conceived for the public release” (id.). According to Gauchet “the public has taken the place of the male” and the “city-soldier [...] takes charge of the fate of his homeland” (id.). We can find some indicators of this “public safety” individual battle in big narratives of current ‘crisis’ in their ecological approach as Anthropocene, Collapsology, Degrowth. The system of reference is planet Earth, for different reasons.

I will treat the largest narrative on species common destiny: Anthropocene. In these narratives is more or less implicit (it depends on the speaker) that the specie’s (disregarding the relevance of this concept) behaviours are called into question. It is also emphasised the human ability to make damages. The Earth as a figure of Nature is something currently familiar but is something recent (Virno, 2015). Scenarios of stories are flattened on the curved sphere of the planet. This is a sort of end of “time disarticulation of the space-time hinges of history” (Danowski, Viveiros de Castro, 2017). The rhetoric of the ‘loss’/‘lack’ invest the World. But with inverted perspective: please, human being, stop acting. This kind of rationality has the model of Odysseus that stops with the ropes his instinct to reach the singing Mermaids (Elster, 2005). To know to be weak (id.) is to recognize the need for an imperfect rationality. Elster retains absurd that people can choose apathy to protect themselves from manipulation but this stabilizing effect of “stratagems to force oneself” is a typical disposition for European cultures.

If we look at the project reacting to these sings of Mermaids (by technology and exploitation) we find Martin Prominski Andscapes. “By using the term ‘andscape’, a dualistic, divisive understanding of nature and culture becomes impossible – instead, the focus is on the dynamic relations between humans, animals, plants, stones, water, and all other elements in the world” (Prominski, 2014). This effort of integration is voiced in Prominski’s landscape architecture projects (Figure 4). He proposes the effect of the design intention not in the final form but in the capacity to let interact vegetal and animal living with men urban traces. Athropocene is Prominski’s framework of reference. Instead of the result of a less governed aesthetics, I find in this action of design a strong reclaim of control. These are beautiful and successful places, integrating an attentive consideration of resources and of uses. “And” is a more feminine conjunction than “or” (Buttarelli, 2017) but at the end these are interactive spaces wants to be recognised as something additive. This is a step to admit multiplicity in the lexicon of project. No more nature vs. human but nature and human. They don’t exclude each other but they don’t add a quality to the dialogue. Is this a branding concept? I don’t want too bold in this consideration and I consider important this response from the perspective of landscape to the perspective of Earth. Is the Prominski’s concept of ‘entanglement’ a way to give peace to a tension? Is it a good sign of change without a stronger awareness of the deep root of this culture in feminine way of thought? The difference from Gilles Clément’s Third Landscape and Planetary Garden is the idea to concentrate not on Clement’s possible points of observations of something transforming but on the effect of an integration of the dualistic world. What Earth crisis perspective reveals is that, another time again, is grammatical and more feminine the key of a new narrative of project integrating uncertainty.

Figure 4 Martin Prominski’s projects [source <http://www.irishlandscapeinstitute.com/2016/04/29/andscapes-ili-may-lecture-by-martin-prominski/>]

“The tale must be rehearsed – and we may amuse ourselves imagining how these must have been, often, acrimonious, or at least in dispute. Whose version of events is going to be committed to memory by the Memories?” (Doris Lessing, *The Cleft*). In this wonderful and terrific book, Doris Lessing tells the story of two populations, one completely masculine and the other completely feminine. This meeting between two species provokes a strong conflict. The translation of the title in *Una comunità perduta*, in Italian version, expresses the problem of common uses and behaviours. Both the sexes have a beasts’ common attitude. The rhetoric of Wilderness, as a movement not totally well framed in landscape architecture, is a step posing the access to the radical wild (of course) nature of living beings. But isn’t city more wild (in the sense of uncontrollable) than vegetable life sometimes? Isn’t this reclaim of wild life a way to escape and deny to the vibrant – non perfectly rational – results of urban co-existence? Gilles Clément invoked to learn to take care of the Garden with the capacity of observation, to let life express. Prominski proposes an accent on co-existence of non-drawable and designed. Well, this is still a Garden more than a unknown Forest. But in both the figures there’s a promise of abundance and future. I want to propose as a final suggestion another fairy figure: the Wood. Into the Wood the tales have place; actors choose a direction or another, they lost and find. Urban Studies scholar opens the experiment to an investigation which gives to the community the posture of doubt, of standing at the crossroads of the insidious path of the narrative wood (Eco, 1994). “The fundamental rule for dealing with a narrative text is that the reader accepts, tacitly, a fictional pact” (id.). The space of the Wood is made of possible crossroads and the protagonist of this path can choose only if he has some traces of orientation and disorientation. According to Eco this pact of said and not said constructs the expectation in the reader. Expectation is the only important thing because it makes to the reader an adventure to the limit between choice and destiny. I use this metaphor of Wood to propose this place of grammatical agreement as a rich relationship to be cultivated: with readers of Urban Studies and with people living their life in Urban dimension. The awareness of being part of a common story and history is a challenge for us as good writers. The moral claim to engage ourselves while we see the transformation of the city must be reached with this discovery of other ways of access to reality.

Engaging Non-Citizens in an Age of Uncertainty:
Lessons from Immigrant-Serving Nonprofits in
Los Angeles County

C. Aujean Lee¹

¹ Assistant Professor, Regional and City Planning, University of Oklahoma, aujean@ou.edu

Abstract:

Problem, research strategy, and findings: Arnstein's (1969) ladder has informed how planners redistribute power among constituents and increase citizen participation. Since the late 1960s, the non-citizen population has increased in the U.S. This demographic shift has affected planning and community engagement because many immigrants experience disparate access to public goods and services more so than native-born residents. Non-citizens are also particularly vulnerable to shifting political landscapes due to citizenship status. I use 29 interviews with immigrant-serving nonprofits to identify unique challenges to serve non-citizen clients after the 2016 election. Immigrant nonprofit experiences are informative because they may be the first and only organization to provide non-citizens with services and resources in times of uncertainty. The interviews inform how planners can improve non-citizen engagement practices and redistribute political power. Interviewees highlight how non-citizens experience barriers to public services and spaces due to fear of deportation and abrupt changes in their citizenship status. As a result, non-citizens are selective in how and where they engage. Thus, they connect to informal and formal spaces that may exist beyond their neighborhoods. These experiences also increase non-citizen dependency on nonprofits. As planners improve immigrant incorporation through these considerations, they can improve how they balance power, constituent representation, and meeting residents' needs.

Keywords: immigrants; nonprofits; participatory planning; civic engagement

Introduction

Arnstein's (1969) ladder of citizen participation arose after the U.S. Civil Rights movement. Community-based grassroots organizations formed around this time to increase low-income resident public participation (de Graauw, 2016; Espiritu, 1992; Smith & Lipsky, 1993). The government also passed policies to increase and/or mandate participation through Community Action Programs and Model Cities programs to address poverty, urban renewal, social services, community development, and participation for the "have-nots" (Arnstein, 1969; Gittell, 1983).

Since then, the ladder has been used to conceptualize participation and the redistribution of power in planning processes (Grengs, 2002). Planners are still grappling with how to engage and increase participation among "the have-nots" who have become increasingly diverse in language, nationality, racial/ethnic composition, and citizenship/nativity status. Planners also manage conflicts in working with a changing public (Qadeer, 1997; Spain, 1993), particularly in the age of immigration.

After the 1965 Immigration Act, immigrants and migrants have steadily grown in numbers. Between 1970 and 2010, immigrants comprised 5% and 13% of the U.S. population, respectively (Frey, 2002; Singer, 2013). Before 1965, most immigrants arrived from Europe, Mexico, the Caribbean, and Central and South America; afterward, a majority migrated from Latin America and Asia (Tienda & Sanchez, 2013). A major reason for this shift is because the 1965 Immigration Act removed racially motivated national origin restrictions that limited immigration from Asian countries (Hing, 1993). Thus, between 1980 and 2018, Asian Americans grew from 2% to 6% of the population, and two-thirds were born outside of the U.S. (Frey, 2018; Gibson & Jung, 2005). During the same period, the Latino population increased from 6% to 18%, and one-third were foreign-born (Frey, 2018; Gibson & Jung, 2005). The 1965 Immigration Act was also the first time that refugees became a permanent migrant admissions category (U.S. Citizens and Immigration Services, 2019).

Several policies after 1965 also changed the composition of non-citizens, including the Immigration Reform and Control Act of 1986, the Immigration Act of 1990, and the Homeland Security Act (Hing, 1993; Singer, 2013). The abrupt termination of the Bracero Program, which brought guest workers from Mexico between 1942 and 1964, also increased the number of undocumented immigrants (Tienda & Sanchez, 2013). These policies aligned immigration priorities with national security and law enforcement and created new statuses, designations, programs, and visas. Now, immigrants include refugees, asylees, Deferred Action for Childhood Arrival (DACA), Temporary Protected Status (TPS), legal permanent residents or green card holders, unaccompanied children, H-1B visa holders, and undocumented residents. The Pew Center estimates that a quarter of immigrants are undocumented (Lopez et al., 2018). These groups interact with government agencies differently by their status, networks, legal rights, and language needs (Allen & Slotterback, 2017; Frasure-Yokley, 2015; Kim et al., 2017; Nicholls & Uitermark, 2016). Unless noted, hereon after I will use "non-citizen" to refer to people of multiple statuses and governmental designations who are not citizens by birth or naturalization.

The relationship between planners and non-citizens are also affected by unstable political contexts. The year following the November 2016 presidential election offers an example of changing immigration policies and incompatibility between local, state, and federal laws (McDaniel et al.,

2019; see also the following for summaries of policies: American Bar Association, 2018; American Civil Liberties Union of Washington, n.d.; Ballotpedia, n.d.; Mueller, 2018). For example, Los Angeles enacted sanctuary city laws, which limits cooperation with immigration enforcement agents and has led to conflicts with the federal government (Dola, 2018; Luna, 2018). In these moments of confusion and swift decisions, planners will experience additional challenges to engage with non-citizens.

The government has also shifted the responsibility of services to nonprofits (Alexander, 1999; Kisanne, 2010; Smith & Lipsky, 1993; Swack, 2006). These organizations first formed to address immigrant social needs and link immigrants to government agencies (Cordero-Guzman, 2005; Hung, 2007). Nonprofits have since increased their role in immigrant community development and in creating inclusive planning practices (de Graauw, 2016; Kondo, 2012; Sirianni, 2007; Vitiello, 2009). Nonprofits are also oftentimes the first and only organization to provide immigrant social services in times of uncertainty (Lee et al., 2018). Thus, immigrant nonprofits can offer lessons for how planners work with non-citizens in shifting political landscapes. These considerations are important because non-citizens support economic and neighborhood development, but also pose demands on public services, including schools and hospitals (Fishman, 2005; Kim et al., 2017; Vitiello, 2009). Planners are also asked to recognize “a special need to plan for the needs of the disadvantaged” by the American Institute of Certified Planners (2016) to meet short- and long-term community needs.

I examine how immigrant-serving nonprofits were affected in their ability to serve non-citizens after the 2016 election to inform how planners can engage with these communities. In uncertain political and policy contexts, non-citizens were challenging to serve because of their fear of deportation and/or changes in their citizenship status. Thus, these groups were fearful of using public services or public spaces. Non-citizens were also selective in how they engage with spaces because they may not use their right to assembly and fear of immigration services. As an alternative, non-citizens were more comfortable with nonprofits, religious institutions, transnational associations, and using social media to connect for services. Immigrant nonprofits also met important government gaps in services because they can offer specialized services. The findings offer three recommendations for planners, including how to spend concerted time to build trust with non-citizens, using alternative spaces to ensure non-citizen safety, and developing partnerships with nonprofits to support immigrant services and immigrant-friendly policies.

In the following, I describe how planners have or have not successfully engaged with non-citizens. I then highlight how immigrant-serving nonprofits have served an important role to increase non-citizen engagement and representation in planning. After, I summarize the method and the three findings and recommendations to increase immigrant engagement in planning practice.

Planners and Non-Citizen Engagement

Studies have documented when planners minimally engage with non-citizens. For example, planners oftentimes do not specify immigrant integration goals, even in jurisdictions with large foreign-born populations (Kim et al., 2017). In addition to a dearth of formal engagement plans, Vitiello (2009) argues that planners have been ambivalent or dismissive of immigrant needs by using rational planning, which claims to be “culturally neutral” (p. 246). Planners then assume a technical position

rather than political role (Grengs, 2002; Lauria & Long, 2017), which discourages them from tailoring engagement methods.

Yet, planners perpetuate unequal immigrant representation through these “neutral” practices and inadvertently address the needs of long-term white native-born residents.¹ Lung-Amam (2017) documented tensions in Fremont, California between older white residents and new middle- and high-income Asian immigrant homeowners over single-family housing regulations. The participation process favored retired white residents who had the time, resources, and knowledge of formalized planning processes. These residents understood public meeting formats, frequently met with planning staff, and researched ongoing applications for building permits. In contrast, immigrants had trouble understanding and speaking English, were not informed about meetings because notifications were only posted in English or circulated only to previous attendees, and/or could not attend meetings due to conflicting work schedules. After, planners passed zoning that favored white residents and insisted the process did not discriminate against immigrants. Harwood (2005) similarly outlined Orange County, California land use conflict cases. Planners claimed to represent all groups, but *de facto* supported long-term white residents when they did not translate information, left out racial/ethnic and immigrant composition data in reports, and chose to only include crime statistics for immigrant-tailored land use requests. Planners also maintained that race/ethnicity did not affect their decisions because these methods were widely accepted community engagement practices (Harwood, 2005).

Over time, some planners have sought to improve immigrant engagement. Allen and Slotterback (2017) describe how planners gathered Somali refugee feedback by working with Somali-serving nonprofits, translating outreach materials, and holding public meetings in the evening. Yet, planners did not meet their participation goals because they were unaware of or ignored religious, group, and cultural considerations, including Muslim holidays, gender dynamics, and high illiteracy rates. Non-citizens experience additional barriers to public agencies due to their citizenship status, which impacts access to employment, economic development, and housing (Kim et al., 2017). Further, increasing diversity forces planners to assess their own biases and cultural frameworks as they work through community nuances (Harwood, 2005; Umemoto, 2001).

Nonprofits and Non-Citizen Engagement

Immigrant nonprofits have increasingly bridged the gap between non-citizens and the government for several reasons. Government entities may not be equipped to work with diverse immigrant groups, which have numerous cultural, linguistic, and socioeconomic needs (Lee et al., 2017; Vitiello & Acolin, 2017; Wilson, 2012). In contrast, immigrant nonprofits provide important culturally- and linguistically-tailored services (Hung, 2007; Roth et al., 2015). Consequently, immigrants and native-born residents have different institutional support networks. Immigrants who are not fluent in English and/or migrate from non-European countries may rely more on group-specific nonprofits while native-born residents can rely more on formal government agencies (Hung, 2007; Vitiello & Acolin, 2017). Furthermore, nonprofits have expanded their role in immigrant communities as the U.S. restructured and passed social service responsibilities to nonprofits (Alexander, 2000). The 1996 Personal Responsibility and Work Opportunity Act particularly affected human service nonprofits because non-naturalized citizens were no longer eligible for welfare benefits, which increased the need for nonprofits to serve these groups (Trudeau, 2008).

Immigrant nonprofits have also expanded their functions and how they intervene for non-citizens. Historically, they focused on addressing immigrants' integration needs and preserving cultural identity (Hung, 2007; Kondo, 2012). Gradually, immigrant nonprofits began to push for political representation and redistribution of resources through advocacy or equity planning (Davidoff, 1965; de Graauw, 2016; Kondo, 2012; Krumholz & Forester, 1990). For example, immigrant nonprofits have asserted immigrant voices in district and community land use and development review processes by using staff technical and organizational skills to inform and engage these constituencies (Espiritu, 1992; Hum, 2010; Ito & Pastor, 2018; Sarmiento & Sims, 2015). Nonprofits also support immigrants in formalized ways, such as speaking on behalf of clients at public meetings (Zapata, 2009), holding positions on planning boards (Sandoval, 2018), and organizing for immigrant-friendly development contracts (Gonzalez et al., 2012). These organizations provide alternative spaces of engagement beyond public meetings or planning boards, such as community meetings to gather resident opinions (Hum, 2010) and rallies or other political actions to challenge planners and policymakers (Sandoval, 2018; Sarmiento & Sims, 2015).

While these organizations may improve non-citizen representation in the planning process, they simultaneously complicate planning processes. Immigrant nonprofits have their own realm of political actors and disparate power dynamics (Bryson et al., 2012). Similarly, planners need to be conscientious of a nonprofit's target audiences to avoid inadvertently prioritizing one immigrant population over another (Allen & Slotterback, 2017). Furthermore, political power and public engagement are complicated in jurisdictions with a "super diversity," or areas with large-scale migration and its resulting diversity in race/ethnicity, national origin, citizenship status, and socioeconomic status (Nicholls & Uitermark, 2016).

Immigrant nonprofits are key stakeholders and institutions that increase non-citizen engagement. However, what happens to non-citizen engagement when political climates shift against non-citizens? This study seeks to understand the challenges that immigrant nonprofits encountered after the 2016 presidential election with their non-citizen clients.

Evaluating Nonprofit Relationships to Non-Citizens

This study draws from 29 semi-structured interviews with executive directors or program staff of immigrant-serving nonprofit organizations with 501(c)(3) status. Semi-structured interviews were conducted with 26 different organizations in Los Angeles County between July and December 2017. For three of the organizations, I conducted two interviews because they had programs from multiple sectors—for instance, health and legal services.

Interviewees were recruited in several ways. First, I used Guidestar.org, a nonprofit database that is searchable by geography, key words, and National Taxonomy of Exempt Entities (NTEE) codes to identify nonprofits in the target area.ⁱⁱ Among more than 12,000 nonprofits in the county, about 230 nonprofits were identified using the key word "immigrant." Of these 230 nonprofits, 48 had the NTEE designation of "ethnic/immigrant services." Additional online searches in newspapers were conducted to identify nonprofits that were active in immigration rights issues during 2016. Using these criteria, 68 organizations were contacted for an interview. Staff members who worked with

immigrant-related services were invited to participate; the executive director was contacted for smaller nonprofits. Other participants were recruited through snowball and convenience sampling.

Participants were asked about changes to client needs and immigrant engagement strategies after November 2016. Staff also described how they work with local, state, and federal governments and public agencies. Interviews were used because they provide insights into staff perceptions of client issues and trends across organizations (Strauss & Corbin, 1998). Interviews lasted from 45 to 60 minutes and were audio recorded. Full transcriptions were analyzed using Dedoose.com, a qualitative coding website. I developed a coding dictionary through an iterative inductive process—interviews were reviewed to develop proposed themes, and parent and child codes were edited after analyzing additional transcripts (Strauss & Corbin, 1998). Two graduate students validated the coding. Nonprofit names are kept anonymous to protect confidentiality.

Table 1 displays summary characteristics of interviewed nonprofits. On average, the organizations were granted 501(c)(3) status in the late 1980s, and nearly half of the organizations had about \$1 million to less than \$5 million in revenue. More than half also had fewer than 50 employees. Nonprofits differed in focus and intervention, ranging from advocacy groups to human service providers, legal services, mental health services, housing, and refugee issues; however, most provide more than one service. Twelve nonprofits focused on Latinos, ten targeted Asian Americans and Pacific Islanders, two worked with Muslims, and four organizations served immigrants or refugees with no specific racial/ethnic group focus; two nonprofits served Latinos, Asian Americans, and Pacific Islanders. The majority of nonprofits offered services in Spanish, and some offered Asian or Middle Eastern languages.

Table 1. Characteristics of Interviewed Nonprofits, FY 2016

Source: Guidestar.org and online searches. Notes: Nonprofit Internal Revenue Service forms report revenue rather than budget, which can be used to assess size of organizations. *Based on NTEE code. The total does not sum to 26 because organizations may have multiple activities. **Some of these organizations serve both racial groups. ***Nonprofits organized by primary function, but some organizations provide multiple functions.

Los Angeles has had a consistent flow of immigrants since World War II (Singer, 2013), which has led to a robust network of immigrant nonprofits. About 17% of Los Angeles County was foreign-born in 2016 according to the American Community Survey—about 67% of Asian Americans and 39% of Latinos were immigrants. About 1 million undocumented immigrants are estimated to live in the Los Angeles metropolitan area, which is second to New York City (Passel & Cohn, 2017). Los Angeles is estimated to have nearly a third of Latino and Asian nonprofits of the 10 largest metropolitan areas (Hung, 2007).

Sampling may contribute to bias in the results. As with most nonprobability samples, respondents elected to participate and may have stronger opinions than those who did not participate in the study. Furthermore, potential participants may also differ from interviewees if they did not have the capacity to be interviewed for the study, which suggests interviewees may work in more established nonprofits. Second, there are no set guidelines for sample size needed in qualitative studies. However, data collection ended at the 29 interviews because preliminary analysis reached the point of saturation, or when no additional themes arose (Saunders et al., 2017). Further, immigrant-related politics changed nearly weekly or monthly during the 6 months of data collection. To address the goal of capturing nonprofit experiences immediately following significant political changes, the data collection period was limited to capture nonprofits reacting to the same political climate. Still, the findings provide in-depth insights about challenges of working with non-citizens in tumultuous political contexts and how planners can improve non-citizen participation.

Three Considerations for Non-Citizen Engagement

Non-citizens experience disparate access to traditional forms of engagement. For example, those without citizenship or legal status typically cannot serve as public officials, vote in an election, and/or are ineligible for some public benefits.ⁱⁱⁱ Nonprofit interviewees highlight how non-citizens experience additional barriers to public services and spaces for a few reasons. First, fear and safety concerns affected non-citizens because of increased cases of detention, arrests, and hate crimes after the 2016 election (Torbaty, 2017; Williams, 2018). Second, non-citizens interact with spaces of engagement differently than native-born residents related to these fears. Third, these considerations increase non-citizens dependency on nonprofits. (Table 2 summarizes the findings.) The following includes quotations from staff members, which were edited only for clarification.

Table 2. Summary of Findings and Recommendations

Non-Citizen Engagement Consideration	Recommendation for Planners
<p>1. Increased fear and safety, depending on citizenship status</p> <ul style="list-style-type: none"> • Uncertainty about how policy changes will affect various immigration statuses • Opting out of or being selective in what types of public benefits they use because of fear of deportation, losing benefits, or penalties 	<p>1. Spend more time with immigrants to build trust</p> <ul style="list-style-type: none"> • Invest in frequent outreach efforts • Offer small incentives • Be proactive in ensuring immigrant safety • Prioritize multiple forms of translation
<p>2. Different spaces for non-citizen engagement (local, state, national, transnational)</p> <ul style="list-style-type: none"> • Limited access to public institutions, public spaces, and right to assembly out of fear of immigration services • Comfort with nonprofits, religious institutions, transnational associations, and social media • Connections beyond the neighborhood, including other countries due to deportations 	<p>2. Use alternative spaces for immigrant engagement</p> <ul style="list-style-type: none"> • Ensure safety at existing public institutions • Incorporate small group or individual participation methods • Push for policies that decouple public institutions from immigration services • Hold community forums in anticipation of or in response to policy changes
<p>3. Dependent on immigrant nonprofits</p> <ul style="list-style-type: none"> • Nonprofits tailor approaches to service group • Government gaps in service • Nonprofits identify policies disproportionately affecting non-citizens 	<p>3. Develop partnerships with nonprofits</p> <ul style="list-style-type: none"> • Establish partnerships with the public, private, and nonprofit sector • Generate funding sources that support nonprofit immigrant services • Collaborate with nonprofits to create immigrant-friendly policies

1. Fear and Safety Concerns

Nonprofits reported that non-citizens of varying immigration statuses had concerns about their safety, changes in immigration status, and deportations. With anti-immigrant rhetoric, members were also

afraid that their legal rights could be taken away. Families were left to make critical decisions about whether they should access public services they are entitled to use.

Interviewees explained how clients were concerned for their family's safety in this context. A participant described how non-citizens were targeted for participating in public events: "[A DACA activist] spoke at a press conference, and then the next day, she was detained... and her mom first was picked up for collateral where ICE [Immigration and Customs Enforcement] was collaborating with the sheriffs." This fear extends to clients who are undocumented: "You have these rights as an immigrant. However, if you have an outstanding deportation order, a criminal conviction, a common name, or someone in your apartment had one of these things, you might be at risk." There are other incidents that ICE agents arrest people who live or work nearby raids who are suspected to be undocumented even though the raid was targeting other individuals (Burnett, 2017; Jacobs, 2018; Sanchez, 2017; Sheets, 2017).

Clients also experienced an increase in hate crimes and discrimination. One staff noted, "Hate crimes reported to us rose significantly in the month following the election, more reports than we'd gotten last year, and this is when hate crimes are underreported." Another interviewee observed, "What is more concerning for our members is the old-school white supremacy that happened through the election...with increases in discrimination and being told to go home when you're getting gas."

Additionally, non-citizen clients were apprehensive that the government would suddenly end their immigration program, which would change their immigrant status and legal rights. A staff member shared how clients approached their organization the day after the election:

There was a lot of tears, a lot of worry, if people are on temporary protection status, or a family member who's awaiting asylum, what's gonna happen? My sister is undocumented, what will happen to her? We were meeting the next morning and at 9 o'clock, people had already gotten calls and messages from their family members and were feeling worried, afraid.

Another interviewee was surprised how "even green card holders were calling us, asking if they can be taken away or if they can travel because people are living in fear of their status." These fears are exacerbated for refugees from a country that persecuted its people: "Our community history and trauma just make them untrusting of the government." Consequently, non-citizens of all statuses were afraid of changes to their programs and whether they would be at risk of deportation.

This distress limited non-citizen access to public resources. Low-income clients were selective in what kinds of assistance they applied for and used because of concerns that the government will track them. A staff member explained: "Clients will receive services from us, but they don't want to apply for food stamps or Medi-Cal because they're worried that the government will deport them." Similarly, a participant noticed, "Clients are hesitant in applying for government services because they feel it would draw attention to them, and they might get penalized." Non-citizen concerns were also elevated due to shifting and unpredictable federal regulations about public programs (Shear & Baumgaertner, 2018). An interviewee used the example of public charges: "The leaked memo about

public charge... didn't become official policy but had a dramatic impact. Our community members weren't applying for public benefits lest they be considered a public charge and not get to stay."

These described fears limit non-citizen access to other services that are assumed to be accessible. A prominent example was public schools. A staff highlighted how students were afraid of attending school: "We're working with school-based children, maybe their parents are not documented, so they don't know if they come home from school one day that their parents might not be there." Alternatively, students opted out of school because of uncertainties around their immigration status. An interviewee explained: "When I was at [High School], staff mentioned that chronic absenteeism has gone up because students, they're new immigrants, they'd rather not go to school." Another staff shared parents' perspectives about deportation: "Parents drop their kid to school and they are worried, should I take my kid?"

2. Non-Citizen Spaces of Engagement

Similar to public resources, non-citizens make decisions about being visible in spaces of engagement based on perceived risk. Thus, non-citizens may not exercise their right to assembly because of their concerns around fear and safety. A staff describes client concerns:

We didn't think much of public press conferences, protests, or rallies because [in Los Angeles] it's a low-risk activity, but that changed after Trump was inaugurated and ICE targeted undocumented activists. All of a sudden organizing became very high risk, and not normal ... We have to be realistic that for a lot of our members it's more than just fear, it's a really intense, dramatic, material consequence if something does happen.

However, this fear of public rallies depends on citizenship status. For example, one interviewee noted how in their campaign for immigrant workers' rights, "Undocumented members won't participate, but those who came out have papers or are citizens." A staff shared another example of clients changing the scale of engagement: "We haven't had as much success in overt forms of organizing, like taking a busload of clients to Sacramento [for lobbying], but we have clients testify at meetings or hearings." These examples show how non-citizens have differential comfort to freedom of speech and assembly than native-born residents in precarious contexts.

Moreover, the neighborhood has been an important geographic unit for the community reinvestment movement (Dreier, 2003) and neighborhood revitalization programs (Martin & Pentel, 2002). Yet, non-citizens may practice democracy or engage with entities beyond their immediate neighborhood, including nonprofits, religious institutions, transnational associations, and social media (Sandoval, 2013; Sarmiento & Beard, 2013; Veronis, 2013). For example, a staff member described their monthly immigration clinics: "We do not have a physical space but we establish relationships with churches to create semi-permanent locations for our immigration consultations." Another interviewee similar shared, "We go out and do advocacy workshops at mosques."

Nonprofits also engage with international agencies and organizations to serve clients who migrated from countries that have agreements with the U.S. to receive deportees. One interviewee described how "few TPS people are going to return to their nation of origin because the situation is worse than

what they're facing here." Many of these individuals are ineligible to apply for permanent residency, and some of these clients sought to cross the Canadian border. To provide cautious information, the nonprofit worked with the Canadian Consulate "to clarify what is the process if someone decides to cross the border into Canada fleeing the unfriendly immigrant policies of the current administration." Other organizations with clients from countries designated for TPS also collaborated with transnational nonprofits to be informed of and influence international agreements.

Non-citizens also used social media to work with immigrant nonprofits across national borders. A participant described how a deported client contacted their organization through Facebook because "his family was left behind, and he wanted help for them to follow him to [home country]. We helped him and used [this incident] to educate our community about when you are arrested and deported." Immigrant nonprofits then use these informal spaces online to further assist their clients.

Finally, when more public spaces were inaccessible, some nonprofits encouraged clients to meet in private spaces. One nonprofit had members meet at home "instead of our membership meetings" to "find different ways for people to resist, like I'm going to your house and you're inviting two neighbors and do an informal Know Your Rights [workshop]." These organizations understand how to use spaces that feel safe for non-citizens that take place in formal institutions—such as places of worship or nonprofits—and informal spaces. These organizations also consider how clients are affected by national and international policies beyond neighborhood borders.

3. Dependence on Immigrant Nonprofits

Non-citizens are dependent on immigrant nonprofits for several reasons. First, the government may not provide services for this group. As a result, nonprofits have developed and/or are mandated to offer specialized services. Furthermore, non-citizens rely on nonprofits because of language barriers, distrust of the government, and fear due to citizenship status. As previously described, nonprofits understand these challenges when assisting clients, and many nonprofits served clients beyond their city or county who do not have alternate resources (see also DeVita & de Leon, 2012). They also identify ways that non-citizen clients are disproportionately impacted by government policies, which affect client willingness to engage politically.

Immigrant nonprofits serve important functions for non-citizens because of their tailored approach, which bridges gaps in governmental services. One critical gap is in-language services for non-citizens. Kondo (2012) described how government agencies might not prioritize translation services for non-English residents, by not placing translators at the front of a meeting and not leaving enough time for translation of speakers during meetings. Similarly, an interviewee explained: "There is a gap in services because they don't have [our language] speakers on staff, so those who used to receive services no longer receive help." Eventually, this organization became a government subcontractor to help with translation in these services.

Nonprofits also mediate in more serious cases when government agencies do not provide translators. A case with Southeast Asian workers illustrates this point. A nonprofit was alerted that a restaurant was raided by "the Board of Equalization [BOE] for tax evasion so the owners are criminals." However, the staff discovered that "workers were handcuffed, and they [BOE] brought in sheriffs,

though we know the workers are being exploited and they're not a threat.” However, BOE did not “take measures to bring people in that speak their own language to explain what’s going on, so [the workers] were scared out of their minds.” The organization then stepped in to clarify that the workers were not involved in the crime.

Government agencies and programs also may not reach out to non-citizens to inform them of their rights. One nonprofit staff “noticed that people were not using their benefits and were hesitant to go show up at clinics because they heard there was an [ICE] agent that went into the hospital.” She then detailed their follow-up process:

So we enroll somebody, then at 30 days we confirming they got in, and then at 6 months that they used their benefits. At 6 months, people were saying no, I haven’t used my benefits, so we’d say, let me help you make an appointment.

This example illustrates how immigrant nonprofits specialize their non-citizen services when government agencies fail to educate non-citizens about their legal rights and benefits.

Furthermore, immigrant nonprofits have a deep understanding of their clients’ needs and how they are disproportionately affected by policies. An interviewee explained how their members struggle with naturalization requirements:

We have a population that was not able to learn English and don’t qualify for the English or Civics Test waiver for naturalization, and now we’re trying to figure out how they’ll pass [naturalization] exams ...the English and Civics waivers are for seniors and you have your green card for 20 years. But since our community is newer, they don’t have their green cards for that long and a lot of our seniors have difficulty learning English.

This nonprofit understand the special needs of their senior clients and roadblocks for members who seek to become citizens.

This issue also extends to intersections of the immigration and criminal justice systems. Nonprofits found ways that minor infractions would escalate clients’ risk of deportation. One participant described the situation of her refugee clients from Southeast Asia, who arrived at a young age:

Our clients grew up in high poverty, crime areas here, have criminal records [from] when they were younger, served their sentence, did their time, and then they were re-integrated into the community, and now have families, full time jobs. But because of this past record, they’re on a deportation list.

Some of these crimes were minor, such as breaking a window as a teenager. Yet, the way the criminal system charged these clients, there are at high risk of deportation. A different nonprofit described their work on street vending, which was considered an infraction in Los Angeles municipal code. When clients did not show up to court “because there was a new fear with the anti-immigrant rhetoric and executive order on fast-tracking deportations,” their infractions turned into misdemeanors and “could put them on the list to be deported.” In collaboration with others, this nonprofit successfully decriminalized this municipal code.

Three Recommendations for Non-Citizen Engagement

Immigrant nonprofits utilize several strategies for planners to build trust with non-citizens and increase public participation. The following describes three tactics (see Table 2 for a summary).

1. Spend Concerted Time to Build Trust

Non-citizens are not an efficient group for planners to engage with for several reasons. First, some non-citizens require significant outreach efforts before they may attend their first meeting. However, this absence does not equate to these groups not needing services. An interviewee detailed how the organization engages with their hard-to-reach population:

There are nuances into outreaching and educating our members before they are even open to receive services. We provide some initial, tangible resources to our members before they're even open to receiving other services and it's all about building trust and relationship.

An example resource is enrolling potential clients in Low Income Energy Assistance, which can decrease utility bills. After a client sees this benefit," we get our foot in the door and then we can have more conversations about their other needs." Planners can offer some small incentives for public participation meetings to build trust. Kondo (2012) also described how an immigrant nonprofit offered families a \$25 gift card for Target as an incentive to attend meetings.

Nonprofits also recognize they need to be proactive to maintain trust with non-citizen clients, particularly those who are concerned about deportation or their immigration status changing. For instance, a participant spent extra time to communicate to clients: "our first priority is to protect their confidentiality, and that we don't cooperate with immigration services looking for information about client immigration status." These messages retain clients who "want to drop out of treatment because they think, if I move, I might be harder to find [for ICE]." Another interviewee described how "we sent letters to our families just letting them know that this is a safe organization and we're here to support them."

These efforts may include more translation efforts for non-citizens who do not speak English comfortably. A staff member described their tactics with schools: "We'll work harder to outreach at schools because immigration [ICE] is going to the schools. We'll hold hands with the school and hire more Spanish-speaking staff to work with families because the language would increase trust." Planning departments may already work with translators or hire staff who can speak another language. However, an interviewee demonstrates how planners can implement multiple forms of translation:

Many immigrant members never had formal education in this country... there are no materials in their language to know about these issues so someone is bilingual, they'll write a kind of memo, and then makes a presentation, these are the key issues, key player in how things happen. We also do some spontaneous translations.

This example shows how planners can create brief written translations, prepared oral translated remarks at the start of a meeting, and additional translations as needed throughout the meeting. By doing so, planners would prioritize translation before, the start of, and throughout meetings. These efforts also signal to non-English speaking non-citizens that planners understand that language issues are about “meaningful access” rather than simple interpretation (Wilson, 2012).

2. Use Alternative Spaces of Engagement for Non-Citizens

Planners can use other spaces to engage non-citizens, and/or using creativity in community events. As previously described, immigrant nonprofits work to engage non-citizens in nonprofits, religious institutions, transnational associations, and informal spaces. Also, planners can push for formal policies that ensure non-citizen safety.

Nonprofits use multiple spaces for constituent participation (Hum, 2010; Sarmiento & Sims, 2015). One organization member further explained their approach:

We committed to do regular town halls here so that members had access to us and could ask questions. We had our first one the same weekend as the first iteration of the Muslim ban, and we’re trying to be ahead of the curve though things are constantly changing.

Interviewees did not indicate a preferred type of space, but rather a multipronged approach and the importance of holding meetings in anticipation of major policy changes. For instance, a nonprofit held community meetings on important dates with government agencies: “The day of the election, we had to have a forum to talk to our immigrant families about their rights.” Another nonprofit also held Know Your Rights workshops with the mayoral office immediately upon anticipation of major policy changes: “When the decision [to end DACA] happened, the Mayor’s office called us and we said, okay let’s do DACA workshops.”

These meetings were accessible to non-citizens because a trusted immigrant nonprofit organized it at a non-government venue. These strategies are similar to Hum’s (2010) example of nonprofits holding community events at a foundation rather than community board meetings that are otherwise inaccessible to immigrants. Additionally, planners need to understand the timing of meetings. They can schedule forums and workshops in anticipation of major changes, which will help assure non-citizens that planners are looking out for their interests and well-being.

When public buildings are used, planners can push for measures to ensure that non-citizens are not concerned about their immigration status when participating. Los Angeles nonprofits worked with policymakers to decouple public institutions from immigration services. After, in October 2017, California legislation passed A.B. 699 (2017), which prohibits schools from collecting immigration status information of students and their families.

Alternatively, some non-citizens may hesitate to attend public meetings because of their concerns around safety and citizenship status. Consequently, an interviewee explained how “we work more on the 1-on-1 because even when we do an action or event inspired and led by the community, most of them don’t come out.” Planners may also need to incorporate individual and/or small group

participation along with posting information on social media with nonprofits or other community institutions.

3. Partner with Nonprofits

Planners also can collaborate with the nonprofit sector to involve non-citizens in governmental processes because these institutions dedicate significant resources to build trust with this population. As previously described, nonprofits are important intermediaries with planners and government agencies. These relationships will prevent planners from “parachuting” into non-citizen communities to gather community knowledge without developing lasting mutual connections.

These partnerships can encompass the public, private, and nonprofit sector to generate new funding and foster policy buy-in (Ashley, 2014; Smith & Lipsky, 1993). An organization describes one such example: “Private philanthropy, the county, and the city provided funding for nonprofits to provide legal services around deportation defense. It took 6, 7 months of advocacy with [our Coalition] and engaging our elected officials.” This partnership created more than half a million dollars in funds. The interviewee continues to describe the benefits with public partnerships because they can share clients’ issues with government agencies “to inform policies and what elected officials need to do now, not in 6 months.”

These collaborations can lead to immigrant-friendly policies (de Graauw, 2016; Wilson, 2012). An interviewee described how a state senator approached this organization “with the California Religious Freedom Act. It’s not something that we brought up with him, so we’ve seen senators and city council putting forth motions, and resolutions.” Through continued relationships, this elected official was proactive in passing pro-immigrant measures, which helps immigrants feel safe regardless of religious affiliation.

Planners can redistribute power and increase immigrant engagement through similar partnerships. Interviewed nonprofits have established networks to help a broader group of clients, such as connecting with other organizations that specialize in indigenous or uncommon languages. These collaborations would benefit planners who may not have the resources to develop tailored engagement.

An “Imagined Future” with Non-Citizens

The findings summarize how planners can redistribute power and build trust to improve non-citizen engagement, particularly in rapidly changing political contexts. I offer several insights about non-citizens’ needs, including increased concerns about fear and safety, restricted access to resources and spaces, and dependency on nonprofits. These findings provide planners with methods to strengthen ties to immigrant communities, including spending time to build trust, using alternative engagement, and partnering with nonprofits.

Planners should understand how issues disparately affect non-citizens by immigration status and context. Groups that are at risk of deportation may experience the highest levels of concern—this group includes undocumented individuals, legal permanent residents, and refugees from countries with repatriation agreements with the United States. Low-income non-citizens will be concerned

about loss of benefits, while non-citizens of all socioeconomic statuses may be confused about their legal rights. Non-citizens who are not fluent in English will require more in-language assistance. Planners may also need to spend more time to build trust with refugees and other migrants who arrived from countries with oppressive governments.

It is important to acknowledge other constraints that will affect planners. Some planners or planning departments may not be equipped to design specialized interventions due to time and resources. When planners cannot implement the first two recommendations, they can focus on supporting immigrant nonprofits, which provide organizing skills and socioeconomic and political infrastructure in immigrant communities (Hung, 2007; Sandoval, 2018; Sarmiento & Sims, 2015).

Planners are also limited by their jurisdictions and political context. First, they may be constrained by state and city policies. Planners in sanctuary cities have more protections to assist non-citizens than planners in jurisdictions with anti-immigrant policies meant to exclude immigrants (Gilbert, 2009). Regardless, all planners can inform constituencies of their legal rights, regardless of status. Second, elected officials and planners may experience tension because of their different objectives. Elected officials aim to win elections and represent their voting constituents; planners aim to reflect the larger public's interests, but are constrained by elected officials (Beckman, 1964; Harwood, 2005). Consequently, planners are embedded in the politics of the planning commission, elected officials, and other government agencies, which may disagree with planners' recommendations (Harwood, 2005).

These considerations can help planners cope with uncertainty from changing demographics and political contexts (Christensen, 1985; Frey, 2002). As Spain (1993) described, "The issue facing planners is how to facilitate the transition from the imagined past to the imagined future" (p. 157). This transition includes shifting planning engagement of long-time residents ("the imagined past") to include new non-citizens ("the imagined future"). These incremental practices will not resolve the broken immigration system. Immigration reform is a long process, and any reforms will likely result in multiple immigration statuses. Still, planners can be unwavering in using inclusive practices to increase non-citizen participation and/or representation as the country undergoes waves of federal backlash and support for immigrants.

ⁱ About 4% of non-Hispanic whites were foreign-born according to the 2017 5-year American Community Survey. The following cases use the category “white” to describe non-Hispanic whites. However, there is evidence that some Latinos may identify or mark the category “white” (see Golash-Boza & Darity, Jr. [2008] and Tafoya [2004]).

ⁱⁱ The Internal Revenue Service categorizes nonprofits by the NTEE system (Guidestar, 2019). Categories include health care; environment; civil rights, social action & advocacy; community improvement & capacity building; employment; and human services. NTEE categories that specify immigrants are subcategories under human services (P84) and minority civil rights (R22). Many immigrant-serving nonprofits are then categorized based on other functions, such as housing, health care, human services, or education. Nonprofits can also be categorized by multiple NTEE categories. Many nonprofits in Los Angeles also service immigrants because their service area or target geography has a large foreign-born population.

ⁱⁱⁱ There are some unique cases where non-citizens can be appointed to planning boards.

Learning from Arnstein's Ladder:
From Citizen Participation to Public Engagement

Citizen Participation in Transitional Society:
An Evolution of Participatory Planning in Serbia

Ana Perić¹

¹ETH Zurich, Institute for Spatial and Landscape Development, aperic@ethz.ch
University of Belgrade, Faculty of Architecture

Abstract: Arnstein's seminal article influenced both the scholars and practitioners to explore the ways of citizen engagement against the public administration and politicians. To illustrate this, I present the case study of Serbia through four phases of its planning history. After the Second World War, the top-down spatial planning for social good was controlled by the elite multidisciplinary technocratic decisions. Citizens were just *informed* about the possibilities for public insight and debate. The state decentralization of the 1970s, influenced the shift of planning from the state focused allocation to the community responsive planning, based on *delegated power* of the civil sector in *partnership* with representatives of local politics. In the 1990s, when the development process was almost exclusively driven by private investment greenlighted by the national government, the citizen participation was not even *manipulated* – it did not exist, neither in planning legislation, nor in planning practice. Today, Serbia faces the privatization of state land and resources, while experts try to find their own place in an arena of manifold interests, making the citizens able to exercise only 'de jure' public *consultation*. The need for substantial citizens involvement is indisputable, however, the step towards its implementation follows the democratic development of Serbia.

Keywords: Sherry Arnstein, public engagement, transitional society, Serbia

Introduction

Arnstein used the metaphor of a ladder to describe examples of citizen participation that projected the cutting-edge progress upward – from securing political rights to obtaining economic justice. People would obtain greater influence for the places they live in by using types of participation with greater access to political authority. Organized civil disobedience and nonviolent protests proved useful in stopping bad redevelopment and highway projects. However, poor people were not integrated into political positions of influence; some other planning approaches (e.g. advocacy or equity planning) dealt with such efforts (Davidoff, 1965; Krumholz *et al.*, 1975). Moreover, global financial crisis of the 1970s affected the shift towards neoliberal governance promoting competition. This designated the crisis for citizen participation, too. The neoliberals weakened the legitimacy and coherence of the state as an instrument for enhancing citizen sovereignty, while increasing divisions that enable elites to lobby for favorable financial benefits. However, the social democracy in the United States (US) called

for citizen participation again – in planning theory this resulted in ‘communicative-argumentative turn’ (Forester, 1989) and, therefore, the resurgence of Arnstein’s approach.

Why should we use Arnstein’s seminal article for the analysis of the Serbian spatial planning that is quite different to the briefly reviewed US context? Due to its universal nature, the ‘ladder’ here serves as a tool for elucidating the “gradations of citizen participation” (Arnstein, 1969: 217). Exploring citizen participation in the challenging case of Serbia means discovering a variety of nuances of public involvement – from passive observers to controllers of urban development. Moreover, the Serbian case clearly illustrates that participation cannot be taken for granted – it must be won over and over again. What is the impact of participation or who has the right to decide? Answering this question helps elucidate participatory planning in both socialist Yugoslavia and ‘proto-democratic’ Serbia. More precisely, this chapter seeks to identify the extent and contextual dependence of participation in the decision-making processes observed through various periods of Serbian planning history.

The chapter is structured as follows. I start with an overview of participatory planning in Serbia in relation to the more general social system covering both the socialist and post-socialist period. This is followed by a distinctive example of how contemporary planning practice responds to citizens’ demands for transparent and inclusive planning. In the discussion part, two specific periods of Serbian planning history are presented: authoritarian regime of the 1970s and 1980s when the public interest was the main system value and instruments for public involvement were advanced, in contrast to contemporary pluralistic society that overrides the voice of powerless citizens. The chapter concludes with basic operational recommendations for improving the participatory planning approach in a highly challenging society.

Citizen participation in Serbian spatial planning

Serbia has undergone tremendous changes in its political, economic and, thus, planning system. As the societal context within which the planning system is embedded provides the framework for the citizens to express and materialize their own interests (by taking part in creating certain policies and implementing particular instruments), the next section briefly describes the extent and nature of citizen participation in spatial planning decision-making in Serbia. Four periods of Serbian planning history, following the main transformation of Yugoslavia (Figure 1) since the Second World War, are identified: 1) integrated planning (1945–1974), 2) participatory planning (1974–1989), 3) centralized planning (1989–2000), and 4) market-led planning (2000–present).

Integrated planning (1945–1974)

The end of the Second World War was a great turning point in Serbian history: in economic terms, the poorly developed agrarian economy was replaced by a centralized planned economy (Zukin, 1975; Liotta, 2001; Perić and Miljuš, 2017), while in political terms, after a short phase of communism (1945–1950), Yugoslavia started ‘experimenting’ with a new brand of socialism accompanied by decentralization, opening to the (state-controlled) market-economy, loans programs with international organizations, and self-management, i.e. societal ownership over productive resources and management of public enterprises by their employees (Ramet, 1995). Following this logic, self-governed interest-driven local communities started to emerge as the main player at the local decision-making level shortly after 1953 (Veselinović, 2017).

Urban planning also experienced great transformation in less than two decades: from a tool to support socio-economic development (Dawson, 1987), across physical planning (i.e. land-use and zoning) introduced in 1957, to integrated and comprehensive planning based on interdisciplinarity among all relevant sectors when dealing with spatial issues (Nedović-Budić and Cavrić, 2006). Looking through the lens of public participation in plan making, even the first postwar planning law (of 1949) prescribed the procedure of public insight into the draft version of a plan, while the laws from 1960s and 1970s considered citizen participation as societal support and

plan verification (Zukin, 1975). However, such planning legislation did not generate real participatory planning practice; rather, participation in planning was raised by the activities of local community on the issues of local interest (Fisher, 1962; Veselinović, 2017).

Integrated planning (1945–1974)

The end of the Second World War was a great turning point in Serbian history: in economic terms, the poorly developed agrarian economy was replaced by a centralized planned economy (Zukin, 1975; Liotta, 2001; Perić and Miljuš, 2017), while in political terms, after a short phase of communism (1945–1950), Yugoslavia started ‘experimenting’ with a new brand of socialism accompanied by decentralization, opening to the (state-controlled) market-economy, loans programs with international organizations, and self-management, i.e. societal ownership over productive resources and management of public enterprises by their employees (Ramet, 1995). Following this logic, self-governed interest-driven local communities started to emerge as the main player at the local decision-making level shortly after 1953 (Veselinović, 2017).

Urban planning also experienced great transformation in less than two decades: from a tool to support socio-economic development (Dawson, 1987), across physical planning (i.e. land-use and zoning) introduced in 1957, to integrated and comprehensive planning based on interdisciplinarity among all relevant sectors when dealing with spatial issues (Nedović-Budić and Cavrić, 2006). Looking through the lens of public participation in plan making, even the first postwar planning law (of 1949) prescribed the procedure of public insight into the draft version of a plan, while the laws from 1960s and 1970s considered citizen participation as societal support and plan verification (Zukin, 1975). However, such planning legislation did not generate real participatory planning practice; rather, participation in planning was raised by the activities of local community on the issues of local interest (Fisher, 1962; Veselinović, 2017).

Participatory planning (1974–1989)

The Constitution from 1974 prescribed further territorial decentralization of the federal state, more developed mechanisms for citizen participation, and support for the self-management system (Lydall, 1989). This mixed-economy continued to reinforce an arena for including actors other than public sector ones in spatial planning activities (Nedović-Budić and Cavrić, 2006). The decentralized system of decision-making was applied to social, economic and spatial planning and policy, and shared by the federal, republic, and local authorities and individual enterprises (Dawson, 1987).

Previously initiated efforts to integrate physical planning into the socio-economic planning system caused the shift in planning as exclusively expert-driven activity: planning legislation (1974) identified local communities as the crucial planning and implementation bodies, and public discussion on the draft plan appeared a regular practice (Čolić, 2009; Maričić *et al.*, 2018). In 1985 the law was updated to improve the coordination and integration of plans and policies, introducing the instrument of expert debate not only on the final, but also on the first draft of a plan (Vujošević and Nedović-Budić, 2006). However, although planning and socio-economic policy usually move together, they have different pace. Influenced by global economic crisis, by the late 1970s Yugoslavia struggled economically (hyperinflation, debt, trade imbalance) and faced internal political tensions and the need to eliminate self-management by 1990 (Mencinger, 1991). In contrast to this, planning still followed the trajectory of decentralization until the mid-1990s (Vujošević, 2003).

Centralized planning (1989–2000)

The fall of the Berlin Wall had substantial social and economic consequences on Europe, however Yugoslavia additionally suffered from the disintegration of its territory, accompanied by civil wars and nationalistic tendencies in all the newly formed states. As a result, Yugoslavia was politically re-centralized (Ramet, 1995), the economic system’s change towards market-based economy was slow due to the absence of institutional capacity (Liotta, 2001), and the authoritarian political regime brought political, social, and, thus, spatial degradation (Zurnić, 2019).

In the 1990s, the national government, i.e. the Ministry of Construction, took over the role of the key actor in spatial planning decision-making (Nedović-Budić and Cavić, 2006). Corruption, non-transparent decision-making procedures, and unregulated economic measures influenced close relationship between the highest government level and the private investors (Zeković *et al.*, 2015; Vujošević *et al.*, 2012; Vujović and Petrović, 2007; Zurnić, 2019). Such symbiosis neglected social goals and greatly endangered citizen participation. Decentralization in planning domain (as prescribed by the law from 1995) was an illusion: master urban plans prepared by local authorities' had symbolic purpose as the central political power directly influenced planning practice at any territorial level (Vujošević and Nedović-Budić, 2006).

Market-led planning (2000–present)

In late 2000, Serbia created a democratically elected government for the first time after more than half a century thus designating the start of a pluralist political culture and a re-decentralization of power. Nevertheless, the absence of appropriate measures, institutional capacity, and political reforms when embracing a market-driven economy constitutes 'a messy and uneven process' (Cope, 2015). Another pillar of a neoliberal system is also challenged in the Serbian society still considered a 'proto-democracy' (Vujošević, 2010). Consequently, spatial planning instruments are ineffective and citizen involvement is low (Maričić *et al.*, 2018).

Three crucial laws clearly illustrate the weak position of spatial planning in the transitional social and political context of Serbia. The planning law from 2003 cancelled the expert debate and even abolished the possibility of informing the public about the beginning of the procedure of public insight, therefore only the debate among the members of the plan approval commission remained (Čolić, 2009). In 2004, the law on privatization made it possible for private consortia to buy the state (social) enterprises, while the new planning law (2009) converted (building and land) use-right into the ownership-right (Perić and Miljuš, 2017). Although the public opinion finds the legal support in the modified planning law from 2014 – 'early public insight' allows citizens to express their opinion on certain urban issues in an early phase of plan making – public voices are not heard enough, citizens are mainly passive recipients of information, and civil sector is usually omitted from the urban decision-making process (Perić and Maruna, 2012; Maruna and Čolić, 2017). Only grassroots movements appear to act as a public interest advocate (Grubbauer and Čamprag, 2019).

Methodology

The previous historical analysis of societal context (socio-political and economic system) and planning system served to identify the position of citizen participation in a planning process through various periods. The following sections elucidate the extent and dynamics of public engagement.

First, I conduct in-depth qualitative case study of the Belgrade Waterfront (BW) project as a paradigmatic example of the current urban development in Serbia. Briefly: 1) I screen the laws, plans, strategies, regulations, and contracts to describe critical relationships between the private developers' incentives and the public sector's responses to them, 2) using the discourse analysis of the media announcements provided by the civil sector organizations between 2012 (i.e. since first advertising on the BW project in the media) and 2017 (in order to keep a proper distance to the present moment), I identify the main narrative among citizenry and their critical remarks to the steps taken in both preparation and implementation of the BW project, and 3) using the content analysis of scholarly articles on the current urban development in Serbia, in addition to previous, I critically assess the professional position towards citizen engagement in public issues with considerable spatial impact.

Second, I draw a comparison based on the Arnstein's seven 'gradations of citizen participation' between two periods of Serbian planning history: the period of the 1970s and 1980s glorifying citizen participation in planning, and the contemporary phase neglecting public involvement. However, as the periods are interpreted considering

also the societal context and not only the formal planning procedures, I derive conclusions on deeper patterns and impact of citizen participation that diminish the initially perceivable contrast between the two periods.

Case study: the Belgrade Waterfront project

Most of the countries and cities of the post-socialist Central and Eastern Europe (CEE) faced the social, political, economic and cultural transformation in the last decade of the 20th century. More precisely, limited role of planners, neoliberal transition, post-socialist transformation, shift to the western model of democratic decision-making, orientation of the legislation towards legitimization of illegal developments, etc. all set the course for a dynamic socio-spatial restructuring in CEE (Stanilov, 2007; Tasan-Kok, 2004; Tsenkova and Nedović-Budić, 2006; Hirt, 2005; Doytchinov *et al.*, 2015). The ex-Yugoslav republics, today all independent states, followed the same transitional pattern, delayed for a decade though.

Before elucidating the current controversies around the BW project, a brief history of the site development is shown (Kovačević, 2014; Perić, 2016; Perić and Hoch, 2017). The idea to create the new urban center of Belgrade on the right bank of the Sava River, at the bottom of the so-called Sava Amphitheater, was embedded in the first master plan of Belgrade of 1923. As it was recognized as a site of regional and even national importance in all the following Belgrade master plans, its potential was explored through a number of studies and urban design competitions organized during the 1970s and 1980s, in the golden era of Yugoslav urban planning and design. The most famous are: the project Sava Amphitheater (designed by Miloš Perović in 1975), and the study Town on Water (*Varoš na vodi*), by the Urban Planning Institute of Belgrade in 1990, important for they included both banks of the Sava River in order to reset Belgrade's urban history and place some public buildings (opera, museums), which Belgrade still lacks today. Even during the 1990s in time of great political crisis, economic sanctions and poverty, the project Europolis (1995) was developed for the area of the Sava Amphitheater, as a capital project of the authoritarian political regime. In the next twenty years, the area continued to deteriorate, and, thus, became one of the largest brownfield areas in the Belgrade central zone covered by old railway tracks and dilapidated housing. The BW project was for the first time announced as the flagship project during the 2012 political campaign of the then largest opposition party, which won the elections with a great majority of the vote. The cornerstone for its future development was set in September 2015, designating a grand political project financed by Eagle Hills, a United Arab Emirates (UAE) investor, with considerable subsidies provided by Serbian government.

The controversial BW project, covering almost 90-hectares close to the confluence of two rivers and the historical core of the city of Belgrade (Figure 2), is currently seen as paradigmatic in the public and real estate domains in Serbia. For the political structures, it is a 'best practice' example of urban development. But professionals claim it as a drastic usurpation of both the formal planning procedures and professional expertise, while citizens have been constantly struggling for more transparency and active involvement in the decision-making process. In sum, the BW project depicts the absence of: 1) accountability in decision-making, 2) monitoring and control systems, and 3) mechanisms for evaluating social, economic, and environmental impacts (Zeković *et al.*, 2018). These aspects speak clearly for insufficient participation of the general public in a project of 'national importance'.

Briefly put, national level politicians (led by ex-prime minister, now (2019) the president of Serbia) made strategic decisions in respect to the BW project, hence, avoiding any kind of a public debate with a range of interested parties. Only the Urban Planning Institute (UPI), the urban planning office of the City of Belgrade, was involved in the process of plan making, due to its tight relationship with the political regime (Orlović Lovren *et al.*, 2016; Perić, 2016). Three distinctive irregularities, serving as a base for creating the plan of the BW area and its further implementation, illustrate inferior professional position and the citizens' response towards both the planners and decision-makers.

Figure 2: The model of the Belgrade Waterfront project

Source: www.belgradewaterfront.com

First, in the regular spatial planning practice, the project elaboration follows the rules and parameters given in the plan. However, in the case of the BW, the international architectural office (SOM Architects) prepared the preliminary design project (without prior consultation with the professional organizations or with the citizens of Belgrade) to serve as a base for its elaboration into the urban plan by the UPI, as a necessary instrument for the future construction on site (Kovačević, 2014). This plan for the BW is in its nature totally different from the rest of the official Master Plan of Belgrade 2021 and, therefore, it was added *ex post* into it in the form of the amendments (Zeković *et al.*, 2018).

As an immediate response, the civil sector through its own initiative, ‘Don’t let Belgrade d(r)own!’ (*Ne da(vi)mo Beograd!*), raised its voice formulating objections to the proposed amendments (Čukić *et al.*, 2015). With a help of another collective, the Ministry of Space (*Ministarstvo prostora*), the citizens of Belgrade together with young experts discussed changes to the plan and filed over 3,000 complaints to proposed changes. The procedure of public insight that followed gathered over 200 people as well as representatives of the city authorities and professional institutions (Čukić *et al.*, 2015). Although the session lasted for more than six hours, all of the complaints were rejected, or only superficially taken into consideration and the Amendments to the Master Plan of Belgrade (OG CB 70/2014) were verified in September 2014. The citizens received a valuable lesson: existing democratic participatory tools proved to be only a simulation without any real effective power (Čukić and Perić, 2019).

Another irregularity of the plan for the BW area is its legal nature. Namely, the Master Plan of Belgrade, as the highest-tier urban plan, cannot be immediately implemented, but only through regulatory plans. This includes the rounds of public debates and approvals. Considering that such a procedure is extremely time consuming, in June 2014, a month before the ‘masterplan’ for the BW area was prepared, the Government made an official decision on creating the special spatial plan (Kovačević, 2014). Namely, the Plan for the Area of Specific Use is, according

to the planning law (OG RS 121/2012), created only 1) for non-urban areas of particular importance (i.e. mining and coal seams, flooding areas, natural resorts, etc.), and 2) in accordance to the higher-tier plans (i.e. regional or national spatial plans). Oddly, none of these conditions were fulfilled in respect to the BW area.

The civil sector (the Ministry of Space), acting again as the safeguard of the public interest in spatial planning decision-making, organized public debates among the prominent national experts in various domains (sociology, economy, public administration, spatial planning, etc.), with the final aim of addressing the decision-makers. However, these gatherings under the title “What is hidden beneath the surface of the ‘Belgrade Waterfront’”, running in October 2014 in parallel with the procedure of spatial plan making (Čukić *et al.*, 2015), gained the popularity among the general public. The ruling political structures, however, stayed ‘deaf’ to the citizens’ calls, thus, demonstrating an elementary ignorance of democratic decision-making (Čukić and Perić, 2019).

The culmination of public actions against the new Plan for the Area of Specific Use happened in November 2014 when the activists of the ‘Don’t let Belgrade d(r)own’ initiative (now officially formed into a NGO and much more numerable) opted for a different tactics to interrupt the process of legitimizing the BW project (Public debate, 2014). In addition to the regularly and officially sent complaints on the new spatial plan, in the performance called “Operation lifebelt” the activists used creative energy to ban the plan approval (Figure 3). Contrary to their expectations, and despite the noise, the interruption did not occur. Instead, the members of the planning commission continued their work, complaints were again rejected, and the session was deemed successful. The spatial plan for the BW was adopted in January 2015 (OG RS 7/2015) without any form of public debate on its quality (Čukić and Perić, 2019).

The third peculiarity refers to the *Lex Specialis* – Act on Establishing the Public Interest and Special Procedures of Expropriation and the Issuance of Building Permit for the Project Belgrade Waterfront, proposed for adoption

in April 2015. In its essence, it is not obvious how the highly commercial BW project can preserve or be in the public interest. If the public interest is even prescribed by law, it is not clear how this works in practice as specific regulations on how to implement the law do not exist (Zeković *et al.*, 2018).

The activists of the 'Don't let Belgrade d(r)own' warned of the core shortcoming of the law – it is not about the choice between the dilapidated private houses, on the one hand, and city growth through the BW project on the other. It is about expropriation for an exclusively commercial project that fulfills the needs of a private investor only. The public interest and the state itself are sidelined (Lex Specialis, 2015). In spite of the public complaints, the law was adopted (OG RS 34/2015), designating the start of the official construction on the BW area, which happened a half year later.

Finally, a detail that clearly explains the political power demonstrated towards the citizens is the demolition of the private property located within the boundary of the BW project. More precisely, during the night of April 26, 2016, the dilapidated building stock (though still used for living) was totally torn down. Communal officers were not reachable that night, so the affected citizens felt totally helpless (Whose city?, 2016). Citizens' protests were held regularly in 2016 and 2017 (Figure 4). The court case is still not resolved.

Discussion: from citizen power to tokenism?

Citizen participation is not a new instrument in Serbian planning practice. However, it was exercised to various extent in different phases of Serbian planning history due to a shift in societal, political, and economic circumstances. Participatory planning reached its peak in the 1970s and 1980s under the socialist regime, while it currently suffers despite a democratic political system. At first sight, this is a paradox. Nevertheless, highly decentralized socialism of Yugoslavia allowed for participatory activities, though limited with the dominant ideology and politics. Today, legislation guarantees the involvement of citizens in planning issues, too, though in the context of a pluralist democracy. However, as the Serbian society is deemed to be 'proto-democratic' (Vujošević, 2010), there are no instruments for the operationalization of citizens' demands, turning them into wishful thinking instead of a reaction to political decisions. The influence of politics on citizen engagement in spatial planning decision-making is inevitable. The basic characteristics of citizen participation in two mentioned phases of Serbian planning – observed through the lens of Arnstein's 'ladder' – are briefly indicated below.

Participatory planning

In addition to other (mainly economic) instruments of decentralized socialism, e.g. small artisan groups operated their private firms, workers' community managed the public industry sector (Ramet, 1995), participatory planning was mainly practiced at the local level. The municipalities were considered socio-political communities, with the power of decision-making in any public action on its territory (Fisher, 1962). This has a direct consequence on the nature of planning process – the procedure of public insight enabled the citizens to discuss, debate, and submit remarks and comments to a plan's proposal. Such a bottom-up participatory approach involving various types of individuals and groups, as well as the general public, sometimes even over-loaded the process of preparation, approval, and implementation of planning decisions (Čolić, 2009; Maričić *et al.*, 2018). Nevertheless, it should be stressed that hierarchical political structures controlled all kinds of associations and organizations, be these professional or civil sector (Liotta, 2001). Hardly any decision could have been made without the previous consent of the local and central governments (Nedović-Budić *et al.*, 2012).

Bearing strong political influence on the nature and impact of citizen participation in mind, two 'ladder' types can be assigned to Yugoslav participatory planning of the 1970s and 1980s. Both of them are characterized with the following: 1) spatial and environmental *information* was readily accessible for public scrutiny in the regional and local planning arena (Nedović-Budić and Cavrić, 2006); and 2) the legislation gave the citizens not only a right, but made them also obliged to participate in the planning process (Maričić *et al.*, 2018) – citizens acted as *consultants* and *advisors* to the expert committees and thus decision-makers. In the first 'ladder' type, the citizens' visions, amendments, and proposals are in line with the dominant ideology and a broader societal interest. Hence, they became *partners* in the planning process, though the space for bargaining and negotiation was missing as both parties – citizens and decision-makers – strive for the fulfillment of the same (public) interest. In such a process, the *delegation of power* was strongly practiced as the local politicians were the ones to transfer the outcomes of local participatory process to the higher governmental levels. Another type of 'ladder' excludes the degrees of citizen power. Briefly, informed citizens entered the participatory planning process, their proposals were recognized, but there was no obligation for the planners to change the plan under discussion. As citizens had a legal obligation to provide the feedback on a planning proposal, such *de jure* participation served only to legitimize the proposed development solutions (Maričić *et al.*, 2018).

In a nutshell, do the previous lines describe pseudo-participation? It was not that obvious in the socialist regime, exempted from the plurality of interests. Namely, achieving the public interest was one of the main goals of socialist spatial and urban planning (Zukin, 1975; Vujošević and Nedović-Budić, 2006), thus overlapping with the beliefs, visions and norms of citizens. Finally, all actors involved had a high level of responsibility and skill in doing their specific tasks under given circumstances, thus jointly contributing to spatial development (Nedović-Budić and Cavrić, 2006; Perić and Miljuš, 2017).

Market-led planning

In 2000, the Serbian democratic government established the decentralization of power and administrative structure as a social and political priority (Vujošević, 2003). However, the share of responsibilities in the spatial planning domain in Serbia from national to local level is not really decentralized: as for the cities in inner Serbia, the spatial development is controlled by the planning committees whose members are also the members of the ruling political party (only in 10 out of 170 municipalities in Serbia the local authority is composed of politicians outside the ruling coalition). In the case of Belgrade's major spatial activities, the relevant ministries steer the spatial development (Zeković *et al.*, 2018). The only partners for the national government are private (foreign) investors. In an absence of regulatory instruments necessary for protecting transparency, limiting corruption, and preserving the national interests, both expert advice and strategic public deliberations are diminished (Maruna, 2015). In sum, citizens do not have enough will to take part in decision-making on spatial and urban development as they have little trust in their institutions' response (Maričić *et al.*, 2018).

Using Arnstein's metaphor, citizens in Serbia are today *manipulated*, as: there is no political will to introduce instruments for meaningful participation, while the notion of the public interest is lost (Maričić *et al.*, 2018); clientelism and paternalism dominate the planning practice (Vujošević *et al.*, 2012); and, civilian initiatives and associations are seen as relicts of the self-management system, one with a highly negative connotation among Serbian politicians (Vujović and Petrović, 2007). On the other hand, planners are also not in favor of citizen participation as they cannot find an appropriate position for themselves. Stretched between the political will, which they depend on as public officials, and private sector's demands that revolve around profit at the expense of any other benefit (e.g. public interest, quality of the proposal, environmental impact, feasibility prospects, etc.), experts have little understanding and patience for citizen activities. The recently introduced legal instrument of 'early public insight' (OG RS 145/2014) does not secure public participation. This participatory mechanism is not promoted enough among the general public, and the guidelines for its implementation are not well clarified. Hence, citizens' interest for the spatial and urban development issues is rather low (Čukić and Perić, 2019). Such an absence of citizen engagement in the planning process is actually an example of *de jure* public consultation. Citizens are not equal participants in the planning debate – while protecting their legal rights, they are mostly seen as an obstruction and a threat to the proposed planning solution supported by powerful interests. It is the superiors' vision that has to be materialized while participation only serves to provide legitimacy for the planning procedure (Maričić *et al.*, 2018).

In comparison to the period of participatory planning, when citizen participation was on the level of *pseudo-citizen power*, in the current market-led planning it is even worse – participation is considered a *pseudo-tokenism*. Briefly, the dominant political party manifests power in an almost one-party political system together with foreign investors capable of achieving their own private interest due to ad hoc spatial planning procedures. Such a symbiosis makes the experts unable to fight for their own position, while citizen participation is intentionally kept as the lowest priority.

In conclusion

It seems that Serbia has never escaped out of this political vicious circle. The authoritarian regime provided advanced instruments for citizen participation to be exercised within the framework of the dominant ideology of the communist party. The current 'proto-democratic' system has no official limits for citizens – they are free to express their own opinion, but this is where the story ends. How can we strengthen citizen participation in a society that neglects citizen's rights?

As a first step, experts and citizens should understand and respect each other. Experiential knowledge of civil sector and professional skills based on instrumental rationality should be exchanged for the benefit of creating planning solutions that meet the interests of the majority – not only for the minor powerholders, as it is the case

today. Feedback between the public officials and citizenry gives insight into ideas, suggestions and remarks, and affects the creation of trust and mutual respect (Čukić and Perić, 2019). This civil-public synergy is essential for the transparency of the planning process – the process guided by the public-sector experts, with the civil sector as a control element, finally designating a shift towards the collaborative planning approach still declaratively promoted in Serbian planning policies (Lazarević Bajec, 2009; Perić and Miljuš, 2017).

Another recommendation is to strengthen the role of local authorities in cooperation with the civil sector (Čukić and Perić, 2019). The local level is a natural ‘place’ for collaboration with the civil sector: municipal representatives are aware of various groups, identities, and public amenities within the local borders. First, legal frameworks and strategic guidelines should support citizens’ initiatives in local development. In addition, financial institutional capacity including various means and resources secures public participation. Local strengthening, however, demands the independence of the local institutions in the hierarchical process of top-down decision-making in Serbia. This coincides with the legally prescribed process of administrative and political decentralization, which needs substantial improvement in order to enable effective public engagement (Zeković *et al.*, 2018).

After almost twenty years on a path towards representative democracy, the impact of citizen participation on the outcome of the spatial planning decision-making process is still low. Citizens usually show no interest to engage in public issues. Once interested, experts do not treat citizens’ input as a valid argument for the public discussion. The lack of professional support toward citizenry is a sign of the weak planners’ position in a highly controlled society, embodied in individual political figures. Therefore, a political monopoly over urban development must be avoided, which at the same time needs the differentiation of political from professional and administrative positions. As a result, citizens would be able to climb to the highest rung of the ladder – to be in control of spatial governance. Such civil-public partnerships are dependent upon a democratic social context, organized civil society, and a capacity to advocate the public interest. Thus, changes in planning instruments and governance mechanisms towards the implementation of civil sector practices in spatial policies depend on political, professional, and social will, as well as a readiness to change the decision-making system. Only when Serbia paves the way towards its democratic development, will public input be truly incorporated in the planning process.

However, the absence of the institutional framework and a lack of expert will to support citizen activities is not the only reason for an insufficient public involvement. As shown in the case of the BW project, a setting with weak institutions, inconsistent policies, and non-transparent procedures is a fertile ground for a wide range of manipulations that appear once international private investors enter the arena of spatial planning decision-making. In particular, urban megaprojects are seen as a tool for both the generation of extra-profit for private sector actors and an increase in corruption among the high-level public authorities (Grubbauer and Čamprag, 2019; Zeković *et al.*, 2018). Consequently, such a relationship has negative effects in spatial and social terms. Namely, gentrification, minimizing public space, and loss of local identity enabled through a large-scale unitary project, strongly 1) jeopardizes low-income and marginalized groups and, 2) diminishes the extent of public participation (Maričić *et al.*, 2018).

Urban megaprojects, as clear manifestations of neoliberalism, affect the decision-making process not only in transitional countries, but also in developed societies. Some lessons drawn from other CEE countries can help improve the citizen participation in Serbian planning practice (Cope, 2015; Stanilov, 2007; Hirt, 2005; Grubbauer and Čamprag, 2019). First, there is a clear need for a critical assessment of the discourse used in promoting such megaprojects. The nationalist and populist language, e.g. project of national priority, project than strengthens nationhood and national greatness, usually hides the political patronage and offers room for corruption, favoring local political elites and, thus, diminishing other social actors. Second, planners should be motivated to create innovative planning procedures (both formal and informal) for meaningful inclusion of various groups of stakeholders. Finally, the key concept is legitimacy, as it elucidates the definition of public interest through regulatory mechanisms. Therefore, the questioning of the official discourse centered on definitions and claims to

public interest is the first step, which should be followed by deconstructions of the regulatory order to analyze on which jurisdictional level, with what means, and with what purpose the public interest is defined.

Smart cities and regions
informing the energy
transition

The notion of sociotechnical system in the planning process of a Smart Region

Jessica Balest¹, Giulia Garegnani¹, Elena Pisani², Laura Secco², Daniele Vettorato¹

¹EURAC Research

²University of Padua, Department of Land, Environment, Agriculture and Forestry

Abstract: Energy transition is a long-term change process of the energy system of regions and cities towards smart and low carbon features. From a technological point of view, energy system is an integrated system including several sources, technologies, and products for energy production, distribution, and consumption. From a social point of view, local population's choices and actions determine the time and the features of energy transition at regional and local scales. Energy system is not only technology matter. Sociotechnical and territorial approaches underline the importance of interactions between energy, society, and space.

Based on these interactions, this research delineates an analytical framework and an applied definition of sociotechnical system for place-based contexts, with the aim to promote recommendations towards Smart Regions.

Starting from the definition of the important concept in the social sciences of sociotechnical system, this research proposes an applied definition of sociotechnical concept in space-based contexts. This applied definition can shape and change the socio-energy system that is another important concept in social sciences, meaning the world that 'one wants to create for the future' (Miller et al. 2015).

Keywords: social science; sociotechnical system; territory; South Tyrol

Introduction

Energy transition is a long-term change process of the energy systems of regions and cities towards smart and low carbon features. From a technological point of view, energy system is an integrated system including several sources, technologies, and products for energy production, distribution, and consumption (Balest 2018). However, energy system is not only technology matter (Miller et al. 2015). From a social point of view, local population's choices and actions determine the time and the features of energy transition at regional and local scales. Sociotechnical and territorial approaches underline the importance of interactions between energy, society, and space (e.g. Sovacool and Hess 2017, Osti 2010, Geels 2007). Based on these interactions, this research delineates an analytical framework and an applied definition of sociotechnical system for place-based contexts.

The sociotechnical approaches are more and more important in explaining the energy transition and its elements (i.e., from Geels and Schot 2007). Sociotechnical system is a complex system that includes society, technologies and the relationships among them. An energy system is a sociotechnical

system which shapes and gets shaped by different dynamics of natural, technological, economic, legislative, social and cultural dimensions of the territory (Balest et al. 2019b). The sociotechnical system exists in different territorial contexts (e.g. municipalities, regions, etc.) including their spatial, technological, and social aspects. Indeed, sociotechnical systems provides societal functions and are the result of co-evolving of mix of technologies, infrastructures, supply chains, regulations, cultural meanings, user practices, markets, and other elements. Geels et al. 2017 (p. 471) recognize that energy transition is a "multi-dimensional process, with complex interactions between techno-economic, business, social, political, and cultural dimensions".

In the interaction among technical-technological elements and social groups, this research underlines how local populations are embedded in territories at several local scales and how local population's choices are influenced by the territorial context that is not only made by technological and social systems, but it also includes natural, cultural, economic, and legislative systems (Figure 1). *Viceversa*, the choices of local populations shape the territorial systems. This framework is the basis of the analysis included in this research and it is an interpretation of the sociotechnical regime presented by Geels and Schot (2007).

The regime can be destabilized by both sociotechnical landscape (the context at a higher scale, such as national ones) and niche-innovations (innovations that are not spread yet), and different regimes will differently answer to them. For this reason and for analysing the long process of transition to a new regime that includes innovations and new landscapes (Geels et al. 2017), it is important to have a clear picture on the actual features of the territory. It is also important to spread knowledge for citizens and public administrations on how local features and civil society can contribute to energy transition.

Figure 1 – Framework for analysing territory. Source: (Balest et al. 2018)

How can the sociotechnical system concept be applied into research? Which are the characteristics of a territory that have an influence on the local populations' choices in terms of renewable energy and energy transition? How do these characteristics vary along the local territories within a region? Does the actual energy governance consider the characteristics of the territories?

A Smart Region is a geographical and administrative area that is able to change towards low carbon emission features, using the local resources and promoting effective relationships

among the actors of civil society. The findings of this research support the increase of competences and know-how of public administrations for achieving the energy transition goals in their regional and local territories. The analysis of the territory based on the interaction among society, energy, and space creates knowledge for developing Smart Regions.

In an ideal Smart Region, public administrations collaborate one another when their territories share features, resources and needs. Collaborative actions mean to save and share resources (i.e., funding, human capital and knowledge). In the scarcity of resources for municipalities (at least in Italy), common plans or, at least, strategies can help for a more effective transition.

Common plans and strategies are realistic if the territories share resources, needs, and features (European Commission 2008). For this reason, the identification of the sociotechnical systems, their features and the existing collaborations in the energy governance is relevant for promoting effective energy actions and Smart Regions.

The sociotechnical system description, analysis and recommendations can address the socio-energy system (Miller et al. 2015) that is another important concept in social sciences. Trying to include social and political dimensions of the energy systems beyond the technological ones, this research works in the direction of socio-energy system concept. This research proposes some “practices and techniques through which potential energy futures are envisioned, modeled, analyzed and evaluated” (Miller et al. 2015, p. 36). The socio-energy system is a matter of design and coherence with the preferences of local populations and administrations.

Methodology

In order to answer the questions in the previous section, this research uses a methodology based on several methods and steps.

First, this research identifies the most relevant aspects of territory that can have an influence on the acceleration of the energy transition, using systematic literature review method (Balest et al. 2018). Based on the analysis of these aspects, the findings propose a definition of energy system as a sociotechnical system within a territorial context (Balest et al. 2019b).

Second, the definition is operatized and applied to a case study: the municipalities of Autonomous Province of South Tyrol. South Tyrol is a region placed on Northern-East Italy. The choice of variables (Table 1) and a cluster analysis defined homogenous groups of municipalities, defined as sociotechnical systems (Balest et al. 2019b).

Third, a social network analysis is applied to define and analyze the structure of the energy governance that includes public administrations and public utilities in the energy sector (Balest et al. 2019a). In this case, a Bayesian Exponential Random Graph Model (BERGM) is applied (Caimo & Friel 2011) in order to model the energy governance network and to understand the network configurations that promote the existence of the actual governance. For having more detail on the methodology, please refer to Balest et al. (2019a).

Dimension	Specific dimensions
Socio-demographic	Population size, household size, population age, strangers, variation of inhabitants, density
Quality of life and household wealth	Services access, quality of life
Socio-economic	Income, economic development, energy focus, tourism
Cultural	Environmental attitudes
Governance and political	Political participation, civic participation, political address
Geographical and infrastructural	Dimensions of territory, elevation, natural parks, land cover, transport infrastructures
Renewable energy	Hot water production from RE, heating produced by RE sources, electricity produced by RE sources, people activity in increase RE share
Climate	Avalanche and flooding phenomena

Table 1 – The table includes the dimensions that describe sociotechnical system in the place-based context of South Tyrol. Source: Balest et al. 2019).

The crossing of the analysis and findings of the three steps of the research define new and important results in terms of sociotechnical system research. This crossing activity capitalizes the findings of three researches creating a basic scientific knowledge of the territory. This scientific knowledge can be integrated with the local ones promoted by people and public administrations that live and manage the territory. The findings are the basis for the creation of socio-energy system, addressing the futures of energy transition.

Results and discussion

The futures of energy transitions are several for the South Tyrol region and they are given by eight different sociotechnical systems. The provincial administration and planner can use the findings of this research for being aware of the differences and specificities of its local territories. This way to look at the territory promotes effective actions for the territories and their contribution to the energy transition, deepening the list of resources available in the territory for the energy transition.

This research defines eight patterns of territories defined as sociotechnical systems in South Tyrol (Figure 2). Each sociotechnical system could have its own path and speed of energy transition. In particular, energy planners and decision-makers should differently act in the patterns of territory for promoting quicker achievements of energy transition targets.

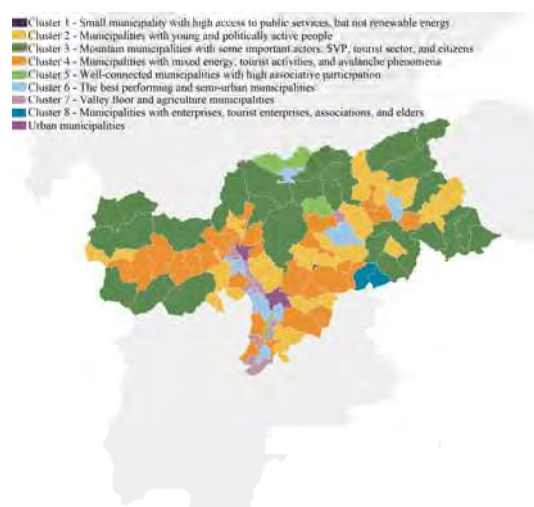

Figure 2 – The map shows the eight patterns of territory in South Tyrol, defined as sociotechnical systems. Source: elaboration of Amy Segata.

For example, cluster 2 (Figure 2 and Figure 3) includes 34 little inhabited municipalities, with high percentage of youths and related higher average of household components. Political participation is high in these municipalities, considering the number of voters in the last local elections and Südtiroler Volkspartei political party is prevalent. These municipalities have, in average, experience in biogas sector for the energy production and high number of people is producing renewable energy or is linked to local thermal energy distribution plants. In this clusters, several resources can be addressed to promote the energy transition. For example, two resources of the sociotechnical system are youths and politically active people (Paravantis et al. 2018). Other two resources or actors, in this case useful for increase and spread awareness on energy topics, are the local associations (Rogers et al. 2012).

The recommendations for the municipalities of cluster 2 are to organize *ad hoc* education activities starting from the primary school and promote a discussion with SVP to increase its public and political commitment to achieve energy transition. SVP can be included in energy planning process emphasizing its role in public commitment, while youths and families could be involved through *ad hoc* activities starting from the primary schools and the actual high people involvement in producing and consuming local energy. This people involvement can be strengthen, for example, promoting and sharing a community RE project based on a collective decision.

These recommendations are considerations not based on the knowledge between cause-effect relationships, but they are fundamental to permit research and findings to be used by public administrations. Based on the findings, public authorities can also be aware on the other municipalities that share the recommendations, resources, and needs, with the aim to promote new and useful collaborations. These collaborations can permit the achievement of resource savings and transition targets.

The listed social and territorial resources can support the effectiveness of energy actions, plans and, consequently, the energy transition. These findings represent a structured knowledge on the territory that goes beyond the local knowledge and that could be integrated with the local knowledge. When more municipalities, sharing resources and having some pioneers in renewable energy production, already collaborate, the use of the recognized resources is easier. A Smart Region exists when public administrations and the main civil society actors recognize the local resources, also in terms of relationships for the energy system planning and management.

Crossing the results of the three steps analysis, this research shows that the potential collaborations among municipalities belonging to the same cluster (i.e., cluster No. 2 of Figure 3) are much more than the actual ones. If municipalities within the same sociotechnical system share resources and features that can support a common planning of the energy system, more relationships among municipalities should exist. However, analysing the actual energy governance, made by relationships among municipalities in the energy sector, the collaborations among municipalities do not consider the specificities of the different territorial patterns in South Tyrol and the collaborations are fewer than the potential ones.

Today, even in the case that municipalities collaborate, they collaborate if spatially closed and not based on similar needs and resources and the findings of this analysis can address new effective collaborations among territories towards the energy transition¹.

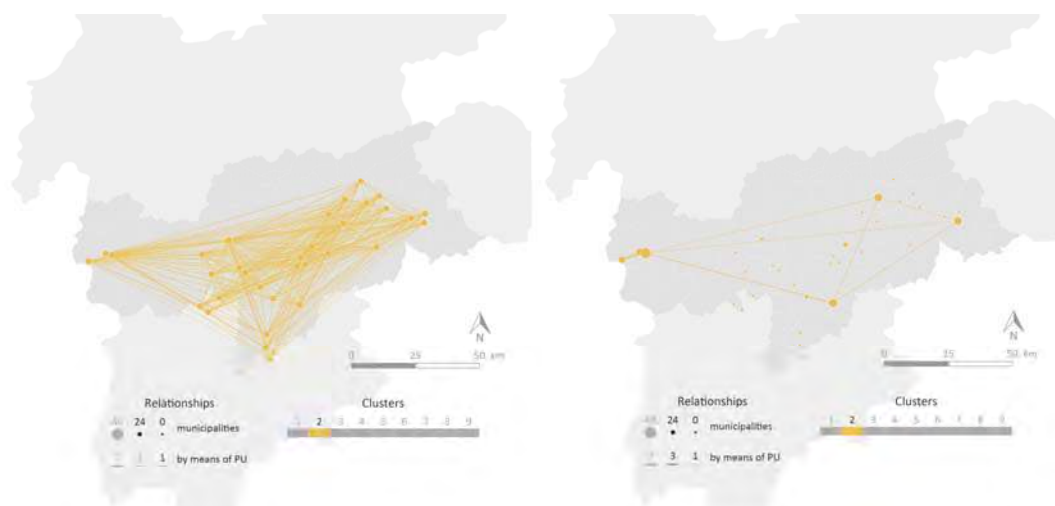

Figure 3 – The map on the left shows the potential collaborations among municipalities of the same cluster, while the map on the right shows the actual collaborations among municipalities belonging to cluster 2, by means of public utilities. Source: elaboration of Amy Segata.

The model for the analysis of energy governance, the BERGM, explains that, according to the considered variables and network configurations, no new relationships should exist (Balest et al. 2019a). For this reason, it seems unlikely that today or in short future the relationships among

¹ For further results of the governance analysis, please refer to Balest et al. (2019a).

municipalities that belong to the same sociotechnical system can be created. Qualitative studies could define important aspects and variables for addressing energy transitions and new collaborations among municipalities that this research has not considered yet.

The relationships among municipalities in the energy sector in South Tyrol are few today and they do not consider the resources available in the territory. With the definition of sociotechnical patterns, public administrations can strengthen the contribution of their territories to the energy transition and they can promote new relationships in the energy sector, based on similar needs, preferences, and available resources.

Conclusions

This research defines an analytical and applied framework for the definition of sociotechnical systems within a region. The framework is applied to a case study: South Tyrol (IT). The application defines eight sociotechnical system within the case study and in which the municipalities are included. Municipalities included in the same sociotechnical system have high potential to collaborate for the energy system planning and management. Indeed, they share resources and specificities.

However, many potential collaborations do not actually exist today in South Tyrol among municipalities that have common resources. Further studies should in-depth and qualitatively investigate the reasons of the existence or absence of these collaborations, promoting a support information for public administrations. Furthermore, the knowledge on the specificities of the eight sociotechnical system is a tool for the promotion of new relationships in the same sociotechnical system for energy transition.

The findings of this research support the creation and development of Smart Regions that are able to decrease the carbon emissions, based on interventions of public administrations. The used framework and the related results are not exhaustive, while further analysis on the social, political, and cultural processes (Geels 2017) and on the social practices (Shove 2018) must be done for having a wider picture on the potential energy transitions of territories. The energy transitions vary along space and they need decades to be happen. This research is an attempt to define analytical and applied framework that is important for supporting public administrations in energy planning for transition. Further research should promote other concepts for the development of Smart Regions such as energy citizenship. The developed methodology and the created knowledge can be replicated in other case studies.

³Eurac Research, Institute for Renewable Energy, pietro.zambelli@eurac.edu

Abstract: Scenario analysis is a particularly interesting tool for the smart energy transition of cities and regions. It allows understanding the possible futures of an energy system with and without the implementation of strategic actions and under different conditions. The presented study deals with the development of alternative scenarios for the energy system of Valle d'Aosta region (Italy) and is aimed at suggesting sustainable pathways for its energy transition. In particular, the strategic actions want to foster the exploitation of Shallow Geothermal Energy (SGE), a renewable source still not exploited adequately in spite of its great potential to increase the energy efficiency in buildings. Two driving forces establish the base for the scenario development. They are: 1) using SGE for supplying the space heating demand of residential buildings, replacing some fossil fuels; 2) refurbishing part of the residential building stock for decreasing its thermal demand. Different combinations of these two drivers shape the developed scenarios, which are then analysed through some indicators. All the data processing is done following a spatially explicit approach. This GIS-based scenario analysis can support the decision-makers during the planning process allowing them to analyse from various viewpoints the alternative scenarios and to prioritise the different energy measures.

Keywords: energy transition; scenario analysis; GIS-based approach

Introduction

The energy transition regards the decarbonisation of energy systems and entails a significant change in the role of different primary fuels and energy technologies. It is widely recognised that ageing of existing energy systems, climate change, energy security, and depletion of conventional fossil fuels

are already modifying traditional patterns and scales of energy supply, distribution, and consumption (Bridge *et al.*, 2013).

In order to support decision-makers upon the energy transition, several tools have been developed. These methods range from the analysis of the current situation of the energy system and the estimation of the present energy demand to the generation of different scenarios at various spatial scales (Nabielek *et al.*, 2018). Scenarios may be particularly interesting tools for analysis in the energy field since they can be used to understand the possible futures of an energy system with and without the implementation of strategic actions and under different conditions (Geneletti, 2012). In this case, the strategic decisions may concern the expansion of specific energy technologies and the combination between various efficiency measures for the building stock. The presented study deals with the development of alternative scenarios for the energy system of Valle d'Aosta region (NW of Italy) and is aimed at suggesting sustainable pathways for its energy transition towards a *Smart Energy Region*. In particular, the strategic actions want to foster the exploitation of Shallow Geothermal Energy (SGE) and the energy refurbishment measures that can increase the energy efficiency in residential buildings.

Shallow geothermal energy is regarded as an environmentally friendly, renewable and sustainable energy (Hähnlein *et al.*, 2013). It represents an attractive alternative to fossil fuels, especially for the heating and cooling of buildings, and it also has competitive advantage in relation to other renewable sources, such as biomass (Zambelli *et al.*, 2018), because of its very limited impact in terms of air pollution. Despite, its diffusion is still marginal; the main reason is the high installation cost of the plant (geothermal heat pump – HP) and the drilling work. The growth of the use of SGE is also limited by complicated and fragmented legislation and by the scarce knowledge on the possible applications of this energy source (Casasso *et al.*, 2017). Hence, it is necessary to increase and spread the awareness of its advantages among policy and decision-makers providing insight and information on how to include SGE source into energy strategies and plans. In addition, in European households the use of energy for heating and domestic hot water (DHW) account for almost 80% of the total final energy consumption (European Commission, n.d.). Therefore, it is impossible to imagine a sustainable energy transition without paying attention to the built environment. The paper presents a spatially-explicit approach to the scenario analysis that, taking advantage of a GIS (Geographic Information System) environment, can support the decision-makers during the planning process allowing them to analyse from various viewpoints the energy scenarios and to localise where is better to address the different energy measures.

Data and method

The construction of scenarios for the energy system of the Valle d'Aosta region was aimed at suggesting sustainable pathways for the energy transition of the case study toward a *Smart Energy Region*. All the features considered in the construction of these scenarios were outputs of previous analyses developed within an EU-funded project under the Interreg Alpine Space programme

(GRETA – Near Surface Geothermal Resources in the Territory of the Alpine Space¹) and within a PhD thesis (Valentina D’Alonzo – Doctoral School in Civil, Environmental and Mechanical Engineering of the University of Trento).

These previous performed analyses are listed as follows:

- spatial evaluation of the space heating demand of the residential buildings;
- spatial analysis of the financial feasibility for the use of SGE to cover the estimated heating demand;
- exclusion of buildings that fell in areas where environmental interferences and hazards for the installation of SGE systems were detected²;
- comparison among the objectives of the Regional Energy and Environmental Plan (REEP) of Valle d’Aosta, on one side, and of the Regional Spatial and Landscape Plan (RSLP), on the other side, to highlight conflicts or need to improve the connection with new objectives;
- formulation of more energy-driven objectives.

Starting from the basis of the abovementioned previous analysis, two driving forces were established for the scenario development. They are: 1) using SGE for supplying the space heating demand of residential buildings, replacing as much as possible the fossil fuels; 2) refurbishing part of the residential building stock for decreasing its thermal demand. Different combinations of these two drivers shaped the developed scenarios, which are represented in Figure 1.

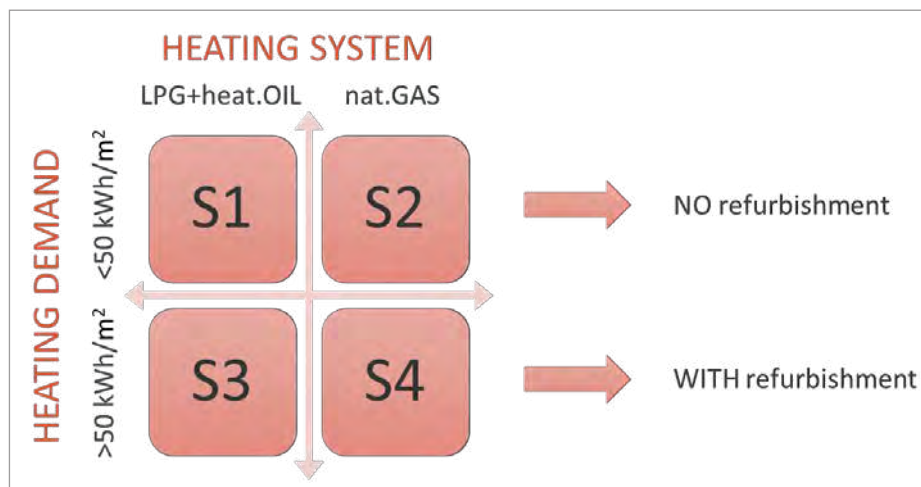

Figure 1: Schema about the developed four scenarios for the case study of Valle d’Aosta region.

In the first two scenarios (S1 and S2), it was imagined that SGE will supply the space heating demand of part of the residential building stock, replacing some fossil fuels but without applying any renovation measures. The buildings considered in these scenarios have a value of estimated space heating demand smaller than 50 kWh/m² per year and are located in census tracts where LPG, heating oil and natural gas are used as fuels for the primary heating system.

¹ <http://www.alpine-space.eu/projects/greta/en/home>

² <http://greta.eurac.edu/maps>

For the second section of scenarios (S3 and S4), the residential building stock was supposed to be partially refurbished for decreasing its total thermal demand. At the same time, SGE systems were imagined to be installed in the renovated buildings in place of fossil fuel plants. In this case, the developed scenarios involve the buildings with a value of estimated space heating demand greater than 50 kWh/m² per year. It is noteworthy that the buildings considered in these two refurbishment scenarios are equivalent to more than one-quarter of the entire analysed building stock (around 27%).

In the scenarios S2 and S4, the combination of a geothermal HP with PV panels and subsidies was considered because this is the only combination in which SGE would be economically convenient compared to the natural gas option. Furthermore, in these two scenarios the geothermal HP is deemed to be used as the primary heating system and the natural gas boiler as the secondary one, to cover the peaks, as the infrastructure for natural gas would remain active even if the heating system changed.

The scenarios were then analysed and compared through the following indicators:

1. Heated surface of buildings involved [m²];
2. Greenhouse gas (GHG) emissions saved [tCO₂-eq];
3. Costs of replacement of heating system with HP [M€];
4. Cost of energy renovation of buildings [M€];
5. Electrical consumption for HP utilisation [MWh].

The GHG emissions saved due to the partial replacement of fossil fuels with SGE were calculated by using IPCC emission factors (Joint Research Centre, 2017) for the different energy sources. In particular, the difference was calculated between the emissions of fossil fuel plants (LPG/heating oil, natural gas) and the emissions of the imagined electrical geothermal HP installed to cover the same space heating demand of the buildings.

Mean values for the energy efficiency of the heating systems were taken from the Italian Inter-ministerial Decree 26/06/2015 on the national energy certification of buildings (Ministero dello Sviluppo Economico, 2015) to convert the space heating demand of each building in energy consumption and then in GHG emissions. The total emissions in Valle d'Aosta in 2010 were taken from REEP and considered as the starting point for the calculation of the saved emissions.

The capital and operative costs were estimated in the spatial financial analysis within the GRETA project. Inside the capital costs, the investment for geothermal HP and the drilling works were considered. The capital cost estimation took into account also a 40% increase of the estimated costs for excavation and HP to overcome the high variability of the analysed cases. Inside the operative costs, the cost of electricity and maintenance of the system were instead considered.

The data on energy renovation costs of the selected buildings (in €/m²) were taken from the outputs of the iNSPiRE project³. iNSPiRE was a 4-year EU-funded project whose main objective was to tackle the problem of high energy consumption in the building sector by producing systemic renovation packages that can be applied to residential and tertiary buildings. The renovation packages developed

³ <http://inspirefp7.eu/>

by the project aim to reduce the primary energy consumption of a building to lower than 50 kWh/m² year.

The increase in electricity consumption due to the installation of geothermal HP was evaluated within the GRETA project, as well as the geothermal HP costs. Also in this case, the total electricity consumption in the Region in 2010 was taken from the Regional Energy and Environmental Plan and considered as the starting point.

Results and discussion

From the scenarios comparison, the third scenario (S3) came out to be the most impactful with respect to all the indicators considered: residential heated surface involved, GHG emissions saved, but also increase of electricity consumption and total costs (energy renovation and/or heating system replacement), see Figure 2. The buildings considered in this scenario are those built between 1946 and 1980, with a value of space heating demand greater than 50 kWh/m² per year, where LPG and heating oil are used as primary fuels. With these characteristics, they represent a relevant part of the entire analysed building stock (around 21%). Overall, the first two scenarios, which consider the buildings with lower space heating demand, do not have a significant effect on the status quo. While, the second two scenarios are more impactful, mainly because they involve energy renovation measures for several buildings.

Figure 2: Comparison among the four scenarios developed for the energy system of Valle d'Aosta.

Concerning the saving of GHG emissions and the increase of electricity consumption, one has to bear in mind that the Valle d'Aosta region is already 100% renewable for the electricity production thanks

to the hydropower source. Therefore, an increase in the electrical energy use inside the Region would have “negative” effects on the national CO₂ balance but not in the regional context. On the contrary, the Region would use more a local energy source instead of buying fossil fuels from outside (LPG, heating oil and natural gas). In this way, the overall sustainability of Valle d’Aosta would increase in terms of energy self-sufficiency.

Concerning the total required costs and the possible related subsidies, the results underlined the importance of the provision of subsidies for the financial convenience of interventions like the installation of geothermal plants and the energy refurbishment of residential buildings. Also the outputs of the financial analysis performed within the GRETA project, underlined that the real discriminant factor on the costs for the installation of geothermal HPs is constituted by the application of subsidies. Thanks to the spatial-based approach adopted, it is also possible to localise the buildings where the ratio between GHG emissions saved and total costs (kgCO₂/€) is higher, in order to intervene with policies and/or subsidies for the replacement of heating systems and the energy renovation of buildings earlier on these buildings and thus have the strongest impact on the reduction of GHG emissions.

This method on the scenario development inherited all the limitations of the previous steps (as listed in the previous section), as the starting points are the estimation of the space heating demand of the buildings and the spatial financial feasibility of SGE potential for covering this demand. In addition, this work would represent an example of how this kind of analysis can support the decision-making process when an energy plan/strategy should be updated or developed. The choice of the criteria to be used in the evaluation of scenarios should be better done by the local stakeholders and/or decision-makers. Another aspect worthy to be explored is the analysis of the different measures proposed on the basis of their effectiveness in promoting a sustainable energy transition.

Conclusion

From this study, the energy renovation of the residential building sector is confirmed to represent a great opportunity for reaching the energy saving targets and the reduction of greenhouse gas emissions, in Valle d’Aosta as well as in Italy given the same national building periods. Therefore, the replacement of fossil fuels with RES for the heating systems should be combined with interventions aimed at decreasing the space heating demand of the residential building stock. In this way, we will be able to foster a sustainable energy transition (at regional, national and European scale).

The integration of Shallow Geothermal Energy in the energy planning of cities and regions can, from its side, contribute to the increase of energy efficiency and utilisation of renewable sources in the heating systems, with the consequent reduction of GHG emissions due to thermal energy consumption of the building stock. The development and analysis of scenarios are particularly interesting tools in the energy field since they can be used to understand the possible futures of an energy system with and without the implementation of strategic actions, like the expansion of specific energy technologies and the combination of different efficiency measures for the building stock.

The spatially explicit method presented in this paper can help during the decision-making process allowing to analyse from various viewpoints the different alternatives and also to localise where is

better to address the energy measures and thus prioritise the interventions aimed at increasing the energy efficiency and reducing the GHG emissions from energy consumption. Future developments of this method are foreseen to be: a) diversifying the refurbishment interventions for different kind of buildings (dividing them according to relevant criteria) and/or defining an annual renewal rate for both the replacement of heating systems and the energy renovation of buildings; b) performing a cluster analysis for gathering together similar municipalities and then develop different scenarios for each cluster; c) performing a spatial multi-criteria evaluation of the scenarios (Pohekar and Ramachandran, 2004) involving the local stakeholders in the weighting system of the considered variables.

Abstract: Within a French context of Energy Transition, the “Energy Justice Tool Suite” project aims at designing, experimenting and optimizing what we call an interdisciplinary and a comprehensive “tool suite” dedicated to energy justice. At the urban, technical and socio-economic levels, the idea is to design a “tool suite” to characterize, assess, evaluate and co-construct an inclusive energy and socio-territorial justice - with the actors of these territories. This research is based on an interdisciplinary approach, combining engineering sciences with social and spatial sciences, in order to co-construct an inclusive territorialization of energy transition, leading to energy justice. For this purpose, the “Energy Justice Tool Suite” project aims at designing, not buildings archetypes, but multiscale energy complex systems archetypes: physical phenomena to design the energy poverty assessment model at the block scale, and human behaviour, within an empowering perspective, through the animation of learning workshops. This experiment will be conducted on two fields of observation: Grenoble-Alpes Métropole and the region of Compiègne, to establish a transect of energy poverty situations. The “Energy Justice Tool Suite” project also aims at designing, experimenting and optimizing a transversal tool to aid decision making and a tool to aid consultation making for energy and socio-territorial multiscale justice.

Keywords: energy transition, energy poverty, energy justice, decision support tool

Introduction

In the French context of the energy transition, fuel poverty demonstrates the existence of deadlocks and impasses, linked to the implementation of the transition, through territorialized public policies, but also linked to the non-adherence of the users or prescribers concerned. Indeed, the fight against fuel poverty involves multifactorial responses between different actors: households, owners, energy suppliers, public actors, specifiers and professionals in the field of thermal building renovation. Often these tensions are posed in a compartmentalized way: either through technology, public action or participation, and in a normative way by neglecting the constraints of past energy and economic choices (incentives to change without understanding how it came to be). At the urban, technical and socio-economic levels, one of the

challenges is to design with the actors of these territories a "set of tools" to characterize, evaluate and co-construct a more effective fight against fuel poverty, with the objective of energy transition.

Our research is based on an interdisciplinary approach, combining space sciences, social sciences and engineering sciences, in order to co-construct an inclusive territorialisation of the energy transition, which will bring about energy justice. We are working on two areas of observation and experimentation: Grenoble-Alpes Métropole and the region of Compiègne, France.

This article aims to present the French context of the territorialisation of energy action, the scientific, technical and socio-economic challenges of the fight against fuel poverty linked to housing, the methodology that the project team wishes to set up and test on two complementary fields of study. The objective of this article is to submit to scientific discussion a methodology for characterizing, writing, evaluating and co-constructing an inclusive energy and socio-territorial justice - with the actors of these territories, through the creation of tools to support the energy transition.

The territorialisation of energy action in the French context

The French energy sector has long been organised around a dominant player, EDF (électricité de France) and centralised production based on nuclear energy. However, this configuration is the result of a historical process that ignores the long-standing presence of cooperative forms in this sector (Artis *et al.* 2017). These characteristics have marked the energy market in France: energy pricing is highly regulated by the public actor; access to energy has long been inexpensive due to subsidised nuclear production. Nevertheless, since then, the landscape has changed somewhat; it has even changed incredibly and become more complicated as part of the construction of the European market. Indeed, the European construction has led to a transformation of the organisation of the energy sector. Today, the energy sector is composed of competitive activities (e.g. customer supply) and regulated activities (transmission and distribution of energy), which has also transformed the price of energy for the consumer. Although the production of a quasi-public service persists in the sense that there is an obligation to provide and connect to public infrastructure, the competitive tendering process has transformed the competitive logic of the players, by developing specific offers (in particular for green offers).

Today, the new configuration of the energy landscape is radically different from the old one. It is characterized by:

- - the multiplicity of actors: public companies, private companies, production and/or distribution cooperatives, management companies, village power plants under various statuses, investors, local authorities, private individuals and producers... and, of course, always the States and Europe; with local and national actors;
- - the multiplicity of possible technical solutions, and in particular the development of renewable energy production;
- - the complexity of the socio-political regulation to be put in place, from national regulatory authorities to the conciliation of projects in the same municipality (with or without municipal control), and not forgetting to reduce fuel poverty (in the North and South), or even areas where there is no connection or supply (in the South) (Artis, 2017).

As a result, several points of tension that were erased in administered energy regulation in the post-war years are emerging. These points of tension are related to the multiscale entanglement of decision-making

locations, competitive logics between operators and the injunction to a cleaner and more sober energy. These tensions are reflected in the implementation of macroeconomic policies at the territorial level.

Following the Kyoto Protocol, France has committed itself to reduce its greenhouse gas emissions by a factor of 4 (MEDDE, 2013). To meet this commitment, the French government has put in place legislative and regulatory measures to ensure that all local and regional authorities take action to reduce greenhouse gas emissions (Chanard, 2011, Chanard *et al.* 2011). This territorialization of energy action (Bertrand and Rocher, 2011, Chanard, 2011, Godinot, 2011, Theys and Vidalenc, 2011, Bertrand and Richard, 2014, Durand *et al.*, 2015, Poupeau, 2016) must be based on quantified objectives (Godinot, 2011) and global territorial action at three levels of public intervention: the exemplarity of its heritage and services, public policies and awareness (Chanard *et al.*, 2011); as well as scenarios for energy transition in cities, linking actors, regulations and technologies (Debizet and Dupuy, 2015).

However, at the local level, to fight against this fuel poverty (Guyet, 2015), which would affect nearly 6 millions people in France (ONPE, 2017), we observe that territorial public action is facing difficulties in setting up:

- - because of the difficulty of working on the real energy efficiency of urban forms at the scale of a city - and not just a building (Maïza, 2007, Arantes *et al.*, 2016),
- - and because of the difficulty of reporting on fuel poverty, on a small scale, through indicators and criteria (Devaliere and Teissier, 2014, Charlier *et al.*, 2015, Thomson *et al.*, 2017).

Fuel poverty and its interdisciplinary modelling

Through its socio-economic and ecological challenges, the issue of fuel poverty is now an important element of the social question because it brings together residential and individual (Fijalkow, 2013, Deffobis, 2015), biographical and social forms of vulnerability with issues of access to resources and the distribution of wealth and sustainable development (Griggs *et al.*, 2017), reinforced by a need for "ecological empowerment" in the territories. All these challenges involve the public authorities and institutions in charge of implementing the public policies planned in this regard. It requires their decompartmentalization and permanent monitoring, necessary for their readjustment over time.

In a way, we can think that the question of fuel poverty and its counterpart in energy justice (Guyet, 2015) are today a perfect expression of the challenges that will structure the future of our societies because it already questions the forms of governance at the territorial level, the role of institutional actors, companies prescribing solutions, and ordinary citizen-users (Heffron and McCauley, 2017 Jenkins *et al.*, 2016). Responding in an equitable and inclusive manner (Clément and Valegeas, 2017) to the challenge of fuel poverty, "for a just transition" (Lavelle, 2015) becomes a major focus of tomorrow's policies at both global and local levels. These new policies must integrate social issues into decision-making, planning and implementation practices (in the sense of technicality), and be accompanied by the large-scale social pedagogies needed to activate the collaborative capital of users - and in particular users identified as "vulnerable" (Lees, 2014, Lees, 2016).

Beyond this obvious vulnerability, fuel poverty remains difficult to quantify, on a small scale, by indicators and criteria (Devaliere and Teissier, 2014, Charlier *et al.*, 2015, Thomson *et al.*, 2017) - and consequently, to support (Guyet, 2015).

The thermal quality of a building and the low income of its occupants are two of the three interrelated factors that lead to a household's fuel poverty (Devalière, 2007, Réseau RAPPEL, 2011, Charlier *et al.*, 2015). Indeed, excessive energy consumption, linked to poor housing insulation, will be all the more harmful if the people concerned have modest incomes. In some cases, poor housing insulation therefore increases the risk of fuel poverty. On the other hand, the thermal renovation of buildings, by reducing the energy consumption of residents, while maintaining - or even increasing - the quality of the "energy services" they receive, is an effective means of combating climate change (Dubois, 2007). It is therefore important to target as a priority geographical areas with homogeneous areas of high energy loss, as well as a high percentage of vulnerable people (Devaliere, 2008, Henriot and Molines, 2016, Molines and Henriot, 2017a, Molines and Henriot, 2017b, Molines and Henriot, 2019). It will also be necessary to set up appropriate awareness and information campaigns targeting all the actors concerned (inhabitants, owners, landlords, craftsmen, etc.). Indeed, improving the energy efficiency of built stock leads to the implementation of new practices, new materials and new financial aid that must be supported in order to make them more efficient and limit their drift.

On the other hand, as they do not themselves own the properties to be rehabilitated, local authorities have a heavy task of raising awareness and consulting with all stakeholders: inhabitants, donors, craftsmen (Bertrand and Rocher, 2011, Chanard, 2011, Godinot, 2011, Theys and Vidalenc, 2011, Poupeau, 2013, Bertrand and Richard, 2014). In this consultation work, it should be noted that serious games have proven their effectiveness in concerted projects (Poplin, 2011). Serious games are also found in urban programming projects (Molines *et al.*, 2018) and in projects to raise awareness of the energy transition (e.g. "islands of the future", "SIMU renov" or "Electricity 2050").

The modelling of energy losses offers concrete quantitative support to assist cities in their decision-making (Caputo *et al.*, 2013). It is generally carried out at two different scales: the building scale on the one hand, and the neighbourhood or city scale on the other.

Building scale modelling is a well-developed field in the scientific literature and many calculation methods and tools are available: TRNSYS (Beckman *et al.*, 1994), Energyplus (Crawley *et al.*, 2001), Pleiades-Comfie (Peuportier *et al.*, 1990). It is based on physical, empirical or statistical data (or a combination of all three) (Wate and Coors, 2015, Magyari *et al.*, 2016). On the contrary, simulations of energy estimation at the city or neighbourhood level represent an emerging field of research, such as Citysim (Robinson *et al.*, 2009). At this scale, energy modelling is done in two different ways. The first, called top-down, uses macroeconomic data (energy prices, geography, social data, etc.) and statistical data to make future energy forecasts. The second, the bottom-up approach, models groups of buildings with similar technical and geometric characteristics (Kavgic *et al.*, 2010, Nielsen *et al.*, 2013). These models require the construction of geometric and non-geometric data. The most commonly used data models are construction information models (BIMs), used for individual construction simulations, and geographic information systems, generally based on 3D technology (GIS), which are suitable for assessing larger territories have become an essential tool for improving dynamic energy modelling capabilities (Bahu *et al.*, 2013, Wate and Coors, 2015, Nowacka *et al.*, 2018). Some models combine building scale energy modelling with urban modelling (Thomas *et al.*, 2014, Martins *et al.*, 2017, Wang *et al.*, 2017, Osterbring *et al.*, 2018).

Similarly, non-geometric data can be retrieved in two ways. Data can be collected, in real time, from sensors. This is the optimal solution but it is expensive and cannot be implemented over a large area. The other solution consists in developing a typology of the different urban forms present on the territory. We speak of building archetypes (Sousa Monteiro *et al.*, 2015, Ali *et al.*, 2018). It is the most commonly used solution in urban-scale energy modelling. However, these databases generally focus on national archetypes and do not integrate the building types characteristic of each region (Ali *et al.*, 2018).

Our case studies: Grenoble and Compiègne: areas of observation of fuel poverty and areas of experimentation with energy justice

These questions are developed on complementary grounds by their degree of urbanity and according to a transect: from the district in a large urban metropolis in Grenoble, to a medium-sized city grouping together urban, peri-urban and rural territories, within the région of Compiègne.

a) The case of Grenoble

The Grenoble area is often seen as a "laboratory", to use the expression used by Ambrosino and Novarina (2015). Even if the authors question this appellation, they retrace the specificities of the Grenoble territorial matrix around several structuring specificities for the territory.

- The first specificity concerns the role and place of the university actor, and in particular the science park. After the Second World War, several research infrastructures accompanied the technological transformation of the ecosystem by strengthening links with universities and companies (Ambrosino and Novarina, 2015). These actions mark the territory on two levels: on the one hand, the importance of innovation and the reference frame for innovation, which are deeply rooted in the logic of companies, academics and public authorities, and on the other hand, the interpersonal links between the academic and political worlds, given that several mayors of the City are engineers from this technopole.

- The second specificity concerns the public actor. In this field, Grenoble is often perceived as the laboratory of local democracy with the actions carried out by Mayor Dubedout and the municipal action group (GAM) which "seeks to develop citizen participation through the establishment of a privileged link with the "neighbourhood unions" (Joly and Parent, 1988, Novarina, 1993, Ambrosino and Novarina, 2015). Although the real weight of this management was limited, it had the particular consequence of forging strong links between political power and associations, in a semantic of co-management or instrumentalization according to historical periods and of building strong public actors on the social question, through the Communal Centre for Social Action (CCAS), then the houses of the inhabitants, establishments managed by the City. Today these two forces are still very active: on the one hand, the town council of the city centre has been supported by citizen networks and on the other hand, the CCAS of Grenoble is an essential actor in the social question. Thus, this specificity has the consequence that the territory is used to self-organizing by groups of citizens, that militant and political associative networks have a strong territorial network, and that the co-management or implementation of public policy is often participatory and bilateral.

- The third specificity is linked to urban planning and the various major urban projects (e.g. Villeneuve in 1968 or more recently the eco-neighbourhoods). These urban projects have the particularity of placing inhabitant participation at the heart of the approach (Ambrosino and Novarina, 2015). Today they are marked by the search for quality of life around the environmental issue and the vision of a post-carbon city (energy and mobility).

These specificities have marked the territorialization of energy in Grenoble with an international university expertise in this field (eco-sesa) together with public actors involved in this theme. In terms of combating fuel poverty, the city of Grenoble and its stakeholders have distinguished themselves early on, as evidenced by the Mur|Mur1 thermal insulation campaign, launched between 2010 and 2014, while the Mur|Mur2 campaign (2016-2020) is now underway, and the number of urban projects marked by the energy issue is increasing.

- The district of *Bonne* | In the Grenoble landscape of exemplary projects, the district of *Bonne* quickly acquires a very particular visibility. Launched in 2001, the project to upgrade the former Bonne barracks (8.5 hectares located in the immediate proximity of the city centre) is part of a guide plan entrusted to Christian Devillers, Grand prix de l'urbanisme 1998. The objectives of the Concerted Development Zone are to reconcile functional mix (housing, shops and public facilities) and social mix (rental and accession housing), urban density and quality of life (conservation of the military buildings existing around the Place d'Honneur, creation of an urban park) with a view to strengthening the main centrality of the urban area and with requirements imposed in terms of innovative energy management (bioclimatic design of buildings, optimisation of energy savings, coverage of electricity and hot water needs through the use of renewable energies and cogeneration). In 2009, as part of a call for tenders launched by the French Ministry of Ecology and Sustainable Development, it won the *Grand Prix national EcoQuartier*. However, today, fuel poverty is settling in for households that are not able to use the technological innovations implemented in this district.

- The district of *Presqu'île scientifique* concerns the requalification of an area previously mainly occupied by research laboratories specializing in nanotechnologies and the properties of the French Atomic Energy Commission. Designed to be the laboratory, symbol and artifact of metropolitan policy, the development of this new district has in fact become an urban demonstrator, a territory where innovations and experiments are developed that should eventually lead to the identification of good practices that can be replicated in the rest of the metropolitan territory. The district of *Presqu'île* offers the opportunity to develop technological innovations in favour of a sober and peaceful city, with cooperative energy management, smart-grids and the implementation of a pass-mobility. In addition to these innovations, actions in favour of an "inclusive city" and a "nature city" have to be planned. However, the constant quest for innovation has led to the search for technical solutions to solve social and urban problems. In order to achieve immediate and exemplary results, it led to a sectoral operational project being given priority over a metropolitan strategy and to a minimization of the importance of public debate in the establishment of strategies and the construction of projects. In this district too, fuel poverty is settling in for households that are unable to use the technological innovations implemented.

(b) The Compiègne case

The region of Compiègne and la Basse Automne (or Agglomération de la Région de Compiègne, ARC, in French) is an intermunicipal cooperation structure located in the department of Oise, in the region of Hauts de France, bringing together, since 1 January 2017, 22 municipalities and 81,000 inhabitants, over an area of 265,000 km². Almost half of the population of the ARC lives in the commune of Compiègne. Like Grenoble, the issue of fuel poverty is a significant one for the ARC. The lowest median incomes are found in the central zone (21% poverty in Compiègne, according to INSEE criteria). The other municipalities have rates of 10% or less. Some inner cities have median incomes well above the urban average (3,000 euros and above for an average turnover of 23,760 euros per consumption unit). According to the presentation report of the territorial master plan (SCOT), « at the level of the Compiègnais Country in 2006, 12,630 individuals, or 17.7% of the total population, are below the low income threshold (12.3% on the Oise), i.e. having received an annual income of less than €7,830 ». The low-income earner is generally young, on short-term or part-time contracts and works mainly in three sectors: operational services (cleaning companies, security guards, temporary employment agencies), health and social work, and retail trade. According to the SCOT, the municipality of Compiègne covers 70% of the population covered by the welfare tax credit in the ARC territory. The ARC's housing stock is composed as follows: 23.1% of social rental housing, the ARC concentrates 73% of its public stock on the city of Compiègne. According to data from the regional observatory GES / Energy ADEME-Region, the average energy consumption ratio of homes for heating and hot water production is 206 kwh-ep/m².

Faced with these poor results, the ARC has placed heating renovation as one of the major challenges in controlling energy consumption and wishes to implement policies in favour of the construction of new low energy building and the renovation of old buildings. The improvement of the old private housing stock is a major focus of the local housing plan adopted by the ARC in November 2009, and remains, with the approval of the Territorial Energy Climate Plan (PCET) in 2015, and the commitment of the Master Plan (Plan local de l'urbanisme intercommunal, PLUI in French), a priority for the ARC.

Moreover, in 2015, with a *Territorial Air Energy Climate Plan* (PCAET), the region of Compiègne was recognised as a "Positive Energy and Green Growth Territory" (TEPCV). Several actions are being implemented. At the beginning of 2015, an aerial thermography campaign was launched to identify roof insulation defects. One of the actions carried out under the PCAET in conjunction with ADEME was the creation of an energy renovation platform from 1 January 2016. The purpose of this platform is to federate and coordinate the various actors involved in energy renovation. This "Renovated Housing" platform is a unique resource center to facilitate access to information and simplify the steps towards energy renovation.

As part of our project, the urban area has already expressed the wish that the analysis of fuel poverty should focus, as a priority, on :

- - The Royaumont Linières district in Choisy au Bac (individual housing in peri-urban areas);
- - The Aramont and Pierre Lamaresse districts in Verberie (individual housing in peri-urban areas) ;
- - The district of the great Gardens in Compiègne (a little individual but especially private collective and social landlord areas) ;
- - The Venette district (joint housing in peri-urban areas).

Overall, the interest of this land is to address fuel poverty issues in all types of neighbourhoods: existing buildings or buildings under construction, for Grenoble, or under renovation, rehabilitated or to be rehabilitated for Compiègne and its urban area.

Based on these grounds, selected by the academic team and its partners in Grenoble and prefigured in consultation with the Communauté d'agglomération de Compiègne, the project studies in particular the loop of the following actions: design-implementation-use-improvement/integrated innovation. The project combines the analysis of technical-environmental characteristics (materials, type of buildings, land, etc.) and the analysis of the dynamics of use of social groups marked by their forms of vulnerability linked to their socio-demographic characteristics, life courses and control of processes involved in the ecological approach (D'ercole and Metzger, 2009). These dynamics of use are also studied in relation to the evolution of building users (e. g. the historicity of buildings) and partnerships with social landlords and/or developers.

Conclusion

The objective of the "ENERGY JUSTICE TOOL SUITE" project is to evaluate the partnership process of energy efficiency of buildings and their stakeholders, while developing a modelling, decision-making and consultation tool to assess the efficiency and cost of the proposed scenarios - and thus to participate in the fight against fuel poverty. Through the project, we propose in particular:

- A global analysis of the fuel poverty of the Compiègne urban area and the city of Grenoble, which will provide decision-makers with a new tool for understanding their territory, assessing spatial discrimination between hyperurban and urban areas in Grenoble and Compiègne, urban and rural areas in the Compiègne urban area, and social discrimination between populations.

- To take a global, analytical and detailed look at the political decision-making processes, the sets of actors involved in these processes (both through rationality logics and ideological or imaginary logics), to analyse the technical and managerial implementation of these decisions and to question the socio-economic logics involved, finally, to be able to identify the postures of users who are faced with these technical achievements, to understand the difficulties they encounter, the fragility of postures that manifest themselves in the face of technical, economic and legal challenges, and finally to identify the needs felt to adhere to or validate their capital of "responsible citizenship".
- It is also a question of defining an interoperable and interdisciplinary multiscale model for the evaluation of the energy consumption of an urban area's built stock. To this end, we propose the design, not of archetypes of buildings, but of "archetypes of complex systems" (Vorger, 2014) of multiscale energy systems, combining physical phenomena (real energy performance, socio-economic statistics of INSEE data at the IRIS and INSEE grid scales - which is unprecedented), and human behaviour - by integrating not only users, but also the whole ecosystem working for energy and socio-territorial justice, and from an empowerment perspective.
- Beyond our territories of study and action, we propose the development of a collaborative database of urban typologies. This database will catalogue all the urban forms present in our two study areas. It can be completed and enriched afterwards. Each urban form will be characterized by the criteria necessary to feed the models. The database will present all the "optimal" energy variants of these archetypal projects, allowing urban planners and architects to be informed of a wide range of potentialities. This work would help them to manage the complexity and understand the influence of their choice on urban energy responses, both in terms of performance, but also in terms of the qualities of architectural and urban environments, as well as in terms of socio-economic impacts, and finally in terms of comfort.
- We also propose the creation of a serious digital game to raise awareness among all stakeholders on the issue of heat loss and energy renovations.

Finally, the project aims to characterize, write, evaluate and co-construct an inclusive energy and socio-territorial justice - with the actors of these territories, through the creation of tools to support the energy transition, either a decision support tool (collaborative platform) and a tool to help.

²*Professor, IHS, Erasmus University, Rotterdam, edelenbos@essb.eur.nl*

³*Professor, IHS, Erasmus University, Rotterdam, alberto.gianoli@gmail.com*

Abstract: One of the major objectives of smart city development is achieving energy efficiency and moving towards a low-carbon energy society. The idea is that ICT-embedded urban infrastructure can enable efficient energy management and contribute to reducing CO₂ emission. In that sense, a smart city can play an important role in the energy transition. In South Korea, the government plays a major role in smart city development. Since the 2000s the governments implemented informatization and digitalization and since 2008 they started smart city implementation across the country. Then how these government-led smart city initiatives perform in the energy transition? The purpose of this paper is to discover the contribution of government-led smart city initiatives in the energy transition. After building a conceptual framework on smart city and energy transition, we develop a Smart Energy Transition Index. The 161 cities in South Korea are grouped into three categories: 1st and 2nd wave smart cities and non-smart cities. The index score is compared among the groups and the analysis showed that there is a significant difference between 2nd wave smart cities and the 1st and the non-smart cities. The analysis provided empirical evidence of the smart city's contribution to the energy transition.

Keywords: smart city; energy transition, smart energy transition index (SETI), South Korea

Introduction

Rapid urbanization and urban population growth have been accelerating greenhouse gas (GHG) and climate change. Currently, more than half of the world population reside in the urban area and according to the UN's prospect, the urban population will be 68% by 2050 (UN, 2018). These people's daily life cannot be separated from energy consumption and GHG emission. According to the Intergovernmental Panel on Climate Change (IPCC), cities consume around 67% to 76% of energy and produce three-fourths of GHG emissions (IPCC, 2015). Therefore, the factors that influence GHG emission in cities need to be managed for sustainable energy consumption. Those factors include population density, economic activity, climate variables such as heating degree days, household size, and urbanization rate (Creutzig *et al.*, 2015). Since urban infrastructures such as buildings and roads are the main place of energy consumption (Calvillo, Sánchez-Miralles and Villar,

2016), urban form and activities (economic activity, heating, and transport) should be considered in urban energy management.

To ensure environmental sustainability, it is important to manage the aforementioned urban attributes, but also change in the energy system. Today the main energy source is fossil fuel, which is a major contributor to CO₂ emission and climate change. If we use energy at a business-as-usual level, the energy consumption will be triple of 2005 by 2050 (Creutzig *et al.*, 2015). Energy transition becomes an important topic because the growing urban population and urbanization rate will increase energy demand. Energy transition means a drastic change in energy consumption and production pattern to a more effective and sustainable way (Rutherford and Coutard, 2014). It represents moving to a low carbon energy system (Bridge *et al.*, 2013). It is derived by both supply and demand, but the most important driver is the end-users (Grubler, 2012). Therefore, both energy production and consumption need modification.

The smart city literature argues that smart cities can contribute to reducing energy consumption and CO₂ emission (Debnath *et al.*, 2014; Snow, Hakonsson and Obel, 2016). The buildings can be designed energy-efficiently in the first place to automatically reduce energy consumption. ICT can be used to sense and monitor energy use in the building so that people can alter their behavior to reduce energy consumption (Navarro, Ruiz and Peña, 2017). On the road, a major difference can be made by the Automatic Vehicle Location System. This system is implemented in public transportation and help reducing fuel consumption and travel time (Debnath *et al.*, 2014). Sharing transport data can also reduce congestion (Snow, Hakonsson and Obel, 2016) and reduce CO₂ emission. In regard to CO₂ emission reduction, alternative or renewable energy sources are introduced, developed, and applied to generate cleaner energy (Zygiaris, 2013). The use of ICT can relieve the environmental burden (Hara *et al.*, 2016) and smart cities have a high possibility in contributing to the energy transition.

Many countries are interested in the idea of a smart city. The Indian government announced an ambitious goal of making 100 smart cities (Datta, 2015), and many other countries already initiated smart city projects. Especially in South Korea, the government has been investing in digitalization and ICT infrastructure since the early 2000s, and promoted smart city development since 2006. The effort of developing smart cities has been continuous: the government announced Ubiquitous-City (U-City) plan in 2004, established the first smart city (u-eco city) in Songdo in 2009, designated Jeju island as a test bed for smart grid system in 2010, and now develop Busan and Sejong as smart city since 2018. Then how these government-led smart cities are different from regular, ordinary cities? Do they perform better in terms of the energy transition? These questions are valid to check the effectiveness of government-led smart city projects.

The purpose of this study is to analyze the government-led smart city's achievement in terms of the energy transition. The remainder of this paper consists of the following. First, we build a conceptual framework on smart city and energy transition. After reviewing the definition of smart city and energy transition we make the link between them and develop evaluation criteria to evaluate government-led smart cities in terms of the energy transition. Second, we introduce South Korean planning history and policies regarding smart city development and energy transition. Then we move on to the analysis, introducing the data collection, analysis methods, and the results. Finally, we conclude with a summary of the analysis and discussion.

Smart City and Smart Energy Transition

After reviewing 78 academic paper on smart city framework, Yigitcanlar et al. (2018) developed a comprehensive conceptual framework for the smart city following the input-process-output model as shown in 오류! 참조 원본을 찾을 수 없습니다.. To this framework, the city itself is an asset (input).

Technology, community, and policy are the main drivers (process) that produce desired outcomes (output) in fields of economy, society, environment, and governance. These desired outcomes eventually make the city smart. This framework does not perceive the smart city as an end result per se, rather as a process to achieve balanced and sustainable development through three drivers. To put it differently, a smart city is a vision to achieve sustainability (Trindade *et al.*, 2017). Therefore, smart communities, technology, and innovative policies are important features in the smart city. The smart community identifies what they need and encourage developing better services and citizen-centric decision making through online platforms (Romanelli, 2013). The smart city provides an environment that citizens can participate through a various channel and enables mutual communication between citizens and the governments through technology (Moss Kanter and Litow, 2009; Bakici, Almirall and Wareham, 2013; Gil-Garcia, Zhang and Puron-Cid, 2016). Policy paves environments for technology to be applied and implemented in desired places.

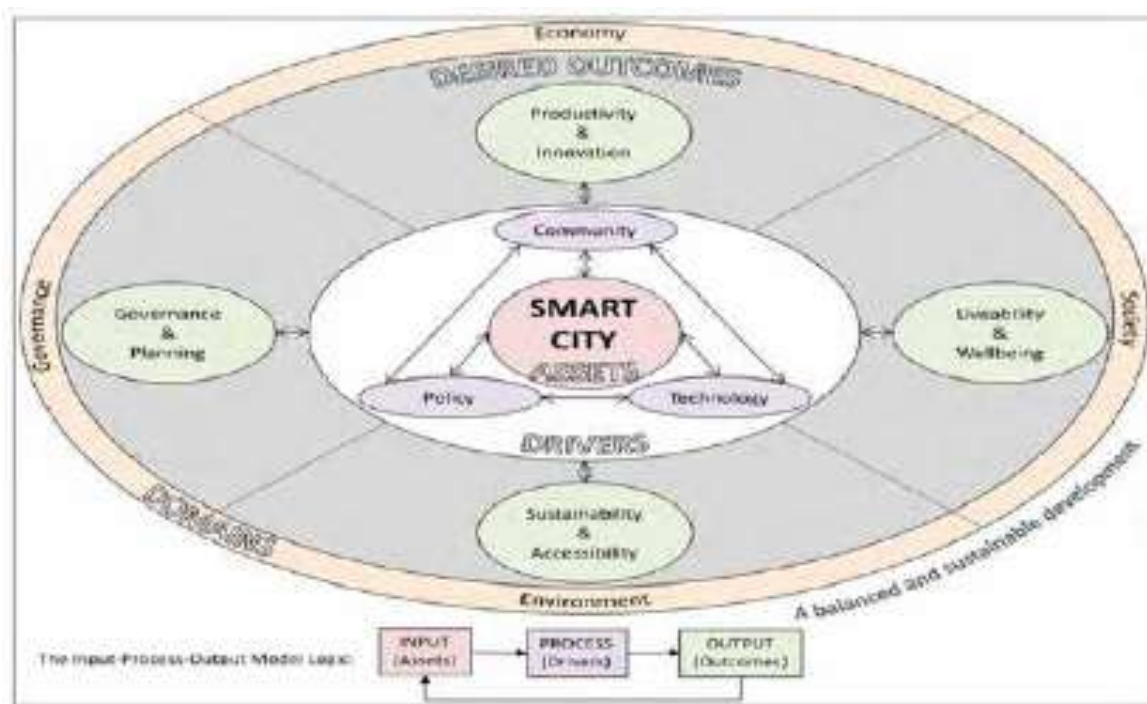

Figure 1 Smart City Framework (source: Yigitcanlar et al., 2018)

Technology in a smart city is mainly ICT such as sensors, broadband, and wireless networks, and mobile devices (Washburn *et al.*, 2009; Schaffers *et al.*, 2011). ICT functions as enabler and facilitator of various actions and innovations in the smart city (Nam and Pardo, 2011b). ICT-embedded infrastructures enable gathering, processing, storing and sharing of real-time information. It creates a ubiquitous connection not only among people, firms, and governments but also with the hard infrastructures (Nam and Pardo, 2011b; Cimmino *et al.*, 2014). Internet of Things (IoT), Cyber-Physical Systems (CPS), and big data are major examples of ICT in a smart city. Technology is a prerequisite that facilitates collaboration and cooperation among actors in the city so that they can find

an innovative solution to local problems and pursue sustainable growth (Nam and Pardo, 2011b). In that sense, community and policy take an important role in shaping a city into a smart one.

A smart community is operated with creativity, social learning, and life-long education and pursuit inclusiveness, cooperation, and democratic decision making (Nam and Pardo, 2011b). Urban Living Lab is an example of innovative community involvement which is public, private and people partnership (4P) model, a user-driven innovation (Schaffers *et al.*, 2011). At the same time, citizens can be empowered and participate more in public decision making in smart cities by providing a communication platform with ICT infrastructure (Stratigea, 2012). It supports prompt communication and higher accessibility to information and data that are needed to solve local social and economic problems (Nam and Pardo, 2011b). Inevitably, the citizens need to have the ability to exploit ICT infrastructure (Stratigea, 2012), and because of this age and socioeconomic difference can create a digital divide (McAllister *et al.*, 2005). To prevent further gaps, inclusive policy intervention is needed.

The policy represents a favorable governance environment for smart city development. In the smart city, e-governance is highlighted because it creates a connection among departments, civil society, and private entities (Nam and Pardo, 2011b). E-governance is the capacity of the government to communicate with citizens via on-line participatory tools regarding public services and satisfying citizens' needs (Odendaal, 2003; Barns *et al.*, 2017). The policies in favor of smart city development include investment in R&D for ICT infrastructure, providing learning programs for citizens who are not used to the ICT devices, and maintaining a good relationship with communities and businesses. Strong leadership, clear goal, appropriate planning, and commitment can encourage and accelerate the smart city development process (Stratigea, 2012). Finally, the government needs to consider what society wants, citizens' ability to exploit ICT infrastructures, and jurisdiction (Odendaal, 2003; Barns *et al.*, 2017).

The three drivers of the smart city do not act separately but they work together to achieve the best results in economic, social, and environmental sustainability (Yigitcanlar *et al.*, 2018). Especially, these drivers can contribute to energy transition. The energy transition can be defined as changing energy production and consumption pattern to a low-carbon society (Grubler, 2012). Low-carbon means producing renewable energy sources that emit less CO₂ emission, storing and distributing electricity according to the supply and demand, and consuming less energy in daily life (Bridge *et al.*, 2013). A radical change in the energy system has been highlighted because of two major trends: technological lock-in to the current unsustainable energy system and the limited amount of fossil fuel that the current energy system relies on upon (Seyfang and Haxeltine, 2012). System-wide change is desired and the smart city can be one of the solutions because the smart city itself is a comprehensive change in the urban system.

In a smart city, ICT-embedded urban infrastructure and open data sharing can enable efficient energy management and optimize energy consumption which can lead to less CO₂ emission (Debnath *et al.*, 2014; Snow, Hakonsson and Obel, 2016). According to Nielsen, Amer, & Halsnæs (2013 p.3), smart energy city means a city with greater energy efficiency using ICT and promoting renewable energy so that it provides a sustainable living environment. Parallel to this definition, Mosannenzadeh, Nucci, and Vettorato (2017) provided a holistic definition based on 5W1H (who, when, where, what, how, and why), in relation to smart city and sustainable city. They define smart energy city as “a component of smart city development aiming at a site-specific continuous transition towards

sustainability, self-sufficiency, and resilience of energy systems, while ensuring accessibility, affordability, and adequacy of energy services, through optimized integration of energy conservation, energy efficiency, and local renewable energy sources (Mosannenzadeh and Vettorato, 2014, p.57).” They also mention ICT and collaboration among stakeholders are important to keep energy transition on-going. In their definition, we could find three drivers of smart city, ICT as technology, major stakeholders including community (civil and private firms) and government (policy).

The energy system follows a procedure of energy production, distribution and storage, and consumption (Calvillo, Sánchez-Miralles and Villar, 2016). In the traditional energy system, there was a clear distinction between who produces and distributes (a government agency) and who consumes (civil society). The traditional energy system involves mass production and distribution of power which needed large infrastructures and investments govern by the government. In a transitioning system, this centralized energy system changes into a more decentralized one, where individuals can become energy producers (Mah *et al.*, 2013). People can install small scale energy production plants such as solar panels to their homes and offices (Mosannenzadeh *et al.*, 2017). Moreover, it is possible to save the residual electricity and sell it to local power plants. The smart grid enables real-time and interactive information sharing on energy production and consumption while the energy storage system (ESS) enables optimizing energy use on demand and enhance stable energy distribution. Also, technological development can increase energy efficiency, meaning using less amount of power to generate the same performance. For example, the household appliance can be designed energy efficiently, so that people can save energy while doing the usual house chore. Energy conservation activities can be promoted by actively involving citizens. For example, people can share cars and bikes and use more public transportation (Geels *et al.*, 2018). As the system changes, the stakeholders’ role in energy systems is changing. The government’s role is expanded from energy producer to comprehensive system manager. The government produces energy, promotes innovation in technology, and facilitates citizens’ participation for a sustainable energy system. The community’s role is also expanded from energy consumer to energy producer using a smart grid system.

Table 1 Theoretical framework

Drivers	Energy Production	Energy Distribution & Storage	Energy Consumption
Technology	Renewable energy	Smart grid, ESS	-
Community	Civil initiatives in renewable energy sector		Energy consumption level
Policy	Supporting technological development Rules and regulations for energy transition		

The main hypothesis is that there is a difference between smart and none-smart cities regarding performance in the energy transition. To check the hypothesis, evaluation criteria are developed as shown in Table 1. The contribution of smart city elements in each process of the energy system is stated in each cell. Technological development enabled more energy production with renewable energy, energy distribution, and storage with a smart grid system including an energy storage system. It also influenced energy consumption by providing energy efficient gadgets and facilities, but we omitted this in the table because those are included in the community’s energy consumption behavior. The community’s contribution is represented as installing small-scale on-site energy generation for energy production, distribution, and storage. For energy consumption, energy conservation behavior and energy consumption level are evaluated. Finally, the policy here means the government’s

activities in regard to the energy transition. It includes the rules, regulations, the legislation's on energy systems, energy conservation campaigns, and supporting technological development in general.

Smart City Development in South Korea

Smart city development is one of the national development strategies in President Moon's administration (Baek, 2017). Smart city development in South Korea started with informatization and digitalization following the introduction of the Internet in the early 2000s. The government then initiated U-Korea Plan (2006~2010) and U-City Plan (2009~2012) and launched 55 U-city projects (45 cities if deducting duplicated projects in the same cities). 'U' stands for Ubiquitous technology that enables unlimited network accessible anywhere and anytime. The main focus of U-city was on technology and infrastructure such as Ubiquitous Sensor Network (USN), Wireless Sensor Network (WSN), CCTV, fast internet network, mobile environment, and public wi-fi. The sensors are implemented in roads, rivers, and major facilities for the management. U-city provides service mainly on transportation information and security (surveillance through CCTV & emergency response). U-city is a prototype of a smart city.

At the same time, the government started to prepare for energy transition under the 'Low Carbon Green Growth' agenda. Phasing with the global trend to low-carbon economy and emphasis on green growth, the government focused on sustainable economic development, especially focusing on green and eco-friendly transportation. The government launched the Guideline for Low-carbon Green City (2009.8) focusing on developing low-carbon green cities to overcome climate change crisis and Low-carbon Green Growth Law (2010.4) regulating compact city, mixed land use, public transportation, new and renewable energy use, water and resource cycle. Also, the government initiated the National Smart Grid Vision (2009), and National Smart Grid Roadmap (2010). At glance, the government's efforts on smart city and energy transition seem to be separated. They both are under the Low-carbon Green City agenda but U-city is rather focused on cutting-edge technology and infrastructure on transportation and security while the low-carbon green city projects focus on purifying and restoring the natural environment and renewable energy. Also, the government used energy transition as a means of economic development, ignoring actual energy transition in general society (Yun, 2009).

Table 2 summarizes the major difference between the U-city and the smart city. Both U-city and Smart city utilize the technology but u-city focus on the technology itself while the smart city focuses on its functionality. U-city focuses on connected infrastructure while the smart city pays attention to human and social capital. The u-city's goal is urban informatization which is implementing technology for efficiency while that of the smart city is urban intelligence, which is making the technology more accessible to the general public. When there is an urban problem, u-city tends to follow ready-made procedures, but smart city diagnoses the problem and prescribes solution based on the data. The initiatives changed from a government-led, city-focused, top-down manner to multi-stakeholder and citizen participation, bottom-up manner. Citizens' role is also expended from mere service users to active service developers. This was administratively assisted by the government as they initiated Open Government 2.0 which is a platform for open administration data service so that people can access to the government data with ease in 2012. The smart city provides more comprehensive and multiple urban services. Based on the lessons from u-city development, South Korean smart city now tries to provide multiple urban services and include citizens and other parties.

Table 2 Difference between U-city and Smart city

Category	U-City	Smart City
Major Focus	Connected Infrastructure (network) Focus on technology	Social Infrastructure (Human & social capital) Focus on functionality
Goal	Urban informatization (efficiency)	Urban intelligence (usability)
Solution to urban problems	Ready-made procedure	Prescription based on data
Initiative	Top-down City focused & Government-led Vertical collaboration	Bottom-up Citizen's participation & Multi-stakeholders Horizontal collaboration
Implementation/ Operation	Limited urban services in telecommunication, security, and disaster prevention Mostly implement in newly developed cities Citizens adapt to provided urban services	Various urban services in administration, transportation, energy, water management, welfare, environment Can be implemented in both new and old cities Provide citizen-centered urban services

Source: Adopted and translated from (Park, Gang and Lee, 2018)

For the analysis, cities in South Korea is categorized into three as the following:

1. First wave smart city (n=34): U-city (u-eco city) and smart city projects by LH and local governments focusing on Transportation and Security (CCTV)
2. Second wave smart city (n=11): Smart city projects providing comprehensive urban management services, including transportation information, facility management, security and disaster prevention, health and welfare, administration, and environment (projects finished by 2016, not including on-going smart city projects)
3. Non-smart cities (n=116): None of the above

Methodology

Administrative districts in South Korea consist of one special city, six metropolitan cities, eight provinces, one special autonomous city, and one special autonomous province (see Figure 2). Including Seoul, Sejong, and Jeju, six metropolitan cities, and 75 Si and 77 Gun, a total of 161 areas are considered as cities for data analysis.

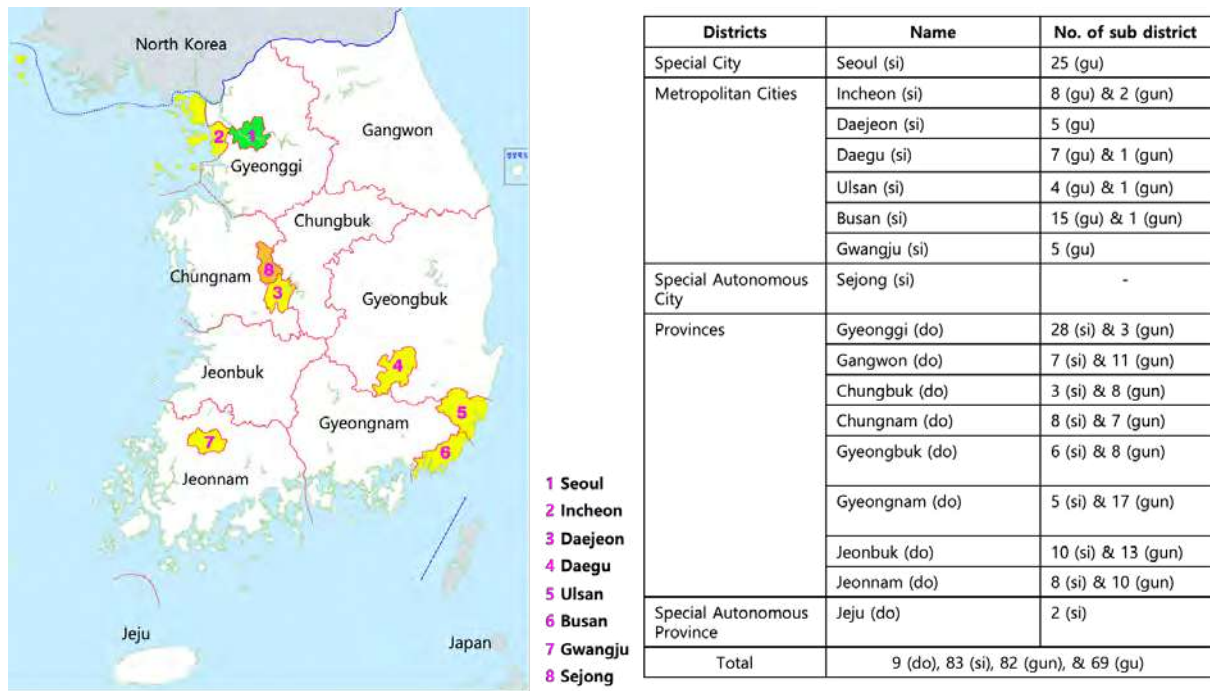

Figure 2 Administrative districts in South Korea

Smart Energy Transition Index (SETI) is developed based on the theoretical framework in Table 1, and the indicators are shown in Table 3. The following indicates how the data was collected and treated for each indicator.

- Renewable energy production: There are provincial level data on renewable energy production, but not on city level. Instead we use ratio of employment in renewable energy power generation to total number of employments. Renewable energy includes solar and hydro.
- Smart grid: The DOE Global Energy Storage Database provides ESS projects around the world. They provide which projects are installed where so that it is possible to establish city-level data.
- Citizen initiatives in the energy sector: There are three forms of the civil initiative that are available as dataset: cooperatives, social enterprise, and town enterprise. It is possible to access to full list of these initiatives and extract the ones specialized in the renewable energy sector. Most of them support local residents in installing or renting solar-panel.
- Energy conservation behaviors: It represents how much people try to reduce energy consumption in their daily lives. The data is from the social survey, which asks whether people try to use public transportation, participate in recycling, use fewer disposable goods, buy eco-friendly goods, and participate in energy conservation campaigns. These are asked on a scale of 5; from 5 (always participating) to 1 (never or not interested). Provinces except for Gangwon, Chungnam, Jeonnam, and Gyeongnam have city-level data on each energy conservation behaviors (n=87). Gangwon, Chungnam, Jeonnam, and Gyeongnam (n=74) only provide provincial level data. It is risky to remove all missing cases so we used provincial level data as each city's data since the provincial data is average of city-level data. The analysis was performed with and without this indicator for sensitivity analysis.

- Energy consumption level: Energy consumption means electricity use. The Korea Statistical Information Service (KOSIS) provides city-level data on electricity use, which is divided into four purposes of the use: home, public, service, and industry. We excluded industrial (agriculture, fisheries, forestry, and mining, and manufacture) electricity use because those facilities are usually built outside of the city. Only home, public and service are considered. The total amount of electricity consumption is divided by the population.
- Financial support: Financial support for technological development is represented with percent of the budget for technology (technology development, R&D, and scientific technology in general) in the local government's annual budget.
- Rules and regulations: Elis.go.kr provides a full list of each cities' current ordinance, rules, and regulations. We count the number of ordinances and rules that are related to energy. The title of frequently appeared includes 'Energy Basic Ordinance', 'Ordinance on Green Roof', 'Ordinance on Response to Climate Change', 'Ordinance on Low-carbon Green Growth', and 'Ordinance on Renewable Energy Provision'.

Table 3 Indicators of smart energy transition index

Dimensions	Category	Indicator	Year	Unit	Weight
Technology	Renewable energy production	The ratio of employees in solar and hydro energy production	2016	%	0.5
	Smart Grid	No. of gov't projects supporting ESS installation	Up to 2018	unit	0.5
Community	Citizen initiatives in energy sector	No. of civil initiatives specialized in renewable energy	Up to 2018	unit	0.33
	Energy conservation behavior	Average energy conservation behavior in using public transportation, recycling, using fewer disposable goods, buying eco-friendly goods, and participating in energy campaign	2016	score	0.33
	Energy consumption	Total amount of electricity use in houses, service sector, and public sector per capita	2016	MWh	0.33
Policy	Financial support	% of the budget for technology (scientific development)	2016	%	0.5
	Rules and regulations on energy sector	No. of local gov't's regulations, laws, or legislation regarding energy sector	2016	unit	0.5

The indicators are normalized and accumulated with equal weighting as shown in Figure 3. We choose equal weighting because three dimensions of smart cities are equally highlighted in the literature (Yigitcanlar *et al.*, 2018).

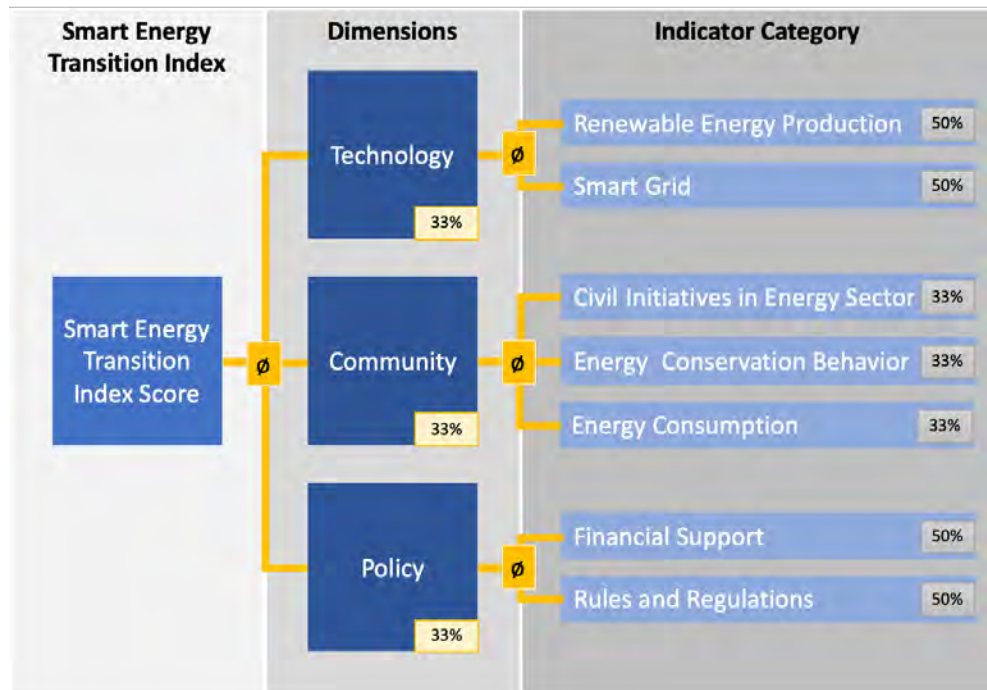

Figure 3 Framework of smart energy transition index

Before normalizing and accumulating indicators into one index, correlation analysis has been carried out to check the suitability of indicators. As shown in Table 4, the smart grid has a positive correlation with community initiatives, technology budget, and energy regulations. The community initiatives are promoting renewable energy use and installing small scale solar panels at houses and both technology budget and rules and regulations represent the government's efforts on energy transition. Therefore, the smart grid has a positive correlation with these three indicators. Rules and regulations on the energy sector have a positive correlation with community initiatives and technology budget. This means the government's effort and communities' effort sync for the energy transition.

Table 4 Correlation among the indicators

	Renewable energy employment	Smart grid	Community initiatives	Energy conservation behavior	Electricity Consumption	Technology budget	Rules and Regulations on Energy sector
Renewable energy employment	1	-.052	-.011	-.111	-.055	-.052	-.051
Smart grid		1	.585*	.073	-.048	.373**	.408**
Community initiatives			1	-.041	-.037	.046	.427**
Energy conservation behavior				1	-.100	.008	-.070
Electricity Consumption					1	-.036	.021
Technology						1	.249**

budget							
Rules and Regulations on Energy sector							1

** . Correlation is significant at the 0.01 level (2 -tailed)

Since the indicators have different measuring units, the indicators are normalized by using z-score and percentile. This way the indicators are on the same scale and they can reveal each city's relative position. Then the equal weight was given to the accumulating total SETI score.

<Smart Energy Transition Index>

<Smart Cities in Korea>

Figure 4 Smart energy transition index scores

The SETI score ranges from 100% being the highest to 0% being the lowest. Figure 4 shows the result of the SETI score and the city categories. Darker blue means a high level of the SETI score. In general, smart cities in South Korea have a higher level of SETI score than non-smart cities. The 10 cities with the highest and lowest score are shown in Table 5. Top 10 cities are mostly smart cities (1st and 2nd wave) and the top six cities are all metropolitan or special cities. The bottom 10 cities are mostly non-smart cities and 'gun' area. However, there are two non-smart cities in the top 10 list and two 1st wave smart cities in the bottom 10 lists.

Table 5 List of top and bottom 10 cities

Top 10 cities with highest SETI score				Bottom 10 cities with lowest SETI score			
Rank	City Name	SETI score	City Category	Rank	City Name	SETI score	City Category
1	Incheon	78.9	2 nd wave smart city	161	Seongju-gun	29.3	Non-smart city
2	Daegu	71.8	1 st wave smart city	160	Goryeong-gun	31.5	Non-smart city
3	Gwangju	70.8	1 st wave smart city	159	Buan-gun	32.1	Non-smart city
4	Seoul	70.7	2 nd wave smart city	158	Gimcheon-si	32.4	1 st wave smart city
5	Daejeon	68.1	2 nd wave smart city	157	Wanju-gun	32.5	1 st wave smart city
6	Ulsan	65.7	1 st wave smart city	156	Jinan-gun	32.8	Non-smart city

7	Yongin-si	62.3	2 nd wave smart city	155	Yeongdeok-gun	34.5	Non-smart city
8	Taejeon-gun	60.3	Non-smart city	154	Gurye-gun	34.6	Non-smart city
9	Cheongju-si	60.1	Non-smart city	153	Boseong-gun	34.6	Non-smart city
10	Bucheon-si	59.6	1 st wave smart city	152	Damyang-gun	35.8	Non-smart city

Table 6 shows the results of the descriptive analysis of each city category and SETI score. The 1st wave smart city is 34 cities, and their mean smart energy transition index score is 47.4, the minimum is 32.4 and the maximum is 71.8. Number of the non-smart city is 115 and their mean score is 44.9, the minimum and the maximum score is 29.3 and 60.3 respectively. The 2nd wave smart city is 11 cities where the mean score is 56.9 and the maximum score is 78.9. The mean score is highest in the 2nd wave smart city and the non-smart city is the lowest. Figure 5 shows the boxplot and histogram of the SETI score by the city category. The 2nd wave smart city has a higher mean and range than non-smart city or 1st wave smart city. The 1st wave smart city and the non-smart city are similar in their position and range but the mean of 1st wave smart city is slightly higher than the non-smart city. In the 1st wave smart city, two cities seem to be outliers: Daegu and Gwangju.

Table 6 Result of descriptive analysis

City	No.	Mean	Standard Deviation	Min	Max
1 st wave Smart City	34	47.4	9.73	32.4	71.8
2 nd wave Smart City	11	56.9	12.2	39.2	78.9
Non-Smart City	116	44.9	7.08	29.3	60.3
Total	161	46.2	8.61	29.3	78.9

Figure 5 Boxplot and distribution of smart energy transition index score

First, including the outliers, one-way ANOVA is performed to check the hypothesis. One-way ANOVA is useful to check whether there is a significant difference among groups in their mean. Before performing ANOVA, the following assumptions were checked:

1. The data of each group is normally distributed (normality)
2. The data of each group has a common variance (homogeneity in variance)

For the normal distribution test, Shapiro-Wilk test is performed. Non-smart city and 1st wave smart city's p-value are 0.024 and 0.027 respectively which is lower than significant level ($p < 0.05$) which means they are not normally distributed. On the other hand, 2nd wave smart city's p-value is 0.848 and it is normally distributed. Table 7 summarizes the results of the analysis. Levene's test shows homogeneity of variance. The p-value is 0.0605 which is higher than the significance level ($p < 0.05$) so the null hypothesis cannot be rejected. This means the variance is homogeneous. However, since the normality assumption is not satisfied, nonparametric test was performed instead of one-way ANOVA. Since the number of the group is three, we adopted Kruskal-Wallis test. The p-value is 0.004235 which is less than the significance level 0.05, we can conclude that there are significant differences between the city categories. To find which pair of city category has a difference, we performed pairwise comparisons using the Wilcoxon rank sum test. The 2nd wave smart city is significantly different from the 1st wave smart city and non-smart city ($p < 0.05$). However, there is no significant difference between the 1st wave smart city and non-smart city.

Table 7 Results of the analysis

Data: Smart Energy Transition Index score by city categories			
Levene's test	Df	F-value	P-value
	2	2.8556	0.0605
Kruskal-Wallis	Chi-squared	df	P-value
	10.929	2	0.004235
Pairwise comparison		1 st wave smart city	2 nd wave smart city
	2 nd wave smart city	0.0291	-
	Non-smart city	0.2495	0.0041

Since the data on energy conservation behavior is imputation, we exclude this indicator for sensitivity analysis. The adjusted smart energy transition index score is summarized in below. Boxplot and distribution charts are similar to the original (see Figure 6) and the result of the Kruskal-Wallis test and post hoc test is similar to the original (see

Table 8 and Table 9). All in all, there is a significant difference between the 2nd wave smart city and 1st and non-smart city in the mean of smart energy transition index score.

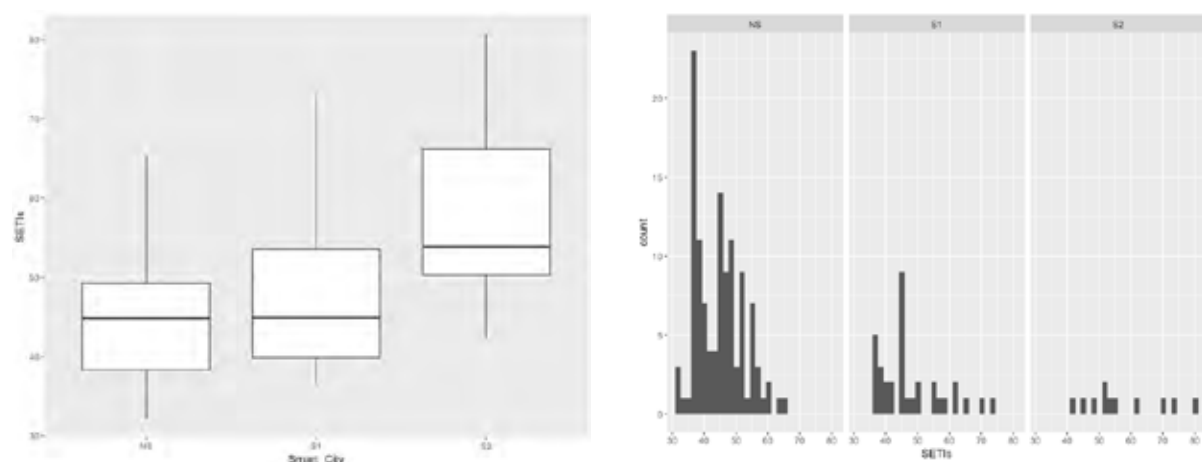

Figure 6 Boxplot and distribution of adjusted smart energy transition index scores

Table 8 Descriptive analysis of adjusted smart energy transition index scores

City	No.	Mean	Standard Deviation	Min	Max
1 st wave Smart City	34	47.6 (47.4)	9.99 (9.73)	36.5 (32.4)	73.0 (71.8)
2 nd wave Smart City	11	57.8 (56.9)	12.3 (12.2)	42.3 (39.2)	80.7 (78.9)
Non-Smart City	116	44.6 (44.9)	7.43 (7.08)	32.2 (29.3)	65.3 (60.3)
Total	161	46.1 (46.2)	9.02 (8.61)	32.2 (29.3)	80.7 (78.9)

Table 9 Adjusted Levene's test for homogeneity of variance

Data: Smart Energy Transition Index score by city categories			
Levene's test	Df	F-value	P-value
	2	2.1121 (2.8556)	0.1244 (0.0605)
Kruskal-Wallis	Chi-squared	df	P-value
	13.688 (10.929)	2	0.001066 (0.004235)
Pairwise comparison		1 st wave smart city	2 nd wave smart city
	2 nd wave smart city	0.012 (0.0291)	-
	Non-smart city	0.206 (0.2495)	0.001 (0.0041)
	2 nd wave smart city	0.012 (0.0291)	-
	Non-smart city	0.206 (0.2495)	0.001 (0.0041)

P-value adjustment method: BH

Discussion and Conclusion

There are some findings from the analysis. First, the indicators showed a correlation. The smart grid has a positive correlation with community initiatives, technology budget, and energy regulations and the energy regulations have a positive correlation with community initiatives and technology budget. This shows smart city drivers (technology, community, and policy) are interacting with each other. The community (community initiatives) and policy (technology budget and energy regulations) promote the technology (smart grid). The community initiatives represent cooperatives and social enterprises that are specialized in renewable energy. The policy (energy regulations) provides a favorable environment for those communities to participate in the energy sector. Second, the results of the analysis showed that there is a significant difference between the 2nd wave smart city and the 1st and non-smart cities in the smart energy transition index. This supports the hypothesis of this paper that smart cities perform better than non-smart cities in the energy transition. However, the 1st and non-smart cities do not have a significant difference. This shows the limitation of the 1st wave smart city. The 1st wave smart cities (u-city) focus on implementing connected infrastructure in limited sectors (transportation & security) (Park, Gang and Lee, 2018). On the other hand, the 2nd wave smart cities account the role of community and provide a comprehensive urban management service. This can be supporting evidence of the argument that a smart city is more than a technology (Hollands, 2008). Third, the SETI score is higher in smart cities (the 1st and 2nd wave smart city) than non-smart cities. However, there are non-smart cities that scored higher than smart cities (Taeang-gun and Cheongju-si). Taeang-gun has a higher ratio of renewable energy employees (61%) and community initiatives (77%). And both cities have a higher score in energy conservation behavior (93%, each), energy consumption level (56% each), and rules and regulation on energy transition (79%, each). The

community initiatives and the energy conservation behavior are direct participation of the community, which sometimes initiated without the government's intervention. When we look into bottom the 10 cities, where two 1st wave smart cities are included (Gimcheon-si and Wanju-gun). Even though these cities have government initiatives, their performance in community initiative (33%) and energy conservation behavior (3%) are way below the average. This shows the community plays a critical role in the smart energy transition. Finally, the smart energy transition index score is higher in metropolitan cities (including special cities) than Si or Gun area. Special cities (Seoul & Sejong) and metropolitan cities are considered as the same administrative level (political power) with provinces ('Do') and their population is more than one million. Among eleven 2nd wave smart cities, four are special or metropolitan cities. Perhaps the reason why the 2nd wave smart city performs better than 1st and the non-smart city is that the smart cities are already advanced cities that have more political power and population. Strong political power and leadership ease the implementation (Nam and Pardo, 2011a) and certain population threshold needs to be satisfied to implement a large ICT infrastructure.

The purpose of this paper is to find empirical evidence of a smart city's contribution to the energy transition. We developed an index with seven indicators that represent the possible contribution of three drivers of the smart city (technology, community, and policy) in the energy transition. This study provides an overview of the smart energy transition in South Korea and compares smart and non-smart cities. As the result shows, there is a significant difference between the 2nd wave smart city and 1st and non-smart cities. This reveals the limitation of 1st wave smart cities which mainly focuses on technology implementation. A smart city is more than a technology implemented city (Hollands, 2008), and community and policy also play important roles.

The limitation of this study is that we have used an existing dataset that is available at the city level. Because of this, we used alternative indicators for some of the indicators. For example, renewable energy production is replaced with the ratio of the employees in renewable energy production, smart grid implementation is replaced with the number of ESS projects. Another limitation is that the paper provides only an overview of the smart energy transition. Why and how 2nd wave smart cities perform better than 1st and non-smart cities are not thoroughly studied in this paper. We leave this for further study, where specific case studies can be carried out to examine success and failure stories of smart cities in the energy transition.

Abstract: District heating (DH) is an energy service based on the centralized production of heat, and its supply to final users. Most DH networks are currently located in the Northern hemisphere, while very few are located in the Southern hemisphere. For what concern the European Union, most networks are operating in northern and eastern countries. Italy, with less than 10% of the population reached by DH systems, has still a significant, but quite low, market share in the European context. The purpose of this review is to present the current situation of the Italian DH sector. The first introductory part concerns the historical evolution of DH systems in a global perspective. Later, the attention moves on the European situation, with focus on the system geographical distribution, the level of technological development, and the implementation of renewables. Italy still plays a marginal role because of climatic differences in the country, the complexity for some areas to access renewable energy sources, and the lack of interest in this technology showed until the 70s. The conclusions of this work underline a large untapped potential that DH systems have in Italy, requiring adequate investments and researches to enhance the use of renewables as energy source.

Keywords: District Heating; Italy; Sustainable Energy Planning; Smart Cities

1.Introduction

The word “district heating” (DH), according to Mackenzie-Kennedy (Mackenzie-Kennedy, 1979), is universally applied to the principle of the utilization of a central thermal source for the heat production and a network of pipes for the distribution of the produced heat to all the different costumers connected to the grid. The thermal source is usually a fossil fuel such as gas, coal or oil, but the production of heat for these kinds of systems can easily integrate renewable sources (RES). In 2012, DH provided 9% of the total heating EU needed for that year but using gas as main primary energy source (40%) and coal as second most used (29%) (‘An Eu Strategy for Heating and Cooling’, 2016). Recently, some RES have been found profitable for the production of energy for heating networks, and sources as geothermal wells, biomass and solar collectors started to enter in the DH businesses. The shift from fossil fuels to RES can be achieved also taking into consideration the use of waste heat from plants and industrial processes, in this way the primary merit of DH networks of providing heating at lower costs than fossil fuels is coupled with fulfilling European directives about lowering environmental impact and contrasting climate changes caused by fossil fuels.

DH is not a new technology for what concern accommodating heating demands: a pioneering example of the utilization of this principle existed already in the XIV century in Chaudes-Aigues, a medieval spa-village in France, where a piping network distributed hot water from geothermal source to town's buildings (P. Raynal, J. Gibert, 1992). In modern times, the world's first commercial system was developed in Lockport, New York in 1877. This system used a central boiler plant in order to provide steam to few neighbor houses and small businesses. By the end of the XIX century DH systems were gaining popularity and in a short time frame numerous small city and industrial centers in the northeast of USA started to install such systems to support local development and people's heating demands.

The network created in Lockport inspired the first European commercial heat distribution systems developed during 1920s in German cities. However, already at the turning of the XX century in Dresden a steam based DH system was initiated to supply heat to priority government buildings in a convenient and practical way and at the same time to reduce fire risks linked to on site generation plants (Council, 1985b).

In the years between 1920 and 1940, the idea of passing from single decentralized heating system to a DH network spread across the European continent. The already existing networks in various German cities (i.e. Dresden, Hamburg, Kiel, and Berlin) became examples for new installments in cities like Copenhagen (1925), Utrecht (1927), Paris (1930), Brno (1930), and Zurich (1933) (Collins, 1959).

After these first examples, DH experienced a considerable development after the end of World War 2. The need of providing the continent with new housing and services after the destruction caused by the war enhanced the possibility for developing networks to deliver heat to the newly built neighborhood. In the 50s extensive networks were laid down in Scandinavian countries (i.e. Finland, Norway and Sweden), Denmark; Germany and in the ex USSR, where in 1976 almost two-third of all the buildings were connected to DH network (Mackenzie-Kennedy, 1979). In the 70s, the oil embargo proclaimed by the OAPC (Organization of Arab Petroleum Exporting Countries) pushed European countries to improve their energy efficiency further to reduce their dependence on imported oil. In this scenario, both central and local government started to award loans, grants and subsidies to encourage the sprout of new heating network systems (Council, 1985a).

2. An overview of Europe

Heating and cooling in industries and buildings represent half of the energy consumption of the European Union (EU). They account for the 50.7% of the final energy consumption, corresponding to 561.3 Mtoe of the total 1,107 Mtoe consumed by Member States (MS) in 2016 ('Review of Available Information on an EU Strategy for Heating and Cooling', 2016).

European households use the 79.2% (222.7 Mtoe) of their total energy use for heating and domestic hot water. Even if it represent a small share of the total final energy use, cooling need to be added to the energy use count, with its 0.8 Mtoe, it affects just for the 0.3% (*Energy consumption in households - Statistics Explained*, 2015). For what concern industry, 70.3% (196.9 Mtoe) of the energy is used for heating and industrial processes, 26.7% (74.8 Mtoe) for electrical processes and lighting, and 2.7% (7.6 Mtoe) is used for cooling (*Heating and cooling - European Commission*, 2013).

As for the last available data, in 2016 still 85% of the total amount of energy needed for heating and cooling was provided by employing fossil fuels, while just the remaining percentage was generated using renewable energy sources. To reach the targets set within the EU 2020 Climate and Energy Package, the emissions caused by fossil fuels and the energy consumption for heating and cooling need to be reduced as much as possible. For this reason, in 2016, the European Commission (EC) launched its first plan to curb energy use and boost RES use in heating and cooling for Europeans households, service sector buildings and industry sector. The strategy includes plans to ease the processes to renovate buildings, guidelines for retrofit projects and modernization of the already existing district heating and district cooling (DC) networks or creation of new networks with the integration, in both cases, of electrical systems ('An Eu Strategy for Heating and Cooling', 2016).

Although EC's plans for the developing of DH systems in Europe are quite recent, the old continent is one of the places where the highest number of DH network are located (Figure 1). It is a wide spread technology across the whole continent with more than 10,000 different networks installed just in the countries part of the EU27 (Euroheat & Power, 2013)

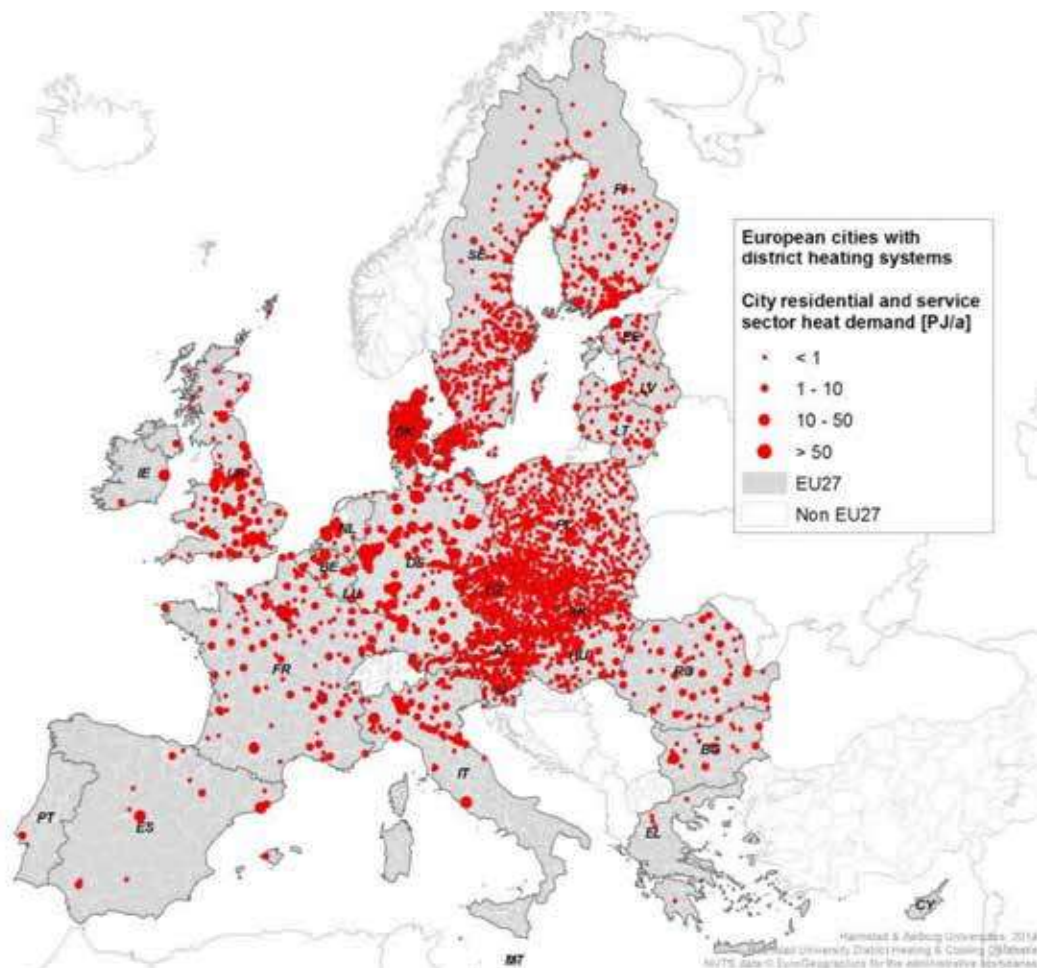

Figure 1 - Map showing European cities with DH systems and heat demand for each system (from Halmstad University District Heating & Cooling Database)

Historically modern DH systems came in Europe after experiencing a technological development in the US because of the commercial nature given to this type of systems in their first applications. However, in EU it experienced a development and expansion different from what would have

happened in the US. In the latest nineteenth century, several small systems found application in Germany, mainly in cities where outdated heating systems were replaced by DH systems to reduce fire hazards in historical buildings containing art treasures (Frederiksen and Werner, 2013). Scandinavian and Baltic countries and Central Europe present a higher degree of DH systems expansion since from the beginning of the twentieth century environmental and energy independence aspects were held in high consideration: the use of MSW in conjunction with coal was a common practice in cogeneration plants. Furthermore, planning practices in Nordic cities used to establish incinerator facilities close to residential areas in order to serve heating in a better way to the housing complexes. The climatic characterization is another important aspect: with its long and cold winter, Central and Nordic Europe have a high heat demand index, this aspect affected the policy makers and private energy societies pushing them to invest into expanding and improving the existing systems (Biele *et al.*, 2014). The oil crisis in the 70s, and the consequent inflation of the oil price promoted by the OPEC (Organization of the Petroleum Exporting Countries) had a devastating effect on the heating sector in the EU. It was not until this time that European countries started to realize the importance of developing regulation for the promotion of sustainable energy sources and the development of alternative systems to single building heating devices. In this situation heat prices were regulated by involving the government in keeping them competitive in the status quo (Amos, Hutchinson and Denman, 1996). As the time passed and the heating demand from the DH grid improved this system first became competitive with traditional heating systems and in the time, it became even more performing justifying initial investments and government involvement. The aforementioned conditions made possible to have a huge expansion of the DH networks in Scandinavian, Baltic and Central European countries (Mazhar, Liu and Shukla, 2018).

For these reasons, a high share of DH applications for residential buildings characterizes Central and eastern EU regions. The success of these systems happened mainly in urban areas where there are reserves of local sources for the production of heating; also, the cost of DH is highly dependent on the scale of the network. If the density of buildings and heat demand is high then this type of technology is more economical compared to others (Persson and Werner, 2011). This context is not so common in southern European regions where the dominant energy sources are gas and fuel oil and the density of buildings is lower, an exception of this consideration are cities: in countries where climate is more temperate the majority of DH systems can be found in densely built-up areas (Sayegh *et al.*, 2017). Urban areas represent an untapped potential: 50% of the demand for heating in Europe is located in areas with a similar heat density to those areas already connected to a DH system. Exploiting this potential by means of district network will increase the share of European demand satisfied by DH systems, that in these days is stationary at around 10% (International Energy Agency IEA, 2017).

In pre-expansion EU countries, there is a more limited use of coal and a slight increase in the use of natural gas and renewable sources, the latter result from the policies of energy containment and environmental protection. However, in the countries of Central and Eastern Europe, new small production units have been commissioned using natural gas. The use of natural gas as a fuel has increased mainly in Austria and the Netherlands (the latter is a producer). In some of these countries, the problem of the monopolistic presence of a single natural gas supplier provokes rigidity in the primary energy supply system.

Despite this, the use of renewable sources in the territories favored by particular environmental conditions has increased, with the largest increase still being in Austria, Denmark, Finland and Sweden. Coal is the most used fuel in the DH of the newly acquired EU countries with an average of 50% heat produced with this energy source (Euroheat & Power, 2013, 2015).

Considerations previously done emerge from Table 1. The countries that have a higher share of RES for supplying DH systems are from Central, Eastern, and Nordic Europe, but in this case, data are quite fragmented and mostly focused on CHP generation for district systems. In these cases, RES share in producing heat for DH are higher than 30% and the country relies on a quite differentiate energy portfolio: there is not a predominant energy source.

Table 1 - Energy sources used in some European countries to fuel DH systems

In Central and Northern European countries, the environmental conditions, which are reflected in a high number of degree-days (above 3,000), have led to the development of district heating in the residential sector. The most significant percentages of the presence of district heating in some European countries are as follows: Iceland 95% (not an EU country), Lithuania 67%, Latvia 64%, Denmark 61%, Estonia 54%, Finland 50%, Sweden 48%. In Southern countries as Italy and France there are significant shares in some regions (up to 10% of the heat market) (Euroheat & Power, 2015).

Table 2, instead, presents the percentage of heat demand satisfied by DH systems and the percentage of people served by district systems, data for these tables are taken from Euroheat and Power surveys on European DH systems (*District Energy in Bulgaria* | Euroheat & Power, 2013; *District Energy in Latvia* | Euroheat & Power, 2013; Euroheat & Power, 2013).

Presented scenarios in DH systems and their differences in European countries confirm that it is hard to create a universal action plan for all EU members to implement and enhance district energy systems, each EU country should have an individual analysis that should take into consideration their

own peculiarities. In the next paragraph, the focal point of the work will be the Italian current situation on DH systems.

Table 2 - Percentage of heat demand satisfied by DH systems and the percentage of people served by district systems

3. The Italian situation

The development of DH networks in Italy started in the 1970s, following the examples of other European and extra-European countries that invested in studying, testing and evolving this particular technology. Specifically, the technology flourished in the north part of Italy after the planning and construction in 1971 of the first DH in the city of Modena (International Energy Agency IEA, 2016). The length of the considered network is of about 10 km and assures the distribution of the heat produced by 4 gas fired boilers, installed in 2015 in substitution of the outdated diathermic oil boilers, to both residential and tertiary buildings. After this first experience in Modena other examples raised before the 80s in new cities: in Brescia (1972) 378 km of piping network supplied by 3 steam turbines, a municipal waste incinerator, and a cogeneration plant. Verona followed in 1973, when a cogeneration system using a gas engine was built to provide heat for a network of 79 km of pipes, Mantua (1978) in which a cogeneration plant provides heat for a network of 65 km, and Reggio Emilia (1979) a network of 213 km supplied by a gas turbine and a cogeneration plant (AIRU, 2017).

During the 1980s and 1990s, other cities adopted DH systems following the success obtained by the pioneer developers in reducing energy costs and CO₂ emissions, passing from 15 Mm³ of heated volume in 1980 to 45 Mm³ in 1990. This trend was not about to stop here. Table 3 shows that between 1990s and 2000s, the heated volumes attached to DH networks had more than doubled arriving to 110 Mm³, showing an increment rate of 12% per year. The increment rate continued to increase even after 2000s: in 2010, the heated volume by DH was 250 Mm³ with an estimated 200 networks working mainly in the northern part of Italy. The last available data is from 2016, at the end of that year, 235

networks were operating in Italy, providing heat for more than 340 Mm³, showing again an increasing interest for this type of heating supply technology (Bottio *et al.*, 2015; AIRU, 2017).

Table 3 - Increase in the amount of volumes connected to DH system in Italy from 1972 to 2017

3.1 Geographical distribution

However, the interest in this type of technology is not equally distributed in all Italian regions. With a deeper analysis at the site where DH plants are located, it is clear that most of the DH networks are in northern Italy with about 200 out of the 236 total existing networks located in northern regions of Italy (Valle d'Aosta, Piedmont, Liguria, Lombardy, Trentino Alto Adige, Veneto, Friuli Venezia Giulia, and Emilia Romagna) (Figure 2). In support of this consideration, it is possible to state that almost the total amount of the volumes heated with a DH network can be found in 4 northern regions: Lombardy, Piedmont, Emilia Romagna, and Trentino Alto Adige. These regions account for 96% of the total heated volume that corresponds to 300 million of m³.

3.2 Networks extension

Considering now the extension of the networks, which supply hot water for the heating of the connected volumes, in the past 15 years it has become 4 time larger than it was in the early 2000s. The total extension at the end of 2016 was 4,270 km. Thanks to a series of investments from local policymakers and stakeholders, the expansion of the piping net for DH systems in Italy, between 2000 and 2016, grew of 193 km per year. In the period after 2010, the yearly increase rate was of 250 km per year, thus demonstrating the great importance that this kind of heating system was, and still is, gaining in the Italian heating sector.

However, since 2013 the number of new connections is constantly decreasing. In 2016, the increase in the connections' number reached 12.5 Mm³, a value 1.1 Mm³ lower than the one recorded for 2015, and this trend is likely to continue in this way. In fact, when considering the heated volumes in direct relation to the network's extension (called linear density of users), it is possible to observe that this

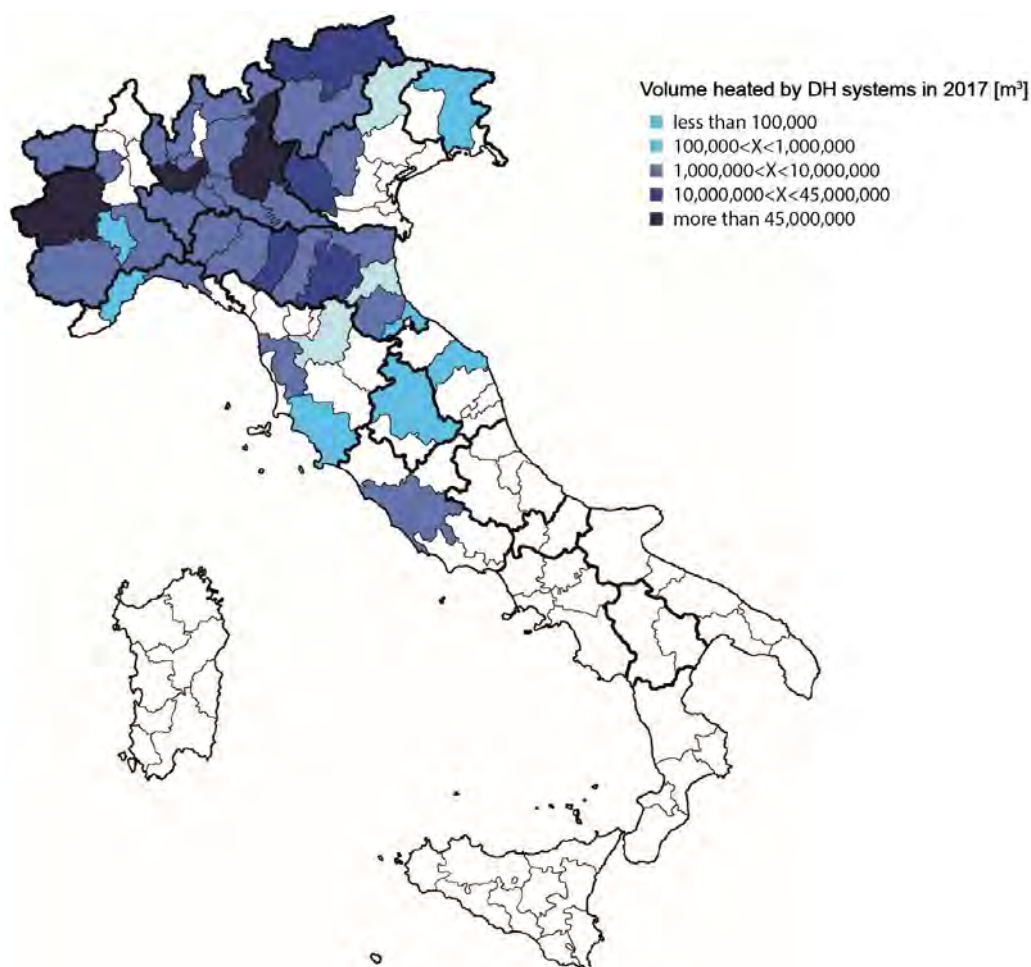

Figure 2 - Volume heated by DH systems in 2017 for each Italian province

particular datum is decreasing year after year. In the last years, the diffusion of DH systems happened mostly in low-density areas, such as rural zones, mountains villages, and small dimension communities. Nonetheless, at the end of 2016 the total volume connected to DH networks was 342.3 Mm³, a value doubled in the last 10 years (in 2006 the total heated volume was 177.3 Mm³), representing a yearly increment equal to 6.8%. As state before the diffusion of DH systems is mostly a trait of norther regions of Italy. This strongly emerge when taking into consideration the ratio between buildings reached by DH and the residing population: the region in which the DH has most diffusion is Trentino Alto Adige with 36.2 m³/inhabitant, followed by Valle d'Aosta with 24.8 m³/inhabitant (Table 4).

3.3. Energy sources

For what concern the energy production in the DH systems, in Italy the most widely used technology is cogeneration systems fired by fossil fuels, particularly more than 1000 MW_t come from thermoelectric power plants, and more than 950 MW_t come from dedicated cogeneration plants that produce also about 800 MW_e. Another type of cogeneration system, which does not rely on fossil fuels, is powered by incineration of municipal solid waste (MSW) and it is responsible for more than 550 MW_t, even if just 13 networks present this type of technology installed. In the last years, cogeneration systems started to include bioenergy derived from biological sources as primary energy,

Table 4 - Heated volume (left) and population reached (right) by DH systems in Italian regions in 2017

reaching 250 MW_t and almost 90 MW_e, but still, these types of biological energies are mostly used as fuel for boilers, producing 370 MW_t at the national level.

As stated in the previous paragraph, a mix of different energy sources is used to create the necessary power for the functioning of the DH systems in the Italian territory. The most widely used vector is still natural gas that represent 71% of the total input, equivalent to 1,313,657 toe, showing that non-RES are still the most used systems to supply energy to power DH systems. The second most used are now MSW, which include both biodegradable and non-biodegradable fraction of municipal waste. In the last 10 years this kind of source passed from representing just a small portion of the total energy mix (1.2% in 1995) to be a quite important representative in the use of RES for the DH in Italy: now it is responsible for 13.7% of the total primary energy used.

Another example on the transition from a fossil fuels-based society towards a greener and more sustainable one is proved by the rise in the use of bioenergy (i.e. biomass, biogas, and bio liquids) for the energy supply in the DH systems. Since 1995, when bioenergy was not used at all, the works done in order to provide cleaner energy vectors for DH systems flourished. In this background made of building new systems and updating and adapting existing ones, bioenergy sources became the third largest energy source used for DH, being responsible for 9.3% of the total amount. For what concern other RES types, energy mix data highlight a positive trend in the use of geothermal sources. The last 10 years prove the interests in this kind of technology: thanks to the inauguration of new plants, the percentage increase was significant passing from 0.8% in 1995 to 1.3% in 2016; however, its full potential is still untapped. Similar considerations can be done for the use of solar collector: only one example of this technology exists in Italy and still it is a young experience with just a one-year lifespan, but this bear witness of the interest that Italian stakeholders have in the use of RES for district systems. Even though this trend is diffuse for almost every kind of renewable source, a different tendency characterized industrial energy recovery processes. During the 90s, the use of this type of process was quite common in most systems that used RES, since it was a first try in finding non-fossil fuels suitable for energy network systems. During the following years, new type of clean energy vectors came up on the market establishing a decrease in the use of recovered heat and energy from industrial processes. In the last survey, this very energy source counted just for the 0.1% in the primary energy mix.

In parallel with the increase in the use of renewables, fossil fuels experienced a decrease. In 1995 gas oil and heating oil were the second most use primary energy source with a 14.3% share, and coal was

in the third position being used in 12.5% of the cases, showing the low interest that was placed in the implementation of sustainable energy. During the last 10 years, the situation changed: coal is now responsible only for 2.6% of the total and the use of gas oil and heating oil almost become insignificant, representing just the 0.1% in the primary energy mix.

A different argument concerns fossil energy used in the national electrical system (NES). In this case, the transition towards sustainable energy sources is still not implemented, and fossil fuels are still widely used to produce energy for the NES networks.

To sum up, in Italy the thermal energy produced by fossil fuels-fired cogeneration plants constitutes 50% of the total energy that flows in the network; 23% is produced by the use of simple boilers that help integrate the energy production during high demand periods. These appliances are powered by fossil fuels, making 73% of the energy that flows into the network produced by non-renewable sources. Energy produced by the use of RES such as cogeneration from renewables, energy recovered from industrial processes, heat pumps, and other technologies constitute the remaining 27% of the produced thermal energy (Bottio *et al.*, 2015; AIRU, 2017, 2018).

The future of the development of district heating in Italy reside in developing and investing for the transition to RES-based DH systems. The same can be said for the entire EU. Usually in the reports where it is mentioned, DH is not seen having a major role in the future decarbonization of European cities. The International Energy Agency (IEA) instead has a different opinion regarding this topic. In its reports from 2012 entitled “Energy Technologies Perspectives”, one of the most important line reads: “Heating and cooling remain neglected areas of energy policy and technology, but their decarbonization is a fundamental element of a low-carbon economy” (International Energy Agency IEA, 2012; Frederiksen and Werner, 2013; Averbalk and Werner, 2017).

4. Energy management in Italy

Every year the International Bank for Reconstruction and Development, a branch of The World Bank, compiles a report about global progresses on sustainable energy policies, showing the importance of a planned strategy for the transition to sustainable-energy based communities. This document goes under the name of “Regulatory Indicators for Sustainable Energy” (RISE) and it rates 133 countries, representing 97% of the world’s population, on electricity access, renewable energy, energy efficiency, and access to clean cooking in the period from 2010 to 2017. The latest draft of this document was edited in 2018 and it finds that the whole world has seen an increasing interest and huge uptake in what concern sustainable energy policies, but there’s still more road ahead: progress is far from where it needs to be to reach global climate goals and Sustainable Development on Energy (SDG7) (*Regulatory Indicators for Sustainable Energy 2018*, 2018; United Nations, 2018).

RISE analyzes the adequacy of the policies for a sustainable development and investments in green energy solutions through three pillars: RES, energy efficiency and access to energy, and it has done the same for Italy, but since the Italian peninsula is one of the High-Income OECD countries this last pillar is not considered, assuming that the situation for this aspect is already adequate.

The data collected for the latest report give a positive image for Italy. Table 5 shows the results for the year 2017: the country position itself in the third spot with a total score of 91 out of 100, 5 points higher than the mean value for OECD countries, and after Germany (94/100) and United Kingdom

(92/100), but the most important datum is the one about energy efficiency. In this category Italy position itself in the first place on the list: its attention for national plans for energy efficiency, minimum energy efficiency performance standards, and energy labelling systems for appliances and buildings made possible for Italy to reach the first position in this list, but there are also some less positive results. Italy needs to improve its policies about information provided to consumers and end users about energy usage for heating and electricity and how to achieve savings and avoid energy wastes, and there's still work to do about improving and make the access easier to incentives for industrial and commercial sectors in switching to RES-based activities (*Scores | RISE, 2017; Regulatory Indicators for Sustainable Energy 2018, 2018; ENEA, 2017*).

Table 5 - First 15 countries in RISE 2017 list. 12 out of these 15 Countries are in Europe

According to the parameters and analyzes of the World Bank, Italy does not seem to show a bad political-regulatory framework for the investments in renewable sources and energy efficiency. Indeed, in many cases the regulations in force are in line with international best practices and even more advanced than those adopted in other OECD countries. What perhaps penalizes investments in Italy and creates the basis for a less positive perception of the situation in the country is the implementation of this political-regulatory framework, which not always is as adequate as the legislative decree. Moreover, the uncertain political context, with its unfavorable situation for potential investments seems to have an even higher negative impact (ENEA, 2018a).

To reach the objectives set by the EC for the reduction of harmful emissions and use of energy, Italian policy makers developed *Strategia Energetica Nazionale* (National Energy Strategy) or *SEN*, a ten years policy document intended as a general guidance and planning tool for the national energy strategies; the aim is to indicate the priorities for the short and the long term to achieve the promotion of renewable sources and energy efficiency (Ministero dello Sviluppo Economico and Ministero dell'Ambiente e della Tutela del Territorio e del Mare, 2017).

Following these directives Italy has reached European targets in advance, with a 17.5% penetration of RES over total consumption by 2015 compared to the 2020 target of 17%, and important technological advances have been made that offer new possibilities to reconcile the containment of energy prices and sustainability and by 2030 the share of renewables on the total energy use is

expected to be at least 27%. To make this prevision possible the policy makers are proposing interventions in various categories such as the use of RES on electricity production, founding programmes to switch fuels to biofuels and most important develop the potential of urban and extra-urban DH systems according to efficiency criteria (*Ecco la Strategia Energetica Nazionale 2017*, 2017; ENEA, 2018b).

To tackle the objective of energy efficiency, from 2021 to 2030 there's the need for a reduction of the consumption of about 9 Mtoe primarily in the residential and in the tertiary sectors, to do so SEN identifies a series of actions. They are all focused on the importance of giving founding for renovation of the existing building stock both from an building point of view and from energy systems aspects, higher the standards for new buildings, promotion of energy efficiency measures also at local levels and switching to sustainable energy sources, but this last aspect, as we can see from Table 6 still need to be implemented, being oil and natural gas still the mostly used fuels in Italy (Ministero dello Sviluppo Economico, 2017; Ministero dello Sviluppo Economico and Ministero dell'Ambiente e della Tutela del Territorio e del Mare, 2017).

Table 6 - Type of fuels used in Italy in 2016 for heating and electricity production

5. Housing stock and consumption

In Italy there are around 31 million houses and 14.5 million buildings, and 84% of them (12,187,698) are housing complexes. These residential units were mostly built before 1976, year in which the first energy saving law came into effect. As Table 7A shows, 65% of the residential complexes used today date back before 1980 and 15% more were built before 1918 (*Edifici residenziali*, 2015).

Table 7 – A (left) shows the construction year of residential building in Italy; B (right) depicts the electrical and thermal consumption for building categories in Italy

In the residential sector the mostly use energy source is natural gas which is responsible for 47% of the total energy consumption, equivalent to 30 Mtoe; electricity and wood are both responsible for a little less than a quarter of the total. Consumption in the non-residential sector has experienced continuous and strong growth over the years, held back only by the economic crisis of 2008, reaching around 20 Mtoe in 2013.

Energy consumption for the heating and cooling in residential spaces absorbs about 76% of total consumption, a value that has grown in recent years. Consumption for lighting and electrical appliances, like food preparation and domestic hot water (DHW), is almost constant over time (Table 8 and Table 9). But there are differences for what concerns other sectors: in health establishments, offices, and tourist accommodations, the electrical consumption is almost as high as the thermal (Table 7B). This derives from the high number of appliances and instruments that work thanks to electrical energy. Even though in the recent years the shares of RES used for electricity production increased considerably, thanks to the importance given since the 50s to hydro generation and the growth of sources like solar, wind, and geothermal, still there's work to do in order to make the electricity production in Italy greener: the first two sources used are natural gas (39%) and coal (17%) (International Energy Agency IEA, 2016; Portale 4E, 2016).

Table 8 - Shares of primary energy sources used for heating and cooling in the residential sector

Table 9 - Energy per dwelling used for heating and cooling, lighting and appliances, and cooking and DHW in the residential sector

6. Conclusions

In the previous paragraphs the European and Italian situation regard DH systems was described, after that we saw how network systems, even if not so spread in all the Italian territory, can still play an important role in the reduction of energy use towards a more sustainable future.

For what concern Italy we saw that the expansion of DH networks in the country is still limited to few examples and most of them are located in the norther regions and in mountain areas. This is mainly caused by the climatic differences that divide the country: DH are used mainly for heating reasons and supported by small appliances for DHW located in the single dwellings or in the single apartment block. This division creates a seasonality in the use of DH that makes the investment for the construction of new networks an investment that does not seem smart. Moreover, the fact that generation for district networks systems are still focused on heat, and not combined heat and power doesn't provide a strong motivation in starting works for developing network solutions in areas where heating demand are just focused in small period of time and, instead, demand for electricity is higher because of the hot climate. Regarding this consideration, "established expertise of district heating has paved the way for introduction and deployment of district cooling systems, mainly for covering space-cooling demands in buildings. However, this district cooling development has been more recent compared to the development of district heating. District cooling systems are therefore neither as common nor as extensive as district heating systems" (Werner, 2017). Being Italy still in the development of vast scale networks for heating, is difficult to imagine that district cooling system will make their way to the top priority works for energy consumption reduction and CO₂ savings without a proper support from researchers and institutions.

Technologies analyzed in this paper, regarding how power is produced show that Italy still rely too much on fossil fuels, being oil and natural gas the two most used sources, and the fact that in the SEN still a major importance is devoted to the use of natural gas in the next years, denote the lack of effort that the institutions are giving in try to find alternative renewable sources with which change the current trend.

This is not enough though. To reduce consumption, energy requalification interventions must be planned on buildings, starting from public building stock such as schools, hospitals, and offices without forgetting about housing complexes. With the same goal, it is necessary to reduce the consumption of primary energy: to do this the spreading of district heating technologies is forecasted.

A reduction on the final energy consumption can be done not only by fostering retrofit works, but also with a rational use of all energy sources and investing on the use of RES in every sector. Subsidies need to be granted in order to increase the share of electricity produced by RES and decrease the number of decentralized energy systems. The same goes for thermal energy: the goal set by SEN in 2017 of reaching 16 Mtoe produced by RES in 2030 passes by a high increase in the use of geotherm sources, heat pumps, solar systems, but mostly through an advancement in the number of biomass-fueled systems in the residential and tertiary sector and the development and spreading in the whole Italian territory of high performance DH networks.

The challenge outlined above is so demanding that, to be successful, it will require the contribution of all the technologies available today, and from now on until 2030, without exceptions (*Come l'Italia può raggiungere gli obiettivi rinnovabili al 2030. Report Free*, 2017).

Maritime spatial planning
(msp) in europe:
challenges in transition

Conceptual approaches of Maritime Spatial Planning. Principles and Planning Parameters

Abstract: Maritime Spatial Planning is a fairly new process that offers a useful and valuable context for the sustainable development of the seas. Various international organizations and institutions of international cooperation (UNESCO, UNEP, EU, VASAB etc) approach MSP through their scope, define it, implement it. Every organization chooses an approach that fits its purpose. Characteristic of this is even the name of MSP. Should it be called Marine or Maritime Spatial Planning? Could these terms be used interchangeably as if they give the same meaning to the process? Examining various definitions of MSP, approaching those conceptually, highlighting similarities and differences, this paper seeks their link to the discipline of spatial planning that was focusing on coastal areas and was rather ignoring maritime areas up until recently. Sectoral policies were applied extensively, as if they were the unique user of the sea, ignoring or giving little importance to spatial impacts. Spatial planners were constantly choosing not to plan the sea, facing it as a landscape, significant for its aesthetic value and environmental importance. Has this absence of spatial planning discipline at the beginning of the process caused spatial planning discipline background gaps? There are considerations over MSP implementation. There seems that most marine/maritime spatial plans already elaborated don't have a spatial planning approach but rather a sea use approach. But if the sustainable development of the seas is what is needed, it can be attained through strategic marine/maritime spatial planning instead of sea use plans, a multi-level spatial planning process and various levels of marine/maritime spatial plans. Planning principles and major parameters will be approached in an effort to set the framework of spatial planning process.

Keywords: Maritime/Marine Spatial Planning (MSP), international organizations, spatial planning principles, spatial planning parameters

Introduction

Maritime Spatial Planning (MSP) is a process chosen to implement the objectives of various intergovernmental institutions regarding the sea. Having different perspectives they choose MSP as a tool of implementation, acknowledging that sectoral approaches were proven unsuccessful. Analyzing the various definitions met, there is the need to find similarities and differences in order to understand whether the different beginning of each one of them leads to a different end. There is also the need to find the spatial planning discipline in them, making the key assumption that the Council of Europe Conference of Ministers of Spatial Planning (CEMAT), European Union (EU) and the United Nations Sustainable Development Goals (SDGs) and Human Settlements Programme (UN-Habitat) documents on spatial planning principles could be the basis for such a quest. The main MSP principles documents come from the EU, the Conference of Ministers "Visions and Strategies around the Baltic Sea" (VASAB) and the United Nations Environment Programme Mediterranean Action Plan (UNEP MAP) as forerunners, but also as approaches of European interest. Stocktaking on this, there will be an outline of principles and parameters found on MSP documents based on spatial planning documents of international interest.

Conceptual approaches to MSP

There is the need to make a conceptual approach to MSP, to analyze the definitions met in institutional work and academic bibliography in order to detect individual features, principles and important elements of spatial planning, taking into consideration that regulation and arrangements of maritime activities and uses, in whichever form, has been an informal form of unconscious planning. Coastal and maritime spatial planning has become a conscious process some decades ago in Northern America, Western Europe and Australia and a bit later from international institutions, such as UNESCO and the EU. (Beriatos, 2016)

An important first step: the United Nations Environment Programme (UNEP) and the Mediterranean Action Plan (MAP)

The United Nations system, showing great interest in coastal and marine environment, launched the Regional Seas Programme in 1974. It has been considered since, as one of the major achievements in the environment, as the only legal framework protecting seas at regional (multinational) level. Regional Seas Programme was based on the 1972 Stockholm Conference outcome. All conventions are subject to ratification, acceptance, approval or accession.

The Convention for the Protection of the Mediterranean Sea against Pollution (Barcelona Convention) was signed in 1975 and was adopted in 1976, by the Conference of the Coastal States for the Protection of the Mediterranean Sea. It adopted the Mediterranean Action Plan (MAP). The Barcelona Convention refers to fighting pollution in the Mediterranean Sea, naming its geographic coverage that extends in the Mediterranean waters including gulfs and seas and excluding internal waters, except if there is a different prevision in its protocols. The main objectives of the Convention are the assessment and control of marine pollution, the assurance of sustainable management of natural marine and coastal assets, the incorporation of the environment into the social and economic development, the protection of the marine environment and coastal areas through the prevention and diminution of pollution and the elimination of land or sea-based pollution, the protection of national and cultural heritage, the enforcement of solidarity of Mediterranean coastal states and the quality of life improvement. The objectives are carried out through the 7 Protocols that address specific aspects and complete the MAP legal framework.

The most recent protocol, the Integrated Coastal Zone Management (ICZM) Protocol, goes further and introduces the necessity of integrated planning for uses and activities in coastal areas, covering a land – sea area, with the sea area extending to territorial waters. It is a tool focusing on land-sea interaction, pressure and conflict management in favor of the environment. ICZM is based on principles, considering the hydrological, ecological, socio-economic and cultural elements in an integrated manner, in order not to surpass the coastal area carrying capacity, emphasizing also on economic activities. It manages possible conflicts between various sectoral policies, taking into account the fact that many marine environmental resources, important for human activities, gather in coastal areas, but also the fact that maritime activities start and finish in coastal areas and demand for space and resources. (Avgerinou - Kolonias and Rampavila, 2017) The Contracting Parties (CPs) to the ICZM Protocol decided in 2017 (COP 20) that they need to introduce a guiding document “Conceptual Framework for Marine Spatial Planning” to facilitate the introduction of MSP, as a management tool, into the Barcelona Convention framework, stepping on the work already done by UNESCO IOC and the EU on MSP. This action aims at supporting the achievement of Good Environmental Status (GES) of the Mediterranean Sea and Coasts, investigating in more details connections between land and sea areas, and proposing coherent and sustainable land and sea-use planning frameworks relating with key economic sectors and activities that may affect the coastal and marine resources. Its objectives are to introduce MSP in the framework of the Barcelona Convention, and in particular link it to ICZM, considering MSP as the main tool/process for the implementation of ICZM in the marine part of the coastal zone and specifically for planning and managing maritime human activities according to ecosystem approach (EcAp) goals and to provide a common context to the contracting parties (CPs) for the implementation of MSP in the Mediterranean Region.

United Nations Educational, Scientific and Cultural Organization Intergovernmental Oceanographic Commission (UNESCO IOC)

UNESCO IOC is considered to be an international pioneer of MSP. Ehler and Douvere (2009) as MSP pioneers in UNESCO IOC, in their step-by-step approach define Marine Spatial Planning as “a public process of analyzing and allocating the spatial and temporal distribution of human activities in marine areas to achieve ecological, economic, and social objectives that are usually specified through a political process”. Their original choice of the term marine spatial planning for MSP is based on the role chosen by the United Nations system on the environment preservation and protection, and on the approach chosen for MSP as a process to safeguard GES. There is a focus on the analysis and spatial – temporal distribution of human activities in the maritime areas and especially on the result of spatial planning and not on the strategic approach of maritime areas, according to theories of spatial planning. The choice of the distribution of human activities in the sea isn't

the spatial implementation choice of one or more objectives, but rather a management choice of good neighborhood. It is not approached as a process with scientific background but rather as a mapping tool resolving neighborhood conflicts. This is a common issue in many definitions, starting probably from the rather empirical approach of MSP, due to the plethora of professionals, regardless of scientific discipline, that work on MSP. The choice of mentioning the distribution of human activities in the sea includes the element of delimitation in the maritime spatial plans (MSPlans) following the marine boundaries and not the administrative boundaries, inherent element of terrestrial spatial planning (TSP). It is a substantial choice aiming at approaching the ocean as a sum of various interfacing and coexisting marine ecosystems. It is an important choice, taking into account that MSP needs to be specified at regional seas level, exclusive economic zones (EEZ) and various regional sub seas, in order to cover the spatial planning needs at national level and specify them in lower levels of spatial planning, so as to assure the needed specification and a more meticulous approach.

Nevertheless, at the UNESCO IOC internet site on MSP there is now a wider, more prescriptive and more elaborated definition. *“Marine spatial planning is a public process of analyzing and allocating the spatial and temporal distribution of human activities in marine areas to achieve ecological, economic, and social objectives that usually have been specified through a political process. Characteristics of marine spatial planning include ecosystem-based, area-based, integrated, adaptive, strategic and participatory. Marine spatial planning is not an end in itself, but a practical way to create and establish a more rational use of marine space and the interactions among its uses, to balance demands for development with the need to protect the environment, and to deliver social and economic outcomes in an open and planned way.”* The experience gained, as MSP attracts the interest of the countries helps in better defining the content and framing a “good” MSP process. Of course, we should admit that the more the definition is enriched the more the lack of theoretical background is evident. Many inherent elements of spatial planning, self-evident to every spatial planner, are described with a specific reference, in an effort to clarify the term, for those that are not acquainted with the spatial planning scientific discipline. The specific feature of this definition is the chosen analytic and descriptive form, preserving the initial definition given by Ehler and Douvere as a first part. The more elaborate definition focuses on the process of analysis and spatial – temporal distribution of human activities in the sea. It emphasizes as elements of MSP, the ecosystem-based, spatial, integrated, adaptive, strategic and participatory approach. The second part of the definition states that MSP is the means to the end of the spatial vision to be implemented.

The European Union (EU)

The EU following the UN Conventions and the Lisbon Treaty for sustainable, inclusive and smart growth has set the pace for policy developments in the EU, affecting the coastal zone, starting with the Blue Book on Integrated Maritime Policy (IMP), the Marine Strategy Framework Directive (MSFD), the Limassol Declaration, the Common Fisheries Policy, the Marine Knowledge Document, the Directive on a Framework for Maritime Spatial Planning, the Communication on Innovation in the Blue Economy: realizing the potential of our seas and oceans for jobs and growth, but also, early in the procedure, the Recommendation on Integrated Coastal Zone Management.

IMP focuses on developing integrated decision making, aiming at the integrated maritime governance, implementation of integrated strategies per sea basin and further development of intersectoral tools, such as MSP. The main strategic objectives set for IMP are integrated maritime governance, development and application of integrated strategies in sea basins, further development of intersectoral tools, such as MSP for ameliorating the synergies and coordination of existing policies and means. It is of crucial importance to gather all existing data and knowledge, to achieve the collaboration of all stakeholders, to ensure the protection and sustainable use of maritime resources. The Roadmap for MSP identified 10 key principles for MSP, in order to achieve a common approach by the Member States. The one that could be quoted is that we need to define the objectives to guide MSP achieving TSP – MSP coherence. In this way the EU has chosen to define spatial planning of the seas as maritime spatial planning, instead of marine spatial planning, acknowledging that it is a tool for the accomplishment of Blue Growth and facing the challenges, in order to achieve greater trust and safety for investments. (Lukic et al, 2018) However Ehler, Zaucha and Gee (2018) argue that the practice of planning does not always confirm a semantic.

MSP, according to the Directive 2014/89/EU, is a *“process by which the relevant Member State’s authorities analyze and organize human activities in marine areas to achieve ecological, economic and social objectives”*. It is a rather poor MSP definition, result of the needed balance among the EU Member States (EU MSs), in order to reach an agreement on the MSP Directive. EU aims at providing MSs with a planning process in order for them to pursue the achievement of sectoral policies’ objectives in their marine areas. It is incorporated into the wider Europe 2020 strategy for smart, sustainable and inclusive growth. Ivarsson et al (2017) consider that ecosystem services are not fully taken into account in the MSP Directive and that, on the contrary, the EU Strategy 2020 on Biodiversity calls for the implementation of recording and assessing of the state and the value of the ecosystem services. Through MSP, EU MSs should focus at developing maritime energy, shipping,

fishing and aquaculture, preservation, protection and improvement of the environment, climate change resilience, as well as sustainable tourism and sustainable exploration of raw materials. The specific reference of these sectors comes from the competences given to the EU by the EU MSs, according to the EU Conventions, and the need to respect the subsidiarity principle. All MSs remain sovereign and independent states and have decided to delegate some of their decision-making powers to the EU, so that they take decisions of common interest together.

Joint efforts of UNESCO IOC and EU

UNESCO and the EU have a different start line. UNESCO has a humanitarian approach seeking to build peace through international cooperation in education, sciences and culture. It sets the pace but it cannot set binding regulation and it lacks implementation experience. The EU makes policy and can enforce its implementation, resulting on practices and restrictions. However, the different start line of UNESCO IOC and the EU does not affect the result (Platias and Rampavila, 2018). Both the EU and UNESCO IOC have common targeting, based on the need to manage activities in the marine areas in a way that will not create conflicts and will prevent or at least moderate the negative effects, helping achieve ecological, economic and social objectives. The definition elaborated by UNESCO IOC, seems more complete, incorporating as major principles for the MSP process the ecosystem-based, spatial, integrated, adaptable, strategic, stakeholder involvement procedure. Directive 2014/89/EC refers to the MSP process characteristics in an analytic way, in articles 9 and 14 and as footnote in article 6. However, MSP refers to strategic planning, having as main characteristics the spatial dimension, the integrated territorial approach, the revision of the plans and public participation. Probably, the need to encompass all these characteristics in the definition comes from the fact that for UNESCO IOC, MSP is a sub-unit of marine management and the rather sectoral interest of the EU.

Lately, the EU and UNESCO IOC acknowledged the need to cooperate and establish a common approach organizing International Conferences and an International Forum on MSP. The main output of this cooperation is the “Joint Roadmap to accelerate Maritime Spatial Planning processes worldwide” (2017). This document aims at improving cooperation or capacity building to cover the needs of different levels of implementation of MSP processes in the world, including regions where MSP is in its infancy or regions where arrangements for MSP may exist but a strategic approach to facilitate coordination would be beneficial.

Other components of the UN system of interest for MSP

There are many cases where MSP is considered as the means to objective fulfillment and is encompassed as a sub-process in already existing processes. The need to protect and manage the marine environment is inherent in the UN system. Starting from the Agenda 21 (Earth Summit, Rio de Janeiro, 1992) and all the way to Agenda 2030 and the SDGs, the need to protect and manage the marine and coastal environment in a planned way is one of the main concerns. The United Nations Conference on Sustainable Development (Rio+20) held in Rio in 2012, adopting the document “The future we want”, launched the process to develop a set of SDGs. This document highlights that the UN aims at conserving and sustainably using the oceans, the seas and their resources, emphasizes the importance of area-based measures.

In 2015, a landmark year for international policy shaping, “Transforming our World: the 2030 agenda for sustainable development” was adopted at the UN Conference in New York. The post-2015 development agenda consisted of two processes coming out of the 2010 Millennium Development Goals (MDG) Summit, the Johannesburg Implementation Plan and the 2012 Rio+20 outcome documents that resulted, among others at the incorporation of MSP into Agenda 2030 Sustainable Development Goals (SDGs). SDG 14, which is the marine goal, stresses the need to “conserve and sustainably use the oceans, seas and marine resources for sustainable development” and its implementing targets, regarding marine pollution, management, protection and rehabilitation of marine and coastal ecosystems, acidification of the seas, fisheries sustainable development, preservation of 10% of marine and coastal areas etc, promoting the United Nations Convention on the Law of the Sea (UNCLOS) implementation. Evidently, MSP is the necessary precondition for the achievement of SDG 14, as a policy tool, that can resolve spatial conflicts. However, MSP is the main tool for the implementation of Agenda 2030, as it can be the main linking tool of SDG 14 with all the other Agenda 2030 SDGs and especially SDG11, the TSP goal.

Additional to the interest of the UN system, there is another very important definition resulting from the need to enlarge the definition of MSP, already stated by the CPs of the Biodiversity Convention in 2012. According to the definition set out at the technical study “Marine Spatial Planning in the context of the Convention on Biological Diversity” (2012), *MSP is a framework and a means to the improvement of decision making*. In this way it frames the limit of action and sets the way of action, setting the terms for better decision making.

Visions and Strategies around the Baltic Sea (VASAB)

VASAB was founded at the 1992 Ministerial Conference that decided on the need for a long term vision and transnational spatial planning at the Baltic Sea Region based on the document “Visions and Strategies for the

Baltic Sea Region 2010” and the outcome of the final report “VASAB 2010: Towards a Framework for Spatial Development in the BSR” (Tallinn Report) – the common actions are being coordinated by the Committee on Spatial Development in the BSR. The EU Commission, recognizing the focus on strengthening and harmonizing of national and regional spatial policies and highlighting it as a best practice, supports the implementation of the VASAB action programme, securing EU fund and programmes.

Early on, VASAB, being based on both UN Regional Seas Conventions Programmes and EU Macroregional Strategies has created a joint working group with HELCOM on MSP (HELCOM VASAB MSP WG) to discuss a common Baltic approach for MSP and develop tools and methods of such an approach. The Declaration of the 7th Conference of the Baltic Sea Ministers seeks to enhance cooperation and among others increase MSP competence in close cooperation with HELCOM regarding environmental aspects and other essential relevant actors. It is an important case study area, since it is the more advanced macroregion of the EU, in terms of cooperation, governance and cohesion. Following the broad scale spatial planning principles that we analyze in the MSP principles section, they have already implemented a transnational strategic spatial planning document on territorial integration “Long-term perspective for the territorial development of the Baltic Sea Region in 2030” (2009), which leads to territorial cohesion in the Baltic Sea Region. It promotes integrated land-sea spatial planning in order to protect the Baltic Sea environment, ensure the sustainable use of marine resources and make it a model region for the implementation of EU maritime policy.

EU Strategy for the Adriatic and the Ionian Region (EUSAIR)

EU Strategy for the Adriatic and Ionian region (EUSAIR) on the other hand, is a fairly new macroregional policy with regards to VASAB macroregion. Both the Strategy and the Action Plan were adopted in 2014 by the EU Council. It will be coordinated by a Governing Board and the implementation level will be at 4 Thematic Steering Groups (TSGs) (one per each pillar according to the Action Plan). It faces great difficulties, since the *acquis communautaire* doesn't apply to all, but 4 countries. However MSP has raised increased interest and it has been incorporated in 2 (blue growth and marine environment) out of the 4 pillars of cooperation as a tool of implementation of the Action Plan. For Pillar 1 (Blue Growth) MSP represents the tool to a proper joint governance framework for the sustainable and transparent use of maritime and marine resources. For Pillar 3 (Environmental Quality), Integrated Coastal Area Management (ICAM) and MSP are considered to be the tools that will ensure the sustainable use of marine and maritime resources.

There aren't many results at the time, since it's a newborn macroregional strategy, but all countries and the EU expect a lot in the future. It is strongly believed that EUSAIR will be the guiding body to implementing transboundary MSP in the Adriatic and Ionian Seas. At the moment there is an effort to synchronize the work done for pillars 1 and 3 on MSP and define in common possible MSP and ICZM projects.

MSP principles or spatial planning principles?

The UN system and the EU have made important contributions to the MSP principles area with three very important documents: “Roadmap for Maritime Spatial Planning: Achieving Common Principles in the EU”, “Baltic Sea Broad Scale Spatial Planning Principles” and “Conceptual Framework for Marine Spatial Planning”. They all seek to achieve their conventional goals and policies by establishing a common context for the implementation of MSP, taking into account that countries show great differences in MSP systems, describing MSP as a tool, an instrument and a process. The EU MSP roadmap builds on existing EU instruments aiming at implementing IMP. The VASAB document seeks to achieve better coherence of MSP systems, being concerned that MSP is not carried out on a whole-Baltic scale, in a way that safeguards the marine and terrestrial biodiversity. The UNEP MAP conceptual framework seeks to strengthen MAP activities in the field of MSP in order to contribute to GES, linking it to ICZM.

In table 1, it is evident that all documents stress the importance of an *area-based approach*, which is a redundancy regarding spatial planning – the scientific discipline that shapes places. However it is being stressed in various ways as the need to plan according to characteristics and special conditions of an area or to plan efficiently. The *strategic approach* to planning, evident in all documents, could be also considered a redundancy. Planning processes, whether they are spatial or not, are strategic, including goal setting, indicator setting, evaluation, and adaptation. *Public participation* wasn't integrated into spatial planning for long, but now one cannot think of spatial planning without stakeholder involvement and consultation. It is interesting, though, that UNEP MAP refers only to cross-border consultation and not on general public participation. The *ecosystem-based approach*, despite the fact that it seems absent as a principle, it is omnipresent since in all documents it is considered something in between a goal and an overarching principle. The *integrated approach*, which is inherent to spatial planning, is specifically mentioned in order to highlight the need for MSP to be coordinated with TSP in coastal areas.

Table 1: MSP Principles in the 3 documents on principles adopted by EU, VASAB and UNEP MAP

PRINCIPLES	EU “Roadmap for Maritime Spatial Planning: Achieving Common Principles in the EU” (2008)	VASAB HELCOM WG “Baltic Sea Broad Scale Spatial Planning Principles” (2010)	UNEP MAP “Conceptual Framework for Marine Spatial Planning” (2018)

Source: relevant official texts processed by the authors

All MSP principles’ documents tend to emphasize on the needs of the decisive bodies and the contracting parties, creating a rather distorted image of MSP. They are mainly oriented in economic and ecological aspects, *downgrading social and cultural aspects of spatial planning*. There is no defined will to achieve territorial cohesion (which fortunately was incorporated for the first time in the MSP strategy 2030 document of VASAB). MSP is approached more as a maritime activities’ organizational plan, like land use plans, than a spatial planning approach. It follows the same process but it lacks in abiding with major spatial planning scientific discipline principles. It seems a lot like spatial planning in its beginnings, lacking a planned approach or a clear spatial vision. (Wassenhoven, 2017)

There are certainly a lot of similarities between TSP and MSP that were made obvious during the analysis of the MSP definitions. However there are also a lot of differences that make MSP a more difficult attempt than TSP. Among the differences we count the four-dimensionality of MSP, the continuous mobility of many maritime activities and species of ecosystems, the lack of private property, (EU/DG MARE, 2008) the up-until-now sectoral approach, the fragmented approach in case MSP is implemented regardless of ecosystem integrity. Due to the different physical characteristics and the inability to delimitate dangers met by the marine environment, marine organisms are quite volatile to water circulation, marine pollution, alien species.

All efforts aimed at highlighting the principles that would help elaborate MSPs, overcoming specific difficulties. But what about the European Spatial Development Perspective (ESDP) (1999), is it included in the MSP effort or is it faced as something completely different? ESDP seeks to pave the road to establishing a balanced and sustainable development of the EU territory, long before the enlargement and a series of other international and EU developments, setting 4 policy aims: *spatial orientation of policies, polycentric spatial development, parity of access to infrastructure and knowledge, wise management of natural and cultural heritage*. We can derive the conclusion that only spatial orientation of policies and wise management of natural heritage are included in the MSP principles documents. It should be a spatial planning research area whether

there could be a maritime polycentric spatial development. Parity of access and cultural management are completely absent. There is some literature on how to include social and cultural aspects in MSP. But we should consider that social and cultural aspects are inherent elements of spatial planning. They should be integral parts of MSP and not add-ons. Society interacts with the sea. The sea is part of our culture and at the same time hosts cultural assets. We need to integrate them in MSP, if we want it to be real spatial planning.

Spatial planning, according to CEMAT Torremolinos charter (1983), *gives geographical expression to the economic, social, cultural and ecological policies of society. It is at the same time a scientific discipline, an administrative technique and a policy developed as an interdisciplinary and comprehensive approach directed towards balanced regional development and the physical organization of space according to an overall strategy.* Once again, we can verify that in all MSP principles' documents there is no mention on social and cultural policies of societies. Nevertheless, the concept of geographical expression to the economic and ecological policies of societies is present. At this point, we need to highlight the fact that *MSP documents consider MSP as a tool or an instrument and not as a scientific discipline or policy, downgrading its scientific substance.* Moreover, all MSP definitions lack a regional development approach, focusing on the spatial allocation of activities.

UN Habitat in 2009, following a process of wide consultation with major stakeholders, published the commonly agreed "International Guidelines on Urban and Territorial planning". Despite the fact that it refers to inhabited areas, representing SDG11, it is interesting to look at the set of principles it has outlined, since we need to keep SDG11 and SDG14 in a common scientific discipline approach:

- Spatial policy and governance: participatory decision-making process linked to a strategy, inclusion, transparency, accountability.
- Social development: adequate standards of living and working conditions, equitable distribution of costs, opportunities and benefits of development, social inclusion and cohesion.
- Sustained economic growth: inclusive economic growth, better connectivity at all territorial levels.
- Environmental protection: integrated and sustainable development, environmental and socioeconomic resilience, enhanced adaptation.
- Planning components: continuous and iterative process, enforceable regulation, synergies between territories.
- Implementation: political leadership, continuous monitoring, periodic adjustments.

Seeking these principles in the MSP guidelines documents, it is clear that the principles regarding spatial policy, governance and implementation are fully taken into account, while the principles on social development are completely absent. The principles regarding sustained economic growth and environmental protection are more or less taken into account. *MSP should incorporate all spatial planning principles and not some of them. The differences of MSP and TSP should be treated as specific planning parameters.*

The need to achieve the ecological, economic and social objectives is the necessary "parameterization" of spatial planning according to the spatial planning discipline. However, after the Rio 1992 Summit, the triptych of economic growth, social development and environmental protection and management are considered the 3 basic pillars of development, followed by the cultural pillar, recognized by the Johannesburg Declaration (2002). Taking into account the United Nations Convention on the Law of the Sea (UNCLOS) that governs maritime delimitation, it is clear that the *geopolitical dimension* is really strong. The geopolitical dimension should be included in the MSP definition, since it is one among the initial reflections made by anyone dealing with MSP issues. The maritime zones' delimitation, despite the fact that the procedure is already prescribed in the UNCLOS, provokes tensions in the bilateral and multilateral relations of the countries.

MSP parameters

Having in mind that TSP and MSP have common principles and are subject to the same political and social framework referring to the society of a country or of a group of countries, we need to identify a set of extra parameters for MSP, adding to TSP parameters. The extra parameters, following the documents analyzed, could be: *delimitation of planning areas* and *four-dimensionality*. Ensuring legal effect, lack of data and lack of private property are significant differences of MSP, but they cannot be considered as special MSP parameters. They could be faced as special parameters in a case-by-case approach, regardless of MSP or TSP.

TSP abides with the traditional administrative boundaries in order to define planning areas regardless of the ecosystem boundaries, since the administrative boundaries are usually outlined by rivers, lakes or contours. Choosing the ecosystem-based approach, which is absent from the UNCLOS zone delimitation, as an integral part of MSP, we cannot elaborate MSP plans following the administrative boundaries. A major element of this approach is governance and especially who holds the administrative jurisdiction. Crowder and Norse (2008) consider that an important step to zone delimitation is to identify concentrations of marine organisms and map human activities in the area, socioeconomic overlaps and existing political and institutional arrangements. UNEP MAP Decision IG. 17/6 (2008) acknowledges that the progressive implementation of the ecosystem

approach in human activities management that could affect the marine and coastal Mediterranean environment is a CPs commitment, in order to achieve a real change of the marine and coastal environment of the Mediterranean, while with the Decision IG. 20/4 (2012) decided on the implementation of an EcAp roadmap for MAP, describing a seven step procedure. At EU level, there was selected the coordination and unification of monitoring indicators and measures. MSFD, being the environmental scale of IMP, seeks to achieve GES in EU marine waters until 2020. (WWF Greece, 2015)

Four-dimension planning is a completely new parameter in planning. It raises a lot of concerns on the technical ability to implement it, since it is a quite difficult effort, facing a lot of mapping uncertainties. Spatial analyses tools need to be developed to work with multidimensional data and the visualization of 4D models needs to progress. It is to be seen in practice, testing various mapping tools in a case-by-case approach to find what fits the purpose of legible, informative, clear and specific MSP maps.

Conclusions

During this attempt to highlight the conceptual approach of MSP and to outline some MSP principles and parameters, we tried to pinpoint the different beginnings but common interests of the intergovernmental institutions involved, the pioneers and the important outcomes from their efforts. Trying to highlight the MSP principles, we really consider it important to *think of MSP from the spatial planning scientific discipline point of view*, following the really strenuous efforts on behalf of CoE, UN and the EU to set a common approach on spatial planning. There was made an effort to note that MSP cannot be considered as a process different from TSP. MSP needs to borrow from the experience gained into the years from theoretical research, best and worst planning practices and the general mentality of spatial planners. Building on that, MSP can be differentiated based on the special conditions and needs raised and in this regard, there is a need to set the adding parameters that will ensure the viability and the effectiveness of MSPlans.

Management plans of Natura 2000 Sites and coastal land use plans: A study concerning an integrated approach to management of coastal zones in the Sulcis Area (Sardinia, Italy)

Federica Leone¹, Corrado Zoppi²

¹*Dipartimento di Ingegneria civile, ambientale e Architettura - University of Cagliari, federicaleone@unica.it*

²*Dipartimento di Ingegneria civile, ambientale e Architettura - University of Cagliari, zoppi@unica.it*

Abstract: The Protocol of the Barcelona Convention on integrated coastal zone management defines integrated coastal zone management as "...a dynamic process for the sustainable management and use of coastal zones, taking into account at the same time the fragility of coastal ecosystems and landscapes, the diversity of activities and uses, their interactions, the maritime orientation of certain activities and uses and their impact on both the marine and land parts."

Although integrated approach to coastal zone management has increasingly acquired importance within the international debate, with particular reference to the European Union context, its implementation puts in evidence relevant issues as regards the conflict between conservation measures related to environment and natural resources, and local development-related strategies.

From this perspective, Strategic environmental assessment (SEA) processes are particularly important since they are based on the implementation of a methodological and technical framework which aims at integrating environmental sustainability-related objectives, defined in national and regional strategies, into the local development strategies whose goals reflect needs and expectations identified by the local governments and communities.

In a SEA-based conceptual framework, this study proposes a methodological approach to the integration of strategies and related measures expressed by the management plans of Natura 2000 Sites into coastal land use plans, which generates a system of consistent objectives and related planning actions. The fundamental assumption is that SEA of management plans and coastal land use plans is very effective to build consistency in terms of sustainability-oriented strategies and local development measures. The proposed methodology is implemented in order to integrate coastal planning strategies and conservation measures related to management plans of Natura 2000 Sites with reference to three case studies concerning three municipalities, Calasetta and Carloforte, located in South-Western Sardinia, Italy.

Keywords: integrated coastal zone management; Natura 2000 Network; coastal planning; local development

Introduction

Since the 1970s, spatial planning policy of the European Union (EU) has been characterized by a marked attention to integrated coastal zone management (Saffache and Angelelli, 2010), as per Resolution no. (73) 29 (26 October 1973) of the Council of Europe, which suggests implementing a holistic approach to conservation and protection of coastal heritage.

At the moment, at the international level, integrated coastal zone management is progressively increasing its relevance in theoretical and practical terms, since it is generally assumed as a fundamental point of reference to define and implement spatial policies oriented to sustainable development (Billé, 2008). The “Protocol on Integrated Coastal Zone Management”¹ (ICZM Protocol) was adopted by the EU Council in 2008, and ratified in 2010 (Decision no. 2010/631/EU). The Protocol defines coastal zone management as a dynamic process which implements the sustainability paradigm into management and use of the coastal areas (article no. 2), by taking account of the weakness of landscapes and ecosystems, of the heterogeneous mix of ongoing activities, which include maritime activities, of their interdependency, and of the impacts generated as regards coastal and marine contexts. Moreover, the context-specific nature of the ICZM approach should be carefully considered (Soriani *et al.*, 2015), since coastal and marine planning issues cannot be addressed on a one-size-fits-all basis.

Nevertheless, integrated coastal zone management as regards the relationship between theory and practice is still a critical issue (Burbridge and Humphrey, 2003). Soriani *et al.* (2015) identify two kinds of problematic questions that may arise, which, on the one hand, are related to policies and strategic approaches, and, on the other hand, are connected to the implementation phases of spatial plans.

In this conceptual context, strategic environmental assessment (SEA) may help decision-making processes related to coastal zone management to be effective in addressing the issue at stake (Rochette and Billé, 2010). The Directive of the EU concerning SEA (no. 2001/42/CE) states (article 1) that “The objective of this Directive is to provide for a high level of protection of the environment and to contribute to the integration of environmental considerations into the preparation and adoption of plans and programmes with a view to promoting sustainable development, by ensuring that, in accordance with this Directive, an environmental assessment is carried out of certain plans and programmes which are likely to have significant effects on the environment.” In other words, SEA processes enhance the quality of decision-making by making consistent and integrated economic and social development objectives and sustainability goals (Leone and Zoppi, 2015a).

Furthermore, SEA is effective in supporting national administrations in implementing the ICZM Protocol into strategies and plans related to coastal management (UNEP *et al.*, 2011). Harvey (2000) analyzes the use of SEA with reference to Australian coastal management. Procedures based on SEA-related approaches are used on a voluntary basis in the definition and implementation of the “Strategy for integrated coastal zone management” of Portugal in 2008, as a decision-making tool (Partidário *et al.*, 2009), even though a systematic technical procedure which integrates the ICZM Protocol provisions and the SEA procedure is not available at present.

The approach proposed in this study builds on SEA in order to define a methodology which supports spatial planning processes in implementing the ICZM Protocol into local decision-making procedures. The objectives identified in different plans, namely spatial plans which regulate land uses in the coastal areas (PLUCs) and plans related to management of Natura 2000 Sites² (PMN2s), are examined and compared as regards their

¹ Available online: [https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:22009A0204\(01\)&from=EN](https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:22009A0204(01)&from=EN), Date of access: 08/05/2019.

² Three types of protected areas feature Natura 2000 Sites: Sites of community importance (SCIs) and Special areas of conservation (SACs), identified under the provisions of EU Directive 92/43/EEC (the Habitats Directive), and Special protection areas (SPAs), identified according to EU Directive 2009/147/EC (the Birds Directive).

mutual coherence. Their strategies are made consistent with each other and negative effects of PLUCs on PMN2s are highlighted and addressed. The methodological approach is applied to two case studies concerning two coastal towns located in South-West Sardinia, in the region of Sulcis.

In the next section, the methodology is discussed, the documents and materials, upon which the spatial analyses are based, are identified, and the two urban contexts, considered in the two proposed case studies, are synthetically presented. The third section shows the results of the implementation of the proposed methodological approach, while implications, limits and suggestions for further research are discussed in the concluding section.

Methodology and case studies

The methodology implemented and discussed in this study focuses on building mutual consistency between PMN2s and PLUCs. It is based on the integration of strategies of PMN2s and PLUCs implemented through a logical structure (LS) which makes reference to the SEA procedure. The LS builds on the conceptual category of sustainability, mutual endogeneity of spatial planning and environmental assessment, and the presence of planning alternatives, which feature SEA-based procedures according to the Italian Law concerning SEA (Decree no. 152 of April 2006), which embeds the EU Directive on SEA into the Italian legislative framework (Leone and Zoppi, 2015a).

The LS was already used by Leone and Zoppi (2015b; 2016), who proposed a comparison between the provisions of the city masterplans and the PMN2s based on the reciprocal consistency of their goals. Here, the relationships between PLUCs and PMN2s are assessed as regards sustainability goals, through the identification of the PLUCs' operations which may generate negative effects on habitats and species protection-related goals identified in the PMN2s. Table 1 shows the diagram of the LS. The five columns refer to: i. sustainability goals; ii. thematic issues; iii. PLUC's goals; iv. PMN2's goals; and, v. PLUCs' operations which may generate negative effects on habitats and species protection-related goals identified in the PMN2s.

The proposed methodological approach is applied to the towns of Carloforte and Calasetta, two spatial contexts of South-West Sardinia located in the Sulcis region (Figure 1). The small Island of San Pietro (San Peter), where Carloforte is located, is connected to the mainland by ferryboats which depart from the Port of Calasetta. These towns were selected since they identify a consistent spatial system, whose coastal and marine areas require an integrated management approach, even though each urban area is governed by an autonomous municipal administration. Furthermore, a number of Natura 2000 Sites are located in each spatial context.

The planning documents used in the study are:

1. the PLUC of Calasetta and the PMN2s of the following SACs: ITB042208 "tra Poggio La Salina e Punta Maggiore," ITB042210 "Punta Giunchera" and ITB042209 "A nord di Sa Salina;"
2. the PLUC of Carloforte and the PMN2 of the following Natura 2000 Sites: SAC ITB040027 "Isola di San Pietro" and SPA ITB043035 "Coste e Entroterra tra Punta Cannoni e Punta delle Oche – Isola di San Pietro."

SUSTAINABILITY GOALS	THEMATIC ISSUES	PLUC's GOALS	PMN2's GOALS	NEGATIVE PLUC'S OPERATIONS

Table 1. The framework of the logical structure (LS)

Findings

The implementation of the methodological approach into the two urban contexts of the Sulcis Region identifies and analyzes coastal and marine processes which combine planning strategies differentiated in terms of scale, since the local municipal administrations, which study and approve the PLUCs, and the regional and national administrations, which define and implement PMN2s, are involved at once.

The LSs concerning the PLUCs and the PMN2s related to the towns of Carloforte and Calasetta are reported in Table 2 and Table 3. Considering contents and objectives of PMN2s and PLUCs, each of the two tables shows sustainability goals concerning conservation of biological diversity, plants and animals. PLUCs and PMN2s are mutually consistent as regards goals and thematic issues. The PLUCs focus on the following thematic issues: i. relations between coastal and marine ecosystems and services provided on the beaches; ii. conservation and enhancement of coastal and marine ecosystems; and, iii. accessibility to beaches and coastal areas. For example, the objectives of the PLUC of Calasetta focus on the integration of services provided on the beaches and coastal and marine ecosystems, identifying ecosystem conservation as the core issue, whereas the goals of the PLUC of Carloforte focus on the same integration issue, assuming accessibility as the main question. This is explained by the fact that the SAC “Isola San Pietro” overlays the municipal land of Carloforte and, as a consequence, the approval process of proposed spatial transformations is based on the Appropriate assessment procedure, established under the Habitats Directive³, which aims at preventing negative effects of projected operations on habitats and species of SACs, SPAs and SICs.

³ Any plan or project not directly connected with or necessary to the management of the site but likely to have a significant effect thereon, either individually or in combination with other plans or projects, shall be subject to appropriate assessment of its implications for the site in view of the site's conservation objectives [...] [T]he competent national authorities shall agree to the plan or project only after having ascertained that it will not adversely affect the integrity of the site concerned and, if appropriate, after having obtained the opinion of the general public.” (Habitats Directive, art. 6, paragraph 3).

Figure 1. The study area. Source: elaboration by Federica Leone on an aerial photography drawn from <http://www.sardegnaeoportale.it/index.php?xsl=2425&s=324505&v=2&c=14488&t=1&tb=14401>, Date of access: 08/08/2019.

It has to be put in evidence that, notwithstanding PLUCs and PMN2s are mutually consistent as regards their sustainability goals, the PLUCs' planned operations can generate negative impacts on the PMN2s.

In the case of Calasetta (Table 2), the coastal and marine areas are planned both as environmental resources deserving protection-oriented measures and as factors of economic development related to leisure and tourism. The PLUC focuses on the definition of a set of planning policies to exploit tourist attractiveness (Goal CL_PLUC_2) and on prevention or mitigation of erosional processes concerning beaches (Objective CL_PLUC_3). The planned operations aim at developing tourism and at increasing the attractiveness of the seashores (Operations CL_PLUC_O_2, CL_PLUC_O_3, CL_PLUC_O_4, CL_PLUC_O_5, CL_PLUC_O_6, CL_PLUC_O_7 and CL_PLUC_O_8). On the other hand, the goals of the PMN2 focus on limiting tourist presence on the beaches (Objective CL_PMN2_3), on prevention or mitigation of the negative effects generated by human activities, animals and infrastructure on dunal habitats and species (Goal CL_PMN2_4), and, in general, on habitats and species (Goal CL_PMN2_1).

SUSTAINABILITY GOALS	THEMATIC ISSUES	PLUC's GOALS	PMN2's GOALS	NEGATIVE PLUC'S OPERATIONS
Preservation and enhancement of coastal ecosystems and biodiversity	Relations between coastal and marine ecosystems and services provided on the beaches	CL_PLUC_1	CL_PMN2_1 Prevention or mitigation of the negative effects generated by human activities, animals and infrastructure on habitats and species protected under the Habitats Directive	CL_PLUC_O_1 Authorization for pet-care services

SUSTAINABILITY GOALS	THEMATIC ISSUES	PLUC's GOALS	PMN2's GOALS	NEGATIVE PLUC'S OPERATIONS
Preservation and restoration of marine and coastal ecosystems, with a particular focus on species and habitats protected under the Habitats Directive	Relations between coastal and marine ecosystems and services provided on the beaches	CR_PLUC_1 Planning beach-related services and activities consistently with landscape and environmental protection goals	CR_PMN2_1 Preservation of coastal waters	CR_PLUC_O_1 Authorizations released to boaters of small boat charters
			CR_PMN2_2 Conservation of reef habitats	CR_PLUC_O_2 Provision of the minimum service level in support of tourism in the most popular sandy and rocky beaches
			CR_PMN2_3 Preservation of dunes and of their habitats	
			CR_PMN2_4 Promotion of sustainable uses of sites and related environmental resources	
			CR_PMN2_5 Conservation of arborescent matorral, thickets and phrygana habitats	
			CR_PMN2_6 Conservation of important botanical species (<i>Astragalus maritimus</i> , <i>Rouya polygama</i>)	
			CR_PMN2_7 Protection of the most significant bird species for Natura 2000 Sites in Carloforte	CR_PLUC_O_1 Authorizations released to boaters of small boat charters
			CR_PMN2_8 Protection of the local fauna	
			CR_PMN2_9 Protection of “ <i>Caretta caretta</i> ”, a species of Community interest	
			CR_PMN2_2 Conservation of cliff habitats	
			CR_PLUC_2 Organization of the access point system and of the parking sites in order to regulate public access to beaches and coastal areas, minimizing environmental impacts	
			CR_PMN2_3 Conservation of dunal habitats	CR_PLUC_O_3 Boardwalks installation which make it easier to access the beaches
			CR_PMN2_5 Protection of habitats such as thickets, phrygana and arborescent matorral	CR_PLUC_O_4 Development of parking sites close to habitats and species protected under the Habitats Directive
			CR_PMN2_10 Promotion of a sustainable use of the site and its resources	

Table 3. Logical structure of the integration of the PLUC and of the PMN2 concerning the town of Carloforte

Two issues characterize the case of Carloforte (Table 3). On the one hand, preservation of coastal waters (Goal CR_PMN2_1) and of *Caretta caretta* (Goal CR_PMN2_9), identified as a protected species under the provisions of the Habitats Directive, conflict with the authorized traffic of small boat charters (Operation CR_PLUC_O_1). Indeed, these boats are allowed to sail with no license or certification concerning the technical knowledge of the boaters as regards coastal ecosystems, habitats and plants, such as *Posidonia oceanica* seabed and other peculiar habitats, or protected species, such as *Caretta caretta*. On the other hand, the boardwalks installation which make it easier to access the beaches (Operation CR_PLUC_O_3), and the development of parking sites close to habitats and species protected under the Habitats Directive (Operation CR_PLUC_O_4), are likely to determine negative impacts with reference to preservation of dunes and of their habitats (Goal CR_PMN2_3) and to protection of habitats such as thickets, phrygana and arborescent matorral (Goal CR_PMN2_5).

Discussion and conclusions⁴

The outcomes of the proposed methodology based on the LS show that negative effects may occur on the achievement of the goals of the PMN2s as a consequence of operations planned by the PLUCs. The LSs defined to assess the coherence of the PLUCs and PMN2s concerning the towns of Calasetta and Carloforte put in evidence that the operations planned in the PLUCs may put at risk the effectiveness of the conservation measures identified in the PMN2s, related to habitats and species, since PLUCs and PMN2s were studied and approved following independent procedures, implemented by different public administrations, that is, the

⁴ This Section partially reproduces a discussion proposed in a previous study of the authors (Leone and Zoppi, 2016, Section “5. Discussion and Conclusions”).

municipal administrations in the case of the PLUCs, and the regional administration in the case of the PMN2s. Furthermore, the two types of plan focus on different core issues, since PMN2s deal with conservation measures regarding habitats and species of the Natura 2000 Sites, whereas PLUCs are related to sustainable coastal zone management aimed at catalyzing social and economic local development based on tourist attractiveness.

From this standpoint, this study defines, and applies to the urban contexts of Calasetta and Carloforte, a methodological approach whose scope is to integrate different plans, which take place in the local public domain, that is the Sulcis Region, into a unique planning instrument which makes consistent nature protection-related and development-related objectives.

The study shows, by detailed comparative appraisals of two PLUCs and related PMN2s, that the LS-based procedure entails an enormous potential in order to build consistency and, much more important, to drive the issue of conservation and enhancement of habitats and species outside the narrow boundaries of sectoral policies concerning the Sites of the Natura 2000 Network. The application of the LS makes the issue a comprehensive and fundamental question related to the PLUCs. The implementation of the PMN2-related sustainability objectives into the PLUCs through the LS approach is based on the environmental characterization of the supporting ecosystem services (ESs) supplied by habitats and species (Millennium Ecosystem Assessment, 2003). In the first place, ESs are identified in the spatial context of the Sites of the Natura 2000 Network, and afterwards, during the application of the LS approach, they become spatial and environmental characteristics of the whole coastal and marine areas (Leone and Zoppi, 2016).

The proposed LS-based approach implements PMN2s into PLUCs and, that being so, not only is suitable to assess and drive the definition and establishment of planning decisions (ex ante phases of PMN2s/PLUCs), but also to support the planning policies to be carried out, since the ES-related sustainability objectives entail a monitoring system based on benchmarks concerning the environmental indicators related to the ESs.

Furthermore, it has to be stressed that the planning policies concerning supporting ESs may generate conflicts related to tourism-related ESs, whose land uses may be prevented by conservative measures entailed by the PMN2s. Therefore, LS-based procedures that imply ES-based sustainability objectives should take account of supporting ESs not only in terms of conservation and enhancement of habitats and species, but also as sources of conflict between alternative land uses related to alternative types of ESs, that is supporting and tourism-related. The conflicts are expressed by the trade-offs between protection and preservation of coastal and marine species and habitats, that is, supporting ecological systems, and the pressure for increasing the provision of services for tourists and local visitors in the coastal areas, that is tourism-related ESs, which is the main focus of PLUCs (Lai and Zoppi, 2017).

The results proposed in this essay are very robust in terms of exportability to other EU contexts, since the LS-based procedure implemented into spatial plans (PLUCs) at the municipal level is always based on the same normative framework, established by the SEA Directive. Moreover, the reference of the PMN2s is always the Natura 2000 Standard Data Form, approved by the European Commission with the Decision of 11 July 2011⁵. As a consequence, it can be applied as such in other EU countries, even though different institutional frameworks and planning practices at the national and regional levels may possibly imply more-or-less huge differences in terms of timing and duration and public authorities responsible for the PLUCs and the PMN2s' planning procedures, the quality of the participatory processes and the qualitative and quantitative size of the participating public and stakeholders.

Shrinking cities
and sustainability

Dialectical Understanding on Urban Shrinkage and Growth in China: Taking the Old Industrial Base Cities in Northeastern China as an Example

Qimin Hu¹, Fan Yang²

¹Tongji University, hqm1637@outlook.com

²Tongji University, fanyangsh@tongji.edu.cn

Abstract: According to statistical data, nearly 60 percent of China's population had lived in cities, by 2018. Recently, research reports show that China's population growth will enter a period of stagnation, followed by a likely rapid decline. This paper selects the old industrial base cities, in Northeastern China, as the research object. Based on the data of population, urban construction, fiscal revenue and LGDP, etc., utilizing data spatial visualization analysis software such as ArcGIS, this research reveals the space-time dynamic association between urban growth and shrink, happening in cities and in regions. Furthermore, the research analyzes the dynamic process of growth and reduction of population and land-use scale in individual city case, focusing on industrial land-use and the situation of related employment. At the same time, it reflects the socio-economic characteristics of urban outflow population, such as age, occupation, income, and the structural characteristics of the urban secondary industry as well as the transition trends. That means, the areas and cities to which the population flows, and the jobs performed, also have important explanatory implications on the things happening in case cities. Based on the analysis above, the paper proposes an understanding and definition of the shrinking cities in the context of contemporary China. And then it argues that, comparing with the economic growth and population accumulation previously, the status of population outflow, industrial decline and spatial shrink happening currently, still can be regarded as an urban development mode which isn't represented by the growth of space and economic, but by the reconstruction of space, population and industry. Furthermore, the reconstruction of space has the rich connotation of smart growth. It is the right way for cities to seek new development engine and the mechanisms by which the engine works.

Keywords: Shrinking cities; urban development; space-time analysis; Northeastern China

Introduction

Worldwide spread of shrinking cities

The unemployment and marketization of labor force caused by German reunification along with the process of deindustrialization is the reason of population loss and economic recession, and at this time, the German scholar, Schrumpfende Städte present the word 'Shrinking Cities'. In the following research about rustbelt region, 'urban decline' had been used to describe the recession and the loss of population. Not until 1996, 'Shrinking Cities' was adopted by the academe field(高舒琦, 2015).

There is no unified answer to the definition of shrinking cities so far. The current definition of urban shrinkage is more of a description of the characteristics, rather than a typical conceptual definition (Rink and Kabisch, 2009). For now, shrinking cities are defined from two perspectives. One of the perspectives is demographic changes, including changes in demographic structure, population loss, and changes in labor force, such as 'population loss accounts for at least 10% of the population', 'cities with an annual population loss rate greater than 1% per year' (Oswalt P, 2006) or 'a population loss of more than 25% over the past 40 years, accompanied by land vacant and the increasing of abandoned residential, commercial and industrial buildings' (Schilling and Logan, 2008); based on this, another perspective considers the policies of economic and industrial as well such as 'urban shrinkage is accompanied by significant population decline, economic recession, or decline in international standing affecting the development of regions or metropolitan areas' (Pallagst, 2005).

With the process of globalization, urban shrinking is widespread around the world. The study of shrinking cities is no longer confined to individual cities. Scholars have gone further to study the mechanism with a global perspective. Globalization has intensified competition between cities and regions. The global flow of capital caused by the economy liberalism has concentrated most of resources on several global cities. The international division of labor system has further exerted competitive pressure on areas with insufficient development momentum. With the continuous loss of resources and the lack of pulling power, some cities inevitably face the situation such as population loss and industrial recession. Some cities might spend a quite long period in this situation. Therefore, the conception of "urban shrinkage" has been continuously expanded and attracted attention widely in recent years. Many scholars from multi-field have focused on the study of shrinking cities, and some planning strategies for the shrinkage of case cities have been put into discussion.

Shrinking Northeastern China

Since the founding of the People's Republic of China, the Northeast has been a national heavy industry basement mainly made up by resource-based cities and heavy industrial cities which are the net outflow areas of the country in the country's large development pattern and urbanization pattern, and in the long run, the outflow trend of various factors is difficult to reverse and the shrinking pressure it faces is hard to resist. In the study of urban shrinkage identification and overall spatial distribution characteristics in Northeast China, the shrinking cities in Northeast China is characterized by globality, non-equilibrium, development paradox and pseudo-shrinkage. The population of Shenyang Dalian and Chaoyang growth slightly with lower latitudes and the remaining 33 prefecture-level cities have been suffering with shrinkage for a long time. Despite the serious population loss, the urban shrinkage in the entire region has always maintained a land use growth.

1. Study Review

1.1 Quantitative Research in Study of Urban Shrinkage

The research methodology of shrinking cities is mainly based on the quantitative research, combined with spatial analysis methods and qualitative research methods in most circumstances. Starting from the definition of shrinking city, it has become a basic consensus to measure urban shrinkage with urban resident population. By reviewing relevant papers, the quantitative research methodology can

be made up by socioeconomic methods, geospatial statistical methods and geographic landscape methods(刘合林, 2016).

Moran's I is widely used when it comes to spatial correlation analysis composed by global Moran's I and Local Moran's I. Global Moran's I is suitable for analyzing spatial correlation analysis from the whole, reflecting the global spatial distribution and verifying the spatial pattern of a certain element in the region when the local Moran's I is suitable for analyzing the local spatial autocorrelation(吴拥政, 2010).

1.2 Reiprocity of Phenomenon and Mechanism in Shrinking Cities

The growth and shrinkage of cities had appeared in various famous cities that have existed in the history of the world. The reasons were mostly wars, plagues, natural disasters, etc. The shrinking cities in the 20th century developed in a more peaceful and stable era, without drastic changes in external conditions, population loss and economic recession are changing slowly correspondingly, and the causes of urban shrinkage have their particularities (杨振山 和 孙艺芸, 2015). The analysis of the causes of urban shrinkage often starts from the four main aspects of the stage characteristics of urban development, migration and demography structural degradation, the transformation of post-socialist countries and the impact of urban policy.

Research based on the stage characteristics of urban development, focuses on economic globalization, industrial transformation and urban suburbanization. Capital globalization caused by the economic liberalism has concentrated a large amount of capital in several global cities, resulting in global inequality in space, and the gradual improvement of the international labor system forced the transformation of industrial and space in some cities, resulting in economic fluctuation and the flow of population. Population mobility is regarded as a core indicator in the identification and measurement of urban shrinkage in most times. However, demographic change not only serves as a sign of urban shrinkage, but sometimes as a motivation. For example, Japan is facing a shortage of domestic labor resources caused by population aging. The natural population growth rate is low, and the young labors tend to accumulate in large cities such as Tokyo, leading to the continuous shrinking of small towns (Martinez-Fernandez *et al.*, 2016). After the disintegration of the post-socialist states, along with the disappearance of the political boundary, the planned economy being affected by the global economic tide at the same time. The state-owned enterprises with insufficient competitiveness were forced to privatize. Take Leipzig as an example, the dominant manufacturing industry not only faces the challenges of the original capitalist region, but also faces competition from the same type of countries in Eastern Europe, resulting in a population loss of nearly 50%(邓嘉怡 和 李郇, 2018). In addition to the above reasons, urban policies have a direct or indirect impact on the urban economy for the purpose of local ecosystem protection or regional resource allocation, resulting in the wilting of some of the leading industries. For example, Yichun in Heilongjiang is promulgating the Forest Law. The Law and its series of amendments have led to a sharp decline in the output of wood processing and furniture manufacturing, local pillar industries. The large loss of population caused by the job lossing has intensified the shrinking of urban industries(高舒琦 和 龙瀛, 2017).

1.3 Summary

Above all, the causes of a shrinking city always come from various aspects, and the resulting economic sluggishness and population loss often act on urban shrinkage again. The underlying causes are difficult to distinguish and different regions have unique internal mechanisms, making it difficult to form a planning paradigm. At present, a large number of studies have been devoted to the shrinkage and growth between cities or regions, however, research on districts in specific city is still scarce. In addition, at the time of transformation from urban growth to urban renewal, how to deal with the role of urban planning in shrinking cities, should be a question worth considering.

2. Growth and Shrinkage among Districts in Case City

2.1 Shenyang: The Study of a Central City of Northeastern China

As the capital of Liaoning Province and one of the regional central cities in Northeast China, Shenyang is representative in terms of history and economy. Since 2000, with the gradual decline of the secondary industry, the Northeastern economy, which is dominated by heavy industry state-owned enterprises as the wilting of the economy, has been severely impacted and intensified, which has also had a tremendous impact on Shenyang's economic construction and urban development, and problems such as the population aging and the failure of industrial transformation are widespread in the region. Shenyang had not faced the problem of population loss, according to the two population censuses in 2000 and 2010, the permanent residents in Shenyang has increased from 7,037,517 in the

fifth census to 8,106,171 in the sixth census. In the past ten years, the population growth rate is 12.53%. Although the population of Shenyang was growing slightly in quantity, non-Shenyang City area is almost completely degraded. Most of the street population loss rate is within 30%, and even some populations lose 60%, such as Xinchengzi residential district in Xinmin (68.9%) and the suburban town of Liaozhong (73.4%). Shenyang hadn't faced the problem of demographic shrinking according to the number of populations, however, when referring to spatial distribution, the rural hollowing couldn't be ignored. From the perspective of the change in the number of juveniles under the age of 14 In the past ten years, it has decreased by 302,982. In 2010, the population age of the population is 798,013, the population aged 14-65 is 6,529,159, and the elderly population over 65 is 844,597. The number of young people was decreased from 15.21% of the total population to 9.7%. It is clear that under this trend, Shenyang would soon face the problem of population shrinking for the foreseeable future.

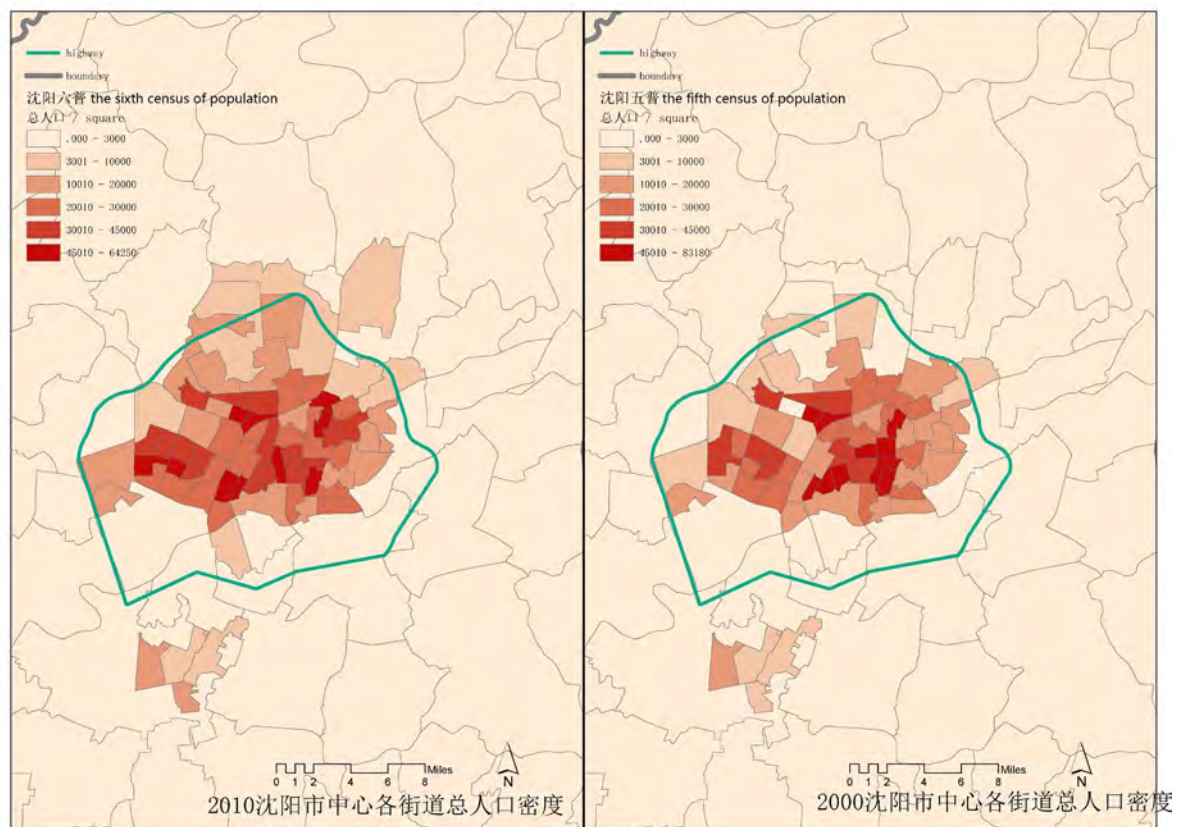

During the interval of the fifth and sixth censuses, the changes in the internal population of Shenyang City also showed certain changes. During the period of rapid urbanization in China, the rural population gathered in large numbers in cities, and the problem of rural hollowing out is also common in China. Although the population of the city has increased as a whole, the agglomeration effect or mutual exclusion effect of the growth and shrinkage of the population within the internal unit reflects the development status of the city. This research perspective has a unique meaning of understanding the urban population shrinkage as well as reflecting the phenomenon.

2.2 Characteristics of Population among Residential Districts in Shenyang

During the two censuses, the administrative divisions of township district in Shenyang had changes a lot. After reviewing the township district directory, the author sorts out the 2000 demographic residential district units that have been split or merged in 2010. The corresponding population is merged into the new unit, with the street unit of the sixth census in 2010 as the basic unit of analysis. In the research area division of Shenyang, the whole area of Shenyang is divided into three layers: the innermost circle is the concentrated construction area enclosed by Shenyang G1501, which is the downtown area of Shenyang; the middle is the boundary of Shenyang. Within the area outside the construction area; the remaining part is the third part, which is the area outside the municipal area within the scope of Shenyang.

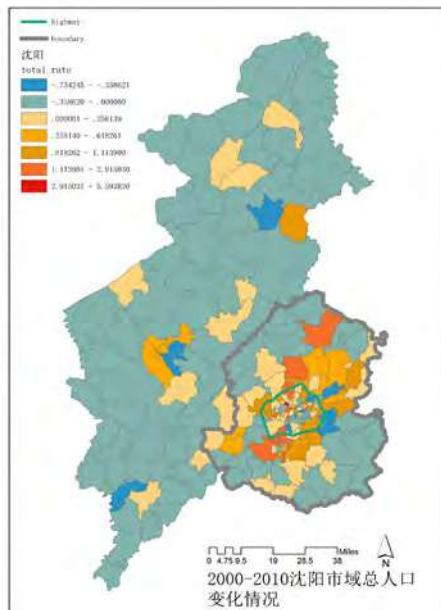

2.2.1 Districts of High Population Density Presenting a Single Center Agglomeration

According to the results of the total population of the fifth national census, the population density of the street units of all towns is less than 3000pop/km² outside the boundary, G1501, the highway around the urban area, in a more evenly distributed state, the second layer of the city beyond the city's high-speed zone also has the same characteristics, while the high-density total population area is concentrated in the innermost layer. From the perspective of global distribution, the high-density area presents the city center. The single-center distribution of the area, the street unit with a population density higher than 20,000 people/km² accounts for 17.13% of the total area. The county-level administrative area under the jurisdiction of Shenyang City has not formed a high-density population distribution pattern, and is at a relatively preliminary stage in the construction of the urban system. However, the distribution pattern of the total population density of township streets in the sixth census after ten years has not changed significantly. The district with a high population density in the urban

Pic.1 Spatial distribution of total population density in municipal

area enclosed by G1501 has increased significantly, and the total population density has reached 20,000 people/km². The number of township units accounted for 21.3% of the total area. From the distribution point of view, it began to appear on the periphery of the original core area, and the area expanded. Comparing the population density distribution of the two census results, the distribution area of the high-density unit of the population began to increase to the north, while the population of the southern part of the urban area did not change significantly, indicating that the area where the population was concentrated in the decade was mainly to the North of Hun River. Regional population change south of the Hun River is still small (*pic.1*).

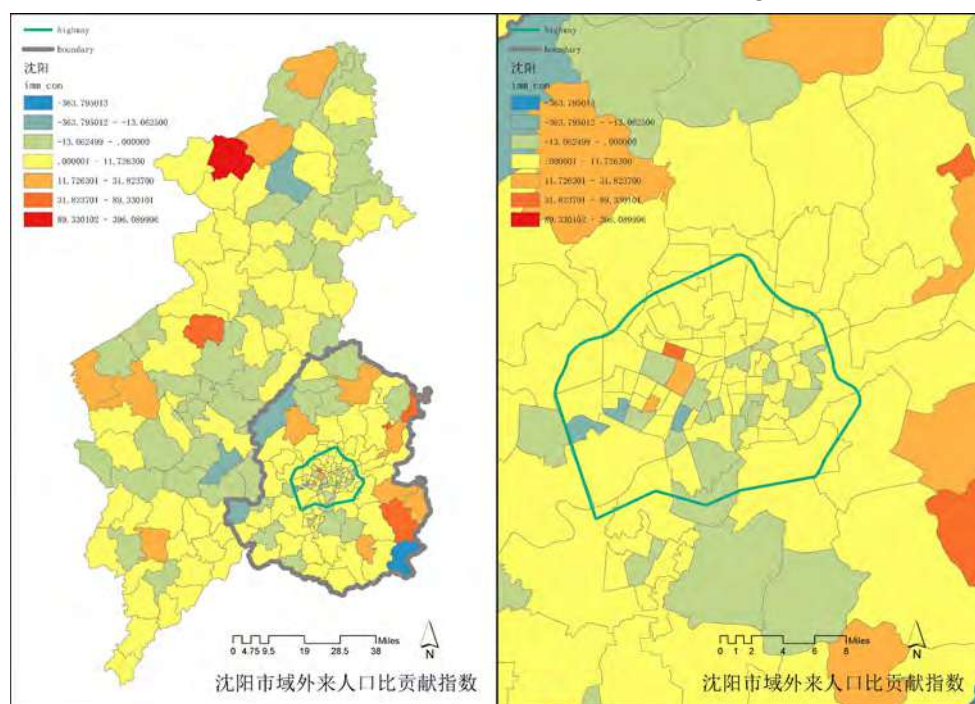

Pic.2 Spatial distribution of changes in total population density

In terms of the change in population density over the past decade (*pic.2*), except for the unit area where the population density has increased significantly within the second circle, the population reduction is the main situation. For the urban area, the population of the old urban area in Shenyang has contracted while the residential district near the G1501 line showed an increase in population density.

2.2.2 Districts of High Ratio of Migrants Presenting a ring agglomeration

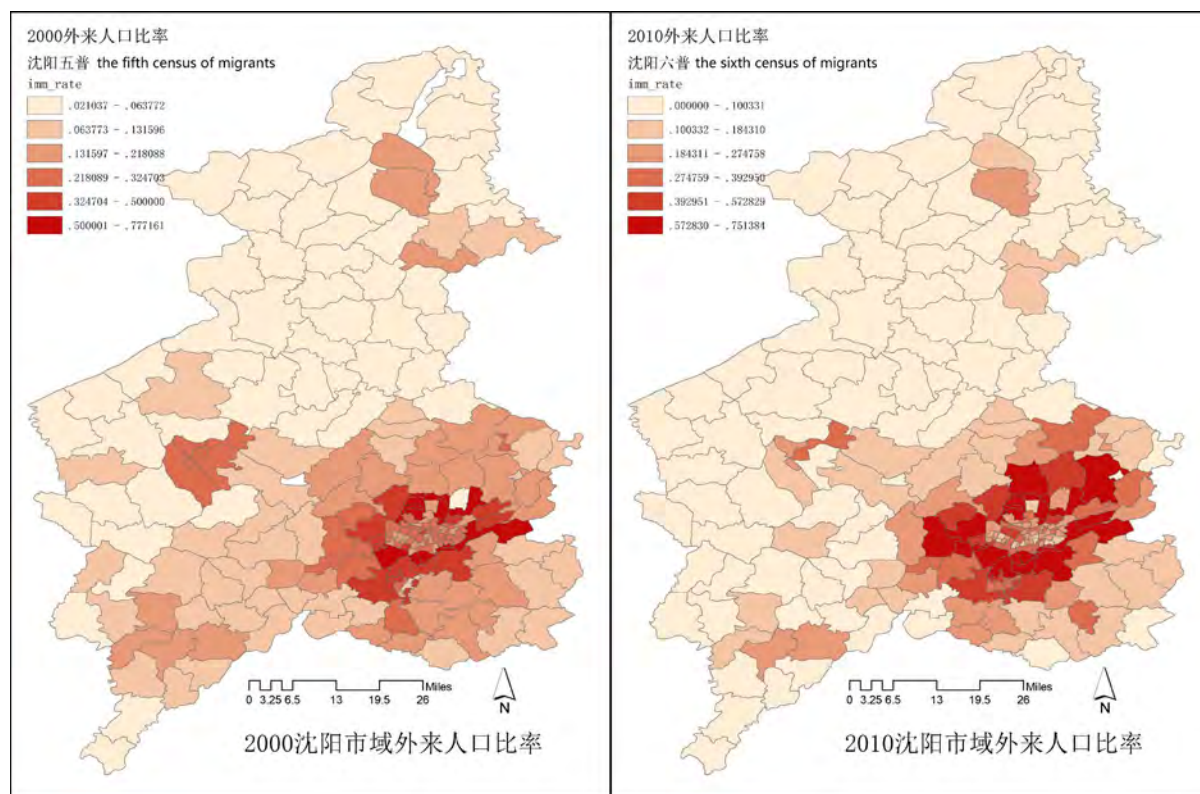

As migrant is the main force of urban development, the contribution index is defined by the change of ratio of migrant rate in the study of Shenyang. Districts with high contribution index will shows more impetus in urban development (*pic.3*). According to the pic. most of districts in Shenyang shows an index lower than 11.7 as well as the index in downtown, but it shows a higher result in the east of

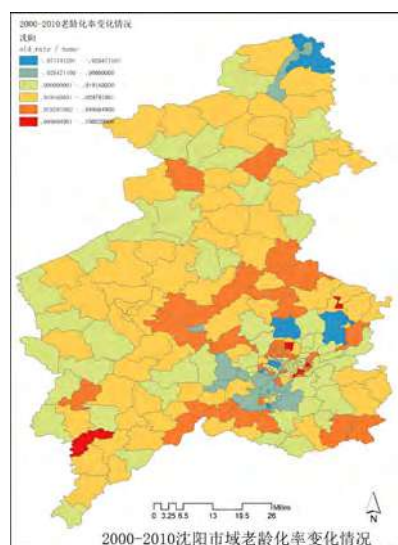

Pic.3 Spatial distribution of contribution index of migrants

Shenyang near to the boundary between Shenyang and Fushun, which means a fierce change in migrant.

According to the spatial distribution of migrant rate, it shows a more obviously concentrate when moving eyes to the edge of the city in the fifth census, and the phenomenon appears again in the result of the sixth census with a more centralized ring around the city (*pic.4*). In the fifth census, the spatial distribution of the migrant rate is more balance over the residential district between G1501 and the boundary of municipal district than it in the sixth census. Overall migrant density become more concentrate over the decade.

Pic.4 Spatial distribution of migrants in Shenyang (two census)

Pic.5 Change of aging rate

2.2.3 Significant Growth of the Ratio of Aging

The outflow of youth labor resources has led to the general problem of aging in the Northeast of China. This section based on comparison of the population ratio of the elderly aged over 65 between two censuses. And take 7% and 13% as the classification criteria which represent the aging degree, below 7% means that there is no aging problem in the city, 7%-13% means that the district has an aging population, and more than 13% means that the district is in an aging society.

In the fifth census, the number of residential district with an aging population below 7% accounted for 22.2% of the total, and the remaining 77.8% of the district ageing population ratio was almost

13%, comparing with the sixth census in 2010, district with an aging ratio below 7% reduced to about 6.9%, one-third of the former quantity; aging ratio in 82.4% of residential district is between 7% and 13%, facing the problem of aging; 9.3% of the districts had an aging ratio of more than 13% which means entering an aging society. In the past decade, the problem of aging in Shenyang has been highlighted (*pic.5*). The overall aging ratio of cities had also increased from 8.6% to 10.3%. According to the data of the sixth census, almost all street units with an age ratio of more than 13% are distributed in the G1501 city expressway, which means the aging ratio is relatively higher in the urban area of Shenyang, and combined with the juvenile population under 14 years old, the population structure of the city is seriously out of balance, the population's development momentum is seriously insufficient, and aging has also increase the city's financial burden, which could do harm to social development.

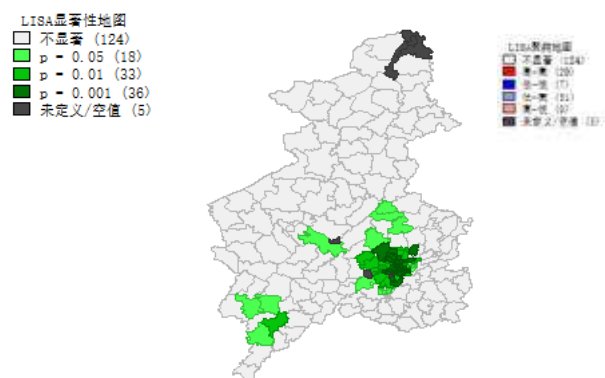

2.3 Spatial Autocorrelation of Demographic Changing in Shenyang

After observing the changes in various population indicators in Shenyang, it's not hard to found that the changes in various indicators have a certain spatial correlation, and continue to calculate the global Moran's I and the local Moran's I and illustrate the point with the graphical representation of spatial autocorrelation. In this case, the method of face and angle adjoining is used as the principle of allocation of spatial weights of each street unit (Queen's Case). The spatial autocorrelation setting $P < 0.05$ was significant, and the credibility reached 95%; $P < 0.01$ means that the credibility reached 99%; $P < 0.001$ means the credibility reached 99.9%. The LISA Significant Map will represent significant residential districts, while the LISA Cluster Map will classify significant districts into high-high, low-low, high-low, and low-high class, the districts are divided into high-high clustering as population agglomeration area; low-low clustering is defined as population contraction area; high-low clustering indicates that the street is in an increasing state to attract populations in other areas; low-high cluster indicates that the street is in a state where the population is being attracted to other regions.

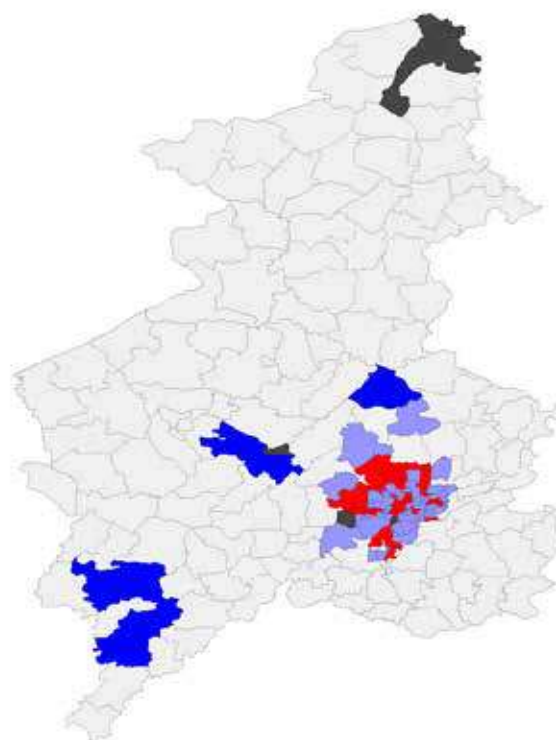

2.3.1 Rate of Change in Total Population

The global Moran index is calculated for the total population change rate of the residential districts in Shenyang, and Moran's $I = 0.0693764$. The global Moran index is positive, indicating that the observed data is significantly aggregated, and the total population change rate has a spatial strong correlation in space. The LISA significance map (*pic.6*) shows that $P < 0.001$ in most areas of Shenyang urban area in terms of total population change rate, which proves that the probability of population change rate in urban areas is 99.9% which is not randomly distributed. In addition, the analysis results of four street units in the western part of Xinmin and

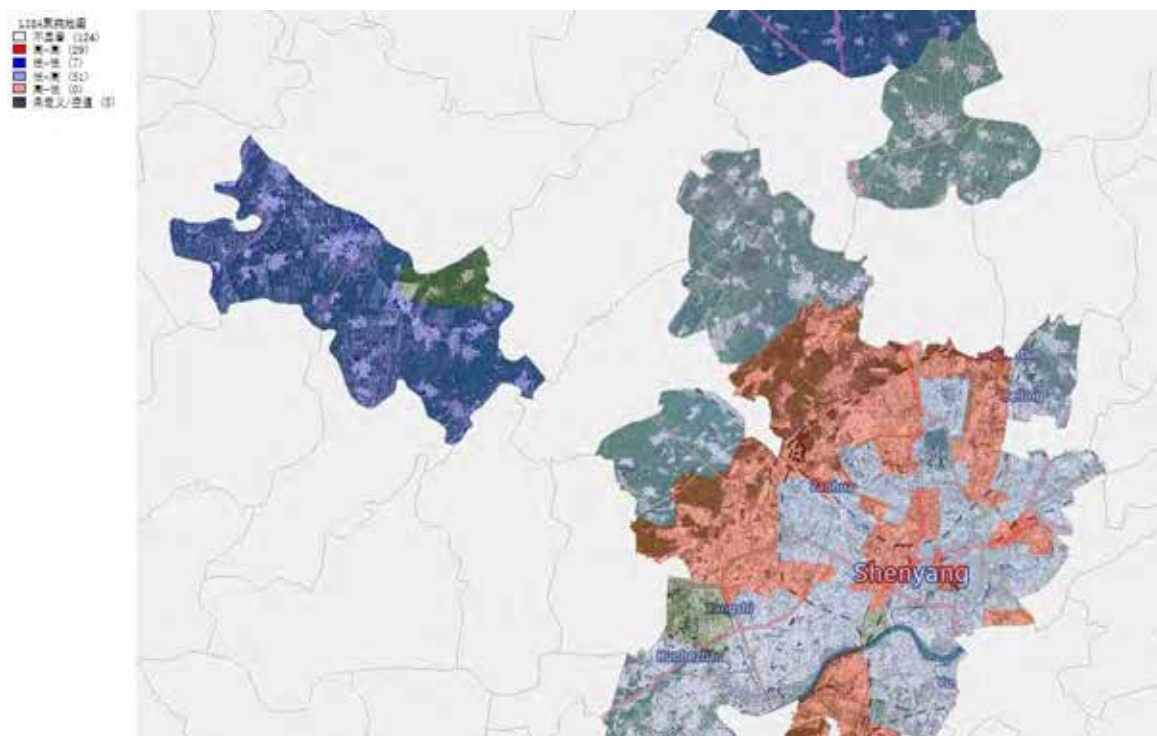

Pic.6 LISA Significant Map of Total Population

Pic.7 LISA Cluster Map of Total Population

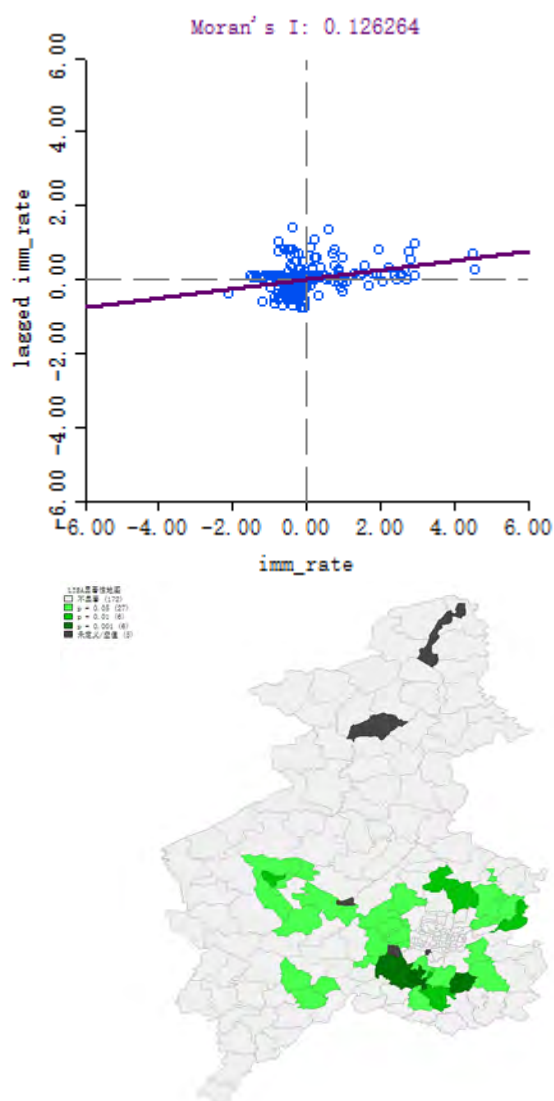

Liaozhong are also significant, with 95% probability being not randomly distributed. Overall, the areas with significant results are concentrated in the urban area of Shenyang.

Pic.8 LISA Cluster Map of Total Population of the Urban Area

The LISA clustering map (*pic.7, pic.8*) shows that the significant areas of Xinmin and Liaozhong are both low-low clusters, which are the shrinking districts of the population, while the urban areas of Shenyang are dominated by low-high clusters and high-high clusters. The high-high cluster area around the northwest of the area forms a semi-ring, surrounded by the built-up area of the city, and several districts in the downtown area also form a high-high cluster area, among other scattered four streets. Four high-high islands are formed in the annulus formed by the low-high cluster, and the other significant regions are low-high clusters. The northwest semi-circular ring has become a significant population agglomeration area, forming a population growth zone, while the urban area has also formed a growth pole. There is a low-high population shrinking zone between the two, and preliminary judgment can be made that people of the shrinking zone was flowing to the both sides. Comparing the quantity distribution maps, it is easy to found that the high-high areas are areas with large population growth, while some districts in the low-high cluster area still have a small increase in population, showing that the population growth is positive, but take a look at the big picture, its population is still in a state of being attracted to other regions.

2.3.2Rate of Change in Ratio of Migrants

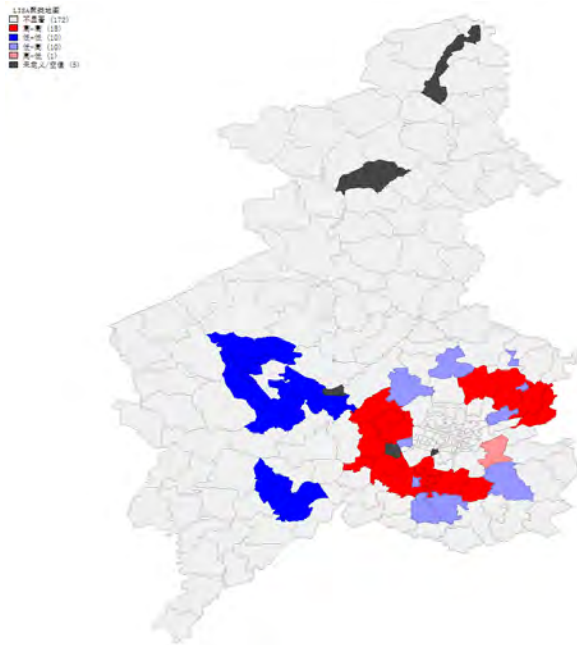

Pic.8 LISA Significant Map of change of migrants ratio

In the spatial cluster analysis of the change of the ratio of migrants in the two censuses, Moran's $I = 0.126264$. The positive value indicates that the changes of the migrants have significant spatial agglomeration distribution characteristics, and the change of the ratio of foreign population has a strong space. Correlation.

The LISA significant map (*pic.8*) shows that the spatial clustering significant area is concentrated in the periphery of Shenyang downtown, showing a roughly complete circular distribution. In addition, the significant area of Xinmin is also connected with the ring, indicating that the districts of Xinmin had an spatial correlation with the urban area. According to the map, P value of most significant areas is between 0.05 and 0.01, the ratio change of the foreign population has a 95% probability of non-random distribution in the spatial distribution, and the area of $P < 0.001$ is concentrated in the outer ring of the urban area. The southwestern region of the belt has a spatial distribution with a 99.9% probability of non-random distribution. The central city area did not show significance under this indicator, and there is no analytical value.

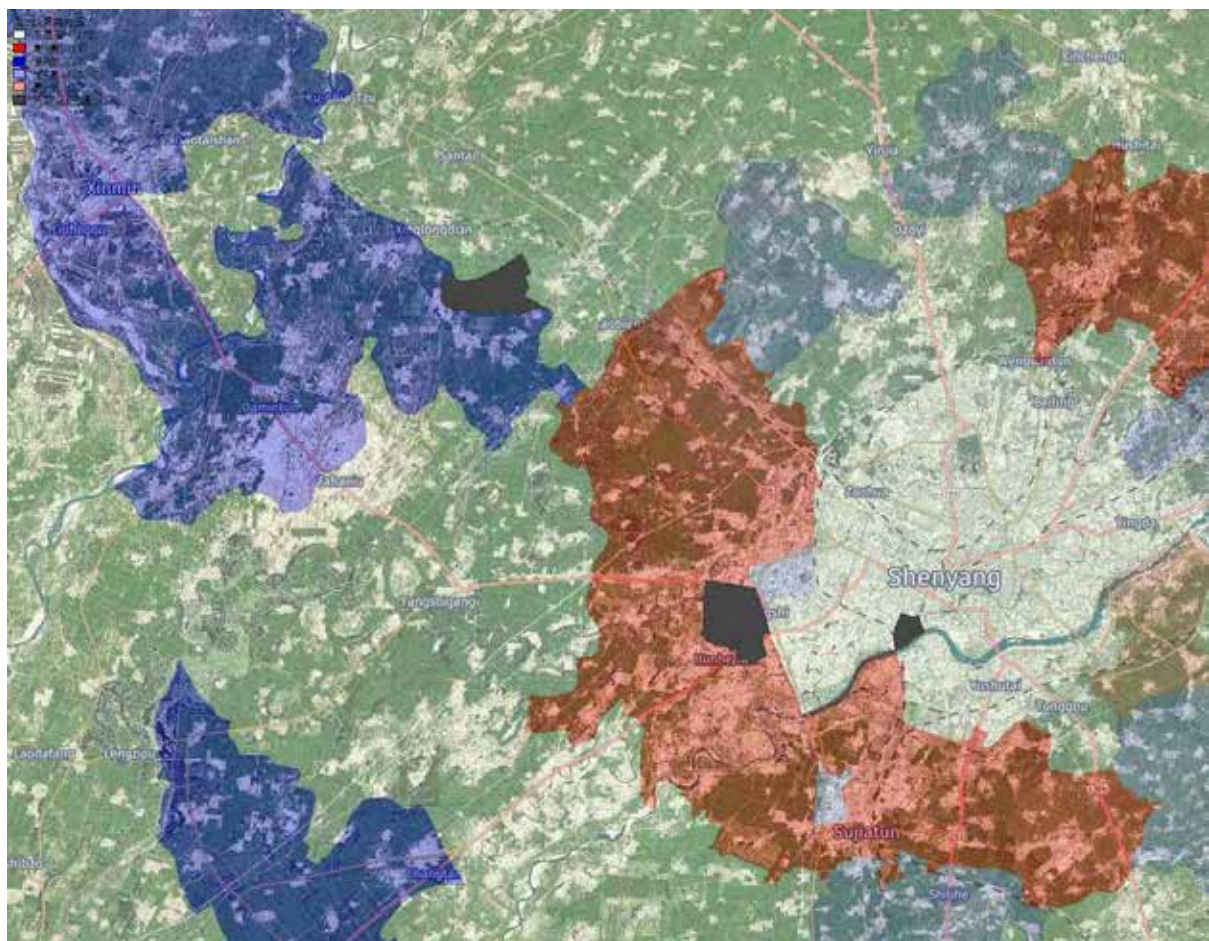

In the LISA clustering map (*pic.9, pic.10*), the

Pic.9 LISA Cluster Map of change of migrants ratio

forms a circle around the urban area, the low-high cluster areas which is composed by attracted districts shows a great increase, so despite the number is growing, they were classified into

significant areas of Xinmin and Liaozhong are completely in the population-loss zone with low-low population clusters, and the population-growth growth zones of high-high clusters in the ring zone are distributed in the southwest half of the outer ring. In the northeast part of Xinchengzi Town (Shenbei New District), the north and south of the ring are two low-high cluster areas, and the high-cluster area is more likely to show the attracted area of the population. In addition, Donghu residential district in Dongling District is the only central gathering area (high-low area), showing the attraction area of the migrant population. Comparing the above observations with the growth rate ratio of the foreign population, there is a similar situation with the change rate of the total population. The region with a higher growth rate of the migrants also

Pic.10 LISA Cluster Map of change of migrants ratio of Urban Area

population-attracted areas in spatial cluster analysis.

2.4 Summary

By comparing the LISA cluster map and spatial distribution of the quantities, it seems that there appears to be a paradox in the index of total population changing ratio and the change of migrants, that is, districts determined shrinking in the LISA cluster map still shows an growth in quantity, which can be defined as a relatively shrinking. This kind of circumstance happens all the time in the process of the analysis, so it is not reliable that identify the growth and shrinkage in cities with the change in value and the synthetic judgement with other index is necessary.

3. Discussion

3.1 Factors of Growth and Shrinkage in the City

In the study of the shrinkage and growth of the inter-city population, a lot of analysis has been done on the causes of the phenomenon of the shrinking, partly because of the stage characteristics of urban development such as globalization, suburbanization and de-industrialization. There are also factors such as the transformation of the state regime, the imbalance of demographic structure, and the side effects of government intervention. However, the reasons for the population shrinking and growing in various districts within the city are obviously different from the research level between cities or regions, and specific analysis is necessary. According to two national censuses in Shenyang, Shenyang City faced the combined effect of the population in the process of urbanization to the large concentration of urban population and the shrinking of the inner-city population at the same time. The period of research in Shenyang is in the decade of China's high-speed urbanization, and the urbanization rate in China has increased from 35.39% to 49.68%, an increase of 14.29%. The rural population migrated to the cities, resulting in the hollowing rural areas. Problems such as aging and population aging, and the expansion of the city's scope has led to a focus on building on the edge of the city, which in turn has caused the population of the inner city to shrink. In the course of the research, although Shenyang City has been found to be facing a severe problem of aging, there has not been a natural decline in population due to imbalances in population structure in countries such as Japan, but associated with the prevalence of minority births and low fertility in the three eastern provinces Shenyang is more likely to face problems such as insufficient population development and lack of labor resources in the foreseeable future.

3.2 Research Prospect

In 2020, the Chinese government is about to announce the seventh national census. Combining with the latest data, the research can study on the changes in the population of Shenyang in the first 20 years of the 21st century more evidentially. In the past ten years, domestic news media have been more pessimistic about the Northeast China region. Shenyang and even the entire three eastern provinces are often come out with keywords such as falling house prices, population loss, aging, and economic downturn. The data of the seventh national census can provide researchers with more accurate information. The source of the data is conducive to in-depth exploration of the demographic changes in the Northeast China, and better feasible strategy can be made. Since 2000, urban renewal is taking the place of urban growth in China gradually, and the shrinkage and growth in city

population must be influenced in a way, this paper just describe the phenomenon of shrinking, and needs a furthermore study of the factor that behind the phenomenon.

A Study on China's County Sports Center Planning Strategy from Smart Shrinkage Perspective

Bin Liang ¹, Yang Wang ²

¹*Xi'an University of Architecture and Technology, 317340482@qq.com*

²*Xi'an University of Architecture and Technology, dayangxauat@163.com, Corresponding author*

Abstract: At the end of 2017, the urbanization rate of China's permanent residents was 58.52%, which has increased by 1.17% over last year. It is expected to exceed 60% by 2020. Rapid urbanization has brought about expansion of large cities and contraction of small and medium cities. Most of counties become population decline areas, which are not suitable for extensive development. Meanwhile, sports facilities in China's counties are extremely lacking. The promotion of sports industry and national fitness policy are imminent. Based on current situation of urban and industry development, this paper points out the problems and misunderstandings of current county sports centers in China, and combines several planning practices to propose the view of “smart shrinkage”. According to the planning and construction of county sports centers, this paper proposes four planning strategies: improving efficiency under shrinkage, intensive scale under precise orientation, function rebuilt under needs and the open and flexible interfaces, intending to guide the development of counties in China and to provide reference for planning and construction of county sports centers.

Keywords: Shrinking County, Smart Shrinkage, County Sports Center, Planning Strategies

1. Introduction

Driven by competitive sports represented by Olympic Games and National Games in recent years, China's sports industry has developed rapidly. The hosting of big events such as the 2008 Beijing Olympic Games, the 2010 Guangzhou Asian Games, the 2013 Liaoning National Games and the 2017 Tianjin National Games led to a construction boom of sports centers. Negative issues were also exposed such as high investment, low utilization and difficult operation. After the reflection of post-Olympic era and the fervent preparation for the 2022 Beijing winter Olympics, the planning and construction of China's sports centers faces new opportunities and choices once again.

For large and medium cities, the planning of new sports centers often follows the principle of “smart growth”, to improve the land exploitation intensity and the output efficiency (Dovey, K., 2012). These sports centers will become catalysts for new developing areas because of their multiple functions and landmark effects. However, for China's 2,856 counties, are in a rapid urbanization process and still developing (Ma, S., and Long, Y., 2018). The condition of counties can't support such extensive development, not to mention the high investment and continuous operation of sports centers. The

strategy of “smart shrinkage” can actively guide land utilization, adapt to the county development trend, and seek the balance between economic input and social benefits (Zhao, M *et al.* 2015). Therefore, author puts forward the smart shrinkage view based on the planning and construction of county sports centers, and carry out a lot of research in order to provide reference for the sports facilities at county level and town level in China.

2. Structural imbalance and planning misunderstandings of county sports centers

2.1. Shrinkage trend of county development

At the end of 2017, the urbanization rate of China's permanent residents was 58.52%, which has increased by 1.17% over last year. It is expected to exceed 60% by 2020. Rapid urbanization has brought about expansion of large and medium cities and shrinkage of countryside (Academic Work Committee of China Urban Planning Society, 2017). But counties are in an embarrassing situation, most of them have become population decline areas. The recession caused by shrinkage is contrary to original purpose of urbanization. The problem is not the shrinkage itself but the methods facing with shrinkage. The construction of large sports centers is obviously not smart, that will overdraw and decentralize limited resources of county under this background. Therefore, it is necessary to form a consensus based on smart shrinkage to adapt to transformation of county economy.

2.2. Unbalanced structure of county sports facilities

Significant achievements of China's sports facilities have been made since new century. However, sports facilities in most of counties are still lacking while total number is growing rapidly, and the quantity, coverage and regional distribution of construction are difficult to meet needs of society. “The Sixth Nationwide Sports Fields Census Data” shows that the number of sports fields in China has reached 1,694,600. Among them, there are 365,983 sports fields in the county, accounting for 22%. The indoor gymnasiums in counties are less than 9%. The rate in towns are even lower, only 5% (General Administration of Sports of China, 2014). The rest are mostly outdoor fields (Figure 1). Compared with the quantity, the quality is also low. They are far from the conditions for organizing sports events or opening to residents. Counties have a sharp contradiction between demand of sports facilities and current conditions.

2.3. Misunderstandings of county sports center planning

For the sports center projects, most governments of counties build for the first time or haven't built for a long time, lacking professional knowledge and construction experience. It is easy to get into blind and luxurious mistakes at the beginning because there is no operational preparation. The excessive standards will increase the cost of construction, operation and even abandonment stage, which will bring continuous burden to local finance. Another situation often facing with is that planning conditions are various and lack accurate correspondence with planning of sports centers, it will result in poor site selection, poor supporting facilities around, poor site conditions and improper scale of site, all of which are negative factors affecting sports center planning.

3. Strategies from the perspective of smart shrinkage

Facing problems and misunderstandings in county sports center planning, author proposes some strategies according to recent projects based on perspective of smart shrinkage.

3.1. Land Use: improving efficiency under shrinkage

3.1.1. Compound development

Traditional sports centers operate on competition economy and related industries. In United States, Europe and some large cities of China, economic returns of sports industry are considerable. However, the county sports centers lack of sports events and population foundation, that can't survive by sports industries. It is necessary to develop multiple functions for sports centers by adding some functions related to residents' life (Thom, M., 2012). For example, the Dongshan County Sports Center in Fujian province, combines cultural functions such as museums, gallery, and theatre to form a culture and sports center that consisted of one stadium and six venues. Meanwhile it connects west an east urban green space to form a city's sports park belt. The Zhongmou County Sports Center in Zhengzhou city merges three gymnasiums in the planning to save land, while adds 42,000m² of commercial spaces

Note	No training track, Complex	No stadium	No stands in stadium	No stands in stadium	Complex

underground as profitable space (Table 1).

3.1.2. Improve utilization efficiency

Different from construction in large cities, the land use and construction scale of county sports center is limited, so we should tighten the layout and shorten the service radius. It takes 2 hectares of land to build a standard athletic track. If you consider some stands and necessary space, that would be at least 3 hectares of land. Meanwhile you must have suitable site on shape and conditions, the cost and scale of land is large for counties. Therefore, the utilization efficiency of land is the key to the success of county sports centers. Table 1 lists planning indicators of several county sports centers. It shows that the land area is mostly in 10-20 hectares, which is also the economic scale of county sports center. According to traditional layout of one stadium and two gymnasiums, we can achieve appropriate plot ratio of about 0.4, but it is difficult to increase training track. In sports center in Tengchong, an attempt is made to plan one stadium and two gymnasiums in mountainous of nearly 10 hectares' site. The density is obviously high that the plot ratio is over 0.7, which affects the quality and usage of outdoor space. Because of limited population and land in counties, priority should be given to building construction, while the outdoor sports fields are less important that can be properly shrunk, without reference to the standard of large or medium sports centers.

3.2. Construction Standard: intensive scale under precise orientation

3.2.1. Reasonable competition level

As most counties lacking of economy, competitions and events support, smart shrinkage should first be considered as decompetition. County sports centers can't host big sports events such as Chinese National Games, Chinese Football Association, Chinese Basketball Association. In a few cases, it can be used as a sub-venue for these events. In "Construction Standards for Public Sports Buildings"(Ministry of construction of China, 2009), competitions hosted by sports centers is classified into special, A, B and C from Olympic Games to local sports games, the level of county sports centers is mostly C-Class or B-Class at most (Table 2). Still take the stadium as an example, Table 3 stipulates relationship between the seats number and urban population. Counties with population less than 200,000 should not build a stadium with more than 10,000 seats, while counties with population less than 500,000 build a stadium of C-Class with 15,000 seats is enough. For small counties, the population should be urban population, because many people are scattered in remote areas that it is difficult to participate in sports, we need to consider the appropriate reduction for this factor. Therefore, it is reasonable that there are no stadium or no stands in some county sports centers such as Xinxian County and Tongbai County.

Table 2 Level of stadium		
Grade	Main events	Seats number
Super	Olympic, FIFA, IAAF World Championships	>60000
Grade A	National and other international competitions	60000-25000
Grade B	Regional and national individual competitions	15000-25000
Grade C	Local and mass sports meetings	5000-15000

Table 3					
Construction scale of stadium according to population					
Area of per seat (m ²) Population	Seats	40000-30000	30000-20000	20000-10000	10000-5000
More than 2 million		1.20-1.25	1.20-1.25	1.10-1.25	1.10-0.80
1-2 million			1.20-1.25	1.10-1.25	1.10-0.80
0.5-1 million				1.10-1.25	1.10-0.80
0.2-0.5 million				1.10-1.25	1.10-0.80
Less than 0.2 million					1.10-0.80

3.2.2. Estimated construction cost

China's county sports centers are in short supply now, especially in the central and western regions. In this case, National Development and Reform Commission of China put forward the overall goal of improving coverage rate of county sports centers, national fitness centers and fitness facilities in the “Implementation Plan of 13th Five-Year Public Sports Popularization Project” (National Development and Reform Commission, 2016). At the beginning of county sports center development, proper understanding of construction standards and costs is guarantee for planning. The cost of Sports buildings is usually estimated by the average cost of seats, but this way is easy to ignore the change of the average cost caused by the increase seats number. If the seats number increases to a certain level, it will cause change in stand form, the building will require a lot of stairs for upper stands, also cause an increase in the span of structure and the area of roof, which leads to a sharp increase in the average cost of the seats (Figure 2)(John, G *et al.* 2017). So, the cost of a stadium with 40,000 seats is far more than two times of one with 20,000 seats. Figure 3 illustrates the average cost of seats in stadium with different number of seats. Choosing an appropriate point on the parabola is the key for government to make decision. For counties, the cost-effectiveness ratio of athletic track and football field is higher than stadium with stands and roofs which should be carefully controlled. The gymnastics have low cost and high utilization rate, so the area can be properly increased. However, it is unnecessary to increase the seats number and diving pools in natatoriums.

3.3. Function planning: function rebuilt under needs

3.3.1. Public fitness function

Including 2021 Shaanxi National Games, there have been eight provinces in China that have hosted this sports event. The participation of whole province benefits the small and medium cities that receive the construction of sports centers. However, current situation in China is that the proportion of large sports center is relatively higher than fitness centers. For the public, small fitness centers are more popular for better participation and flexibility. Those fitness centers should not be the same as traditional stadiums and gymnasiums, but take national fitness as the primary function. In the planning of Tongbai County Sports Center in Nanyang City, Henan Province, we formulated three principles based on the conditions and limitations: Firstly, the park is designed as a national fitness park, adding fitness paths, fitness equipment, open-air fields and other simple facilities; secondly, the old athletic track and gymnasium are completely retained, but reformed the gymnasium into a fitness center;

finally, only a gymnasium and a natatorium are built to save costs. The new two buildings are classified as class-C to serving the public fitness and small competitions. They are designed together and also share some facilities (Table 1). Through above planning measures, with the minimum cost and construction, the fitness conditions for residents have been significantly improved, so that the government and the public get a win-win situation.

Figure 1. Number of venue in China over the years **Figure 3.** Relationship between the number of seats and the average cost of seats in stadium

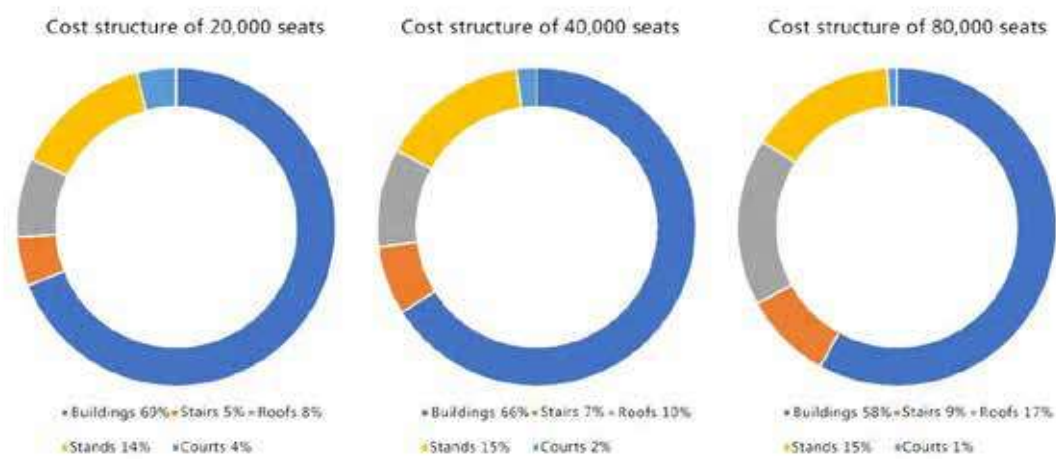

Figure 2. Cost of stadiums with different number of seats

3.3.2 Non-sports function

The county government can not set up sports, culture, media, tourism and other departments separately, instead, a comprehensive bureau is responsible for the operation and management of all those events, creating convenience for the county sports centers to organize activities. Culture, art, commerce, public welfare is highly participatory, which can balance the part of the people and time in sports and form a supplement, which is also a strategy to improve efficiency under the scale shrinkage John, L. K., Philip, E., and Richard, R., 2013). Activities such as commercial performances and exhibition, which are similar with sports in space requirement, can be designed as multifunction; outdoor sport can be combined with sports parks to add entertainment facilities such as outdoor bleachers and theatres, and leave a certain space for temporary facilities as a backup for other temporary events. The Dongshan County Culture and Sports Center will serve as a window to display Guandi Culture and

Minnan Customs after completed, also can be the space for festivals and worships. The Tengchong City Sports Center will also support for cultural activities such as Tengchong Fengma Music and Art Festival and Minority Festival. The sports centers are changing from the traditional “Arena mode” to “Complex mode”, truly becoming the carrier of residents' culture and sports life.

3.4. Continuous operations: open and flexible interfaces

3.4.1. Break up the goal into parts

41.80% of China's sports centers run by public institutions, with redundant personnel structure and weak profitability. And it is easy to leave unused after one-off built, which is not synchronized with regional development. Although the State advocates such modes of operation as "Public Construction and Private Operation" and "Entrusted Management", it is difficult for county to introduce professional operation companies, because counties always lack of geographical and economic advantages. In this case, smart shrinkage is not reflected in the increase of profits but the reduction of operating costs. Smart timing control and building in phases are particularly important. For large projects, one time planning, phased building and flexible strategy can reduce irreversible construction, and operational goals can also be adjusted in the development. The construction of Dongshan County Culture and Sports Center is divided into three phases. In the first phase, a museum and workers' cultural palace are built firstly to meet needs of large festival activities such as the county sports meeting. In the second phase, other gymnasiums will be built to complete the landmark and attract residents. In the third phased, the 20,000 m² platform and other businesses will be built by cooperate with social capital in a long term, after surrounding residential areas developed (Figure 4). Another smart shrinkage is reflected in breaking the whole operational goals into parts to improve operational efficiency and diversity. The planning of Xinyang County National Fitness Center distributes the stadium and two gymnasiums in two blocks. The first two gymnasiums will focus on public service functions such as cultural activities and daily fitness, different from the stadium focusing on large activities and events in the future (Table 1). This strategy can also distract the operational pressure of large sports centers.

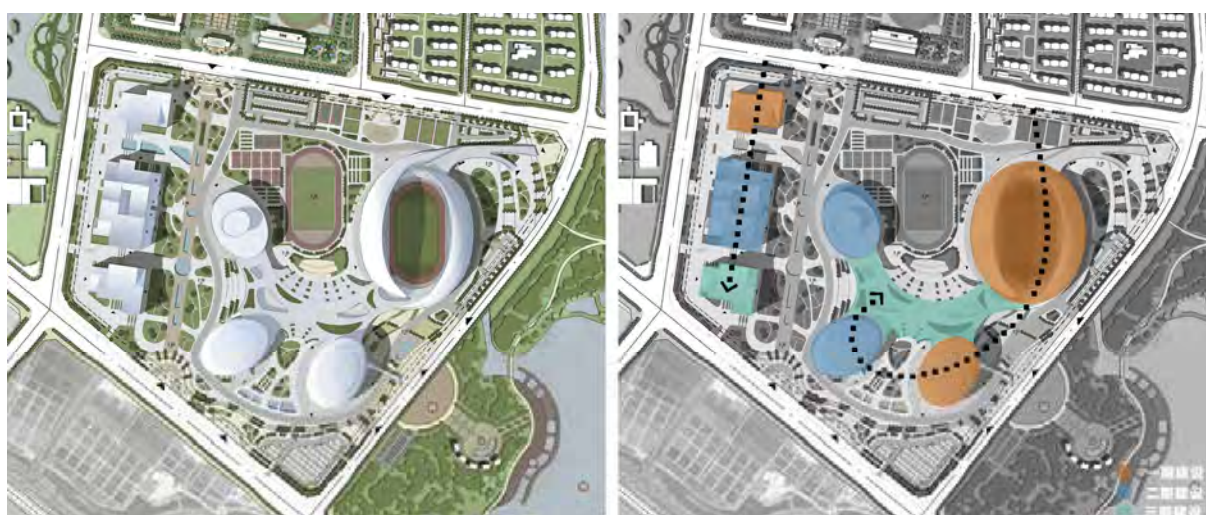

Figure 4. Phased Construction of Dongshan Culture and Sports Center

3.4.2. “Sports +” mode

Blind shrinkage will restrict scale effectiveness of sports centers and lead operation into a alley. Smart shrinkage is also reflected in the focus of performance goals, including the reduction of similar sports functions, the integrating of sports-related industries, and the merger of public services. In order to gather social forces and cross-industry resources to enhance the operation of sports centers, it is necessary to create an open interface of "sports +" for sports centers in planning. "Sports + tourism" is one of the popular models in recent years. Tengchong International Marathon, Mountain Bike Race, Super Mountain Race and other popular sports IP are successful in combination of tourism and sports industry, making the number of tourists increased from 7.5 million in 2015 to 14.14 million in 2017 by nearly 50% per year. The new sports center, which is located face to the Ice and Snow Tourist Town, complements functions and infrastructures each other. By attracting tourists and increasing price, driving great growth of operating income. Another typical model is “sports + training”. Tengchong covers an altitude of about 2000 meters, which is the boundary of the sub-plateau and plateau training base. Huayin Cultural and Sports Center will be built into the largest roller skating base in China. Including the sports center in the high popularity tourist attractions, well-known series events sites, domestic and international competitions, training bases, not only get the benefit of sports, but also the restraint of shrinkage caused by the event-driven economic warming.

4. Conclusions

For a long time, China's county sports centers have been ignored and underestimated due to lack of technical difficulties and major sports events, so they are classified as simple development activities. The meaning of introducing smart shrinkage is that it can help reducing excessive expansion of a single type, unnecessary construction and low value-added projects. By this way, the planning of county sports centers can coincide with regional development. In other words, shrinkage is not an end. It aims to improve efficiency under right scale and makes necessary adjustments on the premise of ensuring quality, fairness and sustainability.

Deindustrialization and urban shrinkage. Achieving urban sustainability in former industrial cities in France: the case studies of Nantes and Saint-Ouen

Varvara Toura¹

¹*Géographie-Cités/Ecole doctorale de l'EHESS, Paris, France, valiatoura@gmail.com*

Abstract: Population decline in former industrial cities is an undeniable fact and preparing to respond to it is a necessity. In my research urban sustainability is defined as a process to recover from social and economic recession which are usually linked to deindustrialization. The main goal is to survey how Nantes and Saint-Ouen became resilient after the period of deindustrialization and if they have the needed capacities of urban sustainability in dealing with population decline. The research method is descriptive-analytic. The descriptive method is used in order to define urban sustainability and relate it to previous studies in shrinking cities. The analytic method is used in order to identify the reasons that led to the population decline and the correlations between sustainable urban development and demographic evolution. The performed analyses included a combination of quantitative and qualitative methods. The outcome revealed that the two cities have reached the goal of sustainable urban development as they almost doubled their population since 2000. The final conclusion is that the urban policies implemented by local authorities as long as the economic decisions taken by local enterprises can assist Nantes and Saint-Ouen inhabitants to encounter to social and economic recession resulting from deindustrialization.

Keywords: shrinking city, population decline, sustainable urban development, urban resilience

Introduction

Urban resilience like sustainable development is a multi-dimensional approach that refers to economic development, social cohesion and environmental protection. In the context of former industrial cities achieving urban resilience seeks to increase the number of city's inhabitants and at the same time develop a new balanced city model. A city is considered as sustainable and resilient when not only achieves the goals of sustainable development, but also when it takes measures against possible crisis (like significant population decline) or, when it is needed, manages crisis that have arisen. The crisis that a city can face include not only the population decline but also issues related to the organization and administration of the city like social cohesion, economic growth and environmental protection.

In this research, the cities of Nantes and Saint-Ouen have been chosen as case studies for their population decline as a consequence of the local deindustrialization. The research tries to survey how the urban resilience policies implemented by local authorities in the two cities contributed to significant population increase especially since 2000. From the municipal archives of the two cities we can see that the closure of local industries in the late 1980's led to a population decline but since the

beginning of projects of urban renewal at neighborhood level in the early 2000's both of the two cities doubled their population. The main goal of this research is to survey how Nantes and Saint-Ouen become resilient after the period of deindustrialization and if they have the needed capacities in dealing with population decline. The two main questions raised in the research are:

- Are the two study areas considered resilient in terms of the criteria adopted in the present study?
- Are the social, economic and environmental capacities of the two study areas in accordance with the needs of the local communities in order to achieve population increase?

Methodology

The method adopted for the research was the descriptive-analytic, in which the descriptive method is used in order to link the current research with previous studies and related literature by searching for common definitions of urban resilience and shrinking city. The correlation between urban resilience and demographic evolution was preformed through an analytic method.

The analysis of the two case studies was performed by using a combination of quantitative and qualitative techniques. The quantitative included the analysis of demographic and economic data taken from the two municipalities and the French national institute for statistics and economic studies. The qualitative included the analysis of interviews with local authorities, inhabitants and the teams of architects and urban planners that participated in the projects of urban renewal of the two case studies. Moreover, criteria have been proposed in order to measure the resilience of Nantes and Saint-Ouen which will be discussed in detail later.

Definitions and concepts

Environmental degradation, social inequalities, economic recession and population decline are among the risks that threaten shrinking cities at international level, resulting in the transformation of their spatial and social identity. The close interactions of these factors affect the organization of cities and for many researchers a way to manage their possible impact is through a systemic approach (De Falco, 2018). In the context of the study we define *shrinking city* as a city which faces population decline due to changing contexts and trends in economy, politics and spatial development that have an impact on urban development at local level (Haase *et al*, 2014).

Several definitions of *urban resilience* are available showing that the notion is multi-dimensional. There are definitions derived from physical sciences (Carpenter *et al*, 2001) while other researchers correlate urban resilience and sustainable development focusing on natural, economic and environmental characteristics of urban systems for effective futures stability (Thornbush *et al*, 2013). In the context of the current study we will adopt the definition of Lu and Stead who define urban resilience as the ability of the city to absorb abnormalities while maintaining function and structure (Lu, Stead, 2013) as the cities we analyze managed to recover population decline and at the same time they preserved their industrial identity.

In the current study we will focus on three dimensions of urban resilience (economic, environmental and social) and also to the correlations between economic and environmental resilience and social resilience and citizen engagement. The question of integrating urban resilience in the procedures of

urban planning is nowadays vital, especially in shrinking cities, even though there are still difficulties in implementing its three dimensions (economic growth, social cohesion, environmental protection) at city level. In the report of World Bank entitled *Ecocities2: Ecological cities as economic cities* we can see the difficulties in integrating the three dimensions identified of urban resilience in the studies of international organizations, but also the possible correlation between economic growth and environmental protection in the procedures of sustainable urban planning (World Bank, 2010).

Economic and environmental dimensions of urban resilience

For many researchers like the French, Lascoumes and Tourraine, the possible correlation between the economic and environmental dimensions of urban resilience is already addressed in French public urban policies (Lascoumes, 2001 and Tourraine, 1999). At international level we can see in many reports published after the Conference of the Parties organized by United Nations in 1992 a possible correlation between the two dimensions of urban resilience in the context of sustainable development (United Nations, 1992). In all these reports we can identify an important point for the current research in French industrial cities which is the impact that have the economic activities in the natural environment and in human living conditions. In the context of French industrial cities we should mention the researches of Jacques Theys who mentions that in order to achieve urban resilience in former industrial cities we must balance the economic growth with the environmental and social issues (Theys, 2000).

The element that interests us from all those theoretical debates in the current research for achieving urban resilience in French industrial cities is how we can implement at city level economic policies, inscribed in the context of dynamic resilience, that respect at the same time the environment and allow it to be reconstructed as in pre-industrial era. We will later focus on the analysis of the economic and environmental dimensions of the urban policies implemented in our two case studies, Nantes and Saint-Ouen, and how these policies contributed to achieving urban resilience at city level.

Social dimension of urban resilience

The social dimension of urban resilience has been examined by researchers across a multitude of academic disciplines as it is a component of community resilience. In the context of the current study we will analyze the notion in a broader context which is the social cohesion in order to identify the correlations between citizen engagement and social resilience. The discussion about engaging citizens in the procedures of urban planning dates back in the 1960's and has its roots in social movements like May 1968 in France (Lefevre, 1968). In the context of urban resilience it is interesting to study how the collaboration between urban planners and citizens in the processes of neighborhood planning contributes to achieving better living conditions for all citizens as a response to social inequalities identified in most cities worldwide and which potentially could lead to social resilience.

At international level the interest to engage citizens in the processes of neighborhood planning starts in 1990 and is linked to preoccupations about environmental protection and urban resilience (Guerard, 2004). We can see in quantitative researches of the era in French industrial cities that there was a significant interest by citizens to participate in community planning as a response to global preoccupations about urban resilience (Rui, 2004). For many French researchers like Hoffman-Martinot and Sorbets the direct participation of groups of citizens in the processes of decision making

at neighborhood level helps to integrate in communities marginalized groups (for example immigrants) and thus achieve social cohesion (Hoffman-Martinot and Sorbets, 2003).

In the context of the research about social resilience the elements that interest us from all those theoretical discussions are the tools and methods used by urban planners and local authorities in order to engage citizens in the processes of neighborhood planning. Another significant point to mention in the analysis of social resilience is the role of professional associations that accompany citizens in the design processes while encouraging marginalized groups like immigrants to actively be involved in these processes.

We will later focus on the social dimension of the urban policies implemented in our two case studies, Nantes and Saint-Ouen, and how these policies contributed to social cohesion and urban resilience at city level.

Process analysis

The analysis and the measurement of the urban resilience of Nantes and Saint-Ouen follow the steps mentioned in Figure 1. In the first step of the study we identified several indicators through our empirical research in the two cities (personal observations, data from interviews) that could potentially lead to urban resilience if appropriate urban policies are implemented at city level. In the second step of the current study we defined several criteria in order to analyze and evaluate the three dimensions of urban resilience that we previously mentioned based on the indicators identified through the empirical research. In the third step, according to these criteria we evaluated whether the two cities accomplish them or not from a scale rated 0% (none urban resilience policy implemented at city level) to 100% (resilient city). In the context of the study we assume that each criteria has the same level of importance in measuring the urban resilience of Nantes and Saint-Ouen.

Figure 1. The steps of process analysis and evaluation of urban resilience in Nantes and Saint-Ouen

Indicators and criteria of measurement of urban resilience

The multi-dimensional notion of urban resilience (economic, environmental, social) made essential to consider all these dimensions and citizen engagement, as social capital is associated with social resilience, in order to define the criteria of measurement of urban resilience in Nantes and Saint-Ouen. From the empirical research in the two cities we identified several indicators for measuring urban resilience, focusing on the study of urban projects at different levels (macro and micro). At macro level, urban renewal projects in former industrial sites due to their strategic position (high-density areas usually at the core of cities) allow urban planners to propose new economic activities and land uses in order to reconvert these sites and thus lead to economic resilience through their reconstruction.

At micro level, public spaces (parks, squares, play areas, libraries, cultural centers) are the places where people of different ethnic groups meet and create social relations.

The same indicators are used in other models of measuring urban resilience like Sustainable Livelihood Framework (Department for International Development, 2000) and City Resilience Framework (Arup, 2015). The combination of these models allows us to measure urban resilience in cities facing population decline. In Sustainable Livelihood Framework, *resilience* is defined as the recovery of an urban system from stresses and shocks while maintaining its capabilities and assets both now and in the future. In City Resilience Framework, *resilience* is defined as the capacity of cities to function so that the people living and working in them survive no matter what stresses they encounter. In our case studies of Nantes and Saint-Ouen the definition of urban resilience provided in City Resilience Framework becomes conceptually relevant as sudden shocks, like the closure of industrial units, threaten the collapse of the social tissue. According to these models the identified indicators are organized in three categories which consist the defined criteria for measuring the urban resilience in Nantes and Saint-Ouen. They are briefly presented in Table 1.

The *economic dimension* of resilience refers on one hand to the ability of a system to limit the magnitude of immediate losses and on the other hand to the ability to reconstruct and recover. In this context we identified for our study four indicators.

- *Unemployment rate.* This indicator implies the correlation of professional activity with economic prosperity of a community. In the context of our study the high unemployment rate that the two cities had in the early 1990's led to their population decline. For the qualification of the two case studies as economic resilient cities, we compare their unemployment rate with the French national one in order to underline the good policies implemented at local level.
- *Research and cultural centers.* Combination of expert and common knowledge allows the exchange of data and information that could potentially lead to the solution of collective problems. Both of these indicators in the French context contribute to the creation of new working positions (researchers, art curators), especially in medium size cities and lead to the reduction of unemployment rate.
- *Industrial units.* The case studies of the current study are former industrial cities and it is reasonable to examine if industrial activity continues after their deindustrialization era. The industrial activity is directly linked with economic prosperity of these cities as most of their inhabitants work on this field.
- *Commercial centers.* In the French context this indicator usually refers to a greater scale of that of a city, (intercommunalité) which includes a network of cities whose inhabitants visit commercial centers in a weekly basis for leisure or shopping. This indicator could also be considered as a parameter of social resilience but in the current study we will focus on its ability to bring economic prosperity to a city.

The *environmental dimension* of resilience refers to the capacity of a system to absorb disturbance and reorganize while undergoing change. In this context we identified for our study four indicators.

- *Green spaces in the city.* In the context of our study we are interested to focus on the possible correlation between economic and environmental resilience as in France the presence of green spaces in the city is a parameter to attract people with high incomes.
- *Rehabilitation projects.* This indicator refers to the ability of reversibility of a city in order to be prepared for the needs of its inhabitants in the present and in the future. Spatial reversibility contributes to the reduction of the ecological footprint of a city as the need to construct new buildings is covered by the rehabilitation of old buildings.
- *Sustainable urban projects.* Sustainability in the new urban projects of a city is a complementary parameter to rehabilitation projects as both contribute to the reduction of the ecological footprint of a city. It mainly refers to the use of eco-friendly materials to the new constructions but also to the form of the buildings.
- *Public urban transport.* This indicator refers on one hand to the accessibility of urban space by all users, especially the weak ones (elderly, children, user with mobility impairments) and on the other hand to the quality of cities' environment through the reduction of air pollution.

The *social dimension* of resilience refers to the capacity of people and communities to deal with external stresses and shocks focusing on community preparedness as a response to internal or external risks. In this context we identified for our study three indicators.

- *Urban projects with citizen participation.* This indicator refers to the ability of a city to generate social capital based on its inhabitants' needs. Social interactions especially on issues as urban design projects facilitate information sharing and collaboration.
- *Social houses.* A typical parameter of measuring social resilience in France is the number of social houses of a city. According to French legislation the percentage of social houses of a city has to be at least 20% of the total amount of houses that exist in the city (Loi relative à la solidarité et au renouvellement urbains, 2000, article 55). For the qualification of the two case studies as social resilient cities, we compare their percentage with the minimum percentage demanded by French legislation.
- *Racial and ethnic diversity.* The presence in a city of people with different racial or ethnic origins is a means of social inclusion as it ensures that each individual will have access to the goods produced in a city. In order to qualify the two case studies of the current research as social resilient cities we compare their percentage of foreign-born inhabitants with the French national percentage. We should mention that a law from 1872 (Bleich, 2001) prohibits the French Republic from conducting census by making any officialized distinction between its citizens in terms of race or religious beliefs. In the context of our study we used the national percentage of foreign-born population for France published in the database of the Organization for Economic Co-operation and Development (Organization for Economic Co-operation and Development (OECD),2018).

Criteria	Indicators
Economic dimension	Unemployment rate (\leq French national unemployment rate) Research and cultural centers Industrial units Commercial centers
Environmental dimension	Green spaces in the city Rehabilitation projects Sustainable urban projects Public urban transport (bus, tramway, subway)
Social dimension	Urban projects with citizen participation Social houses ($\geq 20\%$ demanded by French legislation in every town) Racial and ethnic diversity ($\geq 12\%$: estimated percentage by OECD for foreign-born population in France)

Table 1. Criteria and indicators defined in the current study for measuring the different dimensions of urban resilience

Case studies

Nantes is located in the west of France with an area of about 6500 hectares. Its population in 2017 was about 300000 inhabitants. Nantes, which is known for its projects of urban renewal as Ile-de-Nantes as we can see in Figures 2 and 3, was chosen as a case study due to the significant population decline that faced after the closure of the local industries in the late 1980's.

The second case study Saint-Ouen is a city in the Seine-Saint-Denis department. It is located in the northern suburbs of Paris with an area of about 430 hectares. Its population in 2017 was about 90000 inhabitants. Saint-Ouen, which is known for its industrial activities since 19th century, faced as Nantes a significant population decline in the late 1980's due to the departure of local industries in the

periphery of the city. Nowadays, the city is known for its projects of urban renewal as the Docks-de-Seine as we can see in Figures 4 and 5 that started since 2005.

The two case studies chosen show a different vision of the issue of urban resilience policies as they were not implemented at the same period. In the current research we won't compare the urban resilience policies of the two cities but instead we will present them in a chronological sequence, starting from Nantes where urban resilience policies were implemented first, in order to understand the evolution of the notion of urban resilience in French industrial cities.

Figures 2 and 3. Case study I: Nantes

Figures 4 and 5. Case study II: Saint-Ouen

Nantes dealing with population decline

The history of Nantes is linked with its industrial past. In the 1950's the two most important industrial sectors were the naval constructions and the agribusiness. In the 1960's the industrial activities expanded and many enterprises moved in the periphery of the city. The end of the industrial era of Nantes is marked by the closure of shipyards in Ile-de-Nantes in 1987, which had as a result a significant decline in its population in the early 1990's as we can see in Figure 6 (Institut national de la statistique et des études économiques (INSEE), 2018a). According to the definition of shrinking city that we gave previously Nantes was a shrinking city in the 1990's as the changes in its economic model and its spatial development had an impact on its demographic evolution.

Figure 6. Demographic evolution in Nantes from 1968 to 2017

In this context the municipality of Nantes decided in the early 1990's to integrate former industrial sites in its projects of urban renewal as a policy to control population decline (Comité d'information et de Liaison pour l'Archéologie, l'Etude et la Mise en Valeur du Patrimoine Industriel (CILAC), 2006). The most famous of these projects is the project of urban renewal of the former industrial site Ile-de-Nantes. The new economic model proposed for the site of Ile-de-Nantes reflects the local authorities' vision of urban resilience as it is based in the reconstruction of the economic tissue while at the same time the environmental dimension of urban resilience is achieved through the recovery of the natural elements. We can identify in the strategic plan of the city indicators, that we use in our study to measure the urban resilience of Nantes, like the research institutes and the cultural institutions (Ville de Nantes, 2009), most of which are located in former industrial buildings (indicator: rehabilitation projects) as a means to reduce the ecological footprint of the city due to the construction of new buildings. At the same time the local authorities together with the civil society and the local business owners are interested in achieving environmental resilience through the increase of city's green spaces and the use of eco-friendly construction materials in new buildings (indicator: sustainable urban projects) (Société d'Aménagement de la Métropole Ouest-Atlantique (SAMOA), 2008).

We can also identify indicators in order to measure the social dimension of the urban resilience of Nantes mainly through participatory design processes of public spaces. In this context the municipality of Nantes accompanied citizens to create associations in every neighborhood which would collaborate with the teams of urban planners and architects (Agence d'urbanisme de la région nantaise (AURAN), 2012). Another indicator of social resilience identified both in the strategic plan of the city of Nantes (Ville de Nantes, 2009) and of the region of Nantes/Saint-Nazaire (Nantes/Saint-Nazaire, 2016) was the obligatory construction in every neighborhood of social houses as a means to strengthen social cohesion.

Measuring urban resilience in Nantes

According to the criteria and indicators that we defined for the current study, we used the data that we collected from the archives of the municipality and from the empirical research in urban renewal projects and projects of public spaces in order to measure the urban resilience of Nantes as we can see in Table 2. From *economic* point of view the lower unemployment rate compared to French national one as long as the presence of research, cultural and commercial centers inside the city limits contribute to the economic prosperity of the city through the creation of new working positions. From *environmental* point of view the increase of city's green spaces through the construction of parks, the

rehabilitation of former industrial buildings combined with the construction of new buildings based on the principles of sustainable architecture as long as the presence of a high quality network of public urban transport contribute to the reduction of city's ecological footprint. From *social* point of view, even though the percentage of foreign-born inhabitants is below the limit that we defined in the current study, citizen participation in urban projects with the support of the local authorities as long as the percentage of social houses which is higher compared to the one defined by French legislation contribute to social cohesion.

Economic	Unemployment rate	√ 9,4(French national:10,2)
	Research and cultural centers	√ Hangar 13, Cité des chantiers
	Industrial units	× Exist only in the periphery of the city
	Commercial centers	√ Centre commercial Beaulieu
Environmental	Green spaces in the city	√ Park of the Nefs de la Loire
	Rehabilitation projects	√ Foyer des jeunes travailleurs
	Sustainable urban projects	√ Tripode sector
	Public urban transport (bus, tramway, subway)	√ Tramway:3 lines, buses, Navibus (river shuttle): 2 lines
Social	Urban projects with citizen participation	√ Ma ville demain, Ilotopia
	Social houses	√ 25,09% of the city's houses
	Racial and ethnic diversity	×8% of city's inhabitants have a foreign nationality

Table 2. Nantes: Check list of indicators for measuring the different dimensions of urban resilience

Saint-Ouen dealing with population decline

Saint-Ouen is directly linked with the industrial activities as there was constructed in 1856 a railway station in order to transport goods in Paris. At the beginning of the nineteenth century the two most important industrial sectors were the energy production and the electricity. The end of the industrial era of Saint-Ouen is dated at the late 1980's, even though certain industrial activities as the energy production and the waste treatment still exist, which had as a result a significant decline in its population as we can see in Figure 7 (INSEE, 2018b). Saint-Ouen was a shrinking city at the early 1990's due to the changes in its economic model and its spatial development which had an impact on its demographic evolution.

Figure 7. Demographic evolution in Saint-Ouen from 1968 to 2017

The departure of the factories of Total in 2003 and Alstom in 2004 in the periphery of the city left inactive two significant industrial sites near the river Seine and led the municipality of Saint-Ouen to the decision to integrate former industrial sites in its projects of urban renewal as a policy to control population decline (D'Orso, 2014). The most famous of these projects is the project of urban renewal of the former industrial site the Docks-de-Seine. The new economic model proposed for the site of Docks-de-Seine is based on the local authorities' vision to create a resilient and sustainable city both in economic and environmental terms as it reconstructs the economic tissue and contributes to the recovery of the natural elements. The project is also part of the strategic plan of Grand Paris, a project of urban renewal at greater municipality level that includes the city of Paris and its suburbs. We can identify in the strategic plan of the city indicators, that we use in our study to measure the urban resilience of Saint-Ouen, as the industrial units combined with commercial and cultural buildings (Ville de Saint-Ouen, 2008). Most of these activities are located in former industrial buildings (indicator: rehabilitation projects) or in new buildings that follow the guidelines of sustainable architecture (indicator: sustainable urban projects) as a means to reduce the ecological footprint of the city. The economic resilience is combined with the interest of the local authorities and the civil society in achieving environmental resilience through the increase of city's green spaces and the use of green roofs and walls in new buildings (Agence Parisienne d'Urbanisme (APUR), 2006).

We can identify indicators to measure the social dimension of urban resilience of Saint-Ouen mainly through participatory design processes of public spaces. In this context the municipality of Saint-Ouen followed the example of other municipalities in France and accompanied citizens to create associations which would collaborate with the teams of urban planners and architects (Ville de Saint-Ouen, 2016) as they could potentially lead to social resilience due to their capacity to deal with social discriminations. We can identify in this case study another indicator of social resilience both in the strategic plan of the city of Saint-Ouen (Ville de Saint-Ouen, 2008) and of Grand Paris (Plaine Commune, 2014) which is the obligatory construction of social houses in every neighborhood as a means to strengthen social cohesion.

Measuring urban resilience in Saint-Ouen

According to the data that we collected from the archives of the municipality and from the empirical research in urban renewal projects and projects of public spaces we reached the following results summarized in Table 3. From *economic* point of view, even though the unemployment rate is higher

compared to French national one, the presence of industrial and commercial centers inside the city limits as long as the future construction of research and cultural centers (campus hospitalo-universitaire Grand Paris Nord) contribute to the economic prosperity of the city through its productivity and attractiveness. From *environmental* point of view the increase of city's green spaces through the construction of large scale parks, the rehabilitation of former industrial buildings combined with sustainable urban design policies at neighborhood level as long as the accessibility of the city by public urban transport contribute to the improvement of environment quality. From *social* point of view, the higher percentage of foreign-born inhabitants compared to the limit that we defined in the current study, citizen participation in urban projects with the collaboration of local authorities and teams of architects and urban planners as long as the percentage of social houses which is higher compared to the one defined by French legislation contribute to social inclusion and knowledge sharing.

Economic	Unemployment rate	× 15,4(French national:10,2)
	Research and cultural centers	× Haven't been constructed yet
	Industrial units	√ Big energy pole
	Commercial centers	√ Le Cours des Docks
Environmental	Green spaces in the city	√ Park of the Docks
	Rehabilitation projects	√ Halle Alstom
	Sustainable urban projects	√ Dhalenne sector
	Public urban transport (bus, tramway, subway)	√ Metro lines 13,14, RER C, buses
Social	Urban projects with citizen participation	√ Community gardens
	Social houses	√ 25% of the city's houses
	Racial and ethnic diversity	√ 25,5% of city's inhabitants have a foreign nationality

Table 3. Saint-Ouen: Check list of indicators for measuring the different dimensions of urban resilience

Findings

The findings that emerged from the analysis of the two case studies are presented in Table 4. The last row reports the percentages of each case study related to the indicators that we used in the current study to measure their urban resilience. According to the criteria of the study both of the case studies cannot be evaluated as resilient cities as their percentage is lower to 100% (81,81% both for Nantes and Saint-Ouen) that we considered to be the indication for an urban resilient city. In the case study of

Nantes, with the exception of the social dimension of urban resilience, we can note good performances in the other two dimensions, which show the correlation between economic development and environmental protection. In the case study of Saint-Ouen, with the exception of the economic dimension (the department of Seine-Saint-Denis where Saint-Ouen is located is among the poorest in France), we can note good performances in the other two dimensions especially in social as the goal of the local municipality is to achieve social cohesion.

	Social houses	√	√
	Racial and ethnic diversity	×	√
%	81,81%		81,81%

Table 4. Summary of check list analysis for measuring urban resilience of both case studies

The analysis of the two case studies brings out some remarks about the correlation between the social, economic and environmental capacities of the two study areas for achieving population increase. A general remark concerns the role of local components (citizens associations, municipalities, enterprises, individuals) and their capacity to collaborate in order to create resilient cities. In the context of former industrial cities the activation of local social capital, as we can see in Tables 5 and 6, contributes to develop synergies (private-public sector) leading to economic prosperity. Economic prosperity and social inclusion are the key issues that we obtained from the empirical research in the two case studies as indicators to attract new inhabitants to the cities. It is important to mention that in Nantes citizens are engaged in all phases of the planning processes from consultation to management of urban renewal and public spaces projects, showing that urban resilience has its roots in the development of new practices and tools. In Saint-Ouen the local municipality insisted in the creation

of a citizens' association in order to become the inhabitants responsible for the development of their city.

1. Inhabitants of Nantes
2. Citizens' associations
3. Groups of architects and urban planners (Alexandre Chemetoff, Marcel Smets, Uaps, Jacqueline Osty, Claire Schorter)
4. Group of project management (SAMOA)
5. Local authorities (Ville de Nantes, Nantes Métropole)

1. Inhabitants of Saint-Ouen
2. Citizens' association <i>Mon Voisin des Docks</i>
3. Group of architects and urban planners (Anne Rieth de Jonghe, Alain Pasty et Francis Vary)
4. Group of project management (SEQUANO Aménagement)
5. Local authorities (Ville de Saint-Ouen, Plaine Commune)

Table 6. Actors implicated in the participatory design processes in Saint-Ouen

The economic dimension of urban resilience

As we can see in Table 7 the economic feature is considered to be by the two local communities as a key criteria in order to achieve population increase. The conversion from abandoned area to economic prosperous city shows the ability of local community to recover from a serious crisis and to limit the magnitude of immediate losses (in our case studies the closure of industrial units). In Nantes, former industrial sites like Ile-de-Nantes underused for many years were transformed in spaces where research, cultural and commercial centers are now located contributing to the reduction of the unemployment rate. In Saint-Ouen the transformation of former industrial sites like the Docks-de-Seine with an emphasis on the city's history of industrial activities contributed to a progressive

reduction of the unemployment rate. It is important to mention that the increase in cities' population had an impact on their social identity as the new inhabitants mostly work in research institutes or are senior executives and are not industrial workers (INSEE, 2014a and 2014b). In the context of the current study we show the transformation of the cities' social identity by using Tables 8 and 9 published by the French national institute for statistics and economic studies every five years for the professional activities in French cities.

Nantes			Saint-Ouen
Economic	Unemployment rate	√	×
	Research and cultural centers	√	×
	Industrial units	×	√
	Commercial centers	√	√

Industrial workers	5571	5115

Table 9. Number of working positions in 5 categories in Saint-Ouen (data 2009 and 2014)

The environmental dimension of urban resilience

Urban renewal and public space projects have a positive effect on urban environment and on quality of the surrounding landscape as we can see in Table 10. In both case studies the cities' relation with the rivers that surround them was improved through the construction of large scale parks alongside Loire and Seine. Another remark is that the quality of local landscape was enhanced through the urban mobility policies and the use of eco-friendly materials in new buildings.

		Nantes	Saint-Ouen
Environmental	Green spaces in the city	√	√
	Rehabilitation projects	√	√
	Sustainable urban projects	√	√
	Public urban transport (bus, tramway, subway)	√	√
%	100%		100%

Table 10. Check list analysis for measuring environmental resilience in both case studies

The social dimension of urban resilience

The exchanges of information and knowledge between experts and citizens as long as the development of new skills show the ability of local communities to find solutions for collective problems. At the same time social and ethnic diversity can adapt the space to the different needs of its users. As seen in Table 11 in both case studies we observe collaborations between the teams of urban practitioners and citizens' associations as long as a significant percentage of social houses that reflect the local authorities vision to create inclusive and resilient cities. It is important to comment that in the case study of Nantes, even though the percentage of racial and ethnic diversity is lower to the limit of the current study, the number of foreign-born inhabitants which was stable for almost fifteen years (1990 to 2005, number of foreign-born inhabitants: 6%) has increased due to the economic prosperity of the city.

	Social houses	√	√
	Racial and ethnic diversity	×	√
%	66,66%		100%

Table 11. Check list analysis for measuring social resilience in both case studies

Discussion and conclusions

The research shows that urban resilience policies can achieve population increase in shrinking cities. Through the mobilization of local actors, urban resilience policies become solutions to adapt the urban space to different needs and crisis situations. They can also act as opportunities to experiment new urban planning techniques and to share knowledge by the meeting of different cultures and social classes. The evolution and the transformations of French industrial cities help us to understand the different aspects of cities' interface, where each one of the elements that consist their urban tissue interacts with the others in a direct or indirect way. The new participatory design processes reflect a different vision of urban resilience as the citizens become true social actors who decide about their living and working conditions and don't depend on political decisions usually taken at national level and not at the level of the city. As a final conclusion of the study we should mention that the transformation of shrinking cities in France is on the one hand the result of urban planning policies designed at local level by the local authorities and the inhabitants and on the other hand of programs of urban resilience planned at national or international level (for example the international program *100 resilient cities*). For these reasons the research will have to investigate the interactions between the policies adopted at national and international level and how to transfer good urban resilience policies, especially social capital, from one country to another.

Discussion on the factors of sustainable urban growth in shrinking region: Case study of Eucalyptus Hills in the city of Sakura developed by the private developer Yamaman

Tetsuji UEMURA¹

¹*Nomura Research Institute*

Abstract: There are many previous studies discussing the issues and solutions of shrinking cities, but only a few studies have discussed the sustainable development of shrinking cities. This study focuses on the case of the Eucalyptus Hills development by Yamaman, its private developer, known as a best practice sustainable development of new towns in the city of Sakura in the Tokyo suburb in Japan. The study reviews the recognised aspects and features of the Eucalyptus Hills development as sustainable development by Japanese researchers and aims to abstract the implications for sustainable developments in shrinking cities. As the results, three features, namely, the existence of a mono-developer (town manager), a certain size of population to support living services business and a well-balanced demographic composition, can be considered as the conditions required for sustainable development in shrinking cities. These research results may be applied for dormitory towns in the suburbs of megacities, with sufficient job opportunities for such towns.

Keywords: Shrinking cities, Sustainability, Eucalyptus Hills, Yamaman

I. Introduction

1. Background

Not only in Germany, France and the United States, but also in Japan, there have been many studies on shrinking cities (Adhya, 2017; Baur et al., 2006; Fujii, 2013; Hollander, 2018; Oswalt, 2005; Pallagst et al., 2014; Richardson and CHang Woon, 2014; Ryan, 2012; Yahagi, 2014). There are various patterns of shrinkage in the cities, and one study categorised shrinking cities as having three types: “continuous”, “episodic”, and “temporary”, from the demographic change perspective (Wolff, 2018; Wolff and Wiechmann, 2017).

Generally, population decline is a premise in the discussion of shrinking cities. Most of the research interest is not on adaptation and mitigation of population decline, but on reviving or regenerating urban areas. On the other hand, there is much discussion on sustainable urban developments, including on sustainable urban resource usage and reducing environmental burdens (Cohen, 2017; Flint and Raco, 2012; Moore, 2007). It is very curious that there is such limited previous research discussing the sustainable development of shrinking cities, apart from discussion from a space planning perspective (Ganser and Piro, 2012) and sustainable urban space planning methodology for both urban growth and shrinkage from a spatial planning perspective (Wang and Fukuda, 2019).

What is sustainable urban development specifically? Is it the situation in which urban space with a certain density of urban activity can be sustained in the future? Can these cities be called “shrinking cities”?

The general definition of sustainability or sustainable development is to maintain or to improve the per capita supply or quality of elements in society, the economy and the environment, as triple bottom lines (Elkington, 1998; Hediger, 2000; Neumayer, 2003; Pearce and Atkinson, 1993; World Commission on Environment and Development, United Nations, 1987). In the context of shrinking cities, the situation in which the living quality per capita from social, economic and environmental perspectives is maintained and improved by the degeneracy of the city function and controlling the occurrence of nuisance through urban decline can be described as “sustainable”. However, these general definitions do not provide sufficient knowledge for the appraisal of the validity or special planning of specific development actions for sustainable development in shrinking cities.

In Japan, we have the best practice which most experts agree can lead to successful town development in shrinking cities. This is the Eucalyptus Hills development by Yamaman¹. Normally, typical Japanese dormitory town developments are called “withdrawal type developments”, in which the developer will sell out all the plots in the short term, but the Eucalyptus Hills development is called a “growth management type development”, where the developer will continue to sell plots for a long time, such as over more than 30/40 years (Yamaguchi, 2016). The Eucalyptus Hills case is very well-known practice and many researchers, including the senior director of Yamaman, have already introduced its approach from various aspects (Goda, 2011; Hayashi, 2014, 2013; Iwashina, 2012; Katagiri, 2009; Koutani, 2014; Yamaguchi, 2016). These discussions do not necessarily follow the general definition of sustainability, but their results may have elements of sustainable development in shrinking cities.

2. Aim

This study reviews the case of the Eucalyptus Hills development by Yamaman and the elements that are recognized as success factors by other researchers. Also, this study determines the features of the Eucalyptus Hills development and abstracts the general implications for sustainable development in shrinking cities.

¹ <https://www.yamaman.co.jp/>

II. Methodology

1. Research framework

In this study, 5 axes – demographic change, social aspects, economic aspects, environmental aspects and time frame – are set as a framework to analyze the development activities carried out by Yamaman.

2. Methods

1) Literature study

The literature survey was conducted in NDL-OPAC² and CINII³ using the keyword “Eucalyptus Hills”. Also, the keywords “Eucalyptus Hills” and “sustainability” are used for Google and Google Scholar searches to collect presentations, blogs and published reports.

2) Desktop study

Mainly, the Yamaman corporate website⁴ is checked for the desktop study. Also, information on the population to be supported by living support services are collected as supplementary information.

3) GIS data analysis

GIS data from the National Land Numerical Information download service⁵ and Statistics Bureau, Ministry of Internal Affairs and Communications⁶ are used for spatial analysis.

4) Statistics

The national population census, population statistics for the city of Sakura, and corporate financial data of Yamaman are used as statistics.

III. Results

1. Case study area and company

1) City of Sakura

Eucalyptus Hills is located in the city of Sakura, which is in the Kanto region and 40 km from Tokyo Central Station. It is located between Tokyo and Narita airport, and the highway, Japan Railway (JR) and Keisei Electric Railway line between Tokyo and Narita pass through the city. In particular, the Keisei line has a station at Eucalyptus Hills although only local trains call at the station. Therefore, Eucalyptus Hills is one of the dormitory towns for Tokyo Metropolitan Area.

Source: National Land Numerical Information Administrative Zones Data and OpenStreetMap

Figure 1 Location of Eucalyptus Hills in the city of Sakura in Japan

In the city of Sakura, the population was growing until 2000, but it has become stable since 2000. The population in the city peaked at 177,411 in 2015 and is 175,476 as of 31st March, 2019, which means a 1.1 % population loss in four years (Figure 2).

Source : The City of Sakura

Figure 2 Population trend in the city of Sakura from 1989 to 2019

In contrast to the population, the number of households has continuously increased from 1989 to 2019. As of 31st March, 2019, the number is 77,645 (Figure 3). This means that the size of a household (the population in one household) is declining continuously.

Source : The City of Sakura

Figure 3 Trend of number of households in the city of Sakura from 1989 to 2019

2) Yukarigaoka (Eucalyptus Hills)

The objective development areas include 1 chome (district) -6 chome of Miyanodai, 1 chome-7 chome of Eucalyptus Hills, Minami Eucalyptus and 1 chome-7 chome of Nishi Eucalyptus. These areas are called shrinking cities.

Eucalyptus Hills has been developed by Yamaman since 1971. Yamaman acquired land in 1971, cleared it and started construction in 1977, starting to sell houses in 1979. Its developed area is 245 ha, the target number of houses was 8400, the planned population was 30,000, and the planned number of annual house sales was 200⁷. The calculated development period was 42 years and the planned completion year was 2022. The targeted population of 30,000 was set from the administrative rule that it can be an administrative unit called a city in Japan if there is a population of at least 30,000; the population size in Letchworth in the UK as a representative new town was 32,000 (Hayashi, 2013).

As of April 2019, 18,697 people and 7600 households live there. The progress rate of households taking up residence is 90.5% and the population is 62.3% (Figure 4). The reason for the difference between the progress rate of households and the population is the decline in the size of households. In the plan, the size of households was considered as 3.57 people/household, but the actual number is 2.46 people/household (as of April 2019). Also, the speed of increase in the number per household is less than the annual supply of 200 houses in the plan (maximum 300 houses if the skyscraper tower apartment rooms are provided) (Hayashi, 2013) recently, and the development speed is also slowing down (Figure 4).

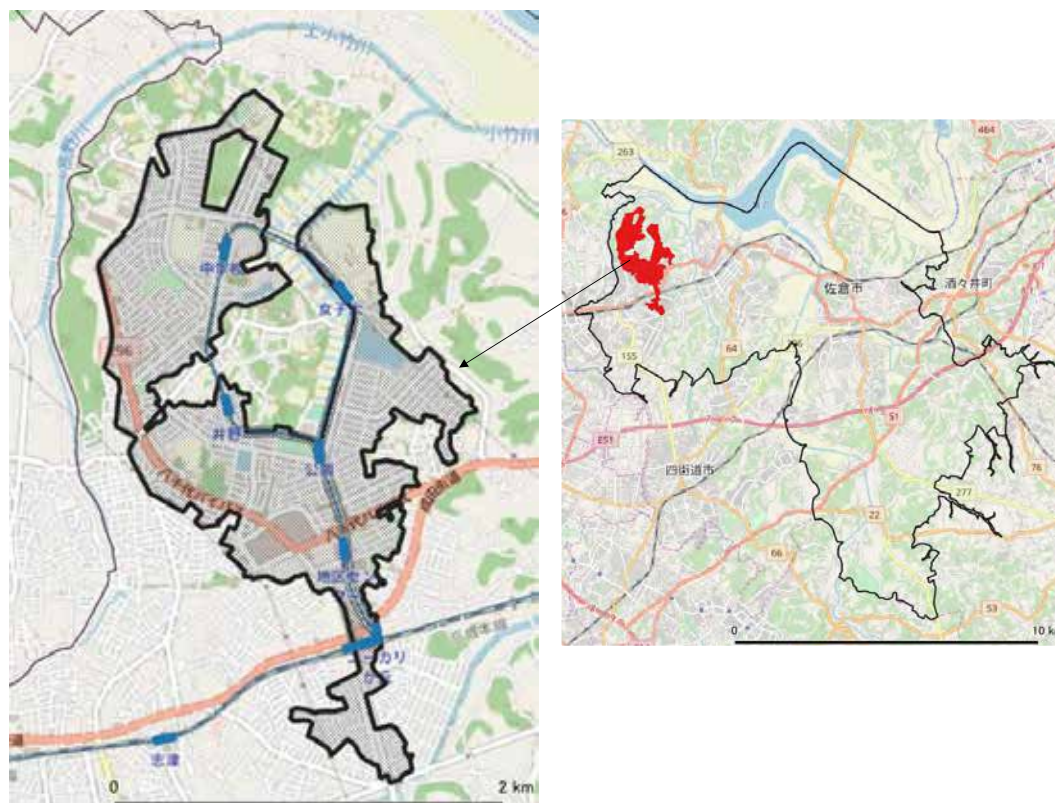

Source: (Hayashi, 2013) and Yamaman website

Figure 4 Goal and progress of the development of Eucalyptus Hills

Eucalyptus Hills is located on the nearside of Tokyo in the city of Sakura and is 7 km from the city centre of Sakura where the city hall is. Eucalyptus Hills is also located in between Makuhari Messe (convention hall area) and Narita International Airport (Hayashi, 2013). Keisei Electric Railway line connects Makuhari Messe, Eucalyptus and Narita airport as well as Haneda airport to each other.

⁷ Step-by-step sale system (Goda, 2011)

Eucalyptus Hills is spread along the Yamaman Eucalyptus line⁸ in a doughnut shape, starting from the Eucalyptus Hills station on the Keisei Line (Figure 5). The centre hole is the original settlements and some woodland and rice paddies still remain next to the developed land. They are outside Eucalyptus Hills.

Source: National Land Numerical Information Administrative Zones Data, Statistics Bureau, Ministry of Internal Affairs and Telecommunications small district boundary data for 2015 National Population Census⁹ and OpenStreetMap

Figure 5 Location of Eucalyptus Hills

Eucalyptus Hills is being developed as a dormitory town for Tokyo and most of the area is being developed as a low-rise exclusive residential area. Many detached houses have been developed there. Middle- and high-rise collective houses (apartments) are also located in the middle-to-high-rise exclusive residential area (Figure 6).

Schools and necessary public facilities are being developed in the Category one medium-to-high-rise exclusive residential area. This is because the urban planning act in Japan allows such public facilities

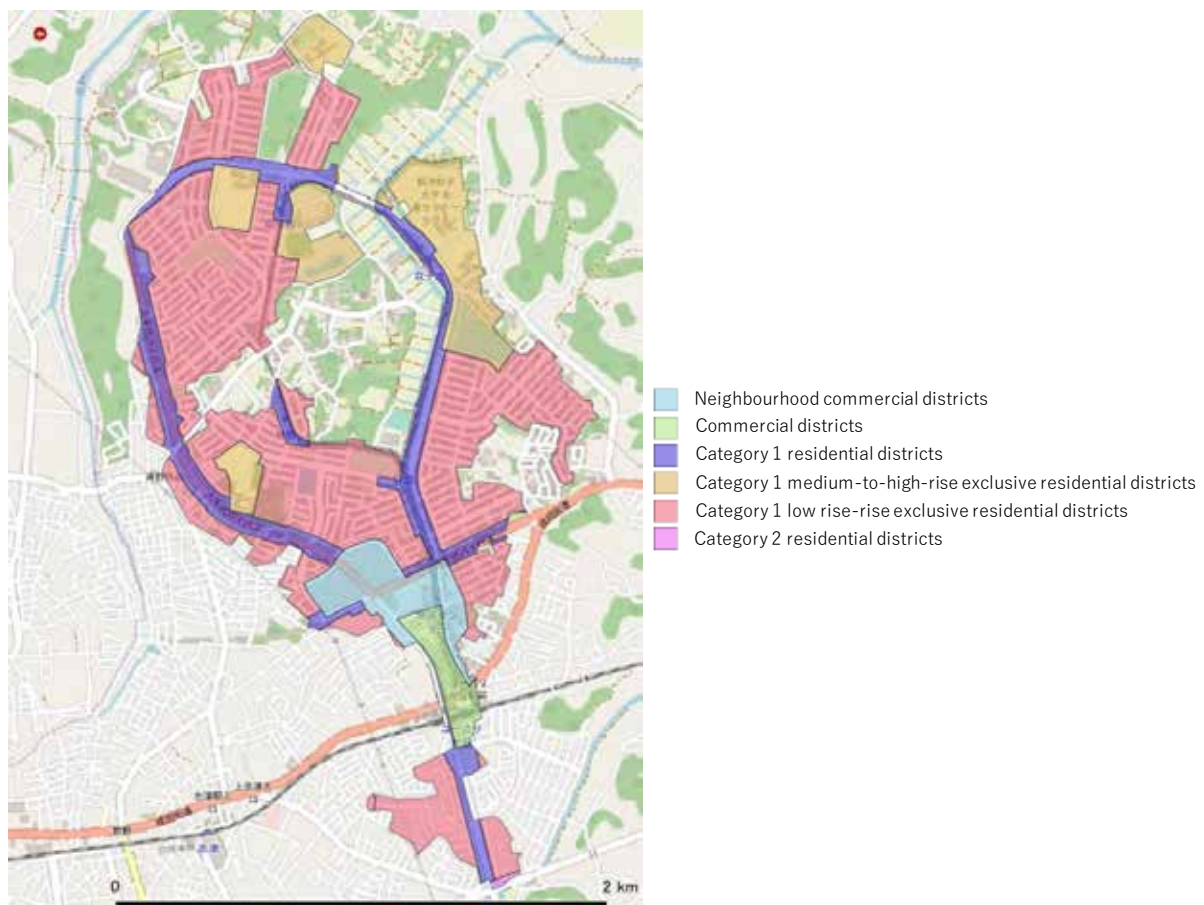

⁸ This is the Automated Guideway Transit (AGT), called Vehicle of New Age (VONA) and middle size public transport

⁹ <https://www.e-stat.go.jp/gis/statmap-search?page=1&type=2&aggregateUnitForBoundary=A&toukeiCode=00200521&toukeiYear=2015&surveyId=A002005212015&prefCode=12&coordsys=2&format=shape>

for residents to be built in these exclusive residential areas. According to the Building Standard Law, the floor area ratio is bigger in the middle/high-rise area than the low-rise area (Figure 7).

Figure 6 Landscape of Eucalyptus Hills

Source: National Land Numerical Information Designated land use districts and OpenStreetMap

Figure 7 Designated land use districts in Eucalyptus Hills as of 2011

In the development areas, commercial zones are also allocated near to the station. The development of office buildings, residential accommodation and commercial buildings is allowed in the zone, but factories and industry-related facilities are not permitted by the urban planning act. Also, the areas along the trunk road and Yamaman Eucalyptus line are designated as a Category one residential district, in which it is allowed to develop commercial facilities like retail shops supporting people's everyday life (Figure 8). These locations are able to support residential consumer life.

Figure 8 Commercial mall in Eucalyptus Hills

Thus, Eucalyptus Hills includes residential areas and commercial zones, but does not incorporate so many office areas and industrial areas. Therefore, the major job opportunities for the residents in Eucalyptus Hills must be sought outside.

3) Yamaman¹⁰

As noted, Eucalyptus Hills is being developed by Yamaman, which also provides community management services after the sales of houses. Yamaman is a private developer. Private developers and public corporations like the Urban Renaissance Agency are typical players in new-town developments in Japan.

Yamaman was founded as a textile wholesaler in February 1951 in Osaka. After that, it moved to Tokyo in 1964 and started residential land development in 1965. It began to develop Shonan Highland in the city of Yokosuka in 1965 and the Eucalyptus Hills development in 1971. It had earlier experience of residential land development before Eucalyptus Hills, including at Shonan Highland, Kami-Shizu housing complex, Uraga housing complex, Yachiyodai housing complex and Koumyouji housing complex. These are all sold-out models and did not specialize in growth management with community management as a necessary element.

In the first case, Shonan Highland is located on the top of a hill, but Yamaman did not provide any public transport services. Access from the nearest station was not convenient and for residents the climb up the hill took 20 minutes. In the last stage of sales, issues of the aging of the first families resident there occurred. These experiences are reflected in the development concept of Eucalyptus Hills (Hayashi, 2013).

The sales turnover of Yamaman in 2018 was 10.112 billion JPY and the number of employees is 136. Yamaman is not listed on the stock exchange. This is because listing a stock is not suitable for long-

¹⁰ This section is based on information from the Yamaman corporate website

term property development like Eucalyptus Hills and it would localize into the Eucalyptus Hills. Therefore, most of the company's employees, including senior directors, live in Eucalyptus Hills and group companies providing community services are also registered to Eucalyptus Hills. Yamaman understands that this localization is useful to determine the community business opportunities because Yamaman can share any conflict of interest with residents and identify needs promptly (Hayashi, 2014, 2013).

The business scope of Yamaman is as follows;

- Real estate appraisal, supervision, trading, brokerage, and management operations of rental rooms, rental buildings, and parking lots and residential land creation sales business.
- Design and construction services for civil engineering, architecture and landscaping.
- General transportation services by rail.
- Management of hotels, sports facilities and play facilities.
- Consultancy services for medical care and health care.
- Lending and selling medical care service business and welfare care equipment.
- Power generation business using renewable energy, etc., and management and operation of it, and business related to buying and selling of electricity.

The following Table 1 shows an outline of the group companies.

Table 1 Typical company of Yamaman group to provide community services in Eucalyptus Hills

Sector	Name of companies	Outline	URL
Facility management	Y.M.Maintenance Co., Ltd	Security guards, general building management, child care business, welfare business, management of leisure facilities, etc.	http://www.y-m-m.co.jp/

2. Factors of sustainable urban development in the case of sustainable development of Eucalyptus Hills

Typical Japanese new town properties are sold to 30-40-year-olds and sold out for 5 to 10 years. This leads to a migration of the younger generation in about 40 years and issues of aging, as a result of which a new town changes into an old town. In order to avoid this, mixed generation habitation is important. Continuous acquisition by 30-year-olds with young families as the primary owners of houses and catching secondary owners from changes of residence within the same housing complex are necessary (Goda, 2011). In Eucalyptus Hills, Yamaman looks forward in 10 years to developing a community management service and is promoting three-generation living and residence changes to maintain the variety of residential generations (Hayashi, 2014).

Yamamoto has defined residents' intention to settle as the sustainability of a housing complex and studied it in Eucalyptus Hills, referring to this as growth management development. The results of a questionnaire survey (valid responses = 142) on residents' intention to settle in Eucalyptus Hills, and analysis of the results of this survey data by discriminant analysis and factor analysis suggest that three major factors, "parents and children living together", "attachment to the Yamaman Eucalyptus Hill line as a symbol", and "Satisfaction with shopping facilities and transportation functions" are highly related to the residents' intention to settle in Eucalyptus Hills. The interesting point of this study is that most of the respondents do not use the Yamaman Eucalyptus line, but they do feel some attachment to it (Yamaguchi, 2016). This suggests that some symbols attracting residents are necessary for sustainable development in shrinking cities, in addition to practical convenience and economic benefits as discussed in social capital.

Yamaman has continued to sell property since 1979, that is, for almost 40 years. The fact that the company is unlisted is considered to be one important reason why Yamaman can continue its policy. Also, the demographic balance is pointed out as another important factor of sustainable development. In addition, the spatial planning of almost all the areas of Eucalyptus Hills, which can be covered within 10 minutes walking distance from the station of the Yamaman Eucalyptus line (6 stations and frequency of every 13'35'') is another key element. Furthermore, Yamaman provides amusement facilities and services for residents (Hayashi, 2014).

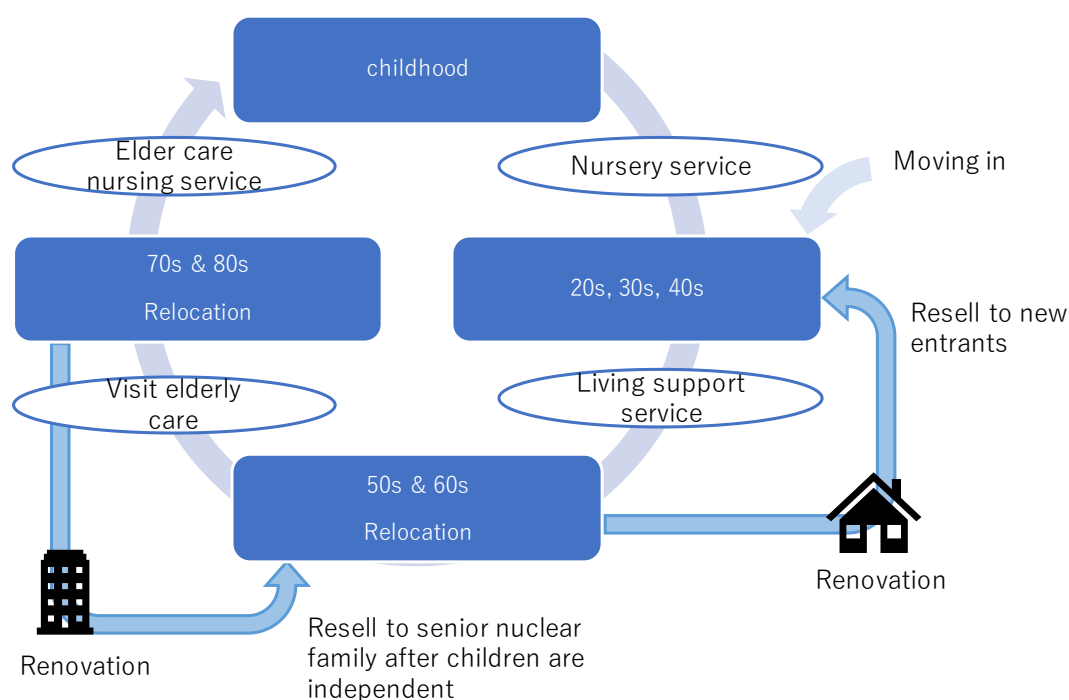

Yamaman has paid much tax to the city of Sakura, but the prefectural government has refused Yamaman's request to establish a police box in front of the stations. So, Yamaman itself established its own security patrolling service centre, comprising four cars and providing 24×7 services.

Moreover, Yamaman pays attention to social care services. In 1997, Yamaman launched the concept of a social caring town development to cope with aging in the Eucalyptus Hills and allocated 15 ha of land for care facilities for the elderly and disabled. Also, Yamaman started to introduce countermeasures to the falling birthrate in the 1990s in order to maintain the demographic balance of the composition of residents in the area. In 1999 it established a nursery with a garden, open till 2200 in front of the station. In addition, non-authorized nursery services, a general child care support centre,

and a schoolchildren's nursery services, Eucalyptus Yuto Pia,¹¹ which is an integrated nursery and elderly care facility, were developed by Yamaman.

From the environmental aspect, Yamaman start to operate an EV community bus service (Hayashi, 2013). Also, historic sites and natural green areas have been conserved as green spaces¹². In addition, an agri-business has been developed for the production of tomatoes and other vegetables in greenhouses and for the provision of farming opportunities for residents (Hayashi, 2014).

Yamaman is now changing its business model from flow-type (sales of property) to stock (sales of services). It proposes a "Happy Cycle System" (Figure 9) to residents. The Happy Cycle System is a package that has been promoting the relocation of residents within Eucalyptus Hills in accordance with their life stage since 2006. Yamaman offers 100% of the purchase price to assess the value of their previous houses, does not charge an intermediary fee for real estate and introduces the next houses to residents. Fifty families have already used this promotion package in 2014 (Hayashi, 2014), and elected not to move out from Eucalyptus hills.

Source : <https://realestate.yukarigaoka.jp/contents/code/happycircle>

Figure 9 Happy Cycle System in Eucalyptus Hills

¹¹ <http://www.yutokai.com/facility/yutopia.html>

¹² The supply of the number of houses is controlled by Yamaman. This means that a small area of development is continuing every year. Some residents complain to Yamaman about destroying the green space and about noise in some cases (Uchino, 2010).

Yamaman has supplied various type of houses and living-support facilities¹³ in Eucalyptus Hills. For example, living-support facilities and high-storey apartments have been developed in front of the station and detached houses with enough space for childcare have been developed in the areas further from the station. These different types of accommodation allow residents to choose suitable houses for their life stage. Yamaman also refurbishes houses purchased from the elderly and sells them to younger people with children in order to attract this generation to Eucalyptus Hills. In Japan, it is often the case that a second-hand house is normally discounted by 20%–30% compared to a new house. Accordingly, the provision of cheaper second-hand houses helps younger families with children to live in Eucalyptus Hills (Goda, 2011).

In addition, Yamaman is inviting a college to set up in order to increase the young population, to provide lifelong learning opportunities, and to utilize the local human resources, including people retired from large companies, research institutes and so on. The aim of setting up a college is to establish a “Continuous Care Retirement Community (CCRC)” (Hayashi, 2014).

In terms of community management by an area management team consisting of three Yamaman employees, the team visits its area of responsibility every day and in some emergency situations, like the Great East Japan Earthquake, it visits solitary old persons to check on their wellbeing as well as to distribute food and drink if necessary (Hayashi, 2014).

Table 2 shows the above-mentioned activities by Yamaman following the sustainability framework.

Table 2 Summary of Yamaman’s strategy and actions for the factors of sustainable development

Perspectives		Actions by Yamaman
Population	Continuous population inflow	Instead of selling homes at one time, the developer will take time to sell to new tenants continuously.
	Balanced demographic composition	In order to develop an area for the long term, it is necessary to consider the development cycle of the area and the population balance. In particular, it is important to make efforts to cope with the aging rate and to increase the number of households with children (increase in primary school children).
Society	Existence of symbol	The presence of a symbol (Yamaman Eucalyptus Hill Line) that enhances the people's centripetal power improves the attractiveness of the residence.
	Provision of crime prevention and disaster prevention services	Yamaman complements its security base in areas where a prefectural police box is not developed and it has the residents operate a crime prevention organization (self-help / co-help).
	Development of childcare facilities	To develop a municipality-approved nursery in front of the station to improve the quality of life of households with

¹³ Multiple commercial facilities have been developed, but some shop space remains vacant. Some residents pointed out the closure of retail shops sometimes (Uchino, 2010). The 20,000 population is not small, but it is true that keeping the service level of living-support commercial facilities is one of the important issues in Eucalyptus Hills.

Perspectives		Actions by Yamaman
		children and attract more families with children. In addition, Yamaman set up a nursery school outside authorization, a general child care support centre, schoolchildren's nursery school for primary school children.
	Development of elderly care facilities	To maintain visiting care facilities and nursing homes in the area.
	Community management by area management team	A team of three Yamaman employees visit the area of responsibility daily. At the time of the Great East Japan Earthquake, they visited the homes of the elderly living alone and distributed rice and water as needed.
	Inviting amusement facilities such as cinema complex	Maintenance and operation of leisure facilities such as movie theatres, bowling alleys, and hot bath facilities
Economy	Ensuring the convenience of commercial facilities	To maintain shopping facilities and attract tenants while considering local needs so that shopping is convenient.
	Localization of group companies and creation of local jobs	To secure local employment by setting up a group company specializing in Eucalyptus Hills.
	Being an unlisted private developer	Being unlisted allows developers to continue development from a long-term perspective.
	Relocation support by Happy Cycle system	By purchasing 100% of assessed value of residents' houses when they relocate within Eucalyptus Hills, Yamaman supports the formation of assets of the residents and reduces the economic burden at the time of relocation.
Environment	Community bus service by EV bus	To operate community EV bus that circulates in the area.
	Leaving moderate amounts of space such as green space and small-scale farmland	The landscape is maintained by developing with the historical green areas in the region and the natural green areas such as Satoyama.
	Tomato cultivation for the purpose of sales inside and outside the area	Tomato cultivation at Eucalyptus farm supplies food to the region and provides opportunities for agricultural experiences in the future.
Time-axis	Town development that looks 10 years ahead	To develop services for the community by forecasting 10 years from now. In the last 10 years, Yamaman improved the facilities for the elderly.

3. Financial situation of Yamaman

As stated, Eucalyptus Hills has been developed by Yamaman. So it can be said that the sustainability of Eucalyptus Hills equates to the sustainability of Yamaman's corporate management. Therefore, the financial indices from 2012 to 2018 in Figure 10 are checked.

Yamaman recorded the highest sales of 16.2 billion JPY in 2013, but its turnover was around 10 billion JPY in each of the last three years. Its net profit is also stable and around 0.2–0.4 billion JPY for these 7 years.

Yamaman provides vertically integrated services, from the housing sales business to living support service after the sales of houses. Because of this, with the maturation of Eucalyptus Hills, the sales composition of the upstream business and downstream business in the Yamaman has also changed (Goda, 2011).

Source: Capital IQ and Yamato Co., Ltd. 61st term financial statement, March 26, 2019 Official gazette

Figure 10 Trend of revenue and profit before tax on Yamaman

To compare the segmented sales volume between 2008 and 2016 when the segmented sales values are introduced, housing sales in 2008 were around 9 billion yen and 61% of total sales, but they have fallen to around 5 billion yen and 50% of total sales in 2016. On the other hand, house rental income has increased slightly from 2008 to 2016, and has increased from ¥ 3.08 billion (21%) to ¥ 3.35 billion (33%). As the development matures, housing land and home sales revenue is decreasing, and the downstream service ratio is relatively increasing. Since the profit is almost constant, it can be understood that Yamaman, as a community developer, does not have a problem with its sustainability as a going concern.

Source: (Goda, 2011) and Nikkei Corporate Profile

Figure 11 Segment sales of Yamaman

In addition, while the net capital continues to increase, Yamaman has recorded net income every fiscal year, while the liabilities have tended to decrease slightly, and the balance sheet has no major problems.

IV. Discussion & Analysis

As stated previously, sustainable community management in Eucalyptus Hills means paying attention to the demographic composition balance, including three generations, as well as developing various social, environmental and economic services which will be needed in the next 10 years. In other words, not only maintaining the population, but also keeping a balanced composition of gender and

ages, as well as drawing in young families with children are all elements of Yamaman's basic strategy. As a result, the demographic composition in 2015 included numbers of residents aged 0–10 years old, 30–44 years old and 60–69 years old that are larger than those in the city of Sakura (Figure 13).

Source: National Population Census in 2015

Figure 13 Comparison of demographic composition between City of Sakura and Eucalyptus Hills

This recovery of young families with children is a critical factor that determines the sustainability of this new town, which is located 40 km from Tokyo. In particular, in Eucalyptus Hills, Yamaman is strategically supplying new housing or renovated housing for young families with children, mainly in districts where the number of primary school children is decreasing (Koutani, 2014).

Although extensive support for children, such as providing nursery schools and schoolchildren's services, is a relatively common method in Japan's depopulated areas, inviting in universities and hospitals are also typical efforts to revitalize shrinking cities in Europe and the United States (Pallagst et al., 2019). In Eucalyptus Hills, a university was invited in by Yamaman, but the aim was a little different from these foreign cases. Yamaman expects to improve the quality of life of elderly persons, and job creation is not the main purpose. Eucalyptus Hills is located between Tokyo and Narita airport and the commutable area to those main working areas. Therefore, job creation in Eucalyptus Hills is not a significant factor in this sustainable area development.

Accordingly, this case cannot be taken as a general case for small and medium industrially declining shrinking cities, but as a case more specifically for dormitory towns in metropolitan suburbs.

The development size of Eucalyptus Hills is a planned population of 30,000, and as of April 2019, the resident population is 18,697. Yamaman, as mentioned, provides many living-support services like a nursery, elderly care service, and the development of commercial facilities to enhance the attractiveness of the area through its subsidiaries. As can be seen in Table 3, a wedding hall and paid

caring facilities are generally difficult to locate in the area because of the service area population, but Yamaman has taken a business risk and provides these services to residents.

Table 3 Population scale of life-support services and service provision in Eucalyptus Hills

		Population size at which ratio of location of service facility becomes more than 80%
Service facility that can be located on Eucalyptus Hills	Food and beverage retail	2000 people
	Books and stationery retail	2000 people
	Dental clinic	2000 people
	Bar and beer hall	4000 people
	Nursery home care service	4000 people
	Learning acupuncture	8000 people
	Short-stay services	8000 people
	Coffee shop	9000 people
	Bank branch	9000 people
	Music classroom	15000 people
	Game house	15000 people
	General hospital	15000 people
	Long-term care health facilities	15000 people
	Nursery service	15000 people
	Visiting elderly care service	20000 people
	Foreign language class	30000 people
Facilities that are located on Eucalyptus Hills which support population size is exceed the population size of Eucalyptus Hills	Karaoke store	35000 people
	Kindergarten	40000 people
	Fitness club	50000 people
	Paid nursing home	55000 people
	Care treatment type medical facilities	65000 people
	Wedding hall	70000 people
	Shopping centre (sales area over 15000 m ²)	85000 people

Source: (Ministry of Internal Affairs and Communications, 2016)

Conversely, other services can be located in the area from this perspective of service area population. In short, Eucalyptus Hills is of sufficient size to provide enough services supporting daily living for the residents. In the case of a much smaller development, the residents might have greater difficulty in securing such services. This means that not only a balanced demographic composition, but also a certain accumulation of population in certain spatial spaces are also critical to achieve sustainable development in shrinking cities.

As mentioned above, Eucalyptus Hills is still maintaining its population growth, whereas the city of Sakura has been losing its population since 2000 (Figure 14).

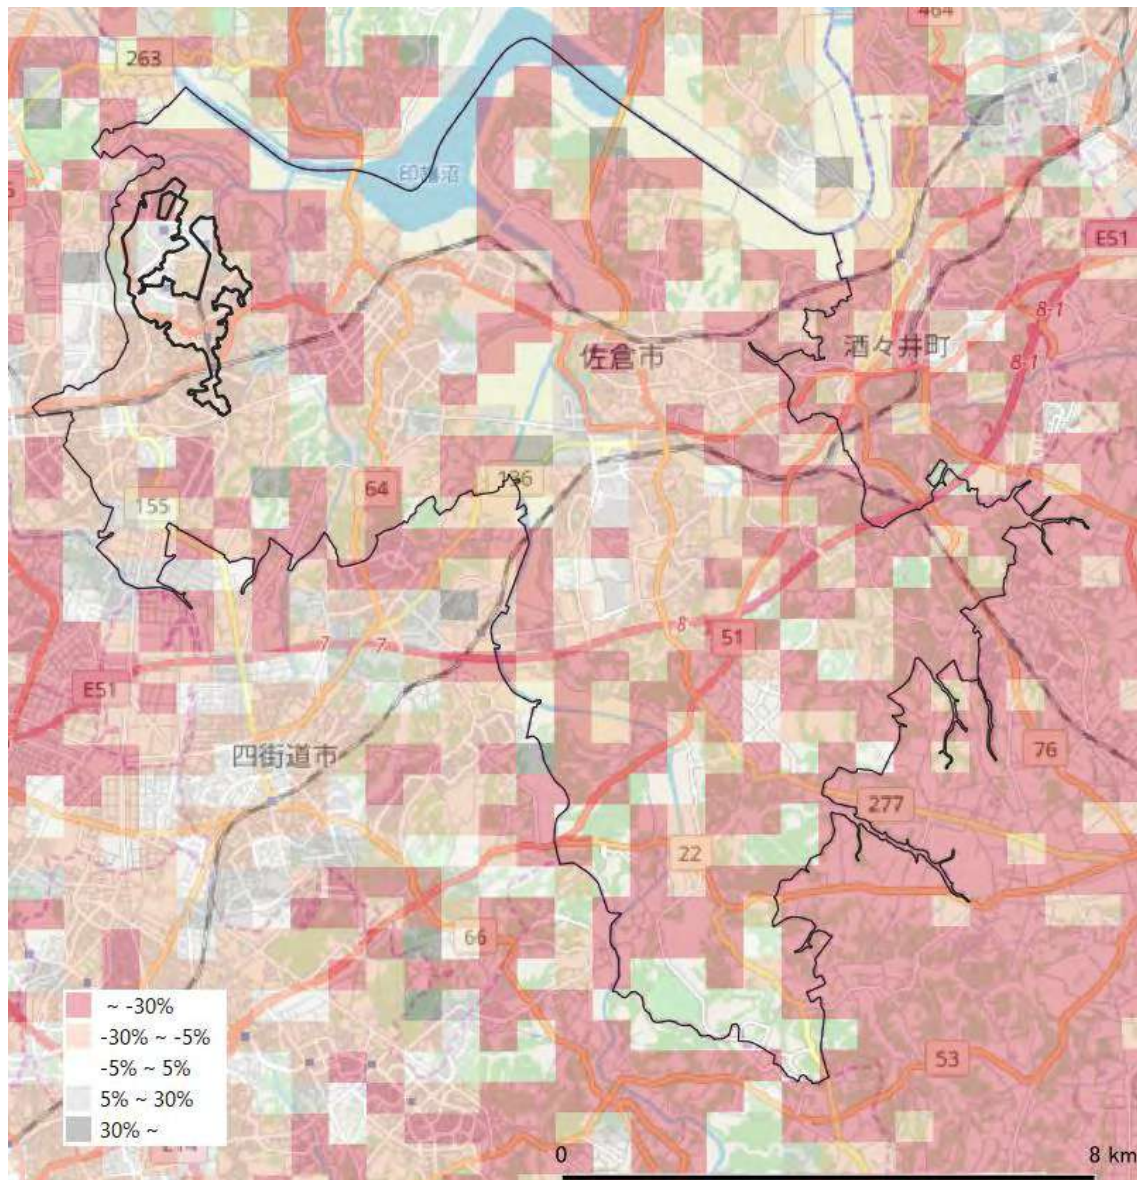

Source: National Population Census each year

Figure 14 Demographic change in Eucalyptus Hills and the City of Sakura without Eucalyptus Hills

This trend is the same for the future. Figure 15 shows the official projected population change rate in a 500 m mesh produced by the Ministry of Land, Infrastructure, Transport and Tourism. The city of Sakura has three big agglomerations of population, namely, Shizu & Eucalyptus Hills, Usui and Sakura. It is natural that the population loss from these agglomerations will be much smaller than in other areas. Of the three areas, Eucalyptus Hills area is losing much less population. Thus, it is firmly expected that Yamaman's efforts may continue to succeed in the future as well.

Next, the development of facilities for the support of daily living will be conducted not only by Yamaman but also by other entities. However, Yamaman retains the responsibility for commercial facilities management. For example, Eucalyptus Hills Safety First Town was developed by Mycal, which was one of the supermarket stores there in 1992, but closed after opening AEON Town Eucalyptus Hills (Figure 8). Yamaman stepped in to revitalize the vacant Eucalyptus Hills Safety First Town as the facility owner, invited in other tenants, and reopened it as Skyplaza Mall in November 2017.

Although vacant commercial facilities in shrinking cities, even in front of the station, can often become a big negative symbol of the downturn, Yamaman was able to prevent such a situation and keep its usefulness for the residents. This type of business activity links to the business model change of Yamaman as introduced in Figure 11.

V. Concluding Remarks

The case of Eucalyptus Hills is well known as a sustainable area development. A key factor for it is to maintain the balance of the demographic composition. It also found that continuously bringing in young families with children is especially important for sustainable community development in the suburbs of metropolitan areas. In addition, it is found that ensuring an appropriate population size in the area, namely, 30,000 people as the planned population (although actually less than 20,000 people as of 2019), and some risk-taking by Yamaman to attract customers are additional keys to success. This suggests that not only the balance of the demographic composition, but also a certain level of

accumulation of population within an area is critical for its survival in shrinking cities. Accordingly, 20,000–30,000 people in 245 ha, namely, 8000 people/km² on average, is the expected density of population needed for survival.

The uniqueness of this case is the continuous involvement by Yamaman in the development of Eucalyptus Hills for 40 years and the transformation of its business structure in accordance with the progress of the development phase. Yamaman can provide the necessary services considering the change of age structure and family structure in Eucalyptus Hills because it owns commercial facilities¹⁴ and can invite in tenants necessary for providing the services. It can be said that Yamaman and the residents have common interests because Yamaman earns from the needs of residents and this co-interest structure results in improving the attractiveness of Eucalyptus Hills compared with neighbouring dormitory towns.

This case can be applied for dormitory towns located in the suburbs of metropolitan regions where job opportunities are available outside these towns, but three conditions are necessary for the application of the case, namely, a single developer (town manager), a certain size of development (at least 20,000 population with more than 8,000 people/km²) and mixed generation living (or long-term development). If these conditions are not met, the following counter- measures are expected.

First, a town management organization rooted in the region, and, if possible, a single entity is needed, and if this is difficult, an organization that is expected to take the initiative will be established. Existing major property companies are good candidates and, of course, a new entity can be established, but the condition is that it should own property like housing land or commercial buildings in the area and that the organization's major sources of income should be from the management of these properties. This co-interest will enable the organization to become a good town manager.

Second, a certain population size (20,000-30,000 people in Japan), which is calculated from the population needing support services to be available for daily living, for a certain density of population (8,000 people/km² in Japan), is required as the target for sustainability in shrinking cities. In other words, if some small community cannot aggregate with an adjacent community because of too great a distance, for example, that community may not be sustainable even in the suburbs of metropolitan areas.

Thirdly, if the age structure is distorted because of the short development period of the area, that structure should be adjusted. In this case, the organization mentioned above should try to control the sales target of renovated houses in the area. Targeting of marketing to families with children and the reduction of some real estate brokerage fees are solutions to consider with that aim. These kinds of countermeasures are also considered to be useful for the revitalization of central city areas.

These three conditions should be satisfied at the same time. This is because some new towns like Shiraoka new town in the prefecture of Saitama cannot satisfy all the above conditions. Shiraoka has

¹⁴ The first well-known case of new town development in the world was Letchworth, and the developer, First Garden City Limited, also owned its developing lands and rented the property for residents and locators (Himeno, 1993).

undergone long-term development for more than 30 years since the 1980s, with a mixed age structure as well as a single private developer (Sougo Jisho¹⁵). But this new town has only 4831 people as of 1st January 2016, about 1200 houses (planned) and 50 ha. The private developer of Shiraoka is planning to withdraw its town management works (Saitama Capacity Building Wide Area Union, 2017). There is no reason for such a withdrawal, but according to Table 3, the population in the Shiraoka new town cannot support living-support services.

The first new town in the world was Letchworth in the UK. Letchworth also had First Garden City Limited as the specified town developer, and it developed not only housing property, but also utilities like the water supply, gas supply and electricity supply as well as landscape management. Later on, First Garden City Limited lost its function as town manager (Himeno, 1993, 1992), but it can still be said that the existence of Yamaman and First Garden City Limited prove the importance of the presence of a responsible town manager sharing co-interests with residents.

In order to expand this case horizontally, the clustering of new towns might be necessary.

Time Series of Urban Shrinkage Elements in Coal-exhausted Cities: A Case Study of Two Typical Cities in Northeast China

Jie Zhang¹, Zhiqing Zhao², Peilun li³

¹ School of Architecture, Harbin Institute of Technology; Key Laboratory of Cold Region Urban and Rural Human Settlement Environment Science and Technology, Ministry of Industry and Information Technology, 434305505@qq.com

² School of Architecture, Harbin Institute of Technology; Key Laboratory of Cold Region Urban and Rural Human Settlement Environment Science and Technology, Ministry of Industry and Information Technology, zhaozq88@126.com

Abstract: Based on the existing research, this paper first classifies the influencing factors of urban shrinkage into three categories: internal factors, external characteristics and potential factors, and further divides them into four categories: population structure change, economic and industrial change, spatial quality change and public facilities change. Secondly, taking Shuangyashan and Jixi city, two typical coal-based industrial cities in Heilongjiang Province of China as the research objects, from the point of view of time, using the method of big data classification and comparative analysis, the time series of key elements in each city is studied, the priority and lag relationship of elements are obtained, and the time law of mutual restriction of elements in each city is analyzed in depth, and the time series of key elements in each city is established. The time series model of the shrinkage of such coal-exhausted cities is put forward in order to put forward a common strategy to deal with the shrinkage of such cities from a time point of view.

Keywords: Urban shrinkage; Resource exhaustion; Time series; Northeast China

Introduction

Northeast China once owned more than 90% of China's heavy industry bases. Since the 1990s, under the background of traditional industrial transformation and changes in China's overall economic environment, with the depletion of mineral resources and forestry resources, the leading industries of many Northeast cities have gradually declined. Most cities developed by relying on traditional industries are facing a downturn in industrial development and urban development (Yu Tingting *et al*, 2017).

In order to alleviate the problem of population shrinkage in the northeastern China and prevent the serious decline of the Northeast area, Chinese scholars began to study the causes and Countermeasures of such urban shrinkage, so that we can re-recognize the phenomenon of backward development and shrinkage in the Northeast area and try to improve the current situation of urban

shrinkage in the northeast area from a scientific point of view, and guide the healthy development of the cities in the Northeast area.

However, the current research mostly on urban shrinkage includes multi-concept definition, identification, dynamic mechanism, impact and coping strategies (GAO Shuqi,2015). Most of the studies are on the shrinking city in a region or the specific research of a single shrinking city, lacking of comparative research on the same type of shrinking city, and lacking of research on the evolution process of urban shrinkage. According to the experience of urban shrinkage in western developed countries, most resource-exhausted cities will experience a comprehensive decline in population, economy, society and environment (Yang Dongfeng *et al.*2013). There are also many studies on urban shrinkage in China based on the hypothesis of population shrinkage - economic decline - space dilapidation (LONG Ying *et al.*2015). If we make a comparative study on the factors of the same type of cities in the process of population shrinkage from the perspective of time, we will find the similarities and differences in the process of population shrinkage in each city.

Therefore, this paper chooses coal-exhausted cities as the research object to explore the shrinkage process of such cities. In view of the shrinkage situation of Shuangyashan and Jixi city in northeast China, based on the time factor, the shrinkage process is analyzed by time series, including the internal factors, external characteristics and potential factors. And the shrinkage of coal-based cities in population structure, economic and industrial changes, spatial quality changes, people's livelihood quality changes are explored. The relationship between priority and lag of specific factors is studied, and the common law of shrinkage factors and the reasons of difference are compared in depth.

Study area

This paper chooses Shuangyashan City and Jixi City in Heilongjiang Province in Northeast China as the research objects (Figure 1). Both of them are typical coal resource exhausted cities in Northeast China. The two cities are facing a reduction in urban population at the same time, but to varying shrinkage degrees. The comparative study of two cities with different population shrinkage and the same industrial type will have a good reference.

Figure. 1 Location of Shuangyashan City and Jixi City in Northeast China

Data and methods

Selection of Time Series Elements of Urban Shrinkage

In the process of urban shrinkage, many factors are changing, some of which have an impact on the process of urban shrinkage, and some of which are the phenomena manifested in the process of urban shrinkage. According to the existing research on the influencing factors of urban shrinkage (Table 1), the main influencing factors of urban shrinkage include industrial transformation (WU Kang *et al.* 2015, Yang Lin *et al.* 2018), economic environment change (LIU Fengbao *et al.* 2018, Zhang Wei *et al.* 2019), population structure change (WU Kang *et al.* 2015, Yu Tingting *et al.* 2015, Yang Lin *et al.* 2018), natural ecological environment change (Yu Tingting *et al.* 2015, Zhang Wei *et al.* 2019), urban facilities (Yang Lin *et al.* 2018), urban space factor (Zhang Wei *et al.* 2019). Based on the characteristics of coal-exhausted cities in Northeast China, the change of natural ecological environment has less impact on urban shrinkage. Therefore, population structure, industrial transformation, economic development, urban spatial elements and urban facilities are selected as time series elements of urban shrinkage.

Table. 1 Summary of factors affecting urban shrinkage

Author	Causes and Driving Forces of Urban Shrinkage
WU Kang <i>et al.</i> 2015	Regional Economic Development, Urbanization Level, Administrative Level, Deindustrialization or Industrial Transition, Population Structure Change
Yu Tingting <i>et al.</i> 2015	Natural environmental indicators, socio-economic indicators
LIU Fengbao <i>et al.</i> 2018	Population Structure, Economic System, Geographical Environment, Government Policy, Zoning Adjustment
Lin Yang <i>et al.</i> 2018	External economy, location, climate, industrial structure, population structure, infrastructure, culture
Zhang Wei <i>et al.</i> 2019	Natural Ecology Background, Urban Scale, Urban Economic Development, Urban Population Structure, Urban Municipal Construction, Urban Ecological

Factor Arrangement of Urban Shrinkage Time Series

Deepening the selected time series factors of urban shrinkage, combining the characteristics of urban shrinkage in Shuangyashan and Jixi, supplementing the above factors with micro-indicators, and establishing the time series research-factor system of urban shrinkage factors (Table 2). It includes the following aspects:

1. Population structure change;

The population structure of Shuangyashan and Jixi City has changed significantly. Firstly, the total population of the city and city district have decreased. It is expressed by the index of population change rate, which is also a big measure of the degree of urban shrinkage. Then, birth rate and natural growth rate of cities. Low fertility keeps the population growth rate in Northeast China at a fairly low level. What's more is the rate of population migration. In the 21st century, especially after 2010, with the deepening of China's economic system reform, the economic status of Northeast China has continued to decline. Northeast residents migrated from north to south in pursuit of better life, with a net outflow of 2.24 million in 2014. At the same time, the age and education level of the outflow population in Northeast China are low and high. Such a structural outflow of population will inevitably affect the shrinkage process in Northeast China (Zhou Daming, 2018).

2. Industrial Economic Change;

In the 1990s, driven by the recovery and rapid development of coal economy, the GDP of Shuangyashan and Jixi cities maintained a relatively rapid growth. The development of coal and related industries led to the growth of the overall economic level of the city, and the rapid development of urban infrastructure construction. The employment opportunities brought about by it attracted the influx of population. In recent years, under the influence of macroeconomic environment, the golden period of coal has ended, the supporting role of coal industry to the economy has weakened and declined year by year, and the salary cuts and job losses in coal and related enterprises, and the employment environment in cities have also begun to become severe. Therefore, firstly, the total GDP and the output value of secondary industry are selected as economic research indicators to explore the time relationship between urban economic environment and population shrinkage. Secondly, the number of employment at the end of the year, the unemployment rate, the number of employment in the secondary industry and the number of employment in the tertiary industry are taken as industrial research indicators to explore the time relationship between the development of different industries and population shrinkage.

3. Spatial Quality Change;

The change of urban spatial quality is the external representation of urban shrinkage. This paper chooses street greening, street pavement and street storefront activity as research indicators which are easy to extract large data, and reflects the change of urban spatial quality with the change of urban street spatial quality. Due to the decline of coal resources, the closure of some coal-related enterprises has made the spatial quality of some parts worse. If the population shrinks seriously, there will probably be a large area of building vacancies, which will affect the urban spatial quality. Therefore, the identification and research of spatial quality changes will be the focus of urban shrinkage in the future.

Table. 2 Time Series of Urban Shrinkage Elements - Element System

Classification	Large class	Subclass
Internal factors	Elements of Population Structure Change	Change rate of total urban population
		Urban Population Change Rate
		Natural Growth Rate of Urban Population
		birth rate
		Urban population emigration rate
	Elements of Economic Industry Change	GDP
		Second Industry Output Value
		Number of employee at the end of the year
		unemployment rate
		Employment in Secondary Industry
		Employment in tertiary industry
External representation	Elements of Urban Spatial Quality	Street greening
		Road Traffic and Pavement
		Street storefront activity
Potential elements	Elements of Quality of Life Change	Number of health institutions
		Number of health technicians
		Number of teachers per 10 students
		Urban public green space area
		Cultural performances
		Number of Fitness Events
		Number of full-time Sports Coaches

4. Changes in quality of life.

The elements of urban life quality change include health care, education, green space, culture and sports. These factors are the important demand factors for improving the living standards of all urban residents. The allocation of public facilities with different completeness will have an big impact on the attractiveness of different cities and different areas of cities. If the allocation of urban public facilities is inadequate, it will also affect people's pursuit of quality of life, and then choose a better quality of life in other cities. Therefore, the study of the time course of quality of life change will help us to understand the relationship between quality of life and other factors of population shrinkage better, and help us to make timely allocation Countermeasures of public facilities.

Data Processing Method of Urban Shrinkage Time Series Elements

- Data Sources

Data used in the study include: Shuangyashan Social and Economic Statistics Yearbook (2007-2016), Jixi National Economic Statistics Yearbook (2007-2016), Baidu Map Street View 2016 and Tencent Map Street View 2013. Among the small elements in Table 2, except street greening, road traffic and pavement, Street store activity data from Baidu Street View and Tencent Street View data, other data are directly derived from statistical yearbook or based on Yearbook for processing and calculation.

- Data Processing

The data in this study were normalized by Min-Max normalization, also known as 0-1 normalization, which is a linear transformation of the original data, so that the results fall in the 0-1 interval and the transformation function is as follows:

$$x' = \frac{x - x_{\min}}{x_{\max} - x_{\min}}$$

In the formula, x_{\min} is the maximum value in the sample data and x_{\max} is the minimum value in the sample data. By transforming all data into 0-1 data, this data standardization process is conducive to comparing the data of different types of elements in different units, and more intuitively showing the changing trend of various elements.

Data Analysis

Analysis of Population Structure Elements

Combining with the Yearbook data, the data of population structure changes in Shuangyashan City (Table 3) and Jixi City are sorted out and processed. The trends of various data over time are analyzed as follows (Figure 2, Figure 3):

Table. 3 Statistics of Population Structure Elements in Shuangyashan City

End of the year	Urban Population change rate (%)	Urban District change rate (%)	Birth rate (‰)	Processed birth rate	Urban emigration rate (‰)	Processed Urban emigration rate	Natural Growth Rate of Urban Population (‰)
2006	-0.18	-0.25	6.68	0.82	18.2	0.63	0.99
2007	0.33	0.25	7.19	1	20.36	0.79	1.29
2008	0.01	0.27	6.77	0.86	18.63	0.66	1.13
2009	0.23	0.18	6.2	0.66	14.29	0.34	-0.64
2010	0.51	0.15	5.93	0.57	11.74	0.15	-0.65
2011	-0.22	-0.09	5.74	0.5	23.26	1	-0.16
2012	-0.55	-0.84	5.94	0.57	16.27	0.49	-1.37
2013	-0.41	-0.68	6.14	0.64	17.13	0.55	-2.24
2014	-0.53	1.30	6.43	0.74	15	0.39	-1.78
2015	-1.04	-1.29	4.29	0	9.68	0	-4.11

Figure. 2 Changes of Population Structure Elements in Shuangyashan City

Shuangyashan city's population was growing before 2000. The total population fluctuated in a small range from 2000 to 2010. The population declined obviously in 2011. Taking the end of 2010 as the demarcation line of population shrinkage, there was a phenomenon of declining birth rate and a sharp decline in natural population growth rate before 2010, which may be the most important potential impact factor before population shrinkage. From 2011 to 2012, with the increase of population emigration rate, the population shrinkage of Shuangyashan city is obvious. The urban population shrinkage rate in 2012 is 0.84% compared with 2011, and the urban population shrinkage rate in 2015 is 1.04%. Therefore, we conclude that the birth rate of Shuangyashan city declined before its population contracted, and the process of population shrinkage is accompanied by a large number of migration.

Figure. 3 Change of Population Structure Elements in Jixi City

The phenomenon of population shrinkage in Jixi City started earlier, nearly 10 years earlier than that in Shuangyashan City. According to the data, during the period of population growth from 1990 to 2001, the population increased by 127,000, with an average annual increase of 106,000, with an average annual increase of 0.56%. From 2002 to 2015, the population gradually decreased by 152,000, with an average annual decrease of 117,000. Taking the end of 2001 as the demarcation line, we can clearly see that the birthrate and natural growth rate of Jixi City have decreased significantly before 2001, which may be the main reason for the decrease of the total population of Jixi City. In 1990, the birthrate of urban population was 15.79 while in 2015, the birthrate of population was 5.13 which was 10.66 points lower than in 1990. Therefore, we conclude that the phenomenon of population shrinkage in Jixi City also occurred after the birth rate and natural growth rate dropped sharply. Judging from the situation of population outmigration in Jixi City, due to insufficient data, there is no trend of change in the Figure 3, However, the relevant data show that in recent years, the net population outmigration of Jixi City has maintained 10,000-20,000 people per year, so the process of population shrinkage has been accompanied by population outmigration.

Elements of Economic and Industrial Change

Based on the Yearbook data, this paper calculates the factors of economic and industrial change in Shuangyashan and Jixi (Table 4), and analyses the trend of various data over time as follows (Figure 4, Figure 5):

Table. 4 Statistics of Industrial Economic Change in Jixi City from 2006 to 2015

	GDP(10,000 0 yuan)	Second Industry Output Value (10,000 yuan)	Employment at the end of the year (10,000 people)	Unempl- oyment rate (%)	Employed population in secondary industry (10,000 people)	Employed population in tertiary industry (10,000 people)
2006	2362214	706349	14.65	0.43	10.52	3.98
2007	2752215	832696	15.08	0.46	10.81	4.21
2008	3158814	1024628	13.99	0.48	9.78	4.13
2009	3538182	1384019	13.79	0.56	9.52	4.21
2010	4194931	1774986	13.59	0.59	9.35	4.18
2011	5078321	2130289	13.65	0.59	9.13	4.45
2012	5823381	2382636	13.2	0.76	8.6	4.5
2013	5709117	2199844	13.6	0.79	8.7	4.8
2014	5160088	1535218	12.8	0.57	7.9	4.8
2015	5146868	1336132	14.9	0.56	7.6	5.8

Figure. 4 Changes of economic and industrial Elements in Shuangyashan City

Figure. 5 Changes of Economic and Industrial Elements in Jixi City

Before 2012, the GDP of Shuangyashan City showed a growth state, and coincided with the growth trend of the output value of the secondary industry. However, since 2013, the GDP of the whole city has decreased slightly, while the output value of the secondary industry has decreased dramatically. It can be seen that after the urban population shrinkage began in Shuangyashan, the momentum of the development of the secondary industry has decreased along with the GDP reduction. Mining employment has fluctuated slightly since 2007, showing a declining trend as a whole, and decreased significantly in 2013, which may also indirectly reflect the decline of mining industry. At the same time, the unemployment rate is at the node of 2012. Before the GDP of the whole city decreased, the urban unemployment rate continued to rise, reaching its peak at the end of 2012. The total employment of Shuangyashan City has increased since 2013, and the unemployment rate has decreased, which shows that urban employment has eased down. The development of tertiary industry provides a suitable environment for urban employment. Generally speaking, Shuangyashan firstly has the problems of decreasing employment in mining industry and increasing urban unemployment rate. Secondly, it has the phenomena of declining GDP, declining output value of secondary industry and employment number of secondary industry, and rising output value of tertiary industry and employment number of tertiary industry.

Jixi's GDP also showed a growth state before 2012, and coincided with the change trend of Jixi's secondary industry output value. Similarly, starting from 2013, the GDP of the whole city has decreased and the output value of the secondary industry has decreased. At the same time, urban unemployment continued to rise before the city's GDP fell, and the most serious problem of unemployment occurred at the end of 2013. Since 2008, the number of employment in the secondary industry in Jixi City, mainly in coal mines, has declined in a straight line, and the total number of employment in Jixi City has also declined in the same trend, indicating the reduction of urban employment. Until 2015, the number of urban employment increased significantly, indicating that the development of tertiary industry has eased employment in resource-exhausted cities. Generally speaking, the economic and industrial factors in Jixi and Shuangyashan have the same trend in time dimension. First, the number of employment in the secondary industry decreases, the total number of employment in cities decreases, and the urban unemployment rate rises. Secondly, the overall GDP and the output value of the secondary industry decrease, and the output value of the tertiary industry and the number of employment increase.

Characteristics of Spatial Quality Changes

Through the evaluation of the changes of street scenery in the main urban areas in 2013 and 2016, the evaluation indicators include street greening, pavement and the street store vitality. The spatial quality was evaluated by scoring method, for example, Greening coverage increased by 1 point, unchanged by 0 points, reduced to -1 points; street pavement also scored 1 point, 0 points, or -1 points; street storefront vitality as a result of the city's obvious shrinkage characterization, so scored 2 points, 0 points and -2 points (table 5). Finally, when the total score is greater than or equal to 0, it is determined that the street level rises. Through the recognition and calculation of street scenery, it is concluded that the majority of the street space quality in Shuangyashan and Jixi has not declined. And the declining areas of urban spatial quality are distributed in the urban fringe, and the quality of urban central space is still steadily improved. Therefore, in terms of time, the decline of spatial quality is later than the decline of urban GDP.

Table. 5 Evaluating Indications of Urban Street View Change

Street View in 2013	Street View in 2016	Location	Spatial Quality Evaluation Elements	Evaluation score
			Street greening	1
			Street pavement	0
			Changes in Street Store Vitality	2
			Street greening	1
			Street pavement	1
			Changes in Street Store Vitality	0
			Street greening	1
			Street pavement	1
			Changes in Street Store Vitality	0

Change characteristics of people's livelihood quality

Based on the Yearbook data, data processing and calculation were carried out on the quality change factors of life in Shuangyashan City and Jixi City. The trend of various data over time was analyzed as follows (Figure 6, Figure 7).

Figure. 6 Changes of quality of life factors in Shuangyashan

Figure. 7 Changes of quality of life factors in Jixi

From the data of the changes in the allocation of public service facilities, such as medical, education, parks, culture and sports, which are related to the quality of life of Shuangyashan citizens, it can be seen that the allocation of other facilities, such as health institutions, teachers and sports coaches, has increased. However, the area of parks, health technicians and the number of fitness activities held have a tendency to get worse since 2015. So far, there has been no obvious decline of public service facilities. On the contrary, with the population decreasing, the per capita ownership of public service facilities in urban areas has increased.

According to the changes of the related factors of Jixi citizens' quality of life, most public service facilities have shown an overall upward trend except the number of health institutions in the whole city has been slowly decreasing since 2009 and the number of cultural performances and the number of health technicians began to fluctuate in 2014. The future fluctuations are unknown, but if there is a decline, it occurs after the decline in urban GDP. The future development of urban public service facilities also depends on the government's adjustment policies and investment in the face of urban population shrinkage.

Results

By studying the time series of shrinkage factors in Shuangyashan and Jixi city, the two coal-exhausted cities in Northeast China, we find that although the shrinkage degree is different, there are many similarities in the time series of shrinkage factors, which may reflect some common problems in the shrinkage process of coal-exhausted cities. First of all, from a broad perspective, before the process of urban population shrinkage, the elements of urban population structure and the elements of urban economic industry are closely related to each other. However, the quality of urban space and the quality of urban public service facilities are obviously lagging behind and the population structure and economic industry change. From the point of view of sub-categories, comparing the four kinds of factors in time, *we can infer that Shuangyashan and Jixi have the similar time series of shrinkage factors in the process of urban shrinkage:*

Birth rate decline -- Natural growth rate decline -- Population shrinkage accompanied by population migration -- Employment reduction in mining (employment reduction in secondary industry) -- Employment reduction -- Unemployment rate rise -- The decline of output value of urban secondary industry -- The decline of urban GDP (The increase of output value of urban tertiary industry) -- The decline of public facilities such as urban culture and health - The overall change of urban spatial quality and people's livelihood quality.

Regional Design: impacts on territorial governance and planning practice

Fuelling energy-transition with regional design ateliers

Annet Kempenaar¹, Marcel Pleijte², Michael van Buuren³

² Wageningen Environmental Research, the Netherlands, marcel.pleijte@wur.nl

³ Wageningen Environmental Research, the Netherlands, michael.vanbuuren@wur.nl

Abstract: Many countries are ‘planning’ for energy-transition in the light of the challenges imposed by climate change. Energy-transition is expected to radically change the structure, the institutional design and the physical appearance of our energy system. One of the critical issues is to integrate energy-transition with other land-uses and spatial issues. In the Netherlands, regional design ateliers were organised to address these challenges. We studied eleven regional design ateliers to find out what the design ateliers contributed to dealing with energy-transition. Our analysis showed that the design ateliers played an important role in creating insights on the spatial implications of energy-transition. This raised awareness amongst regional stakeholders on the impact of energy-transition, and affected their perspectives. However, our study also showed that some important (spatial) aspects, such as smart combinations with other land-uses and the transport and storage of energy, received little attention. Understanding energy-transition took up a lot of time, leaving little room for a full exploration of relationships with other land-uses, of possible solutions, and of integrated strategies. Therefore, we conclude design ateliers should also be organised in upcoming stages of ‘planning’ for energy-transition to further fuel the transition process and fully employ the benefits of regional design ateliers.

Keywords: regional design, energy-transition, spatial planning.

Introduction

‘Planning’ for energy-transition has become an important topic in the planning domain. The challenges imposed by climate change and the 2015 Paris Agreement urge countries to push their current fossil-based energy system towards a sustainable low carbon system. This is not an easy thing. Energy-transition, that is the transition towards a fossil free sustainable energy system, is a ‘persistent’ problem (Rotmans and Loorbach 2009). Furthermore, existing norms, rules and regulations can hinder or block the uptake and implementation of promising innovations, meaning that in energy-transition institutional and societal innovations are as essential as technical innovations (Hackmann *et al.*, 2014; ISSC, 2013; Sovacool 2014; Weaver *et al.*, 2014).

One of the critical issues in planning for energy-transition is to accommodate and integrate the implications of the energy-transition with other land-uses and spatial issues (De Boer and Zuidema, 2015; Oudes and Stermke, 2018). Recent studies show the enormous impact energy-transition will have on the existing landscape (e.g. Sijmons *et al.*, 2017; Kuijers *et al.*, 2018). This impact not only concerns the allocation of renewable energy sources such as wind turbines and solar panels. Energy-transition also calls for new infrastructures and

distribution networks, for energy-storage facilities, for new smart combinations of land-use, and for refurbishment or replacement of existing buildings. These kind of developments go beyond technical innovations and the spatial allocation of renewable energy sources. They call for policy innovations and new institutional structures and arrangements. However, what exactly is needed and which pathways for energy-transition can be followed is unclear.

In the Netherlands, regions are considered the crucial level of scale for addressing the challenges of energy-transition (SER, 2018; Rijksoverheid *et al.*, 2018). In various regions, leading up to regional debates and in preparation of a regional energy strategy, regional design ateliers have been organised to address these challenges and fuel the energy-transition process. Regional design ateliers can be understood as cycles of multiple (generally two to three) one-day meetings in which regional stakeholders, under the guidance of a team of spatial designers, explore and discuss spatial issues and challenges (Kempenaar and Van den Brink, 2018), in this case focussed on energy-transition in the region. We studied eleven energy-transition based regional design ateliers that were held in 2016 and 2017 in the Netherlands to find out what these regional design ateliers contributed to dealing with the challenges imposed by energy-transition.

Regional design ateliers

In regional design ateliers, spatial designers (e.g. landscape architects, urban designers) prepare, organise and hold multiple atelier sessions, in which various relevant regional stakeholders are invited to participate. The results of these atelier processes generally have the aim to be used in (strategic) spatial planning processes (Kempenaar forthcoming). Within strategic spatial planning they serve multiple purposes and have different roles. Regional designs can have a determining character, for example in establishing the common denominators in a region, a problem-defining and agenda-setting character, when it addresses new challenges and issues, a proposing character, e.g. when it support decision making with multiple options, or a composing character, for example in the situation where it connects stakeholders with actions (De Zwart, 2015).

During regional design atelier sessions both the problem and solution space of spatial issues and challenges are extensively explored and discussed with and between stakeholders (De Jonge, 2009; Kempenaar *et al.*, 2016). While doing so, the characteristics of the regional situation and other spatial developments, issues and challenges are always taken into account. After all, the region is no tabula rasa, and multiple trends and ambitions determine the future of the region. Furthermore, regional design envisions possible future regional situations, including how they can come about, and therefore focuses both on the content and process of future developments. In other words the institutional design of the process of change is, next to the spatial dimension, an integral part of the issues addressed.

Regional design ateliers are soft spaces in which stakeholders and designers freely explore spatial issues and their possible solutions (De Jonge, 2009). They generally have little formal power as decision making takes place in other settings and designated places. Interestingly, this relative absence of power, and a strong focus on substantial issues and real situations, is said to create circumstances enabling a genuine dialogue (Ceschin and Gaziulusoy, 2016; De Jonge 2009). In this dialogue, information, knowledge and perspectives are shared and new relationships emerge. Furthermore, this dialogue enables collective conceptualization and envisioning (Kempenaar *et al.* 2016), opening up new perspectives, possibilities, and never-thought-of ideas. It also changes conditions for future developments as it affects the perception of stakeholders, it prepares them for future action and it builds relationships and networks (Kempenaar *et al.*, 2016). These are valuable assets energy-transition processes.

Methods and Materials

In the spring of 2016 the ‘Deal Pilots Regional Energy Strategies’ was drawn up between various governmental organisations in the Netherlands. A group of five regions were selected out of a group of twelve as pilots and

received funding to develop a Regional Energy Strategy (RES). The focus of the Regional Energy Strategy would be an energy-neutral region in the year 2050.

Part of the funding for developing a RES was labelled for organising regional design ateliers. Initiated by Atelier X of the Ministry of Internal Affairs (formerly part of the Ministry of Infrastructure and Environment), a particular goal within the deal was to employ design in exploring and researching the spatial dimensions of regional energy-transition. This resulted in the organisation of regional design ateliers in all five pilot regions.

In addition to the five pilot regions, six other regions are included in this study that organised energy-transition oriented design ateliers supported by Atelier X. Two regions hooked on to the process of the RES-deal, their interest being to learn and gain experience in the ins and outs of regional energy-transition. Four other regions organised regional design ateliers on energy-transition as part of their own (spatial) planning and development processes.

In line with the five pilot regions, all regional design ateliers included in this study took regional energy-neutrality in 2050 (or earlier) as a starting point. Furthermore, they all focussed on formulating and reifying the regional challenges in reaching energy-neutrality, identifying its' spatial impact and opportunities, and the translation of ideas into possible strategies and projects.

To analyse the 11 regional design ateliers we gathered documents on the regional design ateliers via websites, via contact persons, and via personal contacts. The documents were analysed on four different aspects of the regional design ateliers. These are 1) the input for the design sessions, 2) the process or institutional design of the regional design atelier, 3) the output of the design atelier, and 4) the context of the regional design atelier. To supplement the findings from the document analysis, as well as to triangulate the first findings, six interviews were held with designers, consultants and stakeholders involved in multiple of the studied regional design ateliers. These interviews were analysed on the same four aspects of the eleven regional design ateliers. The findings from the document & interview analysis were then discussed with a focus group of 16 experts stemming from various organisations involved in regional energy-transition processes in various Dutch regions.

Results

The spatial dimensions of energy-transition

The analysis of the 11 design ateliers showed that they all created insights on the regional dimensions of energy-transition and its' spatial implications. In each of the design ateliers the stakeholders looked at, and discussed calculations on the current energy-use in the region, the expected future energy-use, the potential for energy-reduction, the existing regional renewable energy production, and the potential for renewable energy sources in the region. The calculations differentiated between gas-, heat-, electricity and other kinds of energy, and between the different demanding sectors, such as industry, housing, transport, agriculture, and offices. For those stakeholders not stemming from the energy-domain, it was enlightening to start learning about what energy-transition actually encompassed.

In addition to the calculations, the use, the expected use and particularly the expected regional potential for renewable energy was translated into spatial dimensions and mapped out for the region. The potential for wind-energy was for example translated into the amount of wind turbines of a certain height, as was the solar-energy potential translated into ha. of solar-parks. These were then placed on a map of the region, clearly indicating the spatial footprint needed for producing enough energy from renewable sources to meet the regional energy demand (as regional energy-neutrality was the starting point of all design ateliers).

In this mapping, specific regional situations were taken into account. For example obstacles or restrictions related to certain land-uses, or protected sites (e.g. nature reserves) were included in the maps. Also the

opportunities for using residual heat was explored, capitalizing on the proximity of housing near heat producing industries.

The visualisations, and particularly the visualisation of the spatial footprint of different renewable energy sources, triggered a lot of discussions. Most of all it created insights and raised awareness on energy-transition amongst stakeholders. Talking about percentages and peta joules (a much used unit to indicate energy) seemed to have kept the discussions up till then rather abstract. Drawing and mapping the implications made them concrete and foreseeable, revealing the radical impact of energy-transition on the existing landscape and spatial situation.

The ateliers furthermore made the stakeholders aware of various uncertainties and unknowns related to energy-transition. Geothermal energy, for example, is seen as a promising potential energy-source. However, its potential depends on the specific geomorphological/geological regional situation. Detailed mapping of this situation is only available for a few areas in the Netherlands, making it hard to incorporate feasible estimations of geothermal energy in the future energy mix of the region. This also accounts for yet unknown, innovations and the development of promising new technologies.

What not addressed

Despite the extensive mapping and visualising of the spatial implications of energy-transition in the regional design ateliers, not all spatial dimensions were fully addressed and explored in the ateliers. Whereas the spatial footprint of renewable energy sources got attention in all ateliers, only a few touched upon the issue of adjusting and renewing the infrastructure for transport of energy. Nor storage facilities for storing the surplus of produced energy, or the spatial dimension of reducing energy use were extensively addressed and explored. Each of these topics, depending on future developments and choices, has specific spatial implications and land-use demands, and is critical in planning for energy-transition.

Furthermore, in most of the regional-design ateliers the relationship of energy-transitions with other spatial issues, challenges and developments was not properly addressed. Energy-transition, as any other major transformation in the spatial domain, leads to opportunities and obstacles for other existing and future land-uses, with potential synergies and trade-offs. One region did incorporate a first exploration of the relationships of energy-transition with economic developments and the revitalization and renewal of neighbourhoods. However, other land-uses and spatial issues such as agriculture and flood-protection were left untouched.

Outside the scope of the region

All 11 regional design ateliers had their main focus on the region, and the discussions were guided by the idea to make the region energy neutral. This raised discussions in all ateliers on the delineation of regional energy-transition. What should be taken into account and what should be left out. What to do for example with national and international transport, both over land, water and by air, related to the inhabitants and businesses in the region? Also the question arose in some ateliers on what to do about other sources of greenhouse gasses (e.g. agriculture or peat oxidation), should these also be included in a regional strategy? Each region took a pragmatic stance on this in the end and clearly indicated what was taken into account and what not.

Furthermore, the relationship with both the local and (inter)national scale was regularly addressed in the majority of the design ateliers. Although the discussions took place on a regional level, implementation of ideas and concrete actions will have to take place on a local level. In addition, some of the investments needed in the future, particularly where new infrastructure is concerned, cannot be decided on, or financed by the region itself. This calls for participation and action from the national government and actors operating on a (inter) national scale.

Finally, in a few regions the discussion also turned to the position of the own region towards other regions. For example, one of the regions discovered during the atelier-sessions that it probably would be able to cover its own future energy demand quite easily with renewable sources, considering the available space in the region. This opened up the exploration of the idea of becoming an energy-supplying region. However, most regions did not (yet) reached the point to address its' relationships with other regions in relation to energy-transition.

Unfinished conversations

The findings on the design ateliers on regional energy-transition in the 11 regions give the impression that the conversations in the regions on the spatial implications of energy-transition have just started and are far from finished. First insights were created, shared and discussed on the spatial dimensions of renewable energy production, the spatial footprint, on the future energy-use and energy-mix in the region. The analysis furthermore shows that other important spatial implications have only been briefly touched upon were completely left out. These include new energy-infrastructure needs and energy-storage facilities, the spatial implications of energy-reduction, relationships and smart combinations with other land-uses and spatial developments, relationships with the local and (inter)national scale, relationships with other other (neighbouring) regions, and a full exploration of the translation of the spatial implications towards a (spatial) strategy.

The seemingly limited scope of the conversations in the regional design ateliers can be explained in several ways. First of all energy-neutrality within the region was the more or less fixed starting point for the design ateliers and the development of the regional energy strategy. This perspective turns the focus automatically inwards to the region itself and less to (possible) relationships with other regions or the local and (inter)national scale.

Secondly, energy-transition is a relatively new topic in the spatial realm, making that stakeholders rooted in this domain still have to become familiar with the ins and outs of the energy-system and future options. This is also the case for all other stakeholders from outside the energy-domain. Furthermore, a similar thing accounts for stakeholders from the energy domain. They have to become familiar with integral perspective and ways of working of the spatial realm. A lot of 'getting to know' and learning took place in the ateliers in order to have a good conversation on the central issue addressed, that is the spatial implications of energy-transition in the region.

Third and finally, energy-transition is encircled with a lot of uncertainties and unknowns. Although a sense of urgency is felt by many, it is unclear what the best way to go is. For example, certain techniques are quite well developed, such as wind turbines and solar panels, whereas others, such as geothermic, are promising but still underdeveloped and unsure. These unknowns and uncertainties inevitably will change in the future, opening up, but also closing down options and possibilities.

Discussion & Conclusion

The results of the study show that all 11 regional design ateliers on energy-transition produced new insights and ideas, and influenced the perspective of the involved stakeholders. To fully employ this influence potential of regional design ateliers two factors are of interest: the embeddedness of the regional design ateliers in the overarching transition management process, and the range of stakeholders involved in the design ateliers. The studied 11 atelier processes all had a different embedding in the overarching process. Some were part of drawing up a regional energy strategy, whereas others were rooted in the development of new spatial visions. Furthermore, the institutional design of each of these processes was different, leading to different use of the results and outcomes. The context in which regional design ateliers are embedded pre-determines where they are expected to have their influence (Kempenaar *et al.*, 2019). This embeddedness should therefore be a point of careful consideration and attention in the institutional design of transition management processes.

The range of stakeholders involved in the regional design ateliers was broad and varied between the 11 studied ateliers. Predominantly, the stakeholders came from energy-related and spatial planning-related public and private organisations. In some cases the amount of stakeholders involved grew during the atelier sessions up to over a hundred people. The involvement of both inhabitants and politicians was limited in most atelier processes, although most included them at dedicated moments during the process. There seems to be no ‘rule of thumb’ on how or when to involve either of these specific groups in regional design ateliers, whereas particularly the involvement of politicians or other decision-makers can be valuable in influencing decision making. Further research into influential regional design ateliers, or in comparable processes, such as design-charrettes in the US (e.g. Condon, 2008; Lennertz and Luzenhiser, 2014), could be the base for developing guidelines for the involvement of different stakeholder groups.

To conclude, the study of 11 regional design ateliers revealed the value of these ateliers in regional energy-transition processes. However, design ateliers are not the only valuable activity. Research, technical innovations, experiments, implementation project etc. can all make valuable contributions. The various activities should be well embedded in the overall institutional design of the transition process, so that all activities can mutually benefit from each other. Furthermore, the analysis also revealed that the potential of regional design ateliers was not fully employed yet. Leading to the recommendation to continue the organisation of regional-design ateliers as part of the regional energy-transition process. In addition, uncertainties and unknowns develop and will disappear or change over time, also from this perspective it can be worthwhile to organise additional regional design ateliers as part of program of activities that fuel regional energy-transition.

Acknowledgements

The authors of this paper would like to thank the interviewees, the focus group attendancee for their involvement and cooperation in the research. Without their input this study could not have taken place. Futhermore, a thanks goes out to dr. Sven Stremke, who regularly gave critical feedback on our work during the research process. Finally, a warm thanks to the commissioners of the research Elien Wierenga and Hans ten Hoeve from Atelier X of the Ministry of Internal affairs.

Regional Design: impacts on territorial governance and planning practice

Land take and regional planning: promoting sustainable settlement development in urban regions

Nina Wahrhusen¹

¹*Department Regional Development and Spatial Planning, Faculty of Spatial and Environmental Planning, University of Kaiserslautern, nina.wahrhusen@ru.uni-kl.de*

Abstract: In Germany the national goal of reducing land take is opposed to the increasing demand for new spaces for housing and commercial construction, especially in already concentrated urban regions. Many dominating regional centers are not able anymore to satisfy the settlement pressure within their own boundaries. So regional solutions are required. Regional planning is an important player concerning sustainable settlement concepts in Germany with almost fully developed tools to provide land reduced settlement structures. Within this paper success factors as well as obstacles for the realization of the vision of compact and environmentally sustainable settlement structures in urban regions are shown. On the one hand, it provides a presentation of the regional planning tools promoting this spatial vision. In the light of an implementation deficit of the regional requirements on local level caused by a lack of acceptance for compact and space-saving settlement structures, there is, on the other hand, a need for innovative approaches of informal cooperation, participation and awareness raising. For this purpose, two case examples from the German regions of Hannover and Stuttgart are presented.

Keywords: regional planning; space-saving settlement development; participation; process design

Introduction

Many cities in Germany are facing increasing settlement pressure due to high immigration rates (Milbert 2017). Especially centres in concentrated urban regions are not able anymore to satisfy the demand for new spaces for housing and commercial construction within their own boundaries. Regional solutions are required to guarantee an appropriate settlement development. At the same time the national goal of reducing land take has to be pursued. Within the strategy for a sustainable development from 2002 the federal government stated to reduce land take for the purposes of settlement and transport nationwide to 30 hectares per day until 2020 (Die Bundesregierung 2002). In 2016 this was updated to “under 30 hectares per day until 2030” (Die Bundesregierung 2017). The long-term perspective is a net-zero land take objective of a circular land use, in which first-time land take is largely replaced by a reuse of existing settlement and transport areas (BMUB 2007). By this, land take is equally recognised as environmental problem as climate change or decline of biodiversity (Rink and Banzhaf 2011).

Since the second half of the 20th century land take for settlement and transport purposes in Germany increases constantly and decoupled from population growth. This has mainly ecological effects (loss of open space, damage of natural soil functions as well as flora and fauna), but also negative social (loss of recreation areas)

and economic effects (increasing costs for the maintenance of infrastructure and mobility costs). Namely the daily growth rate of land take for settlement and transport purposes declines as a result of versatile activities in land policy since 2002. Nevertheless, the development trend of 62 hectares in the annual mean of four years from 2013 to 2016 is still high above the goal of 30 hectares, as seen in Figure 1.

Figure 1: Increase of settlement and transport area in hectare per day (Source: UBA 2017)

Against this background, the development of compact, environmentally sustainable settlement structures in a regional context can contribute to the limitation of negative environmental impacts of land take. Due to cross-border causes and effects a management on local level is no longer adequate. So, regional planning is an important player concerning sustainable settlement concepts in Germany. Based on results from a research project "Compact, environmentally sustainable settlement structures in a regional context" of the Umweltbundesamt (Federal Environment Agency Germany) this paper deals with opportunities and obstacles by implementing this vision. By means of case studies regional planning tools, as well as particularly informal approaches of cooperation, participation and information within the field of action of regional planning, and their management effects were analysed. With regard to latter especially two regions are discussed: the Hannover region and the Stuttgart region. Besides the evaluation of planning documents, it can be relied on intensive expert discussions to conclusively formulate recommendations, how to force space-saving settlement development at regional level.

The definition of compact, environmentally sustainable settlement structures in a regional context

The vision of compact, environmentally sustainable settlement structures in a regional context requires a definition on the basis of qualitative criteria. These rest on the two main negative environmental impacts caused by settlement development: land take and pollution by traffic.

Therefore, settlement structures in a regional context will be compact and environmentally sustainable, if they minimise land take (1), connect new settlement developments to existing settlement structures (2), limit urban sprawl (3) and use land efficiently by developing inner-city areas before greenfield (4). In addition, settlement development should be concentrated on few suitable places, which own an appropriate supply and development

function (5), with accessibility advantages, especially public transport connections (6). The system of public transport therefore serves as base structure of regional settlement development (7) and should be preserved and strengthened (8), so that a reduction of transport related land take and emissions can be achieved (9). At the same time, large open spaces have to be held free from settlement activities (10) and the functions of open spaces to be protected (11). All in all, healthy working and living conditions should be promoted (12).

This definition receives a broad consent among the planning experts of the case studies. It became clear that the aspect of minimising land take is dominant in planning practice, which is why this is focused hereinafter.

Management of compact, environmentally sustainable settlement development by regional planning in Germany

Regional planning in the German spatial planning system is the intermediate level between the both superior levels of national and federal-state spatial planning, and land-use planning on local level. Under the guiding principle of a sustainable spatial development (§ 1 (2) Federal Planning Act (Raumordnungsgesetz des Bundes, ROG)) regional planning concretises the aims and principles of spatial planning, made on national and federal-state level, for the regional level and makes specifications in a regional plan in accordance to § 8 ROG, especially to manage the development of settlement and open space as well as transport, supply and disposal infrastructure. The practical implementation of these requirements on local level occurs by land-use planning. Latter has to adapt the binding aims of spatial planning (§ 1 (4) Federal Building Code (Baugesetzbuch, BauGB)).

The case studies show, that the vision of compact, environmentally sustainable settlement structures in a regional context is embedded in every examined regional plan. Various regional planning tools are used to manage a sustainable, space-saving settlement development. Besides a large-scale location-management (decentralised concentration) and site securing, there are restrictive specifications, which should prevent settlement in unsuitable places and in a not appropriate extent. The single planning tools are designed in accordance to the specific regional conditions in each case.

Basically, the large-scale location-management takes place by defining areas for the concentration of settlement activities; if necessary differentiated for housing and commercial construction. “Central locations” (in Germany defined as municipalities with a determined supra-local supply and development function) generally form such points of concentration for construction. “Development- or settlement-axes” function as regional backbone for settlement development. Public transport stops or stations also often are determined as focal points. This concentration promotes the use and utilization of existing transport infrastructures, whereby simultaneous land take for new ones is avoided. The principle of primacy of inner-city development is also a specification of large-scale location-management. It contributes to the minimization of land take, prevention of urban sprawl as well as keeping and protection of open space.

Another regional planning tool is a small-scale site securing of (preferably regional significant) areas for housing and commercial construction by designated clearly defined priority areas. These prove the connection of new settlement developments to existing settlement structures, the limitation of urban sprawl and focal points of settlement with accessibility advantages.

Besides these prioritised areas for settlement activities, some regions count on a quantitative limitation of spatial development by an obligatory proof of demand for land take. Municipalities have to state their demand for settlement activities on the basis of the expected future population development. The aim is to give them an understanding of strategical consideration of their settlement activities and to prevent open municipal tender planning resulting in land take.

Further limitation of settlement activities occurs by restricting the development framework of certain communes to the extent of their endogenous development (as the reverse of decentralised concentration). This involves the municipalities without supra-local supply and development function. By benchmarking it receives a quantitative dimension. The approaches to determine the local requirement differ in terms of the benchmarks and the related time period. They can refer to a percentage rise of settlement area, but values in relation to population or housing development are more proper, because of their direct reference to the actual needs.

The determination of gross settlement densities for different settlement types to be applied to new housing settlements are another form of quantity management. This contributes to the minimization of land take by using space efficiently. Open spaces and their functions are protected against being built on and damaged.

“Priority areas” and “reservation areas” protecting open spaces work as negative-planning location-management keeping large open spaces free from settlement, and preserving habitats and biodiversity. “Settlement breaks” and “green belts” should, for example, hamper the merging of settlements. Mono- and multi-functional regional planning protected areas complement the open space conversation.

According to an integrated development of settlement and transport regional specifications in terms of securing routes for roads and railways have relevance for compact, environmentally sustainable settlement structures by saving existing lines as well as areas for expansion and new construction. Preservation and strengthening of existing networks prevent land take for transport purposes. Especially routes for new railways are promoting an environmentally sustainable mobility.

Opportunities and obstacles in the implementation of compact, environmentally sustainable settlement structures in a regional context

Opportunities

Objectives and use of instruments in the regional plans in Germany are oriented to the implementation of the vision of compact, environmentally sustainable settlement structures in a large extent. The almost fully developed regional planning tools for this purpose constitutes one of the greatest potential benefits. Regional planning makes use of its regulation and management function in all areas, which are relevant to a sustainable, space-saving settlement development, and influences the development of settlements, open spaces and transport according to the spatial vision. In this respect, it relies on a mix of instruments, which is both qualitative and quantitative, and positive and negative in term of planning. Additional supporting instruments beside the regional plans are systematic monitoring systems for settlement areas on regional level recording factual land take and its change. With steady maintenance these could serve as implementation control of regional specifications.

Off the legally binding possibilities of managing settlement development, currently occasional and regional specific informal approaches in the form of integrated or sectoral concepts, or formats for information, participation and cooperation offer important opportunities for the mediation of the issues and the promotion of the implementation of compact, environmentally sustainable settlement structures in a regional context. Meanwhile mandatory on local level, the use of such informal approaches on regional level is limited yet.

A significant success factor of the vision’s implementation is the awareness of its necessity and the commitment among the regional planners. Expert discussions as well as the design of the regional plan can state this. As addressees and finally responsible authority for the implementation of regional specifications the local level of land use planning and its actors is another important factor. Thus, it is beneficial that awareness and commitment for compact, environmentally sustainable settlement structures is existing among the local planners as well. Formats for exchange between the regional and local level are mentioned as very helpful.

Also, a “strong” status of the regional planning, appearing in consistent assertiveness, has occasionally been stated as an advantage in the implementation of the vision. In connection with inter-community conflicts it is even demanded in the sense of a clampdown. The significance of the regional level for the management of sustainable settlement development is illustrated by this.

Obstacles

Although the regional planning management instruments, characterised by a restrictive locational management approach, constitutes one of the greatest benefit potentials for the development of compact, environmentally sustainable settlement structures, occasionally there are deficits in the implementation of the vision within the regional concept of settlement structure and use of regional planning tools. In particular, wiggle room appears in the limitation of land take and acceleration of a compact settlement structure due to increased densities. Quantified specifications derived from the 30 hectares-goal are hardly made yet.

The regional provisions need to be implemented by the land use planning on local level in accordance with the planning sovereignty derived from the guarantee of municipal self-administration. Therefore, the decision-making as well as their influencing actors on local level constitute central factors. The major obstacle in this context is the citizens’, the business community’s and politicians’ lack of acceptance or awareness of compact, environmentally sustainable settlement structures in a regional context.

Residents influence the shape of new residential areas through their residential preferences, predominant home ownership of single- or two-family house with garden. At the same time, more concentrated structures in their own environment are rejected, caused by stigmatization of clients of multi-floor residential buildings and concerns about traffic-referred exposure or negative effects on city- and landscape. In addition, there is an increased willingness to oppose construction projects. The “Not in my backyard (nimby)”-effect especially occurs, if denser areas of (housing) construction are to be built. Thus, an efficient use of space with reduced land take is hampered and planning processes become increasingly complicated and longer.

Accordingly, a less dense settlement structure is often pursued by political actors as well. Especially in less dynamically developing regions space is even seen as an economic factor, by which the aforementioned residential preferences can be satisfied and residents be gained. This political self-interest at local level is based on financial considerations within inter-municipality competitions, for example for affluent citizens, jobs or income tax. It constitutes an obstacle to the implementation of compact, environmentally sustainable settlement structures and causes excessive land take. Furthermore, the lack of long-term strategic considerations around settlement development at the local level has a negative effect in this context, hampering a needs-based and efficient land use.

Despite an increasing regional way of living, where living, working, shopping etc. take place in different locations, the politicians’ and citizens’ perspective is strongly marked by the local and with regard to a sustainable, space-saving settlement development sparsely beneficial. This is also apparent in the low level of intermunicipal cooperation, especially in the development of commercial areas, which hampers efficient cross-border land use and exploiting locational advantages.

Within the case-study regions, concentrated structures play no role for companies, whereby potentials to save space cannot be taken to advantage. Instead, still space-intensive hall buildings with large parking areas are dominating. Retail mostly is organised single-story as well. Consequently, the accompanying space requirement for industry and commerce regularly is realized on greenfield, followed by a loss of open space and their natural functions.

Another obstacle are speculations by land owners of undeveloped real estate as potential areas for construction or compensation in outer-city areas as well as potential sites in inner-city areas. Therefore, on the one hand development areas, saved by regional planning and suitable in accordance to a sustainable settlement development, on the other hand inner-city development potentials cannot be activated. Efficient land use through inner-city development and simultaneous reduction of land take becomes more difficult, and opportunities for developing suitable sites limited. At the same time, the resulting alternative land take of available open space favours urban sprawl and fragmentation.

Complementary, increased use of informal approaches of cooperation, participation, awareness rising and sensitisation in terms of a space-saving settlement development

The sophisticated regional planning tools indicate, that compact, environmentally sustainable settlement structures in a regional context accompanying reduced land take occurred, if settlement development would follow the strategies of regional planning. But, the regional planning is lacking incentive and executive instruments to strengthen implementation of the vision. Though, within the existing legal framework there are various possibilities to support the regional objective of saving space by increased use of informal approaches and measures. Two good examples of innovative informal participation serve the German regions of Hannover and Stuttgart.

Save space together by regional cooperation and spatial development concepts

Local perspective and motivation of decisions partly differ significantly from regional. Furthermore, a cooperative, intercommunal development of settlement is hardly existing in Germany. So, efficient organisational structures for a more intensive intercommunal or regional cooperation have to be created as a framework for multi-level and multi-actor discussion of this topic. The aim is, at least, to curb local competition for residential populations and enterprise (UBA 2018), to promote a sustainable land use, and to protect open spaces. The basis for collaboration is informal cooperative approaches rested on voluntariness, consensus-building and self-commitment. Building confidence is essential. Within horizontal, network-like cooperation and dialogue, small-spatial as well as thematic aspects can come to the fore. One instrument for showing the results of these processes, and for fixation of objectives and strategies, are regional development concepts (UBA 2018).

Informal cooperation regarding the minimization of land take particularly provides itself in the specific fields around the development of residential and commercial spaces, to come to a fair mutual handling and a win-win-solution for all. Thereby, quantity goals for land take should be discussed and preferably be agreed, and perspectival an equalization of benefits and burden be established. In these more conflict-ridden area, intercommunal cooperation has to be understood as a learning process, which is sometimes suffers backwards steps, before a breakthrough can be achieved. Functioning informal approaches often represent a preliminary stage to official cooperation with long-term impact (UBA 2018).

New elements of process design to convince local decision-makers

As cities and municipalities, as bearers of the planning sovereignty, implement the regional specifications, acceptance for the regional space-saving strategies has to be won among political decision-makers at local level. As a result, inclusion of these in regional negotiation processes is significant to realize compact, environmentally sustainable settlement structures. It is important to put the topic onto the political agenda, to convey the regional-planning vision of settlement development, and to encourage understanding.

A first step is to prematurely involve politicians in the regional plan preparation procedure. Herein regional needs around settlement development, in particular the generation of compact, environmentally sustainable

settlement structures in a regional context, should be clarified and appropriate cooperative goals be identified. By using simulation games, impacts of different development strategies are shown. Results, such as cooperative developed goals, absolutely have to be made visible within the regional plan specifications. A transparent mediation of backgrounds influencing the design of regional planning and of underlying strategies for the regional settlement concept, pursued by the regional plan, contributes to the implementation in local level. The role of regional planning is to initiate, organise and accompany the discussion process as well as show and communicate the results.

Exchange between regional and local level should occur regularly and continuously in order to discuss the themes of sustainable, space-saving settlement. Therefore, an example are mayors' meetings joined by regional planners to convey the regional planning ideas. Further possibilities of awareness rising and required action illustrating are excursions and training events for political decision-makers. By showing best-practice examples for concentrated construction and settlement a positive image is created. Efficient and space-saving land take can be supported by showing or even providing information- and monitoring tools for inner-city development.

Sensitisation of citizens and companies of compact, space-saving settlement structures

Regarding the lack of awareness and even defensive reactions concerning concentrated, space-saving settlement structures among citizens there is a significant need to create macrosocial awareness for compact, environmentally sustainable settlement structures. Thus, the efforts of conveying this vision have to be addressed to citizens and companies as the end users of land as well.

Civil dialogues at local level increased and were specifically planned in the past years, neither did regional coordination and planning processes. Therefore, regional planning should contribute to a public debate and a sensitisation for the vision by using formats of information, communication and participation. Also, persons not directly concerned by construction projects could be introduced to the topic in this way. Especially impacts of behaviour patterns, for example the choice of residential location in relation to working location or the choice of a certain form of housing, have to be discussed. It is important to show regional coherences and effects, which currently increase in everyday live. By including civil and commercial actors in regional planning and development processes their increased need for participation will be met. As already stated, cooperative developed guiding principles serve as legitimisation for regional planning action and objectives' implementation.

The demonstration of positive examples of dense residential and commercial areas, and inner-city development projects, have significant potential to generate acceptance for compact, environmentally sustainable settlement structures in a regional context.

Regional participation process "Vision of the future for the Hannover region 2025" within the preparation of the regional plan

In the run-up to the preparation procedure for its regional plan, the Hannover Region, as a regional planning agency, in 2012 and 2013 carried out a comprehensive new informal participation process in Germany, involving experts and specific stakeholders as well as citizens in order to create a vision of the future for the region. In the following, this served as the basis for the further concrete design of the regional plan.

Through various events for different target groups, two public dialogues as a kick-off and closing event, the internet platform "Dialogue: Future Region Hannover", which offered information but also the possibility of an interactive dialogue for discussion, as well as an accompanying positive dissemination in the media a broad social discourse was created. A total of eight expert workshops and a joint expert dialogue were held for the regional specialist administration teams, the representatives of municipal planning and external experts. An innovative aspect was the early involvement of citizens in the context of regional planning, which was promoted

by the Federal Ministry of Transport, Building and Urban Development as a model project of national urban development policy. Around 12,000 inhabitants participated in five dialogue forums on five core topics and via the internet platform. Regional politics was integrated and informed during the process. In addition, a workshop took place with the regional committee members to discuss the draft of the future vision.

The results of the process are seven “visions of the future” on the topics of equal opportunities in demographic change (1), economic development (2), equal and healthy living conditions (with less space consumed) (3), open space and recreation (4), energy and climate protection (5), mobility (6) and cooperation (7). For each of them, target statements were formulated for the period up to the year 2025, concrete ways of implementation were pointed out and vividly presented via collages. Fixing the seven “visions of the future”, represents the consensual setting of objectives for regional development and serves as a basis for legitimising further regional planning action (Region Hannover 2014). This has created awareness and acceptance among local decision-makers, citizens and companies about the challenges and approaches of regional development. The necessity of a compact, space-saving settlement development with an adequate supply of open space to the cities and municipalities was communicated.

Participation and model process “International Building Exhibition 2027 CityRegion Stuttgart”

An International Building Exhibition (Internationale Bauausstellung, IBA) is an instrument of urban and regional development. It serves the development, testing and presentation of innovative constructing and planning solutions. Under a specific theme, exemplary and forward-looking processes and model projects are carried out in a district, city or region within a limited period of time and space. Current tasks and developments in architecture, urban planning and regional planning should be demonstrated and discussed in and with the international public (Open IBA 2019, Spektrum 2001).

The “IBA 2027 CityRegion Stuttgart” takes place between 2017 and 2027. It is intended to turn the region into a field of urban planning and development by experimenting with exemplary innovative solutions for sustainable urban development. The framework of the “IBA 2027 CityRegion Stuttgart” is built by four different thematic complexes. Within the thematic complex “Building culture of a new modern age” a new urban development and planning model (“Charter of Stuttgart”) should be developed, which in particular addresses the problems of housing shortage and the aspects of mixed use, density, sustainable mobility and urban landscape integration. The second complex “Integrated neighbourhoods” aims at the creation of a mix of urban spatial functions, in which affordable living space is provided and current needs such as intergenerational housing forms and open spaces close to residential areas are addressed. Innovative, space-saving solutions are to be developed against the background of the high regional settlement pressure. The complex “New technologies for the urban region worth living in” refers to resource- and energy-efficient construction and digitisation in urban and regional development. “Region is city and city is region” describes the fourth complex. It deals with bundling regional forces in order to cooperatively manage the current spatial change under the influence of growth, the contrast between building and landscape, city, nature and river (Wirtschaftsförderung Region Stuttgart GmbH 2016). Within the framework of the “IBA 2027 CityRegion Stuttgart” several so-called IBA districts are to be created with model character for other regions and municipalities. The individual projects then form an IBA network: on the one hand, virtually through knowledge transfer and research work in urban and regional development, and on the other hand, in reality through construction and infrastructure measures. Until the final festival of the IBA in the year 2027 further IBA festivals in the years 2023 and 2025 are planned. These are understood as “exhibitions for temporary experimental buildings”. After completion of the IBA, all exhibition projects will be integrated into the region and reused (IBA 2027 StadtRegion Stuttgart GmbH 2018).

Before the start of the “IBA 2027 CityRegion Stuttgart”, a participatory platform process was carried out in 2016. Around 500 people from civil society, politics, planning, architecture, arts and industry took part in various workshops and forums. The results, consisting of the thematic complexes, were recorded in the

"Memorandum IBA 2027 CityRegion Stuttgart" and presented at a closing event (IBA 2027 StadtRegion Stuttgart GmbH 2019). The IBA is managed by the company "Internationale Bauausstellung 2027 StadtRegion Stuttgart GmbH iG" founded in September 2017. Its main shareholder is the state capital Stuttgart. "Verband Region Stuttgart", inter alia responsible for regional planning in the Stuttgart region, and the regional business development are participated as well. Further the Baden-Württemberg Chamber of Architects and the University of Stuttgart have little shares each. An artistic director takes over the artistic and content direction (VRS 2019).

Understood as a field of experimentation, the IBA offers the opportunity to involve a broad spectrum of actors in the themes and challenges of regional development. On the one hand, aspects such as settlement densities in particular can be brought closer to the relevant actors through knowledge transfer and exchange in the IBA networks. On the other hand, IBA projects and neighbourhoods make it possible to experience high-quality, space-efficient settlement structures in a regional context. In this way, they contribute to raising awareness and increasing acceptance of sustainable settlement development. Special interest on the part of regional planning applies to the experimental testing of a greater mixture of spatial functions, the review of regional planning action in view of the lack of implementation instruments as well as innovative approaches of new building law (Region Stuttgart 2018 verbal). By involving planning actors, politicians, companies and citizens in this open-ended framework, new impulses for innovative approaches and implementation instruments for integrated planning as well as awareness rising and acceptance for sustainable, space-saving settlement structures are possible.

Conclusion

The reduction of land take and the realisation of sustainable settlement development are central aspects of the German spatial planning practice. As central interface between federal-state and municipality and equipped with a sophisticated tool box, thereby, regional planning has great importance to the implementation of compact and environmentally sustainable settlement structures in a regional context. Efficient use of space by concentrated settlement structures and active minimization of land take on local level often comes across with acceptance deficits and even resistance among citizens and companies followed by politicians. Informal approaches promoting sustainable, space-saving settlement structures in a regional context can help to rise awareness and commitment. Though, these preparatory and accompanying steps besides legally binding regional planning specifications require additional human, financial and temporal resources. Especially, the increasing need and demand for participation and information, such as rising legal requirements for planning procedures claim manpower and working time of regional planners and create costs. So, there is a need to increase human and financial resources in accordance with the new regional planners' and developers' profile of requirements for an appropriate fulfilment of existing tasks as well as newly arriving ones, like a more intensive participation, communication and awareness rising.

Regional strategy design

– addressing transformations in multiple ways

Timo Matti Wirth¹

¹*RWTH Aachen University, wirth@la.rwth-aachen.de*

Abstract: Regions in the 21st century are subject to global influences which include climate change, resource scarcities, economic transitions, demographic shifts and ongoing digitalisation. If sustainability is to be achieved within this changing context, new collaborations will be required which shape these transformations more proactively. Alongside this, awareness within planning has been evolving, including the recognition that various regional design approaches can complement established planning procedures. Building on these aspects, this article investigates the option to design long-term strategies for the development of regions which are facing fundamental change. To undertake this, a process is considered which took place within a real life experimental situation over a period of four years. This process involved the testing of a new model for “regional strategy design”, which required the cooperation with stakeholders from diverse institutional backgrounds. The Rhenish Mining Area (RMA) in Germany, which is characterised by rapidly changing circumstances, served as a case study. The discussion of the results reflects on the preconditions (e.g. established regional governance), outcomes (e.g. selective interventions) and the question of transferability. It can be concluded that regional strategy design has the potential to develop further as a field of activity.

Keywords: regional design, regional governance, proactive transformation, strategy making

1. Introduction

This article introduces and reflects an approach – regional strategy design – which is intended to address fundamental regional change in multiple ways. Ideas are based on the fact that regions are experiencing worldwide influences including climate change, resource scarcities, economic transitions, demographic shifts and ongoing digitalisation. The 21st century is therefore likely characterised by transformations instead of incremental changes (WBGU 2011, Randers 2012, Schneidewind 2018). In this context, the goal to achieve **sustainability** has been the consensus position of most nations worldwide since the “sustainable development goals” (SDGs, see: UN 2012). On a broad scale, regional societies have to anticipate and qualify “**proactive transformation**” processes beyond crisis management (Wirth 2019a). Within such a context, various changes within planning conceptualisation can be considered as the foundations for this article:

- At the urban and regional levels of action, demands, complexity and integrative needs are high (Albrechts 2004, Healey 2007, Albrechts 2013, Bryson *et al.* 2017), requiring **both short- and long-**

term action (Albrechts 2004, p. 743). Moreover, it is impossible to fully understand and manage interactions between society and space. In this regard, **systemic perspectives** towards regional development offer realistic ways forward. Pragmatically, questions of boundaries, context-specific methods and interventions can be determined on a context specific basis and also simultaneously to some extent (Hartman and Roo 2013, Sposito and Faggian 2013).

- Since the "communicative turn" (Healey 1992, p. 143) and "cooperative action" (Selle 1995, p. 240) in the 1990's, the ambition exists to integrate societal interests into planning procedures on a more frequent and pluralistic basis. In consequence, **multi-functional demands** beyond the scope of land use zoning have come to the fore. Also more generally, standardised planning tools have reached their limits regarding their perspectives, impacts and legitimacies in Europe and beyond (Fürst 2008, Kunzmann 2013).
- In the sense of **planning as an adaptive process** (Wiechmann 2007), **regional governance initiatives** especially have filled gaps – i.e. network cooperation between public authorities, the private sector, academia and civil society (Adamaschek 2003, Albrechts *et al.* 2003). Within regional governance, the coordination of strategic approaches and pilot projects, as opposed to area-wide planning proposals is usually at the forefront (Fürst 2003, p. 442, 2008, p. 94). If open and democratic, this includes or potentially enables **coproduction** approaches, whereby citizens and grassroots organisations take an active role (Albrechts 2013, p. 48).
- In support of regional governance initiatives, (strategic-) planning is frequently concerned with the definition of identity. Often this is combined with efforts to establish **future visions** for a region. In a few, all-too-rare, examples, such as London/UK or Hannover/DE, such visions have explicitly influenced a sustainability transformation of an inclusive and innovation friendly character (Landeshauptstadt Hannover 2011, Greater London Authority 2018).
- Sustainability challenges like climate change (SDGs No. 7, 12, 13, 15) have radical impacts and need untried solutions which must facilitate responses that are both fundamental and explorative in nature. These will require **new implementation models** at different spatial scales using common quality principles (Ganser 2006) and will frequently combine stakeholder knowledge from both practice and science (Schön 1983, Schneidewind and Wissel 2015).

Strategy making, which can be delivered in many different forms (Wiechmann 2007, 2008), has the potential to integrate various demands (Healey 2007), including those previously referred to. Strategies generally describe complex behaviour patterns to achieve long-term goals. In a regional context, strategies are established within complex institutional settings and offer reference points for stakeholder and citizen action. Strategy making can make use of **multi-methodological** working techniques like networking, scientific analyses, plan development, visioning, local implementation and reassessment (Bryson 2016). **Design** can obviously play a major role within regional strategy making processes – at least if understood as a complex and creative decision-making process between rational ambition and intuition (Schön 1983) that is apt to solve even “wicked problems” (Rittel 1973, p. 155).

Specifically considering action at the regional level, **regional design** approaches have been pursued for decades, if not centuries (Neuman and Zonneveld 2018, p. 1). Regional designing has a great diversity of facets, dimensions and performances (Förster *et al.* 2016, p. 5), but generally responds to long-term visions and development perspectives, especially when pressure for change is significant (Kempenaar and van den Brink 2018, p. 80). Often, both physical dimensions and social processes are emphasised (Neuman and Zonneveld 2018, p. 5). In regulatory terms, regional design is a non-binding supplement to the official instruments within planning systems. By addressing specific gaps e.g. limited vision-making capacity within regional planning, its

participants can act in more fundamental, better defined and more experimental ways. In line with this, the range of stakeholders involved tends to be more inclusive and more public compared to formalised planning processes (Balz *et al.* 2014, Förster *et al.* 2016, Kempenaar *et al.* 2017).

There are also examples, where initiatives have **designed regional strategies** aimed at facilitating long-term transformation processes; a theme particularly relevant for this article. In this context, the German IBA Emscher Park (1989-1999) can be regarded as a special example. Based upon a regional change vision, the initiative implemented 91 local projects. The latter included redevelopment of former industrial sites, new housing areas, technological parks for innovation-oriented enterprises and pilot projects which promoted an ecological modification of the entire regional water system (Ganser 1999a, 1999b, Projekt Ruhr GmbH 2005). Nevertheless, one of its leaders retrospectively criticised the lack of long-term impacts and suggested a more “general strategy for the economical, ecological, cultural and social development of a space” (Ganser 2006, p. 545). The relatively recent project “Metabolism of Albania” is an example that may be seen as the modest beginning of a such an approach (Brugmans *et al.* 2016).

Inspired by such examples, this article addresses the option to design long-term strategies for regional development facing and undergoing fundamental changes. To undertake this, an investigation was conducted within a real experimental situation, based upon the application of a new process model for “regional strategy design”. Out of necessity, the approach reflects changing understanding of planning as previously described, to become instead: systemic and multi-functional in orientation, process based and collaborative in character, involved in transformative visioning and also partially responsible for facilitating implementation. In the discussion, preconditions, outcomes and transferability are considered, before final conclusions regarding the potential future of regional strategy design are outlined.

2. Method

For the investigation, the Rhenish Mining Area (RMA) in the state of North Rhine-Westphalia in Germany served as a case study. The region is experiencing a sudden transformation process, due to the accelerated cessation of mining activity and the wider need to develop new spatial, economic and technological futures (Wirth 2019b). With a focus on selected topics of regional significance, the author designed a strategy for the RMA over a period of approximately four-years (2014-2018).

The design process took place in a real experimental situation. Activities were not only geared towards evaluating scientific evidence, but also towards finding solutions to societal interests and needs (Schneidewind and Singer-Brodowski 2014, p. 126). In this case, it meant the author’s own design activity (Pedgley 2007) operating in tandem with the input of other individuals. This role occurred simultaneously both as a research associate at the faculty of architecture (RWTH Aachen University) and as a project manager within a special regional governance initiative dedicated to innovation-oriented projects for the RMA (Zukunftsagentur Rheinisches Revier - ZRR). This resulted in a joint role for the author in two different tasks:

1. In the context of scientific activity, the primary goal was to extract findings, i.e. which outcomes design interventions can produce under certain preconditions in order to guide transformation processes within a region. Responsibilities also included teaching of design studios (architecture / urban design), which were organised in an exploratory manner as part of the investigation.
2. Within practice, the task initially consisted of designing thematic strategies for regional development. Later, the initiation of site-based concepts and operations, would lead on, to potential delivery of clear added value for the region.

The real experimental investigation brought various institutional groups into interaction (see Figure 1). This involved participants from both science and practice:

- 18 key stakeholders in three discussion workshops on the future of the RMA
- Experts / stakeholders from economy, research and policy fields (between 5 and >100 people, depending on topic)
- 8 practitioners in a changing team of regional development (ZRR GmbH)
- 1 research assistant (geography & resource management) at the university
- 38 architecture / urban planning students in design studios

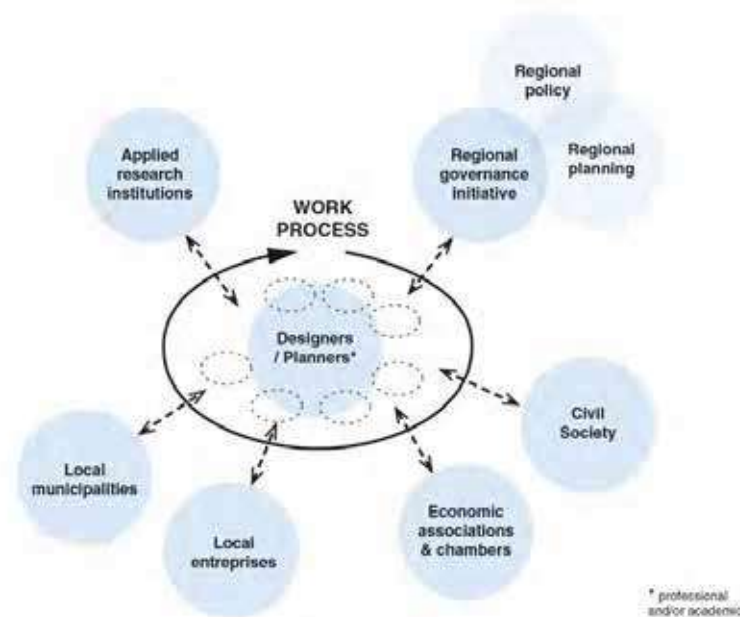

Figure 1: Institutional setting for the real experimental investigation (source: own).

In order to structure the work process, the author tested a new process model for “regional strategy design” (see Figure 2). The model resulted from a criteria-based comparison of six existing models. The latter originated from discourses related to regional governance (Kühn 2008, Bryson 2011), urban metabolism (Oswald and Baccini 2003, Heck 2008) and regional design (Stremke 2010, Brugmans *et al.* 2016). The model for regional strategy design suggests interrelated work sections, which can be understood as building blocks towards a complex strategy. Depending upon the application context, modifications, additions or reductions have to be considered independently on each occasion. Activities within the various work sections can be conducted simultaneously and through partly interactive processes, rather than through use of a traditional linear model. Therefore, linkages and timing were deliberately not specified, at the beginning of the real experimental investigation.

Work of a mainly analytical character was conducted mainly in the scientific sphere and supported by discussions with stakeholders. After the initial activities towards a regional vision (in this case via a series of three events), emphasis was placed upon a second phase with practical activities such as networking within the regional governance institution. Here, actions were considered in more detail, were consolidated and also partially implemented.

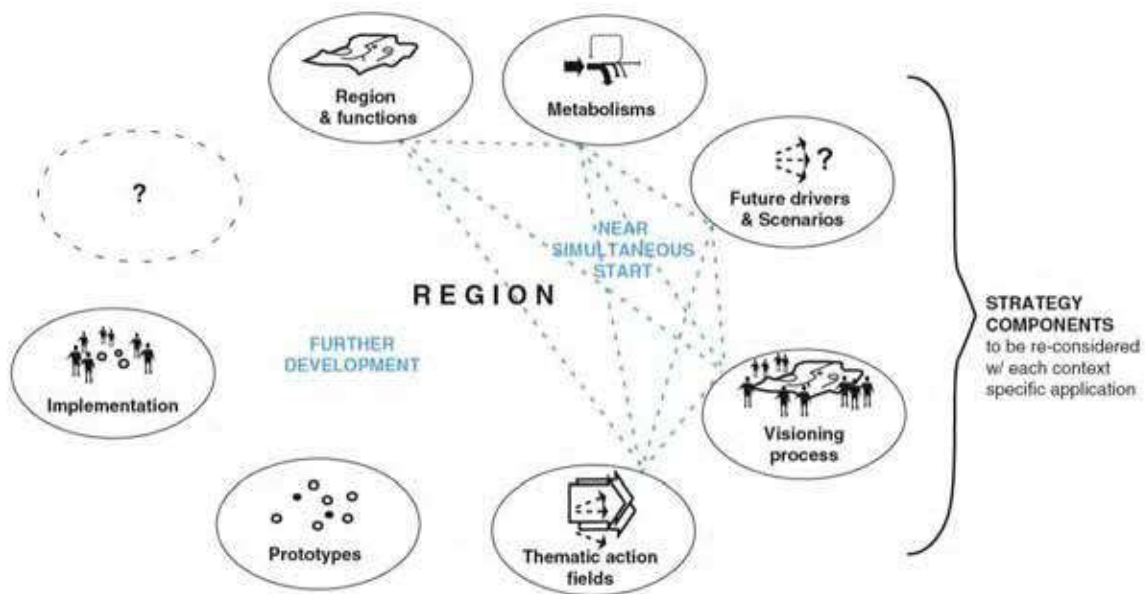

Figure 2: Institutional setting for the real experimental investigation (source: own).

3. Real experimental investigation

This main part of the article reflects the multi-year design process and the resultant experience gained within each work section of the model. Outputs arising from the process, including place-specific results, are also described, in order to provide the reader with tangible examples. However most details regarding these specific results are stated in a further and more comprehensive text (Wirth 2019a).

3.1 Region & functions

In this work section, the space of the region was analysed and key institutions/industries with spatial influence were identified by the author. Later, systematic consideration was given to how far basic socio-ecological needs (e.g. employment, food, recreation or biodiversity) were fulfilled within the region and how far certain assets (e.g. university locations or good soils) were existent. With regards to such questions, a functional analysis was carried out, which concluded with identification of regional strengths and weaknesses. The process started with data-based analysis at university (studies, reports, maps, statistics), then featured visioning with stakeholders (see 3.4) until finally, details were expanded during internal discussions at the ZRR.

The study area is shared by six administrative districts between the cities of Aachen, Cologne, Düsseldorf and Mönchengladbach. An active lignite mining industry is still located in the centre of the Region, although it does not solely dominate the area. About 2.1 million inhabitants live in 64 cities and municipalities (IRR 2014). Overall, various energy and resource-intensive industries such as chemical production, construction, metal, paper and wood processing are active in the region. Regarding land cover, the area consists primarily of fertile loess soils that are used by industrial agricultural enterprises (IRR 2016).

A major **strength** which appeared is that the region is spatially and economically diverse in comparison with other industrial regions in Europe. Moreover, special sites are available for new working and living concepts, including large areas that are being rehabilitated following mining cessation. Advanced knowledge is especially

present in technology-related sectors, e.g. engineering. In the context of a global knowledge economy, the region benefits from prestigious research locations. Finally, albeit still at a purely aspirational level, there is future potential to create a lake type landscape that can evolve following mining activity once open pits are flooded. The core area, the actual RMA, could therefore change in the future from hinterland to become a special destination.

Regarding its **weaknesses**, the study area still represents a region that is largely based upon the consumption of finite resources. In addition to lignite mining, most other industries still act predominantly as linear economic systems. This is associated with negative externalities: CO₂ emissions in the region are high, gravel and sand pits can be found throughout the landscape, nitrate pollution in groundwater and air is problematic, there is low biodiversity within agricultural areas, and aquifers which have been drained for mining now require artificial irrigation to sustain and recreate wetlands. Finally, as far as cultural factors are concerned, the negative effects caused by landscape destruction and relocation/resettlement (also as the result of mining), are obvious and have created considerable controversy for decades.

3.2 Metabolisms

In this work section, metabolic flow analyses were conducted with the help of a research assistant (geography & resource management) at the university. This detailed assessment of inputs, outputs, emissions and sinks for natural resources allowed the development of a variety of conclusions towards creation of a transformative strategy, e.g. one that could lead to a renewable energy supply for the region and/or to circular production patterns for certain industries. With respect to analysis, literature and data were just as important as the exchange of information between experts from statistical agencies and economic sectors. Three out of four investigated metabolisms revealed an acute need for action in the region.

The **energy** system at a state level is facing enormous challenges in view of the nationwide climate protection targets (above 80% CO₂ reduction compared to 1990). This is even truer for the RMA region. The analysis of energy flows demonstrated the great potential for future efficiency measures, which was also confirmed by energy experts. It became clear, that the growth of renewables alone cannot ensure future energy supply and effective climate protection alone.

In **construction** it was revealed that only a small proportion of the raw materials used annually can be substituted by secondary raw materials. A full circular economy is not possible if current consumption patterns continue. Nevertheless, many raw materials still land unnecessarily on landfills or in backfilling. Where recycling still takes place, there is a significant devaluation of the material, since it is only used for earthworks and road construction.

Consideration of the **agricultural** sector could only be made provisionally, due to lack of adequate data. Nevertheless, the high nitrogen excess appears significant. Reduced and more efficient fertilisation is therefore required to minimise excessive inputs of nutrients into ground- and surface waters by agriculture. The small amount of artificial irrigation shows that agriculture has only been irrigated to a very limited extent.

Water resources were still abundant at the time of the investigation. The analysis however, supported by a discussion at the regional water authority, showed potential water issues. With the end of draining currently resulting from mining operations, the hydrological system will fundamentally change (rising groundwater / lakes). Probably this will be barely noticeable for industry and households. However, climate change impacts might require a systematic irrigation of agriculture in the future, which would eventually take a significant toll on the regional water budget.

3.3 Future drivers - scenarios

In this work section the author dealt explicitly with the question of which long-term developments could take place in the region. For this purpose, future influences were examined based on forecasts / literature, often from beyond the regional scale. Scenarios were then derived, which were amended by stakeholders in two workshops. The scenarios illustrated fictive situations in the future with textual and visual narratives, in order to facilitate orientation for the design of the overall strategy.

As explained earlier, the area of the RMA is a versatile cultural space, however it is still characterised by multiple linear economies and their associated negative impacts. Quite obviously this stood partly in contrast to many of the key challenges in the 21st century which were analysed and included:

- climate change
- scarcity of resources
- limited land availability
- rising social inequalities
- economic change
- digitalisation

Hence it became obvious, that the region will undergo a fundamental transformation over the coming decades that will occur across economic sectors and land uses – i.e. well beyond perceived structural change effects due to the end of lignite mining. Subsequently, three future scenario narratives were sketched out. Each of the scenarios described a different speed and intensity of transformation in the RMA until the year 2050. In the "extremely negative scenario" the region reacts too slowly and too defensively to external drivers. The "ambitious scenario" describes the impact more or less of the established policy direction towards more resource efficient and regenerative lifestyles. The "extremely positive scenario" involves the possibility of disruptive innovations (e.g. new energy technologies) and as yet unforeseen, paradigm shifts leading towards a region characterised by rapid material cycles, abundance and an accelerated emergence and urbanisation of the lakes.

3.4 Visioning process

Drawing on information from the work sections described previously, three in-depth stakeholder discussions dedicated to visioning were organised. In this case only about ten regional stakeholders per discussion were involved, although, ideally, this would have included broader participation / coproduction. Within the overall vision, individuals involved also agreed upon theme-related core competencies that should be mobilised in first steps towards a transformative strategy. The potential spatial impacts of the individual stakeholder types were quite different. In terms of interests represented, stakeholders with mainly economic goals (e.g. job creation) as well as those with more environmentally motivated intentions (e.g. climate protection) exchanged thoughts and positions. By using input presentations as starting points, the author also shaped the discussion process in order to steer the positions of stakeholders in a common direction.

Representatives of mining and agriculture had a direct spatial influence on large parts of the region. Both mining and agriculture also provided a significant number of jobs. At the time of the talks, about 20,000 people were directly and indirectly employed by the mining company. The latter was also engaged in regional development

initiatives, for example through the sale of real estate, the support of projects by the municipalities and expert contributions to update procedures regarding state and regional plans. As a result, there were certain interdependencies between mining companies and regional development initiatives. The actors from research and civil society had rather indirect impact upon regional space, in the form of research contracts or initiation and support of public projects.

Figure 3: During one of the stakeholder workshops (Photo: F. Lohrberg/RWTH Aachen)

Although the mix of stakeholders in the discussions was quite diverse and even controversial, the group achieved a consensus of a common long-term vision. Instead of giving free rein to de-industrialisation, one could steer a proactive reorganisation process that was mobilising the RMA as an "area of opportunity for a future industrialisation" with explicit orientation along ecological sustainability goals and a public re-qualification of space. To follow this vision, outstanding knowledge resources within the region were identified including those which were:

- specialised in energy supply for generations, increasingly also renewable energy
- continuing key industrial production with a wide range of industries including chemistry, metal, construction/building and paper/wood
- high-performance agricultural enterprises benefitting from a mild climate, fertile loess soils and proximity to regional sales markets and metropolitan areas such as the Ruhr area
- planning / realising landscape change on a large scale (recultivation, translocation, redesigned highways, watercourses and lakes in the future)
- many renowned universities and research institutions as potential contributors to regional development

3.5 Thematic action fields

In this section, the author designed thematic action fields (Figure 5) in cooperation with associated stakeholders. Based upon the outputs of the common visioning process, the work was carried out at the interface of university and regional development practice. One workshop or more with theme-related stakeholders was held per action field (with one exception). Overall, not only were immediate regional interests decisive; in addition, democratically legitimised policy decisions at state, federal or global level were incorporated (e.g. climate protection goals) within the discussions. Finally, each thematic action field included a vision, goals, courses of action and an overview of relevant stakeholder groups. The fields became flexibly oriented to all scenarios, but were still meant to steer away from the unwanted negative scenario. In retrospective however, the scenarios had a rather small, at best inspirational influence here.

The work took place up until year 3 of the 4 year research period. It was understood provisionally, to be the precursor of a longer and more comprehensive decision-making process in the future of regional development. During this first step, four thematic action fields were conceived.

1. Regional power plant

The entire region transforms from a fossil fuel consumer and energy exporter into a horizontal power plant that interlinks and controls decentralised producers, utilities and users in technically and spatially new ways.

2. Circular building economy

The region establishes itself as a pilot area for circular economy, especially in the construction sector. New value creation effects arise through a cluster approach between deconstruction, recycling, building material production, planning and construction.

3. Food region

The region evolves from a standard agricultural producer (high yield per hectare with low environmental regulations) to a versatile food region with new cultivars and high-quality production, allowing for a more diverse landscape to develop.

4. Regional open space system ‘lakes’

In stages, a multifunctional open space system improves public access, recreational opportunities and landscape quality in the core area of the region (opencast mines, recultivation and surrounding areas) and future lakes can be already spatially incorporated decades before their final emergence.

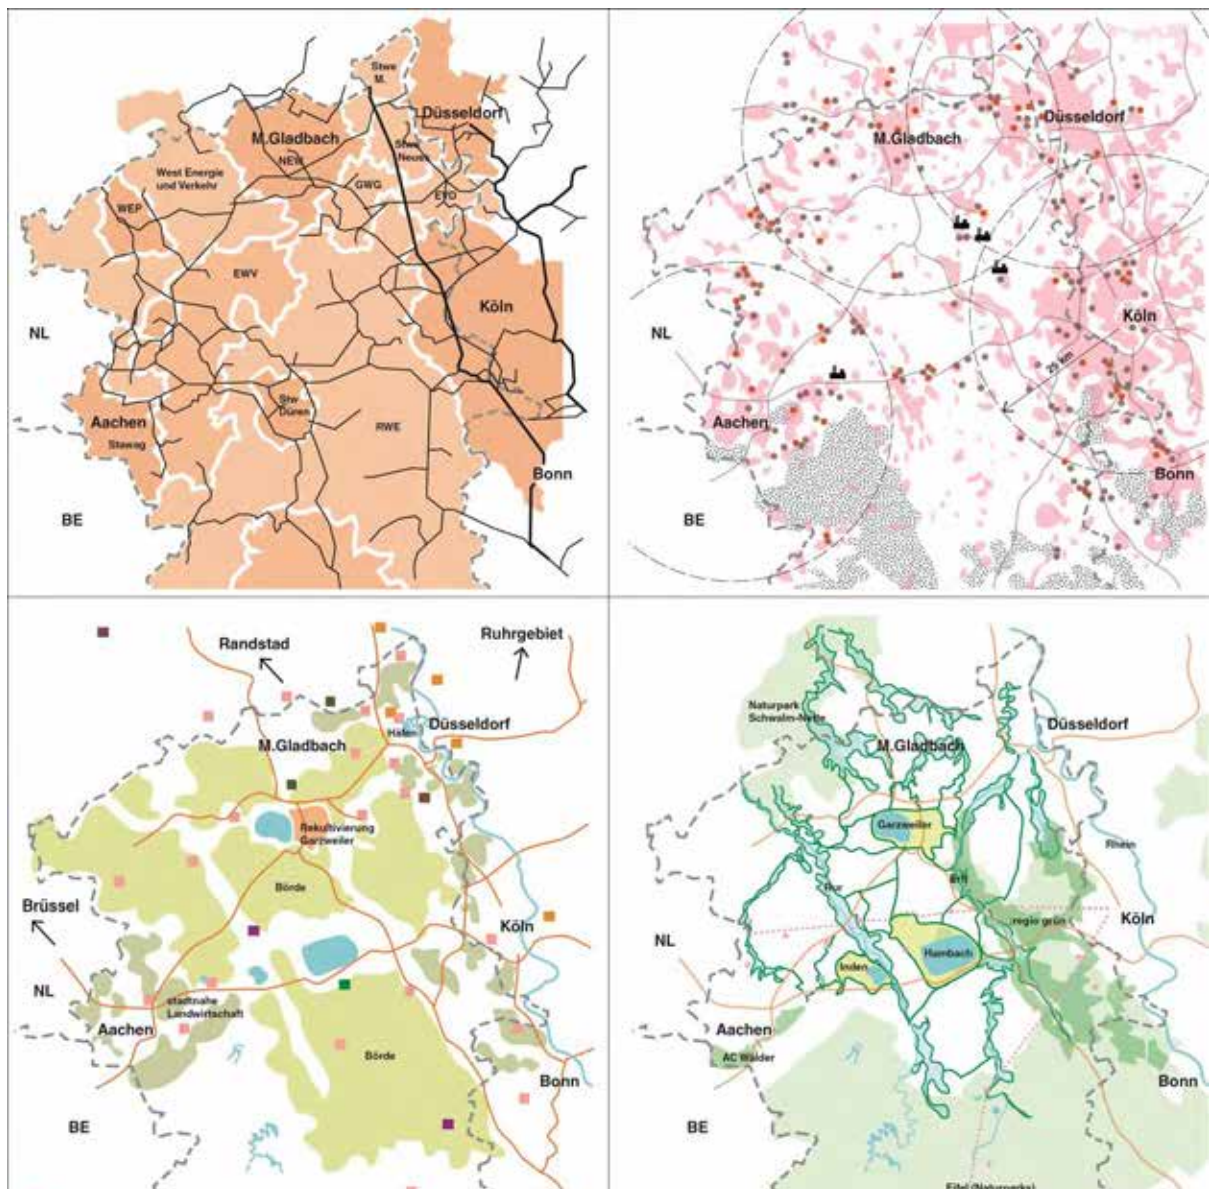

Figure 5: Close-ups of regional maps that were made at university to support the four thematic action fields with strategic considerations.

3.6 Prototypes

In order to direct the thematic action fields towards an actual spatial impact in the future, regional prototypes were designed (Figure 6). In many cases, these already included reference to specific areas or sites. The prototypes 4, 5, 6, 7 and 9 were created in design projects within the context of architectural teaching at university, usually involving a few experts from the region. The other prototypes were conceived outside academia in stakeholder workshops with a more creative orientation. Coproduction via community workshops etc. did not occur, however in principle it would have been feasible with more resources and inputs. Prototype 8 drew upon a best practise example.

A total of nine prototypes were conceived:

1. The **multifunctional energy area** describes the systemic and spatial transformation of energy infrastructure by connecting the networks of electricity, gas and heat with each other and producing renewable energy across different landuses. This included a list of pilot activities and sites from the example of one municipality.
2. The **industrial energy park** demonstrates the application of the same principle, but at the scale of an industrial area including mixed uses.
3. On site of the **circulative building center**, new products are made from building waste. The focus is on applications that have not yet taken place in the state e.g. recycled concrete from the deconstruction of lignite power plants.
4. The **circulative demonstration building** is a prototype to fully preserve the material value after a building's life-cycle by reuse and recycling. Before and after deconstruction, the space can be used as a business incubator for the region.
5. Building on its former use as a power plant, the **industrial redevelopment park** gears towards companies in the renewable energy sector that share common infrastructure, energy, material flows and information.
6. The **food strip** is a startup area that offers land and infrastructure for innovative agricultural businesses, specifically those that are tailored towards regional diversification and sustainability criteria. Each company has 2 hectares of land at its disposal.
7. The **bioeconomy-park** is a place for value-added partnerships in agribusiness, which strive for an integrated production of food, raw materials and energy. A central component is a biorefinery on site.
8. The **open space corridors** feature mainly in the context of the thematic action field that gears towards a regional open space system. The open-cast mines are not expected to become lakes until 2030/2045, but can be embedded within a spatial structure beforehand.
9. Three recultivation areas in the RMA emerge as '**newland**' and need integrated planning. In a first step, visions were developed with students and stakeholders (municipalities, civil society foundation and the mining company). Further needs of society would need to be taken into consideration.

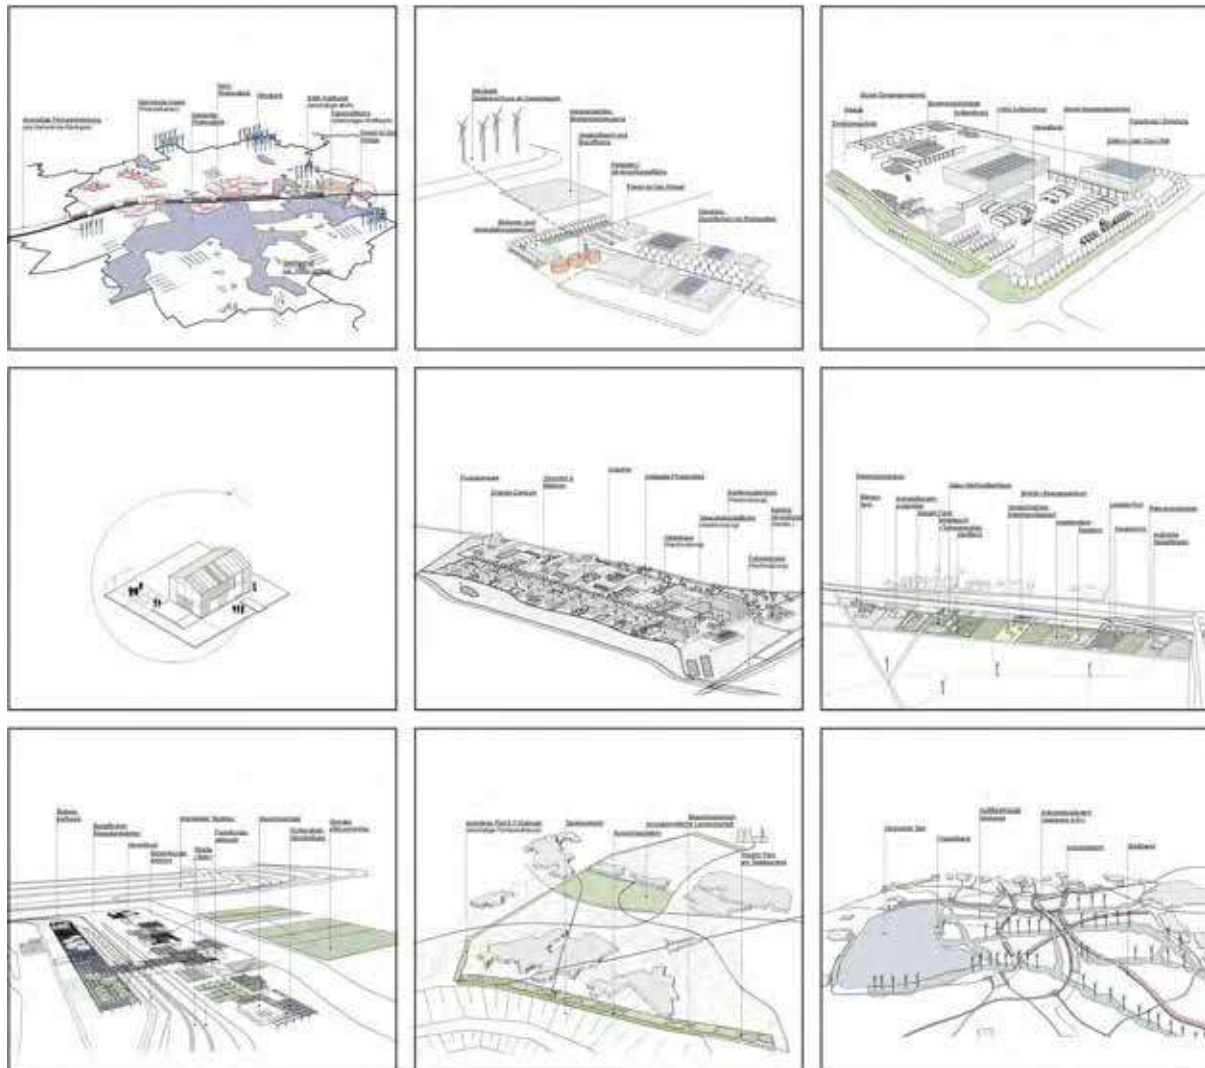

Figure 6: Visual overview of the nine exemplary prototypes.

3.7 Implementation

In this section, implementations of the overall strategy, the thematic action fields and/or the prototypes were tested out. Some of the prototypes could be followed up through network activities and more detailed concepts towards spatial realisation. Depending on how the entire regional governance process will continue (i.e. beyond the scope of the experimental investigation presented in this paper), there is potential for project bids and/or project calls based upon the thematic action fields or certain prototypes.

Complete implementation of the **overall strategy** was not carried out in practice at the regional governance agency. There was a shortage of human and time resources, and the focus of the steering board / shareholders within the initiative was upon starting quick project calls based on public funding options, in order to achieve results within a short time and within a certain critical mass.

The author also attempted further implementations of the **individual thematic action fields** in practice. This was carried out for each topic with different level of input. The effectiveness can only be perceived in qualitative ways through achieving certain milestones:

- A stimulating transdisciplinary workshop, albeit with no further identifiable effects during the time of the investigation, was organised within the strategy field "regional power plant".
- Going further, a comprehensive three-year development project with the author as project manager, was carried out early on in the field of a "circular building economy". Here the implementation could be advanced the furthest. Three of the prototypes could be conceptualised further (see prototypes 3, 4, 5) and stakeholders interested in implementation began the first collaborations. The pilot production and use of recycled concrete in the entire production of a building was initiated, and a strategic follow-project was successfully developed (Wirth and Zabek 2018).
- The thematic action field "food region" was not pursued until further notice, because both the author's expertise and the approval of the chamber of agriculture (as the most relevant stakeholder) were both lacking. Established production patterns were seen as offering little potential for change. However after investigation, a project for the realisation of an agricultural startup site was launched, including interested stakeholders from agriculture and civil society (RWTH Aachen 2019).
- Based upon the initial common ideas arising from the visioning process in the stakeholder discussions, the author brought the concept of an "open space system of 'lakes'" into a regional development workshop, where the idea was developed further. In follow up steps, a professional planning team was commissioned to develop the first planning proposals - both for exemplary implementation projects and the more detailed conceptual work for a regional open space system (IRR 2017).

4. Discussion

How can long-term strategies be designed for the development of regions which face fundamental change? The application demonstrated that it is necessary to interrelate different work sections with each other on a somewhat flexible basis and to include feed-back loops. As expected, design is not conducted in a linear way towards a complex strategy (Figure 7).

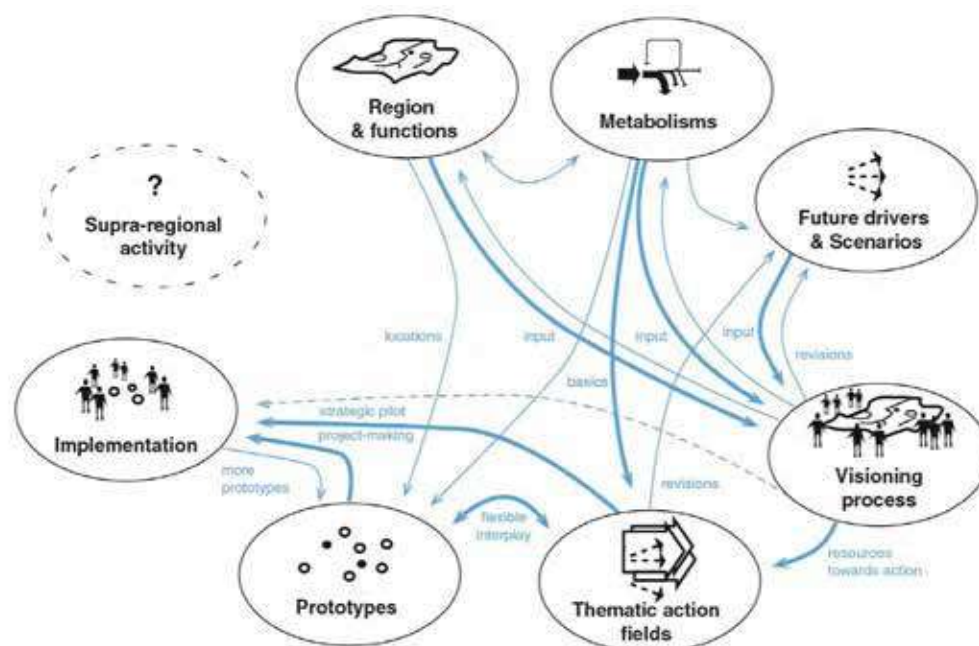

Figure 7: The model applied in the example of the real experimental investigation.

Findings regarding the **preconditions** for conducting regional strategy design can be derived from reflecting upon both the entire design process and its single work sections:

1. **Established regional governance (co-operation or directly embedded).** The multi-year interaction with a regional governance organisation (Zukunftsagentur Rheinisches Revier) and its steering mechanisms proved itself to be effective. Insider knowledge, data, political legitimacy and contacts with the regional stakeholders (business, public authorities, research and civil society) were found here. However, a disadvantage of conducting regional strategy design in the context of regional governance organisations is that these organisations may have a predetermination towards certain results, e.g. in the case of the investigation into new commercial areas.
2. **Functional challenges for society that require collaboration.** The entire strategy design process could only be initiated in response to a requirement for urgent functional challenges, e.g. the need to transform the entire regional energy system, or to enable the compensation of job losses. On this basis, it was possible to expand the range of topics with a view to other functions such as provision of quality food in the region. A more open and democratic process for analysis and later visioning would have been desirable. This should involve the broader public instead of only key stakeholders.
3. **Monetary budgets and workforce.** Initial ambitions and expectations could not always be matched in the process, due to limited resources. The author had to rely on efficient networking, own project acquisition and often voluntary contributions. It would have been more effective with an entire team coordinating regional strategy making. This may be difficult to realise in many parts of Europe and beyond.
4. **Political climate towards change.** Political support for regional governance in recognition of the functional challenges, including support for regional strategy design was crucial. Ultimately as well, the different political motivations of relevant groups of actors was decisive.
5. **Time to act despite urgency.** Despite the need to produce concrete and also short-term results, four years were needed to design the strategy in its multiple dimensions. This stands in contrast to the initiation of a regional development process with rather open / less defined project bids.
6. **Expert knowhow (theme-related knowledge & data).** The intensive need of technical expertise was particularly significant (e.g. forecasts or new technologies regarding energy/reuse/recycling). This also included the possibility of using analytical methods (e.g. metabolic flow analysis) and the availability of particular data (e.g. statistics or GIS data).
7. **Special design skills.** A situational decision-making process between rational ambition and intuition had to be conducted. By definition, this can be the case with any kind of design. A high level of generalist orientation was specifically needed whilst cross sector knowledge was adopted and combined into new solutions. Also, designing the regional strategy required a certain level of expertise in adaptive process management (complexity of different working fields / interrelated activities). Finally, the author had to operate in a mediator capacity between conflicting individual interests, but specifically with a view to long-term sustainability challenges and associated supra-regional policy objectives. An example for this was (inter-)national climate protection goals with democratic legitimation at different spatial scales. Discussions in this context overcame controversy through brainstorming together to determine win-win solutions, instead of fundamental policy debates on fossil vs. renewable energy.

With regards to the **outcomes** of the investigation, the nature of the process model also formed the basis of the results. Nevertheless, more precise observations became possible after application:

1. **Strategy.** A strategy with transformative, i.e. long term orientation, was developed. The strategy is rather complex and is adaptive in its logic. Changes in one of its work sections (e.g. need for more / additional thematic action fields) do not necessarily result in a collapse of the entire concept.
2. **Processual vision, instead of (merely) spatial vision.** The manifold analyses and discussions led to a vision that generally describes a successive and open transformation process of a generative and enabling character, as opposed to a static spatial vision as presented in “the” plan.
3. **Goals, based on multiple scenarios, but targeted appropriately.** Based on multiple future scenarios, thematic goals were set (e.g. model region for circular economy). However, it was agreed with the involvement of stakeholders to navigate towards desirable scenarios, which often coincided with political goals at national level (e.g. climate protection). In retrospect, scenarios were considered less important by stakeholders, compared to the level initially assumed by the author.
4. **New and / or strengthened stakeholder networks for change.** In designing the thematic action fields, a pragmatic synthesis of win-win ideas, institutional responsibilities, and technological progress was sought. This resulted occasionally in a key role of the author as a communicator, while collective work processes within the region were taking place. For developing two of the thematic action fields further (circular economy, regional open space system), the design process helped to initiate new regional stakeholder networks.
5. **Selected projects with explicit strategic focus.** Work on the prototypes led to a rather small selection of models, i.e. potential projects (buildings, work neighbourhoods, infrastructures or larger areas with multiple land uses). For some examples, it was demonstrated that committed individuals can lead such models towards implementation (e.g. circulative building centre). Additionally, project calls in regional development which lead to prototypes with similar thematic orientation would offer potential.
6. **Spatial impact?** Apart from one built pilot project (see 3.7), this aspect remains aspirational and can only be evaluated in the future.

Figure 8: Preconditions and outcomes of regional strategy design, according to the investigation.

The investigation presented in this article has been based on applying a specific process model in the context of a specific case study region. Therefore, the transferability of the findings is not fully guaranteed. Even if a situation matches the described preconditions of the investigation, there may be certain significant variations. For example, regional governance initiatives can take various forms and pursue entirely different goals. There may be examples that do not harmonize with regional strategy design at all. Additionally, in other regions, the influence of the spatial planning system may be more relevant. For the RMA example, the regional planning authorities were not in a position to conduct fundamental strategic work regarding its future. As a result, potential contributions to the process were considered somewhat limited by the author, and only one informal interview took place. In other regions however, this situation may be different, which could alter the entire process and the possible outcome of regional strategy design.

It can also be assumed that other regions might benefit from a modified approach with emphasis upon different work sections, compared with the model introduced by this article. For example, there may be examples of regions that already have pilot projects underway even though there is no overarching regional vision with transformative orientation. Conversely, there may be regions that already have a vision, however no further models and steps towards implementation have been made.

5. Conclusion

How can long-term strategies be designed for the development of regions facing fundamental change? Based upon the example in the investigation and other quite obvious transformative challenges worldwide, regional strategy design has obvious chances to become an emerging field of activity. Apart from using multidisciplinary methodologies, an important precondition is a direct cooperation with regional governance initiatives or other effective steering mechanisms. Moreover, urgent functional challenges, sufficient resources, political support, longer timeframes (of several years) and specific knowledge – including that of the designers / planners – are needed. Overall, regional strategy design requires intensive networking and teamwork.

A strength of regional strategy design is its potential to involve regional stakeholder interests, specialised areas of science and practice in a creative integration process. The latter merges ideas, selects priorities, develops new models and is already partially functioning on a project-specific level. Regional strategy design undoubtedly has a transdisciplinary orientation, and management characteristics. At the same time, it continues to be shaped by the traditional design disciplines such as architecture, landscape architecture and urban design.

A critical point from a practical perspective is the potential predetermination of regional governance mechanisms, which may limit the basic potential of design as an explorative decision making process. This issue leads to academic discourses related to path dependencies, path change and political ecology. From a scholarly perspective, the transferability of the findings remains in question and could be the subject of further research. This could mean further application of the process model in other regions, or comparative case study analysis. Some historical precedents and pioneering examples with similar characteristics exist, and these could provide valuable lessons and a pool of expertise for taking the concept further.

The darker sides of smart city development

Digital participatory planning tools helpful side and side effects

Anas Shahin

University of Florence, anas.shahin@unifi.it

Abstract: Participatory planning is one of the latest directions of the urban planning field which began in the second half of the 20th century. Participatory planning back then used old fashion ways in doing so. Lately, urban planners start using digital participatory planning tools. These tools start to get spread worldwide for their help in the urban planning process. In the same time urban planners start having concerns regarding these tools and their side effects. One of these concerns is the issue of data privacy in digital participatory planning tools. This paper will explore the helpful side of digital participatory planning tools and their role in improving the urban planning process. Second, it discusses one of the side effects of these tools that is the issue of data privacy. Third, trying to find a solution for this issue and its side effects. The Swiss city of Zug experimented a solution which could be a possible solution. The experience of international experts of digital participatory planning tools spread worldwide will be collected. Once these tools are closer to solving their issues, these tools can be upgraded significantly in a way opens up a wide advancement towards effective urban planning.

Keywords: Participatory planning, digital participatory planning tools, data privacy.

Introduction

Digital participatory planning tools start to get spread worldwide for their benefits in the urban planning process and for their help in achieving the overall goals of urban planning. Urban planners urge to research these tools more and more to know their value due to the lack of the appropriate research regarding them. In the same time urban planners start having data privacy concerns in these tools. This research paper builds the background for digital participatory planning tools. Starting with a brief history of these tools, definition, their helpful side and benefits, their data privacy issue and ending with a possible solution for this issue. Solving data privacy issue in these tools is demanding because it stands as an obstacle in the way of upgrading these tools which could lead to a wide advancement towards effective urban planning.

This paper presents an early stage of a more in-depth research of digital participatory planning tools. For this reason, some of the methods followed do not have a final result yet but the conclusion will include expected results of these methods.

Literature review

Digital participatory planning tools:

The early stages of participatory tools described by Roger Katan and Ronald Shiffman (2014) they stated that back in the 1970s the use of mass media-television, newspapers, and radio- or getting the answers to questionnaires as methods and how it did not achieve maximum participation. To achieve that the need for sustaining involvement of people and for constant contact and engagement of people at all levels is required. Later on and in recent times, according to Nader Afzalan (2015) “*web-based technologies and social media have intrigued planners and decision makers in their potential for use as tools to resolve issues inherent in participatory planning processes. This potential lies in the ability of these tools to capture local knowledge and facilitate information sharing, social interactions, and collaborative processes (Afzalan & Muller, 2014; Boyd & Ellison, 2007; EvansCowley & Hollander, 2010; Evans-Cowley & Manta Conroy, 2006; Palfrey & Gasser, 2012; Townsend, 2000).*” The previous statement also agreed by Falco & Kleinhans (2018).

The definition of digital tool: it is an online platform, or a website, or mobile application that uses the internet and depending mostly on Information and Communication Technologies (ICT) in which it allows the use of computers and other electronic equipment and systems to collect, store, use, and send data electronically. There are two main stages in these tools data collection and data analysis.

Digital participatory planning tools are internet-based platform that:

- Can build a bridge between the residents and urban planners.
- Allow the residents to communicate and exchange ideas, raise debates, suggest solutions and share their local-knowledge with urban planners.
- Allow urban planner to collect local knowledge information and data to analyze it statistically and systematically to be used in the urban planning process.

The definition above comes from the description of the early Finnish digital participatory planning tools such as: SoftGIS, OPUS forums, The Urban Mediator, Tell a Story, WebMapMedia and Shadew. (Kahila & Kytä, 2009; Staffans *et al.* 2010; Saad-Sulonen & Botero, 2010; Halttunen *et al.* 2010).

The definition of digital participatory planning tool from strictly participation perspective is defined according to the level of the participation allowed in the tool, which can be taken from Arnstein's ladder of participation stages. Digital participatory planning tools nowadays allow the first two stages of the eight rungs ladder of Arnstein (1969). Respectively, they allow firstly to educate and let the citizens hear about the plan, then informing, consultation and placation which means allowing citizens to hear and be heard but without any further power to make their voices carried out or comes to reality. The third stage is not yet taking into consideration in nearly all of nowadays tools, but definitely considered in the Swiss e-voting tool in the city of Zug which will be discussed later in the data collection part of this research.

The early age of digital participatory planning tools was discussed in the book *Digital tools in participatory planning* (2010). Three different approaches digital tools had back then. The first one is data collecting tools to be used by urban planners, tools empower wider urban planning participation and tools and platforms allows co-develop urban planning participation. But nowadays most tools allow the three approaches together with additional advanced features.

Wallin, Horelli & Saad-Sulonen think that these tools clearly changing and improving the way that urban planner work beside its notable side in obtaining information and its widespread communication for reaching participants. And conclude with the believe that the development of digital participatory planning tools will change the field of participatory urban planning in both practice and research. Simultaneously, Staffans, Rantanen and Nummi (2010) stressed that the urban planning institutions cannot depend only on their own information and data anymore.

For those who have skeptic point of view regarding digital participatory planning tools comes the need to point out the linkage between digital participatory planning tools and Geographic Information System (GIS). The reason for this linkage is to show the importance of these tools and their promising future. The current situation of digital participatory planning tools is similar to the early age of GIS back in the late 1960s and how very few used it back then, and how later on all urban planners start depending strongly on it (Yeh, 1999). Nowadays almost impossible to plan without the help of the GIS. It revolutionized the way urban planners think and prepare their urban plans and so will digital participatory planning tools do. This linkage will be explained technically in the next section. In fact, a number of digital participatory planning tools named with the composition of words including the word GIS such as: Participatory GIS, Participatory planning GIS and SoftGIS.

Another evidences on the success of digital participatory planning tools is there worldwide spread. Falco & Kleinhans (2018) have detected 113 digital platform, which are currently active and used in urban development and spread around the world. But current literature regarding digital participatory planning tools is still limited. Digital participatory planning tools need to be addressed and researched more to learn about their benefits and effectiveness in participatory planning. (Afzalan & Muller, 2018). For this reason, Falco & Kleinhans (2018) Stated that their goal is to conduct more in-depth research regarding digital participatory planning tools. The need for these tools is confirmed for the application, functionality and spread of participatory e-planning (Panagiotopoulou & Stratigea, 2017).

Digital participatory planning tools' helpful side:

The benefits of digital participatory planning tools from the current available literature is discussed one by one in the following paragraphs, but some of these benefits could be very broad assumptions, due to the lack of the appropriate research in the literature. In order to have insights regarding these benefits. Table 1 list some of the Finnish digital participatory planning tools and some of the benefits which were researched in the *Digital Participatory Planning Tools* (2010) book by Wallin, Horelli and Saad-Sulonen (2010).

Table 1 Digital participatory planning tools benefits:

Tool Name	Tool type	Tool Aim	Benefits	Literature
SoftGIS	Web-based SoftGIS	Build a bridge between the residents and urban planners. By allowing residents to generate information about their own living environment	Collecting local knowledge, information and data Mapping data collected to be used in GIS	(Kahila & Kytä, 2009).
OPUS Project	Internet-based platform	Connect online discussions on forums to the actual planning and development processes in terms of their timing and locality. Gathering and combining local information and knowledge on urban planning on Internet forums.	Collecting local knowledge, information and data Better decision-making	(Staffans, Rantanen & Nummi, 2010).
Tell a Story (TaS)	Mobile phone application	Support communication during the early phases of urban Planning and tested these technologies in the field.	Collecting local knowledge, information and data Reduce marginalization	(Halttunen, Juustila & Nuojua, 2010).
WebMapMedia	Web mapping application	Support participatory planning	Increase equality Enhance Participation	
The Kotikatu System	Local website	Connect people and create and channel discussion around different topics for the sake of their neighborhood	Collecting local knowledge, information and data Reduce marginalization Increase equality Enhance Participation	(Kanervo, 2010).
Recommendation Machine	Web-based platform	Plan and co-produce ubiquitous services of everyday life and events, in the context of community development of two Helsinki neighborhoods.	Help in consensus building between different parties of the community	(Horelli & Wallin, 2010).

Source: Own elaboration

Benefits of digital participatory planning tools on the urban planning process:

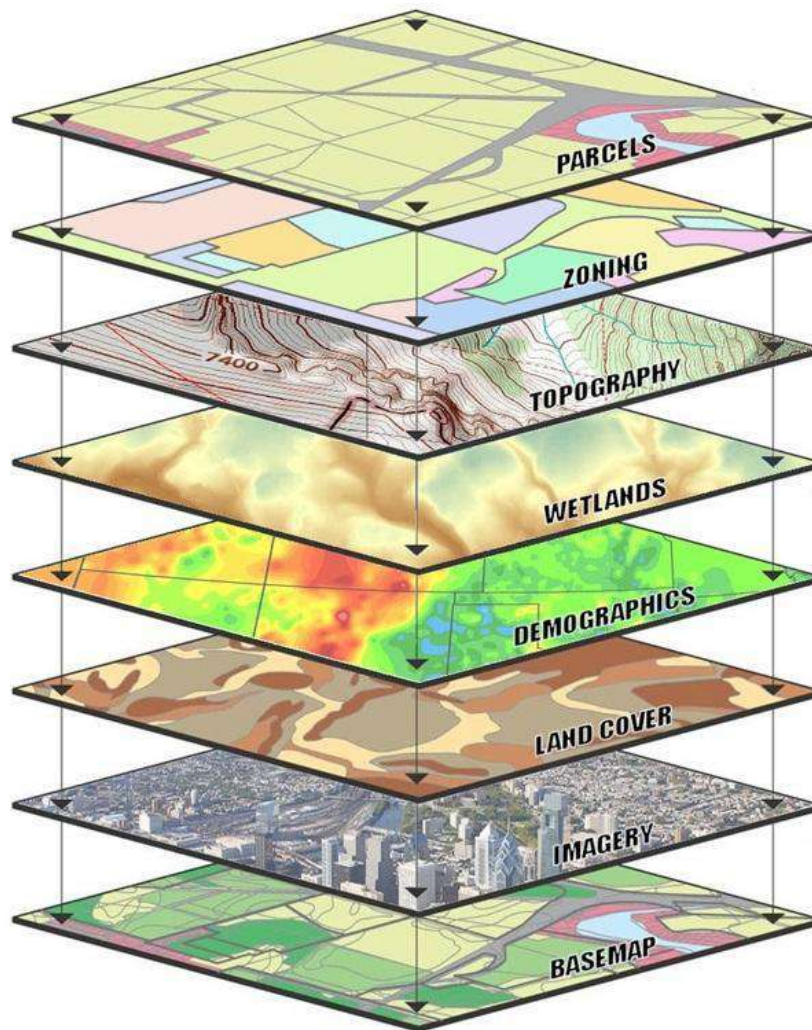

Collecting local-knowledge, information and data: the benefit agreed on by all tools. digital participatory planning tools can help in obtaining location-based data which the urban planners are not capable of obtaining it because they are strangers to the location. Collecting this local-knowledge, information and data to be learned from and used by the urban planners which can benefit the urban planning process and will be explained how in the next paragraphs, along with better decision-making resulting also from the benefits of these tools. (Kahila & Kytä, 2009; Staffans *et al.* 2010; Kanervo, 2010; Wallin *et al.* 2010; Afzalan & Muller, 2018). The instant data collected by digital participatory planning tools can help the urban planner in identifying and defining local needs so they can plan to the need (Fischer, 2000; Rantanen & Kahila, 2009). In which can avoid wasting efforts and resources.

Mapping data collected to be used in Geographic Information System (GIS): In order to explain how data collected by digital participatory planning tools can improve the urban planning process. Digital participatory planning tools are linked to Geographic Information System (GIS). Some researchers even consider these tools as a part from GIS, such as Kahila & Kytä (2009) the SoftGIS tool which comprises and produces a special layer in the GIS to be used by experts, such as urban planners. This special layer will be explained together with the way these tools work in the special layer example later on. According to the *Urban and Regional Planning Education* (2016) book digital participatory planning tools are the transformation of conventional mapping and GIS tools. Usually as long as there are more layers in the GIS which are considered in the urban planning process, the plan supposed to be more effective and the project is more likely to be successful as shown and explained in the above examples of the special layer. In the same way of thinking and using the same logic adding more layers obtained by digital participatory planning tools to the GIS which are could be very useful for current and future planning. For instance, the softGIS (Kahila & Kytä, 2009) is working exactly for this purpose. While Rantanen & Kahila (2009) emphasize on valuing local knowledge by urban planners. Simply the data collected by digital participatory planning tools can be turned into maps and layers to the other layers of the GIS software which will lead to a better and more effective urban planning process, for the reason of considering more data and more input in the planning process. Which it will be explained in the Special Layer examples.

Special layer example: In order to have a clear vision of what this special layer is: I have made an imaginary simple example and illustrate it with some figures of actual layers for further understanding. This example was made after proper researching and understanding the mechanism and the technicality which these tools function and work.

The example begins with listing Geographic Information System (GIS) typical layers, then an explanation about this example with listing the three layers which the special layer consists of and ends with a discussion about the result of this special layer.

Geographic Information System (GIS) typical layers can be: One layer for each of the following: streets, parcels, zoning, topography, wetlands, demographics, land cover, imagery, flood zones, client locations, competition, shopping centers, office parks, demographics, etc. [Figure 1]. When these layers are drawn on top of one another, it allows understanding of the aspects of a certain location.

[Figure 1] Image credit: Ontario County, NY (2016).

Digital participatory planning tools can add to the GIS's layers a special layer. This special layer is based on an instant data and information provided by participants. Basically, this special layer is obtained after mapping participants' instant data and information. In which could be valuable and can help in better planning and better decision-making.

The following simple imaginary example can give a quite understanding of what this Special Layer is: Imagine that urban planners through their annual check, they have noticed that the number of women who marked themselves pregnant is above the usual rate. Through a quick calculation, they found out the need for a new kindergarten in the next couple of years. The goal for the urban planners is to make the most sustainable, ecological, environmental, convenient and low-cost project. The urban planners start the planning process by asking the people of the city to participate and provide them with data, through the following question:

Mark your home location if you are one of following: pregnant, unemployed kindergarten's teacher, unemployed worker, interested in teaching or working in a kindergarten.

The result of mapping the above data is the following three layers: [Figure 2]

Layer 01. Pregnant women

This layer is for women who marked themselves pregnant women and provide the digital participatory planning tool with this data.

By observing the pregnant women's home location. we will find that most the pregnant women are in the center area.

Layer 02. Kindergarten's teachers

This layer is for the kindergarten's teachers. This data obtained through the following possibilities: First, by calculating the number of the unemployed teachers and second by calculating students who are studying kindergarten teaching.

By observing the kindergarten's teachers home location. we will find that most teachers live in the northern part of the city.

Layer 03. Workers

This layer is for the workers needed for this kindergarten. This data obtained through the following possibilities by calculating the number of the unemployed workers, and people who are willing to work in a kindergarten. By observing the kindergarten's workers home location. we will find that most workers live also in the northern part of the city.

[Figure 2] Special layer. *Source: Own design*

The benefit of this Special Layer can help the urban planner allocating the most suitable location for the new kindergarten: After overlapping the three layers: 01,02,03 The digital participatory planning tool can determine the most suitable location for the kindergarten. The kindergarten location will be a walking distance for all the people involved: which will cut and minimize the use of cars, buses and other transportation. In addition to: Environmental solution: which will protect the environment and reduce the pollution of the area. Save money: cut unnecessary expenses related to kindergarten buses, parents' cars, etc. Save time: time to reach the kindergarten (children and their parents, teachers, workers, etc. Satisfaction: for most people involved. This Special layer could be added to the GIS layers as another important factor to be considered in the planning process of the project. [Figure 3]

[Figure 3] GIS typical layers with the special layer on the top.
Image credit: Ontario County, NY (2016). Except for the Special Layer.

Benefits of digital participatory planning tools on urban planning goals:

Marginalization, equality and public participation: From Table 1, Halttunen *et al.* (2010). Believe that ICT could reduce marginalization through allowing the participation of those most isolated. When the marginalization is reduced the equality hits a higher level by their inverse relation. Digital participatory planning tools can ensure equality (Kahila & Kytä, 2006; Kanervo, 2010). ICT reduces inequality through giving everyone especially the disadvantaged segments of the society same chances

and equal opportunities. Because they can reach a larger number of people. Especially those who cannot participate in public meetings for the reasons of time, place or other restrictions. Beside attracting youth who are fond of technology and technological solutions. For this reason, Kanervo (2010) Staffans *et al.* (2010) Afzalan & Muller (2018) claim that use of digital participatory planning tools could enhance public participation. Several scholars agree on that ICT has the potential for enhancing public participation (e.g. Ann Macintosh: is emeritus professor of Digital Governance at the University of Leeds).

Consensus building: Another benefit of digital participatory planning tools is consensus building. (Horelli & Wallin, 2010; Afzalan & Muller, 2018). Which can lead to reduce unnecessary conflicts between citizens, stakeholders and urban planners beside building trust in the society.

(Saad-Sulonen, & Botero, 2010) Based on the result of their case study of Malminkartano in Helsinki believes that digital participatory planning tools and citizen participation in planning has a positive outcome on the participatory planning process. Although digital participatory planning tools can help planners achieve their public participation goals (Afzalan & Muller, 2018). Babelon *et al.* (2017) argue that e-participation outcomes remain weak or indeterminate. And urge future research to further explore and assess digital tools towards knowing their potential value in urban planning. So, for this reason digital participatory planning tools will be furthered researched in the questionnaire of this research to gain more evidences and insights to support these benefits and overall helpful side. In other words, finding an answer for the question of:

- How could for the digital participatory planning tools help in improving the urban planning process?

Digital participatory planning tools' data privacy issue and its side effects:

The meaning of the term information or data privacy was defined by Westin (1970) "*Privacy is the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others.*"

Due to the limited literature addressing digital participatory planning tools and their benefits, there is also limited literature addressing the side effects of these tools. In this limited literature there are increased concerns from urban planners and researchers regarding the side effects of these tools specifically data privacy. Data privacy is the most assured and pushing issue in this era in the literature, which also has general agreement on.

Data privacy is one of the main issues that digital participatory planning tools are suffering from is data privacy and it is preventing its improvements. Data privacy affecting the participation process and the way digital participatory planning tools work firstly and secondly affecting the safety of the city and the society.

Data privacy concerns: The data privacy concerns are not a recent thing; urban planners expressed their concerns more than a decade ago. But these concerns were increased remarkably lately. Urban planners expressed their data privacy concerns specifically in digital participatory planning tools (Afzalan, 2015; Afzalan & Muller, 2018; Blatt, 2012; Foth, 2006; Fredericks & Foth, 2013; Kahila & Kytta, 2009; Khan *et al.* 2014; McNutt, 2014; O'Sullivan, 2006; Shilton, 2012; Zavattaro & Sementelli 2014). Broader kind of concerns came from Angelidou (2014) Van Zoonen (2016) Viitanen & Kingston (2014) who expressed their data privacy concerns in the whole smart city context and its technologies

which includes data related to participation. These concerns include beside data privacy, the possibility of selling this personal data and personal information. Second, data security and the risk of getting this data stolen. Third, data management and data analysis. These concerns exist in both phases in data collection and data analysis.

The above data privacy concerns are a lot considering the literature exists regarding digital participatory planning tools. The question here is why. Could be because of their possible effects on the participatory process, the urban planning process, urban planners and the participants. These effects will be examined and furthered research by the questionnaire of this research:

- How could for data privacy issue in digital participatory planning tools effects the urban planning process and urban planning overall goals?

In favor of understanding data privacy issue's relation and linkage to digital participatory planning tools, the following discussions give quite insights regarding their effects and consequences. Data privacy effects on the urban planning process and on urban planning overall goals:

Participation rate and data Quality: When participants get skeptic regarding their participation data, they might stop participating or they might participate with fake or inaccurate data to protect themselves in which can lower participation rate and lower data quality which are the two main challenges of digital participatory planning tools. So, in order to obtain a higher participation rate and a higher quality of data, participants need to be assured that their data is secured and handled well, so they can contribute and participate more and with an accurate data. Once these tools obtained high quality data, they will produce high quality information and vice versa. Otherwise, the whole effectiveness of these tools is on the line. Staffans *et al.* (2010) consider the quality of the information as one of the most important aspects in these tools. However, Kahila & Kytta (2009) urge more improvements for digital participatory planning tools to guarantee the quality of the information they produce.

Data privacy effects on the society:

Urban planners' responsibilities: Digital participatory planning tools are not like any other platform. These tools collect critical and sensitive personal data from the participants such as: location, income, race, etc. In case this data fall into the wrong hands they can cause a serious damage and a serious harm to the participants and the city. This put urban planners who run the digital participatory planning tool under massive responsibilities. Angelidou (2014) Elmaghraby & Losavio (2014) agree that Smart City technologies can grasp from people real-time demographic data in way violate their privacy.

The above-mentioned consequences of data privacy issue will be further researched in the questionnaire of this research. The next two paragraph will emphasize on the seriousness of the data privacy issue according to the European law and Information and Communication Technologies ICT field.

General Data Protection Regulation (GDPR)¹: A recent shake-up event in the data field was the European Union's new data privacy law. which replaced the old one of 1995, which was agreed on and adopted in 2016, and started to be applied in 2018. Personal data refers to any information that relates to an identified or identifiable, living individual. Sensitive personal data is data related to your: race, religion, sexual orientation, location, income, health record, contact info, political opinion and others. GDPR gives you the right to the following: to know who is processing your data and why, access your data, to object, to correct your data, to delete your data and to be forgotten. Simply, GDPR law allows you take back control over your data. The reason behind GDPR law is the massive increase in the collection,

storing, analyzing and trading of personal data by companies and governments. In addition to the concern of the possibility of getting your information and data stolen if a database got hacked. The GDPR law marked the turning of the personal data privacy and protection issue to the surface.

Data privacy from the perspective of Information and Communication Technologies (ICT) field: is also quite serious and a hot topic recently. The International Federation for Information Processing (IFIP) which was established in 1960 under the auspices of UNESCO and one of the leads gathering in the field. It has created a yearly international conference focuses on security started in 1986 but in 2003 it starts to be focused on privacy. Data privacy remained steady till 2019 and it became one of their aim. The 2017 IFIP summer school was dedicated to the exploration of new legal solutions to encounter data privacy issue. ("IFIP Information Security Conference & Privacy Conference - IFIP Technical Committee 11"). In their publication *Privacy and Identity Management. The Smart Revolution. (2017)* a blockchain solution was presented. Neisse *et al.* (2017) believe that blockchain technology could be a solution for enforcing the GDPR data privacy law because it allows transparency, auditability, and immutability features.

Blockchain Technology: in order to discover this technological blockchain possible solution, let's go back to the definition of Blockchain technology: "*Blockchain*" is a cryptographic data structure often employed in Distributed Ledger Technology (DTL) that is constructed through successive cryptographic hashing of blocks of transactions. Blockchain benefits from Identify Management point of view (Dunphy & Petitcolas, 2018) could ensure data privacy.

While Dhillon *et al.* (2017) consider that "*the fundamental shift that blockchain technology represents is a method for moving away from an attempt to have a central trusted authority in a massively distributed network. But instead to have multiple sources of trust that must all agree, based on an algorithm that this transaction can be trusted as valid.*" Early examples in 2017 extend beyond financial transactions to cover other aspects of FinTech, RegTech (regulation), InsuranceTech, GovTech (eVoting, licensing, records and certification), HealthTech, and many others. The question here is:

- Could Blockchain technology be the solution for data privacy issue in digital participatory planning tools?

To sum up, although current literature suggests that digital participatory planning tools could have a helpful side on the urban planning process. But only limited literature available regarding them and the need for expanding this literature is demanding. Especially since these tools are technologic-based and technology research is time sensitive and it changes in a short period of time.

Methodology

The methodology will be based on qualitative approach. It will depend on several types of evidences such as documents, surveys and a questionnaire. The methodology followed is need to examine and find answers for the questions of this research paper. The questionnaire method consists of close-ended and open-ended questions and it will be explained in details next.

The questionnaire instrument:

The instrument chosen is web-based self-completion open-ended questionnaire. The reasons behind choosing the methodology are coming from its advantages in saving time, provide fast analysis, cheap, accurate and it could be more effective for such topic which handling sensitive issues. In addition, it allows answers to be richer, longer and more revealing specifically for open-ended questions (Brace, 2004).

Questionnaire design and objectives:

The questionnaire was designed following the instruction of Don Dillman (2011) in his book Mail and Internet survey. The questionnaire will be forwarded and aimed towards 113 international experts in digital platforms. These digital platforms are currently active and used in urban development and spread around the world. They were detected by Falco & Kleinhans (2018) and they are going to be the unit of analysis. The total number of 113 digital platforms are spread over the seven continents as shown in [Figure 4]. according to the level of participation allowed in them [Figure 5].

[Figure 4]² Geographical distributions of digital platforms. *Source: Digital Participatory Platforms for Co-Production in Urban Development: A Systematic Review by Enzo Falco and Reinout Kleinhans (2018). DOI: 10.4018/IJEPR.2018070105.*

[Figure 5]² Number of platforms per level. *Source: Digital Participatory Platforms for Co-Production in Urban Development: A Systematic Review by Enzo Falco and Reinout Kleinhans (2018).*
DOI: 10.4018/IJEPR.2018070105.

Questionnaire purpose:

The purpose of this questionnaire is to explore first, the helpful side of digital participatory planning tools. Second, exploring digital participatory planning tools' data privacy issue and its effects. Third, evaluating whether Blockchain technology could be a possible solution for this issue.

Welcome to the study of exploring digital participatory planning tools

What are the benefits of your participatory planning platform on the urban planning process?

(Please, select all that apply)

- Collecting local-knowledge, information and data that is useful for the urban planning process
- Mapping collected data to be used in Geographic Information System (GIS)
- Analyzing collected data help in planning exactly to the need
- Add another benefit

What are the benefits of your participatory planning platform on the urban planning overall goals?

(Please, select all that apply)

- Reduce marginalization
- Increase equality
- Consensus building
- Reduce unnecessary conflicts
- Enhance public participation
- Add another benefit

Approximately, could you indicate the number of the participants in your platform according to the following years?

Number of Participants	Year
	2015
	2016
	2017
	2018
	2019

What are the consequences of data privacy issue in participatory planning platforms?

(For example: this data got stolen or hacked and fell into the wrong hands)

(Please, select all that apply)

- Put the urban planner under massive responsibility
- Put the participants under risk
- Put the city under risk
- Other *(please specify)*

What are the possible effects of data privacy issue in participatory planning platforms?

(For example: When participants get skeptic regarding their data safety, they might stop participating or they might participate with fake or inaccurate data to protect themselves)

(Please, select all that apply)

- Lower participation rate
- Lower data quality
- Other *(please specify)*

Are you currently applying certain solutions to encounter the issue of data privacy in your platform?

- Yes *(please specify)*
- No

Can Blockchain technology be a solution for data privacy issue in participatory platforms?

- Agree *(Please explain why?)*
- Disagree *(Please explain why?)*

Would you like to provide further comments, evidences, data, case studies, pictures, videos?
(e.g. to enrich any the above questions purposes or your answers to them)

(attach a file)

.....
.....

Results and discussion

The promising future of E-participation:

As an evidence on the promising future and growth of e-participation at the urban level, De Cindio & Peraboni (2009) Presented two graphs of the following:

- Number of registered participants [Figure.6];
- Number of messages sent in the CityMap [Figure.7].

In a large field experiment involving ten different municipalities' websites in the Lombardy region, in the North of Italy, for a duration of one year.

[Figure 6]³ The number of registered participants. Source: *Fostering e-Participation at the Urban Level: Outcomes from a Large Field Experiment* by Fiorella De Cindio and Cristian Peraboni (2009). Copyright © 2009, Springer-Verlag Berlin Heidelberg.

[Figure 7]³ the number of messages sent in the CityMap. *Source: Fostering e-Participation at the Urban Level: Outcomes from a Large Field Experiment by Fiorella De Cindio and Cristian Peraboni (2009). Copyright © 2009, Springer-Verlag Berlin Heidelberg.*

The graphs show some basic participation indicators of the activity in the ten websites plotting their e-participation trends. The graphs could tell on the gradually increase in the number of participants and the e-participation over time.

The Swiss possible solution for data privacy⁴ issue in digital participatory planning tools:

In June 2018, the city of Zug in Switzerland made a e-voting platform uses an innovative encryption technology that on one hand anonymizes the votes and on the other hand allows tamper-proof tally and secure audit. This technology is called blockchain and it was created by Luxoft Holding, Inc (NYSE:LXFT) a global IT service provider, partnered with the City of Zug and Lucerne University of Applied Sciences in Switzerland.

The reasons behind choosing the Swiss e-voting platform as role model are the following:

- It's the pilot blockchain-based platform.
- It's an official platform used by government.
- Its purpose is to drive the adoption of this kind of technology in government.
- It is a state-of-the-art platform which was experimented in the middle of 2018.
- No literature on using blockchain-based platform in digital participatory planning tools.
- It is a blockchain based platform uses decentralization which means no authority can see citizens' personal data ("World Economic Forum", 2017).
- The platform is decentralized and deployed on three different data centers in the cloud: two in Switzerland and one in Ireland. By distributing the data into three different data centers,

security and data loss risks are distributed geographically, making the system more robust. What's more, the platform can permanently delete voting data within an agreed time, in accordance with Swiss law.

- “As a result, we believe this technology cannot be owned by a single company. We will make the e-voting platform open source so people can understand what makes up the technology and how it works, ensuring full transparency. Looking ahead, our alliance will encourage more people to develop blockchain-based applications for Governments worldwide.” said Vasily Suvorov, Chief Technology Officer at Luxoft.

50 Giant companies' stand of Blockchain:

Most recently in April 2019, *Forbes* magazine marked the Spring of blockchain technology with a new list features 50 big companies -with minimum revenues or valuations of \$1 billion and U.S. operations, e.g. Amazon, Facebook, Google, Intel, HTC, Microsoft and IBM- that are leading the way in adapting decentralized ledgers to their operating needs. All of these companies plan to use the privacy features of blockchain to profit from their customers' data while protecting their identities. The list of companies' sectors varies from: finance, technology, insurance, transportation, media, retail, healthcare, food to energy. (Del Castillo *et al.* 2019). This list was made through contacting key leaders and consultants in each of these giant companies with positions vary such as: president, VP, General Manager, CTO, CIO, EVP. This list gives insight on the potential of Blockchain technology regarding data privacy issue.

Conclusion

The above-mentioned results and the questionnaire expected results lead to the following conclusion. Digital participatory planning tools can have benefits and a helpful side on the urban planning process and on the urban planning overall goals by providing urban planners with useful information. The future is promising and open for digital participatory planning tools and their importance will be similar to the importance of the GIS. But with the limited literature available regarding these tools comes the urgency to research them more and expand their current literature. Expand their literature towards knowing their benefits and value together with their helpful side in improving the urban planning process (Panagiotopoulou & Stratigea, 2017). Data privacy is quite serious issue in digital participatory planning tools. Because it could affect the urban planning process, the urban planning overall goals and the society. Blockchain technology could be a solution for the issue of data privacy in digital participatory planning tools. The final results of the more in-depth future research will provide additional evidences that support this conclusion.
