Shao Yisheng(shao yisheng,2014) believes that urban water system planning is a framework system based on the principle of urban water cycle. It consists of IUWSP and urban water system special planning. The main goal of IUWSP is to optimize water system structure, improve water system function and promote the water system circulation, to ensure the safety of the water system; the main tasks of the comprehensive planning of the water system are to determine the water resources carrying capacity, water environment carrying capacity, water system facilities support capacity, water safety emergency rescue capability, and balance the water demand of the “three generations(living, production, ecology)”.

Kong Yanhong(Kong Yanhong,*et al.* 2013) also studied the preparation of urban water system planning, and proposed that the water system planning includes water environment system investigation and analysis, water resources optimization allocation, water system layout and space management, water environment protection, water environmental system security, planning and coordination, etc. Based on the overall urban planning, the plan integrates urban water resources, water systems, water supply, reclaimed water, sewage, rainwater and flood control systems, and urban blue line space control, which is a comprehensive plan for the organic integration of water-related special planning in urban and rural planning sequences. From the perspective of planning, Kong believes that the urban system planning is too macroscopic, the control detailed planning is too micro to accurately grasp the city's water problems, while the engineering facilities planning in the urban master planning focuses on the system layout and engineering facilities. So positioning the plan as: An important part of the urban master plan and the strategic plan for comprehensively solving urban water environment problems at the macro level, and the upper plan for each water-related special plan.

(2) Main objectives of IUWSP

According to the characteristics of different cities, the main objectives of IUWSP research are different. The major problems of water system should be identified based on the characteristics of each city. On this basis, different planning objectives and planning strategies are formulated.

According to literature research, the city is divided into water resource utilization cities, flood disaster prevention cities, and comprehensive coordination cities from the perspective of the water system. In various types of cities, the focus of IUWSP is different. The main problem of water resource utilization cities is how to improve the carrying capacity of water resources, to set cities by water, to set people by water, and to set production by water.

The main problem of flood disaster prevention cities is how to adapt to urban flooding through the optimization of urban space, and to prevent floods from occurring through engineering and non-engineering measures.

Comprehensive coordinated cities generally have various types of water problems, and the focus is on how to coordinate various water issues.

As a city with quantities of big river, Wuhan is rich in water resources. In mega-cities, its water consumption and sewage treatment capacity are huge, which leads to the demand for improved water supply quality and water supply safety and reliability in Wuhan. In the aspect of flood control and drainage, serious urban flood occurred in recent years. The situation requires that the comprehensive planning of Wuhan Water System focuses on how to improve the level of flood control and drainage in Wuhan; the water-rich cities as Wuhan city are also facing the problem of water environment management.

(3) The relationship between IUWSP and water-related planning

“The Law on Prevention and Control of Water Pollution” is a fundamental law for preventing and controlling water pollution, aiming at protecting and improving the water environment and ensuring the safety of drinking water in China. This Law has clarified the water pollution prevention and control planning system in China and has also clarified the construction plan for sewage treatment facilities. According to “the Law on Prevention and Control of Water Pollution”, the coordination parts of IUWSP, water pollution prevention planning and construction scale of sewage treatment facilities includes:(Chen Liqun,2013) ①Water environment functional division;②pollutant discharge standard;③Total pollutant discharges;④Urban sewage treatment facilities and pipe network planning;⑤sewage outlets setting. The relationship between the water pollution prevention planning system and IUWSP is as following Figure 9:

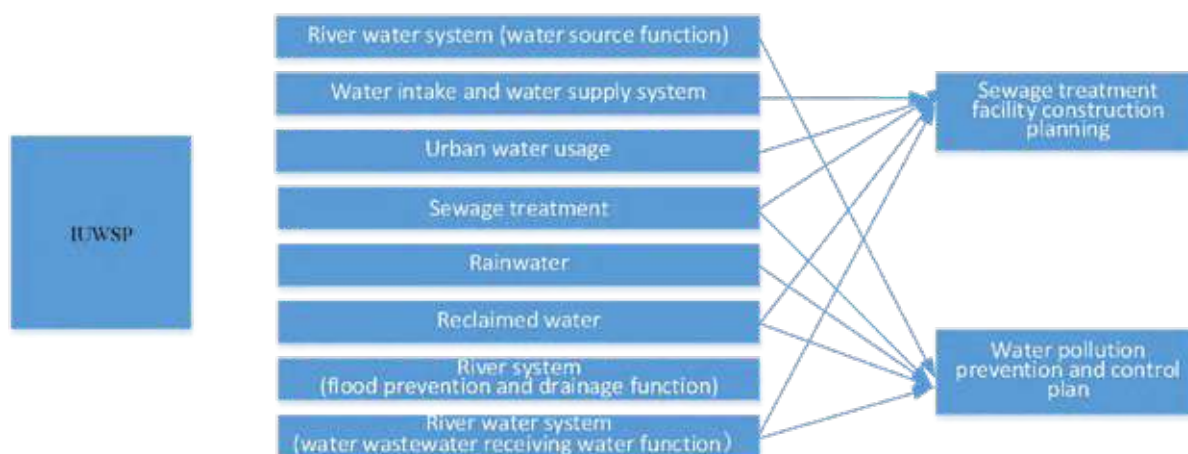

Figure 9 Relationship among IUWSP, water pollution prevention planning and sewage treatment facility construction

“The Water Law” has established a relatively complete water resources planning system, including flood control, drainage, irrigation, shipping, water supply, hydropower, fisheries, water resources protection, soil erosion, sand control and water conservation. The relationship between the water resources planning system and IUWSP is as follows Figure 10:

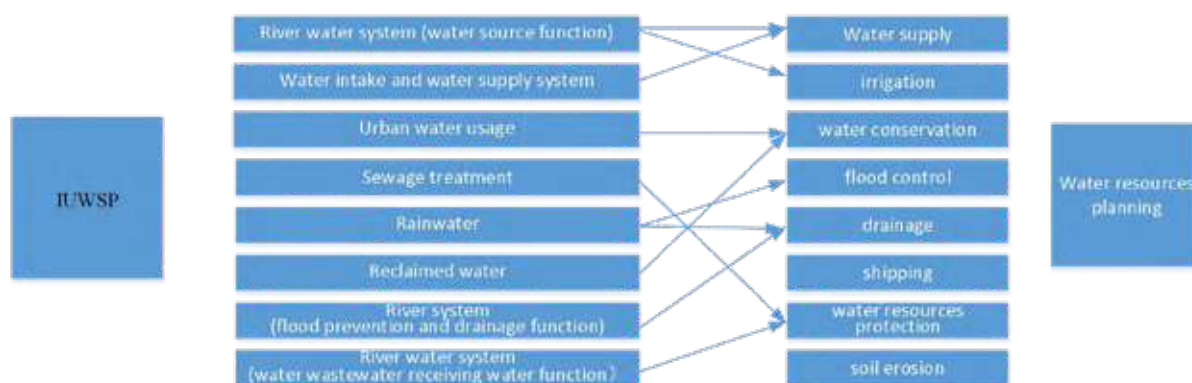

Figure 10 The relationship between the water resources planning system and IUWSP

(4) Planning and management mechanism for IUWSP

According to the functions of the Ministry of Natural Resources in china, IUWSP will be compiled by the Ministry of Natural Resources and its subordinate departments, emphasizing the overall management of the water resources system and avoiding unreasonable and uncoordinated individual plans.

Department of Water Ecology and Environment in Ministry of Ecology and Environmental Protection can: integrate the water function zoning and sewage outlets of the water conservancy department, the non-point source pollution control of the Ministry of Agriculture, and the groundwater pollution control responsibility of the national land department.

The organizational unit model for urban water-related special planning mainly consists of: planning bureau model, planning bureau and industry competent department model, and industry competent department model. To sum up, the urban water-related plan is the guiding document for the industry authorities to carry out water system infrastructure construction and management (Chen Liqun,2013).

From the above, the tasks of the Environmental Protection Bureau, the Planning Bureau and the Water Resources Bureau are relatively clear. The Environmental Protection Agency manages the water environment, sewage and reclaimed water, and the Water Resources Bureau manages water resources and flood control. The Planning Bureau conducts space control, including blue line control. The rest of the special projects such as rainwater, sewage, reclaimed water, water supply, flood control, drainage, etc. are all responsible for the construction department, some are managed by construction department in the Construction Bureau, some are managed by construction department in the Water Affairs Bureau, and some are managed by construction department in the Urban Management Bureau or the State-owned Assets Supervision and Administration Commission. Under various departments, there are also more companies to operate specifically, such as the Water Supply Group, the City Investment company in Water service, and the Reclaimed Water Company. These departments are franchised for water supply, sewage treatment and reuse of recycled water. However, traditional tasks such as flood control or drainage are generally handled by the drainage department(Chen Liqun,2013).

From the above analysis, urban water-related planning belongs to the scope of the city government. However, in order to facilitate the construction of urban water affairs, all relevant functional departments carry out construction and management, but Coordination and integration from the planning level is the current planning reform trends, like energy integrated planning(Huang Zishuo,*et al.*,2018), Comprehensive Transportation Planning, Communication planning.

(5) Implementation path of IUWSP

According to Chen Liquan's research on the implementation path of water system planning (Chen Liquan, 2013), implementation mechanism and management research of IUWSP, IUWSP belongs to the non-statutory planning at the macro level. There are two implementation paths: ① thematic form, relying on the urban development strategy. The planning or master plan is carried out in the form of IUWSP research, and its main results are incorporated into the urban development strategic planning or overall planning, and the implementation of IUWSP is guaranteed by the implementation of urban development strategic planning or overall planning. ② Prepared separately. IUWSP guides subordinate planning - control detailed planning and water-related special planning.

(6) New IUWSP types have emerged

In the current practice, there are few types of projects for IUWSP, including “Wuhan City World Waterfront City and Water Special Project Planning”, “Water System Special Plan in Shenhai Qianhai Cooperation Zone” and “Water System Special Plan in Zhongxin Tianjin Ecology city”. The planning projects such as the Urban Water System Special Plan are dedicated to integrating water supply, rainwater, sewage, reclaimed water and all water-related systems, controlling and regulating the rainwater, utilizing water resources, water pollution management, and improving the water environment, building a safe, healthy and efficient water environment system.

5 How to prepare IUWSP

(1) construction process of the overall framework system

This paper takes the whole theory of urban water circulation as the most important goal and principle to guide the reform of IUWSP. Urban water systems are interconnected and mutually constrained to provide infrastructure for urban development.

This paper takes water source system, water supply system, sewage discharge system, water reuse system and rainwater discharge system in urban water system as the research object, and studies the urban water system planning method from the perspective of urban systematics. IUWSP that satisfies the urban water cycle theory is a good plan to guide the construction of the full text. The specific construction steps of theoretical framework system are:

① Through the analysis of the development history of urban water system planning theory, the characteristics of traditional urban water system planning theory are found. Under the new situation of urban water system development, the traditional urban water-related planning theory and method have a single planning target and urban water system demand. There are drawbacks in the shortcomings of the forecasting method, the lack of information feedback, the evaluation index system is not comprehensive, and the theory that does not reflect the water cycle.

② Based on the theory of water cycle, the concept and planning principles of urban water system circulation are proposed.

③ Under the guidance of the water cycle theory, a set of theoretical system framework for urban water system sustainable development planning that considers China's national conditions is proposed and designed, to meet water supply needs, optimize water resources utilization, improve water environment quality, and ensure urban flood safety. The function of each module in the theoretical system is actually designed.

④ Finally, the level of IUWSP and the general planning process are studied.

(2) The composition of the theoretical system of IUWSP

Introducing environmental protection, service level, resource utilization optimization, and safety assurance into the urban water system planning process, completely changing the traditional single planning method, which is just to solve their respective needs as the sole planning goal. Establishing total water consumption control, water efficiency control, and environment quality control and the number of floods control as controlling indicators. Establishing the theoretical framework structure of IUWSP and designing each functional module in the framework structure.

IUWSP consists of the following modules in Figure 11:

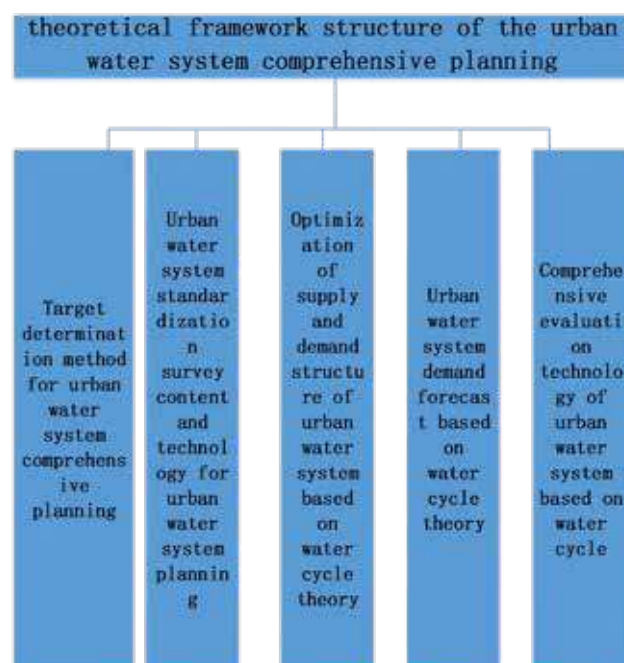

Figure 11 Theoretical framework structure of IUWSP

1) Target determination method for IUWSP

The urban water system planning under the guidance of traditional targets will not only lead to the emergence of “water shortage, water environment pollution, internal security”, but also destroy the urban water environment and waste urban water resources. Under the urban water cycle theory, it is proposed to establish an urban water system planning target system consisting of four aspects: meeting urban water supply demand, optimizing water resources utilization structure, improving water environment quality, and ensuring urban safety.

In view of the lack of research on the implementation and guarantee system for the traditional urban water system planning, it is considered that the establishment of the urban water system planning implementation and guarantee system is also one of the objectives of the plan.

IUWSP target system is composed of the service level index system, the environmental protection index system, the urban security guarantee system, and the resource structure optimization system. The quantitative methods for the specific indicators are studied. The secondary indicators for improving service levels include: resource supply and pipeline network construction. Secondary indicators for improving the environment include rehabilitating the environment, protecting the environment, and saving water to protect groundwater. The

secondary indicators for urban security include security, redundancy, and emergency protection. The secondary indicators for resource structure optimization include: improving efficiency, energy saving and emission reduction.

2) Urban water system standardization survey content and technology for IUWSP

In the IUWSP, the principles of investigation design and implementation should be clearly defined, and the investigation methods should be clearly defined to comply with the principle of water cycle. The purpose of the survey is not only to establish a database of water system information, but more importantly, to investigate the current water system and to discover the problems of the current urban water system that does not meet the principle of water cycle development.

The urban water system standardization survey according to water circulation includes the various components of the water system: water resources, water plants and other infrastructure, water use indicators, water pollution and flood disasters, pipe network construction, flood control standards, and the establishment foundation of the water system (urban population, economy, industry, natural environment).

The survey methods are divided into two categories: data collection surveys and field surveys.

Studying the establishment method of GIS database for urban water system standardization survey according to water cycle, and on this basis, proposing the current urban water system analysis and diagnosis method.

According to the water cycle and metabolism theory, a standardized survey of urban water systems is organized. The content of the standardized survey will include the following: survey methods; survey departments and information lists; survey content; form a database.

3) Optimization of supply and demand structure of urban water system based on water cycle theory

Guided by the above framework, the optimization of water supply and demand structure, the optimization of rainwater supply and demand structure, and the optimization of water and pollutants supply and demand structure are the key to IUWSP. Guided to propose planning responses to key tasks in the supply of urban water system infrastructure. The above three parts are used as a new countermeasure analysis framework to form a complete planning response model. A series of water problems appearing in the future urban water system planning reform can be analyzed according to this new framework and model.

The urban water supply and demand structure is the key to study the urban water resources carrying capacity, and it is the main aspect of supporting the development factors of the city. The water resources carrying capacity is mainly composed of the urban water supply capacity and demand capacity, and the two are mutually constrained. The study of urban water resources is a primary part and a key part of comprehensive urban water resources planning.

The drainage structure of urban water supply and drainage system in China must be established on the basis of China's national conditions. The per capita water resources are small, the infrastructure is weak, and the rainfall is concentrated. This is the basic situation of China, which determines that China must take water-saving measure. The development model of social, environmentally friendly society and intrinsic safety protection focuses on urban connotative development.

According to the characteristics of urban development in China, on the basis of water usage feature, natural conditions and urban scale, population density, urban form, topography and geomorphology in studying urban,

with reference to the experience and lessons of the development process of foreign water systems, IUWSP priorities of different cities should be proposed.

4) Urban water system demand forecast based on water cycle theory

In the IUWSP, the water supply and demand forecast mainly includes various urban water demand. The sewage treatment demand is mainly determined by the water supply demand, and the urban rainwater discharge demand is mainly determined by the urban drainage standard.

In the formulation of planning schemes and strategies, the urban water system construction needs are first defined, and the demand forecasting methods are studied. The most important is to identify the various demand impact factors and construct the systematic dynamics equation of demand.

Urban water system demand forecasting technology is one of the key technologies for IUWSP. Its specific contents include the following: urban water demand forecast; urban water environment governance demand forecast; urban rainwater discharge demand forecast.

5) Comprehensive evaluation technology of urban water system based on water cycle

In the traditional urban water-related planning, the evaluation content focuses on the ability and level of urban water system to solve water problems, water supply planning to solve water supply security, sewage planning to solve sewage treatment, water system planning to solve water system layout, and sponge city planning to solve stormwater runoff control and Rainwater resource utilization, flood control planning to solve urban flooding caused by internal flooding problems, urban flood control planning to solve flood safety problems. While in the IUWSP under the water cycle theory, the evaluation content includes the efficiency of urban water system infrastructure, urban flood control standards, the connection between drainage pipe network standards, the supply capacity of urban water supply facilities, the quality of urban water environment, the perfection of urban sewage treatment facilities, and the efficiency of urban water usage.

Evaluation plays a three-pronged role in urban planning for water cycles. First, the evaluation determines the value of each option and the advantages and disadvantages between the programs. Second, the evaluation provides decision-making information for decision makers. Third, the evaluation provides planners with ideas and directions for the development of water systems.

Evaluate the status and level of the current urban water system development, identify the phenomenon that does not meet the development principles of the water cycle theory, and define the direction of urban water system development; the focus of the planning is to investigate the plan to meet the the water system needs, at the same time whether it meets the requirements of ecological environment and resource consumption.

It puts forward an evaluation index system composed of indicators such as flood control and drainage standard suitability, green infrastructure development rate, water environment quality, urban water supply service level, urban water system development coordination degree, etc. The comprehensive evaluation technology of urban water system network oriented to water cycle is studied.

6 Conclusion

This paper takes water source system, water supply system, sewage discharge system, water reuse system and rainwater discharge system in urban water system as the research object, and studies IUWSP method from the perspective of urban systematics. IUWSP that satisfies the urban water cycle theory is a good plan to guide the construction of the full text. On this basis, Establishing the theoretical framework structure of IUWSP and designing each functional module in the framework structure.

The governance of the circular economy: insights from the Veneto Region

Jon Marco Church^{1*}, Giulia Lucertini^{2†}, Giacomo Bellinato², Erika Guolo², Giovanna Pizzo², Giulia Bonomini²

Paper to be presented at the 2019 AESOP Annual Congress “Planning for Transition” to be held in Venice on 9-13 July 2019, under the theme “Urban metabolism and circular economy”

Abstract

Over the last decade, the notion of circular economy progressively emerged all over Europe. It can be defined as “the reducing, reusing and recycling activities conducted in the process of production, circulation and consumption” (Ghisellini, Cialani, & Ulgiati, 2016), but also as “a system that is designed to be restorative and regenerative” (Charonis, 2012). It is a popular approach towards green economy and sustainability (Geissdoerfer, Savaget, Bocken, & Hultink, 2017). Circular economy systems are being developed in many countries and contexts, particularly China. There is a growing literature on the various dimensions of the circular economy from many disciplinary perspectives, including planning (Murray, Skene, & Haynes, 2017). However, little attention has been paid to its governance. What is the impact of some variables related to governance, such as actors, actor configurations, collective action, policy instruments, compliance processes, as well as institutional levels and policy sectors, on the development of the circular economy? Are some of these variables more important than others? Through which causal mechanisms do they intervene? To answer these questions, we analyze four cases from the Veneto Region in the materials, building, food and textile sectors. Unlike most of the literature, instead of focusing on the peculiarities of each case, we chose to focus on what they have in common and the interaction of these key variables with the planning and institutional system. The insights were collected through participant observation in the framework of a transdisciplinary collaborative research project.

The challenge of the circular economy

Images of islands of plastic in the middle of the ocean or mountains of waste on the outskirts of many large cities remind us of the limits of today's production and consumption systems. Phenomena such as the so-called “triangle of death” in Campania, or debates such as those on the use of incinerators to dispose of waste, remind us that these problems are not confined to developing countries, but also concern the so-called developed countries. These problems also affect Italy and the Veneto (ENEA, 2019), whose production and consumption system, while possessing many specificities, is intrinsically connected with the rest of the world. The concept of “circular economy”, emerged in the 1990s as an operational version for companies of the broader concept of sustainable development (Carroll, 1999; Clark & Munn, 1986), aims at transforming production systems so as to tend towards waste reduction, recycling and reuse; the circular economy also intervenes on consumption in a way that moderates the generation of waste, as well as encourages recycling or recovery and reuse (Ghisellini et al., 2016). The circular economy is considered as a fundamental element of the green economy and a transformation necessary for greater sustainability (Geissdoerfer et al., 2017).

But the biggest challenge of the circular economy is not only the reduction, recycling and reuse of waste, but the tendency to minimize waste, which is often summarized in the probably utopian formula of “zero waste”. This requires not only technical innovations, as pointed out by Prieto-Sandoval et al. (2018), but also cultural changes. For example, the transformation of wastewater into a resource requires not only significant progress compared to current urban and industrial wastewater treatment plants, but also the overcoming of the wastewater taboo among the population and the increase in citizens' confidence in the drinking water distribution system (UN-Water, 2017). The need to combine the reduction, recycling and reuse of waste and systemic changes has clearly emerged from the analysis carried out by Kirchherr et al. (2017) of a hundred definitions of the circular economy found in the scientific literature.

The development of the circular economy often involves the reduction of distances to avoid the decoupling of production sites and places of consumption (Leduc & Van Kann, 2013; Liu et al., 2013) and therefore the excessive distancing of waste from production centers and its accumulation in landfills and in the environment, such as in the case of cattle-bred products, the fertilizers used in the production of feed and the ensuing perturbation of the nitrogen cycle (Brunner & Rechberger, 2017; Morseletto, 2019). This however is not systematic, as there are also more or less long value chains, such as the use of mineral resources, which can often be found only in remote areas, sometimes on the other side of the world, which should not be excluded from the logic of the circular economy and from the process of reduction, recycling and re-use of resources.

The concept of circular economy, if only in a general sense, is widely shared. An analysis of the positions of the five main candidates in the last French presidential elections on environmental and climate issues has shown how the development of the circular economy and short supply chains is with the promotion of renewable energies among the few issues that gather support across the political spectrum from the extreme right to the left passing through the center (Church, 2017). This phenomenon can be explained by the territorial dimension of the circular economy, especially where this coincides with short supply chains. The circular economy in fact transforms potential waste into resources and contributes to local development, also in terms of jobs, and in some cases to the re-industrialization of entire areas (Ratti, 2002).

The political dimension of the economy is therefore important. Korhonen et al (2018) note that research on the circular economy has mainly been focused on practical and technical questions concerning the flow of materials and energy in production and consumption systems. The values, the social structures, the cultures, the visions of the world and the paradigmatic potential of the circular economy remain largely unexplored. The phenomenon of governance, which will be

explored further, includes and goes beyond these concepts. This paper contributes to fill this gap by looking into the governance of the circular economy and particularly the role of some characteristics. The study of the governance of the circular economy is important because it is, for example, through governance systems that the knowledge needed to make the economy more circular is co-produced and circulated by and between various actors, including both experts and decisionmakers. For example, thanks to the results of scientific research and the pressures of a group of economic actors, a public body can realize that the rules in force hinder the re-use of certain resources in a production process.

This paper will therefore identify the actors that currently participate in the development of the circular economy, as well as the configurations of actors that facilitate this type of development. For two sectors of activity, the institutional and spatial levels on which the transformation process is structured will be explored. On this basis, the type of collective action will be characterized on a gradient ranging from cooperation to conflict. Finally, the tools used to promote the circular economy will be identified, as well as the eventual mechanisms for verifying the implementation of these policies. The methodological approach to explore these dimensions is presented first, followed by a conceptual framework that allows identifying the main features of a system of governance from the point of view of the circular economy. These characteristics will then be analyzed in four cases in two different business sectors. The characteristics that emerge from the analysis of these cases will finally be discussed to see how far they can be generalized (Gerring, 2004; Magliocca et al., 2018). The main objective of this text is indeed to identify the main features of a governance system that promote the development of the circular economy.

Pattern recognition of features

The four case studies presented and analyzed in this text have been identified as part of a research and training project that was funded by the European Union with the participation of the Veneto Region. This choice results from many factors including opportunity, proximity and, above all, interest on the part of the European Union, the Veneto Region, the universities and companies involved in the circular economy. These are therefore positive cases that allow us to identify the forces that drive companies to contribute to the development of a circular economy. The cases concern four of the main sectors of activity that are protagonists of the emergence of the circular economy, namely materials, building, food and textile. The four cases are not identical and are placed along a gradient that goes from the large to the small and medium-size enterprise.

Each company simultaneously received a trainee in the framework of the project for a duration of twelve months between May 2018 and April 2019. The trainees have a post-graduate level of education and, in the period considered, were trained on the topics of circular economy. The trainees were therefore able to make a participant observation of the processes of transformation of the respective companies towards the circular economy, including regarding the systems of governance. During four months between January and April 2019, the trainees participated in a special program on governance systems. This allowed them to acquire a common language and common conceptual frameworks regarding governance and therefore the ability to structure the observations that they had been able to carry out in the previous months in a relatively uniform manner. They then presented and discussed their observations on two occasions, individually and collectively. This process made it possible to build a relatively homogeneous and therefore comparable narrative corpus.

The corpus thus obtained was then analyzed in an iterative way to identify features common to the four case studies according to the recurrence method (Young et al., 2006). This approach has also allowed for the emergence of differences that are specific to each case. The following paragraphs present the conceptual framework that has been adopted, the case studies, the common features,

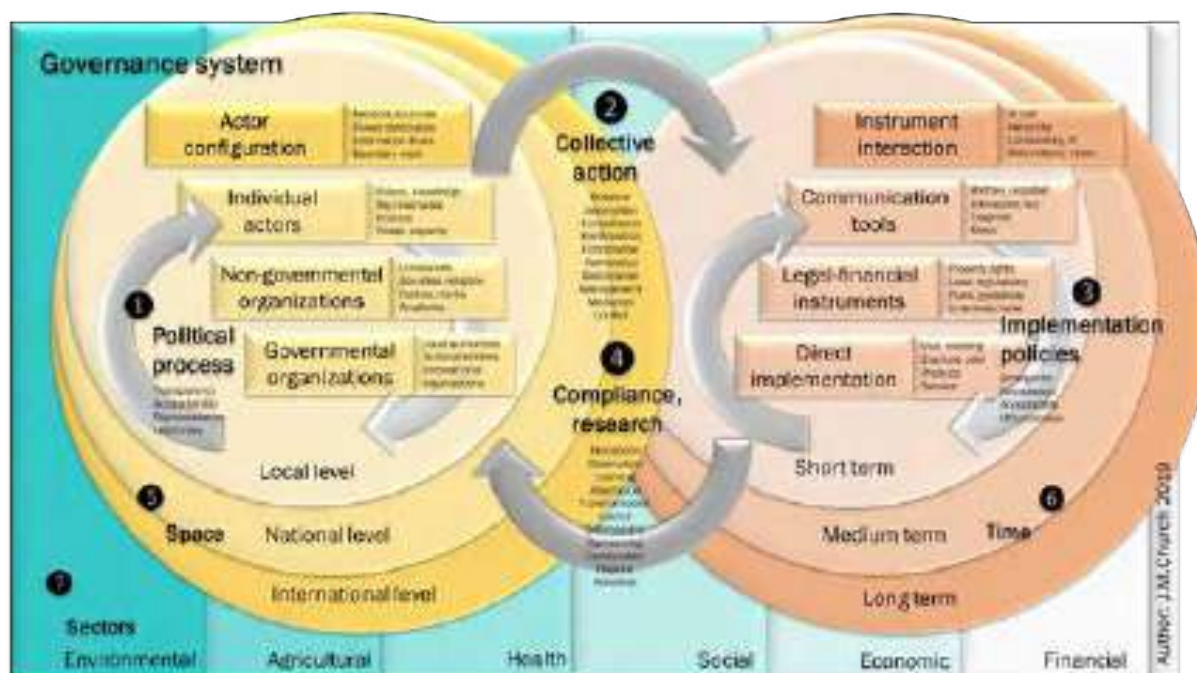

as well as the differences. A synoptic summary of the narratives is included among the supplementary materials.

Governance systems

“Governance” is a concept that emerged between the 1970s and 2000s in contrast with the concept of “government”. As early as the 1960s, authors such as Dahl (1961) showed that government action was complex and difficult to analyze. Even in the case of circumscribed examples like that of the small city of New Haven, Connecticut, it is difficult to understand who exactly is at the origin of a policy and how this policy was decided. If the concept of government refers to a sovereign entity in the sense of the decision-maker of last resort on a well-defined population and on a territory delimited by relatively clear boundaries, the concept of governance reflects the complexity of the act of governing that is exercised by different actors in a context complex characterized by a multitude of governmental, non-governmental actors, including companies and individuals, and by a territoriality with overlapping perimeters and that is articulated along several nested levels (Agnew, 1994; Ruggie, 1993).

We also propose a systemic and cyclical approach to governance, which is not limited to the analysis of the configurations of actors on different levels and spatiality, nor is it reduced to considering the collective action that is exercised by the various actors as a black box generating implementation policies, in this case in favor of the circular economy. The systemic approach used in the case in question is represented schematically in Figure 2. This framework is dynamic, articulated over time as well as in space, does not provide a teleological view of implementation policies, foreseeing their retroaction in the political process, thus leading to new cycles of collective action.

Figure 1: Conceptual scheme of a governance system

The systemic and cyclical approach adopted starts from the **1 political process** intended as an iterative interaction between different types of actors, particularly individuals, and governmental and non-governmental organizations. This political process has its own characteristics, such as transparency and accountability, but also the representativeness of the actors and their legitimacy, only to mention a few of the main features. At the same time, the interaction between the various actors is conditioned by their configuration in terms of network structure, power distribution, information flows and boundary work between one type of actor and another.

The political process allows the transition from the individual action of each actor to **② collective action** that can take different forms. Again, in the aforementioned hypothetical example, the public body can decide independently or in a coordinated manner with other bodies to change the rule in question. In this case, there are two actions: change (not the norm but the act of changing) and the eventual coordination with other actors. The most spontaneous type of action is behavior that can be influenced by the political process. Then, following the scale of Kerkhoff and Lebel (2006), it is possible to proceed to levels of increasing participation ranging from the lowest levels, i.e. information and consultation, to the highest ones, namely cooperation and partnership. If management refers to relatively de-politicized decision-making processes, deliberation is an important form of collective action as it allows choices to be stabilized in a way that will be perceived as more or less legitimate, depending on the type of interaction, and can therefore be disputed. In some cases, mediation can take place between opposing parties, but in others the collective action can lead to a more or less open conflict between parties disagreeing not only on what to do but also on the political process itself.

Collective action can therefore lead to the consolidation of **③ implementation policies** that are essentially a form of crystallization of political processes and collective action, which are naturally fluid. Policies can take various forms ranging from communication tools to legal and financial tools, such as laws, regulations, plans, guidelines, but also subsidies and taxes, up to direct implementation by the actors who participate in the political process. These policies interact with each other depending on the perimeters of implementation and any hierarchy that may exist between them. It goes without saying that they can be more or less consistent and adequate and that it is therefore possible to observe a certain amount of redundancy and a certain level of disturbance between one policy and another. Of implementation policies, we normally go to study not only the emergence and formulation, but also the acceptability and effectiveness towards the specific objectives of the policy itself but also of general objectives such as sustainability (Church, 2015).

A systemic vision of governance allows us to conceive the processes of **④ verification** of the implementation of policies as a feedback that returns them to the political process. Research is a fundamental form of verification, especially vis-à-vis face of complex phenomena. The verification of implementation practices passes through various processes such as perception, which can be more or less distorted, and the observation of phenomena and situations. This process can lead to the learning of the limits of existing policies but also of previously unknown phenomena and concepts and this can lead to the emergence of the need to adapt and possibly transform not only the implementation policies but also the underlying processes. The perception and observation of the failure to implement policies can also lead to attempts to control and execute by certain actors such as law enforcement, which can lead not only to sanctioning deviant behavior but also to contesting policies and their implementation. In some cases, this dispute can lead to disputes between parties with contrasting visions of the policies and the stakes, but also in phenomena of rebellion against the policies and processes that have led to them.

Governance is articulated in **⑤ space** on various levels that may correspond to the main administrative structures and therefore may be distinguished between local, national and international, but which can also either overlap horizontally, for example in the case of economic and environmental regions, or nest vertically, like in the cases of multilevel governance (Hooghe & Marks, 2003), depending on the functional logic. Governance is then a dynamic process that is articulated across **⑥ time**. In the governance cycle, it is therefore possible to distinguish short, medium and long-term processes, but also observe accelerations and rhythms dictated for example by political processes such as the duration of electoral mandates, but also phenomena such as natural disasters. A third dimension or scale, using the terminology of Cash and colleagues (2006), of governance is constituted by the **⑦ sectors** of activity linked to the specialization of collective action and knowledge, which include, for example, the environment, agriculture, health, welfare, as well as the

economic-financial sector. Distinct spatial, temporal and sectorial logics often lead to the compartmentalization of political processes, collective action, implementation policies, as well as verification and research processes, compartmentalization which is however recomposed in various locations, above all in the processes of verification and by certain actors that are transversal to the sectors.

The “Opportunity” project

The “Opportunity” project (ID: 2122-1-1267-2017) is funded by the European Social Fund (ESF) of the Veneto Region. Through a dual approach integrated both vertically (research, training and action) and horizontally (inclusion, economy and environment), has established a network of companies and organizations that, based on their logic on the circular economy, are able to generate social, economic and labor innovation. The project, which ends in the coming months, lasts 18 months and involves numerous partners, including the Università IUAV di Venezia, the Municipality of Padua, the Chamber of Commerce of Padua, three high schools, five companies, the Ecosystems Foundation, the Fenice Foundation, SIVE Training and three partner universities (Université de Reims Champagne-Ardenne; Technische Universiteit Delft; Universitat Autònoma de Barcelona) that supported the project through the participation of some visiting professors. The project has spread the concepts of “reduction, reuse and recycling” among a wide and diverse public, starting from schools, demonstrating its potential both in terms of sustainability and job opportunities. The project has supported companies and institutions in recognizing potentials that are not yet manifest in the production and labor systems, in educating for sharing and collaboration, in training for the creation of value and new work spaces and in creating synergies and industrial symbioses that are relevant for strategic sectors at municipal, regional and national level. Furthermore, the project was able to count on a partnership formed by research, training and education entities, companies supplying products and services, public and coordination bodies that have been able to cover the needs and requirements of a vast project with ambitious objectives.

One of the objectives of the “Opportunity” project was to start a process that would allow the development of a network of public and private actors capable to innovate, through the logic of the circular economy, the labor market in the Veneto region to increase competitiveness and territorial cohesion, reviving the local economy, reducing unemployment and particularly youth unemployment, as well as improving waste prevention and management. To achieve this ambitious goal, the project stimulated the spread of the culture of “reduction, reuse and recycling” through the involvement of private companies, public entities, students, workers and consumers in seminars, network meetings and workshops; it identified the industrial synergies and symbioses that can be developed in the territory in the sectors of materials, building, food, textile and gardening; it supported the development of a network of companies able to work synergistically on the logic of “reduction, reuse and recycling”; it built a specific training course for companies on the circular economy and on possible productive and working innovations; it created a specific teaching package for middle schools and high schools, capable to prepare students for new jobs in the field of sustainable development and the circular economy; it provided a facilitation service to launch innovative start-ups that follow the principles and logic of the circular economy.

Five companies were directly involved in the interventions envisaged by the project. Five research grants of eighteen months were allocated to unemployed graduates, one for each company involved. These fellows, under the coordination of the Università IUAV di Venezia, were each assigned to a company, in which they carried out research on the production system of the company and on the concrete impact of products. This led to work on identifying potential cooperation and synergies with companies in the sector or related sectors with the aim of making the best use of the resources present in the area. The fellows were therefore able to suggest and support companies in the introduction of circular economy principles; they also carried out a careful search for good practices in the specific field of the company to which they were associated. As part of the research grant,

company visits and periods of study were provided, as well as training mobility both at regional, interregional and transnational level. The presence of the fellows at the companies engaged in circular economy processes allowed them to carry out the participant observation of the practices of the specific company and of their sector, as well as of the related governance processes.

Action-research interventions were then conducted in each company participating in the project. These interventions allowed us to discuss and introduce in the various companies, each according to its specific needs, the new logic of the circular economy both in terms of production and business management. Furthermore, this has made it possible to deal with complementary and broader topics such as sustainability, resilience and inclusion. The companies then took part in meetings, seminars and workshops to discuss their respective development plans and to contribute to the creation of a network among companies not only in each sector, but also in a regional circular economy network. The need for this network has been studied within the project. Its realization depends on the assessments that will be made and on the will stimulated by the project. It will in any case follow the project.

Case studies from the Veneto Region

This analysis of the governance of the circular economy is based on the case studies of four companies, all based in Padua and involved in the “Opportunity” project and therefore in circular economy processes. These companies belong to the construction sector, particularly construction materials in one case and buildings in the other, while one is in the food sector and the other in the social sector with aspects related to both textiles and food.

Stiferite s.p.a.

The company operates in the construction sector and more specifically in the production of insulation material for construction and for the refrigeration industry. The insulating product is rigid polyurethane foam, a material deriving from the chemical industry, but capable of meeting energy and environmental requirements. Although the product already reduces the need for winter and summer air conditioning in buildings and despite the company's attention to energy efficiency, the future objectives are to develop an internal process linked to the circular economy, especially for the reuse of waste material in the production and recycling phase and re-use of the material at the end of its life. Currently there are already processes of chemical and mechanical reuse and recycling carried out by external bodies. The main objective of the company is the realization of an internal plant to produce panels from recycled material, also destined for other sectors.

The position of the fellow within the company was to carry out research activities related to the sustainability of the products, carrying out a life cycle assessment and subsequent publication of the environmental product declarations, from the extraction of raw materials, to the production and subsequent disposal of the product. This analysis made it possible to carry out some in-depth studies on the end-of-life scenarios of the product, assessing its impact on the surrounding environment.

Cazzaro Costruzioni s.r.l.

The company has been active in the building sector for over fifty years and is based in Trebaseleghe near Padua. It is a family business that, after the crisis of 2008, decided to specialize in the construction of high-value buildings, paying attention to the quality of living and comfort, devoting itself to fewer interventions in the surrounding area, but in a detail-oriented manner. The company has been collaborating for years with the Università IUAV di Venezia as part of research and development projects. The “Opportunity” project provided the starting point to apply the principles of circular economy in the production process, understood as the entire life cycle of a building, from construction to demolition. The goal of the company is to make the management of the materials used

in the construction more efficient, paying attention to the use of materials with recycled content and the management of any construction site waste. Furthermore, it becomes a prerequisite to digitize projects with the aim of creating a real database of materials, hypothesizing, already in the design phase, the possibilities of recovery, reuse or recycling. The continuous comparison with professionals, sector operators and building materials suppliers has favored the development of innovative strategies to optimize the design and construction processes.

The research fellow worked at the company's technical office where she was able to carry out research and analysis of a project under construction in Treviso. The latter was analyzed and digitized with BIM (Building Information Modeling) methodology to estimate the quantities of materials used in the construction. Strategies were first developed aimed at optimizing the construction process and then aimed at the recovery or recycling of materials used at the end of the building's life.

Ca' Sana (PI.TA.PU. s.a.s.)

The company Ca' Sana Food, Art, Culture, active in Padua since 2014, is a restaurant specialized in vegetarian and vegan cuisine that uses local and organic products from small businesses in the area, but also from fair trade, from lands confiscated from the mafia and from social cooperatives. The company is also active in the catering business and is an active player in the social and cultural life of the city, linking its main activity to the diffusion of a new development model and to the exchange of good practices in terms of sustainable development. Ca' Sana is also a reference point for the ability to develop projects related to agricultural production and the enhancement of the territory, creating new relationships between producers and consumers. The company is strongly interested in the development of circular processes: from the reduction of food surpluses, through careful planning linked to seasonality, to menu planning. The reuse of advanced raw materials after the food preparation phase could be further developed. The optimization of all the parts of the product would lead to minimizing material losses, taking maximum advantage in terms of environmental benefits and economic savings.

The researcher, starting from the actions developed by the company in relation to the circular economy, carried out a first survey to understand how catering in the city of Padua is approaching this theme, with particular attention to the reduction of food waste. Furthermore, it supported the creation of a local network of farms, providing a document that can strengthen local and suburban agriculture at the Veneto level.

Città So.La.Re soc.coop.soc.

Città So.La.Re Solidarity, Labor and Responsibility is a social services cooperative created in Padua in 1997 on the basis of a project by Caritas, ACLI (Associazioni Cristiane Lavoratori Italiani) and Nuovo Villaggio soc.coop.soc. for collecting used clothing, in partnership with APS (Azienda Padova Servizi). The company offers reception, environmental, mechanical and electromechanical assembly services for third parties, job placement and coworking. The company is therefore engaged among other things in the collection of used products, in their reconditioning, in the reuse by people in need and in the resale on the used market in collaboration with other similar entities. Regarding environmental services, collection functions for Caritas-branded containers, collection center management, city decoration, cardboard collection, special waste, exhausted food oil, door-to-door services are proposed to public bodies, commercial users and private individuals for plastic and metal packaging, paper and cardboard, greens and twigs, biodegradable damp, mowing, evacuation and removals, as well as transport for third parties at the national level. Città So.La.Re. intervenes above all in favor of disadvantaged people with problems of job and social insertion or with impairments and temporary difficulties, in conditions of socio-rehabilitative treatment, to have more job opportunities and to improve their quality of life. The company promotes the value of the human person, the protection of health and the social integration of local and foreign citizens.

The research fellow has produced in particular a technical report on the transformation of waste into a resource and on the supply chain and, in particular, on the potential of large-scale distribution for the collection and resale of used clothing, the role of social cooperatives in this sector and their relaunch and on a possible partnership with the large textile districts, such as around the city of Prato. The approach used was that of action-research about reporting, geo-referencing and communication of results and benefits.

Common features and divergences

To better understand the role of governance in the development of the circular economy in the case studies, seven themes were selected from those identified by the conceptual framework based on their relevance. The political process has been separated into analysis of actors and configurations of actors as the circular economy remains relatively confined to the technical sphere. In Italy, the political level has not yet fully adopted this concept, which is still emerging. Also, the time scale has not been the object of specific analysis as the phenomenon is relatively recent. For each of the case studies, the following topics were then analyzed, searching not only for common features of the governance system, but also for divergences:

- ① Governmental, non-governmental organizations and individuals
- ② Actor configurations
- ③ Collective action
- ④ Implementation policies
- ⑤ Verification, research
- ⑥ Levels
- ⑦ Sectors

The following paragraphs summarize the points in common and the differences observed in the four case studies. The selected themes, the analysis of each case study, as well as the synthesis of common characteristics and differences were discussed in internal and external seminars between February and April 2019. In the economy of this text, see Annex 1 for a synoptic table that presents more details.

The fact of analyzing the characteristics of a multiplicity of case studies on the same territory, allows a better understanding of the local governance system thanks to the multiplication of perspectives (Young et al., 2006). However, the external validity of the conclusions outside the Veneto Region remains to be demonstrated. The use of the conceptual framework lends itself to the production of case studies from other areas and other contexts, articulated both in time and in the various sectors of interest for the circular economy, to be compared and analyzed together with the conclusions concerning the Veneto case.

① Organizations and individuals

The protagonists of the development of the circular economy are in the first place the companies interested in the transformation of waste into a production factor and a management level that is sensitive to these issues. In each case there are the producers of raw materials, the distributors and finally the users, which can be different in the different sectors, especially at this level of detail. All the actors observed tend towards the principles of the circular economy diffused by the European Union, thanks also to the use of certified products, special bodies and research activities carried out by universities and research centers, which are always among the actors included in the process. At the end of the life process of the single product, there are companies that deal with reusing waste materials to transform them into secondary raw materials, through different types of companies depending on the sector but with similar purposes. Both in the building sector and in the food and social sectors, there are national or international bodies, particularly the European

Union, which deal with the regulation and definition of the sector rules, providing funding for the sector development and publicizing the results thus obtained.

② Actor configurations

The circular economy develops above all from the bottom through the companies, but the institutions and the networks play an important role for the circulation of information. The relationships between the actors take place both vertically, especially between administrative-legislative-financial actors, and horizontally, mainly between actors who work on the same level and who collaborate with each other, especially companies. The dissemination of information is important for the creation of circular networks among companies that cooperate with each other, but often the circulation of knowledge is difficult, as there is competition and not all actors are ready to immediately accept the guidelines provided by the administrations, with consequent complications in reaching a large user base. In general, in the circular economy process, advantages can be created for some actors, who manage to enter the production process in a given sector for the first time but disadvantage other types of actors.

③ Collective action

Cooperation among companies is minimal, while partnerships are being established among companies, research institutions and public entities. The point in common among all companies can be considered an interest in issues concerning the circular economy. The collaboration between the different realities operating in the same sector is certainly indispensable, but when the economic and strategic factor comes into play the collaboration is interrupted. All companies ask for more effective actions by public entities to favor the application of circular economy principles, find a lack of incentives and ask for regulatory simplification. For some companies, at the economic level, it is not convenient to apply the principles of circular economy because of the time necessary for the return of the investment, which can often be very long.

④ Implementation policies

European objectives and national legislation are important for managers, but company initiatives fall within the scope of pilot actions. In the implementation of the circular economy, the importance of European legislation is noted in all the sectors studied (End-of-life Vehicles, Waste Batteries and Accumulators and Waste Electrical and Electronic Equipment Directive 2018/849; Landfill Directive 2018/850; Waste Framework Directive 2018/851; Packaging Directive 2018/852) which focuses on the prevention of waste production, introducing important objectives that can contribute to achieving objectives of sustainable development. Furthermore, the new legislation, requiring the member states to adopt specific measures, acts as a push for the concrete implementation of the principles of circularity. Italy, like other member states, has already embarked on a path that aims at the progressive improvement of waste management, in line with European standards. This has led to important results, such as the “anti-waste” law (Gadda Law) and the application of minimum environmental criteria (CAM), i.e. the environmental requirements defined for the various phases of the purchasing process, aimed at identifying the best product, service or design solution from an environmental point of view along the life cycle, also in the context of what is established by the plan for the sustainability of consumption in the public administration. The procurement code makes the application of CAM mandatory, while in the food sector the “anti-waste” law encourages actions developed by private individuals and simplifies the procedures for the donation of unsold products for the public and private sector but does not make it compulsory. In these instruments which, despite their specificity, are united by shared objectives, there is no assessment of their adequacy and a unified vision of the actions to be developed, especially in the food sector, where the municipal level, prompted on the basis of practices such as the strategic plans of some cities, can become decisive for giving substance to the regulatory system.

⑤ Compliance, research

Controls vary by sector, but they are rare, while it is the internal improvement of companies that supports the development of the circular economy, together with scientific research. In the building sector, sanctions can be multiple in the case of use of non-certified recycled materials or in the event of illegal disposal of construction and demolition waste, but their application has not been observed. The control bodies are public entities at municipal level (e.g. ETRA), regional level bodies (ARPAV) and ministerial bodies, dealing with environmental and sampling investigations and may issue sanctions in case of illegal disposal or use of non-certified material and material that is dangerous for the environment and for people. The food sector, on the other hand, is not currently subject to sanctions for the circular economy. The impact of local, national and European initiatives for the inclusion of circular processes within the sector cannot be observed at company level. Companies decide to lean towards sustainability based on internal motivations, rather than external factors. The processes are looked at by the actors involved and the role of research and development is fundamental because it allows the creation of the materials and techniques necessary for their implementation and to increase circularity. There is no network of research institutions working on the circular economy at the regional level.

⑥ Levels

The governance of the circular economy is multilevel but varies according to the sector. The levels involved, common for all companies, can be considered nested and each company must comply with the norms and indications of its sector provided by the state (e.g. “anti-waste” law), the region and the municipality (e.g. building regulations). Above all this is the European Union, which establishes guidelines and objectives to be respected and implemented. There are no substantial differences and every company must comply with the legislation that is specific for each sector.

⑦ Sectors

Although the case studies refer to specific sectors, the governance of the circular economy also involves other sectors, particularly the environment, health, social issues and the economy. Despite the difference between the issue area to which the four companies belong, it is clear that some sectors, including related policies, are involved in a transversal manner in the development of actions linked to the circular economy for those operating in the materials and building sector, as well for those in the food and textile sector. Out of all, the environmental sector comes out on top, indicated as being the most relevant in business activities and therefore the one towards which companies tend to operate to intervene in favor of the protection of resources, the reduction and recycling of waste materials, as well as energy consumption. Alongside this, the other transversal sector is that of health, paying attention to the final consumer. Finally, the sector linked to social issues, in which specific aspects related to the figure of the worker emerge, not only with regards to health and its protection, but also to combat exclusion, facilitating return to work and illegal employment.

It goes without saying that the food sector needs to be considered jointly with the agricultural sector, closely linked to objectives such as local production, through forms of suburban agriculture, quality and soil management. Linked more to textiles, the fashion sector must also be considered, once again for the possibility of developing new materials deriving from recycling and as a driver of potential change. A last sector that emerges from the analysis is that of economics and finance: although it is not highlighted in the construction sector, it is likely decisive for actions to be developed at company level. This sector, in fact, can make it possible to overcome the lack of stable incentives, relating to the circular economy, which producers complain about.

Discussion

The aim of this paper was the analysis of the governance of the circular economy. Our goal was to explore not only the values, social structures, cultures, visions of the world and the paradigmatic potential of the circular economy identified by Korhonen et al. (2018) as gaps in the scientific literature on the circular economy, but to do so in a systematic manner, placing these issues within a systemic approach to the governance of the circular economy. Following the reading of Elias (1969) and Tilly (1973), social structures are considered here through the concept of configuration of actors which includes that of the structure of the network of interdependencies between individual and collective actors and which also takes into consideration elements such as the distribution of power, information flows and boundary work.

The systemic approach adopted for this analysis of governance tends instead to link the values, cultures and visions of the world to individual actors, since within a collective actor these elements can vary, as we consider organizations as a common means to pursue different ends (Rawls, 1971). The commonality of values, cultures and visions of the world among individual actors within the same organization, as well as the role of so-called corporate and organizational values and cultures are elements that have been observed but mostly among company managers and not necessarily among the staff. This could be linked to external factors such as the sharing of values, cultures and visions of the world linked to belonging to structures outside our target companies, such as education background, belonging to political movements or other ties that however could not be detected through participant observation within the company.

The question of the paradigmatic and therefore ideological role of the circular economy can also be traced back to the individual actor and to collective actors such as political parties and certain associations. The circular economy as a paradigm is in fact a form of value and a vision of the world that can be more or less shared through information flows within different configurations of individual and collective actors. This can therefore be integrated directly into the communication tools and indirectly into the other types of implementation policies and influence, through the feedback process, on the transformation of production and consumption systems and the political process. The circular economy as a paradigm emerged only indirectly, having analyzed the governance system starting from the companies' point of view. This element would probably have emerged in a more pronounced way by including the point of view of other types of actors such as administrations and associations.

Furthermore, the circular economy is a phenomenon that has always existed, since economic actors and individuals have always tried to exploit all the factors of production. Traditional societies produce very limited waste. It is the collapse of the prices of raw materials and their transport plus the stigmatization of refusal with the spread of the hygienist movement and of the concept of public health that led to the exponential increase in waste from the end of the nineteenth century. The emergence of industrial approaches to waste disposal then allowed to keep costs relatively low. It is the awareness of the explosion of the amount of waste in landfills and oceans that has occurred in recent decades that has brought up the issue and led to the definition of the concept of circular economy, which is therefore itself a tool for implementing a transformation of the production and consumption system.

The selected cases are not representative of all circular economy cases in Veneto. They were identified based on the partnership established due to a commonality of interests within the “Opportunity” project. However, they are representative of the main sectors involved in the development of the circular economy: construction, materials, food and clothing. In this sense, they constitute a gradient that allows to go beyond the individual case study and to extract knowledge with greater external validity (Gerring, 2004). However, negative case studies are not included (Dimitrov, Sprinz, DiGiusto, & Kelle, 2007). This may limit the possibility of identifying the elements that prevent the

development of the circular economy at the company level. The inclusion of companies in the same geographical area involved in the same project also allows the control of the possible influence of external variables and therefore facilitates comparison and generalization. Furthermore, the use of a common conceptual framework and the multiplication of case studies makes it possible to compensate for the intrinsic subjectivity of the method of participant observation and, by objectifying the approach, to reinforce the general validity of the conclusions.

Conclusion

The analysis of the governance system of four case studies of the Veneto Region involved in the circular economy has revealed seven common characteristics:

- ① **Companies, managers** The protagonists of the development of the circular economy are first and foremost the companies interested in transforming waste in a production factor and the presence of a management level that is sensitive to these issues.

The four case studies that were observed are, however, examples in which it is precisely the companies and particularly their managers that autonomously adopt the concept of circular economy for reasons internal to the companies themselves or for the conviction of the managers. In fact, the four companies complain about the absence of more favorable legislation and stimuli, particularly in terms of tax incentives, while employees do not necessarily share the managers' point of view.

- ② **Development from below** The circular economy develops mostly in a bottom-up manner through companies, but institutions and networks play an important role for the circulation of information.

This does not mean that the role of other actors and particularly of local authorities, national entities, European structures, as well as of associations and research bodies, are irrelevant. On the contrary, they play an important role in spreading the concept of circular economy (Finnemore & Sikkink, 1998), encouraging companies to participate in its development.

- ③ **Minimum cooperation, partnerships** Cooperation among companies is minimal while partnerships are established among companies, research institutions and administrations.

In terms of collective action, the target companies have shown a propensity for internalizing production, which can limit the development of recycling and re-use value chains with the participation of other companies. At the same time, we observe the search for partnerships especially in the domain of research and administrations to assist companies in finding technical solutions and to support the development of the regulatory framework and obtain incentives.

- ④ **European targets, piloting** European targets and national legislation are important for managers but company initiatives fall within the scope of pilot actions.

With regards to policies and implementation tools, the European targets for waste reduction by 2025 have emerged as a common concern in all case studies. The national legislation was more present in the construction sector than in the food sector. In any case, the development of the circular economy in the companies studied is more linked to pilot actions conducted directly by the companies, regardless of the policies in place.

- ⑤ **Internal improvement, research** Controls vary according to the sector but are rare, while it is the internal improvement of companies that supports the development of the circular economy, together with research.

The verification of the implementation of policies related to the circular economy varies according to the sector. Certification bodies play an important role in the construction sector. Above all, it is the internal improvement of companies that supports the development of the circular economy.

The research and development processes, also in collaboration with research institutions such as universities and foundations, therefore, play a fundamental role.

- ⑥ **Multilevel phenomenon** The governance of the circular economy is multilevel but varies according to the sector.

If the company level is predominant in this analysis, various levels of action appear clearly, from the most macro (global market, European Union, national government) to the most micro (municipalities, companies, individuals). The gradient tends to be more macro in the building sector with value chains that can be global and more micro in the food sector, with a “zero kilometer” trend.

- ⑦ **Multisectoral phenomenon** Although the case studies refer to specific sectors, the governance of the circular economy also involves other sectors, in particular the environment, health, the social sector, as well as the economy.

The main sectors of reference of the individual companies are obviously the most involved. However, the development of the circular economy requires the involvement of other sectors, particularly the environmental and health sectors for waste management, including pollution, and for limiting health and hygiene risks. The circular economy then intersects with the social economy especially in the food and textile sectors with important social implications. The financial aspects are never to be ignored because of the huge investments sometimes necessary for the development of the circular economy. If in some cases companies manage to finance these investments with their own resources or with the support of banks and investment funds, in other cases they depend on public funding, especially for interventions with a long return on investment.

Bringing waste to the foreground of cities. Towards sustainable transition management in the urban region of Naples (Italy)*

Gilda Berruti¹, Maria Federica Palestino²

¹ *Federico II University of Naples, Department of Architecture, gberruti@unina.it*

² *Federico II University of Naples, Department of Architecture, palestino@unina.it*

Abstract: Circular economy suggests new visions of how the urban space should be lived and managed. These visions depend on metaphors such as urban metabolism, that implies a completely rethinking of the governance model. Achieving such a transition will demand deep changes in dominant practices and ways of thinking, which will in turn call for new knowledge on the part of ordinary people and different responsibilities on the part of institutions. In this perspective, while the production of waste is being reduced through innovative practices, former industrial, rural or infrastructural areas are more difficult to include in a closed loop production cycle. Such wastelands, often merging into wastescapes, need to be completely re-imaged as a precondition for their sustainable transition. Assuming the metaphor of urban metabolism as a device to address the transition, turning the definition of “neglected area” into “wasteland” becomes a tactic for generating alternative policies and practices in urban regions. In exploring how the transition is affecting social actors, decision models, formal and informal practices in the urban region of Naples, the paper focuses on how turning wastelands into resources has the double potential of rehabilitating urban spaces and challenging the governance model in use.

Keywords: wastescape regeneration, multilevel governance, waste circularity, transition management

1. Introduction

Circular economy, one of the pillars of sustainable transitions promoted by the EU, suggests new visions of how the urban space should be lived and, as a consequence, managed. The roots of such rather conceptual visions are strongly dependent on the successful working of the powerful metaphor of urban metabolism. The latter helps not only imaging and organizing strategies for the transition process, but also situating them and completely rethinking the governance model consistent with the urban metabolism itself. Metabolizing such transitions demands deep changes in dominant practices, policies and ways of thinking, which will in turn call for new knowledge on the

part of ordinary people and different research frameworks and responsibilities on the part of scholars and institutions respectively.

The Horizon 2020 research REPAiR, “Resource Management in Peri-urban Areas: Going Beyond Urban Metabolism” promotes the reuse of waste as a resource. In this framework peri-urban areas have to be reinterpreted as those “transition spaces with some degree of intermingling of urban and rural uses” which characterize urban regions of European cities (Wandl and Magoni, 2017, 1).

As for the methodology, the transition management has been adopted in order to experiment how to reduce waste flows in peri-urban areas, beginning from the pilot cases of Naples and Amsterdam¹.

According to the metaphor of urban metabolism, considered as a device to address the transition, urban regions have been interpreted as complex ecosystems. Consistent with this conceptual framework, one of the first steps of the REPAiR strategy consisted of deliberately turning a definition like “neglected area” into “wasteland”, in order to emphasize the shift from the socio-technical regime of the linear economy, where the adjective “neglected” refers to the end of the Fordist domain, to the socio-technical regime of the circular economy, where how regulating the metabolism of waste is crucial. Since this shift has been generating alternative narratives and different public discourses and images, REPAiR researchers have been exploring policy instruments and practices that fit the new vision.

According to the new narrative, waste flows in peri-urban areas have to be tightly related to the entanglement between solid waste and wastelands. The latter to be considered as ruins germinated from the shrinkage or even death of past land uses such as industrial, rural, infrastructural and so on, with the consequent degradation into wasteland.

In the urban region of Naples, Caserta and Salerno waste has often been stock-piled or even concealed in peri-urban areas with the effect of transforming abandoned or soon to be abandoned open spaces and land into wasteland. A few years ago, following the socio-ecological disaster nicknamed as “the Land of Fires”, the plan of the Province of Caserta defined this phenomenon as “negated land”, referring to an amount of about 5000 ha of critical areas, a part of which had informal and managed accumulations of waste (Provincia di Caserta, 2012).

In the same region, due to a previous long lasting, unresolved regional waste emergency, different patterns of wastelands still exist, and in addition there are spaces and surfaces where toxic waste, pollutants, and other dangerous materials are illegally stored and hidden, temporarily or persistently. These wastelands include: stretches of agricultural land housing unauthorized buildings; portions of abandoned historical heritage; polluted sites under designated state tutorship; housing or productive facilities confiscated by the state from the criminal organizations and so on (Berruti and Palestino, 2018).

¹ The academic partners of REPAiR (Grant Agreement n. 688920), together with the *Joint Research Center* by EU, and several public institutions and public/private companies in the field of waste management, are universities and research institutes from Delft (the Netherlands), Naples (Italy), Hamburg (Germany), Lodz (Poland), Pécs (Hungary), Ghent (Belgium). The Naples REPAiR team is composed by researchers from the Department of Architecture of the Federico II University and officials from the Campania Regional Authority, while the mayor of Naples is in the user board. See <http://h2020repair.eu/>.

As a consequence, the quality of life is very low and inhabitants do not trust institutions and even struggle against them in order to defend their rights to urban environments (Berruti and Palestino, 2019).

Moreover, what happens when many wastelands compound the effect of bringing waste to the foreground of cities is the proliferation of wastescapes (REPAiR 2017, Amenta and Van Tjimmeren 2018). Such wastescapes even overspill the administrative borders of each municipality, thus involving different communities and institutions and requiring complex multilevel governance. They need, therefore, to be completely re-imaged, re-framed and re-organized as a precondition for their sustainable transition.

This is why, one of the most important challenges for REPAiR-Naples is the promotion of shared understanding of how to include not only waste and waste flows, but also wastelands, in a closed loop production cycle.

Exploring how the transition toward sustainability is affecting social actors, decision models, formal and informal practices in the urban region of Naples, the paper focuses on how turning wastelands into resources has the double potential of rehabilitating urban spaces and challenging the governance model in use. In so doing the framework of transition management offers an inspiring methodology to collaboratively plan how to reduce, recycle and regenerate waste and wastelands in peri-urban Naples.

2. The theory of transition management at work

The framing of environmental problems triggers complex societal challenges that require socio-technical transitions and modify the working of territorial systems. Contemporary transitions towards sustainability can be considered as those specific processes of long-term, multilevel and multiphase change that happen in complex and adaptive systems such as cities and urban regions. As a consequence, sustainable transitions work as multi-actor processes involving firms, industries, policy makers and politicians, but also consumers, civil society and researchers. It is important to underline that, being focused on the environment, transitions towards sustainability are closely related to collective goods (Geels, 2011).

Being an open-ended process aimed at reframing problems through social learning and experimenting, the transition management approach can be successfully adapted both for supporting policies, and engaging actors, in order to find innovative solutions. As a matter of fact, its recent “urban turn” (Wittmayer and Loorbach, 2016) has provided site-specific applications in domains such as energy, water, mobility or climate change, since the challenges to applying circular economy are frequently localized in cities, towns and neighbourhoods. Furthermore, these applications of transition management describe governance processes where frontrunners from policy, science, business and society are asked to share their understanding of complex challenges. In doing so, they help researchers to deeply analyse urban sustainability, supporting shared visions and strategies and experimenting social innovations (Loorbach, 2010, Wittmayer and Loorbach, 2016).

It is important to add that the transition management is conceived as a kind of selective participative setting that works as an iterative cycle of mutual learning. Thanks to *ad hoc* networks of pivot stakeholders coming from different backgrounds, it develops a plural discourse which is aimed at guiding sustainable transitions. Given the cyclical nature of the transition management framework, strategic level activities are followed by tactical and operational phases, while the cycle itself is closed by means of the resulting appropriate reflexive measures.

The aim of the strategic activities is “orienting” the public discourse and the related narrative through long-term visions. An arena of frontrunners with different backgrounds has to be formed during this stage in order to imagine a future perspective, together with transition pathways.

The tactical activities have to be built in the mid and the long term, dividing the public discourse into steps, preparing the transition agenda and analysing gaps between different scenarios. Consistent with this “agenda

setting” stage, tactics to explore and specific pathways can be further developed by means of negotiation and collaboration among actors.

The operational activities, working in the short term, are oriented towards sharing those specific needs coming from practice, projects and experiments. This stage is based on “activating” communities and anchoring ideas from below.

The reflexive activities offer the basis for monitoring the previous three levels, where the focus is on how to support and enable societal learning processes.

When all four levels are embedded in urban contexts, the related actions are carried out through experimentation at the so-called Urban Transition Labs which are inspired by the Living Labs approach. Living Labs are defined as “user-centered, open innovation ecosystems based on a systematic user co-creation approach in public-private-people partnership, integrating research and innovation processes in real life communities and settings” (ENoLL 2013; Concilio, 2016). With the aim of accelerating the transition, enough time is provided to produce mutual learning and develop solutions far beyond the existing regime contexts.

3. Promoting the waste circularity in peri-urban Naples

As seen in Figure 1, the focus area of REPAiR Naples includes eleven municipalities, going from the eastern city to the town of Acerra, making up a peri-urban area of 519.425 inhabitants and 164,6 square kilometers where different wastelands and waste flows intersect. This vast area, and a smaller sample area were selected, mainly due to the following reasons: its being an area strongly affected by the fifteen-year-old regional waste emergency and socio-ecological disaster known as the Land of Fires (Armiero, 2014; Palestino, 2015), the high percentage and variety of wastelands, and its location within the administrative boundaries of the regional waste management system.

Figure 1 Naples' Focus and sample area in the REPAiR Project

In line with the transition management model, the research was organized by means of an “orienting phase” where the strategy of looking at waste as a resource was defined. In this perspective, redefining the abandonment of places provided the agenda for regenerating them with a new perspective, and using the provided funding. Thus, focusing on wastescapes has supported a vision strong enough to allow putting into practice circular economy principles both through designing new measures and policies, and involving distrustful citizens in taking care of peri-urban spaces. At the beginning, the arena of frontrunners was composed by the research team from the Department of Architecture of Federico II University of Naples, several officials of the Campania Region belonging to the Departments of Environment, Planning and Agriculture and selected user-board members from the City of Naples. Citizens as representatives of local associations and movements were added later.

The “agenda setting” was supported by interviews with politicians and officials aimed at analyzing the governance of waste in the focus area and by institutional meetings where shared knowledge on the working of

the waste management system and the related challenges was collected. Representatives of regional, metropolitan and municipal governments and policy makers, waste management administrators, local company representatives all joined these meetings. In directing them, the research team worked hard to set the agenda, starting from the outcomes of this stage. Later on, with the organization of peri-urban living labs (PULLs) the “*activating stage*” started. Besides institutional actors and companies, social organizations and active citizens were also involved in the experiments of innovation.

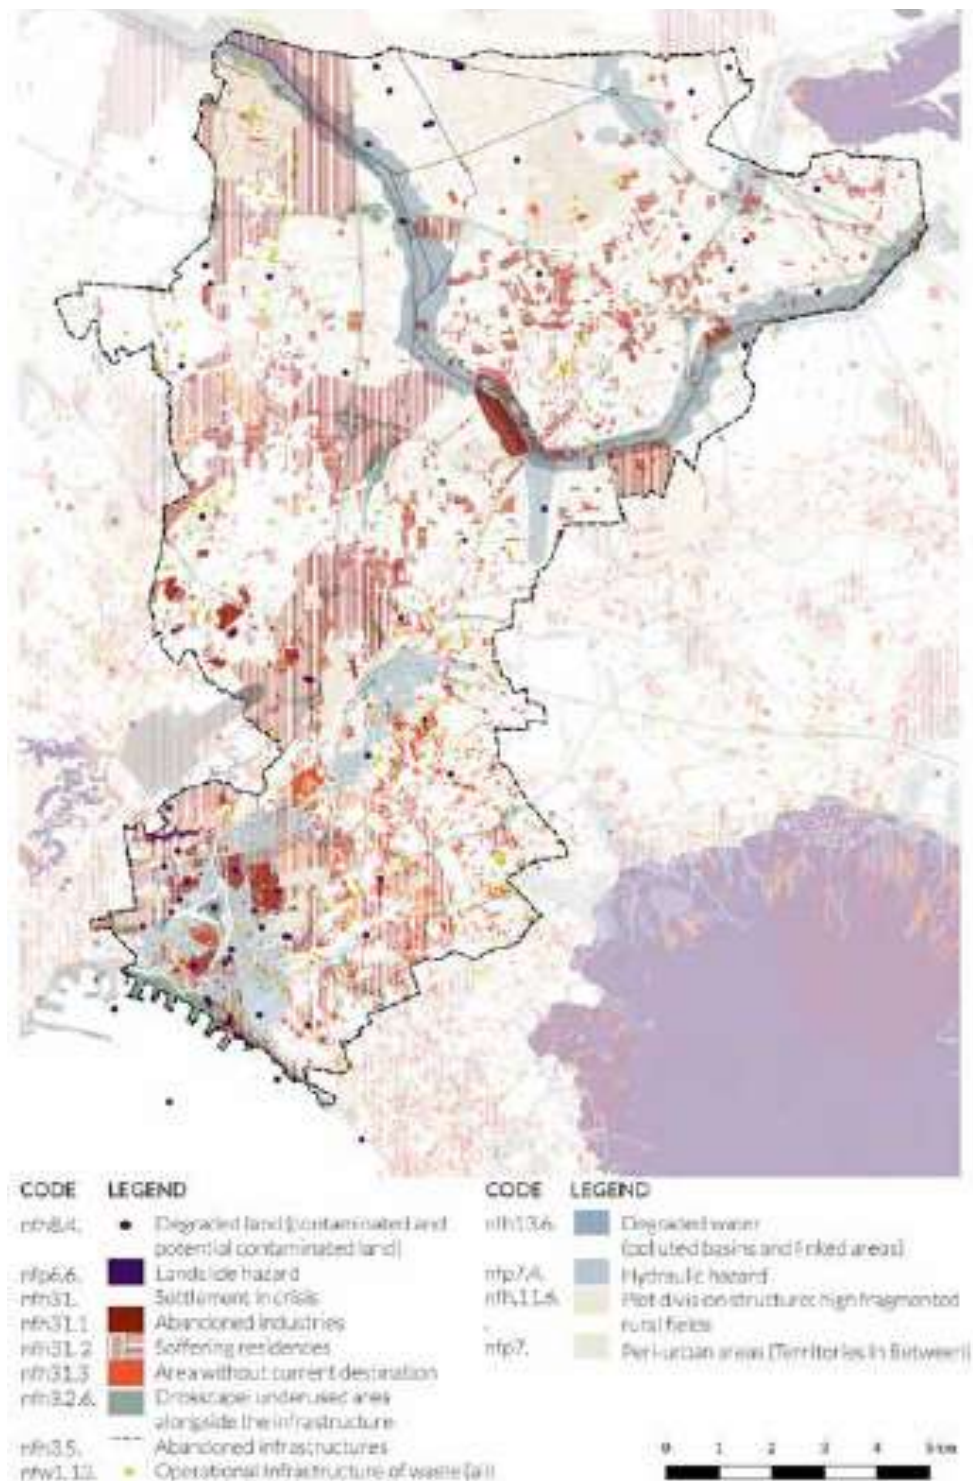

Figure 2 Wastescapes in the focus area: analytical description (Source: REPAiR 2018)

PULLs have mainly focused on wastescapes and eco-innovative solutions. First, participants identified critical wastescapes in the focus area, located them on the map and collectively updated the map and its legend (see Figure 2). Then, they framed solutions for wastescapes. Participants were organized into three worktables, each one focused on a territorial project to carry out together, with the aim of discovering the proper eco-innovative solutions to the investigated wastescapes. Later, proposals coming from previous workshops were analyzed and each territorial project was transformed into action. The current possibility of funding the proposed actions has been explored, as well as actors' commitment to support them.

The “operational activities” included the co-design of actions aimed at solving problems of abandonment related to wastescapes and the attribution of specific responsibilities to the actors involved in Living Labs. At this stage, some negotiations between public administrators and inhabitants were carried out by the REPAiR team in order to reveal previous conflicts or solve those produced during interactions.

Actions proposed during living labs provided the base for drawing eco-innovative solutions, also by means of improvements made by the research team, through the involvement of public sector officials and companies, carrying out part of the reflexive activities. This step aimed mainly at transforming them from site-specific to generally transferable and pointing on aspects of innovation.

The activating phase has been planned as the result of a further learning process in which collaborative decisions shall be taken by means of a geo-design planning support system that is currently under investigation by the research team.

4. Discussion

As shown by the transition management process applied to the metabolism of waste in Naples, the first important step towards transition consists of overcoming the current provisional nature of the waste management system, due to partial enforcement of the regional law on waste management (R.L. n. 14/2016).

On the one hand, though the Campania Region makes circular economy a leading principle in the regional law on the waste management, it seems to be neglected in calibrating laws and plans to local contexts; on the other hand, municipalities are interested in maintaining the benefits coming from the previous waste system, often accruing to companies selected through political nepotism. In so doing, some decision-makers appear to share the same interests as organized crime in maintaining the waste management status quo ante developed during the two previous environmental emergencies affecting the Campania Region. Moreover, the Metropolitan City of Naples which might exert a connective role in the transition stage, has been erroneously excluded from the waste management.

Intra-institutional difficulties in overcoming sectorial policies, together with the lack of shared knowledge about waste management among institutions and for citizens also contribute to hindering the application of circular economy principles. In addition, social attitudes also play their role, through suspicion of the waste quality, and the consequent stigmatization and distrust that prevent the innovation of policies and the development of new economies. For instance, companies managing composting plants do not use organic waste coming from Campania because of its supposed (and often real) bad quality; local communities fight against any proposal

concerning waste coming from above, even if concerned with the location of a new composting plant, that could be effective in resolving the organic waste management system at a local scale².

As for wastescapes, there are some interesting experiences of recovery and re-appropriation in the metropolitan area of Naples that require but do not get the appropriate support from institutions. In addition to governance aspects, the capability of including wastescapes regeneration in an overall vision covering peri-urban areas and defining their potentialities has to be enhanced.

5. Conclusions

In short, the conclusion we can draw from applying the transition management approach to the metropolitan area of Naples, is that circular economy currently works mainly as a rhetorical argument that is still hard to apply through policies, mainly due to ineffective sectorial planning and to difficulties in making urban metabolism work. Therefore, clear suggestions appear for how to enhance circular policies and regenerate circular landscapes.

First, PULLs function as useful environments for driving all the actors involved in the process to co-design site specific policies, while unravelling conflicts and issues coming from the past. Second, people and companies are a reliable source of creative actions and entrepreneurial initiatives on wastelands and waste flows. Third, public officials have to overcome sectorial and departmental barriers within the bureaucratic apparatus in order to apply their theoretical arguments on circular economy to real and effective policies, while at the same time catching the innovations coming from local contexts. As a consequence, we suggest the adoption of a multilevel and cross-sectorial governance as the right way for designing and implementing circular policies.

As for wastelands, the transition management approach revealed itself useful for designing eco-innovative strategies and solutions and for rethinking new uses and practices for their regeneration. Such regeneration implies, on the one hand, that wastelands have to be treated as complex groupings of people and places, and on the other hand that, since landscapes do not follow administrative borders, a synergy between institutions is needed able to create bridges between different actors and centers of responsibility. Innovations always require the courage to change, in multiple sectors (legal, political, economic, social, environmental, technological) and overcoming barriers. Among these innovations we would stress the need for governance of wastescapes regeneration, that has to be designed and implemented in order to effectively re-introduce wastescapes into urban metabolism.

Abstract: The investment landscape for the data center (DC) industry in Europe is currently under transformation, as more DC companies are getting established in the Scandinavian countries; but still the DC surface and power capacity (m² and MW) in these regions has not yet capitalized in the same way as DC traditional locations in central Europe. Nevertheless, the renewable energy as hydropower and a favorable climate for free air cooling that are provided in the North, particularly northern Sweden, among other reasons, are increasingly attracting DC companies seeking to meet their environmental goals at the lowest cost. However, this raises questions on how the land (m²) and energy (MW) demand for new DCs can be met with equity in the local context. While some governments facilitate land management procedures to build new DC facilities and lower the energy tax in order to attract more investors, there has been little attention on how these strategies could support or hinder potential energy synergies with potential social value within the local community (e.g. reuse of DC waste-heat for urban farming). The potential transition that Sweden is facing, due to the DC-phenomenon, becomes a relevant context to investigate alternatives of how to improve urban metabolism's efficiency, in relation with an emerging energy intensive industry; The Data Center industry. The purpose of this research is to investigate how urban planning theory can assist the DC-phenomenon in transitioning towards a circular approach.

Keywords: Circular cities; Multifunctional data center district; Sustainable urban metabolism; Urban planning strategies.

Introduction

Since the establishment of Facebook in Luleå in the north of Sweden, back in 2011, the region's focus in developing strategies to attract Data center companies has increased. These strategies are among others: reduced energy tax, accessibility of cheap land, low time-to-market (Christensen *et al.*, 2018). Some reports state that Facebook has been perceived as a trigger for structural change and economic growth in these northern regions, having had positive effects as: e.g. regional co-location benefits, shared quality workforce, job creation etc. (Ylinenpää, 2014).

However, Sweden and particularly its northern regions are not a traditional location for the data center industry in comparison with the FLAP-D regions in central Europe (Frankfurt, London, Amsterdam, Paris and Dublin). These northern regions have had another industrial tradition based on mainly mining, metallurgy, and forestry (pulp and paper) activities. Despite this tradition, the Nordics and particularly Northern Sweden is facing an industrial transition from a dominant resource extractive strategy to a diversified resource investment strategy (Reffell, 2018). This is partly due to the emerging industry of data centers in the last decade, which has been attracted by tailored economic incentives and environmental assets; in order to balance their high-energy demand with high efficiency standards and greener footprint at the lowest cost (Kontzer T., 2013). However, the Data center industry remains inefficient, as only a small part of the energy is used to store and process data, and the rest of the energy becomes waste-heat. Consequently, there is a recognized need to make data centers more energy-efficient (Summers, 2018).

The described transitional phase that the Swedish industrial system is facing, can be suitable to introduce new paradigms as; *Circular cities*. Introducing possible synergies through a circular approach in the

current industrial linear system can contribute to the DC's need and responsibility to be highly efficient; not only by designing efficient DC facilities but also by defining strategies to locate the DC close to users interested in reusing the high amount of waste-heat they produce. This, since the waste-heat is low grade and airborne and therefore inefficient to transport (Sandberg *et al.*, 2017).

The “city” can be defined as a “platform” enabling material and energy exchange between industries (Rosales Carreón and Worrell, 2018). Urban metabolism theory (Ferrão and Fernandez, 2013) describes how materials and energy flow in a city. The DC sector gives high attention to the energy flows, as energy efficiency is one of their main concerns when establishing a new DC. To achieve maximum efficiency it is essential to measure the amount of energy flowing through the system and the quality of these energy flows (Rosales Carreón and Worrell, 2018). In fact, higher efficiency can be achieved not only with the “right” design of the DC building, but also by choosing the “right” location.

Problem framing

Sweden has had several turning points that led the country into industrial transition periods, as for example the one in the beginning of the twentieth century with the invention of the electricity networks by Edison in 1879 and three-phase technology by Jonas Wenström in 1890; solving the distribution of electricity in long distances (Vattenfall, 2019). This enabled industries, which initially were powered by waterwheels and local small hydropower stations to settle closer to cities, far from the energy source (watercourse), where users and other services were located. Nowadays, Sweden would face a similar challenge within the context of the emerging DC industry transitioning towards a circular approach, where the DC's are energy (waste-heat) producers and have issues to transport the energy (heat) over long distances efficiently to be used by other sectors/ industries. The current situation of inefficient energy use in the DC sector leads to reconsider, from the sustainable urban metabolism perspective, the location of local industries/activities closer to the heat producer (DC), and vice versa, in order to be able to use the energy (electricity) in a more efficient way minimizing waste (waste-heat).

The DC sector need to consider a more efficient energy management (e.g. minimizing waste-heat), in order to tackle efficiency with a more holistic perspective (including social, environmental and economic factors). This would mean changing the perception of DCs from only energy consumers to partly energy producers of waste-heat (prosumers). There are several examples of waste-heat reuse from DC for other activities integrated in the DC building as: swimming pool (Brodkin, 2008), greenhouse (Miller, 2008), housing and non-housing buildings (Miller, 2009), desalination plant (Sverdlik, 2014) and fish farm (Verge, 2015). Nevertheless, these are exceptional cases, which are not the rule; still the concept of “waste-heat reuse” has not yet been introduced as a routine when establishing new DCs. This paper does not focus on analyzing the technological development of this possible integration between the DC and other activities, but does focus on describing and analyzing the events and factors that are currently enabling or disabling, this integration, taking as a case study northern Sweden (the counties of Norrbotten and Västerbotten).

Research approach

Case study methodology was the one chosen for this study as it allows highlighting the details on the DC phenomenon, from the stakeholder's perspective, by using multiple sources of data as evidence (Tellis, 1997). A major strength of having chosen case study's data collection methods is the opportunity to use different sources of evidence, allowing addressing a range of historical, attitudinal and behavioral issues. Most importantly, it allowed the development of a converging line of investigation, “any finding is likely to be more accurate and convincing if based on several sources of information”, (Yin, 2013). Two data collection methods were chosen in this qualitative research approach: unstructured/open-ended interviews and literature review. Unstructured interviews, as an inductive method of data gathering, enabled to discover experiences and knowledge from the interviewees, which had not been taken in consideration before; “When researchers are more interested in knowing greater details about a phenomenon, unstructured questions may aptly accomplish those aims”, (Firmin, 2012). These interviews followed the two simultaneous levels of operation required: the need to follow the line of investigation while at the same time asking questions as open as possible, in a friendly and non-threatening manner (Yin, 2013).

The research was approached: firstly, as an *Exploratory framework*; finding which stakeholders are involved in the DC phenomenon events (who) and in what part of the process (Yin, 2013). Secondly, as an *Explanatory case study*; focusing on the why and how these stakeholders were involved in each event (Yin, 2013) (e.g. tailored strategies, site-selection criteria, establishment process, research and development...etc.), in the context of northern Sweden.

The interviewees are national, regional and municipal key actors involved directly or indirectly in the DC-industry development (Table 1). Interviewees were selected after doing a literature review and identifying key actors inside private/public bodies involved in DC-establishment in the region. Some of the conducted interviews led to the contact of other key actors for following interviews (e.g. interview with stakeholder A, led to interview with stakeholder C). All the interviews were done face to face in arranged meetings.

*	Interviewee	date	stakeholder type	interview type
	stakeholder A	18/03/2019	Regional actor	unstructured/ open-ended
	stakeholder B	26/03/2019	Data Center company	unstructured/ open-ended
	stakeholder C	05/04/2019	Regional actor	unstructured/ open-ended
	stakeholder D	24/04/2019	National actor	unstructured/ open-ended
	stakeholder E	29/04/2019	Data center company	unstructured/ open-ended

	stakeholder G	29/05/2019	Regional actor	unstructured/ open-ended

Table 1: Table of interviews conducted in the case study

Literature review is used as a qualitative research method in this study; as it serves as a tool for data collection and data analysis (Onwuegbuzie and Frels, 2017). As the purpose of this research was to see how urban planning theory can assist the DC-phenomenon in transitioning towards a circular approach, the two main topics selected to search upon were “Urban planning” and “Data center”; identifying subcategories that support the circular approach, as an inclusion criteria. These subcategories were used as key words in the retrieval process of the documents analyzed.

Table 2 shows the main topics relevant for the research divided up in three groups, with subcategories: Urban planning (Circular cities, Urban metabolism system, Urban sustainability); Data center (DC Waste-heat reuse, DC Business trend, DC Energy, DC Sustainability) and a third group where Data center and Urban planning topics are related.

Results

As a consequence of the interviews and literature review methods, a timeline (Figure 1) was created with the aim to understand historical (national/ regional/ municipal) chain of events that contributed to the DC establishment in Swedish northern regions and find traces of strategies, initiatives or attempts that impacted DC synergies within the local context. The timeline shown in Figure 1 was drawn by information retrieved mainly from literature review and the conducted interviews.

The result is a composition of relevant highlights in the DC-phenomenon's history, that enables a longitudinal analysis between different events along a timeline. (e.g. energy tax reduction, successful and unsuccessful synergy attempts, national renewable energy history, business trends, industrial transition...)

The timeline structure was built through Lefebvre's lens, describing a phenomenon divided up in three different periods; construction period, consolidation period and decline period (Lefebvre, 1975). The scope of the study focuses in the description and analysis of the construction and consolidation period of the DC-phenomenon as the decline period has not occurred in northern Sweden context at the time.

Discussion of the results

The DC sector has an interest in establishing in the North, as strategies are tailored to fit their needs in relation to their economic and environmental challenges. As shown in Figure 1 in 2017 there was an unsuccessful attempt in doing synergies; a data center company and a greenhouse vegetable producer built a consortium to reuse the DC waste-heat, but the plan was not realized, as the lack of available electrical power in the location chosen would increase the time-to-market, carrying an investment risk. “Most European data center owners/managers don’t want to commit capital funds to an energy-reduction tactic if the full return on investment isn’t realized in less than two year”, (Garris, 2018). This initiative could have had the potential of being successful if other priorities than economic factors would have been taken into account, by analyzing the value of waste-heat through different cost-opportunity scenario giving special attention to some social and environmental questions: How many jobs would this create? Would this improve the DC company’s Corporate Social Responsibility? How would this contribute to the development of other vulnerable sectors in these regions (e.g. horticulture)?

Regional development strategies should be designed with a more holistic perspective, including not only how the DC sector could contribute economically to the regions development but how could it contribute socially as well. DC-phenomenon is a global economic activity gathering in regional clusters (Sassen, 2002) as in the case of the traditional DC clusters in central Europe and as well as in the case of the emerging DC cluster in the Nordics, where the government has a high risk in losing the holistic perspective when creating new policies (e.g. energy tax reduction) pressured by the urge to become competitive in the global DC market. The county council (e.g. Region Norrbotten) in collaboration with the county administration could be given a higher responsibility in serving the local community by enhancing measures that contribute to both social and economic development. Hence, research on how the DC-sector can be better integrated through synergic models inside the national and regional economic system is of high interest for the national and regional governments. There is a need to do more investigations on the possible different synergic scenarios and display the cost-opportunity in relation with the three sustainability aspects; economic, environmental and especially social.

Nowadays, the majority of DCs in the north do not gain any benefit with the waste-heat, therefore it is valuable to consider the opportunities to gain economic benefit while at the same time fulfilling their responsibility of giving back the benefit to the local community (e.g. food self-sufficiency), as this is not done through the energy tax currently. Since 2017, the state subsidized the DC sector with a tax reduction of 97% (Henriksson *et al.*, 2017), playing an important role in the DC-phenomenon attracting DC not just by the renewable and reliable power supply but by the low energy cost. However, this strategy can make the DC investment vulnerable in the long run, for example, future droughts in these regions due to climate change can question the legitimacy of these incentives in the case of future energy shortage. This arises questions as; Is it legitimate to give subsidies to a highly inefficient DC-industry, as more than half of the energy consumed is converted in waste-heat? Should the state give subsidies instead to DC that want to make use of the waste-heat? How can urban planning strategies support then the national/regional strategies in this endeavor?

Meanwhile, some initiatives of DC waste-heat reuse have been successfully implemented, among other countries (US, Canada, Finland), in Sweden, specifically in the South in the city of Stockholm, by planning Data Parks inside the city where the waste-heat is collected, directed inside a PowerStation and plugged into the district heating network, however, this model is not infinitely scalable (Biba, 2017). In fact, there could be challenges to implement this model in Northern Sweden nowadays, as there is already energy surplus due to the waste-heat from the traditional energy intensive industry (metallurgy, pulp and paper) which the district heating network would not need to absorb. Therefore, there is a need to investigate how these “Data Parks” can be not just a cluster of DCs but instead DC integrated with other local sectors/activities in need of the DC waste-heat. Creating multifunctional-DC districts that can reuse the waste-heat directly in a more efficient way could be an alternative, instead of plugging it into the district heating network, which is a process that is currently inefficient, as it requires additional energy to do it (Biba, 2017).

Despite, the effort of some municipalities in Sweden to reuse the DC waste-heat there is a mismatch with some strategies taken in some institutions working at the national level. A “green” label was created in 2019, as shown in Figure 1, in order to encourage the DC companies to have environmental friendly and energy efficient facilities.

This label measures efficiency through the Power Usage Effectiveness (PUE) metrics, which considers the efficient design of the DC building but does not include the Energy Reuse Effectiveness factor (ERE metrics), which measures the amount of waste heat reuse. Another example of mismatch is the development in 2018 of, potentially, the most efficient DC-prototype in the world, located in northern Sweden, Boden, which did not include reuse of waste heat. Even, the development process of the most efficient datacenter in the world could be improved by not only focusing in just PUE metrics, but as well considering ERE metrics (energy reuse metrics) in order to give a more complete view of DC-efficiency and utilizing its full potential. Hence, there is a need to synchronize the top-bottom national strategies with the bottom-up initiatives from municipalities, as in the case of Stockholm being a reference of good practice, in order to encourage municipalities to integrate the DCs in a more efficient and sustainable way inside the city.

Conclusions

Many other countries in the world, like Sweden, are facing changes in its urban metabolism as a consequence of the emerging data center industry. There is a competition for resource investment within each country, among the emerging DC-industry and the already existing industries/sectors. Tailored initiatives as energy tax reduction for the DC industry should be reconsidered, as future scenarios of energy shortage (NordBER, 2015) could question the legitimacy of these economic incentives. The DC industry still has technical challenges on how to reuse the waste-heat since the waste-heat, which is low grade, airborne and therefore hard to transport (Sandberg et al., 2017). There is a need to improve the way efficiency is tackled inside the urban metabolism energy system in regards to the DC sector. These improvements could be done at two levels: first, at a technical level; by considering ERE metrics (Energy Reuse metrics) instead of solely PUE metrics when creating “green labels” as a national strategy to attract DC investors in Sweden as this circular approach contributes to having a complete view of efficiency. This way DC companies have the possibility to design efficient buildings but as well elect a better location in order to minimize energy waste. And secondly, at a policy level: in the case of northern Sweden, the emerging energy intensive sector as DC could support vulnerable sectors, as for example horticulture, in need of heat for greenhouse vegetable production, in order to cope with the cold climate. It is worth considering local community benefits rather than just the national weight gain on global market, by prioritizing synergies with local activities/ sectors that have the highest need in reusing the DC waste-heat. This can contribute to solve sustainable urban development issues (Barles, 2010), as for example, risk of food scarcity, especially in Northern regions where the subarctic climate makes agriculture become energy demanding (need of light and heat). Creating multifunctional-DC districts inside the city, where diverse activities in need of DC waste-heat can be integrated together with the DC building, in order to re-use the waste-heat directly, could be an alternative to current inefficient strategies.

Abstract: Restoring the nutrient cycles, and assuming their centrality for sustainable management of agro-environmental resources at local level, are key aspects for amending the metabolic rift that has been historically triggered by the emergence of capitalistic socio-spatial organization, and that is currently reproduced and further deepened under neoliberal urbanization processes. This paper aims to explore how organic waste streams can be reorganized and reconnected with urban and periurban agriculture, enabling the proactive role of farmers and food growers in soil nutrient cycling, and reshaping urban metabolism towards more regenerative and resourceful models. In particular, we look at composting practices as meaningful entry points for inquiring the relations between urban metabolism and agroecological practices. The paper builds on some initial insights offered by the case studies of London and Venice, bringing to light which kind of soil nutrition and land management practices are currently prevailing among food growers in these contexts, which connections are established between food production and food waste, to which extent compost from organic waste is valued (and eventually claimed) as an essential asset for nutrient cycling, how access and control on resources can be facilitated and empowered, and finally how the pattern of urban waste streams can be rethought for enabling place-based metabolic ecologies, considering environmental and social justice issues. Unpacking these aspects allows to understand better how metabolic processes are related to (and embedded into) specific practices of labor located in time and place, and to expand the urban metabolism analytical framework in order to move beyond the ‘black box’ effects from which suffer many quantitative approaches strictly focused on material flows.

Keywords: organic waste, nutrient cycling, resource management, urban metabolism, urban agroecology

Introduction

In this paper we look at ways in which organic waste management, soil keeping, and food production interplay in nutrient cycles, as an entry point to understand and rethink urban metabolism. The inherent unsustainability of the current resource-intensive, exploitative and disposable socio-economic model requires a structural transformation of the ways we provide our basic (and superfluous) needs. The most urgent imperatives we must face are 1) to disrupt the reliance on fossil fuels, and 2) to dismantle the dominant linear paradigm that has been shaping the economic and spatial organization production systems, together with the related urbanization models and the underpinning metabolic processes in the last two centuries, shifting towards circular and

regenerative models where i) resource depletion, pollution, waste and greenhouse gas emissions are minimized, and ii) more equitable access and control over resources are provided.

We assert that an emancipatory and progressive change, able to bring forward both environmental health and social justice, can only be achieved by coupling circular thinking with a wider agroecological and resourceful perspective. This means that it is necessary not only to seek for innovative organizational or technical solutions in order to create integrated circular economies, but also to problematize resource-management issues that are often depoliticized under the dominance of technical argumentations. We must recognize that ways in which (urban) metabolic processes are organized and reproduced, underpinning and shaping the functioning of the cities, are structured by the existing political ecologies of power (Swyngedouw, 2004). Thus, for understanding the very political nature of the metabolic models, we should reposition our analyses into a broader discourse on power relations, that use to play at two levels: the power of man over nature (which is turned into a deeply social process through its perpetual metabolic transformation), and the uneven power relationships within society (resources access and distribution, degree of democratic participation in decision-making processes).

In this paper we try to address the burning necessity of redesigning the linear metabolic structure ruling the agri-food system: conventionally, foodstuffs and nutrients extracted from the rural and periurban environments flow unidirectionally into the urban areas, with a continuous loss of nutrients that are never returned back to the land, but rather end up in solid waste and sewage that tend to be disposed, instead of recycled. In this scheme, urban waste and sewage unceasing accumulation constitutes a problem to be solved, that generates high economic and social costs (the need of organizing a municipal collecting and dumping service, of building infrastructures, of charging the related fees to citizens, and so on). At the same time, the constant nutrients removal is tackled by employing energy-intensive, industrially-produced synthetic fertilizers and other agro-chemicals, that from one side do not compensate the loss of organic matter, and from the other side are contribute to the soil degradation and erosion, as well as to polluting (directly and indirectly) other vital environmental matrixes, such as water and air. This vicious and wasteful pattern not only increases the dependency from fossil fuel-reliant external inputs, but also deepens the divide between agricultural and environmental processes, depriving the material conditions and the located knowledges for keeping the essential ecologies upon which even social reproduction relies. In this sense, the costs of the current metabolic system are broad, wide-ranged, and not only monetarily computable. Instead, we look at urban organic waste as a possible driver for building regenerative, closing-loops metabolic processes, by transforming it in compost (and/or anaerobic digestate) to be used as a soil conditioner or plant fertilizer, restoring the nutrients cycling, while reducing the use of destructive external inputs. Composting and reusing in agriculture the organic fraction of municipal waste is widely recognized as «a sustainable practice for FW recycling» which could be very beneficial for the soil (Cerdeira et al., 2017; Sax et al., 2017).

In our vision, organic waste should be seen not only as a valuable resource to be converted into a re-useful form, but also as a common resource to be mobilized upon the needs, visions and priorities of the local actors directly involved in managing the nutrient cycles. In other words, bringing forward resourcefulness (MacKinnon and Derickson, 2012). Therefore, the reorganization of urban organic waste streams should be consistent with the aspirations and the requirements of farmers and food growers, and should create the conditions for enabling their proactive role in implementing circular metabolism under sustainable and fair conditions. This perspective would also require to decolonize the sphere of urban waste management not only from neoliberal approaches, but also from strictly engineering and technocratic discourses.

Problems and limits in the current soil, nutrients and biowaste management system

There are a number of problematic issues linked to the current linear, industrialized and fossil fuel-dependent management of soil and nutrients: phosphorous peak, soil degradation and erosion, nitrous oxide released from fertilizers. High levels of energy consumption, due to the use of fuels (directly) for powering machineries in the

context of a highly industrialized farming, and (indirectly) for producing the artificially synthesized fertilizers and other agro-chemicals that are largely employed in replacement of agro-ecological internal inputs («industrialized farming consumes 50 times the energy input of traditional agriculture; [...] it has been estimated that 95% of all food products in European countries require the use of oil», Jones et al., 2012); as the crises of 2007-2008 bears witness, this reliance also exposes the whole food system to energy price volatility, further questioning food security. Besides, the massive consumption of energetic sources in agriculture entails a large amount of carbon emissions; the rise in carbon emissions is also connected to the decrease of carbon capture and storage (CCS) linked to the depletion of the organic matter into the soil. According to Montanarella (2002) «the welfare of a population can be linked to fertility and land productivity», and «these health indicators are directly related to the organic matter content of the soils». Not only nutrients, but also organic matter and living organisms are essential components of the soil, from which depends to its health and fertility. The increasing process of soil degradation that is occurring worldwide, and that has been identified as a serious problem to be tackled both at global and European level, depends *inter alia* from the loss of organic matter.

«In the linear food system, a very high proportion of food flows into cities where it is processed or consumed, creating organic waste in the form of discarded food, by-products or sewage. According to Ellen MacArthur Foundation (2019), globally, every year 2,9 billions of tonnes of food are destined for cities, that overall produce 2,8 billions of tonnes of organic waste; only less than 2% of «the valuable nutrients present in these organic resources gets looped back to productive use».

Large-scale, industrialized and centralised systems requires high investments in terms of space, infrastructures, costs of establishment, management and transport (plus associated social hidden costs in terms of environmental externalities). This create a certain rigidity of the system, and a path-dependency. Out-of-town: high waste miles. Besides, even when the recycling processes are highly efficient, they could still be disconnected from the local system, and from ecological processes. Thus, to enable the creation of truly regenerative, virtuous cycles that can maximise social and environmental benefits at local level, circular economy needs to be reframed into a deep metabolic perspective.

Re-cycling organic waste streams: an opportunity for amending the metabolic rift and shifting to regenerative metabolic models

The marginalization of agricultural spaces and practices by neo-liberal urban development (Tornaghi, 2017) is at the base of the reproduction of the metabolic rift occurred with the emergence of the capitalistic economic, social and spatial organization. The metabolic rift has been originally theorized to describe «a rupture in nutrient cycling between town and country», alongside «a rupture in the metabolic relation between humans and nature under capitalism» (Scheider and McMichael, 2012). While acknowledging the wide-ranging and multifaced nature of the ‘rifts’ (Schneider and McMichael, 2010), we believe that restoring the soil nutrient cycles (and recycles) is a crucial and necessary starting point to amend them, and to build new regenerative and resourceful metabolisms.

Considering barely the most common and used biowaste recycling methods, among the numerous existing (a systemic review is shown in LOUISE, 2016 and), composting is the only one that permits to mix and transform both the two main kinds of UBW streams (food and green waste), while vermicomposting and biomethanization

(or anaerobic digestion) fits only for food waste, and mulching¹. it is no more a significant Uonly composting fits for recycling jointly, in the same process, food and green waste; vermicomposting, dehydration. Mulching

The recycling methods that maximise environmental benefits are natural composting, vermicomposting, and mulching with chopped green waste (LOUISE, 2016). In terms of treating capacity and scale, natural composting allows to process up to 2.500 kg of bio-waste annually, while (electro-) mechanized composting techniques are more appropriate for more important amounts: from 10.000 to more than 100.000 kg/y.

Exploring the potential of closing the loops between food waste and food growing: initial insights from London, Brussels and Venice

In the city of London, the is very differentiated and fragmentated. Most of . Since the market of waste management is clearly liberalised, besides the municipal companies, there is a number of big, medium or small operators that work mainly with the commercial businesses, offering collection services that are wide-ranged in terms of sorting schemes, pricing systems (including ‘per bag’ option), provided bins sizes, collection frequency, contract flexibility.

London’s city farms seem to be self-sufficient, relying on their own organic resources without requiring external inputs. Both the farms we have visited and interviewed (Stepney and Spitalfields) consider compost as an essential asset for improving soil quality and supply use to compost important amounts of manure from the many animal they host, piled into a number of traditional aerated composting bays. In Stepney City Farm has also been installed a compost tumbler for food waste, which is

Discussion

The explored case studies shows that choice of the most appropriated method, scale, logistic and arrangements for developing alternative models of UBW recycling depend from the local specificities, varying on the base of the physical, technical, organizational, socio-economical, and cultural environments. Analysis and design should consider those aspects, and place the nutrient cycling within urban contexts, as well as into specific labour practices, situated in time and place.

bringing to light which kind of soil nutrition and land management practices are currently prevailing among food growers in these contexts, which connections are established between food production and food waste, to which extent compost from organic waste is valued (and eventually claimed) as an essential asset for nutrient cycling, how access and control on resources can be facilitated and empowered, and finally how the pattern of urban waste streams can be rethought for enabling place-based metabolic ecologies, considering environmental and social justice issues. Unpacking these aspects allows to understand better how metabolic processes are related to (and embedded into) specific practices of labor located in time and place, and to expand the urban metabolism analytical framework in order to move beyond the ‘black box’ effects from which suffer many quantitative approaches strictly focused on material flows

In the case of Brussels, the presence of bridging organizations who are playing a strong advocacy role, and are mutually engaged in a wide action-research process working on many levels (project experimenting, actor

¹ Here we don’t consider manure (a very rich organic resource, much valued in the past centuries), because it does not represent an available UBW stream nowadays, if not in very negligible part, after the building of the modern sanitary sewer system, from the one side, and the ouster of animals from the city, on the other side.

mobilising and policy lobbying), is proving to be essential not only for building alternative, more ecological and socially-driven ways of managing biowaste, but also for strategizing them. At the same time, they seem to meet an apparently open and fertile policy context, with a public administration that is interested in developing new approaches to waste management, also pushed by a changing external regulative framework (the European package for circular economy, and the limitation to landfill). This may suggest that the attitude and the capacity of acting for change locally are conditioned by the context-specific enabling or disabling conditions (spatial organisation, infrastructures, social capital, economic opportunities, etc.), but also by multilevel political, regulative and cultural settings.

The Italian case study reveals that the legislation, both nationally and locally, is more restrictive, and particularly disabling for alternative, decentralized, socially-innovative models of bio-waste management. Changes at normative level, with special regard to biowaste transportation rules, would simplify Moving food waste on long distances before processing it represents a waste of energy, considering that more than 70% of it is water, and that the solid matter gets considerably shrieked during recycling processes. In the case of Venice, it is particularly inconvenient, due to the logistical constrains and to the transportation costs (linked to the high price of the fuel used for ships): hence processing at least part of the UBW on site would be strategic. Besides, for a low-input, closed-loop agriculture.

In order to the amend the ‘knowledge rift’, recovering knowledges and skills is paramount. In this sense, community composting has a great relevance. In both the cases of London and Bruxelles emerged the role that a programme of ‘master composters’ can have in enhancing knowledges and skills.

Conclusion. Reframing organic waste streams management: from to *nutrient sovereignty*?

- taking care of soil health and productivity;
- contribute to food security;
- re-claiming control over nutrients.

In order to reshape infrastructural systems and social practices around urban waste and composting towards a regenerative, circular model enable metabolic agency, also the metanarratives should be renewed. Brenner and Schmid (2015) point out that contemporary debates on (urban sustainability) are dominated by a «city-centric techno-environmentalism», based on neo-naturalist and neo-positives approaches that advocates for engineering solutions, naturalising (and thus depoliticising) socio-spatial organizations and forms, normalizing also territorial control through «sound management» and «market-oriented governance» of urban life and functioning.

Housing policies beyond numbers: a comparative study in Portugal and Italy

Caterina Francesca Di Giovanni¹, Gonalo Antunes²,

² Centro Interdisciplinar de Ci4ncias Sociais (CICS.NOVA), Faculdade de Ci4ncias Sociais e Humanas (FCSH/NOVA), goncalo.antunes@fcsb.unl.pt

Abstract: The paper analyses how housing is structured in Portugal and Italy, focusing in particular on the recent housing policies. The objectives are: a) discuss the legislative solutions adopted in the last years to solve the housing needs; b) show the epistemological difference for the concept of social housing; c) compare the institutional variations, namely, the relevance of the local, regional and central levels. Despite Portugal and Italy having the same percentage of social housing and common characteristics of Southern Europe countries, we find differences comparing housing policies and how the countries deal with social housing. The methodology is organized into: i) bibliographic review; ii) analysis of the principal statistic data; iii) analysis of the legislation; iv) interviews with public decision-makers. Notwithstanding a wide literature about housing studies in Northern countries and comparing North and South housing policies approaches, few studies focus on the comparison between Southern European countries. For this reason, the research seeks to increase the knowledge about the singularities of the South and thus contributing to the construction of a theoretical approach South-inspired.

Keywords: housing policies, social housing, comparative housing studies, Southern Europe

1. Introduction

The literature about comparative housing studies highlights the existence of a clear difference among Northern and Southern countries in the way they cope with social housing, how is the model of tenure, the welfare regime, the rental system adopted and so on.

The comparison among Northern and Southern European countries is a well-known thread of housing studies, with the intention to display the positive aspects of the Northern model and identify the methodologies that South should follow in order to improve the housing situation in their countries.

Nevertheless, comparative housing studies among Southern European countries are less studied in depth, as seen as “*a semi-peripheral region and not at the fore-front of international interest and discussion*” (Bargelli and Heitkamp, 2017).

Hence the purpose of this research is to increase the scientific debate about Southern European countries and the comparison between them, considering the presence of some relevant examples about the correlation of the fascist-dictatorial regimes with the current neoliberal housing policies (Di Felicianantonio and Aalbers, 2017).

Starting from these reflections, the paper wants to present a study that follows an innovative method to study Southern European countries and which can be resumed in three points:

1. Housing in Southern European countries is examined with a comparative and interdisciplinary approach that does not take in consideration only quantitative aspects but also qualitative ones, combining a mixed methodology among geography, sociology and urban planning;
2. Given the scarcity of international publications about Southern Europe, housing is investigated in-depth in Portugal and Italy instead of comparing with Northern Europe, in order to find out opportunities within for the production of new housing policies;
3. After a deep understanding of housing policies in these countries, we concurred on an approach that we called '*Learning from the South*'¹ which aims to find peculiarities from which started to build innovative approaches for housing in Southern Europe.

According to Kemeny (1992), even if two countries have similar size about housing issues, they could differ from each other for many aspects, detectable if we look deeply inside the country.

In fact, if we only look at the numbers, the countries look very similar because Portugal has 2% and Italy 3% of social housing among all the entire housing stock (Housing Europe, 2017), but if we look beyond the numbers we will find out several differences, and mostly we will understand small emerging characteristics that are not appearing in the big numbers.

Despite the similar numbers of home ownership and social housing, these countries have been following different paths, mostly shaped as a consequence from the socio-historical events and the political decisions. The paper thus discusses how the two countries diverge in the concepts used for housing, the age of housing stock, the topics in discussion nowadays, in order to build a critical and constructive discourse of housing situation in these two countries.

The structure of the paper is organized in:

1. The next section includes the theoretical framework and the methodological issues in housing comparative studies that permit to frame our empirical work in the literature review about Southern Europe and the “schools” of comparative housing studies;

¹ Boaventura de Sousa Santos (2016) used the expression '*learning from the South*' to justify the building of a general theoretical literature which permits to extrapolate patterns recognized within countries in exam and to start from them.

2. The third and fourth chapters are the parts related to the study of the single countries, Italy and Portugal, which explain the concepts used for social housing, a brief summary of housing policies with a focus on the contemporary issues at national level.
3. The last chapter is dedicated to the comparison of the countries especially showing the differences on the two countries, using international and national statistical data, literature review and interviews. Therefore, here we stress the link among political levels to understand the various actors and different forms of access present in both countries.

2. Theoretical framework and methodological issues in housing comparative studies

Housing studies are common linked with welfare studies, because in the industrialized societies the State principally supports (or should support) who is in precarious and disadvantaged conditions. This kind of approach is called Welfare State and it aims to reduce social inequalities and to guarantee social rights and services, such as health care, public education, retirement pensions and housing.

If on one hand housing should be identified by welfare state, on the other hand it is a mechanism affected by unstable market rules making it the *“fourth wobbly pillar of welfare”* (Torgesen, 1987). As opposed to other areas of welfare (education, health, work, retirement pensions), social housing is not supposed on the universalistic system of public provision but is addressed for a minority and after selection controls, determining his shaky role in public policies (Kemeny, 1992).

Before displaying our empirical work about the comparison of the two countries, it is necessary to frame the topic in the political studies as well as in housing studies.

According to Landman (2003), comparing many countries would lead to a high level of abstraction for focusing on general dimension of macro-social variations. On the contrary, single-country studies permit to distinguish characteristics in depth rather than an analytic relation among the variables. In fact, what we expect from this study is more than a mere reading of graphs and tables, but a profound understanding of the principal features and the current housing situation in the two countries.

According to Kemeny and Lowe (1998), different approaches of comparative housing studies have become relevant from the last decades of twentieth century and still remaining applicable: the first one is the universalistic approach that sees countries submitted to global imperatives of the neo-liberal transformation of cities such as capitalistic logics, market failures, structural privatization and so on; the second one is the particularistic approach that sees each country as unique one, giving thus more strength to the empirically evidence in exchange of a theoretical part less developed; the last one is part of middle range theory that identifies a middle way between particular and universal ones and it

seems the most reasonable to understand all the factors that influence both countries, placing them in the European housing studies as well as finding peculiarities of the single country.²

According to Allen *et al.* (2004) the principal traits of the Southern European countries that allow them to be combined in a cluster are:

- High levels of home ownership and low percentage of social housing;
- High levels of second homes and holiday homes;
- The important role of the '*extended family*' for the supply of housing for the relatives;
- Largeness of self-promotion and self-production as crucial factors of home ownership.

The concepts of the 'extended family' (also defined with the Italian term *parentela*) is expressed in preserving the property at all costs and in providing autonomously housing to its members through the self-promotion or self-construction. This expresses how strong is the role of the family in these countries, not as a passive beneficiary of welfare policies but with an active role for the well-being of the households, representing one of the providers for the access to housing.

The State tends to take advantage of this configuration, encouraging policies of tax reliefs for the access to home ownership and supporting a model of '*public action*' (less state intervention on social housing sector, large private rented sector, weakness on land use control systems and so on).

The southern welfare system is influenced by others factors, as the link between formal and informal labour market, in which the over-protected workers have plenty of benefits (the virtually impossibility of losing their jobs, good retirement pensions, etc.), being able to easily access to home loans and the under-protected are precarious workers with very small or no social guarantees at all.

On this line, other studies explain the relation between residential property and the social security system, called as a '*real big trade*' (Castles and Ferrera, 1996), because homeowners prefer to guarantee their safety in old age buying a house since low pensions do not propitiate the payment of renting.

Nevertheless, nowadays the Mediterranean model is gradually moving in other direction due to the consequences of crisis (job precariousness, geographical mobility, the scarcity of public resources and so on). Each country is developing different approaches to cope with these issues, sometimes displaying successful results on small and local experiments. However, the general root seems to offer

² The idea of Southern Europe or Mediterranean countries gathers the cluster including Portugal, Spain, Italy and Greece, or else the countries analysed in the literature about comparative housing studies in Southern Countries.

resources to families instead of providing a product, to enlarge the public-private partnerships of public assets or public functions and strengthen the privatization of public housing stock.

The analysis of the literature review helped to build a ‘South-inspired’ theoretical approach, additionally supported by the bibliographic review about the study in-depth of the two countries. The methodology used also adds the analysis of the principal statistic data (e.g. dimension and age of the public housing stock, owner occupied houses and unoccupied houses etc.) and the recent legislation as well as interviews with public decision-makers.³

About the methodological issues on housing studies, it is also important to stress the possible ‘*conceptual and methodological traps*’. According to Baptista (2001), the analysis of housing policies is dependent on data produced by public bodies, which can create propagandistic interpretations to legitimize the options taken. Critical analysis, multidisciplinary, cross-referencing and multiple validation of data could help to support adequately any work about it.

Other methodological issue that comes up in housing studies is the definition of social housing, which it becomes crucially especially when we are comparing two or more countries. According to Hansson and Lundgren (2018), the term social housing is a “*a term with no agreed-upon meaning*” and “*the lack of a definition leads to misunderstandings, rather than constructive dialogue on the advantages and disadvantages of such a system*”. In order to achieve a general definition of social housing, the authors established a set of criteria. The first key criterion analyses to whom is social housing addressed (i.e. a target group), identified in “*low-income households*” or “*households with difficulties in finding housing*” with limited financial resources and/or a fragile position. The second criterion mentions the form of tenure of social housing, which it is mostly the rental systems, even if sometimes appears the accession to ownership. The type of providers embodies the third criterion, which is commonly the State but sometimes we find other actors (non-profit and private for-profit), publicly subsidized on three forms: regulation, subsidies and direct provision.

Even though the text gives a clarification of what social housing is, the lack of defining a unique term of social housing across Europe remains. Each country makes own definition referring to funding arrangement, providers and beneficiaries, as well as the housing regime adopted and the political and cultural circumstances (Braga and Palvarini, 2013; Housing Europe, 2017).

³ All translations of documents, texts and interviews from Italian or Portuguese to English are ours.

Therefore, given the absence of a single, uniformed and standardized definition of ‘social housing’, it becomes necessary to create a convenient sort of ‘vocabulary for housing’, focused on the two analysed countries, which will be presented at the beginning of each chapter about the country.

3. Social housing in Portugal

In Portugal it is common to use the concept of ‘social housing’ (*habitação social*) to refer to housing built with the support of the public administration. This situation stems from the conceptual legitimacy given by the legislation in 1983 when we find the definition of social housing⁴:

"Social housing shall be deemed to be the controlled cost housings (habitações de custos controlados) promoted by the City Councils, housing cooperatives, Private Institutions of Social Solidarity (Instituições Particulares de Solidariedade Social) and private initiative with the support of the State and intended for sale or rent under the conditions established in this diploma".

Until 1983, in Portugal there was no legal definition of ‘social housing’, since up to this date social housing assumed various designations, such as “casas económicas”, “casas de renda económica”, “casas de renda limitada”, among others. In addition to this, up to the beginning of the 1980s, public bodies with responsibilities in the construction of social housing did not always have consensual understandings about the cost, dimension and the quality of this kind of houses.

In 1988,⁵ the concept of ‘social housing’ (*habitação social*) was replaced in the legislation by the concept of ‘controlled cost housing’ (*habitação de custos controlados*), a decision that was maintained later in 1997⁶ and also recently in 2019⁷. Several factors contributed to this alteration, including the creation of a housing program designated ‘controlled cost housing’, destined to private companies and housing cooperative (*i.e.* non-profit and private for-profit). Additionally, it contributed to overcoming the stigmatization that the concept of ‘social housing’ had gained within the Portuguese society as usually associated with disqualified urban spaces. At the same time, the change from ‘social housing’ to ‘controlled cost housing’ was intended to disassociate the idea of social

⁴ Ordinance (*Portaria*) n. 580/83 of 17 May.

⁵ Ordinance n. 828/88 of 29 December.

⁶ Ordinance n. 500/97 of 21 July.

⁷ Ordinance n. 65/2019 of 2 February.

housing from only public ownership and to approach other concepts such as affordable housing, in line with the European common trend.⁸

Nowadays, the term ‘social housing’ is usually used in the scientific, political and popular discourse to refer to the only public housing, and the term ‘controlled cost housings’ to refer to housing built with public support from private companies, private institutions of social solidarity and housing cooperatives (*i.e.* non-profit and private for-profit).

The first social housing policy in Portugal dates back to 1918. The development of social housing policies in Portugal was recently studied, namely by Antunes (2018), which analyses the policies of social housing, rent and urban rehabilitation since 1820, and Agarez (2018), which analyzes social housing policies published since 1918. Based on the Antunes (1918) study, the *history of housing policies* in Portugal is briefly established:

- *1910-1926*: period of the First Portuguese Republic, in which the first social housing policies were created. The housing policies created at 1918⁹ and 1919¹⁰ were extremely unsuccessful and did nothing to alleviate the problem of housing.
- *1926-1974*: period of the Portuguese dictatorship (*Estado Novo*), in which a coherent housing strategy was created. It was in this period that was created the first social housing policy with impact in urban spaces (*casas económicas*, at 1933¹¹ – ownership model), and also the first housing policies related simultaneously with housing and urban planning (*casas de renda económica*, at 1945¹², and *casas de renda limitada*, at 1947¹³ – rent model).

Despite many housing policies enacted by *Estado Novo*, the housing construction with public support was always insufficient and answered particularly to the social segment that the corporatist regime intended to satisfy. In general, the housing policies were marked by the traditionalist view of the dictatorship, especially in the first half of the regime, so social housing policies served to support the dictatorship itself.

- *1974-present*: period of democracy characterised by several phases. The first period (1974-1976) happened during the process of post-revolution¹⁴, where the Provisional Governments

⁸ Remember that Portugal joined the European Economic Community at 1986.

⁹ Decree n. 4137, of 25 April 1918.

¹⁰ Decree n. 5397 and Decree n. 5397 of April 1919.

¹¹ Decree-Law n. 23052, of 23 September 1933.

¹² Law n. 2007, of 7 May 1945.

¹³ Decree-Law n. 36 212, of 7 April 1947.

¹⁴ The dictatorship ended with the *Carnation Revolution* on 25th of April 1974.

chose progressive and left-wing policies, usually associated with direct and participatory democracy, as the case of *Serviço de Apoio Ambulatório Local* (mainly know as SAAL)¹⁵.

In the following decades (1976-2000), the Portuguese Governments improved the initiative of private companies, housing cooperatives and public housing under a joint of housing policies promulgated without strategy, continuity and systematization. On one hand the housing cooperatives and the private companies (programme called ‘*habitação de custos controlados*’) were only successful during the 1980s and 1990s, especially aimed to the middle class. On the other hand, the public promotion was only visible at 1990s, after the creation of the Special Programme for Rehousing (*Programa Especial de Realojamento* [PER]) in 1993, that has built about 35.000 public housing dwellings in Lisbon and Porto metropolitan areas to rehousing the population who lived in slums.

Table 1 shows how much the Portuguese State spent for all the housing programs between 1987 and 2011. As we can see, the social housing programs only used 22,4% of the total amount, namely 22,1% to public housing programs and 0,3% to controlled cost housings program (supporting housing cooperatives and private companies – non-profit and private for-profit). Furthermore, we can stress the most important housing policy as the ‘mortgage interest rate subsidy’, which allowed the acquisition of home ownership by the middle class. That means that in this period the State preferred support directly the Portuguese families than invest in social housing.

Programs	Budgeted		Used	
	(€)	%	(€)	%
Mortgage interest rate subsidy	6.672.508.894	65,9	7.046.685.145	73,3

¹ Support to public / municipal housing.

² Support to housing cooperatives, private companies, etc.

³ Social housing.

Table 1 – National budget to housing policies between 1987-2011. IHRU (2015), Resolution of the Council of Ministers n. 48/2015.

It’s also important to stress that a substantial part of the social housing stock was sold right after the construction, mainly in the 1980s and 1990s by the housing cooperatives and private companies that

¹⁵ Created in August 1974.

built social housing with financial / public support. In Portugal there are almost no housing cooperatives using the renting model and that means they sold the houses right after the construction, embracing in this way the ownership model.

Today almost the entire stock of social housing in Portugal is public housing and the public bodies own approximately 120.000 dwellings, most of them localized in Lisbon and Porto metropolitan areas. This situation displays why in Portugal ‘social housing’ (*habitação social*), ‘controlled cost housing’ (*habitações de custos controlados*) and public housing (*habitação pública*) cause so many misunderstandings and can be treated in practise almost as synonymous.

Nowadays, housing in Portugal is under pressure, especially in urban areas, such as Lisbon and Porto. On this line, the central housing institution (*Instituto da Habitação e da Reabilitação Urbana* [IHRU]), conducted a national study presented in 2018, which identified 25.000 families urgently needing new housing. In order to cope with this situation, the current Government has recently prepared a housing programs reform package, usually referred to as the New Generation of Housing Policies (*Nova Geração de Política de Habitação*), which is currently taking the first steps.

Table 2 – Table of actors and their competences about the social housing in Portugal.

In the Portuguese case, social housing policies have been dominated by the central power. The most important policies were created by the Governments, which later proceeded to the construction of social housing with the collaboration of the local power, housing cooperatives or private initiative (Table 2).

In the absence of autonomous regions in Portugal (with the exception of Madeira and Azores), the political articulation is made directly between the central government and the local authorities (308 municipalities). At the same time, the local authorities have recently begun to create housing programs, especially in Lisbon and Porto municipalities, making use of the municipal budget.

4. Social housing in Italy

In Italy the common and currently used concept is '*edilizia residenziale pubblica*', which can be the translation of '*public housing*'. This represents the largest part of the current social housing stock, owned and managed by the former *Istituti Autonomi per le Case Popolari*¹⁶ (IACP), public bodies that provide housing for low-income families registered in municipal lists.

The term comes from Law n. 865 of 1971, which has supplanted the previous one (*Edilizia Economica e Popolare*) and has determined the State intervention in three areas which are identified by the types of subsidies financed for the provision of housing: subsidized, agreed and assisted.

On the other hand, the term 'social housing' has been recently defined with the Italian concept '*alloggio sociale*'. It appears for the first time in the National Law of 2008¹⁷ which defines:

“Social Housing [Alloggio Sociale] is the real estate unit used for residential use in a permanent lease that carries out the function of general interest, in safeguarding social cohesion, to reduce the housing problems of disadvantaged individuals and households, who are not able to access the rental of housing in the free market”.

The dwellings built under this concept are mainly promoted by private or third sector companies through public contributions¹⁸ with the goal of being rented or sold at affordable prices and achieving a social mix as well as 'financial mix', among promoters, funding, tools and practices.

¹⁶ We indicated 'former' because the Italian public housing agencies, created in 1903 with the name of IACP, have now different nomenclatures based on regional autonomy. This is the result of a long process of decentralization since the 1970s but only concluded with the Constitutional Reform in 2001.

¹⁷ Decree 22 April 2008 of the Ministry of Infrastructure and then Law n. 133/2008.

¹⁸ According to Lungarella (2010), the ERS does not exist without a direct or indirect public contribution.

The target is the ‘gray band’, namely the lower-middle class in economic difficulty for the loss of work, marital separation and so on. In this sense, the provided solutions are set to fight temporary problems under provisional conditions¹⁹. Nevertheless, the examples of this new concept are intended as the unique ‘social housing’ presented in Italy, although it is formally incorrect because we should also consider the public housing examples as part of the entire social housing stock.

According to FEDERCASA²⁰ (2015), the Italian public housing companies own about 750.000 dwellings, distributed differently between North and South, since the majority is owned in the North.

- *1903-1949*: the beginning of social housing can be traced back to the early years of the XX century, when in 1903 was created the IACP²¹ as a public institution to build and manage the public housing stock at a municipal level, even though managed by the central government. During the fascist dictatorship, an important legislative text²² was created about indications for the construction of public or economic houses and for the public actors involved.
- *1949-1980*: after the end of dictatorship and the Second World War, in 1949 a relevant political instrument for housing demand was created (the INA-CASA Plan²³) to respond to massive migratory processes and the strong demand for homes and also the employment growth to revive the economy. The state’s total investment in public housing was considerable while encouraging indirect public intervention to support home ownership²⁴. In 1963 the INA-CASA Plan ended and a new instrument was created (GESCAL fund²⁵) that guaranteed a continuous cash flow to housing, generated by the contributions from both

¹⁹ Some of these, as temporary residences in Turin, are predicted for a time even up 18 months.

²⁰ FEDERCASA (*Federazione Italiana per le Case Popolari e l’Edilizia Sociale*) is an association that represents the public agencies entitled to manage public dwellings. It was interviewed for this study in the last February 2019.

²¹ IACP is the acronym of *Istituto Autonomo per le Case Popolari*, as explained above.

²² *Testo unico sull’edilizia economica e popolare*, R.D. n.1165, of 28 April 1938

²³ Law n. 43/1949, of 28 February, which takes its name to the Minister of Labor and Social Security (*Amintore Fanfani*).

²⁴ According to Balchin (1996) a total of 800.000 social-rented dwellings were built between 1951 and 1970 and 850.000 dwellings were privatised in the same period.

²⁵ GESCAL was the acronym of *GESione CAse per i Lavoratori* (Management Houses for Workers) and was a fund destined to the construction and the assignment of houses to workers, disciplined by the law n. 60 of 14 February 1963.

workers and employers. In the 70s started the decentralization process from the State to the Regions²⁶.

- *1980-2008*: 1980 marked a turning point (Padovani *apud* Balchin, 1996:198) for the decline, in opposition of the three previous decades, in the number of new houses built; the drop of withdrawals from the housing stocks; the statistical increase of second homes. The 90s was the period of regeneration policies (called Complex Programs or Integrated Programmes) that seek to co-ordinate initiatives and investments, both public and private in urban regeneration projects. In 1993 the law of privatisation of public housing was approved to cope with the deterioration of the public stock. At the beginning of 2000s the IACPs were transformed into public agencies with independent legal status, finally concluding the decentralization process started in the 70s. In 1998 the GESCAL fund was abolished, and rents were liberalized to revitalize the market, even if the reform did not produce specific results, on the contrary, the number of families living in rent reduced.
- *2008-2019*: after years of silence, a revival for housing policies comes out for many reasons: firstly, in this period the disposable incomes of Italian families have never grown so slowly over the last 60 years; secondly, the housing prices have reached levels never seen before (Baldini, 2010:166-167). With a new regulatory package approved in 2008²⁷, new operators (private and non-profit) were added in the social housing scene, along with the creation of an integrated real estate fund, set up for a national fund²⁸ and a network of funds for financing social housing (Integrated Fund System - SIF)²⁹ (Poggio and Boreiko, 2017).

Italy is an example of multi-level housing policies (Bianchi, 2017:74); the competence of ERP is indeed distributed between State, Regions and Municipalities, as shown in Table 3.

²⁶ The law n. 865 of 1971 (*Norme per l'edilizia residenziale pubblica* or *Legge per la casa*) establishes the transfer of many competencies from State to Regions, legislating about the discipline for assignments and the organization of public entities in the sector of public housing. Lately the Decree of President of Republic n. 616 of 1977, especially with the art. 93 comma 3, and law 457/1978 transferring the functions related to IACP from State to Regions. Nevertheless, the transfer will become effective only with the constitution reform, Constitutional law n. 3 of 2001 within the modify of the Title V of the Italian Constitution.

²⁷ Decree-Law 112/2008 – Law 133/2008.

²⁸ The main shareholder is *Cassa Depositi e Prestiti S.p.A. (CDP)* which is an Italian financial institution, controlled about 83% by the Ministry of the Economy and Finance and about 16% by various banking foundations.

²⁹ The SIF is based on public-private funding, with the main shareholder is *Cassa Depositi e Prestiti*, aiming at developing the affordable housing for lower-middle families, resulting from the National Housing Plan of Berlusconi government.

Principal actors and distribution of competences of the public housing in Italy				
	State	Region	Municipality	IACP (or how called locally)
Assignment	Guarantee the uniformity of the assignment criteria	Fix rules with regional law (incomes, priority criteria)	Issue the announcement and manage the lists	Receive of those entitled and priority. Assign the fees
Rents		Regional law (definition criteria)		Apply the fees
Management		Regional law (standard regulations)		Management regulations and rent contracts
Users monitoring		Regional law	Verification at the moment to assign	Biennial verification of incomes
Decay and revocation		Fix criteria (e.g. incomes.)	Provide for the decay/revocation	Report to the municipality the illegal situations. Provide for the evictions if required from municipality
Sales	Define prices and requirements of those entitled (L. 560/1993)	Eventual regional law for sales housing. Approve the sales plans		Draw up the sales plans. Apply the normative. Stipulate the purchase acts

Table 3 – Table of actors and their competences about the public housing in Italy. Source: Federcasa, 2015.

Due to the transfer of jurisdiction from the Central State to the Regions, the boundaries between exclusive and competing competences are subtle and often object of controversy. According to Baldini (2010:162) the Constitutional Court has expressed several times and has articulated public housing on three levels³⁰:

- The State has the responsibility of the determination of the minimum housing offer destined to satisfy the needs of the most disadvantaged classes;
- The competence of planning ERP settlements is belonging to the concurrent matter “territorial government”, which is shared between the State and the Regions;
- The management of the public stock refers to the Regions through the public housing agencies. With the decentralization, the nomenclatures of the agencies have changed: in some Regions they are still called IACP, in others they changed names as non-economic public bodies or economic public bodies with the obligation of balance, and only in few cases they are a sort of joint stock company³¹.

³⁰ With the ruling 94/2007.

³¹ As the General Director of FEDERCASA reported in the interview.

5. Comparative analysis and final reflections

About the vocabulary of housing

As we have seen previously, in Italy the concept of social housing created in 2008 has added new characteristics to the public housing, but has concurrently generated a confusion and different interpretations throughout the country. According to Tosi (2016:92), in addition to '*edilizia residenziale pubblica*', some people use '*alloggio sociale*', others '*social housing*' or '*housing sociale*', few say '*edilizia residenziale sociale*' (ERS) or '*edilizia privata sociale*' (EPS).

However, these terms are part of the Italian social housing scenario that is actually divided into two parts: one older, public and larger, and the other recent, private (profit or non-profit) and residual.

Regarding to the vocabulary of housing, we can stress the shift of the notion from the “negative definition of public housing”³² towards another positive, “*like a catharsis process*” (Lungarella, 2010). This shift could be also understood as an extension of the meaning, an “*extensive social*” as Tosi (2016: 87) states, which broadens the issue to a wider catchment area, while supplying practices and financing models already consolidated in the European context.

On the contrary in Portugal the concept of the ‘social housing’ (*habitação social*) is older (from 1983) and it was changed at 1988 into one similar to the affordable housing (‘controlled cost housing’ [*habitação de custos controlados*]), even if it has generated some misunderstandings – even between the experts.

Although in Portugal ‘social housing’ is formally called ‘controlled cost housing’, the expression ‘social housing’ is still used to refer to housing built with public support by housing cooperatives, private companies and by public bodies as the municipalities. However, the social housing built with public support by the third sector and private companies (profit and non-profit) is usually referred as ‘controlled cost housings’; while public housing is termed as ‘social housing’. At the same time, wide public housing ensembles are usually known as social neighbourhoods (*bairros sociais*), facing issues of stigma and prejudice.

Recently, the New Generation of Housing Policies package proposed several housing policies more closer to the affordable housing. This was especially visible recently in 2019 with the last legal

³² Over the decades, public housing has had a higher stigmatized perception and a prejudiced definition of the targeted model of the inhabitants who use them, leading to phenomena of social as well as territorial segregation.

change to the concept of *habitação de custos controlados*, with a more flexible understanding and action.

To conclude, Portugal seems to be more in step with times considering the use of the concept of affordable housing which instead has not yet entered in the Italian vocabulary of housing. Even though, both Portugal and Italy's concepts of social housing seek to be in line with the European and global trends (flexibility, new governance, access to non-public resources, empowerment of civil society, etc.), there are still misunderstandings about which concept to use in the political, academic and common language.

The Constitution

The inclusion of the 'right to housing' in the Constitution represents a relevant difference among the two countries because Portugal has an article entirely dedicated to "*Housing and urbanism*", as opposed to Italy. In Portugal, the 'right to housing' is enshrined in the Constitution of the Portuguese Republic (1976) in the article 65, referring:

"Everyone has the right for himself and his family to have an adequately sized dwelling that provides hygienic and comfortable conditions and preserves personal and family privacy".

The Portuguese Constitution not only enshrines the 'right to housing' in the Art. 65 as it directly refers to the support to "*housing cooperatives*", "*local communities*", and "*self-construction*", between other ideas. This Constitutional consecration is usually taken as progressive and avant-garde in the political perspective (Farha, 2017), even if several authors bring forward a very critical view of how the right to housing has not been respected by governments.

In Italy the 'right to housing' is not explicitly considered in the Constitution of the Italian Republic (1948³³) but the article 47 refers to the encouragement of the home ownership:

"The Republic promotes the access of the popular savings to the home ownership, to the direct cultivating ownership and to the direct and indirect investment of stock in the great productive complexes of the country".

Therefore, we can see a distinction on the value given to the 'right to housing': while in Portugal the right to the adequate housing for families is defined regardless of the providers, in Italy it would seem the access to housing is only considered within the home ownership as a form promoted by the State.

³³ Promulgated on 27th December of 1947 and became effective on the 1st January of 1948.

Governance and the management

The framework of actors and competencies is truly different among the two countries because in Portugal the governance is between State (Government and central public body - IHRU) and municipalities and in Italy among State, Regions, Municipalities and public agencies.

If in Italy the State has very limited competencies on housing due to the decentralization to Regions, in Portugal the State has the principle role for housing policies while municipalities simply perform. Nevertheless, the multi-level governance in Italy doesn't work since creating inequalities and territorial differences in terms of social performances and answers to the housing problems.

The Italian model does not work for: i) the scarce management, ii) the lack of economic resources, iii) to satisfy a very marginal set of families leaving out lots of people in growing waiting lists. Furthermore, the ex-IACPs are victims of a continuous replacement of directors, put by political bodies, which is not favourable to the long-term growth perspectives of the public bodies. Additionally, they have to maintain and manage an old stock, mostly build 40 or 50 years ago, basically without financial instruments³⁴. Moreover, the reduction of public resources in the 90s and the alienations of the stock led to the paralysis of the offer of social housing.

On the other hand, in Portugal there is 2% of social housing, almost all public. Of these 2%, 1,8% is municipal housing and 0,2% public housing owned by IHRU (central public agency). The management and maintenance of these 120,000 public dwellings faces a diverse scenario, depending on the effort of each municipality. For example, IHRU it's generally not known for making good maintenance of the buildings and the same happens with several municipalities. In the biggest municipalities with more municipal housing, it's common the management be ensured by municipal companies and not by the municipality directly, like happens in Lisbon, Porto, Cascais, etc.

About the dwellings

According to ISTAT (2011) the Italian housing stock was principally built in the decades 1960-1980, in the 90s the percentage of dwellings built was less than half. In Portugal we see a different trend because in the 80s and 90s Portugal had been built more than in other European countries.

³⁴ To explain this situation, the General Director of FEDERCASA reported in the interview: “*we fry the fish with water*”. This is a typical expression that comes from Naples (*friggere il pesce con l'acqua*), which means to get good results even in difficult situations and without proper tools.

	Period of construction			
	Before 1946	1946-1980	1981-2000	2001 onwards
EU-28	22,3	44,1	22,1	9,8
Italy	20,7	51,4	19,8	7,9
Portugal	10,7	37,1	36	16,3

Table 4 – Period of construction – national and EU average.

Another difference concerns the unoccupied dwellings. As happens in many Southern European countries, the presence of second home for tourist reasons is very common along the coast. The unoccupied dwellings in Portugal are considerably higher than Italy, especially because many families living in Porto and Lisbon metropolitan areas keep the home ownership in the countryside to go in the holidays. As the Eurostat data shows³⁵ (2011), the majority of the Portuguese NUTS3 as more than 30% of unoccupied dwellings, while in Italy the average does not exceed the 30%.

After the comparison analysis of some data, we can state that our initial hypothesis is confirmed. Beyond the similar percentage of low social rental housing, high home ownership and the similarities of the Mediterranean model explained in the theoretical chapter, we have demonstrated that an in-dept study of the single countries can show a different scenario. In fact, we have found some visible dissimilarities in the vocabulary of housing, in the framework of actors and competencies, in the value given to the right to housing in the Constitution as well as quantitative data about the age of dwelling, the empty dwellings and the resident home owners.

We are certainly aware that this study represents a first effort to compare social housing policies in Italy and Portugal, that is still in progress in our researches.

Nevertheless, our purpose was to stress the importance of this kind of studies that help to develop a “South-inspired” theoretical approach in opposition to the only “North-inspired” one. This means to look beyond the numbers and discover features that we actually did not expect to find in a general framework and with which it is possible to make a critical discourse on existed housing policies as well as proactive one to propose innovative trajectories or to develop emerging practices.

High-density Living in Hong Kong from the Perspective of Teenagers

Pu Hao¹

¹ *Department of Geography, Hong Kong Baptist University, Hong Kong
Email: ppuhao@hkbu.edu.hk*

Abstract: Being one of the world's densest cities and the most expensive to buy a home, Hong Kong is infamous for inadequate housing and small living spaces. Living under such crowded conditions is often accused of aggravating stress and social problems. However, the effect of high living density on juveniles remain ambiguous. Using a 2017 survey of secondary school students in Hong Kong, this paper examines residential crowding and satisfaction experienced by juveniles with respect to objective densities of their homes measured by number of persons per room. The results suggest for juveniles in Hong Kong high living densities do not necessarily lead to the perception of crowding. Moreover, residential crowding, if perceived by the juveniles, is not directly translated into dissatisfaction. The variables which explain the residential (dis)satisfaction of juveniles are the composition and ethnic and socioeconomic backgrounds of their families. The paper argues that family composition and ethnic and socioeconomic backgrounds contribute to juveniles' varying degrees of tolerance to high living density, which lead to different levels of perceived crowding. The effect of perceived crowding on residential satisfaction is further mediated by the interactions of family members and the overall quality of family life.

Keywords: residential satisfaction, juveniles, housing crowding, family background

Introduction

The high-density living environment in Hong Kong caught the attention of American statistician and planner Robert C. Schmitt half a century ago. "The Colony of Hong Kong is one of the most densely populated territories in the world. Over-all density is 13 persons per gross acre, and individual neighborhoods exceed 2,800. Residential floor space averages 155 square feet per household or 32 square feet per occupant. Unlike congested areas in the United States, however, Hong Kong has relatively low death, disease, and social disorganization rates. These data suggest that density standards recommended by American planners may be unrealistic as requirements for public health and social welfare." (Schmitt, 1963: 210). Today, both the dark and bright sides of the situation in Hong Kong are still present. Schmitt's question on whether high density is harmful to health remains unraveled. Despite Hong Kong's extremely high density, if we look at social order, life expectancy, and mental health, the city is doing much better than many other places. Hong Kong's suicide rate is lower than the United States, the European Union average and certainly Japan where socioeconomic development levels are comparable to Hong Kong, but living densities are considerably lower. Given all this evidence, how can we make sense of Hong Kong's situation? This is a question puzzled Schmitt half a century ago. It is still puzzling us today.

At the same time, Hong Kong is also one of the most expensive cities to live in. For eight years in a row, an international survey of nearly 300 cities has named Hong Kong the world's least affordable housing market. Many Hong Kong citizens have been priced out of the housing market, including young people forced to live with their parents. Their discontent is said to have contributed to recent street protests like the 2014 Umbrella Movement. Young people in Hong Kong are increasingly dissatisfied with inadequate housing and small spaces. With housing prices rising even higher, it is extremely difficult for the young people to obtain a basic living space, let alone developing their housing career. The government of Hong Kong has recognized the housing problem as the most important on both the political and urban development agendas.

Ample space is not always experienced as spaciousness, and high density does not necessarily mean crowding (Tuan, 1977). While the two concepts are related, density is directly measurable and unambiguous, but crowding is intangible and should be understood under specific conditions. Home is the most stable and secure place for humans. Under what conditions density is translated into crowding at home is of great interest and importance. Based on a recent survey, the paper tries to understand how young people in Hong Kong perceive and experience the density of their living environments and how such perceptions contribute to residential (dis)satisfaction.

Conceptualizing density and crowding

Density influences people's behavior, mood, and consequently mental health. We all experience it. Research around the world has found high-density living is harmful to people's mental health, especially that of the children, because their physical and mental states are taking shape. For instance, research in Austria finds there is significant impact of crowding and housing type on children's mental health. Three housing types are examined, detached house, townhouse, and apartment units. Denser housing types are found to be more harmful to children's mental health. For each type, higher density also causes poorer mental health, especially for apartment units (Evans et al., 2002).

By Hong Kong standard, even the type of multi-story apartments in Austria is considered low-density housing. Hong Kong's density is way much higher. While public housing and private housing roughly accommodate 50% of the population respectively, both types of housing are in the form of high-density apartment buildings (Figure 1).

Figure 1. Public (left) and private (right) housing estates in Hong Kong

This level of density is rare in other places. In literature, the condition that is comparable is the density in prison. Research done in prisons in the US found more inmates per cell increases perceived crowding, and consequently increases illness complaints (Cox et al., 1984). In those prisons under investigation, the density is 1 to 6 inmates per cell. Corresponding figures for ordinary families in Hong Kong can be even worse, which will be demonstrated later.

Essentially, there is a distinction between density and the experience of crowding. Density is the physical condition purely in terms of spatial parameters, and crowding is a motivational state aroused through the interaction of spatial, social, and personal factors. Density does not necessarily lead to the experience of crowding. The experience of crowding is also subject to the relationship between people. People with good relationship often find a higher density setting create a more intimate environment that is pleasurable, while for people without social ties or affections, a high-density environment can be unpleasant or even unbearable. On a more general level, how density is perceived also has to do with culture. People with certain cultural backgrounds or in certain cultural contexts perceive density differently.

For the situation at home which is a rather enclosed and stable environment, people's experience of the environment is highly dependent on the relationship between family members. Although higher density is usually perceived as more crowded. Family relationship can moderate the effect of density on perceived crowding. In other words, when one enjoys the intimate relationship with family members, density does not or to a less extent translate into perceived crowding. When family relationship is dreadful, one may feel crowding even when a big house is shared by few people. This is especially the case for children, because they are in a rather passive position in the family and do not command the power to make a change.

Methodology

The first question is how juveniles in Hong Kong perceive their dense living environment and what is the role of family relationship. The hypothesis is density generally predicts perceived crowding, but good family relationship weakens the effect of density on crowding. When family relationship is less gratifying, density will more directly translate into the perception of crowding. To implement the conceptual model statistically, an interaction term is included in the model. If the interaction is significant, the moderation effect of family relationship is detected (Figure 2). The data distinguishes three types of family backgrounds: Hong Kong local families, immigrants from Mainland China, and immigrants from other countries. It is expected the specific cultural background and situation will play a role in these mechanisms.

Figure 2. Conceptual moderation model

The second question is in the condition of extremely high density, what factors contribute to residential satisfaction. To identify those factors, a hedonic modelling structure is used to break down residential satisfaction into its constituent characteristics, and then estimate the contributory value of each characteristic. These factors include location, facilities in the neighborhood, size of residence, whether having own space at home, whether like your family and whether like your neighbor, which are aspects that are expected to have effects on the overall housing satisfaction.

To collect data for the proposed analyses, a questionnaire survey was carried out in 9 local middle schools in 2017. A variety of schools were included in terms of their ranking to obtain a representative sample of students of different backgrounds. The age of respondents is about 16 to 17. More than 1000 questionnaires were distributed in class. The response rate was more than 90%, because the teachers set aside time in class and obliged the students to fill in the questionnaires. English questionnaires were provided for non-Chinese students. The final valid sample includes 1213 observations.

Table 1 presents the profile of the sample. The respondents are balanced in gender. Local-born children account for 67%, while 24% were born in mainland China, and 9% were born in other places. Family size varies from 2 to 12 people. The median size is 4. The size of residence varies from 49 sq. ft. to 3000 sq. ft. with a median size of 500 sq. ft. On average, there are two rooms in a home, but many families live in one room and few wealthy families have as many as 8 rooms at home.

Table 1. Profile of the sample

Attribute	Statistics	
Gender	Male	50.7%
	Female	49.3%
Place of birth	Hong Kong	66.8%
	Mainland China	24.4%
	Others	8.8%
Family size	Min	2
	Max	12
	Mean	4.15
	Median	4
Size of residence (sq. ft.)	Min	49
	Max	3000
	Mean	587
	Median	500
Number of rooms	Min	1
	Max	8
	Mean	2.49
	Median	2
Sample size		1213

Considering the students know more accurately about the number of rooms they have at home rather than how many sq. ft there are, the number of persons per room is a more accurate measure of housing density. It is also more widely used in behavioral research. In terms of the types of housing, roughly half of the respondents live in public housing including public rental housing and subsidized

homeownership housing (Figure 3: right). The other half live in private housing. In the most recent census, a smaller percentage of people live in public housing (Figure 3: left), which is understandable because if a family has dependent children, it is prioritized in getting public housing. Consequently, tenants of public housing are overrepresented in the sample, but for families with children, the sample offers a more representative picture.

Figure 3. Residential density in Hong Kong

Living density and residential crowding

Family sizes vary from 2 people to as many as 12 people. Most families have 3 to 5 members (Figure 4: top). Numbers of rooms vary from 1 to 8. Most residences have 2 to 3 rooms (Figure 4: middle). Based on the statistics, residential density is calculated (Figure 4: bottom).

Figure 4. Frequency distributions of family size (top); housing size measured by number of rooms (middle), and residential density measured by number of persons per room (bottom)

In ordinary homes in Hong Kong, residential density ranges from half people per room to 8 people per room. The great majority has to share a room with one or more family members (Figure 4: bottom). Given that the density of prison in the US varies from 1 to 6 inmates per cell, housing in Hong Kong is definitely comparable.

Four statistical models are built to explore whether density is perceived as crowding and whether family relationship mediates the effect. The dependent variable is perceived crowding. Table 2 presents the result for the overall sample regardless of family background, and Table 2-4 present the results for the sub-samples of respondents who were born in Hong Kong, mainland China and other places respectively. For the overall sample, the effect of density is positive and significant; and the effect of family relationship is negative and significant. But there is not mediation effect by family relationship. The results suggest if family relationship is bad, density is perceived as crowding. When family relationship is median and good, density is still perceived as crowding.

Table 2. All respondents

Note: Significance *** <0.0001

For Hong Kong local families (Table 3), no mediation effect was detected. For immigrants from mainland China (Table 4), we see some different effects. Density causes perceived crowding, but family relationship has no effect. In addition, family relationship does not mediate the effect of density on crowding. For immigrants from other countries (Table 5), interestingly, no effect was given by density nor family relationship.

Figure 5 summarizes the causal mechanisms between density and perceived crowding as well as the effect of family relationship for families with different cultural backgrounds. In the usual situation found in other contexts, density leads to perceived crowding, and family relationship mediates the effect.

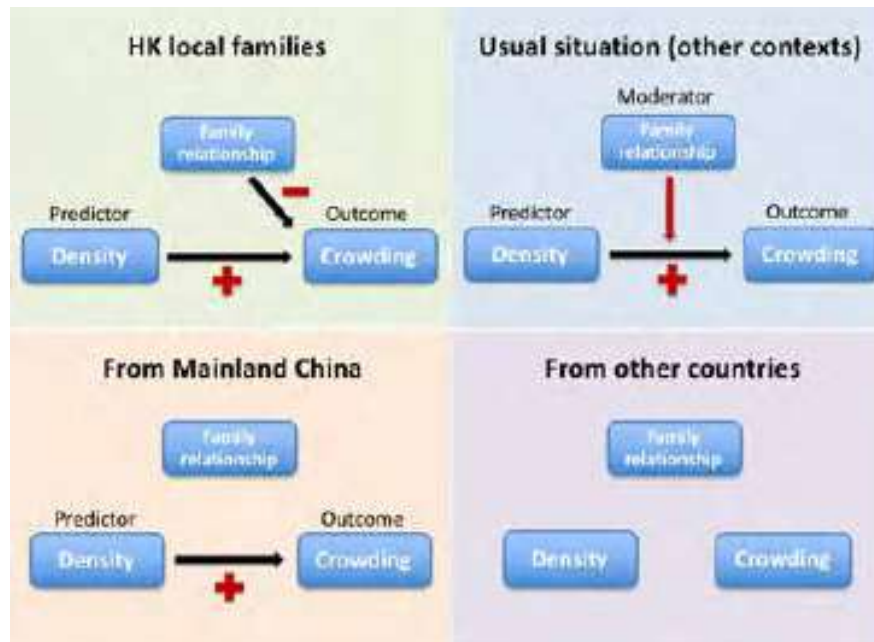

Figure 5. The causal mechanisms between density and perceived crowding for families with different cultural backgrounds (Note: arrow indicates the direction of effect; + and - indicates positive and negative effect respectively.)

For Hong Kong local families, density leads to crowding, but family relationship does not mediate the effect. Instead, it has a direct negative effect on crowding. A plausible explanation is that different from the situation in other contexts where a child can easily find a place to stay alone, in Hong Kong, there is no such luxury. The family is not escapable from at home. One has to literally face his/her family members no matter the relationship with them.

For immigrants from mainland China, density leads to perceived crowding. But family relationship has no effect. For immigrants from other countries, even density does not have an effect on crowding. A plausible explanation is that children in immigrant families are more tolerant of family problems. Moreover, in immigrant families from less developed countries, especially as refugees, children as well as their families are more likely to feel satisfied with their tinier but safer abode. Their high expectations for a brighter future also tend to diminish their discontent with the current situation.

Residential satisfaction

In the context of extremely high density, what leads to residential satisfaction? The results of the multiple regression are reported in Table 6. Location is not significant, because unlike working adults, activities of school children are carried out in a relatively fixed and bounded space whose location in the city is almost irrelevant. Facilities, which enable more diverse activities, have a positive effect. The size of home is very important, because as previous discussed extremely high residential density directly translates into crowding regardless of family relationship. In addition, having own space is important because it guarantees privacy and autonomy. Family relationship is important, but relationship with neighbor is not significant.

Table 6. Residential satisfaction

	<i>B</i>	<i>Std. Error</i>	<i>Beta</i>	<i>t</i>	<i>Sig.</i>
Location	0.037	0.028	0.040	1.331	0.184

Constant	0.685**	0.110		6.221	0.000
<i>R</i> ²	.493				
<i>F</i>	189**				
Number of cases	1213				

Note: Significance * $p < 0.05$; ** $p < 0.001$.

Conclusions

The most interesting finding is the moderating effect of family relationship does not exist in the condition of extremely high density. Maybe it is because the extreme condition forces people to develop a different way to get along with the living environment and with each other. What is evident, though, is the conditional effect of density on crowding varies with culture and situation.

As for residential satisfaction, home size, privacy, family relationship and neighborhood facilities are important determinants for children in Hong Kong. Location and neighbor are non-significant. The results manifest differences from adults in Hong Kong and from children in other places. For adult in Hong Kong, location is of critical importance, because it increases both the practical value and transaction value of a housing unit. For children in other contexts, having friends in the neighborhood to play with is highly desirable. But in Hong Kong, a combination of the high-density built environment, Chinese culture and the pressure of study prevents such behavior and preference.

Reach Homes - A Critical Extension of Dwelling

Sam Holden¹

¹*University of Manchester, Samuel.holden@manchester.ac.uk*

Abstract: This paper formalises a nine month engagement with REACH Homes, a small startup that is testing decommodified modes of construction, non-monetary forms of tenure, reusing construction waste, and alternative methods of land acquisition to critique and ultimately overcome the housing problem in the UK - from within. The purpose of this paper is twofold, firstly I will situate REACH within the housing crisis through a brief history of UK policies, whilst setting REACH apart from other solutions that call for a rejuvenation of public housing. Secondly I will demonstrate REACH's praxis through a selection of working examples that I have either been actively involved in or visited. These points allow me to argue that REACH reveals a holistic method for combatting the housing crisis which stops profit being extracted further up, or down, the supply chain; this holistic method is rarely being explored within housing activism.

Keywords: Decommodification; Affordable Housing; Alternative Modes of Construction

Introduction

Although autonomous spaces that occur simultaneously within and against capitalism were studied prior to 2008 (see Chatterton & Pickerill, 2006; Gibson-Graham, 2006), the 2008 crisis has been understood as a tipping point for these radical spaces, which have multiplied since in the global north (Berlant, 2016). On the one hand, austerity programmes decimated what was left of the social contract and, on the other, solidarity networks and living alternatives to austerity have manifested to fill this gap (Thompson, 2015; Arampatzi, 2016; Dalakoglou, 2016).

Despite the emergence of these experiments, a resistance to the financialisation of housing - the cause of the market crash (Marcuse in Brenner *et al.*, 2012; Harvey, 2013) - has been largely absent in the UK. Although there are examples, such as cooperative housing and eco-housing, these occur on a small scale and are generally considered one off projects. Although they still have a tendency to connect to other autonomous spaces and communicate their ideas to a wider society (Chatterton & Pickerill, 2006) they don't challenge the wider structures of housing. Also gaining traction in the UK is the community land trust movement (CLT) they strive for community ownership to fight against speculation and gentrification (Thompson, 2015). Powerful though they may be in their respective struggles, these movements rarely engage in a resistance to the financialisation of housing holistically; this means profit can simply be extracted further up, or down, the supply chain.

REACH Homes is a start-up Community Interest Company (CIC) on the outskirts of Sheffield. REACH aims to create the future in the present; from first glance it is clear that REACH is aiming to use new construction methods to provide affordable housing, but to see REACH as only a not-for-profit housing provider is to miss the wider point. For REACH, the construction of houses is a means to an end of undermining the whole system of housing provision. Construction should be seen as one action (albeit made of many others), it is the everyday reality that leads to a wider change.

Working from a one bedroomed house-cum-prototype (to date REACH's only built structure), REACH's existence provides a working example for alternative forms of land acquisition, design, construction, and dwelling; and we have ideas for ownership, dwelling past first occupancy, and end of life that we are keen to

make reality.

My research supports and explores REACH's critique to the financialisation of housing by understanding their actions as a critical extension of dwelling, in other words to critique housing in its current state we must explore not just how it is consumed but produced and reproduced as well. The purpose of this paper is twofold, firstly I will situate REACH within the housing crisis through a brief history of UK policies, whilst setting REACH apart from other solutions that call for a rejuvenation of public housing. Secondly I will demonstrate REACH's praxis through a selection of working examples. This paper will allow for a deeper understanding into how a grassroots solution to the housing crisis emerges, survives, adapts, and negotiates between market and non-market forces through trial and error, whilst advocating for a holistic approach to solutions to the housing crisis. Housing is a critical fighting ground, the site of social reproduction (Madden & Marcuse, 2016), a housing producer therefore plays a critical role in the production and reproduction of values. Removing the profit motive from this role enables new visions of the urban to emerge.

Dwelling on the UK

REACH's vision for housing echoes those of Turner (2017) and Ward's (1987) that evolved from their critiques of the 1970's onwards - alternatives to a dependency on capitalism and the state, in housing and society, must be sought. Autonomous housing enables dwellers to establish social connections, have control over their built environment, and undermine fundamental values in both state and privately owned housing (Ward in Turner, 2017).

In the late 1960s to the early 1970s there was a growing discontent with modernism within architecture (Aureli, 2013). Day (2010:219) believes that social housing was the key battleground that revealed the broken promise "*between the initial visions and the progeny of cheap developments that followed*" which "*provided a powerful image for a wider crisis in social confidence*". Above all it was a critique within the left of those who sought to reform capitalism by those who opposed capitalism altogether (Aureli, 2008; Deamer, 2015; Kaminer, 2016). Central to this argument was the notion of the plan, which was denounced by the radicals who opposed capitalism as embodying the alienation and social-control of the urban environment - which served only to create a hegemony of capitalist growth (Stickells, 2011; Kaminer, 2016). Accompanying this critique of modernism was a neoliberal market driven attack that appropriated the critique of the plan to call for a "*freeing of urban development from the constraints of planned society and a return to land and property speculation.*" (Kaminer, 2016:50). This attack succeeded in the destruction of the reformist; modernist middle ground, however the left critique was short of popular momentum, leading to a neoliberal hegemony of deregulated markets, and the reclus of the left to knowledge production (Aureli, 2008; Kaminer, 2016). The shift towards neoliberalism was accompanied by a fundamental change of logic towards the welfare system, the once progressive calls for 'autonomy' and 'self-reliance' which were originally used to critique the Keynesian welfare state from becoming too authoritarian were co-opted by neoliberalism to justify privatisation and competition (Brenner, Marcuse & Mayer, 2012). This enabled a succession of Thatcherite housing policies, including diminishing public housing stock, abolishing rent controls, deregulating the private rented sector, introducing buy to let, and giving housing benefits to subsidise private rented tenants (Bowie, 2017; Minton 2017).

Since then a series of subsequent UK governments have, either through neglect or by design, continued this trend. Housing policy since the 1980s has been focussed on public services being provided by the private sector and a retreat of government through an austerity agenda (Bowie, 2017). this trend can be demonstrated by comparing the years leading up to the Thatcher government which witnessed roughly 100,000 houses built by the state and 150,000 built by the private sector, and the years post the 1979 election in which although the private sector has remained largely the same, the state has barely built any (Minton, 2017).

Reflective housing policy

Turner (2017) argues against the notion that housing is an outcome of political assumption, housing policy including and succeeding the Thatcher government has been a vehicle to justify an austerity agenda (Bowie, 2017), demonstrating a far more Reflective relationship. The Housing Act of 1980 forced councils to diminish their stock by selling to tenants at a reduced rate; this policy was used not only for the state to gain support from the working class but also to cut a main funding stream from city councils - many of which were in open revolt (Holden, 2016).

The policies of the Thatcher and Major governments were supported through the Blair government (Bowie, 2017). The decent homes programme enabled the transfer of 200,000 council homes a year to housing associations which cut direct public investments into the social housing stock, causing commodification (Minton, 2017) as housing associations do not receive tax income.

The 2012 Localism act of Cameron's coalition created uneven geographical development by forcing families to accept the housing offered to them, often miles away from their social networks; If they refused the council was discharged of their duty to house them (Minton, 2017). The government also introduced the growth and infrastructure Act 2013 which allowed house builders to oppose planning obligations for affordable housing. The government's position was that deregulating the planning system was the best way to stimulate the housing market after the housing crisis (Bowie, 2017), which had seen a drop in construction of 68% in 2012 (Dorling, 2014). Instead this led to underhand ways for house builders to bypass most affordable housing production through viability assessments which have stipulations that for a development to be viable it must make a return of 20%. Even when affordable housing is constructed the definition for affordable housing was, and is, 80% of market rate, meaning an affordable house in London would cost £450,000 and £250,000 outside of London (Bowie, 2017; Minton, 2017).

These outcomes demonstrate housing has legitimised neoliberal policies where private businesses and landlords flourish in a climate of speculation and land banking whilst tenant's wellbeing is placed second to profit (Dorling, 2014) and this is legitimised through councils who have such little budget that they are competing against each other to woo private capital (Brenner, 2016). In the present, the linking of housing benefit to private rent simply means landlords can put prices up as the government has to pay, 40% of former council homes are now owned by private landlords, and between 2010 and 2015 the 5 biggest house builder companies saw a 480% rise in profit but they are still using viability assessments to claim that affordable housing isn't viable (Minton, 2017). Yet for tenants, due to the lack of social housing the current government's Housing and Planning Act 2016 marked the end of lifetime tenancies, meaning that social housing renters have to move to private accommodation within 2 to 5 years (Dorling, 2014; Minton, 2017).

Proposals

The Free market answer to this is for the further deregulation of the planning system - the argument being that loosening regulations allows developers to build smaller homes which will bring prices down, unfortunately this is stupidly simple. The UK housing market is primarily an Investor market which is different to a user market - investors attracted to the Extra supply which feeds inflation and speculation and excludes users (Minton, 2017), the extent to which it is an investor market is staggering, with Dorling (2014) noting that housing equity represents 61% of the UK's net worth. Reformists, such as Bowie (2017:39), call for:

“Expanding the programme of social housing, building houses as well as flats, and building in mixed tenure and mixed-income areas would enable access to social housing to be widened again to include more working households and reduce the stigmatisation of both the tenure and its occupants.”

But how is this different from what came before which was critiqued for being too centralised, alienating, and controlling rather than liberating (Ward, 1983; Turner, 2017)? This solution is not realisable in the UK at present which is still under increasing pressures from austerity measures. To cut this Gordian knot is to

acknowledge both the state's and private sector's failings, REACH Homes provides one proposal to this - constructing not-for-profit housing that is locally owned and managed; in this way critiquing both the private and public sector of housing delivery. This does not entail self-build communes that are cut off from society at large, Ward (in Turner, 2017) states that in order for social wellbeing within communities to flourish they require a degree of self-control, whether that be in management, construction or otherwise - autonomy is a way to stimulate social network development outside the project.

What I have learnt from REACH, and REACH has developed since my engagement, is that the key to undermining private development is to stop any attempts at commodification within the housing delivery system. If REACH was to just produce not-for-profit houses and sell them at a much lower price (owing to no profit being derived from the sale) the consumers could simply put them on the market at many times the price they paid. Conversely, if REACH was a decommodified home ownership scheme, akin to a CLT, then the people who built the houses would derive a profit from the buyers, and so REACH would have to charge more to residents to make up for the high price of construction. This is not to say that all of these functions need to be contained within REACH itself; engaging with groups such as CLT's can be a valuable way to build solidarity networks, enable reflective debate, and safeguard against any link of the chain from becoming dominant.

Within this paper I will explain how REACH undermines both state and private sector housing delivery through working examples as opposed to ideological statements; this praxis is key because it responds to a critique from reformists who claim that people who use slogans such as the right to the city don't provide working solutions (see Bowie, 2017). In the next section however I will briefly explain my engagement within REACH to differentiate the research undertaken in the PhD from the goals of REACH.

Methodologies

Since August 2018 I have been collaborating with REACH on a journey to at once understand and further their mission through an action research (AR) methodology that has seen me integrate into the team. My research is no less valid because I am a dedicated member of the team, it creates a different layer of legitimacy. I hold no notions of objectivity and am confident in vocalising my critiques of REACH precisely because I want them to succeed and it is only through a reflective praxis that this can happen. This section exists as a reflexive piece on my work with REACH, and to differentiate the future aims of REACH from the outcome of the research.

What we have collectively discovered through our actions is that solutions to the housing crisis need to be created holistically from proof of concept experiments that build into larger schemes. Although this is not something we intended to do, it is something that members of REACH have helped each other to understand. For example, Jon made it clear to me that maximising the use of recycled or upcycled materials in the construction allows us to undercut for-profit construction and critique waste in the industry, and I have raised the necessity of exploring protective covenants on the housing to stop it being sold for profit post first occupancy.

This discovery was not my specific aim when heading into the fieldwork, nor was it an agreed upon idea with REACH, it was something that emerged naturally. As Fals Borda (in McTaggart, 1997:109) explains, this research belongs to a different type of science "that of the common people's knowledge (popular or folk science) based on practical reason and communicative sociability"; I contend that it is difficult for 'popular science' to fit within the framework of a three year PhD (even then it was only possible through me being a, relatively, familiar face within the Sheffield activist scene). In order to make the fieldwork more productive therefore, I entered the field having loosely identified which groups I would be engaged with but without a defined research design. Action researchers could argue that as the research design was not co-produced then the project is not true AR (see Gaffney, 2008), however I have joined REACH in their struggle, designed a building, led meetings, created social connections, and much more. Rather than following a traditional AR approach - undertaking a proscribed intervention, measuring the outcomes, and implementing improvements (see McTaggart, 1997; Gaffney, 2008), I have applied my experience in design and architecture firstly to create a

less exploitative research project, then to become a part of REACH (an externality which has given me greater access into REACH), and finally to collectively critique REACH in order to ultimately improve it.

As such, although I may call it my research I am merely one collaborator, the person writing it up and connecting it to wider theories. I use the singular therefore to differentiate the outcome of the research from the future goals of reach, which I will refer to in the plural (for instance: I am revealing how REACH critiques housing production holistically, whereas REACH, or we, are attempting to provide non-profit construction methods to critique current housing provision).

REACH Homes

“What I’m proposing is something that’s just not happening at the moment. Everybody’s just throwing their hands up and saying ‘we need a solution to affordable housing’. The government’s best efforts are just not... y’know, there’s a lot of rhetoric and then I think there’s a lot of actual wanting to do something about it or acknowledging that they’ve got to do something about it. But they just don’t know how to do it. And because of the pound signs they’re just completely focussed on the money. The whole industry is unfortunately...”

- Jon, founder and resident of REACH Homes, 18/08/2018.

It is 2015. Jon, a retired police officer of 30 years, is sitting at the kitchen table with his partner assessing a model LEGO home, of their own design. They had been looking to move but couldn’t afford anything on the housing market when, watching an episode of Grand Designs on shipping containers, Jon decided to build his own.

“I costed this idea up with containers and was like ‘that’s less than ‘undred grand [£] for a 3,500 square foot house with atriiums and a garage for Barry’s Ferrari’ he was 12 at the time, he still wants a Ferrari, he knows it’s got to be an electric one though.”

Realising his exclusion from the housing market was not isolated, Jon used the principles of the project as a method to critique traditional modes of production and residence. Thus REACH Homes was born. Operating out of Jon’s house-cum-prototype REACH ground’s its work through everyday praxis. Housing and austerity policies are why REACH started, not as an idealistic goal but because Jon, a retired police officer of 30 years, couldn’t afford a home on his pension. This section will explore two projects that REACH undertake and how these are representative of how they understand the future, namely:

1. The material supply chains for the prototype and how they critique waste in the construction industry.
2. The land agreement between REACH and Heeley City Farm as an example of non-monetary tenure.

Materials

“This is 84% [upcycled] were not gonna be able to do that at scale, well not to start with at least, ‘cos those logistic supply chains and getting all those kinds of stuff sorted out... it’s not gonna happen straight away. So we’ve costed up buying new and as environmentally friendly as possible, I wanna get away from using - ‘cos there’s a lot of recovered Kingspan sheeting on this - but anything petrochemical I want to try and stay away from; so we’re looking at developing a straw bale panel system that bolts onto the wall”

We look round the room and Jon speaks candidly about different objects and their origins, salvaged from the excess of consumer society. All the wood is reclaimed, the bedheads are old pianos, the panelling in the shower is from the counter of an Indian takeaway, and the Kingspan came from the roof of the Madina Masjid when they were redoing the dome.

- Jon and I discussing the prototype, 18/08/2018.

Materiality for REACH is a key issue, we have to use materials that are simultaneously cheap or free, recycled/upcycled or as environmentally friendly as possible, and easy to work with - all whilst looking as aesthetically pleasing as possible to legitimise our work. All this allows us to critique waste in the construction industry, question who has the right and knowledge to build, and undercut commercial builders.

- **Who's right?** - Once inside, the house - through its act of simply being - raises the absurdity of professionalised and abstracted labour in the construction industry. Small though it is, it is perfectly homely and designed to a far higher, and infinitely more personalised, standard than houses found on the glossy pages of estate agent brochures. The space resembles a studio apartment, I am greeted by a stylish kitchen of what look like reclaimed wood cupboards, with a lounge over to my right - laying claim to the glass facade, and a copper curtain rail with desk and raised bed behind. An alcove behind the kitchen hints at a bathroom. The high ceilings, large windows, and hardwood floor erases from my mind visions of dank shipping containers and is more reminiscent of a Nordic chalet.
- first visit, REACH Homes, 18/08/2018.

At base principles, REACH's prototype is a shipping container insulated with kingspan sheeting and rendered on the outside, spray foam and board on the inside - it is worth noting that spray foam is being ruled out from future builds and we will instead be using a blown wood cellulose product. Although the use of shipping containers may illicit condescension from the architectural community, Jon's lack of exposure to this snobbery has served him well in finding a material that works. For him shipping containers do not represent uncomfortable memories of first year projects, but instead are a cheap; upcycled building material, that require minimal techno-popular knowledge to work with, and that are not labour intensive to convert. All these points make the construction process easier for builders with no previous experience and REACH is one of those, having constructed the prototype with the closest relevant qualification being an NVQ level 2 in carpentry. The future of REACH, which is currently being tested through our first external project, is offsite production. Working with several modular factory partners the offsite construction technique means we can estimate a 2-3 week lead time on the houses. This is not as a method to flood the market with cheap housing that can simply be commodified but to build housing to a high standard, for minimal cost, that can remain affordable through working with CLT's; this method was only able to be explored through our simple construction method that proved the concept.

- **Waste** - The UK sends 100m tonnes of building waste to landfill every year - 25% of all materials on a building site - REACH wants to cut down on this through an environmentally conscious lifecycle. In the prototype we achieved 84% upcycled or recycled materials with panelling coming from a local restaurant and Kingspan insulation coming from the local mosque. Although insulation from the rooves of mosques is not a long term supply chain, we have reliable sources for upcycled wood, containers, and window frames and we believe many more streams will be discovered. For example, with the UPVC windows Jon told me how end of life recycling is an energy intensive process; as such manufacturers recycle the glass and keep the frames in their yards. REACH paid a nominal fee to acquire the frames, which are perfectly usable but second hand, and it has freed up space in the manufacturer's yard. This critique extends to not just waste in the construction industry but also regulations such as Passivhaus, which only measures the environmental benefits of a building from the moment of residence, not from construction meaning, for example, that although a

house may be environmentally friendly to live in it still could be using petrochemical insulation.

This critique of waste initially emerged from Jon's other business, the social enterprise, Strip the Willow which is a wood upcycling workshop and handily provides us with donated wood from myriad sources. From Strip's initial materials REACH's prototype was able to be created and now from the prototype REACH is looking to expand at scale. With a long term vision to undercut other waste management companies as a way to gain both materials and income. The issue we may face is the use of potentially variable environmentally friendly and upcycled materials needs to be reconciled with a standardised; modular construction process.

- **Undercutting** - The construction process, through upcycled materials and not-for-profit delivery, means that REACH has costed, not including the price of land, a one bedroom house for ~£35,000 and a two bed for ~£65,000 - a fraction of the market rate. The not-for-profit model means REACH's costs are the sum of labour + materials, with a contingency fund and any surplus being used to subsidise people who wouldn't be able to afford a home under REACH's scheme. As Jon bemoans, the big house builders have used their lobbying powers to remove both the Zero Carbon Hub in 2015 and the Code for Sustainable Homes, but REACH demonstrates that these goals can be achieved for a fraction of the price. Affordable housing doesn't, and shouldn't, be an excuse for bad design and construction, nor should it be only for people who are excluded from the housing market.

When I first visited the prototype I saw its quaint charm but was blinded by my own visions of architecture faux pa's and assumed that because REACH used shipping containers that it wasn't about the glorification of the aesthetics of the material, but about a good material that will do its job. This idea has changed within me Jon has made it explicit that creating these beautiful communities with resident control instils a sense of ownership and pride that is currently missing from most UK housing projects - unless you include the jealous pride and gloating over the newest; unnecessary extension.

By looking at the role of materiality within REACH holistically a series of critiques emerge around construction waste, cost, and knowledge. Externalities that we did not expect include a critique of fuel poverty - the prototype has not paid a fuel bill due to its solar panels and insulation. We have also provided a critique of a series of policy decisions on housing and, as Jon reminds me, the prototype would be Passivhaus rated if only REACH could have afforded triple glazing in the initial build.

Land

Jon's proposal, to consider the social value of land over its financial value is simple enough, but we are so weighed down in the existing system of profit that it will take a big leap to get there. He puts the crisis of land ownership into clear terms, it's not just the "undeserving poor" anymore:

"35% of people, that the New Resolution Foundation Report the other month said, are never going to aspire to home ownership. Which is good if you're a landlord, cos you've got an income forever" Jon laments. "it's basically 12th century feudalism dressed up in 21st century clothing, with the veneer of democracy to make people think they've got a say, which they then don't listen to anyway, and even if, y'know, even if another government does get elected it still has to work on the same civil service and the same investors and the same lobbying groups, the petrochemical industry, the big builders."

- Jon and I discussing land ownership, 18/08/2018.

With little start-up capital, lack of access to developable land has been the key barrier for REACH. A Catch-22 has emerged whereby major funding that has been granted to REACH has been contingent on a piece of land to work on and certain local authority's will not allow a transfer of their land without the funding being in REACH's bank account. This section will explore REACH's non-monetary tenure at Heeley City Farm and the barriers we are currently facing in our search for the site of our first housing project.

- **Heeley City Farm** - The prototype is located at Heeley City Farm, the farm was started in 1981 and was born out of the community's fight against a proposed bypass that would split the neighbourhood. It is a not-for-profit charity and community centre specialising in energy and environmental efficiency, and health and wellbeing. Being a not-for-profit start-up, REACH had little financial capital to rent or buy land in the traditional way. Instead they approached Heeley City Farm and made an agreement that rather than paying for the land in money they would provide energy through their roof-mounted solar panels. This tenure model has been well received as the prototype uses only 10% of the energy of a traditional house, meaning it hasn't paid a fuel bill and has produced a considerable surplus for the farm. Jon also mentioned his presence in the prototype has reduced anti-social behaviour on site, including drug consumption and graffiti - these externalities were unimagined by REACH when the prototype was constructed but because the land transaction is decommodified neither party is losing out - the farm is not having to pay reach extra for the security benefits and we wouldn't expect them to.

This transaction is leading to many different decommodified land acquisition strategies for REACH, from opening up further discussions with local interest groups (who have land but no capacity to build), to explorations into formalising alternative tenure models. This is something I steered REACH's decision on, originally they were not concerned if their houses were sold on for profit as they believed that their job was to provide immediate housing. I explained that if an investor could buy a house and then immediately either rent it or sell it on the market they would gain a profit many times higher than our cost of production and therefore would increase speculation. This would mean rather than us combatting the housing crisis we would be simply exacerbating it without gaining the profit. To combat this, REACH are researching different tenancy models and contracts, such as LILAC Co-operative's model which is a Mutual Home Ownership Scheme which allows democratic control of the housing community and fixes the land value. This discussion was enabled through the decommodified transaction between Heeley City Farm and REACH; it forms the foundations to REACH's goal of undermining existing land ownership.

- **Barriers** - whilst the construction of the prototype has been a tool for legitimising REACH, wading through the quagmire that is the bureaucracy of the state to acquire land has been, and continues to be, arduous. A key example was a meeting that had been cancelled 3 times over a 3 month period. The meeting was for a small site in an estate that would allow REACH to build around twelve houses; positive discussions had been going on for around 18 months. Despite the delays we felt sure the council was going to allow us to develop the land. Here is an extract from their email post 20 minute meeting (19/12/2018):

"the Council does not feel that this site is the best location for your proposal given the proposed mix. The site is located in an area of low cost, low value and therefore there are a range of affordable and low cost housing options in this area which people can access. The Council is keen to promote more mixed communities and therefore it is felt

that this site is better suited to more traditional housing.”

Unfortunately, as one REACH member pointed out, this Council’s policy for ‘mixed communities’ appears to be building luxury five beds in poorer areas to increase land value whilst keeping affordable housing options away *“from’ posh end ‘v town”*.

Whilst we understand the council is under immense pressure from austerity cuts and has been put in competition with other councils for private capital we are also aware that much of the current affordable housing stock is severely dilapidated and not meeting environmental targets. We also found out, through sympathetic dissidents in the council, that Jon’s vocal support of the Sheffield Tree Action Group had been a factor in their decision to not grant us development.

This is one example but highlights a continued problem we have been facing, the private sector is profit oriented and trying to avoid building affordable housing, the state is unwilling to provide the land and is looking to entice private capital. For REACH to infiltrate these institutions we need to provide credible alternatives and become a legitimising force for change.

Heading back to first principles we realised that, apart from providing the basis for alternative ownership models, the primary actors in the prototype land deal, REACH and Heeley City Farm, were both community projects. Since then, although we have been continuing engagement with local state actors, we are focussing on the community sector, specifically groups that have land granted from previous councils and state actors. We find they have a tendency of wanting to do ‘something’ but don’t have the capacity (either in knowledge, time, or confidence) to build. We propose a shared vision for their land to be productive, for community benefit, and without profit being derived. This land development proposal critiques not only the private sector’s ‘race to the bottom’ bids for land development, resulting in poor design, but also stands against state bureaucracy which is impeding sustainable, truly affordable housing. This direction for REACH, borne out of the prototype tenure, provides a workable alternative for infiltration into the market system.

The Critical Extension of Dwelling

Through my time at REACH I have discovered alternative material supply chains, decommodified tenures, the difficulties of land acquisition, participatory methods of construction, and the series of barriers that need to be broken to allow these processes to be reproduced. Yet although we have grand ideas being tested on the ground, REACH is still in its infancy - carving our niche in the housing construction industry that is monopolised by a small cartel of companies, who use their hegemony to artificially keep demand for houses high in order to bypass any notion of sustainability or truly affordable goals (see the forced the closure of the Zero Carbon Hub in 2015 and the demise of the Code for Sustainable Homes). As such, we are having to reflexively consider our position on taking jobs. Our first external project, rather than being a house, is a meeting room for an environmentally driven building society. The phrase we are accustomed to saying is *“it’s not a house, but”* followed by several differing explanations of how this next project will allow us to refine our offsite building technique, secure new supply chains, and build a relationship with the building society who have potential capital at their disposal. Perhaps more importantly it is a method of legitimising our work because, although it has been a catalyst for our next project, Jon is forever explaining *“This is just the badly torn up sheets version”*, when referring to our prototype. This build is critical as many actors are waiting to see our outcome, we have attracted interest extending to both the House of Commons and Lords, a series of charities, and leading offsite production companies. Although REACH doesn’t have a housing project yet, we are influencing other parts of the sector. REACH launched the National Federation of Affordable Builders (NFAB) in July 2018 to provide a voice to SME’s in the construction industry so we can work collaboratively to promote the building of homes that are financially, environmentally, and ethically sustainable. The founding of and work on defining NFAB’s terms of reference, has meant we are engaged with national policy in several meaningful ways; Jon has recently contributed to the government White Paper ‘Neighbourhoods of the Future’.

These activities, that may appear strange to traditional activists, are necessary for a change in the UK housing situation. Instead of waiting for full blown revolution to topple the government creating the change to housing requires negotiations between REACH and diverse actors. For instance we want to demonstrate to developers that we can build the affordable housing stipulated to them by the Planning Department for cheaper than paying a contribution to Section 106 would be. This isn't watering down our values but a means to an end, a method to produce within, and against, the housing market. These homes could have protective covenants to stop them being objects of market speculation and this would require a negotiation with Council's to create new policy. Thus by looking holistically at the problem we consider modes of production, consumption, and reproduction that critique the current housing model whilst working within it - creating workable alternatives and demonstrating to a range of actors that change is possible. Though perhaps Jon has always known that the housing problem must be looked at holistically, 18/08/2018:

"That's why it's so important that this works, because we can show a completely different model and a completely different way of making a success out of building houses that people actually want, where they want them, so community led, involving people in the design and the place where they're gonna be living. That gets round some of your more outside the box things your builders don't normally take account of like mental health and wellbeing, crime, antisocial behaviour. If you're building the right houses in the right places with the right things around them... you can do all sorts."

Acknowledgements

Massive thanks to the REACH team for being the fantastic people they are and keeping me going on this journey, and to my PhD supervisor Leandro Minuchin for being hugely supportive and keeping me on the straight and narrow.

Identifying the Impacts of Union Stations on Housing Price in Kaohsiung City, Taiwan

Cheng-Kai Hsu¹, Yen-Jong Chen²

¹*Imperial College London, ckh4618@ic.ac.uk*

²*National Cheng Kung University, Taiwan, yj_chen@mail.ncku.edu.tw*

Abstract:

The aim of this study is to investigate the impacts of proximity to different mass rapid transit (MRT) stations on housing price in Kaohsiung City, Taiwan, in terms of the number of their transit lines. Kaohsiung is the only city in Taiwan where more than four different transit services were developed and built jointly in/around MRT stations as union stations, i.e. High-speed Rail (HSR), Light Rail Transit (LRT) and Commuter Rail Transit (CRT). Constructing such union stations is a way of implementing Transit-oriented Development (TOD) to synergize land use and transportation for promoting accessibility and sustainability in cities. This could lead to an increase in land value and housing price around the TOD project due to the increased proximity to the transit station. The uplift for housing price has been well studied by analyzing single stations or comparing stations across cities; however, little attention was paid to different types of transit union stations, where multiple transit rail lines converge. This study proposes that a union station project, in particular, could lead to a greater increase in the housing price due to its greater connectivity. This study hypothesized that if more types of transit lines are jointly constructed in a union station, it will bring about a larger effect on lifting housing price. The study collected housing transaction data from a real estate information system published by the Department of Land Administration, Taiwan, and built four regression models to test the hypotheses. The results show that union stations generally have larger impacts on lifting housing price, but rejected the hypothesis that three-modal union stations can exert a larger impact on housing price than two-modal union stations. The discussions and limitations are noted in the conclusion for further study.

Keywords: transit-oriented development; union station; housing price

Introduction

Transit-oriented Development (TOD) aims at synergizing land use and transportation to guide city development, by providing various benefits — reduced cost, time, congestion, clean air, walkable neighborhoods. The land around TOD projects thus could be valuable, uplifting neighboring housing price due to the increased proximity to transit stations.

The literature has cited accessibility provided by different types of transit stations as a factor positively influencing housing price significantly. The most common way of assessing how housing price is affected by the accessibility is to include the proximity factor in the analysis (Higgins and Kanaroglou, 2016, Duncan, 2011a). Some assessed the influence of single transit station, e.g. CRT station (Shi and Guo, 2009, Zhang *et al.*, 2016), MRT station (Grass, 1992), LRT station (Hess and Almeida, 2007, Duncan, 2011b), and Bus Rapid Transit (BRT) station (Dubé *et al.*, 2018).

The impacts of different transit services on land-value can be uneven (Cervero and Duncan, 2002), e.g. rail stations have a higher positive impact on the housing price compared to LRT and MRT stations (Debrezion *et al.*, 2007). By comparing more than 130 analyses across 60 studies over 40 years, Higgins and Kanaroglou (2016) also found significant differences in changes to land value across transit modes, and concluded that MRT and CRT have larger impact on land value compared to LRT and BRT.

However, little attention was paid to different types of transit union stations in terms of what joint rail types are built in the stations. Although the uplift for housing price has been well studied by analyzing single stations and comparing these stations across cities. Station construction guided by TOD could take form in union stations, where different types of rail lines converge and share the facilities, in order to provide higher connectivity between among various rail line services, allowing the passengers conveniently transit.

This study proposed that union station projects, in particular, have a larger impact on the increase of housing price in the neighboring communities. That is, more types of transit services jointly constructed in a union station could bring about a larger effect on lifting housing price. Thus, it was hypothesized that union stations have a more powerful impact on housing price compared to single stations. Another hypothesis is that union stations constructed by three-modal union stations have more impacts on housing price than two-modal union stations. This study employed official housing transaction data and regression models to test the hypotheses.

This paper is structured as follows. First, the study area, data sources and methods used in this study are discussed. Second, research results are presented. Third, the results were discussed by comparing previous research, and suggestions are noted for further study in the conclusion.

Data and methods

The empirical analysis in this study utilized multiple regression models to investigate the influence of proximity to stations on housing price. Prior to the model building, official housing transaction data in Kaohsiung were collected, and processed using ArcGIS. A model was then built for analyzing the transaction data within 1km to MRT stations in Kaohsiung, followed by three models being built for investigating the difference in influences of three types of stations, namely three-modal union station, two-modal union station and one-modal station.

Data collection and processing

Kaohsiung provides a particularly rich setting for studying how the housing price is impacted by different transit stations. It has four different modes of public transportation, i.e. MRT, LRT, HSR, and CRT, which is a trait other cities in Taiwan do not share.

The study employed housing transaction data for the empirical analyses, which consist of houses, apartments, and condominiums. The core data were drawn from the official website, a real estate information system published by the Department of Land Administration, Ministry of Interior, Taiwan, covering the information about real estate transactions from 2011 to 2015. In total, 174,913 housing transaction data were obtained, as shown in Figure 1(a).

According to the number of transit lines jointly built in an MRT station, this study specified three types of MRT stations as representatives, i.e. New Zuoying Station as a representative for three-modal union stations (MRT, HSR and CRT), Kaohsiung MRT Station for two-modal union stations (MRT and CRT) and Judan Station for one-modal stations (MRT only), as shown in Figure 1(b). The study used only those transaction data within 1km from the stations because people generally are willing to have a 10 minute walk to MRT station (Dwess, 1975; Anas and Duann, 1985), and particularly around 1km in Taiwan (Chen, 2016, Lin and Hwang, 2003, Tai *et al.*, 2011).

Figure 1 Transaction data in 1 km buffer zones of MRT stations in Kaohsiung

The data contain detailed records of transactions which include the transaction price, transaction site and transaction date, and various attributes, including property type, floor area, and floor level. This study used Geographic Information System (GIS) tools to extract the transactions within a 1km radius to the closest stations; 14,825 housing transactions were specified as those near the MRT stations out of 174,913 housing transactions. Among 14,825 transactions, 839 of them are within 1km proximity to New Zuoying Station, 1,231 to Kaohsiung Station, and 2,086 to Judan Station, as shown in Figure 1(b).

Table 1 presents the descriptive statistics of the data. Within 1km buffer zone of MRT stations in Kaohsiung City, the housing price is ranged from TWD 10,000 to 104,413,300, with an average price

of TWD 7,859,500. The average floor area is 151 m². Around 18% of the housing sold are terraces, and about 37% of the housing sold are located in the commercial zone.

Table 1 Descriptive statistics of housing transaction data

Vector	Variable	Code	Min.	Max.	Mean	Std.
Structural	Housing price (TWD 1,000)	PRC	10.00	10441.33	785.95	1416.07
	Floor area (m ²)	HSAR	5.91	4752.09	151.23	147.10
	Fourth floor (1: yes)	STOR	0	1	0.08	0.28
	Building type (Terrace or not) (1: yes)	TYPE	0	1	0.18	0.38
Neighborhood	Commercial zone (1: yes)	COM	0	1	0.37	0.48
Proximity	Distance to station (meter)	ST_DIS	21.98	999.19	559.34	232.89

Source: Ministry of Interior, Taiwan
The exchange rate is USD 1 to TWD 33

Due to the fluctuation of GDP, the data before 2015 were adjusted by the consumer price index (CPI) and GDP deflator, as listed in Table 2.

Table 2 GDP deflator in Taiwan (2015 as base year)

Year	2011	2012	2013	2014	2015
CPI	100	101.93	102.74	103.97	103.65
GDP deflator	1.036	1.016	1.008	0.996	1

Model specification

Empirical studies mainly employ four model specifications for housing price estimation, namely linear, semi logarithmic, double logarithmic, and log-linear (Debrezion *et al.*, 2007), which were all employed in this study. The basic linear regression model for estimating the housing price is given by Eq.1 below.

$$P_i = f(X_i, Y_i, Z_i) \quad (1)$$

The dependent variable P_i is the estimated price of housing i , X the vector of structural characteristics (e.g. floor area), Y the neighborhood characteristics, and Z the vector that measures proximity to the transit station. As shown in Table 1, the vector X includes housing price, floor area, floor level (fourth floor or not), and building type (terrace or not). The neighborhood vector attribute is property location (whether it is located in a commercial zone). The vector Z includes distance to the nearest station. Six variables were included to explain the housing price. Accordingly, the above model was refined as the following model given by Eq.2.

$$PRC_i = \beta_0 + \beta_1 (HSAR)_i + \beta_2 (COM)_i + \beta_3 (STOR)_i + \beta_4 (TYPE)_i + \beta_5 (ST_DIS)_i \quad (2)$$

HSAR represents housing area; TYPE is whether the housing sold is located in a commercial zone; COM shows if the housing sold is a terrace. STOR means whether a transaction involves the fourth floor, as people tend not to buy a housing on the fourth floor, which shares a same pronunciation of

death in Taiwanese (Lin *et al.*, 2012). Since variables COM, STOR and TYPE are dummy variables, this study adjusted the double logarithmic model accordingly as follows.

$$\ln \text{PRC} = \beta_0 + \ln \beta_1 (\text{HSAR}) + \beta_2 (\text{COM}) + \beta_3 (\text{STOR}) + \beta_4 (\text{TYPE}) + \ln \beta_5 (\text{ST}_{\text{DIS}}) \quad (3)$$

Results

This section explains the result of each model. Prior to investigating influences of different union stations using three local models, a global model was built to fit the data within 1km buffer zones of all MRT stations in Kaohsiung.

The global models for all MRT stations in Kaohsiung

This study first confirmed that the correlations among variables are low enough to not cause the collinearity effect. Table 3 shows the highest correlation among the five variables is less than 0.3, suggesting all variables are not considered highly correlated.

Table 3 Result of the correlation analysis

	HSAR	COM	STOR	TYPE	ST_DIS
HSAR	1				
COM	.044	1			
STOR	-.050	-.030	1		
TYPE	.028	-.222	-.142	1	
ST_DIS	.003	-.243	.005	.090	1

The results of the four regression models are listed in Table 4. Each variable in the four models has a high explanatory power at the 99% confidence level, as shown in Table 4. This means all independent variables could help explain the housing price within the 1km buffer zone of all MRT stations in the study area. Among the four models, the double logarithmic model has the highest explanatory power with an R² of 0.718, followed by the linear, log-linear, and semi logarithmic models.

Table 4 Effects of the independent variables on housing price in four regression models

	Linear		Double logarithmic		Log-linear		Semi logarithmic	
	coefficient	p-value	coefficient	p-value	coefficient	p-value	coefficient	p-value
Const.	139.285	***.000	0.586	***.000	5.663	***.000	-3865.11	***.000
HSAR	6.646	***.000	1.234	***.000	.004	***.000	1159.237	***.000
COM	88.636	***.000	.190	***.000	.084	***.000	217.382	***.000
STOR	-92.533	**.002	-.194	***.000	-.283	***.000	-111.472	**.002
TYPE	221.926	***.000	.285	***.000	.368	***.000	227.307	***.000
ST_DIS	-.258	***.000	-.067	***.000	-.001	***.000	-167.543	***.000
Adjusted R ²	0.493		0.718		0.388		0.270	

*p<0.05 **p<0.01 ***<0.001

The signs of coefficients for HSAR, COM and TYPE are all positive, showing that housing price tends to be higher due to greater floor area, neighboring commercial area and building type (terrace). The

signs of STOR and ST_DIS are both negative, suggesting the presence of the fourth floor and a greater distance to station would lead to a lower housing price.

In the linear model, it suggests when an increase of 100m in distance to station, a drop in housing price of TWD 258,000 could be expected. In the double logarithmic model, when the distance increase by 0.1%, the housing price would drop by 0.07% at 95% confidence level.

The local models for New Zuoying, Kaohsiung, and Judan MRT stations

To test the hypothesis proposed in this study, three representative stations were chosen for their different mode types in the union station. The New Zuoying Station has three railways, i.e. HSR, CRT, and MRT; the Kaohsiung Station has two railways, i.e. commuter rail and MRT; the Judan Station has only MRT. Since the double logarithmic model has a higher explanatory power among global models. It is used to test the hypotheses. The results are shown in Table 5.

Table 5 Results of the local model

	New Zuoying		Kaohsiung		Judan	
	coefficient	p-value	coefficient	p-value	coefficient	p-value
Const.	1.267	***.000	1.387	***.000	.631	***.000
HSAR	1.181	***.000	1.229	***.000	1.255	***.000
COM	.120	***.000	.077	***.000	.112	***.000
STOR	-.029	.440	-.145	*.010	-.112	***.000
TYPE	.466	***.000	.545	***.000	.178	***.000
ST_DIS	-.123	***.004	-.182	***.000	-.045	** .004
Adjusted R ²	0.770		0.798		0.757	

*p<0.05 **p<0.01 ***<0.001

It was initially hypothesized that more modals in a union station would have a greater influence on housing price and thus have a larger elasticity. Thus, three null hypotheses are proposed, i.e. $\beta_{ST_DIS}^{ZUO} = \beta_{ST_DIS}^{JU}$, $\beta_{ST_DIS}^{KAO} = \beta_{ST_DIS}^{JU}$ and $\beta_{ST_DIS}^{ZUO} = \beta_{ST_DIS}^{KAO}$.

The first two hypotheses are rejected as the F-values are 160.3 and 130.58, compared to the critical value of 3.12 (df=5, ∞). Hence the reduction in the elasticity is therefore significant at the 95% level, indicating that the union stations generally have larger impacts on housing price than single-modal stations. However, comparing the coefficients of ST_DIS in the New Zuoying model, and Kaohsiung model shows that the influence of Kaohsiung MRT Station as a two-modal station is larger than that of New Zuoying MRT station.

Conclusions

The impact of transit station proximity on housing price has received wide attention in the transport and land economic literature. Several studies investigated the impact by analyzing a certain mode of transit station or comparing different modes of a transit station. This study further introduced a new factor, the number of transit mode in station, to explore the difference in the impacts on housing price. This study confirmed that union transit stations have larger impacts on housing price as the elasticity of proximity with respect to housing price is greater. However, the results show that the impact of three-modal stations is not greater than that of two-modal stations.

The Kaohsiung MRT station is built before the New Zuoying Station and its influence on the housing market might inherently be larger. The study found that the housing price fluctuation is significantly higher between 2010 and 2015, compared to Wu (2010) that employed data from 1997 to 1999 and suggested an increase of TWD 38,000 when a drop of 100m in proximity to the MRT station. This indicates that further study should take temporal factor into account.

Moreover, a bus transit hub is located near the Kaohsiung MRT station, which is considered in the study as it is not physically constructed in the station. Nevertheless, further study could attempt to include other transit services near the union stations.

On the other hand, HSR in the New Zuoying station provides regional transit instead of intra-city transit service, which possibly reduce the impact on local housing price. Further study could expand the research scope to include different cities that also have HSR to confirm that inter-city transit rail has less impact on the local housing market. Different combinations of modes in union stations could also be explored, e.g. MRT station combined with LRT, or that with HSR, for a deeper understanding of their influences on housing price.

The possibilities and limitations of the state and local authorities' activities in resisting financialisation of the housing sectors in Central and Eastern European Countries

Piotr Lis¹

¹*Poznań University of Economics and Business*

Abstract: The liberalisation of the housing sectors in Central and European Countries since the beginning of this century, given the macroeconomic stabilisation of these countries, influenced the development of housing loans as a primary instrument of satisfying housing needs and wants, with large growth dynamics of the household debt. The main aim of this paper is to evaluate the possibilities and limitations of the state and local authorities' activities in providing adequate and affordable housing and resisting financialisation in the years 2000-2018. A growth in financialisation resulted partly from the fact that newly established households preferred in particular the ownership right, especially due to its limited scope in the period of the centrally planned economy. Furthermore, this growth came as a result of the fact that the segment of dwellings for rent – both private and social – did not work well. Significant commodification of dwellings, mass privatisation of the housing stock and the accompanying process of decentralisation in some countries, with a residual character of social housing and marginal private rental, as well as higher social stratification are the features of the contemporary system of provision for housing in CEEC.

Keywords: housing, liberalisation, housing policy, state intervention, Central and European Countries

Introduction

The main aim of this work is to assess the capabilities and limitations of conducting housing policy in Central and Eastern European Countries. When it comes to the capabilities of housing policy, there are arguments justifying state intervention in the economy, transferred to the area of housing. On the other hand, as for the housing policy limitations, there are arguments against state intervention. The author makes two theses: firstly, what should be the priority in housing policy is the creation of institutional bases and stimuli in order to increase the participation of dwellings for rent in the housing stock, while the state should not take over the exclusive rights in this respect, and secondly, there must be principles in the social housing stock which create credibility of this segment and enable its efficient functioning.

Housing policy is one of the sector policies conducted both by central and local governments, engaging public and private entities as well as social organizations to attain its main, long-term goals within the housing area. These goals include: a) creating conditions for all citizens to purchase or rent housing stock, b) ensuring the availability of dwellings, and c) ensuring an appropriate quality of the housing stock throughout the period of usufruct (Cf. Lis 2008). Housing policy is also understood, in a broader

depiction, as major directions and methods of functioning of the state and other public institutions, as well as political and social organisations, which have an influence on housing and satisfying the housing needs (Cf. Andrzejewski 1978, Lis, 2011, Zubrzycka-Czarnecka 2016). From the macro perspective, housing policy is partly convergent with economic policy in terms of the functioning of housing, financial and capital markets. From the meso and micro perspectives, housing policy is an element of urban policies (Cf. Zubrzycka-Czarnecka 2011, 2012).

Detailed specification of the main aims of housing policy should refer to the housing needs of the citizens and the housing demand reported at a given time and place, whereas the manner of realising the “right to reside” has an influence on the social model functioning in a particular country (Cf. Lis 2005, 2017). The shape of the housing needs and their change in time and place is a key determinant of defining the main aims of housing policy. Determining the scale and character of the housing needs of a given community requires at least specifying the housing standard, including the minimum requirements in this respect, the structure and features of households. It shall be noted that assessing the housing needs from the perspective of housing policy is made externally, in an aggregated manner, and not by particular, individual households. Consequently, there may occur a discrepancy between the expectations of individual households and the housing needs of a society, identified at a local, regional, national or international scale. The expectations are individualised and refer to the perception of oneself, one’s own aspirations and social status which people want to gain (more in Levine 1995, King 2009). Levine (1995) stresses that expectations may and should be realised with the use of market mechanisms, whereas unsatisfied basic housing needs should become an area of state intervention. That is why the expectations should be closely connected with the possibility of choice, while satisfying the housing needs may include certain limitations of choice, depending on the wealth of particular economies or regions.

Taking into consideration the experiences of the CEEC countries, the common forms of realising social housing include above all housing for rent, and especially municipal housing realised by local authorities, social housing for rent, which is completely or partially dependent on local authorities, as well as social ownership housing realised by private investors with the use of public funds. Municipal housing is interventional or social in its character, most frequently understood as satisfying the housing needs of households with the lowest income. Dwellings created within municipal housing are identified, especially in the countries which have undergone economic transformations, as the low-standard stock, placed either in central or peripheral spheres of cities and inhabited almost exclusively by low income households. Making such low-standard districts inhabited by a certain group of people may cause social tensions in a given town, social exclusion, increase in the crime rate and degradation of urban districts. The above solutions serve as a strong argument for expending the influence of social housing policy to other forms of housing and aiming at the complementarity of housing programmes with intervention conducted within economic, social and spatial policies. Social housing for rent may be realised by non-profit organisations, which many a time belong to local authorities, with the use of public subsidies. The access to the social stock for rent is most frequently limited to a certain target group. State intervention within social housing policy may also apply to collaborative housing, such as co-housing, housing co-operatives and other forms of collective self-organised housing (Czischke 2018). Housing intended for rent or sale is realised with an aim to obtain a profit by different investors. Without possessing adequate financial resources for realising a bundle of aims, the state looks for ways to include the private sector more and more broadly in providing and co-financing the social housing. In this

respect, of key importance is the issue of the scope and conditions (rules) for investors' participation in social investments and the phenomenon of information asymmetry, as well as negative selection, which occurs within this kind of partnership. The scope of indirect intervention of local authorities depends of the size of public funds assigned for social housing, but also on the ability to utilise market mechanisms for financing housing investments in order to realise the social aims. Taking into consideration the housing sphere in the CEEC countries, we may observe growing involvement of private investors as we move upwards the income segmentation of households, i.e. towards wealthier residents. As a result, it is necessary to exercise caution in housing policy while financing housing investments for wealthier members of the society with public funds.

Justifying the state's active policy within the housing sphere. Determining the capabilities to act

Attaining the main goals of housing policy in contemporary market economy requires some activities undertaken by the state. The state's main roles are: ensuring proper functioning of the housing market in the areas where it is economically efficient, correcting market failures, ensuring social justice and aiming at social, financial and political stability.

Contemporary state activity in correcting housing market failures should regard providing complete information about the functioning of housing markets, shaping the prices of particular segments of the real estate market in the long run, the number of transactions made, geographical placement of transactions, potential for development of particular housing markets. The state's actions should lead to reducing the expectations concerning further growth in real estate prices, especially at the ascending phase of housing cycles. Given such a high level of financialisation of the housing sector, it is yet another accelerator for further growths in real estate prices and separation of housing markets from their foundation of a long-term and stable growth.

Another premise of state intervention is an increase in social justice, which determines the allocation and redistribution of the housing stock. Social justice may be interpreted either from the perspective of the equality of chances and their compensation from the very beginning (horizontal justice) or from the perspective of the redistribution needs (vertical justice). One of the key aspects of the former approach is an equal access of all citizens to 'market gambling', even though 'the game' may bring different results to the participants, depending on their capacity and the amount of work they have done. The latter approach emphasizes the necessity of compensating the results (income), irrespective of the capacity or the amount of work performed by the citizens. In market economies, both depictions of social justice may be found, yet they function to a different extent and in different configurations. This serves as a crucial criterion for determining the welfare state models, including the housing system models.

The concept of social justice (horizontal and partially vertical) within the housing area concerns above all two aspects: aiming at social cohesion and shaping conditions to fulfil housing needs of young people who enter the labour market for the first time. Creating the conditions for shaping social cohesion by the state follows the assumption that one's surroundings and housing conditions serve as one of the elements which determine the citizens' chances for success in their lives.

The concept of vertical justice in the housing area is closely connected with the realization of the so-called social housing policy set apart from housing policy. The realisation of the main housing policy goals requires specifying particular instruments with reference to the homeless and housing-excluded,

people with a low-economic status, particular social groups (including the disabled, long-term unemployed, single aged people, families with many children, single-parent families, emigrants and refugees, ethnic minorities, people threatened with eviction onto the street, people living in dangerous neighbourhoods, young married couples, students). However, it has to be highlighted that the criteria allowing for the identification of sensitive groups vary considerably according to the country and tend to change with time. The basic criteria included among all income, age, marital status, health condition, social class, race, place of residence. The main aim of social housing policy is to fight against homelessness and housing-exclusion.

What shall be highlighted while realising the conception of horizontal justice is the fact that the state's actions are concentrated within the social housing stock (Przymeński and Oliwa – Ciesielska 2014; Suszyńska and Rataj, 2017, Szelągowska 2011). Proper functioning of this stock requires specifying and following by the state both the principles of accessing the stock and the conditions determining the necessity to leave the stock, estimating the households' capability to rent or purchase dwellings in the social stock, as well as defining the scope of legal protections of the tenants and owners of the social housing stock. At the same time, it shall be noted that the principle of allocating the social housing stock on the basis of the income criterion will not always reflect the most "urgent" housing needs (Lis 2011). Such a situation may lead to omitting those individuals who have serious housing problems at an income which is temporarily above the criterion of accepting into the stock or choosing (by the administrators or owners of the social stock) those persons from the waiting list who are characterised by the lowest risk of failing to fulfil one's duties as a tenant. What shall be highlighted at the same time is the fact that implementing the criterion housing needs as a supplement to the income criterion should entail imposing the principles of inhabiting the social stock (including the conditions, limitations and requirements) on the beneficiaries of state support, together with the possibility of excluding those individuals who fail to comply with the principles or relocate such individuals to lower-standard dwellings.

The last highlighted premise for state intervention in housing concerns ensuring sustainable development of the economy. Housing crises may extend and deepen the impending economic recession. They may also lead to banking crises. Ensuring sustainable development of the housing sphere makes it possible to overcome economic recessions in a less drastic way, taking much less time. Thus, contemporary housing policy becomes one of the important areas of economic stabilisation (Lis 2015). It seems justified to describe this premise in more detail.

The process of marketisation of the housing sphere developed incredibly dynamically since the 1980s in Western European countries, and since the 1990s in the CEEC countries. The state (government and local authorities) began to withdraw from direct intervention in the housing sphere, limiting themselves to satisfying the housing needs of the poorest or identified sensitive groups, and especially families with many children or first-time buyers. The institutional surroundings, including the actions of the Directorate-General for Competition in the European Union, were greatly unfavourable of wide state support in the housing sphere in the first decade of the 21st century. An example of this were, among others, explanatory proceedings concerning the Netherlands and Sweden for with regard to their overly developed system of social dwellings (Lis 2018). The global financial crisis of 2008, which subsequently turned into an economic crisis, and in some EU countries also into a debt crisis, exerted an incredibly strong impact on the changes in the assessment of the state's actions within the housing sphere. Social housing is becoming an increasingly important part of European economies, more and

more accepted by EU institutions. A strong connection between the global financial system and local housing markets, which has been created over the last decades, resulted in the fact that social stability in particular countries is closely related to balanced development of the housing sphere (Lis 2015b, 2015c). It has been proven that the greater the participation of ownership dwellings in the housing stock, the greater the instability of the housing sphere of a given economy (Lis 2015a). An explanation for this kind of interdependence occurring in 1990-2014 in the CEEC states was an extremely strong connection between the real sphere and the financial sphere at that time. The financial system strengthened the force of its influence alongside its development. Thus, the financial depth increased considerable, which may be corroborated by the fact that the higher the level of granted loans was compared to the GDP in a given country, the higher the participation of less wealthy persons in the credit structure was (Lis 2012). Another issue concerns the available and relatively cheap money in the housing sector, and the threats which it entails. The influence of cheap housing loans, which is very dangerous yet positively assessed from the perspective of an individual household, accelerated the growth dynamics of housing prices extremely fast. It results primarily from the fact that an increase in the real estate value becomes an additional benefit for those who had a chance to take out a mortgage loan to purchase a dwelling. Obviously, only these benefits are generated together with growing transactional prices for housing real estate. Increasing the participation of dwellings for rent (applies to rent based on market principles) in the housing stock breaks this dependence. The condition is to change the structure of the housing stock, and not just new housing institutions functioning within the housing surplus.

The state's weaknesses within the housing sphere. Determining the limitations to act

Research on housing systems often omits such limitations of the normative ('classical') theory of housing policy as the nature of entities and the behaviour of politicians (Acocella 2002). The housing system does not consist of uniform entities, i.e. the owners and tenants, and the politicians and officials who take housing-related decisions are not anonymous. Particular entities form groups based on similar interests, needs or opinions, and they operate through their organizations – interest groups, lobbies, political parties, in order to ensure the realization of their own preferences, irrespective of and even at the cost of other groups. Politicians, on the other hand, express their own preferences and interests, and their main aim is reelection for another term of office (Nordhaus 1975).

On the basis of the above limitations concerning the normative housing policy, one may articulate the guidelines for limiting state intervention, especially in the area of direct interaction, i.e. the social housing stock. The major accusations concern the process of planning, designing, financing and realizing social housing investments, as well as managing the social housing stock that has emerged. Duncan MacLennan and Alison More (1997) discuss four main problems resulting from the state's engagement in the housing area as: preferential unadjustedness, excessive costs of realizing an investment, inefficient exploitation of the stock and politicising the process of allocation and management of the social housing stock.

In the CEEC countries, it is noticed that social housing is becoming unadjusted to the housing needs of future tenants (for example, social dwellings are located on the outskirts of towns). Furthermore, the social housing stock, in which the basic principles of admission and departure have not been specified, becomes unadjusted to the changing structure of tenants over their course of life. On the other hand, lack of market mechanisms in terms of the investment process in social housing resulted in obtaining the costs of producing 1m² of residential usable area which are higher than their market value. A non-

market price for the housing stock and non-market rent rates do not lead to an optimal use of social dwellings.

In relation to CEEC, the weakness of housing policy is also the creation of an imbalance between the ownership and rental of the housing stock. The subsidy regime and privatisation led rational households to prefer homeownership over municipal and private rental housing (Csizmady *et al* 2017). Of course, an excellent factor strengthening this imbalance is the financing of the housing sphere so typical for CEEC countries.

Conclusions and discussion

The main aim of the work has been to assess the capabilities and limitations of conducting active housing policy in contemporary CEEC countries. What should be the priority in housing policy is the creation of institutional bases and stimuli in order to increase the participation of dwellings for rent in the housing stock, while the state should not take over the exclusive rights in this respect. In general, housing policy should be incorporated into market mechanisms, and not supersede or replace them. Of crucial importance in housing policy, especially in the face of cheap money available to a part of society, excluding the other part of the inhabitants, is to provide information to market participants about the development of housing markets, market cycles, shape of prices and rent rates, possibility of renting dwellings and consequences of purchasing dwellings.

The state's actions should be arranged depending on a segment of influence reflecting the urgency of objectivised housing needs, with limitations to public funds necessary to finance the needs, from primary instruments supporting the homeless, to secondary instruments supporting those who have a court ruling on eviction awaiting a social dwelling, to third-rate instruments supporting persons with low income, to fourth-rate instruments supporting selected sensitive groups. Within the primary instruments, the key aim should be eliminating the phenomenon of long-term homelessness (Cf. Przymeński 2001,¹ Rataj 2018). This elimination may take place via realising the process of bringing people out of homelessness. The state's actions cannot be limited to ensuring an adequate number of places in lodgings and shelters for the homeless. Within the secondary instruments supporting those who face court-ruled eviction, awaiting a social dwelling, the state should act in a very determined way and on a large scale. Unblocking the queue for social dwellings is a fundamental condition for the functioning of a mass market of private rent. Within the third-rate instruments supporting poor persons, it is of key importance to define the principles of leaving the housing stock, after specifying the criteria for its residence as well as the solutions in order to reduce rent arrears. The social stock is not allocated for the rest of the tenant's life; it is supposed to play a motivational role. It is necessary in the social stock to implement and execute the principles of reducing troublesome neighbours, as well as a firm and restrictive action against the asocial tenants. The direction of increasing the patency of moving from social dwellings to municipal dwellings (changes in regulations from the social stock to social rent), which gives social tenants a possibility of social advancement and increasing the standard of dwellings (see more in Rataj 2013, 2014, 2018). It is important to resolve the issue of those who are in a difficult housing and living situation, without their own fault, those who should not be degraded by being placed in extremely sub-standard dwellings, worse than other social dwellings (Przymeński and Oliwa – Ciesielska 2014). It is of vital importance to improve the quality of the local space and public services, the environment in the immediate vicinity of residential buildings and to build a community, create a system which would involve the tenants in decision-making within this stock (Tobiasz-Lis *et al* 2019).

Particularly urgent become the actions for increasing the quality of the gmina's housing stock, bringing the social and municipal dwellings to contemporary norms concerning the housing culture. Furthermore, it seems justified to resolve the technical problem of maintaining the municipal stock within the area of implementing in housing stocks the solutions concerning the adaptation to climate changes, including low-emissions and intelligent management. Within the fourth-rate instruments supporting vulnerable groups, a comprehensive approach to social groups with special needs should be developed, in particular: people ending their stay in child care homes, large families, seniors (Hrastet *et al* 2019), disabled, immigrants, refugees. There is also a lack of complex solutions for students and graduates.

Finally, it should be emphasized that housing investments do not change the long-term trend of economic growth, but may increase the amplitudes of fluctuations in cyclical economic variables. The period of housing deficits in many housing markets in the CEEC countries has come to the end and there is no longer a unique "security buffer" (Cf. Lis 2018). The housing cycles will have more and more amplitudes, which may lead to deepening economic crises if the housing sphere is not offset by the functioning of an efficient segment of rental housing.

Suburbs and Subsidized Housing in the United States: What Makes Some Suburbs More Receptive to Low-Income Housing Tax Credit Housing Than Others?

Abstract: The Low-Income Housing Tax Credit (LIHTC) is the largest affordable housing production program in the United States. The program has been the subject of some criticism because it has done an unimpressive job of placing low-income renter households in high-opportunity neighborhoods, especially in suburban jurisdictions. This research will examine, at the municipal level, what kinds of communities tend to include LIHTC properties and which do not. The receptive communities will be compared to the exclusionary communities in terms of many measures of opportunity offered including school quality, access to gainful employment, and access to transportation. The analysis will also examine the effect of population size, socioeconomic and demographic characteristics, housing stock characteristics, and willingness to accept multi-family development. The contribution of this research will be that it will be among few efforts to analyze the LIHTC at the municipal level, adding to the knowledge needed to guide the LIHTC toward better placement of housing in the future.

Keywords: Low-Income Housing Tax Credit, Suburbs, Location of Affordable Housing, Fair Housing

Introduction

The Low-Income Housing Tax Credit (LIHTC) program is, by far, the nation's largest affordable housing production program. Since its inception in 1987, the program has produced 2.8 million housing units for low-income renter occupancy. Of these units, 2.3 million are still in service (U.S. Department of Housing and Urban Development, 2018). Created as part of the Tax Reform Act of 1986, the program has become a relatively efficient mechanism to create units for occupancy by renter households with income no higher than 60 percent of the metropolitan area's or non-metropolitan county's Area Median family Income (AMI).

Government influences where LIHTC properties are located, but the influence is indirect. Private for-profit and non-profit developers select sites for the affordable housing. The developers then apply for an allocation of tax credits from the state's pool of tax credits. If allocated, the developer uses these credits to assist in financing the development by exchanging the tax credits for equity funds from investors. The allocation of tax credits to a project is not automatic but is generally highly competitive. Developers compete with each other for a limited supply of tax credits. Each state awards its tax credits to developers based upon the merits of the proposals. The merits of the proposals are determined by scoring each against a set of so-called preferences detailed in the state's Qualified Allocation Plan (QAP). Some of these preferences are federally mandated. For example, developers receive extra credits for location properties in Qualified Census Tracts (QCTs) which are areas with concentrations of poverty. Others preferences are chosen by the state so as to direct the allocation of tax credits toward housing developments that can best serve the affordable housing needs of the state. For example, if a state has a soft market and does not need additional units, it can award preferential treatment to development proposals that rehabilitate existing housing rather than proposals that add new housing to the market.

The LIHTC program is capable of entering virtually any housing market in the nation. The program can add new units to a market, or it can rehabilitate existing units. The program can serve families that are in the work force, or it can serve populations are elderly or have special needs. Despite this flexibility, there is concern among policy analysts that the program is concentrating in some municipalities and not in others. The fear is that this concentration is causing the program's units to be located in municipalities that do not offer high quality opportunities to the assisted renter households and denying these households access to municipalities that do.

When allocating tax credits to a development proposal, the community where the proposal is to be located will be consulted. Knowing that communities will often attempt to exclude housing for low-income households, the states are not required to obtain approval from the community. However, many states require some level of local support of any proposed LIHTC development in order to award it tax credits. If communities withhold their support for a development, the lack of support can block the development from going forward. Low-poverty communities are more likely to block development of affordable housing (Scalli 2012). Ellen et al (2015) found that states were giving increased preference to projects with community approval over the period 2002 to 2010.

The research presented here determines the extent to which communities exclude LIHTC proposals. It compares receptive communities to exclusionary communities in terms of many measures of opportunity offered including school quality, access to gainful employment, and access to transportation. The analysis also examines the effect of population size, socioeconomic and demographic characteristics, housing stock characteristics, and willingness to accept multi-family development. The contribution of this research is that it is among few efforts to analyze the LIHTC at the municipal level, adding to the knowledge needed to guide the LIHTC toward better placement of housing in the future.

Literature Review

Policy analysts have hoped that the LIHTC program would accomplish more than the provision of affordable shelter. The hopes have been that LIHTC properties would be located so as to provide assisted low-income households to access to neighborhoods offering the opportunity to live safe and successful lives in economically, racially and ethnically integrated neighborhoods. These hopes mean that LIHTC properties should locate so as to serve the twin goals of, first, movement to high-opportunity communities, and second, fostering racial and ethnic integration.

Several research efforts examined the extent to which the LIHTC program located properties in high-opportunity, especially suburban neighborhoods. The expectation was that the program would not perform as the tenant-based Housing Choice Voucher (HCV) because of the mobility offered with the voucher approach and because the project-based LIHTC would confront political opposition to locating in desirable neighborhoods (McClure, 2008). Research found that, in the early years of the LIHTC program, properties were disproportionately located in distressed central city census tracts. However, as the price for tax credits

rose over time, the program became increasingly popular with developers who helped the program enter low-poverty suburban communities. The LIHTC performed as well as the Housing Choice Voucher Program in helping low-income households reside in high-opportunity suburban areas (McClure, 2006). Later, McClure and Johnson (2015) reinforced this result, arguing that the LIHTC program developers were finding ways to overcome the barriers preventing entry of affordable housing into the suburbs. Despite the improvements in LIHTC property placement, the authors found that LIHTC units were located in low-poverty tracts in smaller proportions than found in the rental market as a whole and that the share of LIHTC units located in high-poverty tracts continued to be in greater proportions than the rental market as a whole. These location metrics for the LIHTC program were found to be better than public housing and very comparable to the tenant-based Housing Choice Voucher program.

The LIHTC program is both making entry into high-opportunity communities, but it is also disproportionately placing units in high-poverty tracts. Oakley (2008) finds that the LIHTC works at crossed purposes. Looking at four metropolitan areas, she found that the added incentives given to developers to place LIHTC units in QCTs cause developers to disproportionately locate units in these areas of concentrated poverty. This pattern of clustering does not serve the goal of spatial dispersal of the poor, but it may not make matters worse. Ellen, Horn and O'Regan (2016) found no evidence of increased poverty concentration because of LIHTC locations, and they found some evidence that the program may reduce poverty rates in high-poverty neighborhoods over time. The research seems to suggest that the locations of LIHTC developments do little harm and have the potential to reduce concentrations of poverty but, overall, do little to reduce overall poverty concentration on a large scale (Freedman & McGavock, 2015; Ellen, O'Regan, & Voicu, 2009).

The concentration of poverty is an important metric to assess neighborhood quality, but it is not the only possible metric. Ellen, Horn and Kuai (2018) examine the neighborhoods where LIHTC developments are placed across a range of additional measures of neighborhood quality. These authors used a unique dataset describing the households in the LIHTC units for 12 states. This dataset permits research comparing the racial composition of the LIHTC property to the racial composition of the neighborhood to see how neighborhood outcomes vary across subsets of households. They find that, compared to all renters, LIHTC units are in neighborhoods with higher poverty rates, weaker labor markets, more polluted environments, and lower performing schools, but better transit access. Compared to other poor and minority households, LIHTC households live in neighborhoods that are significantly more disadvantaged.

Horn, Ellen, and Schwartz (2014) find that schools nearest to HCV households have higher math and reading proficiency than those schools near public housing but lower proficiency scores than those schools in close proximity to LIHTC properties and other poor renter households with children. Thus, LIHTC developments are better located in terms of proximity to higher performing schools than are households with vouchers.

Lens, Ellen, and O'Regan (2011) examined crime levels as a measure of neighborhood health. They developed a crime index for the 91 U.S. municipalities for which consistently measured crime data were available. They found that LIHTC properties tend to be located in high-crime neighborhoods at a greater rate (11.3 percent) than is true for all households (3.1 percent) or for all low-income renter households (6.0 percent). Thus, there seems to be a disproportionately high concentration of LIHTC properties in high-crime areas. Freedman and Owens (2011) looked at crime as well. They noted that the topic is poorly researched due to the lack of data at the neighborhood level across municipal boundaries. They overcome this problem by aggregating crime reports up to the county level. They found that when LIHTC properties are developed in the poorest neighborhoods, they result in significant reductions in violent crime at the county level, but they found no detectable effects on property crime.

Access to gainful employment is another metric used to assess the quality of neighborhood for low-income households. Lens (2014) created an index for the number of jobs in a neighborhood. He used this index to assess the proximity to jobs for assisted households in public housing, LIHTC properties, Section 8 New Construction developments, and the HCV program. He found that public housing households live in census tracts with the greatest proximity to jobs, especially jobs for the low-skilled workforce. He found that LIHTC developments were located less well but did locate in tracts with greater job access than did households in the HCV program.

Thus, the record of the LIHTC in poverty deconcentration and movement of low-income households to high-opportunity neighborhoods is mixed. The program is making entry into desirable neighborhoods, especially in the suburbs, but the potential for greater success remains.

The second issue surrounding the placement of LIHTC units deals with the level of minority concentration in the receiving community. Dawkins (2013) found that LIHTC properties cluster into census tracts with predominantly black populations. He suggests that the program be revised to eliminate incentives to cluster housing in QCTs with inherently higher poverty levels and often greater minority concentrations. Similarly,

Rohe and Freeman (2007) model the location of LIHTC units by census tract. They found that the percentage of black population in a neighborhood was a strong predictor that LIHTC properties would be located there. Horn and O'Regan (2011) addressed the same issue with a different approach. They examined the channels through which the LIHTC program could influence racial segregation. They found that LIHTC properties do not contribute to increased overall segregation, even those in high-poverty neighborhoods. Rather, they found that the LIHTC program contributes to small declines in the level of racial segregation found at the metropolitan level.

The possible contribution of the LIHTC program to racial integration has become increasingly important given a recent decision by the U.S. Supreme Court. In 2015, the Court heard a case on the locations of LIHTC properties and racial segregation. The case was the *Texas Department of Community Affairs v. Inclusive Communities Project, Inc.* (ICP). The plaintiffs, ICP, argued that the Texas Housing Finance Agency violated the federal Fair Housing Act by disproportionately allocating tax credits in a manner that furthered existing patterns of racial segregation. Trial evidence showed that over 90 percent of Texas LIHTC units were in majority minority census tracts. The plaintiffs brought the claim under a disparate impact theory of liability, by which plaintiffs need not show evidence of intentional discrimination, rather, they only need to demonstrate that the action had a disproportionately negative impact on a protected class of households as identified in the Fair Housing Act. The Court endorsed the disparate impact theory. This decision has caused Texas to rework its QAP to affirmatively further fair housing which will likely cause other states to follow (Walter, Wang, & Jones, 2017).

The LIHTC program's is demonstrating a capacity to overcome the resistance to affordable housing so often found in suburban low-poverty neighborhoods. Further, the program may be contributing to racial integration. With the adoption of the Affirmatively Furthering Fair Housing process by HUD, greater attention is being placed on fair housing, dispersal of affordable housing, and helping the poor locate in high-opportunity neighborhoods through assisted housing programs including the LIHTC program.

Dispersal of the poor to areas of high-opportunity and promotion of racial and ethnic integration remain only part of the goals for the LIHTC program. Many developers of LIHTC housing, especially non-profit community-based development organizations endorse the LIHTC program as a tool for neighborhood revitalization. They see the program as a means to generate spillover effects that will help to revitalize a neighborhood. These effects are typically measured in terms of increases in the values of properties near to LIHTC developments. The research results on this topic are mixed, and context matters. Lee, Culhane

and Wachter (1999) modeled changes in the values in Philadelphia for properties in close proximity to LIHTC properties. They found that the LIHTC properties had slightly negative effect upon the value of nearby properties. Ellen et al. (2007) modeled change in values in New York City for properties in close proximity to LIHTC properties and found a significant positive effect in some, but not all, cases. For a sample of LIHTC properties in New York City, these LIHTC developments replaced deteriorated properties. Thus, wherever one of these LIHTC properties was developed, it removed a property that was harming the values of adjacent properties. In this context, the LIHTC development transformed the deteriorated property into a stable, new asset enhancing the value of the surrounding properties. Ellen, O'Regan and Voicu (2009) extended this analysis, suggesting that there may be a trade-off in building LIHTC units in low-income areas. Although building subsidized housing in high-poverty neighborhoods may further the concentration of the poor, it may also contribute to improvements in these neighborhoods and thereby lessen poverty concentration in the long run. They found little evidence that the program is exacerbating poverty concentration and found that the program can encourage community redevelopment when the LIHTC property is part of a well-designed community revitalization plan.

Recent work by Diamond and McQuade (2016) came to very different conclusions on the likely spillover effects of LIHTC properties. They estimated the spillover effects of LIHTC developments on surrounding neighborhoods. Using parcel level data from 129 counties joined with data from many public and private sources, they found the spillover effects to be dramatically different depending upon whether the location is rich or poor. They found that, in low-income neighborhoods, LIHTC properties tend to revitalize the neighborhoods, increasing house prices by about 6.5 percent. They LIHTC properties also lowering crime rates and attract populations that are more racially and economically diverse. These benefits can generate significant aggregate welfare gains for the affected communities. In high-income neighborhoods with majority white populations, they found that LIHTC developments cause house price declines of 2.5 percent and attracted low-income households.

The spillover effects of LITHC developments can be positive but finding the right context can be hard. Edsall (2015) criticized affordable housing development as a strategy for community development. He contends that an alliance of nonprofit housing companies, local politicians, state and local housing agencies justify the placement of affordable housing in the poorest sectors by arguing that it will encourage neighborhood revitalization and economic growth. Rather, this practice “serves only to further concentrate disadvantage.” Mallach (2011) agrees suggesting that, “Instead of focusing on buildings, we should be thinking about the needs of low-income renters as a whole.”

The literature on LIHTC property location is mixed. Some communities seek out LIHTC properties to help revitalize distressed areas. Some developers seek out high-opportunity suburban location to provide affordable housing in desirable neighborhoods. Some communities fear loss of property value and the influx of poor people, especially poor people of different racial or ethnic characteristics (Bratt, 2012). This research will explore which communities seem to attract LIHTC properties and which communities seem to exclude these properties.

Data and Methods

This research looks at characteristics of the housing stock as of 2017, as well as changes in the housing stock during the years 2009 through 2017. This time period was a period of economic recovery from the turbulence found over the housing bubble of 2000 to 2007 followed by the crash of the mortgage market which lead to the great recession. There is an advantage of examining the growth and change in the LIHTC program during this time; it is a period of steady growth without the confounding conditions of recession.

The U.S. Department of Housing and Urban Development (HUD) provides data on all properties placed in service between 1987 through 2017 for which location information is reported. These data describe 33,784 properties with 2,168,247 units. The lack of complete location information affects about one-fourth of all LIHTC properties. The complete records cover 73 percent of the LIHTC properties and 76 percent of the units, and there is no reason to assume that the LIHTC properties that are not reported properly have any different location characteristics than those for which complete information is available.

The LIHTC data are paired with data on the approximately 29,000 municipalities in the United States. These data are supplied by the American Community Survey using its five-year summaries. The counts for 2017 are the combined survey results from 2013 through and the 2009 results combine data from 2005 through 2009.

Table 1 describes theses data.

Municipalities range in size from only a few people to New York City with 8.5 million people. Growing municipalities, defined here as those municipalities with any population expansion from 2009 to 2013, make up only about one-half of all municipalities. The remaining one-half experienced either stable or declining population during this time period. Growing municipalities are of interest to this research because

the LIHTC is a production program designed to augment the stock of housing. The program can also rehabilitate existing units, thus, the program can enhance the quality of the existing stock of housing without increasing the scale of the stock. In addition, even newly constructed units do not necessarily increase the stock. Newly

Table 1. **Low-Income Housing Tax Credit Properties

<i>Cities with LIHTC family projects</i>	8,233	4,430
<i>Average LIHTC family projects</i>	1.9	2.4
<i>Average LIHTC family units</i>	120	160

constructed units can be built on a site cleared for construction by demolishing existing units. However, the program tends to favor new construction and is associated with adding units to the stock. For this reason, the research pays particular attention to the municipalities where the population and the housing stock is growing as the LIHTC program can be a tool these municipalities use to ensure that a share of the new growth is priced to serve low-income households.

The average municipality has a population of only 8,200 people housed in 3,400 units of which just under 30 percent are rental. Growing municipalities tend to be somewhat larger with an average population of 13,300 and a commensurately larger housing stock of 5,400 units.

Of concern for this research are the municipalities that do not permit LIHTC properties into their jurisdiction. Some municipalities are not absorbing LIHTC properties. This exclusion becomes especially

concerning when there is growth in the housing stock and even growth in the multi-family stock, but little or no absorption of LIHTC properties.

The typical municipality with any LIHTC properties has about 4.1 properties for a total of 260 units. The LIHTC program is not distributed thinly across all municipalities. Rather, they are concentrated in a few municipalities. Note that LIHTC properties are found in only 8,240 municipalities, only 28 percent of all municipalities. Among the 13,955 municipalities with growing populations, LIHTC properties are found in 4,942 municipalities or a slightly higher 35 percent of these municipalities.

Our concern is with exclusion of LIHTC properties. Nearly all LIHTC properties are multi-family developments. The typical LIHTC development contains about 60 units, typically in multifamily buildings. Multifamily properties, defined in this research as properties with 5 or more units per structure, do not make up an especially large share of the nation's housing stock. The typical U.S. city has only 7.5 percent of its housing stock in multifamily properties. In growing municipalities, the share rises to only 9.4 percent. The willingness of a community to absorb multifamily properties into its housing stock is an indicator of the community's acceptance of housing for households in the lower end of the income spectrum. Note that renter household income in the United States is \$36,700, almost exactly one-half of the median income of owner-occupied households at \$73,300 (American Community Survey, 2019). The willingness of a community to absorb LIHTC properties into its housing stock is an indicator of the community's acceptance of housing for low-income households, those confronting the greatest difficulty in finding affordable housing.

LIHTC properties for family occupancy are harder to locate than are properties designed for the elderly or for special needs populations. Family occupancy means household who are not elderly, disabled or suffering from any special needs. Despite the difficulty in finding sites for family properties, they seem to be distributed in the same number of municipalities as all LIHTC properties (8,233 of the 8240 municipalities with LIHTC properties).

This research examines the trends in the development of housing within the LIHTC program, especially housing designed for family occupancy. It finds that there is a tendency away from development of LIHTC housing for family occupancy and a shift toward housing for the elderly and special needs populations. The analysis then turns to the role the metropolitan location plays in the ability of LIHTC housing to enter the market. The analysis then examines the share of housing that is found in municipalities based upon their

status as central cities, suburbs, or other communities. It finds, unsurprisingly, that multifamily housing holds a larger share of the housing market in larger central cities. Finally, the analysis models the variation in the acceptance of LIHTC units in communities as a function of exclusionary practices which are proxied by the share of multifamily housing found in the market controlling for a variety of factors that assess the need for affordable housing as well as the other measures of the opportunity levels on the community.

Analysis

Table 2 examines the production of LIHTC units over time and the proportion of LIHTC units that are designed for family occupancy.

The program took a few years to get going in earnest. By 1992, it reached a level of productivity that added over 1,000 properties each year until 2013. After 2013, the program experienced a lower rate of production.

The percentage of all properties produced that are designed for family occupancy has followed a very clear trend. In the early years of the program, 1987 through 1992, over 60 percent of all LIHTC properties were designed for family occupancy. In the “middle years” of the program, 1994 through 2004, family occupancy fell, ranging from 50 to 60 percent. After 2004, the percentage of properties for family occupancy fell to below half. During 2013 and 2014, the production of family properties reached a low of 37 to 39 percent.

Table 3 distinguishes municipalities by their metropolitan location and their absorption of LIHTC properties. All central cities in large metropolitan areas have LIHTC properties within their jurisdiction. Among suburban municipalities in large metropolitan areas, only 45 percent have LIHTC properties. The share is smaller still in municipalities in small metropolitan areas and in non-metropolitan areas, with only 23 percent containing any LIHTC properties.

There is nothing inherent in the LIHTC program that drives developers to select large central cities as the locations of the LIHTC properties that they produce. The need for affordable rental housing is

**Table 2. Low-Income Housing Tax Credit Developments
By Year Placed in Service
Total and Percent for Family Occupancy**

<i>Year Placed in Service</i>	<i>Number of Projects</i>	<i>Percent for Families (non-elderly, non-disabled)</i>
1987	473	70.2%
1988	1,011	68.7%

2012	1,125	42.3%
2013	1,016	38.7%
2014	782	37.0%
2015	834	43.6%
2016	671	43.7%
2017	65	29.2%

widespread. Suburban municipalities and communities in small metropolitan and non-metropolitan areas offer high levels of opportunity which should make the good candidates for the development of LIHTC properties. It is difficult to believe the developers of LIHTC properties have not pursued development opportunities in one-half of all suburban communities and over three-quarters of all municipalities in small

markets. It seems much more likely that developers are being prevented from making entry into these markets.

Table 3. Municipalities by Metropolitan Location and the Presence of LIHC Properties

	<i>Cities without LIHTC units</i>	<i>Cities with LIHTC units</i>	<i>Total</i>
<i>Central city in large metropolitan area</i>	0 0%	49 100%	49 100%
<i>Suburb in large metropolitan area</i>	2,998 55%	2,453 45%	5,451 100%
<i>City not in large metropolitan area</i>	18,043 77%	5,536 23%	23,579 100%
<i>Total</i>	21,041 72%	8,038 28%	29,079 100%

Table 4 examines the contribution that the LIHTC makes to the housing stocks of the nation's municipalities. The data include all municipalities in the American Community Survey, a total of 29,092. About 5,500 of these municipalities are located in metropolitan areas where populations of greater than 1 million. A population of 1 million is used as a threshold to identify where the distinction between a central city and its suburbs becomes meaningful. Below this threshold, metropolitan areas tend to have fewer communities at the periphery of the central city and the central cities tend to be a very dominant share of the total area.

A total of 5,501 municipalities are in these large metropolitan areas. A total of 23,591 municipalities (cities and suburbs) exist in small metropolitan areas and non-metropolitan areas. As would be expected, the central cities in the larger metros are themselves very much larger with an average size greater than 830,000. The suburbs for these larger metropolitan areas are much smaller at about 18,000 population on average.

The remaining 24,000 municipalities are much smaller with an average population of about 4,000 people. The average number of housing units in each category of city are proportionate to population size.

Table 4. **Municipalities by Metropolitan Location**
Population, Housing Units, Multifamily and LIHTC Share of Units

	<i>All cities</i>	<i>Central city in large metro</i>	<i>Suburban city in large metro</i>	<i>City in small metro of non-metro</i>
<i>Number of cities</i>	29,092	59	5,442	23,591
<i>Average population 2017</i>	8,237	834,493	17,550	4,022
<i>Average percent growth population 2009-2017</i>	9.9%	5.5%	12.3%	9.4%
<i>Average housing units 2017</i>	3,431	352,874	6,861	1,766
<i>Average percent growth in housing 2009-2017</i>	8.0%	3.9%	11.0%	34.7%
<i>Average percent housing in 5+ unit structures 2017</i>	7.5%	31.3%	13.6%	6.1%
<i>Average change in percent housing 5+ unit structures</i>	0.4	1.5	0.5	0.3
<i>Average LIHTC as percent of units</i>	2.5%	4.1%	2.6%	2.5%
<i>Average LIHTC units developed as percent growth of all units</i>	7.6%	30.4%	2.5%	9.6%

The percent of the housing stock that is multifamily is much larger in the larger central cities averaging over 30 percent compared to 14 percent in the suburbs. Only 6 percent of the housing stock is multifamily in the smaller metropolitan and non-metropolitan areas.

Table 5 addresses the differences between growing and non-growing municipalities. The conclusions that can be drawn from this comparison is that growing municipalities are much more like non-growing municipalities than different. The only areas where growing municipalities are different are few. Growing municipalities are larger. Their typical owner-occupant households tend to have higher incomes and have higher value homes, and typical renter household has higher income as well. Many other comparisons find no significant differences between growing municipalities and all municipalities. They have similar shares of housing that is rental, have similar rental vacancy rates, median rents, and shares of the renter households who pay more than 30 percent

of income on housing, a commonly accepted standard for identification of a high housing cost burden. The housing stocks have comparable shares that are multi-family. The populations are similar as well in terms of the incidence of poverty, high school dropouts, unemployed workers, and worker commuting patterns. With all of these similarities, it is unsurprising that the LIHTC program is making entry into both growing and non-growing municipalities at comparable rates.

Table 6 explores the differences between those municipalities with and without LIHTC units. Municipalities with LIHTC units are fewer in number. They comprise only 28 percent of all municipalities. Municipalities with LIHTC units are:

- Larger in terms of population and the size of the housing stock,
- The share of rentals in the stock is greater,
- The percentage of renter households suffering from a high housing cost burden is higher (48 percent to 43 percent), and
- The share of the housing stock that is in multifamily buildings is much greater (14 percent to 5 percent).

Municipalities with LIHTC properties and those without have populations with:

- Comparable unemployment rates, workers with complete high school educations, and worker commuting patterns, as well as
- Median gross rents and rental vacancy rates that are similar.

The populations in municipalities with LIHTC properties and those without differ in some respects. Municipalities with LIHTC properties have:

- Greater minority presence (30 percent to 21 percent), which is growing faster (3.4 percent to 1.9 percent),
- Slightly greater poverty (17 percent to 15 percent), and
- Lower median income for renter households by over \$5,000 and is growing more slowly (24 percent to 41 percent).

It is difficult to come away from this preliminary analysis without noticing that municipalities with LIHTC properties have renter populations that are poorer and contain more minorities, while municipalities without LIHTC properties have fewer renters, fewer poor households, and do not allow as much housing to be developed in a multifamily format.

Table 6. **Demographic and Housing Characteristics of Municipalities by Presence of LIHTC Units**

Table 7 provides the details of a regression model that explains variation in the percent of a city's housing stock that is made up of LIHTC units. The first model looks at variation in all LIHTC units; the second model looks at variation in only LIHTC units designed for family occupancy.

The typical city's housing stock is only 1 percent LIHTC units, but the variation is wide. The maximum is 39 percent and the minimum is zero. Recall that over 70 percent of the municipalities have no LIHTC units.

The model explaining variation in any LIHTC units is unimpressive. Nearly all of the coefficients are significant and generally of the correct sign, but the R Square statistic is only .15. The model is, however, sufficiently strong to indicate the contribution of various variables in explaining why some municipalities absorb LIHTC units into their housing stock and some do not. The single strongest variable explaining the presence of LIHTC housing in a city is the percent of housing that is multifamily. This variable indicates the willingness of a community to permit multifamily structures as most multi-family structures are rental properties and most LIHTC properties are multifamily properties. The extent to which a city's share of the housing stock is multifamily is inversely related to the presence of LIHTC housing. This suggests that municipalities with strong growth in multifamily housing is squeezing out the LIHTC housing.

Among the control variables there are few surprises. LIHTC units are found more commonly in large central cities and less in suburbs whether the units are all units or just units for family occupancy. LIHTC units are more common in municipalities with greater poverty and greater incidence of racial or ethnic minorities. The share of LIHTC housing is greater in municipalities with lower rental vacancy rates, suggesting that developers seek to enter tight markets rather than soft markets.

The model that explains variation in family LIHTC units is even less impressive with an R Square statistic of only .09. Again however, among the strongest variables at explaining variation in the absorption of family LIHTC units is the percent of housing that is multifamily. This reinforces the notion that the willingness of a community to permit multifamily structures signals the ability of LIHTC developers to enter those markets.

Table 7. **Models Explaining Variation in LIHTC Units as a Percent of the Housing Stock In Municipalities in the United States**

Dependent variable	All LIHTC Units as a Percent of the Housing Stock Standard			Family LIHTC Units as a Percent of the Housing Stock Standard

** Significant at the .01 level						

Conclusion and Policy Implications

The willingness of a community provide space for multifamily housing drives the presence of LIHTC properties. Suburban communities permit much smaller percentages of the housing stock to be in the form of multifamily housing. This probably drives the smaller share of communities that participate in the LIHTC program and the smaller share of their housing stock absorbed in the program. Yet, these suburban municipalities offer higher levels of opportunity. They have lower poverty exposure, more highly educated populations, and lower unemployment.

Zoning is a planning exercise controlled almost entirely at the municipal level. Each city can decide the extent to which it will designate land for multifamily housing. Where communities fail to accommodate this type of housing, the LIHTC program is less able to enter these communities offering higher opportunity levels.

Gentrification and Community-led design: Renegotiation and limitation of the rent gap in the UK

Tom Morton

Open University, tom.morton@open.ac.uk

Abstract: Socio-spatial issues are a consequence of underlying social relations - in the case of gentrification delineated by the rent gap theory. Community-led initiatives work to renegotiate and limit the impact of this relation, making understanding the capacity of these initiatives to provide alternative models of development crucial when austerity weakens government's ability to intervene. This paper offers the Fountainbridge Canalside Initiative (FCI) as an example case, gathering data as an interview with a steering group member and capturing the socio-spatial context, the participant's theories, and any actions they have taken. FCI attempt to enable their community to tackle gentrification in three senses; through the renegotiation of the socio-spatial relations that facilitate gentrification, through limitation of the socio-spatial issues associated with it, and through symbolic acts of design activism. These findings may demonstrate the generalisable capabilities of community-led practise to tackle problems around land value and cuts to services, potentially informing best practise and approaches to planning, placing an emphasis on not only planning environments but infrastructuring the socio-spatial relationships that produce them.

Keywords: Gentrification, community-led, housing, activism

1. Introduction

'Since money, materials, land and authority to act were necessary and since the ruling power was the only force capable of furnishing him with these means, the architect had to identify himself with it, even transforming himself into its operative appendage' – from Giancarlo De Carlo's lecture 'Architecture's Public'

(Jones, Petrescu, & Till, 2013)

Housebuilding in the UK has been steadily rising since around 2014, following a six-year slump after the 2007/8 financial crisis. New development has been so sustained that the number of additional dwellings has almost returned to its pre-crash peak (see figure 1), yet the country is still struggling with housing shortage. In 2016/17 net additional dwellings were up 0.92% on the previous year, with the vast majority of gains resulting from new builds (HCLG, 2018). These additional homes failed to have any impact on the rates of statutory homelessness, with households in temporary accommodation rising over the same period by 8% (DCLG, 2017). This rise in statutory homelessness cannot be explained away as population growth, with average rate of annual change sitting far lower at 0.6% (World Bank, 2019). Part of the explanation is that the stock of *vacant* dwellings rose faster than houses were being built - a 2.7% increase – creating the situation in which the number of vacant properties (605,891 dwellings) vastly surpasses the number of statutory homeless (82,310 households) (HCLG, 2018). In short, we are building new developments, but they are not developments that are designed with the purpose of housing those who need it.

If it is not housing need that has fuelled the sustained growth in housing stock, then what? As figure 1 shows, since the late 1980's additions to the housing stock have come largely from the private sector, with new developments of social housing by local authorities all but disappearing. This transition is to what David Harvey terms the 'speculative city' (2013), where housing development acts as part of the machinery of capital accumulation. In fact, the UK's *National Planning Policy Framework* (HCLG, 2019) places 'significant weight' on new developments supporting economic growth. This attention to growth shifts the emphasis away from housing and on to the land it is built on, with the speculation of investors driven by the differential existing between the current value of land's use and its potential value under a different use/improvement. This is known

as the ‘rent gap’ theory of gentrification (Smith, 2002), a process which leads, in its worst cases, to the displacement of a land’s use and/or its inhabitants.

Figure 1. Permanent new build dwellings completed, by tenure, England 1946 to 2017. Source: Ministry of Housing Communities and Local Government 2018

So, the explanation for the continued housing crisis is (at least in part) the heavily financialised housing market. However, each one of these new developments has been produced by architects, planners and designers. Acting as De Carlo’s ‘operative appendage’ to the ubiquitous power of financialisation, urban development is *designed* to maximise the highest return on investment. In these contexts, community-led design (CLD) initiatives offer alternative models of development, initiated and steered by grass roots community organisations who, as non-profits, foreground the use value of urban environments to the communities who live in them. Unlike government sponsored planning programs in the UK such as the Localism Act (Bevan, 2014; Brownill & Bradley, 2017; Gallent, 2013) these initiatives make non-statutory interventions into their built environment fundamentally challenging the politics of planning practise with their own radical interpretations of urban planning and the socio-spatial issues they associate with development. If exchange value driven planning has - at least in part - produced the gentrification of our urban environments, this paper seeks to understand what we can learn from planning practises unmotivated by profit.

2. The case study

This paper offers a case study of a CLD initiative working within the context of gentrification and with the ambition - amongst other aims - of providing accessible housing for the locality. FCI is an ongoing CLD project based in Edinburgh. The location of interest to the initiative is a brownfield development on a former brewery site, a post-industrial area very near to the centre of the city. The 11-acre site had been cleared having changed ownership a number of times, but the impetus to form FCI came when the council brought the land into public ownership to build a school in one corner of the site, with initial plans to build offices on the rest. FCI’s objection to the proposed development of additional office buildings was that it would extend Edinburgh’s business sector into the socially mixed and fragmented communities surrounding the canal, an area that was already experiencing recent high-end development including office space, student accommodation, and hotels. For the purpose of this research FCI steering group representative and founding member Joan was interviewed (participant name anonymised).

The aim of the case study was three-fold, to gather data relating to the context in which the initiative undertakes their work, to distil from the case study the participant’s theories about the work that they do, and finally to analyse how both context and theory inform any actions they have taken in the form of practise and process. To investigate these lines of enquiry, Joan took part in a face-to-face interview. It was first necessary to understand her basic assumptions about the socio-spatial issues affecting the community, but in turn the interview aimed to gather FCI’s assumptions about what the solution to these problems might look like. These lines of inquiry covered both how they perceived the solutions to the problem of gentrification, as well as how the social relations between stakeholders and their relations to the sites of redevelopment could be structured differently.

This paper will argue that these basic assumptions about gentrification and the social relations underlying it form elements of FCI's approach to CLD, offering alternative models of planning and the production of housing.

2.2. Case selection

For the purpose of this research it was necessary to adopt a stringent definition of CLD in order to filter potential cases. It was decided that for a case to meet the criteria of being genuinely community-led, the project must be a self-initiated act. In practise this relates to grass-roots projects based in beliefs and desires or projects that are reactions to contextual changes in the socio-spatial landscape (Zamenopoulos et al., 2016). This understanding of CLD excludes responsive acts that are supported or initiated by state sponsored programs such as the Localism Act in the UK. Secondly the cases needed to be undertaking work within the context of gentrification. This paper shares a materialist understanding of gentrification with Smith's rent gap theory as described above. However, in many of the cases interviewed the conception of gentrification also included post-Fordist understandings of gentrification as the transition from industrial/productive economies to service-based/consumption economies (Hamnett & Whitelegg, 2007; Rousseau, 2012), as well as post-modern revaluations of urban space (Hackworth & Smith, 2001).

Using these criteria potential cases were selected following scoping meetings with third sector organisation the Glass House, a national CLD organisation that supports communities to work collaboratively on the design of places in the UK. From these meetings a number of case CLD initiatives were identified, before using the above criteria to filter these down to six. Of these six case initiatives this paper deals solely with FCI a case that highlights the need to reappraise and offer alternative modes of planning and development.

2.2. Interview Design

Once cases had been selected, members from each initiative's steering group were invited to take part in a face-to-face interview. The interview involved the completion of a resource which consisted of five components (see figure 2), each with the aim of collecting data relating to different aspects of a CLD project. In this section a rationalisation for each component is provided:

1. *Where you were*: This section of the interview gathers data relating to the socio-spatial context in which the CLD project is undertaken. This includes participant's perception of any socio-spatial issues that were problematic at the time of the projects initiation, as well as how they perceive the relevant social relations to be configured.
2. *Where you hope to be*: Here is where data relating to participant's theory is gathered. By outlining an envisaged future, they hope to achieve through their work, participants reveal potential re-configurations of the socio-spatial landscape as well as specific outcomes of development.
3. *The players*: In this section key stakeholders are identified. This includes discussing the relationship of these stakeholders to the development site and how these stakeholders relate to one another.
4. *The project*: Here the actions taken as part of the project are recorded. This in part includes the creation of a timeline of events or a map of a journey, but also how decisions were made/achieved and what has been created towards the project's completion.
5. *The transitional qualities*: Finally, the attributes of the project are discussed in relation to how the work of the CLD initiative will help make the movement from where participants *were*, to where they *hope to be*. These may be material properties of the final outputs of the project, though they may also be characterised by re-configured relationships or symbolic properties.

In short, this resource seeks to understand how context informs participant's theory, a theory which is the basis of an alternative model of planning and in turn how this theory informs their action. The fact that these activities are community-led, means that by their very nature these insights are based in the pragmatic and experiential knowledge of community members affected by developmental issues such as gentrification. These experiential perspectives contain within them potential solutions to developmental crises, based in a lived experience of the phenomena.

Figure 2. The interview resource to be completed by participant with the researcher

3. Where you were

When gathering data relating to the context in which FCI was initiated, Joan identified austerity cuts as contributing to a general decline in the area, with these cuts to local services resulting in a lack of community-based activity. At the time of the interview the area was still undergoing very recent high-end development. The former brewery offices along the canal-side had been demolished and redeveloped in the previous six months, including hotels and cafes.

I think to be honest it was quite depressed around Tollcross because it had a lot of cuts to the community centre. It's not a very rich area actually and I think it looks a bit grim to be honest round there and the canal certainly was a bit grim. Services hadn't disappeared but they were being cut and now of course more, so it's almost disappeared. There was a lot of anger in Edinburgh about the planning committee letting things through that people didn't want. Big shopping centres and stuff that people thought was pretty poor actually. So, there was a lot of feeling of I suppose alienation about politicians and councillors, and not a big community action project around here.

Fountainbridge is an area experiencing the disinvestment/reinvestment cycle of the rent gap theory. As a publicly owned site, disinvestment in the form of austerity incentivises the council to exercise a policy of municipal entrepreneurialism (Beswick & Penny, 2018), speculating on the exchange value of the site in the hope of ensuring a financial return. In practise this means a change in land use, replacing the industrial buildings with office space and hotels. This economic transition from production economy to consumption economy had in turn created a fragmentation of the surrounding communities formerly connected by the industry in the area. The already socially mixed communities – along lines of class and ethnicity – now had the additional factor of being faced with a gentrification frontier (Smith, 1996) as what Joan describes as the ‘new business sector’ expanded into the former industrial area.

Figure 3. Data relating to context, as captured by participant and researcher.

4. Where you hope to be

FCI envisage a future where instead of office buildings, working class communities can live in the centre of Edinburgh. To this end their primary interest is in the inclusion of social housing in the final development of the site, with an additional desire for homes on the development to be sustainable utilising alternative energy systems like district heating. After the technical priorities of the site, FCI value non-tangibles in their theory of development citing terms like ‘mixed’ and ‘lively’. In the following passage, Joan outlines how the CLD initiative’s theory of development diverges with the local authority’s planning orthodoxy.

We used to laugh when all these master planners and architects talk about vibrancy and we know what they mean is Costa coffee shops and tourist hotels. That's what they see as economically attractive...I don't think they understand what makes it an interesting area for everybody. People like quirky things. They like little workshops. They don't want everything to be all the same, sitting in coffee shops looking at other tourists...So there are a lot of ideas about what we call vibrancy as well. I think that areas that are attractive to most people...are slightly old kind of quaint things or perhaps people working on something...You know you could wander in to kind of locally run businesses or see activity on the canal boats. Just draw more people and ages in...The whole mix of the population being there. You know some of the visuals you get for these master plans, it always amuses me. They show very smart young couples usually or people or individuals...Not usually old people, or kids, or black people. It's very mono-cultural stuff they tend to promote...it doesn't have to be art shows or exhibitions. Just people being busy. When you go to visit places something about people engaging in some kind of purposeful activity, or artistic activity, or something, it's always very enjoyable...because we've become passive consumers in some way I think.

Here Joan expresses an understanding of vibrancy similar to that of the post-modern planners and discussions around ‘exuberant diversity’ (Jacobs, 1961). This approach to planning considers an exuberant diversity to be a mix of land/property use, tenure, age, ownership and takes this diversity to be the ultimate aim of a sustainable and gradually implemented urban plan. FCI appear to share this post-modern theory of development, placing an emphasis in particular on a diversity of enterprise, and craft. This final point is interesting to note in relation to Joan’s framing of their theory of development as against the move to becoming ‘passive consumers’. This situates FCI’s theory of development as against the post-Fordist transition to a consumption economy, a kind of industrial revival.

Figure 4. Data relating to theory as captured by participant and researcher.

5. The players

In the identification of the key stakeholders connected to the site, Joan delineates a triumvirate of interested parties (see figure 5). These are what we can term first the organised community (in this case FCI and its co-opted organisations), an authority (City of Edinburgh council), and a developer (arm's-length developer EDI). The configuration and structure of these social relations is a crucial dimension for CLD initiatives in envisaging future models of development. Here Joan begins to outline FCI's theory of how a CLD project should be infrastructured. The first stakeholder she identifies is the community, however she specifically identifies the politicians as the *key* players, providing the following rationale.

[I]t's owned by the council. If it wasn't, I don't know what I'd be saying. But I do think people underestimate the democratic pull. People often moan, but they don't actually engage the councillors. They just think they are rubbish. But come on they are our elected representatives. So, the councillors, the politicians, not just the officials. On this particular site the elected representatives were the key people on our side and we kind of created that relationship with them deliberately.

Here Joan has identified the local councillors as the 'key' individuals in the project and stated that a conscious effort was made to engage with them. Finally, the third stakeholder is identified as the developers, which in this project includes one arm's length developer engaged by the council and one private developer working on a separate section of the site. Whilst the private developer was identified as a stakeholder the efforts of FCI have been focussed on the council owned section of the site. This presents FCI's theory of CLD infrastructure; an organised community engaging collaboratively with two sets of power brokers (i.e. stakeholders with jurisdiction over money, materials, land, and authority). In the next stage of the interview the aim was to understand how the community became organised, how this engagement with power brokers was infrastructured, and the planning process as it unfolded up and until the present day.

Figure 5. A triumvirate of stakeholders as identified by the participant

6. The Project

When CLD projects are undertaken within the context of gentrification, it is common for them to be a reaction to a contextual change in the socio-spatial environment. Initially FCI was the work of three retired community workers who were engaged with one another through an existing social network. The point at which this initial group were galvanised to take action was when the brewery site was brought into public ownership.

[T]he council bought it to build a school, which they have built now, what they were going to do was sell off the rest of it. Just at that time we were very lucky it was local elections and we made it a whole campaign to push the council to keep hold of it. That was really important to us that they keep hold of it because we felt we'd have a better purchase on them.

This passage is consistent with FCI's theory of development, in which they acknowledge the need to renegotiate the socio-spatial relations of the rent gap theory. For FCI this means that land must be held outside of the private market place if it is to be developed with the needs of the community as its foundation. This renegotiation is a struggle between competing interpretations of value across a socio-spatial landscape, with the council on the one hand seeing the site in terms of its exchange value and the community members fighting to keep the land in public ownership to better realise its use value in their interests. The tension between these competing interpretations of value and how it is mediated and engaged with plays a crucial role in the style of CLD process and how it unfolds.

The campaign to keep the site in public ownership was the first instance of the community taking action in an organised sense and would lead to the formation of FCI. Once the land was brought into public ownership the initial group began outreach in the community, organising the first formal FCI meeting.

I think our original aims that we bashed out then were a bit the same, it was about the belief that the community should be involved in every stage of the design process. We had people volunteer to be part of [the steering group] which had about 12 members in the beginning. We also co-opted a lot of local organisations...So, we had like local housing associations, the nursery and all the other people that were kind of like co-opted reps. So that group met for the first time, elected a chair and a secretary. Set up a constitution and a bank account to get organised and then we just started having meetings about what can we do next/what needs to happen.

This passage demonstrates that the organisational structure of FCI is the first thing that is created in the project's journey. The creation of this organisation was aided by the communities access to expertise in the form of the retired community workers who lived in the area and who took on the role of enabling community members to infrastructure themselves. The first stage in the planning process for FCI was the creation of a community design brief. By holding an event which they termed a 'visioning day' the aim was to create a space in which community voices could engage in discussion and debate, building a strong mandate within the community for FCI going forward. The event was split into 5 themes:

1. Social;
2. Culture and recreation;
3. Economic;
4. Environment;
5. Napier site and park.

Each of these themes detailed the desired qualities of the development for community members. These included aesthetic qualities such as a rejection of faceless concrete and glass, suggestions for specific form such as colony style housing, and desirable functions for the development such as a mix of tenure and use. The report from the visioning day was then presented to other community groups and organisations as part of an open-ended process of outreach within the area. It is clear that FCI are interested in empowering a multiplicity of voices around the site of contestation and had utilised existing social networks to engage with as broad an audience as possible. This again illustrates FCI's theory in relation to how to infrastructure an organised community, co-opting existing organisations and collaborating with them under the umbrella of FCI. Hereafter it is the interactions between this organised community and the power brokers – both councillors and developers – that becomes the relation of interest.

Whilst FCI place a clear emphasis on collaboration with the City Council, the engagement is not built on deliberative consensus building. The two stakeholders participate with one another agonistically, with the engagement being designed to bring power relations out into the open to be examined and contested (Inch, 2015; Mouffe, 1999, 2000). For instance, FCI's initial engagement with the council was primarily as single-issue lobbyists, using direct activism aimed at communicating the political interests of the council to the wider community. Joan explains some of the kinds of activity FCI were engaged in.

Before the election we did actually have posters around saying, these are the people standing, ask them what they are going to do about Fountainbridge. Do they want it to be all these things we said it should be? And we actually sent questions to all the candidates. It was a survey saying what do you think about this? And we published that.

However, an adversarial relationship does not alone make for agonistic planning. It was not until FCI sought to engage design expertise from the Glass House, that an agonistic planning *process* was undertaken. FCI managed to secure a free 'planning-for-real' workshop from the Glass House in which participants would model potential developments with plasticine. The participants at the workshop were divided along the lines of 50% Councillors, council officers, and developers, and 50% community representatives. Dividing participants in this way begins the construction of an agonistic pairing, as opposed to the two groups occupying adversarial positions. By grouping council and developers together we begin to see the creation of an 'us' – an organised community - by the definition of a 'them' – power brokers (Mouffe, 1999). Creating this agonistic dynamic is touched on by Joan in her reflections on the workshop.

At that point there was people in the council who thought we were trouble and didn't want anything to do with us. So, when we actually wrote to them and the leader of the council had agreed to this day, we asked him to chair it because we knew it would bring the people [council officials and developers] along, and he was supportive. But his officials, some of them were awful. One of them when I wrote to him saying we were going to have this planning day, he actually wrote back to me, saying 'you have no right to organise this planning day. The council is going to decide what to do and there will be consultation in the future'. So, I sent a copy of that to one of the councillors and said, 'Is this the councils reaction?' There was another department, that were a bit reluctant. So, I was sending out emails saying that 'I think the leader of the council will be quite disappointed if you don't come, because so and so is coming'. You have to try and persuade them all that it's an important event and of course they don't think that community events are. Or they think they are going to be got at. So, there was a lot of reluctance and we had to do a lot of work to get them all out. Of course, the beauty was that they all did come and because it was playing with plasticine, modelling stuff, it wasn't like a confrontational public meeting. But I think the thing that was really important that the officials and the politicians realised they could have a meeting with the community that wasn't antagonistic. It wasn't getting at them, it was constructive, and I think that then enabled the sounding board to be developed.

The Sounding Board that Joan refers to is the main agonistic mechanism utilised in the planning process. A forum constituted in the same manner as the planning-for-real workshop - 50% community representatives and 50% council and developers - it was suggested as a mechanism by FCI and the council agreed to take part. The sounding board members – both community and power brokers - have equal power to submit papers for discussion in the forum, and it is chaired by the head of the council in an effort to lend the forum authority and legitimacy. Unlike the neighbourhood forums that exist under the Localism Act, the sounding board has no formal decision-making ability. However, Joan rationalises this fact in saying that the real purpose of the sounding board is as a mechanism to 'hold the ring' when the economics and the politics of the socio-spatial landscape changes. This makes the purpose of the sounding board two-fold, not only does it enable FCI to be active participants in the planning process but also to hold power-brokers accountable for any deviation from the decisions made in the forum. This open acknowledgement of power relations in the design process is similar in nature to the Scandinavian participatory designers, particularly in its utilisation of assemblies around objects of contention (Bjerknes, Ehn, Kyng, & Nygaard, 1987; Björgvinsson, Ehn, & Hillgren, 2012; Ehn, Nilsson, & Topgaard, 2014). As well as the agonistic model, FCI shares with the Scandinavian designers an open-ended process of infrastructuring in which community participants are capable of setting up their own separate forums, actions, and lines of enquiry. Joan details an example of this open-ended infrastructuring process in relation to the struggle to include a district heating system as part of the development.

[W]e raised it [district heating] at some meeting at the sounding board, but we could feel they weren't going to go for it. So, we organised a meeting about district heating and we invited all the experts. So, in Aberdeen for example, the council has actually done a district heating scheme on some of its council housing and it was really successful. The other side of it was the legal side, because nowadays when you can choose your own energy supplier it's a bit tricky if everyone has to have the same one. So, I got in touch with...a big law company here and got this chap who knows a lot about this contract stuff who came free because he supported us. We got the technical expertise from the university and then we decided that instead of us chair it we would get the Green councillor to chair it because again we knew they [power-brokers] were more likely to come if he chaired it. [The developer] wanted to influence it, so they came along to the meeting with their architects. They were a bit suspicious with the idea in the beginning asking, 'will it work?' and 'will people want it?' and 'investors won't invest' and as they put forward their worries, all the expertise we had round the table answered their queries and about half way through the meeting [the developer] said, 'Well this could be an eco-site' and suddenly it's their idea and it's all wonderful.

This passage demonstrates that when the agreed mechanism of the sounding board proved unable to further the material aspirations of FCI, the group were able to infrastructure a separate mechanism dealing specifically with the issue of including a district heating system on the site. This open-ended process of infrastructuring would be used repeatedly in FCI's undertaking of future action.

In the visioning day report ‘Brewing New Life’ a desire was expressed to hold so called “Meanwhile” activity on the site as it would be left empty for an extended period of time. This included landscaping activity and using the site as an event space. It was agreed in the sounding board, seemingly without controversy, that the meanwhile activities would be allowed on site. Each of the activities brought on to the site in some way related to elements identified in the community’s visioning report (aside from, for obvious reasons, the provision of housing). This included:

- Temporary community gardens in line with the report’s call for greening of the site.
- Metal, wood, and glass workshops in compliance with the report’s call for artisanal workspace.
- A “Pianodrome”, a 100-seat amphitheatre constructed entirely from reclaimed pianos and in line with the report’s call event space on site.
- A community wiki-house in line with the report’s call for a community hall on the site.

In each instance these activities were facilitated by FCI, sourcing materials and funding either through community donations, sounding board partners, or grant agencies. Again we see the open-ended infrastructuring process at work. For each meanwhile activity, FCI enabled the participants to create separately constituted organisations, Joan offers the following example of the process in relation to the meanwhile garden.

About 40 people came to the first meeting about a community garden. Where they asked do you want a community garden or an allotment and then they developed it. They've got their own constitution, they got their own bit of funding I think initially, they've got their own Facebook page, they're their own organisation. They're separate but we supported them, and they're linked with us. We do things together.

This open-ended process of infrastructuring within the community fulfils the agonistic call to empower a multiplicity of voices in the struggle for hegemony over the site. The previously empty site, surrounded by fragmented and unintegrated communities had been transformed into a hub of activity, providing access to resources, training, and social networks. Suddenly it was not only FCI with a vested interest in the site, but a network of community groups. This aspect of the FCI project features as a central concept in Joan’s discussion of the transitional qualities of their work.

Figure 6. ‘The Grove’ meanwhile community garden (right). The construction of ‘Pianodrome’ seating (left)

7. The transitional qualities

Of the work they have undertaken so far FCI attribute the main transitional qualities to the meanwhile project. We can think of these meanwhile projects as acts of design activism in the sense understood by Markussen (2013), aesthetic disruptions placed into the socio-spatial landscape in an effort to create a conceptual space in which accepted ideas can be re-evaluated and challenged. Joan describes the transitional qualities of the meanwhile projects as follows.

[I]t was actually a living demonstration of what we are talking about. In terms of the social vibrancy and the greening of the site and the pleasure people have in it. It's a living demonstration of what we are talking about when we say social capital or a vibrant neighbourhood. We had a mini-community there if you like that came together and was very welcoming to everybody. To old ladies and to younger kids a very nice inclusive community actually. From the tow path it looked kind of like a hippy camp and I think people weren't really sure what was going on there. Which is why we had all these events like the spring fling and so on, to invite people in and they were very well attended.

Here the aesthetic disruption is the introduction of rustic, handmade, installations often built with reclaimed materials such as shipping containers and wooden pallets (see figure 6). These activities exhibited the style of community that *could* exist in Fountainbridge and the local appetite for a diversity of activity at the site. Specifically, it challenges the post-Fordist transition from production economies and the disinvestment that created the rent gap, to consumption economies and the reinvestment that creates gentrification. This is in keeping with FCI's theory of development and Joan's earlier call for an industrial revival.

However, the transitional qualities of the FCI's model are not solely symbolic. Joan highlighted the capacity of the community-led vision to facilitate wealth building within the locality, through the provision of workspace for local enterprise. This again draws our attention to the competing interpretations of value that exist across the socio-spatial landscape. Joan outlines how the local authority's understanding of wealth building differs from that of FCI.

[A] lot of Local Authority economic development guys are really a bit old fashioned about how they think the local economy works. They still seem to be wedded to the idea of big hotels, tourists, and that that creates jobs. I don't always think it does. I actually think that a small local enterprise, probably brings more to the local economy. The council are now actually moving towards an innovation centre, where the ground floor will be workshops for little businesses etc.

FCI's focus on small local enterprise is an attempt to build reciprocity into the local economy. This is a challenge to the local planning convention which to this point has focussed on high-end development of services and a consumption-based economy. It is these competing interpretations of value that engage with one another in an agonistic planning process in the sounding board. It is through this mechanism that FCI have built the capacity to materially further their aspirations and work collaboratively from within the positions of power that hold jurisdiction over money, materials, land, and authority.

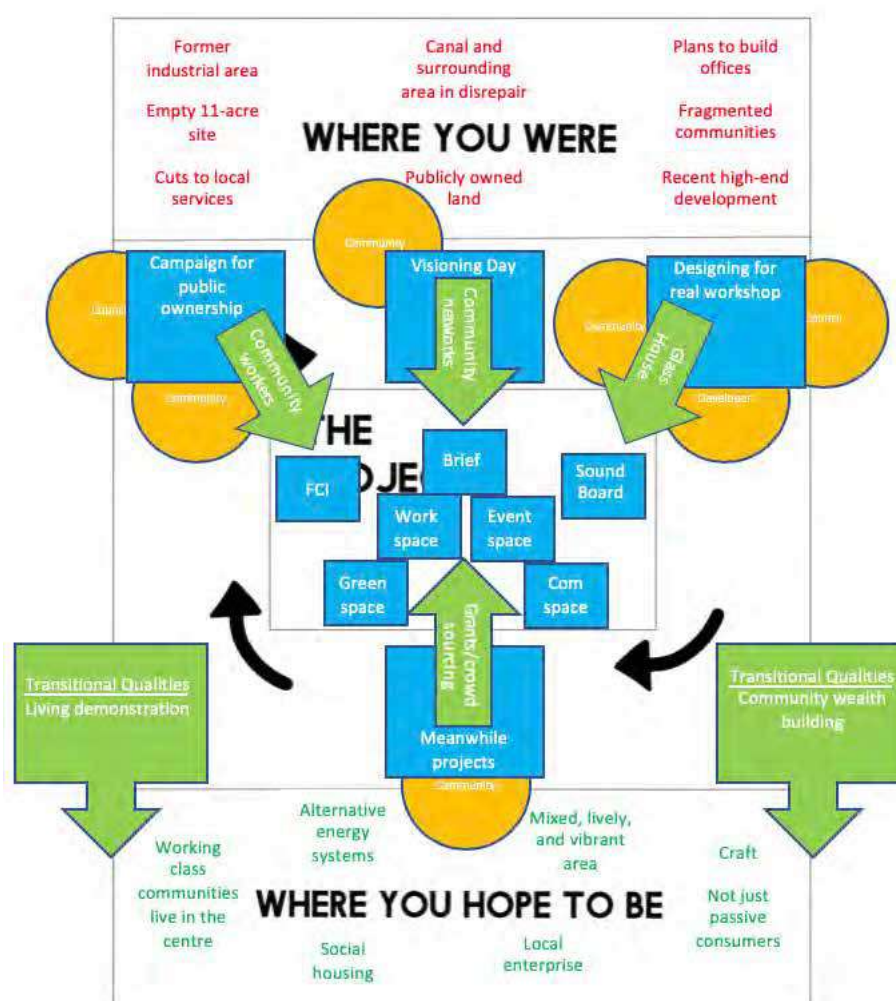

Figure 7. Interview resource as completed by participant and researcher.

8. Conclusion

This research argues that there are three aspects of FCI's practise that can tackle the socio-spatial crises associated with gentrification. First there are acts of renegotiation of the socio-spatial relations described in the rent gap theory. This necessarily entails some reconfiguration of socio-spatial relations or the removal of land and/or property from the market place, a kind of urban re-commoning, enabling the production of buildings and space to be entirely dictated to by the needs, desires, and tastes of the end users. Second there are acts of limitation on the socio-spatial issues associated with gentrification. This includes work undertaken within the confines of the speculative land market, attempting to restrain its excesses and its impact on communities. Finally, there are acts of design activism where aesthetic interventions are made as disruptions to existing systems, creating a space in which ways of living and working can be engaged with critically. This research joins the conversation surrounding new models of public ownership of land such as the so called "People's Land Trust" (Stratford, 2018) and the inclusion of citizen participation in public ownership (We Own It, 2019), attempting to decipher what lessons can be learned from existing community-led models.

The work of FCI can be understood as an attempt to renegotiate the socio-spatial relationships underlying the financialization of urban space. This theory of development begins at the point of land use, believing that such a central location should be used as residential space for local workers. The desire to house a working-class community so centrally necessarily requires a subversion of the market forces driving the rent gap, in short detaching the land in some sense from the market place. FCI centralise public ownership and/or social rent in their proposals for the brewery site, this renegotiation foregrounds the use value of urban space and challenges the "common-sense" of speculative, exchange value driven development, querying its economic arguments and even contesting its understanding of abstract concepts such as vibrancy. The central achievement of FCI's work has been in the development of new spaces and forums in which de-facto community power has been created and in which the socio-spatial manifestations of social power can be brought to the fore and interrogated. They identify a triumvirate of key stakeholders across a socio-spatial landscape, amongst whom the tensions between competing interpretations of value must engage. Working collaboratively within this triumvirate, FCI create an agonistic 'us' (the organised community – FCI and its Co-opts) by the establishment of a 'them' (the power brokers – council and developers) and through an open-ended process of infrastructuring, empower a multiplicity of voices in the struggle for hegemony in the planning process. They utilise a variety of tactics, from formal collaboration to direct action, using design activism to communicate ideas and create the conceptual space in which new ways of living can be engaged with. In practise and despite their vision, the work of FCI and their engagements with power through the sounding board, may in the end only act as a limitation to the socio-spatial issues associated with development. Whilst FCI have developed forums through which the material aims of the organised community can be furthered, they are none the less engaged in a *struggle* for hegemony, with no guarantee their vision will be realised.

ICD - An Alternative Affordable Housing Initiative

Abstract

Affordable housing is a key issue in major urban centers of New Zealand with homeownership rates declining particularly in Auckland. Lack of tenure options is creating gaps in the housing continuum. This paper discusses a people-centered approach that addresses affordability by placing users at the center of housing decisions. An Intergenerational Community Development model or ICD is a specific term coined in this research that redefines affordability as per buyers' financial capacity. ICD comprises three essential components. The *organizational* component of cross-sector collaboration ensures optimum utilization of resources, risk minimization through shared responsibilities and funds through ingenious solutions like cross-subsidization. The *financial* component offers alternative procurement models (APM) as income-compatible tenures for households. The *physical* element offers a variety of architecturally-designed multifamily typologies. A multi-case methodology qualitatively examines 16 UK and US ICDs. The findings reveal ICDs can provide effective affordable housing alternatives if well-executed by the consortium. Also, architects effectively contribute through high-quality sustainable design and a tenure-blind strategy to address affordability. In conclusion, a strong collaboration with clear agendas, robust understanding of APMs and early engagement with architects are essential for ICDs' success. The key, however, lies in user engagement and community consultation during early decision-making processes.

Keywords: Affordable housing, Collaborative housing models, Alternative procurement models, People-centered approach to housing.

1. Introduction

Auckland continues to face an unprecedented demand for housing in recent years (NZPC, 2012; Auckland Plan 2012; PWC, 2018) . Significant growth of 8.5% in the last years coupled with high rates of immigration has resulted in an increase in housing demand, escalation of rental prices and declining rates of homeownership (Council, Auckland profile, 2014, p. 2). “Affordability pressures are particularly evident in Auckland, reflecting the city’s high house prices” (NZPC Summary version, 2012, p.4). With a sharp increase in housing demand but limited pathways to homeownership, a lack of choice in tenure options further exacerbates low rates of homeownership. Intermediate renters¹ , in particular, find current pathways to homeownership restrictive in nature. A growing number of intermediate families are unable to transition into homeownership (NZPC Final report, 2012; Goodyear & Fabian, 2014). Such perpetual restrictions in mobility may be due to costs, location or a limited variety of available housing models (Flint-Hartle & Stangl, 2014).

Some suggestions for a long-term approach to developing affordable housing in New Zealand include access to land at below market price through varying degrees of subsidization, and developing financial ingenuity to sustain projects (HSAG, 2015; AC, Nov 2018). Other recommendations to rectify negative housing trends include changes in existing fiscal policies and the addition of new supporting ones (Preston, 2013, p. 59).

Nevertheless, most proposals seem to disregard the buyer’s capacity to purchase property *at the time of purchase* and are positioned from the supply end that expects income to match the available housing stock and not vice versa. As such, income-compatible options for interested households are currently missing from the Auckland housing market.

Some of the less explored options for households unable to meet the standard bank lending criteria for homeownership in Auckland are non-conventional tenures also known as shared equity products or alternative procurement models (APM). International research indicates APMs hold the possibility of expanding choices for intermediate renters (Pinnegar et al. AC, Nov 2018). However, researchers caution, the complex nature of APM contracts and its’ associated risks, must be first fully examined (Monk and Whitehead, 2010) to avoid “misjudged probabilities” by buyers (Belsky 2013).

APMs or hybrid tenures are either are state-sponsored, offered through a third sector such as housing agents in the UK and Community Land Trust in the US or, utilize a collaboration of stakeholders. Some studies indicate such cross-sector partnerships for housing can mitigate risks associated with experimental housing and offer possible affordable housing solutions. The pathway of public-private partnerships in housing promises opportunities to experiment with housing typologies and leverage public funds against private dollars and create sustainable communities through effective placemaking (Carter & Roberts, 2000; Watts et al., 2000; Bohl, C. C., 2007; Austin 2013). However, when compared to overseas examples of partnership-based housing “good quality affordable housing” largely remains under-serviced and unexplored in New Zealand (Austin, 2013 p.75).

This paper focusses on the above mentioned affordable housing initiatives that take into consideration the income capacity of a buyer at the time of property purchase. Thus, *collaborative endeavours* that utilize *APM as hybrid tenures* to create affordable *multifamily housing* solutions by engaging users in the decision-making processes are termed, Intergenerational Community developments or ICDS by this research. ICD, a three-component multifamily residential model promotes intergenerational mix and adds tenure options to expand housing choices. The main purpose of this paper, therefore, is to examine,

¹ The intermediate housing market is a subset of the households who struggle to afford housing. It is defined as working households in the private rental market who are ineligible for social housing but could not buy a lower quartile home without paying more than 30 per cent of their income to service a mortgage. Auckland Council (2018, p. 4): *Affordable housing in Auckland*.

how do ICD processes create affordable alternatives? And, how can Auckland learn from such a people-centered approach to housing?

However, to understand such processes it is vital to discuss the concept of *choice* in housing and examine what the term *affordable* means from the perspective of a buyer. This paper primarily focusses on opportunities of homeownership through affordable tenures. It first establishes a case of missing choices in tenures and models from the Auckland housing market by analyzing several housing market studies. Later, it utilizes Kings' theory of effective choice in housing (2003) as a theoretical framework to establish the significance of 'information' and 'access' to alternatives as necessary means to empower end users so that they may choose effectively.

A qualitative methodology compares 16 cases of affordable housing from the US and the UK to understand the dynamics between the ICD components and ascertain the legitimacy of the proposed alternative. Later, a summary of findings discusses appropriate options that may be suitable for Auckland.

2. The Auckland housing market – tenure, household structure & models

Key trends

A demographic study of Auckland indicates substantial growth in population in the last two decades with shrinking household sizes and a greater number of families with children in need of affordable housing. Between 2011 and 2016, Auckland's population increased by 154,700 (+10.6%). The growth rate doubled from 1.2 to 2.8% (Auckland Growth Monitor, 2017, p. 8).

Housing affordability is far worse in Auckland when compared to other major urban centers (Johnson et al, 2018). The median price of Auckland houses rose by 65% in the last 5 years and over 90% in the last decade (p.16) and "Between 2012 and 2017 population estimated growth outstripped estimated housing stock growth by 2.1%" (p. 16-20).

Similarly, demographical studies observe noticeable shifts in homeownership patterns, changes in household structures, and interest in previously less preferred housing models in the last couple of decades (Goodyear & Fabian, 2014, p. 18-45).

Rents were also found to be highest in Auckland with a majority of households from low-income group. Thus, 83.7% of the total (35%) Auckland renters found concentrated in the open market may have no option except to pay the market rent (Statistics NZ 2014, p15). The homeownership rate in New Zealand decreased to 64.80 % in 2013 from 66.9% percent in 2006 (Census, 2013) and renting was up 18.5% during the same period (Goodyear & Fabian, 2014, p. 45). In addition to an overall drop in homeownership, the largest falls were observed for working adults in 30s and 40s, possibly comprising households with children. However, tenure preferences in Auckland indicate a stronger interest in homeownership in comparison to renting.

As per a focus group survey from Auckland and Wellington, 58.4% indicated a strong desire for homeownership and only 2% indicated renting as a preferred choice. Also, around 50% of the renters stated insufficient deposits as the primary reason for renting and 43% of indicated renting as a negative experience (Flint-Hartle, Stangl, 2014, p 7-12). Thus, 'insufficient deposit' appears as the number one obstacle when it comes to property purchase. 'Perceived difficulty of servicing mortgage repayments based on current income levels', was cited as a second barrier in advancing towards homeownership (p 4).

It emerges, it is not just initial 'setting foot' into the property market that poses a challenge for potential homeowners but a long-term financial commitment in the form of a heavy mortgage thereafter, that also causes sufficient uneasiness among house buyers.

Polarized preferences indicate low-income households concentrated in the private rental market and high-income households have a preference for but unable to acquire homeownership. The scenario confirms challenges faced by households to negotiate the widening gap between the two tenures. Thus, with a clear desire to advance into homeownership but an inability of households to do so, suggests, inflexibility in current pathways to homeownership limiting choices for households.

Besides the above limitations, Auckland is also witnessing a significant shrink in the average family size and changing the household composition. An overall trend witnessed in the household structure indicates a reduction in the average household size with a rapid increase in one-person households as well as couple-only households. A projected family distribution by Statistics NZ 2017 suggests the number of couples without children is projected to increase by 64% in a 25-year period between 2013 to 2038 in Auckland. The average household size is projected to further decline from 2.6 to 2.4 people per household between 2006 and 2038. However, multi-story private joined dwellings have increased 3% between 2006 and 2013 suggesting new trends of larger or extended families residing together. Thus, not only is the traditional definition of a family comprising two adults and two children being replaced by smaller households, a demand for a more complex set up of family units and greater multigenerational living maybe on the rise (Goodyear & Fabian, 2014, p. 34-67).

The above-mentioned changes in family typology are significant and must be catered for in designs of future dwellings. Thus, a need to experiment with housing typologies to match changing household structures is apparent.

Trends in preferences for housing stock also reveal interesting findings. Standalone houses remain the highest consented dwelling type as per latest building consents issued in Auckland suggesting, increasing housing unaffordability has had no impact in the popularity of this land consuming- high priced model. According to the Auckland Monthly Housing Update (Building consents), “46% of new dwellings consented in January 2019 were houses, 30% were apartments and 25% were townhouses, flats, units, retirement units, or other types of attached dwellings” (March 2019). However, another parallel trend indicates a sharp increase in the number of consents lodged (and presumably being built) for apartments. This trend with high rise apartments continues to be on a steady rise but primarily restricted to the CBD and popular with one-member households, such as students (Apartment Dwellers, 2006 Census).

Thus, there seem fewer incentive for private developers to invest in similar multifamily dwellings in residential zones other than CBD for some reason. Multi-family residential dwellings with common amenities remains an underexplored housing typology in Auckland (Flint-Hartle, Stangl, 2014). Therefore, the lack of alternative family housing models may also explain the polarity in preference towards standalone dwellings. In addition, minimal experiments with collaborative housing also reduce the possibility of experimenting with newer housing models that may offer suitable alternatives for families.

Interestingly, a recent study on housing preferences reveals households’ willingness to consider the apartment typology in a non-preferred location, if the apartment models are well-designed, spacious, affordable and well connected. Thus, households are prepared to consider “something other than detached housing”, such as apartments, other than the first preference of standalone dwellings when faced with financial constraints (p.4). However, in spite of such willingness to consider an alternative model the demand for apartments by families, even in well-connected CBD, remained fairly low in the survey, at “just over 1%”, further suggesting the inadequacy of either space or amenities in CBD apartments (Yeoman & Akehurst, 2015, p.12).

Thus, not only are current tenure options a clean split between renting and the conventional bank mortgages but changing household structures and preferences also need newer models to address housing needs. Till alternative options are available for both, from a buyer’s perspective, a choice may be deemed missing from the current Auckland housing market.

How can choice make housing affordable for households? What are the essential components of housing choices that may enable and not encumber households?

The next segment discusses the concept of choice from the perspective of households and what flexibility to choose entails.

3. Theorizing affordable – the role of ‘choice’

Housing choice seems essential for consumers to be able to make suitable housing decisions around tenure, model, location and affordability. For choice to remain legitimate, information and access to resources must be supplied by the stakeholders as essential parameters, such that households can make informed decisions out of the free will. “Choice is an illusion unless there is an actual capability to take decisions” (Brown & King, 2005, p. 73).

King (2003) defines housing choice in the context of “autonomy, liberty, and responsibility”, as the ability to choose or “select from alternatives”. The choice must allow consumers, “make a preference and thus distinguish between entities”, even if, “the alternative is an either/or between two less than perfect solutions” (p. 36). Further adds, choices carry inherent connotations of duty, accountability, and liability by the customer when exercising the preferred option.

Lusk (1997) expresses choice as a bilateral agreement between consumers and suppliers, suggesting, “Suppliers also have a choice over the sector of the marketplace at which they aim and exercise this choice by price and specification”. However, cautions, neither party must dominate the transaction and disrupt the flow, failing which, it may cease to be a “sustainable pattern of exchange” and automatically result in the loss of choice (p. 70).

An understanding of choice offered by King (2003) and Lusk (1997) seems applicable to missing alternatives of homeownership from the Auckland housing market. As per King’s argument, a lack of choice can be viewed as restricted access to homeownership and, based on Lusk’s advocacy for fairness in supply and demand, one may deem the current equation in the Auckland housing market as a disbalanced equation and therefore likely unsustainable in the long term.

Thus, based on the market findings and the theory of choice, the research conjectures missing alternatives in the current homeownership pathways in Auckland. However, the limiting nature of the current pathways disguises opportunities for experimenting with alternative models and multifamily typologies. The missing elements when put together create a distinct possibility of introducing an alternative homeownership pathway to the market.

Termed as, **Intergenerational Community Developments** or **ICD**, a specifically coined term for the research, such alternatives can be described as a collaborative initiative for affordable housing with a three-element intersection. The elements comprise an organizational, financial and physical element in the form of a multi-sector organization that offers alternative procurement models for multifamily housing.

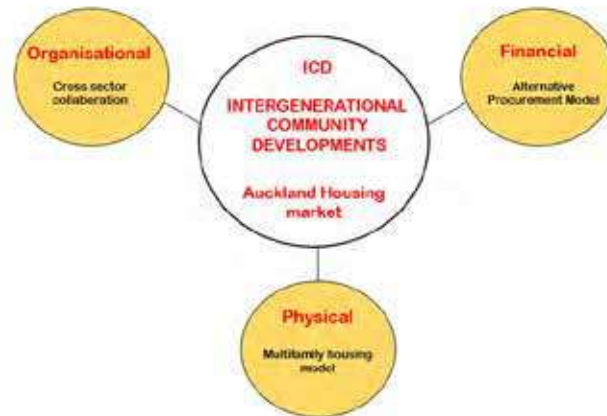

Figure 1 ICD – A proposed affordable housing alternative
Source: Author

Thus, this paper further examines multiple overseas cases to uncover the dynamics between the core elements of an ICD to better understanding of people-centered housing that involves user feedback for solutions.

4. A Note on methodology

The study draws from 16 selected ICDs with diversity in the type of collaboration, size, and nature of development and variety of housing models. Examining multiple cases in different locations allows for an understanding of the unique set of conditions and the processes behind the formation and operation of ICDs. Multiple case study allows researchers to explore differences within, between and across cases with an aim of either literal replication – predict similar results across cases or theoretical replication – to allow contradictory findings to generate theory (Yin, 2003). Similarly, Eckstein argues, multiple case studies are likely to be more effective in confirming hypothesis rather than generating one as they assist in theory testing especially where a minimal value is attached to a conventional theory, such as, in the initial query stages of the researcher, 1975). Also, as per Flyvbjerg, a few selected cases provide deeper insights behind causes and their consequences and establish validity (2006, p. 229).

The study considers several cases to the point of ‘redundancy’ (Lincoln Y & Guba E, 1985, p. 210). Once repetition between case credentials begins to emerge, no more cases are added to the selection. Upon reaching the point of saturation (Yin, 1994) or point of diminishing return (Glaser and Strauss, 1967) the study finalizes a range of ICDs. The final 16 cases are located all across the city from CBD, abandoned inner city location to large suburban sites. Thus, 4 basic categories emerged based on the location and co-relation with the nature of the development, namely,

- urban infill - small inner-city developments on vacant plot
- estate regeneration - demolition, re modification, addition to existing housing
- suburban developments - new city fringe or suburban projects
- neighbourhood renewal - large scale greenfield transit-oriented developments

The decision to assimilate cases from a design perspective emerges from the fact, even though, the organizational element of a collaboration initiates the processes and the financial component propels major decisions, it is the physical element of housing that actualizes the core intention behind any ICD intervention. Thus, from an architectural perspective, a thorough understanding of an ICD may occur only as a consequence of un-layering the design strategies. Thus, it seemed appropriate to create categories that appear to further an architects’ understanding of an ICD. The discussion on findings in this paper is, however, theme-based and generic in nature.

Data collection includes documentary analysis of established housing projects completed in the last 10 years and endorsed by institutes such as the National Housing Institute, USA, Urban Land Institute, USA, U.S. Department of Housing and Urban Development, Community Housing Institute, UK as well as winners of the National Housing Awards, UK, and winners of affordable housing projects of the Royal Institute of British Architects.

5. Discussion on findings

The findings are arranged in three distinct themes corresponding to the core elements of an ICD.

I. Key findings: Collaborative endeavour

Figure 2 ICD Element 1– Collaborative endeavour
Source: Author

The fundamental step towards creating any ICD originate from the entrepreneurial initiatives of the main housing provider who forms a consortium with other stakeholders. An overall values-based vision then acts as a necessary binding factor. The findings reveal 56% of the initiatives originate from either the state or local councils and 38% of the cases are led by a third sector agent. However, the main purpose of a unified vision is to be able to develop a clear understanding of others' motivations, strengths, limitations, and resources to ascertain the precise nature of housing assistance it may best offer to end users.

The collaboration agenda may range from providing affordable below-market housing for workforce families, creating affordable mixed-income housing for intergenerational living, creating good quality energy-efficient buildings or, in bigger projects, envision complete regeneration of neighbourhoods through housing and infrastructure development.

Also, a unified vision allows clarity to set up early processes of end-user involvement to determine the exact profile, income background and eligibility criteria of prospective households. Such clarity in processes further establishes the necessity of 'stewardship' required to build financial dexterity of households, especially in the low-income category. 'Stewardship' or 'placemaking' refers to guardianship roles that require a housing agent to provide financial mentoring to householders prior to and post-purchase. In 88% of the ICDs, the main housing agent executes extended stewardship roles spanning from pre-sale agreements to active tenancy management and resale.

Most public and third sector housing agents also readily seem to fulfill this obligation owing to their inherent motivation to provide affordable housing to low-income families. The findings reveal 50% of initiatives from public sector agents and 44% from the third sector. The stewardship roles may spread through the entire duration of the property purchasing cycle or may be limited to a single phase.

There also appears a connection between the extent and duration of stewardship with the type of procurement models. However, no direct correlation appears between the sector background of the agent and the duration of stewardship. Also, a likelihood of financial stewardship seems almost unavoidable in ICDs offering 100% affordable homeownership.

II. Key findings: Tenure choices

Figure 3 ICD Element 2 – Tenure choices
Source: Author

- **A holistic view of the housing continuum**

ICDs seem to allow stakeholders the opportunity to serve several segments of the housing continuum through a single intervention by offering multiple APMs simultaneously. Inclusion of a variety of income-compatible tenure options offers choice to the households thereby increasing financial flexibility. A “flexible approach” as per the householders’ requirements of “space, standards, and affordability” within the housing continuum ensures suitable allotment of housing, instead of a random distribution of resources (Thorns, 1989, p. 256). “A successful housing system provides shelter for all while facilitating people moving up the continuum to improve their own socio-economic well-being, which can also contribute improving the socio-economic well-being of an entire nation” (IHA, 2017, P. 1)

- **Balancing agendas**

However, offering the above-mentioned choices, in turn, requires stakeholders to experiment with ingenious strategies for financial autonomy. One such consequence of similar strategies that directly affect the end users is affordability clauses of the APM that preserve long term affordability for future families and offer opportunities of asset accumulation through equity building.

Striving for a balance in opportunities of wealth creation and affordability rather than independently offering opportunities for either one, remains the most challenging aspect of alternative models (Jacobus, 2007). Whereas the Shared equity homeownership (SEHO) models from the US are primarily rooted in preserving affordability their UK counterparts shared ownership (SO) and shared equity (SE) allow relatively quick access to homeownership.

- **Opportunities of homeownership**

Opportunities for homeownership and asset building correspond to the percentage of dwellings available for homeownership through APMs, excluding all rental stock.

The findings confirm ICDs offer a diverse range of asset building opportunities for homeowners through alternative tenures irrespective of the size of the development. The affordable homeownership component in the tenure mix fluctuates from 3% to 100%. Also, 4 types of APM are widely utilized for expanding homeownership opportunities in ICDs in combination with other tenures such as social rental, affordable rental, and open market sales, in varying combination. The options include CLT and below market rate homeownership from the US, and shared ownership (SO) and shared equity (SE) from the UK.

33% of ICDs in the US utilize the CLT model and 83% use below market rate homeownership for key workers. Also, affordable housing projects seem to have much wider access to dedicated funding in the US. To safeguard inbuilt community subsidies, long term deed restrictions ranging between 20-55 years may be enforced every time the property renews owner.

In the UK, 90% of cases utilize SO as an effective alternative pathway for homeownership and 20% of the total ICDs utilize the SE as an alternative for mid-income households. SO promises gradual transitioning into homeownership by initially allowing a certain percentage of ownership corresponding to the financial ability of the homeowner. The remaining portion is purchased gradually from housing

agent in affordable ‘blocks’, with the value of the block based on the current market price of the property. Such a staircasing mechanism undoubtedly introduces initial flexibility but can impose a challenge for households to match continuous escalation in share values usually proportionate to increasing house prices. Similarly, the concept of SE involves a primary mortgage and a silent second mortgage with the housing agent on the reduced portion of the house price. SE poses a tougher lending criterion and a higher expectation from the homeowner to keep up with their financial commitment, a fact that may explain fewer households qualifying for the loan. Nevertheless, with realistic financial goals set by households and financial education both options promise ownership opportunity for households from low-high income ranges.

III) Key findings: Housing outcomes

Figure 4 ICD Element 3 – Housing outcomes

Source: Author

a. Architect's role

Thus, user involvement in early decision-making processes significantly assists an architect in achieving the right balance between economies of scale, optimum resource utilization and quality of housing for which the designers must adopt a broader approach of ‘community development with housing provisions’ in ICDs.

ICD processes eventually rely on design to translate the original intent of the housing agent. The architectural contribution encapsulates the vision of the stakeholders, expectations of the community and spatial requirement of the residents. However, architects must be involved early in the project. Findings reveal, in 75% of the cases, the architects were employed during planning continue to be part of the collaboration till the construction stage.

Earlier inclusion seems to offer two benefits. Firstly, entrepreneurial roles of an architect requiring engagements with the planning authorities have a direct time and costs savings for stakeholders. Efficiently prepared planning applications directly lower costs for the users and/ or establish long-term affordability for the housing providers. Also, architects working in the pre-design planning stage can reduce recurrent costs for affordable housing developers by locking-in long term savings through energy efficient strategies.

Secondly, facilitation roles of architects allow community agenda to become an intrinsic part of the design process from the start. Architects engage users in fundamental decision making in such a bottom-end approach to housing. User engagement again proves beneficial directly in two ways. Firstly, ‘prior approval’ by the client shortens lengthy planning application processes thereby saving development time and costs (by avoiding reapplication and hearing) and speeds up construction processes. Secondly, end-user engagement and information gathering during interactions in workshops, open days and community consultation events result in continuous refinement of design from an early stage. The decisions may comprise neighborhood regeneration through holistic planning, transit-oriented housing development, site-specific master planning, energy efficient dwelling design and; most importantly, an income-neutral design approach.

b. Specific features of ICDs

• Transit-oriented development- TOD

It is noted, 56% of the ICDs are TODs irrespective of the size of the development.

All cases occur either near an existing rail corridor or adopt efficient commuting strategies for an effective linkup with the existing facilities. Therefore, proximity to existing public infrastructure seems one of the fundamental decisive factors for initial master planning that may directly impact vehicular traffic & car parking decisions. Transport plans also act as vital pre-design parameter dictating site planning, massing and open space distribution of the housing development. Well-catered transport provisions also allow the developer to apply for minimal onsite parking in the planning application and in some cases declare the development completely car-free. Overall, councils often seem to review a proposal's 'travel plans' to ensure feasibility studies have been carried out by the developers to cater to a pedestrian-friendly development and access to public transport.

• Street frontage & corner treatment

'Boundaryless' design features as a site response seem essential in community housing developments such as ICDs to allow the neighbouring resident to interact with the new development. Interactive corner features and deliberate setbacks to accommodate street furniture facilitate interaction. However, the degree of interaction can be controlled to safeguard privacy for the residents through design. Street furniture such as seating, landscaped trees, and bicycle racks can balance dual agendas of interaction and intrusion by adding a unique threshold treatment at the street level and offering privacy to the ground floor residents at the same time.

• Pedestrian ways & open spaces

Site planning in ICDs seems to lay a lot of emphasis on pedestrian-friendly design. Nearly 88% of the cases show preference to pedestrians and cyclists over vehicular traffic and cater to features such as landscaped courts, seating, planters, child-friendly play areas and small parks along with the pedestrian ways. Pedestrian pathways in multifamily residential dwellings encourage resident participation and promoting safety through neighbourhood watch.

Similarly, landscaping appears integral to overall design unification. It fosters interaction through carefully planned break out spaces. However, privacy and crime prevention must be balanced through effective landscaping. Too much foliage around open spaces can reduce visibility and hinder vigilance of common spaces. Clear visual access also seems essential for effective adult supervision of children playing outside.

ICDs also seem to offer a variety of open spaces including 75% providing large open greens, 56% incorporating smaller pocket parks, 56% catering to children's playground, 44% offering a communal vegetable garden for the residents and 1 case with an open amphitheatre topographically aligned to the natural slope. Large single open spaces also minimize maintenance work for the management.

However common challenges of a single open space with overlapping functions remain to segregate intergenerational requirements. Therefore, outdoor environments for multi-generational residents may benefit from a hierarchy of open spaces. A combination of open areas can offer privacy with smaller 'quiet zones' for elderly use and large playgrounds for the younger residents.

• Shared facilities

Nearly 63% of the developments offer a community center to its residents for social gathering. Interestingly, 34% of the cases such spaces double up as an indoor child play area or a creche. The provision of shared facilities with regular housing in ICDs lends it the 'plus more' factor, in contrast to, only dwellings offered by regular multi-residential developments. The communal facilities act as a

binding factor to facilitate resident interaction. Some designs encourage intergenerational mix between seniors and children by deliberately placing provisions for the elderly next to a childcare center.

Smaller ICDs with a limited area incorporate either a shared vegetable garden, a small green with some seating or a communal room. Larger ICDs offer a more diverse range of facilities to its residents. Overall, ICDs with a greater market sales component may provide more indoor facilities such as a leisure center and those with a larger affordable component tend to offer shared outdoor spaces. Exceptional cases include a swimming pool, fitness center and an amphitheater.

- **Multiple typologies in the same development**

ICDs seem to offer multiple choices in housing typologies for families. Overall, 63% of the ICDs offer mixed typology catering to multiple sizes and tenures, 31% offer only high rise apartments.

The housing choice ranges from single storey standalone dwellings, detached townhouses, semi-attached duplexes and triplexes, double storey flats and row housing to condominiums with shared areas in multi-story apartments and high-rise apartment blocks.

- **‘Tenure blind’ design**

One of the characteristic features of ICD lies in tenure-neutral design. 81% offer full tenure blind design, 13% offer partial tenure blind and 6% deliberately offer tenure specific typologies.

One of the main objectives of an ICD designer remains to adopt an income-neutral architectural vocabulary to conceal the tenancy background of the residents. This visual architectural homogeneity referred to as a ‘tenure blind’ approach aims at effectively blurring the financial status of the homeowners behind a uniform external treatment. Thus, multifamily residential living can offer a new approach to reduce stigmatization through ‘type’ in housing.

It appears, even though an in-depth knowledge of APMs may not be essential for architects of mixed-income housing, familiarising oneself with the financial background of prospective end users helps to develop a greater understanding of their housing aspirations that ultimately enhances the design quality.

Summing up ICDs

Overall findings reveal, 63% of cases reflect extensive people’s participation from the planning phase. It appears, user involvement as a fundamental approach to housing solution can prove successful with transparent stakeholder interactions that throughout empower end users. Early community engagements mutually benefit both parties. Resident participation helps stakeholders better understand the nature of the housing need, financial capability of the households and integrated concept of housing and community developments. Innovative solutions as a result of public participation also create a sense of pride and belongingness among the residents. Similarly, customized, cost-effective and community-focused solutions created with prior approval of the community not only eases the process of gaining preliminary consents from the regulatory authority but also, saves short- and long-term costs for the stakeholders. Cost savings can occur through reduced proposals for planning and minimal delays in project execution.

Early engagement of architects from the project conception stage seems beneficial to ICD processes. Early architect-stakeholder consultation can address multiple design issues during site feasibility studies. Community consultation allows the final design to reflect diverse needs through various housing typologies. In addition, ICDs seem to provide multiple opportunities for architectural design to integrate dwelling design, income diversity and a sense of community as one experience.

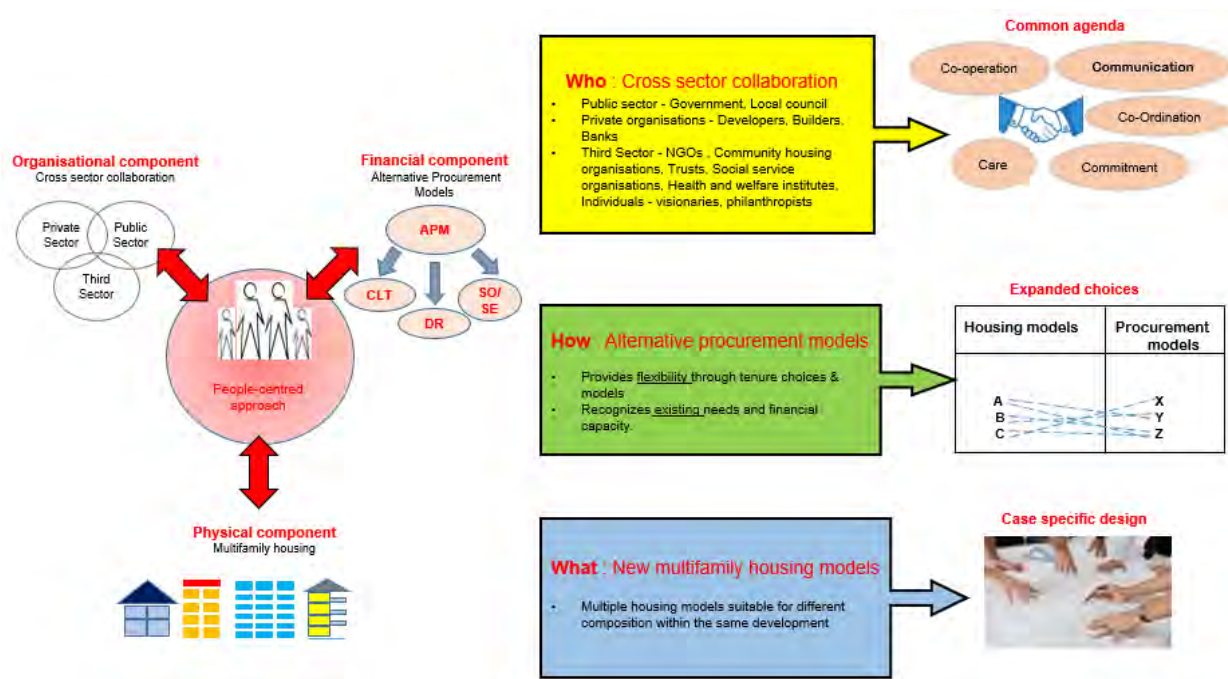

Figure 5 ICD – A people-centered approach to affordable housing
Source: Author

Thus, housing outcomes through ICD comprise a broad, holistic approach to housing that encapsulates a social, financial and physical dimension tailored for the users.

Overall findings reveal ICD can prove effective affordable housing alternatives if well-executed by the consortium. It appears the nature of collaboration has a direct bearing on the financial component of an ICD. The availability of finance, in turn, dictates the choices of APM collaboration may offer in the development. Such parameters further reflect on the density of the housing development, variety of housing models and size of the dwellings. Thus, housing outcomes through ICD comprise a broad, holistic approach to housing that encapsulates a social, financial and physical dimension tailored for the users. However, the processes must be transparent, thorough, mutually beneficial and flexible to accommodate accompanying uncertainties that may arise at any stage of the development.

Learnings for Auckland

An effective housing collaboration requires the involvement of all three sectors, each with clearly defined roles. Participation from private developers allows building the market rate component with sale profits acting as a subsidy for the affordable component. Similarly, third sector agents seem particularly effective financial stewards as they are able to closely monitor the financial performance of the households. Again, the state seems more suited as facilitators providing land and initial capital for investment. Local councils can also assist with expediting planning proposals and granting approval for infrastructural development. Thus, each sector has a distinct role to play in collaboration.

A multisector partnership with pre-defined roles is also likely to create transparency amongst the agents and preserve mutual interests in the overall proceedings. A multi-sector representation ensures a balance between dual agendas of safeguarding affordability and asset building opportunities for homeowners.

Evidence also indicates, the nature of partnerships bears a direct impact on fundraising processes for the development. Raising equity, particularly when subsidies are either non-existent or low, assists the collaboration to overcome financial constraints.

The absence of overarching policies that incentivize private developers and safeguard affordability in new build developments, currently inhibit explorative housing experiments in Auckland. Therefore, an ideal constitution for a potential ICD collaboration in Auckland must consist a private sector agent working, a third sector and a public-sector agent with a mutual stake in the development for all such that, private dollars can be leveraged with public funds effectively. This strategy can be successfully utilized irrespective of the scale of s development as evident in the overseas cases.

After the setup of a cross-sector collaboration with a clear agenda and priorities for different income groups, a spectrum of alternative tenures can be selected for Auckland. This paper recommends a range of homeownership models for the Auckland housing market. However, to fully grasp the merits and risks, develop a relational understanding between all products, and generate an effective cross-subsidization; the models must operative in the context of housing development and not through individual new builds in the open market.

The US-based CLT models seem to offer maximum stability to non-state low-income households who seek stability tenure and experience benefits of homeownership. Individual equity building opportunities may be limited in such models that are primarily focussed on the preservation of community equity. However, the stewardship component remains maximum in CLTs.

Government-funded key workers in the mid-income category who are unable to afford market rate homeownership but succeed in securing a partial deposit for slightly lower house prices and, financially capable of furnishing home loan thereafter, may considerably benefit from the ‘below market rate sale’ model from the US. A rental version of below market rate may work equally well for such income stable workforce households with low homeownership priorities but requiring stability of tenure. Either tenure assigns dedicated number of units as permanently affordable. Also, due to long term affordability covenants, both versions fully justify dedicated state funding for essential housing.

Shared ownership models from the UK act as a hybrid between renting and ownership. Since the model allows a gradual build-up of ownership based on individual financial capacity while rent may or may not be payable on the remaining part, it requires a thorough understanding of ‘how the passive portion is bought back’ on behalf of the household. The seeming flexibility of ‘buy what you can when you can’ can be misleading particularly if the clause requires mandatory purchase of shares based on the market value within a time frame. Such clauses may then prove financially cumbersome for low to mid-income families. Therefore, although an effective alternative to renting, shared ownership may not be suitable for households with either fluctuating or unsteady sources of income. Post-occupancy financial data to ascertain risks of such a model and the financial constraints imposed by the new market is essential prior to its transference to parallel economies.

‘Shared equity’ model from the UK, offering a silent second mortgage with a housing agent suitable for income-stable mid to high-income households. Asset building opportunities may be slightly higher through this model due to the use of minimal or no state subsidies. Although, a restriction on market rate sale is desirable and must be monitored through resale conditions, for the affordability agenda to remain in part. The shared equity model also imposes maximum financial responsibility on the homeowner partly due to reduced financial stewardship from the agent.

Overseas cases also offer insights on how a combination of housing typologies can be utilized within the same development for different household compositions. This includes lifestyle options such as semi-detached townhouses, midrise semi-attached townhouses with common courtyard spaces and, spacious high-rise apartments with family-friendly amenities. Also, effectively collaborating with a multi-sector agent, processes of community consultation and applying tenure blind strategies offers new areas of learning for the architects. Also, ICDs demonstrate, sustainability concepts and affordable dwellings can remain intertwined concepts for affordable housing solutions.

6. Conclusion & Future scope

Successful outcomes through ICD processes rely on deep engagement and positive interactions between multiple sector agents, each independently yet collectively executing their respective pre-defined roles. However, ICDs demand a greater level of co-ordination, co-operation, and co-operation from individual stakeholders of the collaboration as compared to housing projects without alliances.

The approach considers housing and community as fused concepts and thus adds a dimension of community participation as a prerequisite to house design and master planning. It, therefore, encourages designers to not view housing as an isolated response but to develop a holistic view that considers symbiotic associations between new housing, extended neighborhood, and the city. ICD design processes can also prove powerful tools in naturally creating a social mix as an automatic result of a tenure mix.

Understanding and implementing ICDs may require a shift in perspective from the stakeholders in Auckland, a fundamental deviation from the linear equation of demand and supply with which we currently view housing issues.

Meanwhile, an initial impetus for ICDs may require an atmosphere of interest to raise funds through effective stakeholder collaboration and reliant mechanisms like cross-subsidization for financial sustainability of the projects. Thereafter, ICD mechanisms may quickly become robust with increased multi-party interest that allows greater innovation, transparency, and efficiency in the processes. In addition, sophisticated, technologically superior and environmentally efficient design decisions can further enhance housing outcomes. A people-centered approach remains the key to its overall success.

This paper establishes the merits of collaborative housing developments. The research also opens avenues for architects to look into community housing models with tenure blind design as an expansion of their existing knowledge field. It encourages building professionals to research APMs to develop an overall understanding of user-centered affordable housing initiatives. It creates a platform for policy debates about a people-centered approach that utilizes a choice-based theory to develop a deeper understanding of housing and cities as a whole. The scope of the current study is limited to homeownership models. However, further exclusive research on rental ICDs may especially benefit low-income households and vulnerable groups.

Houses Beyond-the-Threshold. A new paradigm of housing for the third Millennium

Nausicaa Pezzoni

Città metropolitana di Milano, nausica.pezzoni@gmail.com

Abstract: 'Houses beyond-the-threshold' is a project that has seen the transformation of public housing 'under threshold' flats in the Calvairate district of Milan into living spaces for unaccompanied foreign minors, guided in a self-recovery path of the apartment they would have lived until becoming of age. The project introduces an idea of welcoming based on reciprocity, within a cultural operation that keeps together the architectural space with site-specific artistic works created for each of the apartments. Beyond the threshold of inhabiting as an answer to the need of a shelter, an unprecedented model of encounter between art, architecture, urban and social disciplines is outlined. At the same time, this initiative acts as an interpreter of a crucial need, which underlies inhabiting conditions in social houses and which finds in a lack of cultural texture the main reason for it to remain marginal. Moreover, by triggering new forms of relationship between migrants and inhabited space, the project suggests to urban planning a perspective to deal with transiency as an issue that increasingly characterizes the contemporary city.

Keywords: housing; temporary living; social inclusion; migrants integration.

Introduction

Housing Beyond-the-Threshold are public apartments renovated after a long period of abandonment, through an innovative architectural and cultural project where a new urban population – the non-accompanied foreign minors – have been included into the building process. The project, realized between 2016 and 2017 in the Calvaire district in Milan, originates from the necessity of this particular historical condition to open the city and the territory to welcome policies able to respond to the contemporary issues. A group of 20 foreign minors was guided in a path of auto-restoration of the apartment they would have lived in until their becoming of age, within a complex program of hosting and working inclusion planned by the architect Simona Riboni of Architettura delle Convivenze¹ in collaboration with Paolo Ferrari of Centro Studi Assenza² who introduced his art and science works.

This intervention has generated a place which is not only a shelter, but which is oriented to create a wider and richer idea of inhabiting. It is a place where people can learn useful professional skills, space of knowledge and encounter with the European culture in its most innovative expressions. The 7 houses so far renovated, restored from a previous ‘under-threshold’ condition, represent the catalyst of an urban regeneration process which is at the same time the result and the trend of an effective citizenship construction.

Beyond the belonging. Living in a different place

The project of Housing Beyond-the-Threshold responds to more than one issues that are nowadays questioning urban policies.

The first issue regards the renovation of the degraded building heritage. In this contest, it assumes a strong social importance, because the apartments are located in a historical district of public social housing in Milan: these suburbs are effected by deep changes of inhabitants’ economic conditions, by the progressive degrading of physical structures, and also by problems deriving from the coexistence of people with different geographical origins (AA.VV., 2005; Di Biagi, 2006). On top of these problems typical of all the peripheral areas of our cities, we can find a local condition where in the last two decades the results of the social texture dissolution became more evident: a district originally inhabited by the working class, which breaking apart produced conflicts and discomfort, mistrust between old and new inhabitants, nucleus of deep poverty, loneliness. A number of fragilities surfaced during the

¹ Architettura delle Convivenze is a social architecture firm that realizes projects for the weak population categories (rome and sinti, homeless, Italians and foreigners at risk of marginalization, unaccompanied foreign minors) through participatory planning, self-recovery and self-construction.

² Centro Studi Assenza is a non-profit scientific-cultural association active in various fields: psychotherapy and psychiatry, philosophy, theater, art, architecture, music and literature. It deals with the relationship between art and science and care in the different variations concerning the territory (artistic-scientific-architectural installations), the species (theater), the individual (psychotherapy).

90s, were faced by the Municipality in 2004 with the «Contratto di quartiere II Molise Calvairate»³. The entrance of a foreign presence in this urban and social context – the newest of the populations arriving on the urban scene, the most fragile – with an active role in space restoration, represents the paradoxical input to a complex, radical reconstruction of that social texture (figure 1).

Figure 1: View from one the apartments in Calvairate district, Milan (Photo by Sara Magni)

The second issue regards the direct involvement of inhabitants in the restoration process, and the contribute they could bring in more general urban regeneration. The project of Housing Beyond-the-Threshold responds directly to the issues of participation through a process of appropriation (and disappropriation, as we will see), of integration and of public space care through different points of view: first, the material intervention on the building renovation, second, the immaterial action concerning the relationships generated by the restoration activity, and last the kind of the involved population.

The third issue concerns urban planning at the heart of contemporary inhabiting, because it opens glimpses on a dimension, transitory living, which is increasingly characterizing the processes of cities transformation, while urban planning tools are still linked to a sedentary perspective. That is to say, the project Housing Beyond-the-Threshold shows how a new paradigm of inhabiting, based on precise ethical issues, could be a model for a discipline which is today confronting itself with temporariness – in space uses and in the permanence of inhabitants in that space – as a distinctive and updated characteristic of its own study matter.

3 Contratti di quartiere (Neighborhood contracts) are urban redevelopment interventions to promote housing and social integration within public housing districts.

There is a fourth question, starting from here and embracing all the previous ones: it is the model of welcoming proposed by this project. An ethical model questioning itself about how to build a culture of hospitality as a condition of mutual enrichment. “What could we give – what is more beautiful, more interesting, more valid – to people arriving from other countries in our culture, in our history, in our landscape? What could we exchange?” This question was posed by Paolo Ferrari, author of the works present in the apartments, on the occasion of the public presentation of the project during the ‘Giornata del Contemporaneo’⁴.

Inside each apartment a site specific work has been inserted as an open window on the landscape, which introduces a new perspective in the architectural space: the sea horizon, the mountains outline, the track around the ricefields, the vine border (figure 2), the far end of a wood path. These are Italian landscapes in black and white taken by the camera, doubled by the painting act of the author, and even more layered with transparent graph paper with pen drawings mostly representing ancient biblical shapes. Each layer composing the work contributes to the formation of a complex system so that the landscape moves from its usual place – with its traditional shapes – to other-place, introducing an horizon where the *otherness* can enter, which is the otherness brought by young people who will inhabit these spaces, and it is the otherness living in all of us.

Figure 2: Paolo Ferrari's work inserted in one of the apartments.

⁴ ‘Giornata del Contemporaneo’ (The Day of the Contemporary) is an event that since 2005 AMACI (Friends of Italian Contemporary Art Museums) has dedicated to contemporary art. Every year in October the museums and all the institutions that adhere to the initiative, open their doors for free, accepting exhibitions, events, conferences and workshops (www.amaci.org). The Houses Beyond-the-Threshold have been opened to the public on October 14th 2017, during the XIII Day of the Contemporary, during which the authors explained the conception and contents of the project, with the presence of all the minors involved in self-recovery, in a meeting open to citizenship.

A welcoming policy capable of reciprocity

The Housing Beyond-the-Threshold project is based on a reciprocity idea and it applies this idea thinking of a high cultural exchange. The complex artistic-architectonical, educative and political program, where the auto-restoring process is inserted, aims to satisfy not only the primary needs, but also to create spaces which can be at the same time learning spaces generating new culture. It indicates an alternative, putting in it a radical innovation, to the European solutions which are trying to give answers to the question of immigrants welcoming: by adapting industrial buildings, ex hotels, ex discos, old people homes, as extraordinary welcoming centres.⁵ Recovering barracks, building camps, allocating dismissed areas – even a missile base –⁶ for the permanence of people in need of a place, even if temporary, where to live. Making use of places which are very often the rests of a dismissal of not residential spaces.

The ethical and cultural more than the methodological horizon towards which welcoming policies move – except in few and at the moment isolated exceptions –⁷ seems not to be able to consider the articulated process of access to the city by migrants outside an emergency logic, necessarily connected to the exclusion of those populations from the inhabiting system that the Western world has been using at least since Modern age.

Nevertheless, contemporaneity challenges us right on the field of inclusion policies in relation with an epochal migration movement. Men and women, families and individuals, of all ages, cross the world ready to change not only their existences, but also the consolidated geometries of landing spaces and the paradigms on which the inhabiting project is based.

The history of the new Millennium is the history of a walking humanity: one of the greatest revolutions ever happened, may be of the same importance of when the primates started moving from Africa and started to travel the seas and discover new lands. “It seemed that nothing should happen anymore, that everything was already done. And here is, instead, the new Millennium! Like never before a new Millennium has arrived full of future. All the western world seems to believe in the possibility to continue to breath the same air, to live on the same land, while the world has rolled in an invisible, silent, un-perceptible way in new times, as if the atmosphere of the planet, its oxygen, the burning rhythm and all the watches springs had changed” (Quirico, 2016).

⁵ In Italy, CAS (Centri Accoglienza Straordinaria) are defined by the Ministry of the Interior "temporary structures" and, according to the decree 142/2015, must satisfy the "essential needs" of welcoming. In reality they represent the base of Italian hospitality with around 3,090 structures. “They are imagined in order to make up for the lack of places in the ordinary reception structures or in the services set up by the local authorities, in the case of large and close arrivals of applicants. To date, they are the ordinary mode of reception. These structures are identified by the prefectures, in agreement with cooperatives, associations and hotel structures, according to the procedures for awarding public contracts, having heard the local authority in whose territory the structure is located. The stay should be limited to the time strictly necessary for the transfer of the applicant to the second reception facilities ” (www.openmigration.org).

⁶ The reference is to the former Cona missile base (Vicenza) used as a first reception center, in a completely isolated place.

⁷ The case of the Municipality of Riace remains the only example in Italy of urban regeneration and rebirth of an entire territory through the inclusion and work of migrants and the construction of a new model of coexistence (Cfr. Pezzoni, 2016).

The western culture not only is un-ready to this great transformation, but it opposes defensive walls controlling its borders, walls that the pressure of poverty and war keep on breaking down vigorously. It builds, within itself, surveillance and confinement devices which are not able to contain the entrances nor to territorialize those who don't belong. Trying to maintain as a whole the 'same previous land', barriers exclusions rejections produce, in an effective way, new conceptual categories that inevitably have an impact on those 'welcome measures' that should generate the inhabiting policy of the Third Millennium. In the very short time witnessing the transformation of Europe into a Fortresse – less than 20 years – categories like 'humanity in excess' (Rahola, 2003), or even of 'in-humanity' (Galli, 2005), became popular in the political debate and in the common perception determining the field where to face the complex challenge of coexistence.

It is necessary to change the interpretative paradigms of a fast changing reality, trying to see in the 'other' not an excess, to expel or to limit and reduce to numbers, to dimensions and to impacts, but a foreign presence who is asking to be welcomed on a ground of equality.

Under the Threshold, beyond-the-Threshold

The Housing Beyond-the-Threshold project is directed to young immigrants arrived in Italy unaccompanied, persons who are looking for new resources not only to survive with the satisfaction of primary needs, but also who are looking for knowledge sources of new models of reality, different from their origin ones.

In front of a complex question of welcoming, the project aims to respond with a multilevel program, promoting an inhabiting solution which is not located outside *our* inhabiting space, nor it can be considered a pure shelter from a hostile world to escape. It is a place open to new learning perspectives: a place for the mind, for the body and soul of people looking for dignified spaces where to live.

To introduce young immigrants into one of the historical districts of the city, one of the first examples of rationalist architecture in Milan (the architects Cesare and Maurizio Mazzocchi won in 1932 a contest to host 2250 inhabitants) means to include the new inhabitants in the heart of our architectural and housing culture (figure 3). To renovate dismissed spaces, making the old residential standards applied to plan those apartments functional to the contemporary life, through the work of the migrants themselves, means to engage people arriving from other geographical and cultural contexts in urban regeneration processes. It means also to renew and give a new life to a space originally built to host, almost one century ago, a new urban society who would have found in that environment functional answers to the different needs of modern life.

The apartments destined to the project are classified "under the threshold" as they are under-dimensioned in relation to the actual laws: Regional Lombardy rules n. 1/2004 imposes that an apartment of less than 28.80 square meters cannot be considered available for the public residential building classification and therefore it cannot be stated as inhabitable. Other apartments, with a little bigger surface, are defined "under threshold" because they are degraded, lacking in toilet services and with unfitted structures. These apartments have been empty for years and only recently the Municipality and ALER (Azienda Lombarda Edilizia Residenziale) have extrapolated them from their heritage and given them to associations or cooperatives which are in charge of their renovation. Often the renovation

is carried putting some of them together and later assigning to members with sustainable renting for those who cannot afford the private market (Molinari, Pala, 2014).

Restoring these apartments means to take away from the degrade a relevant part of the public buildings – the unrented apartments in the municipality of Milan are about 3.200 – and to make it inhabitable again by “families or singles, with a strong need of houses”, as the responsible of one of the involved cooperatives says.⁸

Figure 3: View from one the apartments in Calvairate district, Milan (Photo by Paolo Ferrari)

To this incremental and point renewal program, the project Housing Beyond-the-Threshold adds two factors that, in synergy, make it an outpost of the urban regeneration policies and at the same time of the welcoming ones. The first factor concerns the choice by Comunità Progetto – one of the cooperatives indicated by Alers to handle some under-threshold apartments – to start a welcoming path for foreign minors including them directly in the process of renovation. A choice deriving from an educative project of autonomy and from the need of keeping the costs low, so as to include in the new apartments people with specific housing needs: the economical, related to an affordable rent; the social, related to an integration on different levels – housing level, relationships, education, and job creation. The second factor is about the new conceptual language and the method applied by Architettura delle Convivenze and Centro Studi Assenza, to which the cooperative assigned the project, in dealing with this work. A conceptual language deriving from a years long research about a new paradigm of care – of the

⁸ From the description of the DAR = CASA project, one of the cooperatives involved in the processes of recovery and re-allocation of housing.

individual and of the community – as an open, and necessary disposition to the *other from oneself*. A method able to set the conditions to build an effective citizenship route.

The architectural project: hosting *the other from oneself*

“This side of responsibility, there is solidarity. Beyond, there is hospitality” (Jabès, 1991).

Beyond the Threshold is a concept with different degrees of complexity. It springs from the definition of unfeasibility based on the building regulations in respect of the condition of some apartments, and it indicates a consequent requalification project of those apartments.

In this way it answers to the first issue questioning today urban policies: the issue of an urban regeneration characterized by being selective and gradual in facing the contemporary problems (Gabellini, 2014), and that considers public residential districts as a “great opportunity to start social and spatial regeneration processes, as important and with similar impacts as those registered, in the recent past, by the intensive season of projects dedicated to the reuse of industrial abandoned areas” (AA.VV., 2009).

Beyond the Threshold refers to a housing and social inclusion program where the restoration of inhabiting spaces is realized by the users themselves: not the research of an emergency solution, nor the protection in a specific structure for minors, but skills exchange and a common work are set as necessary to build integration. Beyond the threshold of the nowadays welcome policies. According with the method of Architettura delle Convivenze, minors were taught the fundamentals of the job necessary to requalify the space where they would have lived.

A method that twists the ‘asylum seekers’ condition from a *waiting* one (where people cannot work until they are recognized as refugees) into an *active disposal condition* to build a place where to live. This means the migrants can make use of their time and their learning and job skills instead of living in a resentful limbo; whereas this means for the arrival society to use the energies and the industriousness of young people coming here to work, and to offer them a hospitality based on equality rather than charity.

Beyond the Threshold tells also about an exit from home though which the formation acquired during the restoration of their own dwelling becomes technical knowledge to use outside, in the labour world, through a learning process which is not generic but oriented to address each of them towards the individual abilities. Beyond the threshold of the economic dependence and the social services reliance.

Like in any participated intervention, the learning practice where the minors have been included generated an appropriation process of the space they were transforming. A process that allowed an identification with the place to inhabit, and therefore the recognition of a sense of belonging necessary to start a citizenship process; at the same time it has allowed a not permanent belonging, since the apartments are designed for a transitory inhabiting. The work of self-recovering, together with the construction of premises to an effective integration, is conceived as an activity for themselves and for the ones who will come later: the hosted migrants become the welcome creators. Beyond affirming their own presence in the place they took care of, they also take care of a space belonging to all the people

who will inhabit it, in this way opening to that care of the common space which is fundamental in every real plan of co-habitation.

Figure 4: Plan of the apartment in Via degli Etruschi 5, Milan.

This process of appropriation and dis-appropriation of space gives important suggestions to urban planning. In fact, the territorial government can select ordinary residential places to be transformed in a not temporary way, but in a wide perspective, into transitory inhabiting spaces within an articulated and complex program of habitability for those people who become architects of the material and immaterial requalification of the city.

Some indications for a first organic plan of transitory inhabiting have been recently introduced, in Italy, by an urban planning tool as the 'Extraordinary Program for urban regeneration and peripheries security' (ex D.P.C.M 25/5/2016). In the framework of this tool, the Metropolitan City Authority of Milan has proposed a plan called 'Metropolitan welfare and urban regeneration. Overcoming emergencies and planning new spaces of cohesion and welcoming' where the requalification of abandoned spaces is oriented to a transitory inhabiting, together with services concerning integration and formation, so as to allow "the inhabitants to feel involved in a program of renovation regarding different aspects of civil coexistence" (Città metropolitana di Milano, 2016).

This plan can show how it is possible to construct experimental planning tools aimed at contemporary issues, despite the delay of policies in order to re-define social housing as a part of an articulated range of services aimed at guaranteeing the habitability of the city (Guerzoni, 2012; Poggio, 2005; Tosi, 2004, 2016). These experimental planning tools are disposed to govern phenomena with a more rapid dynamic than that faced by ordinary planning tools, and moreover they don't premise a regulatory framework before; but they require a deep reasoning on the sense of inhabiting, so that their projects can be grounded in the processes of transformation under way.

In this perspective, the Housing Beyond-the-Threshold project stresses urban planning on the valence of house as a possible pivot of a social infrastructure for the contemporary city, open to transience. Beyond the house as a place where one can recognize himself, a new paradigm of inhabiting is proposed, where the sense of *habitus* proper of a dwelling that finds its habits in the inhabited space, is replaced by an approach intrinsically open to the other by itself (Pezzoni, 2013).

Figure 5: One inhabitant is studying in front of a landscape (Photo by Matteo Fiorini)

An opening also induced by the artistic gesture, which crosses the apartments expanding the physical space and inviting the observer to widen the gaze beyond the horizon of everyday life – to explore the new landscape that manifests itself in the heart of every home (figure 4). Each work of art replaces almost entirely the central wall, which becomes a membrane permeable to the observation and to the presence of the observer in relation to it (figure 5): placing the ulterior plane of an unknown universe, it welcomes the inhabitant and at the same time it leads him outside – beyond the threshold – unlike his own being estranged, unlike his own simple inhabiting.

A network project for Milan, a city of hospitality

The outcome of an architectural project that places at the centre of its intervention an aesthetic operation with implications on the social level – the extra space with which to “address the unexpressed wishes of the stranger” (Ferrel, McNamara, 2018) – the Housing Beyond-the-Threshold form a network of *doubled* and *dematerialized* apartments, like a writing that overlaps with the history of the Molise-Calvaire district, tracing a new narrative.

In turn, the entire installation is part of a network of interventions in the territory of Milan and beyond Milan, where other public spaces have been previously transformed through the same process: places

for work, culture, sociality, to which these houses intertwine creating a space for living that does not appeal solely to itself, but which recalls a larger project at the urban scale.

The redevelopment interventions carried out over the years through the inclusion of Ferrari's site-specific works have involved a robotized furnace, tòpos of the repetitive work of the factory, in Valenza (1997 and 2007); a Milanese cultural association - *Isolacasateatro* (2003); the interior space and the front of a restaurant - *Il Luogo di Aimo e Nadia* (2000 and 2008); the self-construction social projects *Il Dado* in Settimo Torinese and in the self-managed House in via Morigi, in Milan (2009), as well as the headquarters of the Centro Studi Assenza association (1981) which is the masterly place of all the installations. The specific sign of the works that *double* these different places becomes the presence on the territory of an artistic gesture recognizable in each of the installations, which propose to act as catalysts capable of increasing the quality of life and work in the places with which relate.

The works included in the Houses Beyond-the-Threshold are intertwined with the most recent installations that affect the historical cores and the paths of the agricultural landscape around Milan: the itinerary *A new landscape feeds the traveler*,⁹ and its development along the Navigli canals right on the shores of the Darsena (figure 6), in the heart of the city, they form the articulated weave of a transformative aesthetic project in which art becomes “constructor of world” (Verri, 2010), opening in each place “new ways - in the territories of the eye” (Altman, 1998) generative of values not only aesthetic, propulsive of a different vision of the world.

Figure 6: The façade of the municipal market on the Darsena, Milan (Photo by Paolo Ferrari)

⁹ The project “A new Landscape nurtures the traveller” has been presented at the IX Day of Studies INU (Istituto Nazionale Urbanistica) “Blue and green infrastructures, virtual cultural and social network” on 18/12/2015.

The network formed by these ‘artistic-scientific-architectural’ operations becomes a sign of welcoming for the city, the open weave of an inhabiting condition that leads out of the habitual pattern of a pre-established reality. Marking, for those who already live there, an irreversible gap concerning the processes of identification with their own places, to be defended and preserved from an extraneousness that subverts them. Defining, for those who are new arrivals, the outlines of a new kind of belonging, given by the learning of a language – artistic, architectural, urban policies – capable of reciprocity, although not immediate, as is the project of a hospitality not enslaved to a dynamic of power but aimed at the development of the best skills of those who have to inhabit these places.

An aesthetic and ethical project at the same time, where the relationship between inhabitant and inhabited place is triggered by a reciprocity generated by an architecture that has become the interpreter of the ‘spirit of generosity’ on which its social role is based, as recently affirmed by the curators of the 2018 Architecture Biennale. Where the city takes care of all its inhabitants in leading them to the threshold – beyond the threshold – of a space that opens up to the other, tracing the path of a project through which old and new inhabitants can access what it does not belong (yet), within which it is possible to build a belonging rich in (own) extraneousness.

Housing deficit and housing opportunities: implementing collective ownership in the centre of São Paulo, Brazil. The case of FICA fund

Maurizio Pioletti¹, Renato Cymbalista²

¹*DIST, Polytechnic of Turin, Italy. maurizio.pioletti@polito.it*

²*College of Architecture and Urbanism, University of São Paulo, Brazil. rcymbalista@usp.br*

Abstract: In the centre of São Paulo, numerous people are excluded from the legal formal housing market, because of too high rent prices in proportion to average salaries. In fact, the speculation on housing prices is widespread, determining unsustainable rent prices for poor and lower-middle classes, who often must live in peripheries while working in the centre, and suffer from long daily commuting. Exclusion from housing market firstly regards the lowest income people, but they need comprehensive social support, and not just an adjustment of the proportion salary/rent, to improve their living conditions. Nevertheless, it is possible to invert this trend thanks to non-profit initiatives of collective ownership. In fact, in 2015, in São Paulo a citizens' formal association created the Community Real Estate Fund for rent. It is legally able to collect donations in cash and in real estate, buy and refurbish an apartment, and rent it to people at risk of exclusion. Throughout further donations and an economically sustainable, but equal financial management, the Fund will be able to buy other apartments and rent them to other people. Assuming a community-based approach to private property, private interests can be replaced by non-profit ownership, providing accessible houses to the members of the community. Rent prices can be defined with respect to the minimum salary, and so, not overcoming a critical threshold, including more people in the housing market.

Keywords: Collective ownership, social rental housing, São Paulo, Brazil

Introduction

In the last ten years, the federal and municipal Brazilian housing policy has shown that limits of the ordinary private property regime are critical, whether the legal attribution of private property titles is the main procedure to ensure adequate housing for people, including the lowest income group.

Although building over 4 million of housing units, in the end, the notorious federal housing Minha Casa Minha Vida (MCMV) programme¹ resulted in the inflation of the land price (Geraldo, 2014), because it paradoxically depended on the availability of low-priced land, to realize the targeted projects (Klintowitz, 2016).

¹ Activated in 2009 by the Lula's federal government, is one the largest national housing programmes worldwide. <http://www.caixa.gov.br/voce/habitacao/minha-casa-minha-vida/urbana/Paginas/default.aspx>

The high prices of buildings realized throughout the MCMV explained why the programme failed in providing accessible housing options in the central regions of Brazilian cities (Rolnik et. al, 2015). The large distance between the localization of the new residential neighbourhoods and the central regions of the targeted cities increased, showing larger and larger barriers to access to central locations for the new settlements (Lima Neto, Krause e Furtado, 2015). However, that was not a new, or surprising effect, but an evident risk, that had already been foreseen by some experts, when the programme was announced (Bonduki, 2009).

In general terms, one of the main housing options in Brazil, defended by progressive political groups, is the housing policy based on rent. In this option, the renting relationships imply the division of the land-use exchange value of a property, avoiding that the new dweller sells the property he has just received with public financial support and goes back to precarious or unhealthy settlements. Policies based on rent do not imply debts or financial interests for the beneficiaries, who pay for housing as a service, and not as building stock. Further, when the property of the rented house is public, there are more chances to control the rent prices.

Numerous academic studies on the social rent have defended this approach as a “principle” and are addressed to illustrate this type of housing initiatives more than properly analyse and assess them. A dossier entitled “housing and social rent in Brazil”, elaborated by Mourad and Baltrusis (2014) contained articles on the national situation of housing rent (Pasternak e Bogus, 2014); on problematizing the absence of a social rent programme in Salvador (Baltrusis e Mourad, 2014); on data regarding housing and tenants in Curitiba, denouncing the absence of social rent programmes (Moreira, 2014); on the need of a programme of social rent in Belem, and the existence of buildings which could be used for this aim (Mercês, Tourinho e Lobo, 2014). Finally, just an article reports some realized experience in São Paulo (D’Ottaviano, 2014).

Another recurrence is the citation of international experiences. Santos, Medeiros & Luft (2016) on a paper regarding the social rent in Rio de Janeiro, on the one side, pointed out the permanent absence of renting housing policy, and on the other, refer to the French case. Balbim (2015) mentions such examples as France and Italy, in order to show the feasibility of housing policies based on rent, to defend a national programme called Social Housing Service, proposed by the Ministry of Cities in 2009, but that has never been regulated and so neither implemented. Paolinelli (2017) discusses the feasibility of rent-based policies, mentioning international examples and São Paulo as the unique advanced case in Brazil, followed by Belo Horizonte, but just for expectations and opportunities.

A single experience on public owned social rental is in course in the country so far, in the Municipality of São Paulo, that since the beginning of the XXI century has promoted social rent, built and preserved more for the effort of some officers than for the municipal political will.

In São Paulo 6 projects are currently managed by the system of social municipal location: Parque do Gato (486 units, 2004), Olarias (137 units, 2004), Vila dos Idosos (145 units, 2007), Asdrubal do Nascimento (40 units, 2009), Senador Feijó (45 units, 2009), Palacete dos Artistas (50 units, 2014). Just a few works present assessments on this issue, based on empirical evidence. The Municipality of São Paulo produced three assessment reports (2005, 2008, 2012, apud Gatti, 2015), Kohara et. al (2012) distributed 28 questionnaires; Gatti (2015) realized a field research in Parque do Gato and Vila dos Idosos and was based on the assessments produced in the town hall. For the settled families involved in the programme and remaining in those units the living conditions improved, but many of them were coming from situations of extreme poverty or using most of their income for paying the rent (Kohara, Comaru, Ferro, 2011).

From the point of view of public power, the situation is quite complex. One year after the beginning of the implementation of the first two projects, the non-compliance was more than 50%. The wider project, the Parque do Gato, presented since the first two years the most critical situation: non-compliance, informal exchange of units, illegal constructions in open lands, lack of realization of the commercial areas initially planned, irregular

occupation, illegal water and electricity connections. In fact, Gatti (2015) underlined the lack of dedicated civil servants for this rent programme, the management difficulties in the block of flats, the absence of a clear division of responsibilities.

Gatti (2015) underlines also a huge contrast between this case and the project in Vila dos Idosos, for elder people and points out the homogeneity of the group, due to a constant income of retired tenants, the need for housing and not the accumulation of building stock, the presence of leaders, organizing the community. All of them contributed to the good physical condition, the low noncompliance and absence of informal transfers of units. A similar situation occurs in the Palacete dos Artistas, another project addressed to elder people in 2014. Good management is always ensured by elder ladies: Olga, Neide, Dóris (Vila dos Idosos), Maitê, Valéria (Palacete dos Artistas). Kohara et. al (2012) reiterate this position, showing that for elder people the rent housing solution is considered as definitive, differently from younger beneficiaries in the programme. Of course, it totally inverts the positions.

In brief, the literature discusses all the expectations from housing rent, also sustained by international examples, but at the local level, the absence of cases and not implemented policies is observed: São Paulo is an isolated exception, but it has been a little assessed so far. When the problems of the municipal programme are discussed, in general, the responsibility is attributed to the lack of state support: management, lack of civil servants, lack of organization before the beneficiaries, failures in the social work.

However, even supporting social rental policies, the empirical evidence shows that in the Brazilian current conditions ordinary public policy does not achieve relevant advancements, public policy critical points should be seriously considered to recognize all the challenges and propose solutions for specific aspects of the functioning of an effective social rent housing programme.

As first, a high level of default emerges. Also, the emission of tickets of rent paid by the municipality is critical because of the difficult monitoring of rent payments, lately ticket deliveries, fine payments. Even if all these challenges were addressed, one major question would remain: what doing with noncompliance? In the relationships of private rents, this risk is calculated and marked by the need of guarantors, by contracts of insurance-bonds, for deposit-caution. When all these tools are not sufficient to regularize payment, there is a tool for the legal eviction. In the case of informal rent, the risk assumed by the owners is accounted as a money amount, converted in illegal values paid by the tenant.

What is trivial for a private person is a huge problem for the state. Constitution assures the right for housing in the Brazilian State. A defaulting tenant can advocate for this right, mobilizing the support of the public defence, or specialized technical advice, as to avoid an eviction. It means a political risk for the public managers, not usually available to assume this kind of risk. Even in the case of evicting a defaulting tenant, a municipality cannot simply put people in the street, it should provide any kind of alternative housing solution, rent aid, etc. This can cost as much as paying for the rent of a dweller in his/her rented house. It is not by chance that so far, in the 15-years-programme, nor a unique family was evicted for not paying the rent in São Paulo. From the point of view of the stability of families this makes sense, but for the financial and administrative health of a housing programme is very problematic.

Beyond the humanitarian dimension, the noncompliance in a programme of social location in public buildings has other difficult dimensions. It is epidemic: if a dweller does not pay the rent for months, or years and no eviction is executed, other tenants will follow and default becomes epidemic. Therefore, projects of social rent in São Paulo show that the noncompliance increased very rapidly, and decreased very slowly in specific moments, even with intense social work on the tenants.

If a dweller does not pay the rent of public property for 5 years without the State's opposition, according to Brazilian law he/she can apply for property rights, in an instrument called "concessão especial de uso para fins de moradia" (special use concession for housing purposes). The building can be in practice privatized through default

of the tenants. A dilemma results from this situation: getting paid for the defaulting tenants affects financial, administrative and political consequence, as well as not getting paid. Assuming that dwellers will pay the rents just out of goodwill is not realistic, low-income people have urgent needs to spend their money on than paying rent, especially if they considered there is no risk of eviction.

In addition to noncompliance, there are other issues: how could buildings and apartments' maintenance be ensured? How would it be possible to involve the dwellers of a block of flats in building management, as to optimise the disbursement? How could the value of rents be calculated? These points can be solved, but the effort and the people to be mobilized are relevant, and there is a permanent lack of staff and resources in the Brazilian housing sector. Political actors assess the risk to orient their actions towards social rent housing, and it appears as too risky. In the electoral perspective, a property title is much better valued than a rent contract. For all these reasons the example of São Paulo is the only one in the country for 15 years approximately. On the one side, activists and researchers have defended and promoted the policies based on rent, thus showing a more theoretical and ideological perspective; on the other hand, public managers are quite sceptical about this kind of program, attempting to the adversities.

A small group in São Paulo is producing an alternative, approaching the social rent from the perspective of the civil society. In 2015, a non-profit association was created to promote low-priced housing rent and this paper aims to illustrate this unique case in Brazil, aware that it is not a new experience worldwide. In a series of countries, this type of organization has been developed for years. The so-called third sector is a structuring element in numerous international experiences, mentioned by Brazilian researchers, in France, Italy and South Africa, among the others. Indeed, in many of these cases, incrementally housing promoted by the third sector have anticipated the public initiative. The third sector produces incrementally experiences, technical knowledge, and tangible results. It has assumed the role of a reliable player in the state's eyes. It is also true that the state has often contributed to the creation, growth and strengthening of the non-profit housing sector. In spite of knowing the cases, Brazilian literature usually proposes an exclusively governmental agenda for this issue.

Building a formal framework for the institution

At the beginning of 2015, in São Paulo a group of people began a collective reflexion on the issues related to the no speculative property, in the *Lanchonete Association*², a cultural platform, created to assess the feasibility of a cultural project, not having gentrification effects. A challenge of this initiative was to buy a space which could be a cultural and leisure centre. In this way, the same space would stay apart from speculative processes. Eventually, that project was successful in buying a place in downtown São Paulo with resources from other sources. The awareness of the need for money and properties was there since the beginning, and since the first meetings funds have been collected. Lanchonete.org promoted the voluntary participation of guest chefs for meetings in the first half of 2015 throughout social events, that were fundamental to strengthen the cohesion of collaborators with different qualifications: architects, sociologists, artists, economists, lawyers, historians.

Since the beginning of the project, it was clear that the organization should be formal and that the group was acting beyond a simple idea. Among the first supporters of the project, there were two lawyers of an office specialized in public law, who elaborated *pro-bono* a proposal of institutionalization. Within the Brazilian legal order, there were two possible alternatives: the creation of an *association*, or a *foundation*. In principle, the model of a foundation was more appropriate to manage building stock, but creating a foundation implied a complex and expensive administrative structure, whose cost was not sustainable for Lanchonete. Therefore, the association option was selected and the "Association for Community Property" was created³.

² www.lanchonete.org

³ Associação pela Propriedade Comunitária

Because of the lack of large financial sources, the association structure was as simple as possible. There is an executive directory board – lasting 3 years - composed of a president, vice-president, a financial manager and two supplementary directors, elected by an assembly, having an annual meeting.⁴ The directory board has civil and juridical responsibilities, runs the association on a daily basis and is accountable to the assembly.

In October 2015, the Statute was approved in a first foundational assembly, the association was thus legally founded. The association's name "Associação pela Propriedade Comunitária" appeared very technical, and after a proposal from a specialist, has adopted the public name Fundo Imobiliário Comunitário para Aluguel (community real estate fund for rent) The acronym FICA means "stay" in Portuguese, evoking the struggle to maintain poor people in central locations.

In the following year, a functioning framework was created: registering the association formally, opening a bank account, and establishing a fundraising campaign through crowdfunding. FICA accepts any kind of cash donation, but campaigns for signatures or monthly donations. The consistency of the donation and the conscience that it is a long-term project with no immediate results are more important than the monthly amount of each donor. At the beginning of 2017, it was all ready for further publicization.

The fieldwork of the initial phase

No large financial resources were available at the beginning, and Brazilian society has not a strong philanthropic tradition. The initial work was almost exclusively voluntary, including professional activities. People are busy, and we were aware that we could not press anyone with goals and deadlines. The project was set up as a long-term one. It was crucial that the fund grew, even if slowly.

Nevertheless, the fundraising got momentum. On top of monthly donations, some larger ones appeared, up to USD 5.000. The most important step happened when a couple of FICA supporters offered as a kickstart to the project to buy an apartment and give it to FICA for 8 years in usufruct. That was an essential step.

The first apartment was bought in the market in July 2017, for R\$ 162.000 (approx. € 37.300), paid by the donors. It has 47 square metres, had been idle for 10 years, and was in bad conditions. This first location was also essential to increase the visibility of the initiative. The association can meet there, invite journalists and bring possible supporters to visit the Project to show that it was not just an idea. A working team was set up among associates to make a collective project for the refurbishment.

Having a formal institution, a crowdfunding campaign, some institutional partners and a flat made people pay attention to the project. First invitations to participate in public debate started to appear, as well as the first articles in the press about the project. FICA was invited to participate in the XI São Paulo Biennial of Architecture, that took place from October to December 2017. For that occasion, the apartment itself was exhibited, with a very simple expography explaining the project. When in December 2017 FICA was invited to participate of a public debate on social rent sitting together with the municipal secretary on housing and a municipal councillor people understood it was definitely accepted as a player in the discussion.

⁴ The Statue of the Associação pela Propriedade Comunitária is available at: www.fundofica.org

The pilot phase: using the first apartment

Having the apartment, we had to calculate our financial model. FICA was never aimed to substitute the state, and it was clear we did not want to subsidize ordinary housing costs. The idea was to calculate what we called the “cost price” of the flat. In several rounds of discussions, the end cost was the following:

So, the following financial scheme was set. Apart from the IPTU and the building costs (R\$ 300, IPTU exempt, i.e. approx. € 70), the value of rent would have been built, as follows:

R\$ 100 (i.e. approx. € 23) for the wear rate of the apartment, in case of breaks and repairs;

R\$ 100 (i.e. approx. € 23) to support the association,

R\$ 100 (i.e. approx. € 23) to support the fund, aimed at buying new apartments,

R\$ 20 (i.e. approx. € 23) for the fee of the building insurance.

On top of it, R\$ 300 is charged as a block of flats or house costs (maintenance of the building, doorman, water) charged by the building to all the housing units.

➤ R\$ 620 (i.e. approx. € 142), as a total per month.

The total value (R\$ 620) was considered too high by some members, who had in mind the price of the municipal social rent, R\$ 300 about. But eventually, it helped FICA to understand its current public. We should not select a dweller in a highly precarious situation, who needs more structured public policies which this association is not able to provide. FICA could have lodge people who have functional lives and work, but simply don't have enough income to live in good conditions in a central regional. At our model, a family earning two minimum salaries would spend less than 30% on the rent, a proportion internationally considered as adequate.

Having the price set up, other criteria were necessary. Tania Christopoulos, a member of the association, realized a workshop in the apartment on November 2017, using the “personification” methodology, in order to collectively build a “character”, starting from personal questions. The resulting criteria are the following:

- a family led by a woman,
- any family composition,
- the presence of a baby, or a child,
- employed dweller working in the central region.

The major dilemma regarded the original location of the new dweller. For some people, she should be currently leaving in the outskirts of the city, so that arriving in the new flat she could avoid long commuting hours. For others, it should be someone already living in the centre of São Paulo but threatened by the high rent costs or by eviction, thus avoiding the gentrification and preserving the neighbourly ties. In December 2017, the assembly decided the ideal tenant would have already lived in the centre of São Paulo and in the outskirt so that she would be able to narrate her different experiences.

After defining the criteria, a selection process should be opened. The first option was a public call throughout social networks, but a social network leader observed that it would have moved several candidates, making all of them frustrated, except the selected one. It could risk the project's image. She proposed a selection done through trusted institutions. In February 2019 a questionnaire was built, in order to highlight the main elements of the

trajectory and current state of candidates. From February to April 2019, 9 partner institutions were contacted, and a group of FICA members and advisors has coordinated the process. The partner institutions have selected 12 candidates, and 6 of them were interviewed. In June 2019 the first family was selected.

Figures 1 and 2. The first apartment was bought in July 2017. In October it was exhibited in the XI São Paulo Biennial of Architecture, an important moment for the exposure of the project. The main character of the exhibition was the flat itself, and it was very important to show that it was real and that civil society had the resources to make such a thing happen. Simple boards in the wall explaining the project and some tape marks on the floor were showing what could be built in the flat.

Figures 3 and 4. The flat has performed quite a lot in 2017 and 2018, strengthening the project. In November 2017 a workshop with a Dutch institute was run in the flat. It was painted green and turned into a studio where a video was shot. In November 2017 a workshop on the criteria took place in the flat to help to define criteria to select the first tenant ((right).

Figures 5 and 6. In 2018 a thorough process of renovation was carried out in the first flat of FICA. The design process was collective and resulted in a non-authorial plan. Flat is long and thin (12x3 m), its original display presented natural lighting and ventilation through space. Most of the material for the renovation was donated.

Conclusion

Starting from scratch, FICA has adopted a pragmatic and incremental approach with remarkable results. The process to acquire the property throughout the crowd-funding seems to be successful. Besides holding the first flat renovated and the having chosen the first tenant, in May 2019 FICA had R\$ 120.000 (i.e. approx. € 27.600) in its account, that is a sufficient amount to buy a second apartment. The members have been improving the knowledge on the property alternative models and have even designed a course in the second semester of 2018, to share its knowledge.

In 2019 FICA is participating to the Chicago Architecture Biennial, with an installation reproducing the first flat, and the campaign “What does an ethical landlord look like?”. In partnership with a lawyer bureau, FICA proposed the mobilization of the protected public building stock to support rent social housing in Villa Itororó, a symbolic place in the centre São Paulo. With the support of a lawyers’ office, it is searching to intervene in tenements and in traditional rent housing where the high rents paid by tenants, contribute to precarious conditions and violation of housing rights.

The promotion of alternative housing policies to private property in Brazil has not several empirical pieces of evidence. One of the main debated challenges are the policies based on social housing throughout the creation of a public housing real estate stock managed by the state. Nevertheless, FICA allows looking at the housing problem from another perspective. As a small-scale experience, without previous clear reference models, it is an interesting lab to re-think the mechanisms regulating social housing.

With this initiative, the project expects to contribute also to the literature on social rental in Brazil, which devotes almost exclusive attention to the state and is silent about civil society’s responsibility and potentials on this issue.

Chicana Neighborhood Activism: Gender, Race, and Urban Planning

Gerardo F. Sandoval, University of Oregon, gsando@uoregon.edu

Citlali Sosa-Riddell, University of California Los Angeles

Ada Sosa-Riddell, University of California, Davis

Abstract: This article weaves the activist narrative stories of three Chicana neighborhood leaders that have transformed redevelopment projects in their barrios to gain more community benefits. Chicanas pressured the city, redevelopment agency staff, politicians, and developers to transform market-based redevelopment housing projects into affordable housing. These projects encouraged links to social and educational services, supported locally owned retail, and built Chicano/a culturally appropriate public spaces. In particular, we analyze how these Chicana neighborhood activists were influenced by the Chicano/a movement; how they became involved in urban planning issues; and finally, how each transit-oriented project changed to encompass more community benefits as these Chicanas pressured the city and developers. The projects include Fruitvale's Transit Village in Oakland, California, the expansion of East LA's Goldline in Los Angeles, California, and the transformation of El Mercado Del Barrio redevelopment in San Diego, California. The narrative stories help to conceptually and empirically ground the larger structural barriers that create inequitable and racially segregated neighborhoods and demonstrate how Chicana activists challenged and pushed back against those structures to protect their barrios.

Keywords: Activism, gentrification, gender, neighborhood revitalization

Introduction

The status of women and the nature of cities have been dramatically altered since Mexican-Americans became part of the United States. However, instead of validating their impacts on cities, the urban planning field has neglected the important role Chicana activists have played in reshaping and protecting their neighborhoods from cities' redevelopment efforts (Cordova 1997). Chicanas have historically fought for issues of environmental justice, against gentrification, and ameliorating neighborhood inequality (Pulido 1996, 2006). Chicanas' historical role as community change agents in protecting their barrios provides a lens into urban struggles over gender, race and politics in the contemporary city (Pardo 1990, 1995, 1998).

Urban history has, since the 1980s expanded its boundaries beyond space and particular behavior of people in that space to include multiple paradigms of city life and urban culture.

During the 1960s and 1970s, the field of “new urban history” focused narrowly on space and behavior without much attention to architecture, politics, gender, or culture. This essay is also in discussion with the broad field of urban history and its wide attention to culture and urban shifts in the late twentieth century.¹

This article weaves the activist narrative stories of three Chicana neighborhood leaders that have transformed redevelopment projects in their barrios to gain more community benefits. Chicanas pressured the city, redevelopment agency staff, politicians, and developers to transform market-based redevelopment housing projects into affordable housing. These projects encouraged links to social and educational services, supported locally owned retail, and built Chicano/a culturally appropriate public spaces. The barrios examined in this study include The Fruitvale in Oakland, Boyle Heights, and Barrio Logan in San Diego. These three barrios are historically important Latino neighborhoods experiencing pressures of gentrification.

We analyze how these Chicana neighborhood activists were influenced by the Chicano/a movement; how they became involved in urban planning issues; and finally, how each transit-oriented project changed to encompass more community benefits as these Chicanas pressured the city and developers. The projects include Fruitvale’s Transit Village, the expansion of East LA’s Goldline, and the transformation of El Mercado Del Barrio redevelopment in San Diego. The narrative stories help to conceptually and empirically ground the larger structural barriers that create inequitable and racially segregated neighborhoods and demonstrate how Chicana activists challenged and pushed back against those structures to protect their barrios.

Chicana Neighborhood Activism and Chicana Feminist Epistemology

Chicanas have played a large political and sociocultural role in reshaping their neighborhoods. They have been at the forefront of the Chicano movement (Ferre and Martin, 1995; Garcia, 1997; Pulido, 1996). Chicanas were even organizing in the foundation of the urban planning field during the progressive era as women organized to bring attention to the tenement housing conditions in New York were also joined by Mexican American women whose legacy has not been adequately acknowledged in urban planning history. Hence, historically, the story of Chicanas politically organizing to defend their communities, especially in the urban planning literature, has not gotten the important recognition it deserves. In fact, it has gotten almost no attention.

The key book that does address this important issue is Mary Pardo’s “Mexican American activist: Identity and resistance in two Los Angeles communities” (Pardo, 1998). Pardo’s book tells the stories of Chicanas involved in neighborhood activism in Los Angeles. Pardo argues that Chicanas transformed everyday problems they confronted in their neighborhoods, such as the building of a prison in East Los Angeles or the building of a parole office in Monterey Park, Los Angeles, into political mobilization. Pardo’s Boyle Heights case tells the story of Mothers of

¹ Gilfoyle, Timothy J. “White Cities, Linguistic Turns, and Disneyland’s: The New Paradigms of Urban History.” *Reviews in American History*, Vol. 26, No. 1, *The Challenge of American History* (Mar., 1998), Pg. 176. (pp. 175-204)

East Los Angeles (MELA), a grassroots group of women who worked via the Catholic Church and mobilized the Chicano community to stop the construction of a state prison in Boyle Heights. Gloria Molina, who was then a California State representative, played a key role in that resistance. MELA, at their height in 1986-1987, was able to create a grassroots movement that forced planners and state officials to stop their plans of creating a prison in that community.

Pardo explains that Chicana activist women had a long history of involvement in neighborhood issues. But they really became politicized in the 1960's social movements that transformed civil rights across the country. Pardo attributes dynamics of women activism in East Los Angeles to three things: 1. Gloria Molina seeking grassroots activist support in Boyle Heights after state officials ignored her arguments. Molina argued that state officials did not provide responsible public participation forums or procedures. 2. The Catholic church legitimized the anti-prison struggle and served as a vehicle for communication and grassroots networking. 3. Women relied on their gendered identities via roles as mothers and protectors of the neighborhoods. MELA defined mothers as a woman who "does for children", so it went beyond a biological connection. Hence, members of MELA were defined as 1. protectors of neighborhoods and 2. those that "do for children". Lastly, Pardo argues that the women of MELA used their ethnic identity as a tool for resistance.

Key themes from Pardo's work are very useful in helping us understand the role gender plays in Chicana neighborhood activism. For example, women formed community identity as resistance. "Women used their life experiences in the neighborhood and the relationship of those experiences to outsiders to build positive collective representations of the community. Constructing community identity became a key element in defending Eastside Los Angeles" (Pardo, 1998: 81). She also describes how social networks played a key role in collective community concerns. "As women became activist, they reflected on their experiences as mothers and working-class Mexican Americans, converting long-established social networks into political networks. In transforming their social networks, they expressed what were formerly individual concerns as collective community concerns" (Pardo, 1998: 106-107). These networks that Chicana activist developed and maintained were extremely important to securing the resistance to the prison. These networks originated through impacts on their families and then evolved to larger community issues. "In both communities, women's activism originated in family concerns and community networks, then generated broader political involvements. This pattern is similar to that found in other studies of woman's activism" (Pardo, 1998: 228). Their gender identity was very closely linked to their cultural identity and directly materialized into political opposition. Pardo writes about a MELA participant, Juana Gutierrez, who identified family, community and ethnic identity as the impetus for her involvement. "I say "my community" because I am part of it. I love my Raza, my people, as part of my family". She clearly uses motherhood and family as a metaphor for civic responsibility and action. She has expanded her responsibilities and legitimized militant opposition to projects she assesses as detrimental to the community" (Pardo, 1998: 115).

Pardo's important study provides a clear linkage between the gender Chicana literature (Pardo, 1990; Pardo, 1995) Esquire and Segura, 1997; Platt, 1997; Pulido, 2006) and urban planning justice scholarship (references). One study that does provide this link is Teresa Cordova's study of the Southwest Organizing Project (SWOP) (Cordova, 1997). SWOP is a

social justice organization fighting for environmental and economic justice in New Mexico. Cordova argues that the Chicana movement literature is dispelling Chicanas as passive political actors. But Chicanas have a long history of community activism originating in the Chicano movement. Cordova points out that research on Chicanas makes four key points: “1) Chicanas are not passive but instead have a long history of action for social justice; 2) mobilizations by Chicanas reflect an identity tied to class; race, and gender; 3) consciousness and mobilizations by Chicanas are reflective of ties among family, household, and workplace; 4) Chicana’s organizing skills and strategies stem from their experiences and conditions” (Cordova, 1997: 32). Cordova builds on Pardo’s study by pointing out the important role of gender networks and how they were transformed politically. “The Mothers of East LA accomplished this by turning their preexisting gender-based networks, e.g. those related to church and school, into political benefits, bringing forward previously “invisible” women into leadership positions” (Cordova, 1997: 34). Cordova calls on urban scholars to further research these gendered dynamics as Chicanas social movements directly relate to urban planning issues. “Armed with knowledge, oppositional consciousness, and principled strategies, Chicana grassroots activists are inserting themselves into questions of international economic integration, local economic development, neighborhood change including issues of gentrification, infrastructure, tax abatements, natural resource management, zoning, and an array of other development issues” (Cordova, 1997: 49).

We engage the role of gendered activism to understand how these Chicana leaders were able to transform large scale transportation infrastructural projects. We do this by engaging a form of gendered epistemology within an urban planning praxis. We view urban planning as an epistemology of intervening in the urban environment. Epistemology involves the nature, status, and production of knowledge (Harding, 1987). Hence, we engage the concept of Chicana feminist epistemology within the education field and apply it to issues of Chicana neighborhood activism (Bernal, 1998). As Dolores Bernal argues, Chicana feminist epistemology educational research thus becomes a means to resist epistemological racism and to recover untold histories” (Bernal, 1998: 556). Highlighting untold stories of Chicanas struggling and ultimately reshaping large scale planning projects reflects a turn in planning scholarship that advances the contributions Chicana activist are making to the field. This epistemological turn directly challenges past racist and sexist scholarship that silenced the voices of Chicanas. This type of gendered centered epistemological planning praxis demands a methodological transition to one that directly asks questions of gender. As Bernal challenges the educational methodology, we challenge planning. “A Chicana (centered) methodology encompasses both the position from which distinctively Chicana research questions might be asked and the political and ethical issues involved in the research process.” (Bernal, 1998: 559).

Historical Context

During the 1970s and 1980s, Chicana feminists in California demanded their role in the city would be focusing on community revitalization, non-profit development, and transit communities that would connect affordable housing, social services, retail development, and public transportation in poor Latino communities.

Almost one hundred years earlier, in the 1860s, Mexican-American women developed new approaches to city life by creating religious charity groups. Elite and middle-class Mexican-

American women sought a role in urban life largely through their historical remembrances, Catholic charity organizations, and Latino immigrant support groups. Women reformers began to push in the 1890s for environmental issues by acting as “municipal housekeepers” extending their role from the home to the urban environment.²

Californio-Mexican women such as Antónia Perez de Woodworth, Francesca Sepúlveda, Ysabel del Valle, and Refugio Bandini all were involved in the Los Angeles based *Daughters of Charity* organization, a Roman Catholic organization dedicated to fundraising for their orphanage and school beginning in the 1850s.³ By the late 1880s, women around the United States had begun to develop a concept of “organized womanhood” that emphasized the power they could create by working in solidarity across numerous organizations in the United States.(136) Many Mexican-American women belonged to Catholic organizations, Spanish-language groups, and were involved in the social life and charitable work of the major cities of California.(137) One of the most visible organizations that in the beginning of the twentieth century in Los Angeles was the organization that developed the public celebration of the Fiesta de las Flores, a celebration that drew heavily on the regions Californio-Mexican past.(138)

After numerous clashes between the American and Californio women in the early club movement, Californio women created a space for themselves beginning in the 1920s by focusing on two specific areas within the larger club movement, Spanish language and Californio cultural instruction and the historic preservation of the Californio past.⁴(141) By the 1920s and 1930s, the descendants of the early Californio-Mexican women had become a part of the Los Angeles women’s club scene that work to remake the California cities to reflect historical events and preserve(or reenact) old homes, family histories, family artifacts, and family historical clothing.(141) In terms of language and cultural preservation, the Californio women gathered in the Friday Morning Club beginning in the 1910s to meet and discuss Spanish-language texts and read the Los Angeles Spanish-language newspaper, *La Opinion*.(143) These Californio women and newer Mexican immigrations to California created organizations to raise their visibility in California public life in the cities. In organizations like the Friday Morning Club, Californio-Mexican women worked to rebuild, shape, and protect buildings, history and memories of public space in Los Angeles and around the state.

The women’s movement of the 1970s, known in American society as the Second Wave was a continuance of the fight for women’s rights. As part of a broader feminist movement and the Chicano Movement, continued the fight for women’s rights and civil rights.

This article illustrates how women in three metropolitan California cities established their place in the city during the height of the contemporary women’s movement and in the wake of the Chicano Movement. Like their white contemporaries, Chicanas focused on spaces created

for their communities. They were also involved in broader issues of the entire Latino community such as job training, adult education, social services, retail development, childcare centers, and financing services for low-income community members. (see Arabella Martinez interview)

Chicanas and The Post War City: The 1950s

The women's movement and the Chicano Movement desegregated the previously gendered spaces of the 1950s which had seen the separation of men and women to the urban workforce and the non-working suburban world. Although this segregation was particularly sharp among white men and women, Chicanos in the 1950s, especially the upwardly mobile had moved out of the urban core and faced similar gender patterns. (Spain 155) Among the poor and urban, the Chicano population stayed in place as the city was systematically ignored or slated for urban renewal and left in a state of blight with many losing their homes.

Narratives of Chicana activists

Gloria Molina became involved in the Chicano Student Movement at East LA College despite being a night student who worked during the day as a legal secretary while most of those involved were young students. She was introduced to various organizations during her time at East LA College and she described how it was difficult to avoid what she calls, the "so-called "student movement" at the Chicano Moratorium, the antiwar movement, and everything else." (Session 1, May 25, 1990, pg. 30-Carlos Vasquez interview of Gloria Molina). She was part of the East Los Angeles high school walkouts of 1969 and was involved with the organization, MASA, the Mexican-American Students Association while a student at East LA College but explained that she was largely involved as a follower rather than a leader.

Molina began her involvement as a self-described follower because while she agreed broadly with the ideas of the Chicano student organizations she did have some reservations about particular attitudes which she found, "almost too radical." (pg. 31) She found herself agreeing with the ideas of the Chicano student movement about "how we were constantly being discriminated against how we had to stand up and challenge all of that." (pg. 32) But, Molina did not agree with two other ideas that circulated in the Chicano student movement. First, she disagreed with the idea that "somebody owed us something," because she felt that it was "more of a socialist [idea]." (pg. 31) Secondly, she did not agree with the Chicano Student Movement perspective of racism in a way that she viewed as conspiratorial, "that it's all planned and staged, and we're just all little puppets in this process." (pg. 32) Instead she suggested that racism could be challenged directly through action.

Gloria Molina suggested in her interviews with Carlos Vasquez, an oral history interviewer at UCLA, that there was widespread hypocrisy among the male Chicano activists who spoke against discrimination and pushed Chicanos to speak out against white racism while "they would oppress me as a Chicana." (pg. 32) Molina's frustrations the male sexism of the Chicano student movement, led to her increasing desire to work with Chicana women who shared a more Chicana feminist ideology that she found lacking in the white feminist movement

of the time period. This was the impetus to her involvement in Chicana female centered groups and she found common ground with the women of the Chicana Service Action group, where she found a space to push for the voice of Chicanas and to find a way to help them gain autonomy in the workforce. (pg. 38)

Gloria Molina

Gloria Molina became a very powerful politician in Los Angeles. She was first elected to State Assembly in (?) and then the Los Angeles City Council in (?) to represent the newly founded District 1. District 1 represented a mostly Latino district and was formed from MALDEF's redistricting civil rights efforts. Molina represented this district from (? To?). In this capacity, she fought for more resources to be invested in her impoverished district. She then went on to run and win a seat on the Los Angeles County Board of Supervisors. She served in that capacity (from?) until she retired in (?). The Board of Supervisors is a powerful board as they control the county's resources and have seats on powerful county agencies such as the Metropolitan Transportation Commission (METRO), who sets public transportation policies and control the agency's resources. But Molina's political start was not in formal city politics but instead in grassroots efforts and community struggles.

In Molina's time as a state assembly member representing Eastern Los Angeles, she began to reshape the political and spatial struggles in Boyle Heights. She played a central role in opposing the construction of a new state prison in Boyle Heights. The state board of prisons had planned the construction of a new prison facility without any participation or involvement from the public. Molina opposed the prison plan and advocated to build the prison elsewhere as her district was already overrepresented by prisons. But the prison board ignored her advocacy. Hence, she let her community know about the prison plans and that unleashed a grassroots oppositional movement to the prison that ultimately led to the stoppage of the prison construction.

Mary Pardo's book describes Gloria Molina's initial involvement in the prison fight:

Assemblywoman Gloria Molina, familiar with uphill battles, vehemently opposed the Eastside site. Considered an aggressive community advocate and an outspoken feminist, she had opposed a male-dominated Latino political network to win election to the Eastside Fifty-Sixth Assembly District in 1982. Later she became the first Latina elected to the Los Angeles City Council (1987-91) and the first woman and the first Mexican American elected to the five-member Los Angeles Board of Supervisors, which oversees an annual budget of \$13 billion. Molina did not object to the construction of a prison in Los Angeles County; instead, she argued that the chosen site was too close to the long-established Boyle Heights neighborhood, and she pointed out that it was also within two miles of thirty-four schools. She pointed out that 75 percent of the county's prison population was already housed in her district; thus, another prison would add to the over-concentration of penal facilities in the East Los Angeles area. Downtown Los Angeles houses twenty-five thousand prisoners, the largest inmate population of any city in the

nation. Five inmate facilities, including a county jail, a federal prison, the men's city jail, and a juvenile detention center, also lay within a six-mile radius of the site.

When the DOC brushed aside Molina's objections, she explored the possibility of grassroots mobilization” (Pardo, 1998: 54–55).

The Mothers of East Los Angeles (MELA) grassroots organization originated from these struggles. This was a women’s organization that came out of the local Catholic church and fought against the construction of the prison as well as other environmental justice neighborhood concerns. MELA was led by Chicanas who had been politicized during the Chicano movement and were activist’s women who had a long history in Boyle Heights. The community was angered at the lack of public outreach and opposed the prison which led to the formation of the group. The local Catholic priest helped organize the women and they also worked with Representative Molina, and a progressive urban planner who provided the planning technical expertise, as MELA gathered enough support to stop the construction of the prison. MELA participated in many marches, political rally's, they outreached to media, and traveled to Sacramento to lobby against the prison construction. Gloria Molina would herself translate the prison hearings at the state capital into Spanish since there were no interpreters. Mothers of East LA also connected with universities in LA, like UCLA, to gain support for their fight. They were ultimately able to stop the state's plans to construct the prison. Hence, MELA members used their life experiences in the neighborhood and the relationship of those experiences to outsiders to build positive collective representations of the community. Constructing community identity became a key element in defending Eastside Los Angeles” (Pardo, 1998: 81).

Pardo attributes dynamics of women activism in ELA to four things:

1. Gloria Molina seeking grassroots activist support in Boyle Heights after state officials ignored her arguments. Officials did not provide responsible public participation forums or procedures.
 2. Catholic church legitimized the anti-prison struggle and served as a vehicle for communication and grassroots networking.
 3. Women relied on their gendered identities via roles as mothers and protectors of the neighborhoods. They defined mothers as a woman who "does for children". So MELA were defined as 1. protectors of neighborhoods and 2. those that "do for children".
 4. Used their ethnic identity as tool for resistance.
- The concept of resistance has been at the core of Chicano Studies and Ethnic Studies as a means to explore the responses of the oppressed to their mistreatment.⁵

Molina’s Role in shaping transit’s light rail Gold Line extension to East LA.

⁵ Ramirez, Catherine. “Saying “Nothin”: Pachucas and the Language of Resistance.” *Frontiers: A Journal of Women Studies*, Vol. 27, No. 3 (2006). Pg. 2.

Gloria Molina also reshaped Boyle Heights with her efforts as a County Supervisor as she advocated to bring the Gold Line subway into Eastern Los Angeles. The battles over Los Angeles rail have been intense, filled with political conflict and racial undertones. The Metropolitan Transit Agency (MTA) began their investments into rail by building the Redline which was a subway that ran from downtown Los Angeles and stopped at MacArthur Park. The plan was to extend the subway along Wilshire BLVD into West Los Angeles but that was not completed due to lawsuits, residential opposition, and environmental lawsuits. Los Angeles was also investing in a commuter rail system that took away funds from bus services. Hence, MTA was subsequently sued by the Bus Riders Union on racial discrimination grounds. The Bus Riders Union argued that MTA was discriminating against public transit dependent communities who were mainly communities of color and favoring suburban and higher income rail riders by investing their resources on commuter rail (Elkind, 2014).

Gloria Molinas' role in these transit conflicts was to advocate for a subway line extension into East Los Angeles. She argued that most of the population in her district was transit dependent and would greatly benefit from more regional transit connectivity. But most of the transit capital investments were planned for the West of Los Angeles. Hence, Molina relied on her political networks to press the MTA, the County Board of Supervisors, and the state of California to invest in a subway that would run into Boyle Heights. Molina served on the Board of MTA and in 1998 led a charge within the board to reaffirm their commitment to Eastside subway investment (Elkind, 2014). But the political fights continued as the West side and East side fought for transportation investments. These fights culminated over Measure R (R stood for relief as in traffic congestion relief) that would increase county sales taxes to raise \$30-\$40 billion for 30 years for rail investment in Los Angeles. Molina opposed the measure as East LA was only allocated to get light rail instead of a subway but the measure still passed and Boyle Heights got their light rail. If it was not for Gloria Molina's championing of a subway into Boyle Heights when most of the attention was on the West side, Boyle Heights would probably not have seen as much public transit investment and the current light-rail would most likely not exist.

Arabella Martinez

Arabella Martinez was the director of the Spanish Speaking Unity Council a non-profit community organization in Oakland's Fruitvale district. The organization started during the Chicano movement as a coalition of service and community-based organizations in the neighborhood. Arabella Martinez was their leader until she left to Washington DC to serve in President Carter's administration as the first Chicana sub secretary in the US. She was sub secretary of the Human Services Administration. The Unity Council's work needs to be understood from a broader context of community revitalization and history of non-profits in the area. The Council worked on providing job training, adult education, a childcare center, and financing services for the low-income Latino community. But their main project is now the Fruitvale Transit Village, which is composed of low and market rate housing, social services, and retail development that is adjacent to the BART Fruitvale station. The Fruitvale Transit Village has now become a model for conducting equity-based TOD's in a low-income community.

The Fruitvale Transit Village was conceptualized, its funding secured, built, and now managed by the Unity Council. Hence, the Transit Village would have not happened without the leadership coming from the Unity Council. The Unity Council's approach to making the TOD project happen was a combination of gaining community input and participation, collaborating with local government officials, and using its federal connections to help secure funding and support. Arabella Martinez was the president of the Unity Council, and through her strong leadership style she was relentless in developing a vision of the transit village. Her initial community services work in the Council helped her to get appointed in President Carter's administration which subsequently provided her with the important federal contacts she later relied on to gain funding for the Transit Village.

The original idea for the transit village actually emerged from a retail leakage study that UC Berkeley Professor Ed Blakely of the City and Regional Planning Department conducted with his students. Arabella Martinez and Ed Blakely had met during their War on Poverty work and through their social movement experience. Their study revealed that a lot of the residents were shopping outside of the neighborhood, and his idea was to create a connection through street design from International to the BART station to encourage more people riding BART to shop on International. This gave Arabella Martinez the initial idea of creating a paseo between both spaces.

Through Mrs. Martinez's strong leadership style, the Unity Council used a more top-down community driven approach because the organization not only stopped BART from building its initial parking structure (which was to cut off the main street running through the neighborhood to the BART station), but it then created an alternative vision in the establishment of a community-led TOD project in the neighborhood. Arabella Martinez framed the stewardship role the Unity Council played in establishing the TOD, and made facilitated venues for the community's voice a priority in the process. "We were stewards of the community. This wasn't an outside developer [building a TOD]. It wasn't the government coming in. We, in fact, opposed BART in terms of what they wanted to do. We led that fight. We led the fight in terms of community policing too. We led the fight in terms of better recreational facilities and programs. So, I think partly it has to do with that sort of *stewards of the community* mindset." This mindset gave the Unity Council a lot of power to influence the process of developing the TOD. Since they had been working in the community since the 1960s, they had established a great deal of trust and legitimacy in the area.

Arabella Martinez said that community members really got involved when there were grant applications and the Council needed to demonstrate community support for the project. She was adamant in explaining that it was always, from the visioning to the ground-breaking, a Unity Council project. Another former staff member explains how Mrs. Martinez's leadership shaped the project and how the project depended on her connections: "The Transit Village would not have happened without Arabella Martinez's will. She would say, 'You are with me or not with me.' She promoted it and had a lot of say. She brought powerful people from DC to fund it, the Clinton Administration gave lots of funding. It came from community development block grants. But the process was not organic, bottom up. It's not a blueprint for other communities unless they also have all the [political and financial] connections."

Arabella Martinez' networks played a crucial role in supporting the large project. After taking over the Unity Council for the second time, she was also appointed to the board of directors of the National Council of the Raza. During a fundraising celebration event for the National Council of the Raza, she connected with Secretary of Transportation Pena, who was interested in her work in linking affordable housing to public transportation and other social services. That same week, Mr. Pena flew out to Oakland and provided the Unity Council with a check of around \$500,000 for an environmental impact study focused on TOD. That was the initial funding that helped the planning and initial fundraising drive for the Transit Village. Hence, Arabella not only possess the necessary networks but a belief in gaining the urban planning technical skills to embark on a multi-million-dollar TOD effort. Her reputation was key to the success of the project. She possessed two important characteristics: 1) the trust of the community because she had worked for decades in the Fruitvale working on War on Poverty and social service and community development efforts. 2) She was the first Latina sub secretary in US history and that gave her "clout" to link she community and government networks together. She describes the Unity Council's efforts as not top-down or bottom-up but actually being in the middle. "We were the ones that were doing all the planning for it but had the community in mind".

These community connections helped Arabella Martinez secure their key tenant in the development, La Clinica, an important Latino focused health clinic that brings thousands of clients to the village each year. The Unity Council's strategy was to build social services by targeting La Clinica as the development's anchor. La Clinica is a well-established and well-respected community health center that has been in Oakland since the 1970s. La Clinica has 32 sites, and in 2012 served over 80,000 patients and handled approximately 370,000 patient visits. It is the largest community health clinic in the state of California. Hence, it was critical for Arabella Martinez to convince La Clinica's leadership to relocate into the Fruitvale Transit Village to serve as the anchor tenant and add credibility to the TOD project. BART was also very interested in having La Clinica as part of the project. At 40,000 square feet, La Clinica's space in the transit village is the largest facility in its system, which provides medical, pharmaceutical, laboratory, behavioral health treatment, and dental services. The TOD has also helped increase the number of clients for La Clinica in the Fruitvale neighborhood.

The Unity Council demonstrates how women leaders were able to transform this large transportation project. In Fruitvale, Arabella Martinez called most of the shots when it came to making direct decisions on the Fruitvale Transit Village's development. Mrs. Martinez had access and connections to federal and local politicians and staff members. A male staff person who worked on the design of Fruitvale Transit Village called her "La Coronela" and thinks a large-scale project like the village needs someone like her to get things done. "A project like that needs a Godmother." Another key leader within the Unity Council commented on the gendered relationships and sometimes the conflicts that emerged with the male Latino business owners on International Boulevard.

Between Arabella and me, Latinas, and most of the businesses along International Boulevard are Mexicanos. So, you have the big mouth Latina leading the organization and you have the Mexicanos [accentuating the "os," for males]."

Ha, ha, ha, ha, capital OS, right, so there was quite a bit of tension there. I didn't have time to play the subordinate Latina. Right away they wanted to criticize.

In an interview, a UC Berkeley professor, who had been involved in the project from a distance, commented that she believed the project was successful because of Arabella Martinez and her strong leadership style and connections. The participation of strong women and their access to decision-making processes affecting different parts of the TOD projects was also a factor that we believe contributed to the equitable outcomes of both projects. But it wasn't just the Latina leadership through the council where Latina participation was present. From the very beginning, the community participation for revitalizing the Fruitvale was led by women. Before the Fruitvale project, the Council was tackling issues of crime in the neighborhood as a form of community improvement. Women were the ones doing community outreach to form safety committees. As Arabella Martinez explains, "Many of them were women. They took the date down, they wrote when the drug deals were being made and where. That is real bravery". And that also happened when we were organizing in terms of open spaces and recreation because we were talking about their children, and having a safe place for their children to play". The Unity Council specifically organized around women's issues. Arabella Martinez explains, "We were organizing around things that were really local, that they could see, could make a difference and did make a difference in their lives. And the lives of their children".

Community-based organizations in the area also played a key role in developing the necessary political capital to ensure the TOD projects had community benefits. Without the Unity Council in Oakland, the Fruitvale Transit Village would most likely not have been envisioned, funded, or built. The TOD project was the Unity Council's key project for almost a decade, and Arabella Martinez's key leadership helped sustain its process. The Unity Council's role was critical because it served an intermediary role between the government's efforts to build a TOD and the community's needs. Mrs. Martinez had strong connections with federal, regional, and local funding agencies that were able to provide the necessary resources to finish the project. The Unity Council also had strong community-based connections because of its 20-year history of providing important social services in the neighborhood. Hence, they were able collaborate with local businesses that initially opposed the TOD (because they viewed increased competition as a barrier to their continued success). The Unity Council was extremely effective in getting key community leaders on board to create a community vision for the TOD. They also had the needed political capital to oppose BART's initial plans to build a parking structure that would have cut International Boulevard off from the BART station. As Arabella Martinez explains, "you have to have strong Latino institutions to pull something like this off".

Rachel Ortiz

"The movement is everything. Like I told you, the movement is everything". – Rachel Ortiz
Interview

Barrio Logan is an important historically Chicano neighborhood in San Diego. This is the site of Chicano Park, a space under a freeway that was taken over by Chicanos and made into a vibrant public space with dozens of murals painted on the freeway pillars depicting Chicano

history, culture and political struggle. Scholarship has focused on Chicano Park as a space of cultural resistance and self-determination (references). But the community revitalization efforts that in many ways sustained the Latino neighborhood has not been the focus. And even less focused on has been the role that women activist has played in that struggle. Most of the scholarship focus on male muralist that transformed the cultural milieu of the park. However, many of those women activists were involved in the Chicano movement of the 1960's and 70's. They also organized during the takeover of Chicano Park in the late 1970's. One key activists, Rachel Ortiz, the head of Barrio Station community center in Barrio Logan had worked with Caesar Chavez organizing farmworkers. She grew up in the neighborhood and started Barrio Station, a youth community organization that has been in the neighborhood for 20 years. She is probably the most influential activist who was behind the urban revitalization efforts and the construction of the TOD as she fought to maintain its affordability and also fought to gain community benefits from the project.

Rachel Ortiz had spent time in prison as a youth due to her drug addictions but recovered from those addictions and became politicized once she entered the Chicano movement. She had been working in the Mission District in San Francisco when she became involved in the movement. "I just fell in love with the farmworkers. Yeah, Filipinos and Mexicans, some nuns...from the Bay Area who were helping [the United Farm Workers] with their grapes boycott. And Dolores Huerta...she would say, "Rachael...I want you to do this and that...we need an apartment, a refrigerator, we got to get a phone...here's the projector...I want you to..." It was during Rachel Ortiz' organizing work with farmworkers in the Bay Area where she met Arabella Martinez. "That's where I met Arabella...we called her Marty. I don't know why we called her Marty? Marty...she was involved in everything". Ortiz also joined the Chicano national militants group Brown Berets, worked on a prison justice campaign for Los Siete de la Raza (who had been falsely imprisoned) and also took part in the Third World Liberation Front (which was mostly made up of Latinos and Blacks).

She explains how the Chicano movement influenced her generation of women, "Well, I think that the Chicano Movement had a lot to do with...it spurred academia to demand Chicano Studies and you know, farmworkers, and women...I think it spurred us to be vocal, you know. I mean once you're vocal, you're in it. You're in it. I think that it was empowering for us. But the good thing I think was that the empowerment was for the neighborhood, not just for themselves. I think seeing Dolores Huertas...for me...wow, man...the first time I saw her, when those kids put me in that huelga office in San Francisco, she right away started talking to me like I was a regular...she didn't know me...she thought I was a regular in the area".

Rachel Ortiz became involved in urban planning work via environmental justice concerns regarding the concentration of junkyard recycling businesses in the neighborhood. Barrio Logan had the highest concentration of junkyards in the city and Ortiz started a community organizing campaign to rid the neighborhood of those business. This captured the attention of a progressive urban planner who encouraged her to use urban redevelopment as a tool for community improvements. This redevelopment effort lasted 22 years and encompassed the creating of a community plan for Barrio Logan and the construction of the El Mercado Del Barrio commercial development and affordable housing complex.

In the late 1970's, Barrio Logan was the only neighborhood in San Diego that did not have a community plan. Hence, in her efforts to kick out the junkyards in the neighborhood, Ortiz set off a historical undertaking in the community. She pressured then mayor (Pete Wilson), the planning department, and city council to change the codes, land use and zoning in the neighborhood to make it more difficult for junkyard business to locate or remain in the community. Much of her political capital came from Barrio Logan residents who testified at the city council meeting and attended planning meetings in a show of unity and community support for the plan. Her efforts culminated with the creation of a community plan for Barrio Logan neighborhood in 1978.

Rachel started to use redevelopment power to fight for the neighborhood. She took over the planning mechanism in Barrio Logan and even supported the city in their use of eminent domain to kick out corrugated metal junkyards and auto painting dealers where the current site of El Mercado Del Barrio stands.

GS: You actually used a lot of planning tools to push for change?

RO: You have to. You have to get out there. And you got to network...not for yourself, you know? You got to network for the neighborhood. Everything you run into...write it down. Phone number. Now it's email. Yeah, so Rich Juarez, he liked me a lot. He was with Model Cities...that's before Community Development Block Grant money. Model Cities came from the War on Poverty.

RO: They used eminent domain against us with the freeways, and didn't give us notice. So, we reversed it and used it for ourselves.

The revitalization project culminated with the construction of El Mercado Del Barrio development. That development encompasses 200 units of affordable housing, which were initially market based but changed to affordable via the community opposition to market-based projects that emerged. The development also has a Latino themed grocery store. The first grocery store in the neighborhood in 25 years. The project's other commercial developments include locally owned businesses like restaurants, a barber shop, a CrossFit fitness club, a brewery, and Latino art painted on the building's facades. It is also to the construction of a new community college, Cesar Chavez community college, and is a short walking distance to the light rail system. Rachel Ortiz played a key role in ensuring the project moved forward with the community's interest in mind. As one planner explained, "Rachel has a lot of power in Barrio and if you don't get her approval, your project will not go forward". Rachel Ortiz grew up in Logan Heights and has been organizing in the neighborhood for the past 30 years. Her youth organization maintains a lot of legitimacy in the neighborhood as they do a lot of anti-gang work with youth and played a key role in creating a safer neighborhood. Rachel Ortiz has also been a key community voice in the transformation of Barrio Logan in particular. She was on the neighborhood planning group that gave input to the city council and tirelessly worked to help push through and gain community support for the Mercado Del Barrio project. Planners see her contribution, as one explained, "Rachel Ortiz and her pack head the effort for all those affordable housing projects. In any redevelopment project you had to have an arts component and it was important to use local artist to display the art". In many ways, Rachel Ortiz was the person

spearheading the equity components of these projects and making sure local residents benefited from the affordable housing developments in the neighborhood.

Rachel Ortiz also worked with The Environmental Health Coalition who have been organizing around environmental justice work in the neighborhood and has done this by incorporating city planning tools. The coalition were a key group in pushing the update of the community plan in the area that had not been updated since the 1978 plan. The update of the community plan became a very heated political debate between neighborhood interest and industry who catered to the Navy industry. The conflict came down to a small buffer zone that changed the zoning from allowing industry to discouraging it. The community update was approved by the city council but then a referendum was put to vote city wide and the plan was shot down. One former social service worker in the neighborhood observed that, “The city council approved the updated community plan, twice, and then came measure B and C and it was defeated. That was put out into a vote for the entire city of San Diego. And people could care less about communities of color. Nowhere in SD is there a community that has been waiting 37 years for a community plan update. That is criminal. By not having an update with all these incompatible land uses, they are responsible for the health and cancer rates in the community”. The Environmental Health Coalition and Rachel Ortiz’ organization helped lead the way in this community plan which is tied to the TOD because the original vision of the Mercado development came out of the original community plan in 1978.

Activist played important roles in the revitalization of Barrio Logan and the construction of the transit-oriented development project: El Mercado. Rachel Ortiz’ specific role is important to understand because she was there from the beginning and working upfront to gain community support and reshape the revitalization efforts.

Discussion

The stories of these powerful Chicanas demonstrate the key role they played in reshaping socially, culturally, and physically these barrios. Gloria Molina, Arabella Martinez, and Rachel Ortiz were all activist that were influenced by the Chicano movement, began as neighborhood activists, and became involved politically to reshape urban planning interventions in these neighborhoods. Their political activism led to specific community benefits, such as increased affordable housing, access to regional public transportation systems, increased local businesses and social and health care services in these barrios.

Certain themes emerged through these women activist narratives. The important roles their networks served to secure financial resources and political support for their projects. They were linked to developers, non-profits, social service providers, urban planners, politicians and government staff at the local, state, and federal levels. Arabella Martinez had those federal government and philanthropic connections that supported the Fruitvale Transit Village. Gloria Molina had the grassroots support in Boyle Heights as well as her state, county, and city connections. Plus, she was a powerful Los Angeles politician who served on important boards that controlled transportation funding in Los Angeles. Rachel Ortiz had a long history of neighborhood activism and grassroots connections. But she had also supported local Barrio

Logan politicians that later went on to serve important political roles at the state level. Hence, all these Chicanas were well connected and relied on those networks to influence these Barrios. They were all situated in very important positions within these networks. They were the “middle-women” between the state, capital, and these barrios. These projects would not have been built without their support. Hence, this middle position between government planning interventions and the communities’ interest provided them with power.

There was also a gender element in their advocacy work. The women were inspired by their time during the Chicano Movement and had uniquely gendered experiences depending upon the groups they were involved with. For example, Gloria Molina was involved in the student youth part of the Chicano Movement and heard the group rhetoric of speaking against racism while also feeling silenced as a woman. Working with the United Farm Workers, Rachel Ortiz had a different experience as a woman and she highlighted her interactions with Dolores Huerta as a pivotal experience for her political activism. It was these types of experiences that structured the ways that each of the women moved forward as gendered subjects with Gloria Molina becoming more involved in women’s spaces and then moving towards urban politics while Rachel Ortiz became involved in organizations that were not solely focused on women.

Drawing from the research of Mary Pardo’s work on the Mothers of East LA, she argues that the women who were politically involved suggested that their participation was an extension of their role as mothers. She found women who drew an extended metaphor that viewed their own local communities as an extension of their own families and that as mother’s their role was to take care of their communities. In contrast, the women who worked in these political settings to change their urban spaces did not actively highlight the relationship between their own motherhood and their role as community leaders. While Arabella Martinez did mention that some of the women working for the Unity Council in the Fruitvale neighborhood of Oakland did aim to improve their neighborhoods for the sake of their children, she did not highlight her own role as a mother in the work that she did as an activist nor did she extend metaphors of motherhood to her larger community.

Yet what did stand out in the interviews was the comments by a man involved in the process of the creation of the Fruitvale Transit Village’s development. He highlighted Arabella Martinez’s tenacity in the long process of the development and suggested that the project needed a “godmother”, extending a familial metaphor into the realm of the small Oakland community. All their work related to maintaining the community health of their neighborhoods and in a sense they were the protectors of those communities. The women’s advocacy work they engaged included: issue of safety, health care and women’s health, affordable housing, access to daycare, youth development, improving public spaces, and women’s leadership development and empowerment.

Finally, they all learned and engaged the tools of urban planning for revitalizing their community. Such planning tools as urban redevelopment, zoning, land use, linking to public transportation systems, spatially linking social services and education to their plans, and they all advocated for affordable housing. In a real way, these Chicanas transformed urban planning to better represent the cultural identity of their neighborhoods and bring more government investments into those barrios.

Mass housing, relocation, and mothers' and children's residential satisfaction: Evidence from Ankara

Yucel Can Severcan¹

¹ *Department of City and Regional Planning,
Middle East Technical University, Ankara, TURKEY
yucelcan@metu.edu.tr*

Abstract: This study investigates the effects of relocation on 9-12 year-old children's and their mothers' satisfaction with mass housing built in the context of squatter housing regeneration. The results are based on a survey of 235 nine-to-twelve-year-old children and their mothers living in three recently built inner- and outer-city mass housing developments in Ankara, Turkey. Results show the importance of prior place of residence, location of the mass housing estate, and dwelling and neighborhood characteristics in children's and their mothers' residential satisfaction. In general, compared to their mothers, children reported higher satisfaction scores for all the features of the current home and neighborhood. However, there were some differences in what children and their mothers liked and disliked about these places. The implications of these findings are important for designing communities for all ages.

Keywords: urban regeneration, residential satisfaction, children, mothers

Introduction

The restructuring of the global economy in the last quarter century has given rise to new kinds of places (Shatkin, 2007). Cities, which aspire to be 'global' or regional centers of activity, are forced compete with others by replacing what threaten the flows of trade, tourists and highly qualified labor with large-scale housing projects, state-of-the-art office and museum buildings and luxury hotels (Sassen, 2001). In Turkey, the replacement of squatter housing developments by mass housing projects has been an outcome of such an aspiration. A government report highlighted that between 2003 and 2016, the housing and development administration of Turkey built approximately 740,000 mass housing units across the nation, 110,000 of which were constructed in the context of squatter housing regeneration (TOKI, 2016). This report announced that the number of mass housing units in Turkey is projected to increase to 1.2 million by the year 2023. These trends led the author to question whether such large-scale housing developments are designed in a way to promote the residential satisfaction of low-income women and children – two groups that are highly dependent on

near home environments because of their restricted mobility (Johnson, 1997; Fyhri et al., 2011).

There are a growing number of studies discussing the impact of mass housing developments on the lives of adult mass housing tenants (e.g. Berkoz et al., 2009; Herfert et al., 2013; Dinç et al., 2014). More recently, the urban regeneration literature has been extended to cover the impact of such developments on disadvantaged groups like women (e.g. Erman and Hatiboğlu, 2017) and children (Severcan, 2019a, 2019b). However, no study has ever investigated the effects of relocation on children's and their mother's satisfaction with mass housing from a comparative perspective. This paper aims to contribute to the existing literature by addressing this gap.

The paper starts with a review of the concept of residential satisfaction and the literature on the factors that influence this construct among children and women. Then, the paper describes an empirical study conducted in Ankara, Turkey, which aimed to understand the effects of relocation on 9-12 year old children's and their mothers' satisfaction with mass housing built in the context of squatter housing regeneration. In a previous paper (Severcan 2019b), the author presented the results obtained from children. In this paper, the author aims to contribute to literature by reporting the findings obtained from these children's mothers and compare these findings with the ones reported by Severcan (2019b). It asks whether, how and why children and their mothers' residential satisfaction changed (or did not change) after moving to mass housing developments. It questions the role of various dwelling and neighborhood characteristics in this change and which characteristics are mentioned both by children and their mothers as factors affecting their residential satisfaction. Data were obtained using a residential satisfaction survey. The paper ends with the implications of the study results.

Residential Satisfaction and its Explanatory Characteristics: Findings from Children, Women and the Urban Environment and Behavior Literature

Residential satisfaction refers to individuals' appraisal of the actual conditions of their residential environment in relation to their desired (or aspired) needs (Morris and Winter, 1978; Galster and Hesser, 1981; Mohit et al., 2010). A greater degree of congruence between actual and desired conditions reflects a higher residential satisfaction; incongruence leads to residential dissatisfaction (Li and Wu, 2013).

The concept of residential satisfaction is often employed to evaluate one's satisfaction with home and neighborhood (Kaitilla, 1993; Ogu, 2002). When individuals evaluate their residential satisfaction, the characteristics of both home and neighborhood are assessed.

Since human needs vary from one person to another and that the needs of one person change over time, many studies have shown that being young or adult, or male or female affects individuals' residential satisfaction (Lu, 1999; Iben and Amole, 2013). In a comparative study conducted in Beijing (China), Zhang and Lu (2016) found that younger and female

people are more likely to report higher levels of residential satisfaction. Nevertheless, little is known about how children's residential satisfaction differs from women's residential satisfaction in different housing environments.

A review of children's residential satisfaction and women's residential satisfaction literature shows that there are some dwelling and neighborhood features that affect both groups' residential satisfaction. At the dwelling level, these factors are: perceived housing opportunities like size of the house and the presence of a garden and high-quality furniture and appliances (Cook, 1988; Baillie and Peart, 1992; Hadjiyanni, 2000; Darab et al., 2018); architectural style of the dwelling and its interior design (Ladd, 1972; Baillie, 1990; Devlin 1994); views from windows (Kearney, 2006; Severcan, 2019a, 2019b); building infrastructure and construction quality (Erman 1997; Severcan, 2012); presence/absence of a safe and social home environment with family and peers (Darab et al., 2018; Severcan, 2018); and maintenance of building interiors like halls or elevators (Ladd, 1972; Cooper Marcus, 1975). Cook (1988) and Severcan (2019a) have shown the importance of location of the dwelling in children and women's satisfaction with home. Darab et al. (2018) found that stability and security of tenure is influential in affecting women's satisfaction with home, but this factor is not mentioned in children's residential satisfaction literature as an explanatory variable.

At the neighborhood level, among the factors which affect both children's and women's residential satisfaction, the role of the presence of friends and relatives and lack of undesirable people (e.g., gangs, vandals) in the home range are one of the most frequently mentioned (Bruin and Cook, 1997; Severcan, 2019a). Some other highly mentioned neighborhood characteristics are the accessibility, safety and maintenance of neighborhood public spaces and the land uses that support the public realm (e.g. presence of shopping areas, cultural facilities, child-care services) (Cooper Marcus and Sarkissian, 1986; Cook, 1988; Day, 2000; Freeman, 2010).

Research from Canada and United States shows that when poor families move from substandard dwellings to public housing, they show satisfaction with the infrastructure of their new dwellings, but dissatisfaction with the social composition of their neighborhoods since these apartments are occupied by families with a variety of social and health problems (Yancey, 1971; Michelson, 1977). Similarly, in a study conducted in the mass housing estates built in the context of squatter housing regeneration in Turkey, Severcan (2019b) found that because of the high crime rate in the neighborhood, children were afraid of using public spaces alone and that the most negatively affected children were those who moved from non-squatter neighborhoods. This study also showed that while children's satisfaction with the quantity of playgrounds and green open spaces increased, their satisfaction with the accessibility to commercial and cultural facilities decreased after relocation. Various scholars discuss the negative effects of relocation on children's and women's social capital; after relocation, these groups tend to show dissatisfaction with their new residential environment, especially in the short-term, due to the loss of friends and neighbors (van Vliet, 1986; Ryff and Essex, 1992; Gifford, 2007). To sum up, depending on how individuals comparatively assess the characteristics of their prior and current place of residence, relocation may influence individuals' residential satisfaction positively or negatively.

Individual factors, such as education, income and length of stay in residence, may also affect individuals' residential satisfaction (see Lu, 1999; Chapman and Lombard, 2006; Zhang and Lu, 2016). Such factors may either directly or indirectly influence individuals' residential satisfaction by shaping their place perception.

Context of the Study

This article focuses on a study conducted in Ankara – a city where until the 1990s, the percentage of the squatters in Ankara's total population was approximately 58% (Keles, 1993). Ankara's squatter dwellings (*gecekondus*) are usually located on illegally subdivided land. There are no building codes, and originally, had no infrastructure. They have grown spontaneously, without any plan. According to Mahmud and Duyar-Kienast (2001) such developments were originally compact, composed of physically similar housing units. They had small gardens or courtyards. Over time, many of these informal developments were associated with poverty, poor infrastructure, lack of public amenities (like parks and playgrounds), crime and drugs, but also with a number of positive features, such as a strong sense of community and public life.

Especially after 2000, with the influence of neoliberal economic policies such as the loosening of controls on capital flows and attraction of foreign investment, the Turkish government started putting greater emphasis on the regeneration of squatter neighborhoods (Karaman, 2013). Between 2004 and 2007, a series of laws were passed, granting local municipalities rights to execute squatter housing transformation projects in collaboration with the Prime Ministry's Mass Housing Administration of Turkey (TOKI).

TOKI's squatter housing regeneration projects starts with the evacuation of residents. Thereafter, TOKI replaces the squatter houses with high-rise standardized apartments constructed on the same site at a higher density (Karaman, 2013). This is often done without consulting the residents, neither adults nor children. The mass housing units are then made available to displaced residents for purchase via mortgage loans and to the public at market prices.

Method

Site and Participant Selection

The author selected the project participants in five steps. First, four mass housing estates recently built (2008 and later) in Ankara were selected. Two of these estates were located in the inner-city (Altindag Gultepe TOKI and Mamak Yatikmusluk TOKI), while the other two were located in the outer-city (Altindag Karacaoren TOKI and Mamak Kusunlar TOKI). Later, to minimize threats to the accuracy of the findings, only the data obtained from Altindag Gultepe TOKI, Mamak Yatikmusluk TOKI and Mamak Kusunlar TOKI were used

for the purpose of this study (for the details of this site selection process, please see Severcan, 2019b).

The selected inner-city mass housing estates were located within walking distance (300-350 meters) of each other and were still surrounded by squatter housing areas. They were near important functions of the city (e.g. hospitals, manufactories). The number of mass housing units in Altindag Gultepe TOKI and Mamak Yatikmusluk TOKI were 1448 and 528 respectively, making these two inner-city sites larger than the other inner-city mass housing estates built in Ankara within the context of squatter housing regeneration. Being one of the two outer outer-city mass housing estates in Ankara built in the context of squatter housing regeneration, Mamak Kusunlar TOKI was surrounded by open lands. The number of mass housing units in this project area was 1374.

The selected sites had physical characteristics similar to many other TOKI's mass housing estates across the country. Buildings had the same physical characteristics, and were designed only for residential purposes. High-rise apartment buildings were clustered around small parks and playgrounds or large parking lots. Wide roads separated the clusters. Parks and playgrounds were places with few standard play equipment and sitting furniture. They rarely contained outdoor gym equipment and none had sports fields. Supermarkets existed only in the outer-city mass housing developments. Although there were no supermarkets in the chosen inner-city estates, they were available in the vicinity of these developments along with some other land uses like traditional commercial establishments (e.g. greengrocers, grocers). Child-oriented cultural establishments were lacking in all selected sites: Altindag Gultepe TOKI, Mamak Yatikmusluk TOKI and Mamak Kusunlar TOKI. Vast lawns surrounded the apartment buildings in all project areas. The buildings consisted of 2-3 bedroom apartment units in the chosen inner-city mass housing estates, and 2 bedroom apartment units in Mamak Kusunlar TOKI. All buildings included a number of interior design elements provided by TOKI: a kitchen cabinet, laminated floors, wooden doors and painted walls.

In the second step, the author chose all the public schools in the selected neighborhoods. Third, the author gave a presentation describing the project in each classroom of third, fourth, fifth and sixth graders in the chosen schools. Fourth, the author asked the children who wanted to take part in the project to sign an assent form; parents approved their child's participation by signing a consent form. With the same consent form, children's mothers indicated their willingness to participate in the project. Lastly, the author selected all the children and mothers who wanted to participate in the study.

Data Collection

This study is based on the results of a residential satisfaction survey administered to children and their mothers. The survey was anonymous and separated into five main parts. The first and second parts were about the respondents' satisfaction with their previous home and neighborhood. All respondents were asked to rate their overall satisfaction with their former residential setting on a five-point Likert scale ranging from one (not at all satisfied) to five

(very satisfied). A ‘don’t remember’ response option was included. Additionally, they were asked to describe (in close-ended question format) the type of their previous dwelling (i.e. squatter house, multi-story apartment, single family housing, other), and (in open-ended question format) why they felt satisfied/dissatisfied with their previous home and neighborhood. Mothers were asked to rate their level of satisfaction with a range of pre-defined characteristics associated with previous home and neighborhood on a five-point Likert scale (10 home level features and 26 neighborhood level features). In defining these characteristics, the author drew on the available literature related to both children’s and adults’ residential satisfaction. These Likert scale questions about the previous residential environment were not asked to children due to a possible memory bias in the recall of early childhood experiences.

The third and fourth parts of the survey focused on children’s and their mothers’ assessment of their level of satisfaction with a range of current home and neighborhood characteristics (for children: 9 home level features and 25 neighborhood level features; and for mothers: 10 home level features and 26 neighborhood level features) and also their overall satisfaction with these places. Again, these questions were asked using a five-point Likert scale ranging from one (not at all satisfied) to five (very satisfied). Questions related to home and neighborhood characteristics were same as those found in the previous parts of the survey (for a list of these characteristics please see Severcan, 2019a or Severcan, 2019b). These parts also included questions about respondents’ years of residency (YOR) in the current home, neighborhood and city, and open-ended questions about any other things that made them feel satisfied/dissatisfied with their environment.

The final part of the survey asked respondents to describe their socio-demographic characteristics. Children and their mothers were asked the same questions in the same order and with the same wording. Exceptions to this include questions that were asked to mothers but not to children like the questions asking mothers to rate their satisfaction with the maintenance cost of their dwelling, location of their workplace (if applicable) or asking them to provide their home-ownership status in the previous and current home. All Likert scale questions were presented in a visual analogue scale to facilitate the comprehension of the response options and open a window for the use of parametric tests.

Analysis

The analysis presented here is based on the survey responses of 137 children aged 9-12 and 98 mothers aged 25-55 living in three mass housing estates in Ankara. The imbalance in the number of participants between the two groups was a result of some mothers’ unwillingness to participate in the survey. The number of children from inner- and outer-city mass housing estates was 63 and 74 respectively. For women, these numbers were 59 and 39 respectively.

Table 1 shows the socio-demographic composition of the survey participants by location. Of the 137 child respondents, 60 were male and 77 were female; 58 (42.3%) said that they had previously lived in squatter housing, while 79 (57.7%) were in a non-squatter housing area

(hereafter formal neighborhood). Of the 98 mother participants, 41 (41.8%) had previously lived in squatter housing, while 57 (58.2%) were in a formal neighborhood. Most mother participants were not working (77.6%). There were more working women in the selected inner-city estates perhaps because of the availability of job opportunities in the vicinity. Accordingly, in the inner-city and outer-city, the monthly average household income of the residents were between US\$300-\$450 and US\$150-\$300 respectively. These amounts are way below the country's poverty level for a family with two children, which was approximately US\$750 in 2016 (TURK-IS Haber Bulteni, 2016).

¹ Retrieved from Severcan (2019b)

Children's and their mothers' mean YOR in current home was 2.9 ($SD=1.32$) and 2.77 ($SD=1.45$) years respectively. This indicates that response inaccuracy and bias associated with remembering the previous place of residence were not significant given the findings of Quas et al. (1999), who reported that children interviewed within 3 years of an event provide more correct information about it compared to those who were interviewed 3 or more years after the event.

The effects of relocation on children's and mother's overall satisfaction with home and neighborhood were examined using a t-test (paired t-test for comparing respondents' residential satisfaction for the prior and current place of residence and unpaired t-test for investigating the difference between children's and their mothers' and inner- and outer-city children's/mothers' residential satisfaction). To understand why children and their mother's satisfaction changed (or did not change) after relocation, the responses to the open-ended questions were content analyzed. To this end, the author began by reviewing the data closely. Segments of text were coded and then grouped into similar themes, which were later grouped into larger categories. Finally, the author compared the themes associated with the previous and current place of residence.

Results

Effects of Relocation on Children's and Mothers' Satisfaction with Home

Compared to their mothers, children reported higher satisfaction scores for their home (Table 2). For the current home, this difference was statistically significant between the two groups ($M_1=3.90$, $M_2=3.16$, $t=4.26$, $p<.05$). While children's satisfaction with home increased (Severcan, 2019b), mothers' satisfaction with home decreased after relocation. However, the overall mean pre- and post- satisfaction scores were not significantly different for both children and their mothers ($p>.05$). Severcan (2019b) showed that no change was observed

in the residential satisfaction of children who moved from squatter housing. However, this paper shows that moving from squatter housing had a significant affect on mothers' satisfaction with home ($t=2.09$, $p<.05$). After relocation, satisfaction with the home increased among mothers who were once living in squatter settlements. Similar to their children's responses, moving from non-squatter housing had no significant affect on mothers' satisfaction with home. While no statistically significant change was observed in the residential satisfaction scores of mothers who moved to the inner- or outer-city, Severcan (2019b) found that moving to the inner-city positively and significantly affects children's satisfaction with home ($t=3.12$, $p<.05$).

Table 2. Mean residential satisfaction scores of children before (pre) and after (post) relocation.

	Home				Neighborhood			
	Pre	Post	t	p	Pre	Post	t	p
Children ¹								
Overall satisfaction	3.68	3.90	1.53	.12	3.74	3.45	1.52	.13
Moved from squatter housing	3.48	3.88	1.70	.09	3.51	3.38	.41	.67
Moved from non-squatter housing	3.80	3.89	.68	.49	3.89	3.48	2.09	.03*
Moved to inner-city mass housing	3.18	4.10	3.12	.00*	3.41	3.27	.60	.54
Moved to suburban mass housing	3.92	3.73	.76	.44	4.01	3.59	1.65	.10
Mothers								
Overall satisfaction	3.13	3.16	.05	.95	3.54	2.74	4.38	.00*
Moved from squatter housing	2.83	3.45	2.09	.04*	3.32	3.00	1.15	.25

Residential Relocation and Factors Affecting Children's and Mothers' Satisfaction with Home

Results obtained from children show that, before relocation, children liked hanging out in their yards and the location of their dwelling in terms of convenience to city center and desired amenities (like cultural areas, bakeries and groceries) (Severcan, 2019b). Relocation affected children's satisfaction with mass housing negatively with respect to these dwelling features because of the lack of private yards and cultural and commercial areas in the mass housing estates. It was also found that after relocation, children did not complain about the infrastructure problems of their dwellings – e.g. children did not mention any leaking pipe issues in their current home, a problem that was frequently mentioned by children who moved from squatter settlements (Severcan, 2019b). Nevertheless, the construction quality of the apartments was still a problem for children after relocation (Severcan, 2019a, 2019b). Additionally, many children expressed their dissatisfaction with the efficiency of the housing

management and administration because of the malfunctioning elevators and poorly maintained apartment buildings in mass housing (Severcan, 2019b).

This paper shows that the way mothers assess their prior and current dwellings is not significantly different than those of their children. After relocation, mothers expressed greater, but not statistically significantly different, level of dissatisfaction with the type of their dwellings (e.g. living in a house with a yard versus living in a high-rise apartments), construction quality and efficiency of the housing management and administration. Additionally, in their responses to open-ended questions, many mothers expressed how their satisfaction with the location of their home decreased after relocation:

Our previous house was in the middle of the city. It was close to everywhere. We never had a transportation problem. Shopping areas are too far away now. We can hardly meet our needs. (A mother from an inner-city estate)

We do not have shopping and leisure areas nearby. Transportation to the city is a huge problem. (A mother from an outer-city estate)

Like children, mothers who moved from squatter settlements, mentioned the infrastructure problems of their previous home (e.g., “the roof was leaking,” “there was no toilet infrastructure in the house”), but they did not mention such problems for their current home.

Both children and their mothers rated the brightness of their dwelling as the most satisfying, and the efficiency of the housing management and administration as the most dissatisfying features of their current home. Compared to their previous dwelling, mothers were more happy with the climatic comfort of their dwelling ($t=4.05$, $p<.05$). Especially mothers coming from squatter settlements seemed satisfied with not using coal stoves in their current dwellings. Severcan (2019b) found that climatic comfort inside the home ($M=3.97$, $SD=1.29$) was one of the top three most liked features of the current home by children.

In general, like their children, mothers were satisfied with the views from windows, especially the views of nature, but some mothers indicated that because all the buildings in the neighborhood are too high, they block the view.

Children who moved to the outer-city were less satisfied than the children who moved to the inner-city estates with respect to the size of their dwelling (Severcan, 2019b). This was perhaps because, as mentioned earlier, some inner-city children were living in apartment buildings with more rooms. Although mothers’ overall satisfaction with the size of their home decreased after relocation, similar to the findings obtained from children, this change was statistically significant only for the mothers who moved to the outer-city estate ($t=2.51$, $p<.05$). Additionally, housing type ($t=2.66$, $p<.05$) and efficiency of the housing management and administration ($t=2.52$, $p<.05$) were the two other dwelling characteristics that were rated statistically significantly different by the mothers living in inner- and outer-city estates.

In general, mothers who moved from the squatter settlements expressed their satisfaction with the physical qualities of their current dwellings. Typical problems mentioned by these mothers were related with the lack of yards, where (like their children) they stated that they miss hanging out in these areas with their families and friends, poor workmanship of their new buildings and the lack or small size of the balconies in their new residential environment. Compared to mothers coming from squatter settlements, more mothers coming from formal neighborhoods complained about the size, appearance, construction quality and management issues of their current dwellings:

We live in gated, high-rise apartment buildings. They don't look very beautiful from outside. The buildings are too high. Our kitchen is very small. The doors are like papers! You can clearly see the bulges in the wooden door frames. The window frames are also very poor in quality. The windows are streaked with dirt. I assume that they used second hand windows. I don't think that they are conducting inspection and maintenance of the elevators. We are sick and tired of paying for the mistakes done by our housing managers. (A mother from an inner-city estate who moved from a non-squatter settlement)

Effects of Relocation on Children's and Mothers' Satisfaction with Neighborhood

As Table 2 illustrates, compared to their mothers, children reported higher satisfaction scores for their neighborhood. For the current neighborhood, this difference was statistically significant between the two groups ($M_1=3.45$, $M_2=2.74$, $t=4.09$, $p< .05$). While children's satisfaction with neighborhood increased ($p> .05$), mothers' satisfaction with neighborhood significantly decreased after relocation ($t=4.38$, $p< .05$).

Severcan (2019b) showed that no change was observed in the residential satisfaction of children who moved from non-squatter housing, or who moved to an inner- or outer-city estate. He also found that, at the neighborhood level, the only statistical change was observed among the residential satisfaction of children who moved from a squatter housing to a mass housing development. From the data obtained from children's mothers, the author found totally opposite results. Moving from a squatter housing had no impact on mothers' satisfaction with neighborhood. However, after relocation, satisfaction with neighborhood significantly decreased among mothers who moved from a formal neighborhood, or who moved to an inner- or outer-city mass housing estate.

Residential Relocation and Factors Affecting Children's and Mothers' Satisfaction with Neighborhood

Severcan (2019b) found that, after relocation, significantly fewer children mentioned that they had many friends in their neighborhood. Compared to other pre-defined neighborhood characteristics, children gave higher satisfaction scores for the level of social ties and number of trusted people (other than parents) in their current neighborhood (Severcan, 2019b).

Additionally, sense of safety was one of the most influential factors negatively affecting children's satisfaction with current neighborhood. Accordingly, the most disliked characteristic of the current neighborhood by children was the inadequacy of measures taken to mitigate safety concerns (Severcan, 2019b). Inaccessibility of cultural places (like theatres and culture centers), informal play areas (like yards and streets) and commercial establishments (such as grocers, restaurants and coffee shops) were mentioned as some other important factors negatively affecting children's neighborhood satisfaction (Severcan, 2019b). For some neighborhood characteristics, there was a statistically significant difference between the inner- and outer-city children's mean neighborhood satisfaction scores. These characteristics were: proximity to school from home, safety of street crossings, speed and number of cars using the local streets, proximity of public transportation stops to the home, frequency of public transportation vehicles passing through the neighborhood, number of public transportation routes servicing the neighborhood, strength of social ties in the neighborhood (e.g. whether neighbors greet and visit each other), and level of sense of community (i.e. whether people act together or help each other when they face common problems) ($p < .05$ for all) (Severcan, 2019b).

We see both similarities and differences across the responses obtained from children and their mothers. Like their children, after relocation, significantly fewer mothers mentioned that they had many friends in their neighborhood ($t=5.27$, $p < .05$). This problem was seen especially among mothers who moved from non-squatter housing areas since mothers coming from squatter settlements were mostly seeing their old friends as their neighbors.

As the author has observed from the data obtained from children (Severcan, 2019b), the level of sense of safety in the neighborhood significantly declined among mothers after relocation ($t=7.37$, $p < .05$). In their responses to open-ended questions, many mothers mentioned the drug selling and vandalism activities in their neighborhood and wrote about their concern for their children's safety.

I was living in a safe neighborhood. It was a good place to raise my kids. People were affluent. In my current neighborhood, I am not satisfied from the quality of the neighbors. They are selling drugs in front of us. We hear the gunshots around. I don't want to live here! (A mother who moved from a formal neighborhood to an inner-city estate)

I worry when my children go to school or grocery alone. There are gangs everywhere. (A mother from an outer-city estate)

Additionally, mothers thought that in terms of several neighborhood characteristics, the previous neighborhood environment was a much better place to live than the mass housing estates: adequacy of the measures taken for mitigating safety issues in the neighborhood; the traffic volume and speed of the cars in the local streets; safety of street crossings; and care taken by neighbors to protect the environment and keep it clean ($p < .05$ for all). For mothers, the most disliked characteristic of the current neighborhood was same with what their children indicated: the inadequacy of measures taken to mitigate safety concerns ($M=1.70$,

$SD=1.07$). Hence, in their responses to open-ended questions, like their children, many parents stated that they aspire to live in safer neighborhoods.

Similar to the responses obtained from children, inaccessibility of cultural places, informal play areas (like yards and streets), parks with a variety of furniture and play equipment, and commercial establishments (such as grocers and restaurants) were mentioned as some other important factors negatively affecting mothers' neighborhood satisfaction. After relocation, satisfaction with proximity, quality and quantity of shopping places, cultural places and public open spaces declined significantly among mothers ($p < .05$ for all).

Compared to their previous neighborhoods, mothers assessed their current neighborhood significantly more negatively in terms of the following neighborhood features: the quality of their children's school ($t=7.52, p < .05$), the quantity of greenery ($t=2.66, p < .05$), frequency of public transportation vehicles passing through the neighborhood ($t=3.74, p < .05$), number of public transportation routes servicing the neighborhood ($t=3.65, p < .05$), number of people using the open spaces ($t=3.56, p < .05$), and noise level in the neighborhood ($t=3.44, p < .05$).

Like their children, compared to those living in the outer-city estate, significantly more mothers living in the inner-city were satisfied with the location of the school ($t=2.80, p < .05$), frequency of public transportation vehicles passing through the neighborhood ($t=2.82, p < .05$), and number of public transportation routes servicing the neighborhood ($t=2.47, p < .05$). As mentioned in Severcan (2019), in interviews, children living in outer-city estates explained that since their school is located on a steep slope, access to it requires great effort. The author assumes that in the outer-city, children's mothers were dissatisfied with the location of the school for a similar reason.

Differences between children's and their mothers' responses were observed a number of neighborhood characteristics. While children were highly satisfied with the presence and number of trusted people (except parents) in the neighborhood who can help or protect them ($M=3.94, SD=1.16$), mothers were highly dissatisfied with this aspect of their neighborhood ($M=2.99, SD=1.14$). Finally, Severcan (2019) found that inner-city children were significantly more satisfied with the safety of street crossings, speed and number of cars using the local streets, proximity of bus stops to the home, strength of social ties and level of sense of community in the neighborhood than to outer-city children. However, this study does not show any statistically significant difference between inner-and outer-city mothers' satisfaction with respect to these neighborhood characteristics.

Conclusion

Creating neighborhoods that are loved by different generations requires urban designers to understand the common characteristics of child- and adult-friendly neighborhoods. With this goal in mind, by focusing on the mass housing estates that were built in the context of squatter housing regeneration, this study questioned whether, how and why mothers' residential satisfaction changed after relocation, and compared these results to those of

children reported in Severcan (2019b). To the best of the author's knowledge, no study has ever compared children's and mothers' satisfaction with mass housing.

Results showed that moving from a squatter or non-squatter housing or moving to an inner- or outer-city estate does not affect children's and their mothers' residential satisfaction levels equally. At the neighborhood level, mothers are more negatively affected from relocation than children. However, moving to mass housing affects children's and mothers' residential satisfaction in the same direction; for example, at the dwelling level, moving from a squatter housing to an inner-city mass housing estate affects both children's and mother's residential satisfaction positively.

In line with the findings reported by Zhang and Lu (2016), compared to their mothers, children reported higher satisfaction scores for all the features of the current home and neighborhood. However, there were differences and similarities in what children and their mothers liked and disliked about these places. In general, children and their mothers liked the following characteristics of their environment: brightness and climatic comfort of their dwelling, building infrastructure, views from windows and presence of parks and playgrounds. Both groups were unsatisfied with the following features of their environment: construction quality of the buildings, efficiency of the housing management and administration, proximity of commercial and cultural places, quality of parks and playgrounds, presence of sports areas, speed and number of cars using the local streets, safety of street crossings, neighborhood safety, care taken by the neighbors to protect the environment and keep it clean, and adequacy of the measures taken for mitigating safety issues in the neighborhood.

Because the numbers of mass housing developments is rising in Turkey, the results of this study could guide urban planners and designers in their efforts to build communities that are loved by different age groups. First, results suggest that to increase children's and their mothers' residential satisfaction in mass housing, planners and designers need to integrate the existing land use system with retail, cultural and recreational services. These areas should attract the attention of not only adults but also children. Some strategies to achieve this include: converting the lawns into sports areas, using the ground floor of the apartment buildings for commercial and cultural purposes (e.g., bookstores, cafes, grocers) and providing cultural centers for women and young people in the neighborhood.

Second, planners and designers should put greater focus on increasing residents' sense of safety. There is voluminous literature discussing ways to design safer neighborhoods (see, e.g., Loukaitou-Sideris, 2006). Strategies may include increasing the land-use mix, providing more sitting spaces in outdoors, improving crosswalks and putting territorial symbols such as neighborhood watch signs. Such environmental design strategies should be complemented by other strategies, which may include policing and/or surveillance by neighborhood watch groups.

Rethinking Partnerships for Affordable Housing: Planning Policy + Design Nexus

Sasha Tsenkova¹

¹*Professor, School of Architecture, Planning and Landscape, University of Calgary, 2500 University Drive NW, Calgary, T2N 1N4, Canada, tsenkova@ucalgary.ca*

Abstract: A growing affordability problem in Canadian cities has prompted a renewed commitment of the federal government, complemented with provincial and municipal programs, to increase the supply of affordable rental housing. Consensus has been building across Canada that an effective response requires multi-sectoral partnerships to meet growing local needs within limited resources and capacity. Recently large Canadian cities have joined their efforts with non-profit and private organisations to provide affordable rental housing in mixed-income experimental projects.

In this context, the research addresses a significant gap in the evaluation of partnerships, focusing on the nature of multi-agency collaborations in the provision process (design, build, finance, operate). Partnerships capitalise on the effective role of the public sector in the mobilization of resources, the efficiencies of private agencies in the development process (design, build) and the hybridity of the non-profit institutions (management, service delivery). The research develops a conceptual framework, based on the political market model to explain adoption of planning and housing policies by municipalities. The alignment of policy instruments—regulatory, fiscal and financial—is an important determinant of the ability of partnerships to deliver adequate, affordable and sustainable housing. The framework presents a typology of affordable housing partnerships using highlights from case studies in the large Canadian cities—Toronto, Vancouver and Montreal. The methodology is based on review of the literature and analysis of innovative developments of mixed-income affordable rental housing projects.

Findings suggest that economies of scale and sustained funding are critical for efficient partnerships (design, build and operate). However, their effectiveness often depends on institutional capacity, coalition building/inclusive governance and neighbourhood integration. We argue that a shift from the traditional ‘public-private’ model to multi-sectoral partnerships is required to address the housing crisis in Canadian cities.

Keywords: partnerships, affordable housing, evaluation, cities

Introduction

A growing affordability problem affecting over 5 million people in Canada (1.7 million households in core housing need) has prompted a renewed commitment of the federal government, complemented with provincial and municipal programs, to end homelessness and increase the supply of affordable rental housing (Government of Canada, 2018; Statistics Canada, 2017). Nearly a quarter of all Canadians are experiencing housing insecurity, defined as spending more than 30% of their income

on shelter costs. In Calgary, around 17,000 households are at risk of homelessness because they earn less than \$30,000 and spend more than half on rent. Housing affordability is under further threat due to skyrocketing home prices and rising interest rates. Finding solutions to increase the share of affordable/social housing (6% on average) is important in Canada's big cities. Given the devolution of government involvement in housing (CMHC, 1998), consensus has been building across Canada that an effective response requires a multi-sectoral approach, including all levels of government, the private for-profit and non-profit sectors, as well as local communities (Moore and Skaburski, 2004; Wolfe, 1998). This is perceived as the most effective way of producing affordable housing to meet growing local needs within limited resources and capacity (Angel, 2000; Scanlon, Whitehead & Arrigoitia, 2014). The last few years have seen large Canadian cities join their efforts with non-profit and private organisations to provide affordable rental housing in mixed-income, mixed-tenure projects (CMHC, 2014). While these projects are experimental, they have demonstrated a viable alternative to address vulnerabilities in the housing market as well as make Canadian cities more inclusive and competitive (Conference Board of Canada, 2010). In this context, empirical studies show that despite the significance of partnerships for affordable rental housing, important gaps remain in the capacity to implement them in practice (Moore and Skaburski, 2004; Tsenkova and Witwer, 2011).

Conceptual Framework and Approach

The 'market failure' in affordable housing has been typified by Berry (2014) as lack of stable and consistent policies, absence of planning mechanisms that regulate affordable housing and provide infrastructure funding, and a failure in governance to coordinate and strategize. The theoretical framework for evaluation of housing partnerships is based on collaborative planning (Healey, 1997; Booher and Innes, 2002; Forester, 2013) and institutional interaction, communication and empowerment (Boase, 2000). Multi-sectoral partnerships have mainly been studied as 'public-private' partnerships advantageous for economies of scale and scope (Brown, 1999). The conceptual approach taken in this research is to understand how partnerships can be effective in planning, building and delivery (Bovaird 2004; Innes and Booher, 2010). Brinkerhoff and Brinkerhoff (2011) articulate such partnerships as those that maximize democratic processes to ensure sustainability through jointly determined goals, collaborative and consensus-based decision making, non-hierarchical and horizontal structures and processes, informal, as well as formalized relationships, synergistic interactions among partners, and shared accountability for outcomes and results. Partnerships address the impasse in the delivery of affordable, adequate and secure housing focusing on solutions—policy alternatives, planning and design strategies (Kemeny, Kersloot and Thalmann, 2005; Tsenkova, 2019).

A central question in the literature refers to implementation of new partnership models in the development process. Over time, the compositions of actors and agencies involved have shifted drastically from public provision towards multi-actor/ agency collaboration (Berry, 2014). What are the models of these collaborations? While there is a common mandate to provide housing that is affordable, the definitions and criteria for allocation and eligibility of recipients, governance and management policies, and typologies of housing forms vary widely (Carmona, Carmona and Gallent 2003). Socially owned housing managed by non-profit, private and community-based organizations in 'hybrid' forms, has replaced public housing to address the needs of targeted groups (i.e., the

homeless; seniors; vulnerable households), but is under threat of funding cuts, despite a well-documented increasing affordability gap in many cities (Hoard, 2012; Oxley, 2000).

A second question relates to the design of adequate policy to develop partnerships for affordable rental housing. Public authorities employ various policy instruments to implement transformation (Gilbert, 2016; Tsenkova, 2009). Public expenditure cutbacks have contributed to the decline in federal and provincial provision of socially-owned housing in Canadian cities (Dalton, 2009; Schembri, 2014). In its place has come a wide range of innovations in public/private approaches to funding and planning instruments with varying capacities to address the affordability gap (Allan, 2001; Tsenkova and Witwer, 2011). Further, the need to mobilize the network of public, private and non-profit organizations, as well as the local communities, to support reforms for affordable housing partnerships is essential as is the capacity to effectively manage the interdependence between organizations (Tsenkova, 2014) and adapt to risks (Gilbert, 2016). Practitioners identify this as a challenging area, with municipalities often taking a strategic leadership role, particularly in large Canadian cities. Finally, the outcome of such partnerships is often mixed-income affordable housing (Whitehead, 2007; Tsenkova, 2019). Research highlights that historically public housing has played a significant role in shaping communities, but in the era of neo-liberal reforms, its future is challenged by declining investment, aging infrastructure and design that is less conducive to social integration (Bacher, 1993; Oxley, 2000). The built form and spatial patterns of new affordable housing use planning and design strategies to facilitate social mix and integration of projects in communities.

Defining a Partnership

According to the Canadian Council on Private Public Partnerships (CCPPP), a PPP is “a cooperative venture between the public and private sectors, built on the expertise of each partner, that best meets clearly defined public needs through appropriate allocation of resources, risks, and rewards” (2017). Although this can be considered the standard, several other definitions exist throughout the literature which allude to the complexity of the partnership (Kernaghan, 1993, Armstrong, 1997, Rodal & Mudler, 1992). The overall sentiment defines a cooperative pursuit that is predicated on shared, compatible objectives. In return for the need of shared mutual benefits is a shared risk and therefore authority on the project. The definitions tend to outline the idealised form of partnership amongst private and public entities, but in different forms.

Figure 1 situates the variety of partnership types on a continuum, depicting the transfer of liability and therefore risk from the public to the private sector (IPSASB, 2008). A project can be defined as any combination of the following operational elements; Design, Build, Finance, Operate, Maintain, Own, Transfer, Lease, Develop, Buy (Allan, 1999). The location of a project on the spectrum is dictated by the nature of the project in conjunction with the entity performing key tasks. The following definitions of partnership types have been adapted from the International Public Sector Accounting Standards Board’s (IPSASB) consultation paper on concession arrangements (2008).

1. **Service and Management Contracts** – services that would otherwise be performed by a public sector entity are contracted out to a private sector entity, but risk and responsibility for the delivery of the service remains with the public entity. Contract arrangements are short term, renewed only if the private sector entity delivers the service in accordance with requirements set by the public sector.

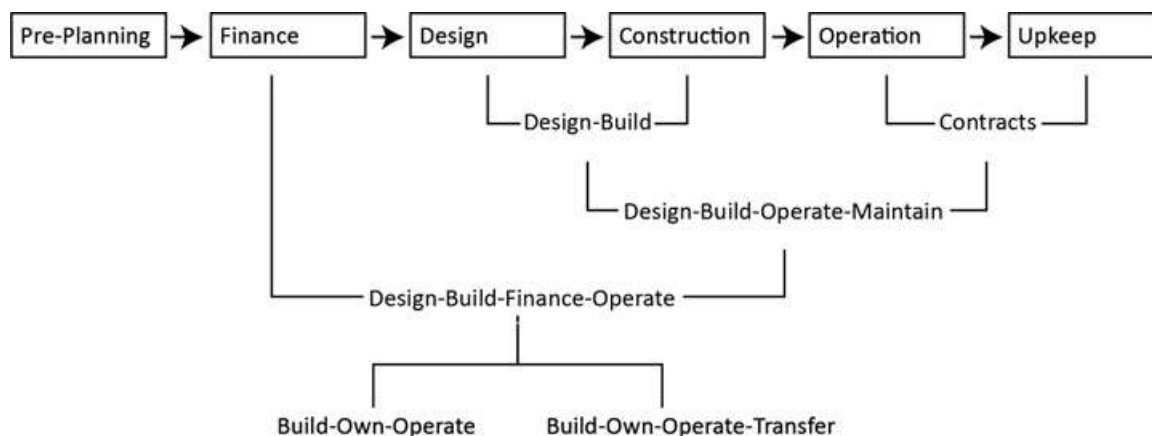

Figure 1: Partnership Typologies & the Housing Provision Process

2. Design-Build – private sector entity assumes full construction risk and is responsible for the liability associated with the construction process. Upon completion, the public sector entity assumes responsibility for both the operation and maintenance of the project, leaving the private sector with little to no residual project risks.
3. Design-Build-Operate-Maintain – construction, operation, and maintenance risks are assumed by the private sector entity. Public sector involvement is typically limited to financing, characterising the typology of the project, oversight of operations/outcomes.
4. Design-Build-Finance-Operate – private sector entity designs, builds, and finances associated construction costs. In addition to being heavily involved in the construction of the project, the private sector is also responsible for the delivery of services through long term concession agreements.

Affordable Housing Partnerships

The designing, building, financing, and operation of affordable housing through public private partnerships (PPPs) is further complicated with the inclusion of a third entity; the non-profit sector. The above definition is rendered incomplete when viewing affordable housing partnerships because of the strong role non-profits have in catalysing investment (Moskalyk, 2008). To compensate for the lack of non-profit inclusion in the CCPPP definition cited above, CMHC offers the following adapted definition: PPPs are defined to included agreements where development is undertaken with a combination of not-for-profit, private, and public participants of programs, however, PPPs are not undertaken within the context of a single mainstream program. They represent a more dynamic involvement of public sector, and not-for-profit interests in which each contributes and shares some sort of the risk (Wallace et. al., 1998:2).

This research proposes a new term that will capture the essence of such collaborations, particularly in the development process of new affordable housing. A PPNP (*public private and non-profit partnership*) does have a strong involvement and leadership of non-profit organisations that often Operate-Own affordable housing. They can also act as developers with the goal of engaging private companies in the Design-Build phase, while mobilising public sector financial and fiscal support to

ensure financial viability. The construction and operation of affordable rental housing is typically dependent on the inclusion of the three sectors listed above (public, private, and non-profit). The following will detail the different types of agencies that represent the three sectors and the responsibilities that they may have in the partnership.

Public Sector

No level of government accepts full responsibility for developing affordable housing. Certain aspects are federally regulated (CMHC and the National Housing Act), but provincial governments have key responsibilities. This creates a diversity of partnership types, with fundamental characteristics differing from province to province, and in cases between municipalities.

Federal Government – The Federal government’s involvement in affordable housing is through national funding strategies. Historically, these have fluctuated in value and are heavily dependent on the political party in power. Since 2011, funding for affordable housing has been provided through the Investment in Affordable Housing (IAH) (CMHC, 2017). The IAH is the most recent national funding strategy, with 2016 marking the end of a 5 year, \$1.9 billion plan. The 2017 federal budget announced the first National Housing Strategy with \$11.2 billion investment in affordable housing over the next 11 years (Young, 2017). Direct federal involvement is limited to capital investment targeted almost exclusively at the supply side of the housing equation. Funds are allocated to encourage the construction of more rental units.

Provincial Government – Under bilateral agreements with CMHC, provinces and territories match their respective federal funds and are responsible for allocating money to specifically designed provincial programs (CMHC, 2017). Although the programs vary province to province, an average of roughly half of the total IAH fund was spent on increasing supply of affordable housing through new construction. The rest of the funds were allocated to improve the quality of existing housing stock and to foster safe, independent living (CMHC, 2017). In addition to investment, provincial governments can influence affordable housing feasibility through regulatory means (e.g. provincial policy statements define the context for inclusionary housing policies and plans).

Municipal Government – The responsibility of municipal governments varies across the country, however a generalised overview of their role in the affordable housing spectrum includes research-oriented, policy, regulatory, financial, and administrative approaches (Starr, 2001). Since policy devolution, municipalities have resorted to incentives to stimulate the construction of housing. These can include, but are not limited to waiving development charges, selling municipal lands at discounted rates, lower property taxes, or start-up grants/loans. In addition, municipalities can expedite the planning process through planning approvals and encouraging private developers to join partnerships to construct new developments.

Private Sector

The private sector represents the agency typically tasked with the design and construction of affordable housing developments. Private developers bring the skills, labour force, an expertise in the construction process into the partnership and have proven to be an effective means of getting projects built. In addition to construction, private capital investment firms/banks can be involved in the project to assist with the funding of large scale projects, but public support is required to incentivize the

investment made by a private equity firm or developer to reduce the risk and help to guarantee a suitable return on investment.

Affordable Housing Partnerships in Action

A successful affordable housing development addresses and closes the ‘affordability gap’. The gap is characterised by the difference between the break-even cost of the development and the income generated through affordable rent levels. As argued above, in order for a project to be both affordable and sustainable, the traditional construction process (private capital finance, developer, purchaser) needs to be offset. Traditionally, this was done through public subsidy typically in the form of capital investment and/or land holdings. The introduction of PPNPs as an alternative for fiscally constrained governments has resulted in a more complex framework of financing, construction, and operation of affordable rental developments. The case studies below illustrate different ways of approaching affordable housing and the important role of the non-profit sector.

Toronto Community Housing Corporation (TCHC) – Ontario

TCHC is a city-owned corporation that operates in a non-profit manner. It is the largest social housing provider in Canada, and the second largest in North America, managing 2100 buildings and 110,000 residents. 55 per cent of operating funding comes from rent, 39 per cent from subsidies provided by the City of Toronto, and the remaining 6 per cent from the rental of commercial spaces, parking, laundry, cable fees, and investments (TCHC, 2017).

Figure 2: Toronto Regent Park Redevelopment

Regent Park Community Redevelopment in Figure 2 is synonymous with public housing. It is the largest, and oldest publicly funded housing development in Canada, representing the postwar strategy of slum clearance and the application of Garden City design principles. In 2003, Regent Park joined other infamous post-war social housing projects, when a redevelopment plan was approved to demolish and replace existing public housing Rent Geared to Income (RGI) units. In addition to modernising the housing stock, the 12-to-15 year, six phase redevelopment includes an overall masterplan (new roads, amenities, park space, public buildings) to integrate the once physically segregated site back into the city (Moskalyk, 2012). The budget for the redevelopment stands at \$1 billion, boasting a multilayered funding structure constituting of government funds (federal, provincial, and municipal), private sector, savings generated on site, and TCHC equity contributions and loans.

The completion of the project is predicated on a three-sector partnership between the public, non-profit, and private sectors (PPNP). In addition to approving the project, the City of Toronto waived development and realty taxes on all new RGI units for the duration of the development, and absorbed the infrastructure costs with assistance from senior level of governments (Landau, 2016). Under the Canada-Ontario Affordable Housing Agreement, \$1.61 million funding from the federal and provincial governments was allocated to stimulate construction. The TCHC owned and operated the 2,087 RGI units at Regent Park and conducted several feasibility studies to determine how to best accomplish the 69 acre revitalization. The Daniels Corporation represents the private sector aspect of the partnership, and will oversee the design and construction of the entire project. In addition to the physical infrastructure, the Daniels Corporation is also offering qualified purchasers of the market and below-market housing options an additional 5 per cent loan under its Downpayment Assistance Program (Moskalyk, 2012).

Both the risks and rewards of the project are shared between the TCHC and the Daniels Corporation. The scale of the project helped to mitigate the risks associated with the rollout of the development, making Regent Park a unique case study in the theorised benefits of mixed-market housing (Rowe & Dunn, 2015). For example, in an effort to erase the stigma associated with Regent Park, the partnership decided to front-load phase 1 with the financing and construction of market units, holding off on the RGI units. The influx of higher income tenants is expected to have a higher, positive impact on the social and economic fabric of the community (Moskalyk, 2008). Ensuring the market units will be desirable, and attracting commercial activity are both means to bolstering the overall economic status of the partnership and offer continual funding for the RGI units that have a much lower return on investment.

Societe D'Habitation Et De Developmet De Montreal (SDHM) – Quebec

SDHM was created in 1988 as a municipal non-profit corporation and a social housing provider with the capacity to undertake independent land acquisition and development roles on behalf of the municipal government (HPC, 2015). Understanding the spectrum of housing types and users, SDHM openly establishes itself as a provider of 'gap' housing, leaving very low income social housing to the public housing agency and luxury housing to the private market. 2,082 units are currently owned by SDHM, but throughout the corporation's history, they have assumed a variety of roles within the design-build-maintain matrix of affordable housing. This has materialised in the form of buying, renovating, and selling properties to co-operatives or non-profits, entrusting the management of

properties to organizations once they are constructed, or acquiring and rehabilitating existing rental housing units (HPC, 2015). As of 2015, SDHM became one of the only affordable housing agencies in the country to be able to maintain a significant (4,700 units) with no ongoing operational subsidies. This is partly due to the fact that nearly all of the units (except for roughly 230) are rented at 80% of market value which enables operating costs to be covered by tenants (HPC, 2015). Innovative business strategies have also given SDHM the ability to thrive independently of government subsidies, best characterised by their initiative Access Condos. The program partners directly with private sector developers, offering prospective homeowners a 10% purchase credit to lower the down payment to as low as \$1,000. The SDHM holds a second mortgage for their share of the equity, recovering this through a share of appreciation on future resales (HPC, 2015).

City-Led Partnership in the Olympic Village – Vancouver, British Columbia

Figure 3: Olympic Village

The Olympic Village (Figure 3) was built to house athletes during Vancouver’s 2010 Olympics under the ambitious planning goal of creating a model of a sustainable community. Bidding for city owned land, the Millennium Development Group—a Vancouver-based private company—paid 193-million-dollars the highest price per square foot of land in Canadian history (Taylor & Callihoo, 2011) and set to achieve LEED Platinum status and make this one of the greenest developments in the world. The vision included new water management tools, green roofs and Neighbourhood Energy Utility (drawing heat from sewage system) and access to a new rapid transit station built for the Olympics. The initial plan for the Olympic Village was to have “one-third social housing, one-third below market housing and one-third market housing” (Taylor & Callihoo, 2011, pg.34). The 570 units would be a huge push forward in Vancouver’s plan to tackle the housing crisis. As the developer was caught up in the global financial crisis and went bankrupt, the city had to assume the costs (costing taxpayers

over \$100 million), so the share of social housing was reduced to 20% and market-modest rentals were replaced by luxury condominiums.

Following the 2010 Games, the Olympic Village retained 252 units of social housing and 119 units of “modest market housing” (City of Vancouver, 2014, p.3), built at an average cost of \$436,500 per unit (not including land value), which would likely make these the most expensive social housing units ever constructed (McCarthy, 2012). The framework implemented by the City to help ensure the success of the project is based on a revenue sharing model, where land is leased to non-profit organizations for 60 years at “nominal prepaid rent” to provide social housing.

Concluding Comments

A growing affordability problem affecting over 5 million people in Canada (1.7 million households in core housing need) has prompted a renewed commitment of the federal government, complemented with provincial and municipal programs, to end homelessness and increase the supply of affordable rental housing. Given the devolution of government involvement in housing, consensus has been building across Canada that an effective response requires a multi-sectoral approach, including all levels of government, the private for-profit and non-profit sectors, as well as local communities. This is perceived as the most effective way of producing affordable housing to meet growing local needs within limited resources and capacity. The last decade has seen large Canadian cities join their efforts with non-profit and private organisations to provide affordable rental housing in mixed-income, mixed-tenure projects. While these projects are experimental, they have demonstrated a viable alternative to address vulnerabilities in the housing market as well as make Canadian cities more inclusive and competitive.

This paper profiled some of the key characteristics of such partnerships and delineated risks and opportunities associated with effective implementation. Notwithstanding the diversity of such arrangements in Canadian cities, it is important that they are nurtured by stable and consistent housing policies, robust planning mechanisms that regulate affordable housing and provide infrastructure funding, and a coherent system of governance to coordinate and strategize.

Dispossession of the Poor through an Urban Renewal Project in Narlıdere İzmir, Turkey

Ayça Uysal¹, Assoc. Prof. Dr. Adile Arslan Avar²

¹*aycaauysal@gmail.com*

²*İzmir Institute of Technology, adilearslan@gmail.com*

Abstract: In this paper, the dispossession process of the people living in a squatter housing area is explored in Turkey's third largest metropolis, İzmir. In the case of İzmir-Narlıdere, the İkinci İnönü Neighbourhood was declared as a disaster risk area and an urban renewal project was proposed by the municipality. The proposed housing project addresses to the luxury, exclusive and to a different lifestyle than that of the existing squatter housing inhabitants. Although the declared aim of the project is the redevelopment of the area with its existing inhabitants, it has a one dimensional spatial and market-driven feature and is insensitive to the economic, social and cultural characteristics of the inhabitants. The project will be undertaken and carried on by the Municipality and private real estate partnership drawing on of 50% shares for each. More crucially, despite the renewal project was submitted by the Municipality to the approval of the Ministry of Environment and Urbanism, there is no contract defining the framework for the inhabitants' right to title deeds. As the findings of the research conducted within the scope of this study indicate, this renewal process will work as slum clearance and will end with dispossession and displacement of the squatter housing inhabitants.

Keywords: housing question, financialization, slum clearance, dispossession

Introduction

The aim of this study is to examine the housing question of the poor in the process of neoliberal housing production through an urban renewal project in Narlıdere, İzmir. Neoliberal policies and speculative urbanization affected housing production types. Housing was encompassed in the circuit of capital through commodification and financialization turning housing to a market tool. Under neoliberal urbanism, urban renewal and urban transformation projects were instrumentalized to produce housing where the urban rent is high. With the urban renewal policies, the squatter housing areas that were encircled by the areas with higher urban rent were included in the housing market. The problem of the research is the dispossession of the poor, with the pressure of the instrumentalization of the urban renewal projects under the neoliberal housing production. Within this context, this study inquires how and in what ways neoliberal housing production contributes to the housing question of the poor.

The study is mainly composed of two sections as literature research and field study. Concepts related to urbanization process are examined in the literature review. This research is based on a pluralist, qualitative and quantitative field study. The financialization of the housing, housing production under neoliberal policies and the situation of the squatter housing residents against the housing production and the dispossession process are examined based on the case of the urban renewal project in İkinci İnönü Neighborhood in Narlıdere, İzmir. The urban renewal project directly addresses to the squatter housing residents and the squatter housing area which has been encircled by a rapidly increasing luxury housing production in recent years. During the fieldwork, the spatial development data, institutional data, municipal and neighborhood unit data, the data about socioeconomic

characteristics of the squatter housing residents and squatter housing characteristics were collected; and they were supported by interviews, focus group and face-to-face deep interviews and questionnaires. Also, the housing affordability index for the inhabitants is calculated in order to predict the situation of the residents of the squatters against the urban renewal project. As it is to be seen in the following pages, almost none of the squatter housing residents would have housing from the renewal project, hence what waits for them is dispossession.

Urbanization under Capitalism

Lefebvre and Harvey theorize the relationship between space and capitalism with respect to the movements and crises of capital accumulation. They emphasize how the capital creates spaces of its own production and reproduction relations in the urban built environment (Harvey, 2006; Lefebvre, 1991). Urbanization and capital accumulation are integral to each other in capitalism. The capital accumulation has been immanent to the changes that have affected the relationship between capital and urbanization (Coq-Huelva, 2013).

Lefebvre argues that capital is shifted to the secondary circuit by anchoring on the urban land to overcome the economic crisis in the primary circuit. David Harvey develops Lefebvre's concept of "the secondary circuit of capital" as "urbanization of capital." He explores the relationships between capitalism and built environment in cities in terms of the changes in society through production, consumption, and reproduction (Merrifield, 2011). According to David Harvey, city is a complex phenomenon with its spatial, economic, political and social aspects. The urban process creates a physical infrastructure that the capital needs for production, reproduction and consumption. The formation of this infrastructure is through the production of the structured area, which is the source to produce value and surplus value. Thus, capital is involved in the urban spaces, as it shifts to the secondary circuit of capital operating on production and consumption of the built environment and reproduction of labor (Harvey, 1985).

Harvey explains the urban rent with the dynamics of capital accumulation. He links the emergence of rent capital and crisis of accumulation. The capitalist system depends on the maximizing profits, otherwise, it falls into a crisis from time to time. The competition among the capitalists leads to an excessive accumulation. This accumulation problem leads to crisis; the way of ensuring stability is to direct capital to the built environment, hence urban spaces become "spatial fixes" (Harvey, 2006).

As capital shifted into the secondary circuit, the change in cities became important to stabilize the capitalist production. As different areas develop and investments increase in specific areas for the sake of capital accumulation, other urban areas decline. Thus occurring unevennesses between urban areas and the differences between the use value and the exchange value of the urban land result in the rent gap (Smith, 1979, 1987; Morales, 2009).

Neoliberal Urbanism and Housing Production

Neoliberalism is an economic, political, institutional and ideological structuring which has ruled the period after the 1970s. Its defining characteristics are privatization, deregulation by decreasing the dominance of the state in public services and market-led regulatory system in the economy (Brenner and Theodore, 2002; Jessop, 2002; Peck and Tickell, 2002; McCarthy, 2004; Harvey, 2005; Brenner, *et al.*, 2010). According to Harvey (2006), four basic elements of neoliberalism are privatization, financialization, management and manipulation of crises and state redistribution policies. Neoliberalism emphasizes the effectiveness of market competition, the role individuals play in determining economic outcomes, and the disruptions of government intervention in the markets. Neoliberalism involves a profit and market-oriented accumulation logic that culminates in "accumulation by dispossession" (Harvey, 2006).

With the dominance of neoliberal policies on economic and urban restructuring processes, housing is harnessed to privatization, financialization, and commodification, as well. The dominance of the private sector and capital-

oriented housing production at the expense of social housing production by the state has led the housing production turned into a real estate sector (Çelik and Gough, 2014; Marcuse and Madden, 2016). Housing as an accumulation tool has always been undergoing financialization. With financialization, housing has become a commodity which is managed by the real estate market. Managers, bankers, and rentiers produce profits from housing through buying, selling, financing, owning, and speculating. This indicates the rising importance and power of actors and firms against the poor for whom housing is of importance because of its use value (Marcuse and Madden, 2016).

Real estate investments constitute a large part of the recent global financial system. In addition, the commodification of housing today became a key engine of urban capital accumulation and the privatized housing sector became having a greater impact on the global economy with a direct relationship with global processes (Forrest, 2008; Lamarca and Kaika, 2016). Financialisation and commodification of housing exclude the poor from the housing market by increasing housing prices (Uzun, 2017). As a result, the living space is shared depending on the ability to pay and provided to the extent that it produces a profit (Marcuse and Madden, 2016).

Urban renewal and redevelopment projects were instrumentalized to obtain the maximum rent from the urban spaces. These projects create space for real estate investments to generate rent for urban growth by working as slum clearance. The fact that housing policies do not cover the rights of the poor cause the poor to face such problems as displacement, exclusion, dispossession, segregation and gentrification (Doshi, 2013; Fraser and Kick, 2014).

Urban Renewal and the Poor in Turkey

Urban renewal projects emerged as the most important urban development strategies in Turkey in the 1990s where productivity, profit, and privatizations are at the forefront (Demirtaş-Milz, 2013). The 1990s were the years of significant transformations in the urban space. In the city centers, large business centers in the form of skyscrapers, luxury housings, and mass housing areas that responded to the demand of the upper-income group have been built. To meet the housing needs of the middle-income group, mass housings have been produced in the areas obtained by the transformation of the squatter housing areas in the peripheries. Therefore, the residents of the squatter housings which were displaced and excluded through dispossession continued to build new squatter housings in new areas (Özdemir, *et al.*, 2005).

In the 2000s and onwards, the urban transformation projects have been the main mechanisms of the neoliberal urbanism. Urban governance and housing markets have also undergone significant changes in Turkey (Kuyucu and Ünsal, 2010). The housing production sector is dominated by private investors and it became market-driven. The main tool of the 2010s regarding the urban process is the law on Redevelopment of Areas under Disaster Risk (no. 6306). The aim of this law is to determine the principles and procedures for improvement and renewal in the areas that are at the risk of disaster (Official Journal, 31 May 2012; Genç, 2014; Waite, 2016). The law redefined the concepts of reserve building, risky area, and risky building in a way of creating a real estate stock that is to be redeveloped according to market logic. The Ministry of Environment and Urbanization and Housing Development Administration (HDA) are endowed with the authorities for the implementation of the law. According to the law, the priority is to make an agreement with the existing residents and title holders of the project area. Temporary housing or rent assistance can be made to the owners, tenants, and residents of the apartments or buildings that have been evacuated through the agreement. For the destruction of the buildings in the risk area, notification is sent to the owners. The buildings that are not destroyed within the given time period are to be demolished by the project executives. The Ministry can also carry out the detection, evacuation and demolition works of the buildings. The Ministry has also the authority to consolidate with all kinds of maps, plans, zoning, projects, and land arrangement procedures related to risky structures and reserve structure areas; to convert the immovable property related to the risky area into a security value upon agreement; to determine the value of the lands and make public-private partnerships; to determine the standards and plan decisions, to prepare plans and urban design projects. With the law number 6306, The Ministry of Environment and Urbanization can delegate HDA or private

companies for urban transformation projects (Genç, 2014). Within this institutional and regulatory context, urban transformation projects turned into the tool of privatisation and marketisation of the urban or non-urban areas.

Housing production based on this law uses urban transformation as a tool to transfer the lands of the squatter housing to the state and to transform informal urban residential areas into formally governed commodities. Private and public actors also use legal ambiguities and tactical maneuverings for fast and efficient transfer of squatter lands (Atasoy, 2017). Squatter-housing areas where the residents mostly benefited from the unregulated land market and incompletely commodified housing rights are the main target of these transformation projects. These areas are important for the real estate investments as they are encircled by the high-rent areas and have rent-gaps. With the neoliberal housing production through the urban transformation projects that result in slum clearance, high-incomes began to have higher living standards with luxury housing, however, on the other side, poor had to move into mass housings constructed by HDA on the peripheries or had to live in squatter areas surrounded by the luxury housings (Genç, 2014). This situation deepens socio-spatial unevennesses, and intensifies social, economic and spatial pressure on the poor.

Case Study: İkinci İnönü Neighborhood in Narlıdere, İzmir

Within the neoliberal urbanisation, the poor have been faced with the dispossession problem in İzmir. To understand the housing question of the poor in İzmir, the squatter housing area in İkinci İnönü Neighborhood was chosen as the case study. This squatter housing area is surrounded by the luxury housing development, and was declared as urban transformation area according to the Redevelopment of Areas Under Disaster Risk Law (no. 6306).

The most significant characteristics of the squatter housing area is that it is localised within Narlıdere District revealing a deep uneven development. Having been surrounded by the luxury housing projects, the squatter housing units and their inhabitants are exposed to an increasing pressure of the urban rent. Figure 1 shows the housing types around the case study area. There are four types of housing: multi-storey housing sites which include the mass housing of the previous transformation project on the area that located on the southernmost of the image, luxury housing which refers to the housing produced under the neoliberal policies, multi-storey detached apartments and squatter housing units.

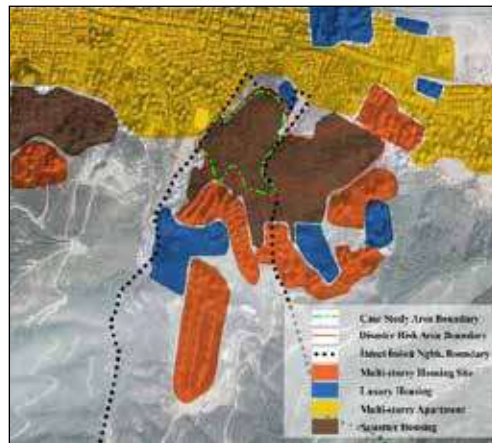

Figure 1. Housing types around the case study area (prepared by the authors based on the fieldwork data)

There are 1710 squatter houses under the scope of the urban renewal project developed on the basis of the Redevelopment of Areas Under Disaster Risk Law on 25th June 2013. The field research was restricted to 14.74 hectares in İkinci İnönü Neighborhood that covers the 622 of the squatter housing units.

Structural Characteristics of the Buildings

The study area covers 622 buildings on 14.74 hectares. 0,64% of these buildings are licensed buildings, 35,20% of these buildings are the structures having benefited from the development amnesty in 1984, 63,8% of the buildings have the characteristics of squatter housing, and the last % 0,32 of the buildings is derelicted ones. Among the “illegal” structures defined as a squatter, there are institutional structures like a mosque, 3 school buildings, 1 community clinic, and 1 head office building. The distribution of property ownership is as follows: private ownership is 36,90%; the State Treasury and Narlıdere Municipality ownership rates are 16,96% and 11,53%, respectively. 93,56% of the buildings in the area are used as housing. 4,98% of the buildings in the area for commercial purpose; and, 1,125% of the buildings are institutional ones.

According to the structural quality analysis, 55,62% of the buildings are in medium condition. Although the rate of buildings in poor condition is 31,02%, the rate of the structures in good condition is 13,02%. In this case, the structural quality of the buildings in the area is ranged from bad to medium degree. Most buildings in the area are illegal structures with low quality.

The average housing size is 90 m2 and the average plot size is 115 m2. The average room number for a housing unit is 2 and there are basic facilities but mostly in poor conditions in the units. All units in the area have the technical infrastructure. 58.33% of the squatter housings have courtyards.

Socio-Economic Characteristics

In the study area, 60 questionnaires were applied to the residents of the squatter housing. The data on income, ownership and preferences is based on the fieldwork. Total population of the area is 2839. The average household size in a squatter housing area in İkinci İnönü Neighborhood is 3,6. While the maximum household size is 8, the minimum is 1.

The rate of people with regular wage is 14%, while 26,0% of people work in low-waged and irregular jobs such as construction works, of which annual average is below the minimum wage. 46,8% is retired; and 3,8% of people own a workplace. The rate of unemployed people is 11,6%. In 75% of households, more than one person work.

In the squatter housing area, 73,33% of the residents have social security. The rate of the residents having no social security is 20%. The main reasons for not having social security is unemployment and precarious works. And, 6,66% of households live depending on government aids.

Table 1. Average household income range (Source: The data is based on the fieldwork)

Household income (TL)	Number	Percentile
0-1000	5	8,33%
1001-2000	38	63,33%
2001-5000	14	23,33%
5001- over	3	5%
Total	60	100%

As it is seen in Table 1, 63,33% of the households have an income between TL1001-2000. In the households whose income is between TL2001-5000, there are more than one worker in the household. Most of such households are traditional extended families composed of different generations living in the same house. The

families whose monthly income is above TL5000 have an additional income like rent of an house or workplace. Considering the table 1 and comparing the hunger and poverty limit in March 2019, about 72% of households have an income below the hunger limit. According to the data calculated by Türk-İş for March, 2019, the hunger limit of the four-people family is TL 2.014 and poverty limit is TL 6.561. This means that almost all the squatter housing area residents of İkinci İnönü Neighborhood live below the poverty limit (Türk-İş, 2019, date of access: 17/04/2019).

Table 2. The reasons for preferring İkinci İnönü Neighborhood (Source: The data is based on the fieldwork)

The reasons for preferring İkinci İnönü Neighborhood	Number	Percentile
Job opportunities	24	40%
Closeness to the city center	4	6,66%
Cheap land	11	18,33%
Education	3	5%
Relatives living in İkinci İnönü Neighb	12	20%
Born in İkinci İnönü Neighb	6	10%
Total	60	100%

As Table 2 demonstrates, the primary reasons why people prefer to live in the İkinci İnönü Neighborhood are the closeness of the neighborhood to the job opportunities, the existence of cheap land when they firstly came to the neighbourhood, and having relatives who already live in this neighborhood.

Table 3. Existing ownership status (Source: The data is based on the fieldwork)

Ownership status	Number	Percentile
Owner	46	76,66%
Live without paying (relative's house)	8	13,33%
Rent	6	10%
Other (public housing vs.)	-	-
Total	60	100%

Table 3 indicates that 76,66% of residents are the owners of their houses. Squatter housing owners are the ones who built their dwelling when they moved to İkinci İnönü Neighborhood. The residents who live without paying rent are those who live in the dwellings that their families have built when they moved to İkinci İnönü Neighborhood. Extended families are included in this group. Tenants who are 10% of the total residents of the squatter housing area stated that they live in İkinci İnönü Neighborhood because the rent was cheap and they cannot afford the rent elsewhere.

All inhabitants living in the squatter housing area desire and have an expectation to be a homeowner through the urban renewal project. Those who saw the project state that they may have serious difficulties in paying the

installments and even if they can able to pay the installments, they cannot afford the monthly dues of the projected houses. On the other hand, the tenants in the squatter housing declare that they cannot afford to live in Narlıdere after the transformation project and have to move to another neighbourhood where rents are cheaper than here. Table 4 summarizes the relevant responses to the questionnaire.

Table 4. The living place preferences after the renewal project (Source: The data is based on the fieldwork)

Willing to live in İkinci İnönü Neighb. after the urban transformation	Number	Percentile
Not able to afford; migrate to hometown	6	10%
Not able to afford; willing to live in Narlıdere	13	21,66%
Not able to afford; willing to live in İzmir	11	18,33%
Stay in İkinci İnönü and pay the monthly payments	26	43,33%
Sell the share and move	4	6,66%
Total	60	100%

The data in the table can be interpreted that 43,33% of the residents prefer to stay in İkinci İnönü Neighborhood, and pay the monthly installments to become an owner. However, when not able to afford groups were summed, 50% of the residents do not have the ability to afford the houses of the urban transformation project. In addition, 16,66% of the residents consider moving because of the monthly payment of the house from the transformation project. In the following section, before going well into the Housing Affordability Index calculations, the urban renewal project that is to be carried out in the Neighbourhood is examined based on the available but restricted data.

The Urban Renewal Project

The prepared urban renewal project was submitted to the approval of the Ministry of Environment and Urbanism by the Narlıdere Municipality. The financial and approval procedures have not been completed, and the negotiations between the Ministry and the Municipality still continue. What is striking here is that the squatter housing inhabitants have no information about the financial structure of the project or about their rights or losses arising from the project. Our information about the transformation project is based on face-to-face meetings and interviews with the officers of Narlıdere Municipality because of the restrictions on data sharing.

As it is implied by the officers, the project is to be undertaken and carried out by the Municipality and private real estate partnership based on of 50% shares for each. It is also declared that the Municipality would accept squatter housing inhabitants, including tenants, as “title holders” within the framework of the project. However, there is no contract defining the inhabitants’ right to title deeds yet, and the repayment plan is uncertain. Following the approval of the transformation project by the Ministry of Environment and Urbanism, the process of reconciliation with the squatter housing owners shall be initiated and the agreement defining their rights shall be signed. Besides, the intended owners of this transformation project are defined as the middle- and upper-income groups by Narlıdere Municipality (Face to face interview on 26.11.2018 in Narlıdere Municipality).

The Narlıdere Municipality promoted the urban transformation project on the squatter housing area based on the following statements: “title holder citizen”, “peaceful and reconciliation based urban transformation”, “healthy living area integrated to the city”, “modern social infrastructure”, “a housing complying with the disaster

regulations”, “100% compromising with the inhabitants” (The Brochure published by the Municipality before the Local Government Elections on 31th March, 2019).

Figure 2. Urban Transformation Project covering the squatter housing area in İkinci İnönü and Atatürk Neighborhoods according to Redevelopment of Areas Under Disaster Risk Law no. 6306 (Source: Narlıdere Municipality)

Figure 3. 3D visuals of the Urban Transformation Project covering the squatter housing area in İkinci İnönü and Atatürk Neighborhoods according to Redevelopment of Areas Under Disaster Risk Law no. 6306 (Source: Narlıdere Municipality)

Figure 3 shows the top view and figure 4 is the visuals of the project on the squatter area. The project is designed as the complex area with residential units, commercial area and social infrastructure, including green areas. As it is seen in the figures, the housing units consist of high-rise, massive blocks that are not compatible with the socio-spatial and natural characteristics of the area. The data about the details of the area size and land distribution, number of the units was not shared during the interviews due to restrictions arising from the project approval procedures in the Ministry.

Besides, some residents state that this urban transformation project is for creating rent, and that residents of the squatter housing would have no benefit of it. In the face-to-face deep interviews and focus group interviews, it was observed that most of the residents had an expectation to become a house owner through the urban transformation project, but they preferred detached housing instead of apartment blocks.

The apartment form is small for the average family size of the squatter housing area and not address their lifestyle. However, they support the urban transformation project. What firstly makes them willing to the project is their desire to have a decent house. They also state their hope to have a whealtier life and to provide their children of a more secure and comfortable future. Thus, instead of this transformation project consisting luxury housing, they are willing to cheaper mass housing project that may be affordable for them.

Housing Affordability Index (HAI)

Housing affordability is defined as the ability to afford a house that is suitable with the household's financial situation (Suhaida, *et al.*, 2011). Housing Affordability Index (HAI) is a metric to calculate whether or not housing

is affordable for the households. Household income, housing prices, interest rates and loaning terms are taken as primary factors affecting housing affordability (Aşıcı, *et al.*, 2011).

To predict whether the squatter housing residents can afford a house after the renewal project, HAI was calculated based on two different scenarios by using the average household income data and average housing price of the İkinci İnönü Neighborhood. The average housing unit area is fixed as 80 m² for both scenarios according to the housing unit size of the previous urban transformation projects implemented for similar neighbourhoods with similar socio-spatial and economic characteristics in İzmir. The outputs of HAI calculations are interpreted depending on the loan repayment capacity.

The first scenario depends on the advance payment which also has four cases that the advance payment changes as 20%, 30%, 40%, and 50%, because the details of the repayments of the project is not defined yet. It was declared that the Narlıdere Municipality planned to subtract the land cost from the housing price in the calculation of the payback of the loans. In this type of scenario, the share of the credit repayment in the household income is fixed as 25%.

In the second scenario, the shares of the credit repayment in household income change as 20%, 30%, 40%, and 50%. The reason why we create this alternative scenario is the social and cultural characteristics of the squatter housing inhabitants and our observations about their desire to own a proper and new home.

The data required for calculations are the average housing price, mortgage payment plan, household income. Average housing price of İkinci İnönü Neighborhood was calculated based on the data obtained from online data sources in March 2019. In İkinci İnönü Neighborhood, an average housing price in March 2019, is 4.726 TL per m². (Sahibinden Emlak Endeksi, 2019, Date of access: 17/03/2019).

Based on the housing price in March 2019, the mortgage payment was calculated with the help of the online mortgage calculator. Ziraat Bank was selected as an example because it was the public sector bank that offered the most favorable interest rate when the calculations were done (Ziraat Bank, Date of access: 20/04/2019). Necessary mortgage loan repayment plan was assumed to have a maturity of 120 months.

Monthly qualifying income refers to the income required to pay the loan easily after subtracting the amount of money for the basic needs and other primary expenses. To calculate the housing affordability index, household incomes are fixed at the average value of the income ranges in the field work findings. There are four groups of household income as TL500, TL1.500, TL3.500, TL7.500.

To calculate housing affordability, the equation is;

$$\text{HAI} = \text{Median Family Income} / \text{Qualifying Income} * 100$$

The HAI has a value of 100 when the median family income is sufficient to purchase an existing median-priced home. A higher index number indicates that more households can afford to purchase a home.

Scenario 1-a

In this scenario, it was assumed that 20% of the price of the house would be paid in advance, and the remaining 80% would be paid with housing loan. Qualifying income of households was calculated depending on the monthly repayment plan of these loans. Table 5 shows the price of the house and the amounts of the housing loan repayment.

Table 5. Calculated data of scenario 1-a

Typical housing units (m ²)	80 m ²
m ² price	TL 4.726
The sale price of a typical house	TL 378.080
Advance payment	TL 75.616
120-month maturity loan	TL 302.464
Monthly repayment	TL 5.333
Monthly qualifying income	TL 21.332

Table 6. HAI calculation in scenario 1-a

Income group	Equation	Result
TL 500	$HAI = TL500 / TL21.332 * 100$	TL 2,34
TL 1.500	$HAI = TL1.500 / TL21.332 * 100$	TL 7,03
TL 3.500	$HAI = TL3.500 / TL21.332 * 100$	TL 16,40
TL 7.500	$HAI = TL7.500 / TL21.332 * 100$	TL 35,15

Table 6 indicates if the housing price in the urban renewal project is TL100, the income groups have TL 2,34, TL7,03, TL16,40, TL35,15 in order. In this scenario, there is no family which can afford the price of house produced through the urban transformation project.

Scenario 1-b

In this scenario, it was assumed that 30% of the price of the house would be paid in advance, and the remaining 70% would be bought with housing loan. Table 7 shows the calculation results about the qualifying income of households depending the monthly repayment plan of these loans.

Table 7. Calculated data of scenario 1-b

Typical housing units (m ²)	80 m ²
m ² price	TL 4.726
The sale price of a typical house	TL 378.080
Advance payment	TL 113.424
120-month maturity loan	TL 264.656
Monthly repayment	TL 4.666
Monthly qualifying income	TL 18.664

Table 8. HAI calculation in scenario 1-b

Income group	Equation	Result
TL 500	$HAI = TL500 / TL18.664 * 100$	TL 2,67
TL 1.500	$HAI = TL1.500 / TL18.664 * 100$	TL 8,03
TL 3.500	$HAI = TL3.500 / TL18.664 * 100$	TL 18,75
TL 7.500	$HAI = TL7.500 / TL18.664 * 100$	TL 40,18

As Table 8 demonstrates, if the housing price of the renewal project is TL100, each income group will have TL 2,67, TL8,03, TL18,75, TL40,18, respectively. In this scenario, too, no family can afford the house from the project.

Scenario 1-c

In this scenario, it was assumed that 40% of the price of the house would be paid in advance, and the remaining 60% of the price would be met with housing loan. Table 9 sets the typical house sale price and qualifying income depending on the monthly repayment plan of these loans.

Table 9. Calculated data of scenario 1-c

Typical housing units (m ²)	80 m ²
m ² price	TL 4.726
The sale price of a typical house	TL 378.080
Advance payment	TL 151.232
120-month maturity loan	TL 226.848
Monthly repayment	TL 4.000
Monthly qualifying income	TL 16.000

Table 10. HAI calculation in scenario 1-c

Income group	Equation	Result
TL 500	$HAI = TL500 / TL16.000 * 100$	TL 3,12
TL 1.500	$HAI = TL1.500 / TL16.000 * 100$	TL 9,37
TL 3.500	$HAI = TL3.500 / TL16.000 * 100$	TL 21,87
TL 7.500	$HAI = TL7.500 / TL16.000 * 100$	TL 46,87

Table 10 shows if the housing price in the urban transformation is TL100, the income groups have TL 3,12, TL9,37, TL21,87, TL46,87, respectively. In this scenario, there is no family which is able to afford the house after the renewal project.

Scenario 1-d

In this scenario, it was assumed that 50% of the price of the house would be paid in advance, and the remaining 50% of the house price would be paid by retiring the housing loan. Table 11 indicates the data of qualifying income of households and monthly repayment plan of the loan.

Table 11. Calculated data of scenario 1-d

Typical housing units (m ²)	80 m ²
m ² price	TL 4.726
The sale price of a typical house	TL 378.080
Advance payment	TL 189.040
120-month maturity loan	TL 189.040
Monthly repayment	TL 3.333
Monthly qualifying income	TL 13.332

Table 12. HAI calculation in scenario 1-d

Income group	Equation	Result
TL 500	$HAI = TL500 / TL13.332 * 100$	TL 3,75
TL 1.500	$HAI = TL1.500 / TL13.332 * 100$	TL 11,25
TL 3.500	$HAI = TL3.500 / TL13.332 * 100$	TL 26,25
TL 7.500	$HAI = TL7.500 / TL13.332 * 100$	TL 56,25

Table 12 shows if the housing price of the urban renewal project is TL100, each income group would have TL3,75, TL11,25, TL26,25, TL56,25, respectively. In this scenario, too, no family can afford the house from the urban transformation project.

Scenario 2

In case of scenario 2, the loan payment shares in the household income changes in the range of 20%, 30%, 40% and 50%, and the advance payment is fixed at 25%. Table 13 shows the qualifying income of households and monthly repayment plan of the mortgage loan.

Table 13. Calculated data of scenario 2 (Source: prepared by the authors)

Typical housing units (m ²)	80 m ²
m ² price	TL 4.726
The sale price of a typical house	TL 378.080
Advance payment	TL 94.520
120-month maturity loan	TL 283.560
Monthly repayment	TL 5.000

To calculate the loan repayment share, household incomes are fixed at the average value of the income ranges in the survey results. There are four groups of household income as TL500, TL1.500, TL3.500, TL7.500. Consequently, the repayment amounts of the households' share change in different percentages, as it can be shown in Table 14 below.

Table 14. Payback money in changing shares of the income according to the scenario 2 (Source: prepared by the authors)

Household income	Share (%)	Payback (TL)
TL0-1.000 -500-	20%	TL 100
	30%	TL 150
	40%	TL 200
	50%	TL 250
TL1.001-2.000 -1.500-	20%	TL 300
	30%	TL 450
	40%	TL 600
	50%	TL 750
TL2.001-5.000 -3.500-	20%	TL 700
	30%	TL 1.050
	40%	TL 1.400
	50%	TL 1.750
TL5.000- and over -7.500-	20%	TL 1.500
	30%	TL 2.250
	40%	TL 3.000
	50%	TL 3.750

In this scenario, there is no family who can afford the monthly repayment of the loans, even if they set the half of their monthly income aside for the repayments.

On the other hand, as an alternative case, it is presupposed that the land cost for the advance payment and the share of payback installments is 50%, and the households can use 50% of their monthly income. Among the respondents of field work, only one household's the income is "TL5.000- and over", and it may afford the monthly paybacks of the renewal project. This means that only 5% of the squatter housing residents in İkinci İnönü Neighborhood have the payback capacity to buy a house.

Conclusion

Under the neoliberal policies and speculative urbanism, housing production is defined by the dominance of exchange value over the use value of housing. For the sake of capital accumulation from housing, urban renewal projects are instrumentalized to create land in squatter housing areas where the urban rent potential is high. As the urban transformation projects became a tool of producing luxury housing, the housing question of the poor turned to be a dispossession with no reservation. The renewal project concerning the squatter housing area in the İkinci İnönü Neighborhood aims to redevelop the area with its inhabitants. However, due to economic imperatives, the residents are condemned to live in the squatters rather than alternative housing. Considering the economic conditions of the target population of the renewal project and the increasing house and land prices under the

pressure of surrounding luxury housing development in the İkinci İnönü Neighborhood, it is obvious that the renewal project will result in a radical exclusion of the poor by dispossession.

It is stated that the Narlıdere Municipality would accept all inhabitants of the squatter housing area as title-holder. However, the process of reconciliation with the squatter housing owners was not initiated and there was no agreement or contract defining their rights to housing. Let alone being informed about their rights or losses arising from the renewal project or its financial structure, the squatter housing residents were completely excluded from the project desing phase. Such information was kept secret from the squatter residents, whereas the Municipality submitted the project to the approval of the Ministry of Environment and Urbanisation.

All informants have an expectation to have a home after the transformation project. However, almost all the households live below the poverty limit. Because of precarious works with low wages and unemployment, it is not possible for them to afford the housing price range defined under the pressure of the surrounding luxury housing development.

According to the scenarios, under these economic circumstances, only 5% of the households in the squatter housing area can afford the price of a house after the transformation project. The advance payment is counted as 50% share, and the household can use 50% of their monthly income to buy a house. They can pay the installments after the land cost is counted as 50% of total house price and substracted from the total price. But it is possible only on the condition that are the squatter housing owners accepted as having already owned their building plot. It is an extremely optimistic assumption that they could regularly pay the installments and monthly dues.

As a result, the housing production does not address the socio-economic conditions of the squatter housing inhabitants. The housing projects do not meet the need and demand of squatter housing residents. The inhabitants of the squatter housings are under pressure of their economic circumstances. Since their income will not be enough, they will have to find new jobs until they are dismissed from their homes because they cannot pay the installments and dues on time. Besides, considering the characteristics of the renewal project designed and submitted to approval of the Ministry, it will be carried out as slum clearance and result in the exclusion and displacement of the poor through dispossession.

As to what is to be done, housing must be produced within the framework of the right to housing. The use value of housing must be defended against exchange value by emphasizing the priority of the needs and demands of the poor. The state should increase its efficiency in housing production, the dominance of the private sector should be reduced. The aims and priorities should be defined in terms of the socioeconomic context and affordable housing production.

The urban transformation and renewal projects must be planned and implemented by taking into consideration the social, spatial and economic needs of the poor. The process of transformation should be open to the participation and the area must be designed with the squatter housing inhabitants. For housing payments to be sustainable, full employment should be provided to those who live in squatters and do not have a regular income.

The potential of alternative housing initiatives to ‘transform’ the housing sector: Examples from New York City and Berlin

Ayse Yonder¹, Meta Brunzema²

Abstract: *Most major cities around the world are faced with a housing crisis, as real estate has become the dominant sector of the economy. The purpose of this paper-in-progress is to review selected affordable and integrated housing initiatives from New York City and Berlin to consider how they can be supported, scaled up, and sustained to resist the financialization of the housing sector, and potentially, lead to a transition toward de-commodification of housing. Despite the differences between the two cities in terms of scale, history and socio-economic context, the majority of residents in both cities are renters, unlike the rest of the country, and both have a legacy of working-class activism that led to the establishment of successful collaborative affordable housing development and programs in the second half of the twentieth century. After a brief review of the current affordable housing crisis, we provide an overview of some past and recently proposed low income and integrated housing models. We consider their potential and limitations in terms of sustainability and scaling up. The methodology is based on a review of previous studies, newspaper and agency reports, and interviews with housing experts, activists, and local government representatives.*

Introduction:

Most major cities around the world are faced with a housing crisis, as real estate has become the engine of the capitalist economy. Madden and Marcuse argue that housing policy is based on the *myth of the benevolent state* since housing programs have always facilitated the goals of the real estate capital rather than meeting the needs of those who need support the most: “Historically the state has used the housing system to preserve political stability and support the accumulation of private profit”(Madden and Marcuse 2016, 120). In his recent book, Sam Stein goes a step further to point out that as “[r]eal estate developer Donald Trump becomes first a celebrity and ultimately a president,” we now live in a “real estate state, a political formation in which real estate capital has inordinate influence over the shape of our cities, the parameters of our politics and the lives we lead” (Stein 2019, 5).

Local government policies and planning interventions facilitate the gentrification process. With the relative decline of the manufacturing sector, municipalities have become dependent on real-estate tax revenues to provide the urban services they are responsible for. Stein (2019) argues that even though city planners play a key role in developing schemes to meet the demands of and create investment opportunities for real estate capital, they also have the capacity to devise strategies to dismantle and weaken the control of real estate capital over cities. Yet, “[n]aming alternatives ... is much easier than enacting them, as the political conditions in New York and elsewhere make such actions difficult at best” (Stein 5/28/2019).

The purpose of this study is to review selected affordable and integrated housing initiatives from New York City and Berlin that serve the needs of very low-income residents who are faced with displacement. We explore how they can be supported, scaled-up, and sustained to resist the *financialization* of the housing sector, and potentially, lead to a transition toward de-commodification of housing. After a short review of de-commodification of housing and the gentrification processes, we first provide an overview of some past and current proposals for low-income and integrated housing provision. We then consider their potential and limitations in terms of sustainability and scaling up. The qualitative analysis is based on information gathered through a review of previous studies, newspaper articles, and agency reports, as well as interviews with housing activists, planners, and staff from both municipalities. This paper, however, reflects only the first phase of this study and, for logistical reasons, is focused mainly on New York City. Since we are still in the process of conducting interviews and research on the case of Berlin, a more in-depth analysis of the selected experiments and their potential to make an impact on the housing conditions in these cities will be the next phase of our study.

NYC and Berlin are both faced with an affordable housing crisis. Despite the differences between the two cities in terms of scale, history and socio-economic context, the majority of residents in both cities are renters, unlike the rest of the country, and both have a legacy of working-class activism that led to the establishment of successful collaborative affordable housing development and programs. And recently, Berlin has been successful in pushing for more radical measures to address these issues.

In Berlin and other German cities, citizens have begun large protests against rising housing costs. Berlin, a city in which 85% of people rent their homes - has been at the center of this fight. After 2008, for-profit corporate landlords started buying up hundreds of apartment buildings in Berlin, and since then, housing costs have doubled. On April 6, 2019 - 40,000 people marched through the center of Berlin in support of a referendum for nationalizing large landlords that own more than 3,000 units and to demand the expropriation of approximately 200,000 rental units. If the protesters are able to gather 190,000 signatures by next February, the referendum could take place in mid-2020. If successful, it could set a legal precedent for housing as a human right.

Background: Commodification of Housing

David Madden, the co-author of “In Defense of Housing: The Politics of Crisis” argues that homes have become commodities – which is a key driver of inequality in the City. Madden defines housing commodification as the moment when “all possible uses of residential space are subordinated to economic exchange, i.e. when housing’s existence as real estate comes to dominate its ability to function as home” (2019, 1). Specifically, Madden describes three related dimensions of residential commodification:

Starting in the 1970's, commodification was set into motion with the de/re regulation of housing - particularly the weakening of rent regulations and the privatization of social housing by municipal governments. A few decades later, commodification was aggravated by the aggressive financialization of the housing sector by private equity firms and real estate investment trusts (REITS) for whom luxury real estate became a new investment vehicle. Indeed, housing was redefined as a means to generate financial returns rather than providing for a person's home or shelter. Finally, the globalization of the housing market and the exponential increase in foreign real-estate ownership in large cities has been mired in corrupt practices - including tax evasion, money laundering, and the consolidation of illegal assets. Since 1990, the EB-5 Immigrant Investor Visa Program has allowed globally mobile elites to purchase US visas with real estate investments in the United States. This program has been plagued with fraud, corruption and cronyism.

As a result, luxury housing has become a tool for speculation which is more sensitive to global financial trends than to local housing needs. Indeed, at a time when affordable housing is increasingly hard to find – much of this “investment housing” remains vacant.

It is important to note that the luxury housing trend is accompanied by the simultaneous disinvestment and exploitation of existing affordable housing stock for working class and low-income residents by corporate landlords. In many global metropolitan centers, including New York, London, and Berlin, housing investors purchase existing affordable housing – and then push for exponential rent increases. New landlords often seek to displace low-income tenants with aggressive tactics including lack of building maintenance and other harassments – in order to increase their profits. Most often, the victims of housing commodification are low-income people of color who end up being displaced from their neighborhoods and/or forced into overcrowded housing.

Madden (2019) concludes, like Stein (2019) and others, that housing commodification is much more than a neoliberal economic instrument, and that its impact on cities is deeply political - exacerbating racial and class tensions. Indeed, commodification has caused increasing housing precarity, insecurity, and unaffordability - especially for working class and low-income households.

Affordable Housing Initiatives in New York City (NYC)

Alex Schwartz (2006) argues that housing for the lowest income households must be heavily subsidized; it is not possible without support from the State. There is a myriad of affordable rental or homeownership programs in New York City. Some of these are remnants of past programs that were created in response to demands of strong working class movements, and account for the majority of current affordable housing stock in New York City. Summary Table 1 groups some of these strategies and programs under five categories. These range from measures to regulate the market by building the capacity of housing advocates, legal protection of tenants and prevention from landlord harassment, as well as rent controls. The city has been losing not only unregulated low-rent units in low-density neighborhoods, but also thousands of rent regulated units through the loopholes in the current rent law. As the state's rent stabilization law is up for renewal in June, currently there are nine rent-regulation reform bills that are being considered at the state level to stop this trend. The bills aim to prevent landlords from raising rents after improvements to the apartment or building, to end vacancy decontrol and the vacancy bonus, to make preferential rents permanent until vacancy, to extend time for tenants to file rent overcharge

complaints, to ensure rent control and rent stabilization parity, and to expand the emergency tenant protection Act to all settlements across New York State (Brown 2019).

More radical measures to prevent speculation and preserve long-term affordability and access to land and housing involve de-commodification or taking properties out of the market. These include public housing, community land trusts, mutual housing associations, limited equity cooperatives. New York City Housing Authority (NYCHA) is the largest and most successful in the country where residents pay 30 percent of their income for rent. There are 326 NYCHA developments around the city, accommodating more than 400,000 people, and an additional 235,000 people receive rental assistance through NYCHA's Section 8 Leased Housing Program (<https://www1.nyc.gov/site/nycha/about/about-nycha.page>).

Income-restricted limited-equity cooperatives are a type of affordable housing where members buy shares at below-market rates and receive tax abatements and other public subsidies but there are restrictions on resale prices. Through limiting the resale price to the cost of initial investment plus interest and a small profit, affordability of the unit can be preserved in the longer term. While New York city can be considered the cooperative capital of the country, not all cooperatives serve low or even middle- income households. In fact, the first cooperative in the city was built on Fifth Avenue for elites. The first generation of low- and moderate-income housing cooperatives were built during the first half of the twentieth century by trade unions and from the 1950s to 1970 through the United Housing Foundation and the state's Limited Profit Housing Companies Law, or Mitchell-Lama program.

The second wave of low-income housing cooperative development started in the 1970s, when New York City inherited more than 11,000 abandoned, foreclosed properties. Urban Homesteading Assistance Board (UHAB) was established then to help the tenants of those buildings stay in their homes through their conversion into limited-equity cooperatives. The first ones were created through "sweat equity" with tenants contributing their time and labor as down payment. Later, Tenant Interim Lease (TIL) Program transferred properties to tenants once they demonstrated their capacity to manage it. In the 1990s, through the Third Party Transfer Program of such properties, Housing Development Fund Corporation (HDFC) cooperatives were created. Despite some building based restrictions and flip sale tax to control speculative sales, gentrification related market pressures have led a lot of HDFC coop units to be sold, leading to increasing the purchase price of such units despite the income limitations.

A number of alternative pilot projects the City has created in response to persistent demands of housing advocates have not received adequate resources or support. Community Land Trust program is one of these. A community land trust (CLT) is community-governed nonprofit organization that holds ownership of the land to ensure permanent affordability of housing units on it. Housing or other (commercial, etc.) buildings on the property can be sold or rented to low-income residents. A CLT with a Mutual Housing Association on it would provide tenants affordable housing without equity but with long term security of tenure, and ability for democratic governance and control of their building. In 2017, the City, with funding from Enterprise Community Partners, created the CLT Capacity Building Program. In addition to the two existing CLTs, Cooper Square CLT that was established in 1994, and the East Harlem El Barrio CLT that is in formation, eight community based organizations were selected to participate in peer-learning exchange and explore strategies for developing a CLT.

Another strategy to preserve existing low income housing is to regularize and incorporate illegal basement conversions into the market. The challenge is to preserve their affordability while

improving their safety and quality. The citywide BASE Campaign and the East New York Community Plan (that was prepared in response to the city's rezoning of the district) finally led to a pilot program in East New York last year.

Given the targeted number of units in Mayor De Blasio's Housing Plan, creation of new affordable units, rather than the preservation of existing subsidized low-income apartments, has been the major focus of New York City (Elmedni 2018). In fact, the legal definition of what is 'affordable', as it is used in the development of new housing is highly controversial. The calculation of 'area median income' is based on the median household income of the New York metropolitan region, which is not only higher than that of the City, but is often double or triple the median household income in the district it is located in.

Every mayor of New York City since the 1980s came up with an ambitious affordable housing plan, following Mayor Koch's model. His success was based on the fact that NYC already owned 100,000 units of *in rem* housing and foreclosed properties that the city had inherited. Working with nonprofit and for-profit developers, his plan succeeded in producing 180,000 units of affordable housing. Without the same amount of publicly owned property, later mayors focused on rezoning to increase density allowances and give away development bonuses as well as substantial tax breaks to attract developers. For instance, former Mayor Bloomberg rezoned 40 percent of the city. The justification for partnership with and significant giveaways to private developers has always been to achieve scale. Even the 'progressive' Mayor de Blasio administration relies mainly on market-based solutions to reach its goal of creating 300,000 affordable units by 2026, and has already rezoned about half of the 15 targeted neighborhoods, the majority of which are low-income communities of color.

Moreover, a number of innovative strategies and capacity building programs provide tools to support existing and create new affordable housing, as well as organizing for that purpose. Non-profit housing research and advocacy organizations, such as the Furman Center and the Association of Neighborhood Housing Development (ANHD) have taken advantage of the City's Open Access Data System to develop databases, inventories and interactive maps working in partnership with housing activists. These tools help local organizers identify landlords' holdings, location, and status of subsidized housing, alert them to vulnerable properties, etc. in their neighborhoods. Such sources of information build capacity and level the playing field. Another example is ANHD's *Anti Displacement Toolkit* that provides a comprehensive inventory of programs and policies that housing and community activists can use to fight residential displacement.

Innovative strategies are also critical in financing, reducing the costs of developing new and preserving affordable housing. For instance, the cost-effective building technologies used by large design/construction/development companies can be adopted. Efficiently manufactured and prefabricated building components and/or new construction materials would lower costs, and lower the carbon footprint.

Land prices significantly contribute to the cost of new housing - and vacant lots are especially scarce and expensive in rapidly densifying cities. In response to this lack of affordable land, developers have recently started to build large additions on top of existing buildings and to creatively adapt and enlarge older structures. Advances in high-rise construction technology and prefabrication have supported this trend.

This trend of building large additions or adaptations of older buildings is especially promising for publicly-owned properties - since the public sector may sell or lease their land/or air rights at prices that favor the production of deeply affordable housing. For example, housing advocates have identified huge unused airspaces above municipal firehouses - which could potentially be developed as deeply affordable housing in every neighborhood. Similarly, these advances in building technology and lightweight prefabricated building components may make it possible to create large additions to currently existing public housing.

Some community based organizations and environmental justice organizations have started initiating climate change related strategies, such as weatherization of existing affordable units, to reduce maintenance costs. UPROSE has recently up a community-owned energy cooperative.

Summary Table 1.	NYC	NOTES
I. REGULATION OF THE MARKET – to even out the playing field through tenant protection & landlord control		
Rent control	NY State rent stabilization law protects about a million tenants	State rent stabilization law up for renewal in June - 9 reform bills proposed to expand it and close loopholes
Taxation and Land Value Capture	To get public or community benefits from private development	Inadequate example: Hudson Yards Project on the West Side of Manhattan
Tenant protection measures	Those targeting tenants: Right to legal council, etc. Those targeting landlords: Certificate of No Harassment, etc.	Some measures passed during De Blasio administration
Capacity building and information access to level market inequalities	ANHD, Furman Center, Displacement Alert Project, etc.- provision of inventories, interactive databases and maps for housing advocates and community activists	Nonprofits took advantage of the city's open data system to create tools for advocates
II. TAKING LAND/PROPERTY OUT OF THE MARKET – to preserve affordability and prevent speculation		
Public Housing and Section 8 programs	New York City Housing Authority (NYCHA) best/largest in the US - administers NYCHA developments and Section 8 program	Administration in deep financial trouble; serious maintenance problems
Subsidized housing with term limits (Mitchell Lama, etc),	Flip taxes to prevent sales and privatization of coop units	Expiring term limits
Limited Equity Cooperatives and HDFC units (Housing Development Fund Corporation)	Income limits and resale restrictions preserve it for low income households; flip-taxes and building based regulations to prevent speculative price increases of HDFC units	Management and financing issues need technical and management support; HDFC resale price increases
Community Land Trust (CLT)	Only 2 in NYC; 8 community based organizations received support for peer learning technical learning to create CLTs	High land prices and limited public land requires consideration of other options for access to land/property
III. LEGALIZING INFORMAL HOUSING – to improve safety and quality of existing low income housing.		
Squatters	Allocation of occupied <i>in rem</i> housing to squatters in East NY -Self-help finishes; 99 year lease	One shot, not continued Mutual Housing Association of NY created
Illegal basement conversions	East NY pilot program & citywide BASE campaign to improve safety & supply of legal affordable units	Risk of price increase as a result of regularization
IV. DEVELOPING NEW AFFORDABLE HOUSING – to increase the supply of affordable housing		

Market based strategies - incentives to private or non profit developers (rental or private ownership)	Mayor's 10 year Housing Plan: Rezonings (8nghds) & Mandatory Inclusionary Housing (MIH) (options for different levels of affordability) Goal: 300,000 affordable units by 2026	MIH only in upzoned areas; insufficient quantity of units and/or sufficiently affordable units
Non Profit Organizations (rental)	Created with city and/or private foundation funding; often on public land	Often insufficient maintenance \$
Faith-based organizations' initiatives (private ownership)	Nehemiah Housing program (revolving housing fund of East Brooklyn Congregations and South Bronx Churches) on public land in partnership w/ HPD	Nehemiah Housing was allocated land and infrastructure subsidy- one-shot
V. APPLICATION OF INNOVATIVE COST REDUCTION/FINANCING STRATEGIES		
Financial tools	Proposed Public Bank (ongoing campaign); Socially responsible investments by faith based organizations and trade unions (retirement funds); proposed "Robin Hood Tax", etc.	Proposed strategies
Innovative use of architectural and planning techniques	Density/ air space techniques to reduce construction costs	Strategies used by private sector but can be adopted by public or non-profit sector
Other (greening) strategies	Lower utility and maintenance costs; creation of weatherization programs; Community-owned energy coops; etc.	Limited innovative examples

Conclusion:

Clearly, affordable housing crisis cannot be solved simply by increasing the number of residential units, as New York City's rezoning and Mandatory Inclusionary Housing Program attempts to do. Nor are a few technical tools or innovations sufficient to address this complex and political issue in isolation from all the interrelated issues. Affordability is very much related to access to living wage jobs, transportation, and community services, and in short how it is integrated into the city. Gentrification is not limited to residential areas, but commercial strips are also gentrified. Displacement of businesses that cater to low-income residents further makes it difficult for low income households to afford to remain in their communities. In contrast, luxury housing such services are often integrated into the development. In fact, improved City services generally follow such developments, improving the quality of life in the neighborhood whereas low-income communities fear that such improvements will be followed by gentrification and displace them. And finally, given that New York City is among the top 10 cities vulnerable climate change sea level rise, innovative and collaborative approaches are necessary to build community resilience and equitable ways to adapt to impacts of climate change. Therefore, even if planners may have the technical capacity to devise ways to dismantle to control of real estate capital, building coalitions and linking to social change movements are necessary for a more systemic transition to de-commodification of housing and to "remake our cities from the ground up, and gain control over our homes and lives" (Shiffman 2007; Stein 2019, 12).

The Spatial Characteristics and Supply of Urban Affordable Housing -- An International Comparative Study

Xiuning Zhang¹, Fan Yang²

¹College of Architecture and Urban Planning, fanyangsh@tongji.edu.cn

² College of Architecture and Urban Planning, silverz03@outlook.com

Abstract: It is an emerging issue for the supply of urban affordable housing that the spatial distribution marginalization and the separation of workplace and residence lead to socio-spatial problems. This study takes an international comparative approach and analysis the different of spatial distribution characteristics in urban area and the formation mechanism of affordable housing, focusing on cities in developed countries, e.g. Amsterdam, London and Singapore, as juxtaposition to Shanghai, China. Before conducting a transnational comparison, this research reveals the socio-economic characteristics of policy takers under the state context by analyzing the policy objectives of affordable housing in various countries, because of the significant differences in definition of beneficiary and supply mode between countries. Based on that result, this research maps the spatial distribution pattern of affordable housing clusters where the comparable resident groups living at the four case cities, and analysis the socio-economic mechanism behind spatial characteristics. It points out the implicit meanings of affordable housing policy connotation are reflected by urban residents' willingness and proportion to own housing. And, government and market-led intervention also have a profound impact on affordable housing's spatial distribution in the city. Finally, this research argues that the classification standards of the citizen groups are different due to diversity in state institution and cultural context, which further leads to the difference in social justice represented by spatial pattern, comparing these four cities. European cities may be more concerned about the equity of human development opportunities, while cities in East Asia may be more concerned with the equality of household wealth. And these different are presented in terms of spatial features.

Keywords: Affordable housing; spatial characteristics, supply mechanism, international comparative

Introduction

Decent dwellings are one of the most fundamental human rights that guarantee the well-being of people (Tusting *et al.*, 2019), and urban housing usually features the pattern of certain social group in the city (Zhang *et al.*, 2017, Dawkins, 2013), which provide a significant insight into the research of city structure (Zhang *et al.* 2019). Affordable housing plays a special role in urban housing, with the effect of city orientation and policies. Besides, the beneficiary group is mostly the disadvantage in the city, thus underlining the question of social justice in spatial pattern analysis of it.

After a length development took 70 years, contemporary Chinese cities established a dual-housing supply system, with support from both the market and government (Li *et al.*, 2015). While affordable housing is mainly provided by government with dwellings and rent subsidies (Qu and Xiao, 2015). Under the effect of land-based finance and straining land supply, major Chinese cities failed to match the demand for affordable housing (Hu and Qian, 2017), with the existing ones showing problems like distant location, dwellings clustering and spatial

mismatch (Zheng and Zhang, 2010, Song, 2011, Liu and Xing, 2013, Dong and Zhang, 2014, Fang *et al.*, 2015), which is defined as the “typical problematic feature” of Chinese affordable housing (Shi and Meng, 2013). By comparing the spatial pattern of affordable housing in the city, this research tries to understand the location choice of affordable housing in global context, and find out how the differentiated definition of affordable housing and beneficiary group could lead to various spatial pattern.

There has been an extensive research on the spatial pattern of affordable housing, but current essay focus on counties or regions with similar context, and they mainly research on the spatial effect that single policy has on affordable housing. By establishing the perspective of spatial pattern analysis, we run a comparison between Shanghai and other global cities in Europe and Asia, such as Amsterdam, London and Singapore. At first, we stress the diversity of policy context between every country, and by developing the concept of advantage location in the city, we can evaluate the location choice of affordable housing in every country, and we find that spatial pattern of affordable housing between China and other countries show a significant difference. Affordable housing in Chinese context strengthen the idea of basic dwelling for disadvantage groups, while other countries stress opportunities and variety in the city, and difference in definition affect their location choice.

Research on the Spatial Pattern of Affordable Housing

Current literature points out the problematic location of affordable housing in cities, then adapts analytic methodology to examine it. In Chinese context, scholars pay more attention to distant location and large-scale construction (Chen *et al.*, 2015), while spatial clustering of disadvantage groups features more in global context.

The effects policy has on affordable housing is a common motive in literature, while both nationwide orientation in urban development and specific housing policy will affect the spatial pattern of affordable housing (Alawadi *et al.*, 2018). Under the scheme that housing is market commodify, developers tend to take a conservative attitude towards affordable housing (Ryan and Enderle, 2012), which could lead to problem in project financing. Some policies aimed at encouraging the construction of affordable housing resulted badly in spatial problems like clustering (Ryan and Enderle, 2012, Dawkins, 2013). However, as some literature point out, policies aren't the only aspect affecting the spatial choice of affordable housing, the amount of available stock in urban housing markets, location of occupation and historic district, some, if not all, played a part in the spatial pattern of affordable housing (Park, 2013, Fan *et al.*, 2014, Fang *et al.*, 2015).

Location of affordable housing has effect on the benefit for residents. Compared with the original dwellings, residents in affordable housing acquired improved housing condition (Park, 2013), however the spatial mismatch between occupation and residency in distant located housing could lead to an overall loss of social benefits. Besides, large-scale affordable housing construction, displayed as the clustering of disadvantage groups, marginalizes and segregates residents inside. (Oakley and Burchfield, 2009, Allen and Goetz, 2010, Kontokosta, 2015)

Scholars have responded to these problems: Chen *et al.* (2015) adopted spatial analytic model and proposed a research framework for the spatial pattern of affordable housing; Ding (2012) taking transportation, land price and infrastructure into consideration, propose a guideline for the location choice of affordable housing. Aside from that, emphasizing the mix between job and dwellings instead of simply mixing social group, Transit oriented development (TOD), higher density of street could partially soothe the wounds (Kostourou and Karimi, 2017, Palm and Niemeier, 2017).

After a thorough review of the literature, we find that researches on spatial pattern of affordable housing has two distinct frameworks in Chinese and global context. Foreign scholars tend to treat location as the spatial presentation of policy effects, and their researches are usually based on certain policies, while most Chinese scholars propose the spatial problem of affordable housing first, with policies as their background.

Data and Methodology

In this research, authors adopted a global comparison perspective, and proposed a research framework for spatial pattern of affordable housing in global context. The methodology consists of three progressive parts.

Because of diversity among countries, there is no standardized definition of affordable housing, which is subdivided into several policies and housing types in different countries, thus in the research, identification of affordable housing in global context is needed. Urban housing subsidy is usually realized in two forms: dwelling and rent, and this research mainly focuses on the dwelling aspect, which could be further categorized into rental and sold affordable housing. After establishing research subject, we build up a database for affordable housing in each city with open data, then apply GIS into analysis procedure.

The mere spatial pattern of affordable housing in the city could not provide sufficient result in global context, however by comparing it with location dominance within the city, the characteristics of affordable housing is revealed. Therefore, the authors define “advantage area” in the city, which is district with denser population and richer infrastructure, knowns as CAZ (Central Activities Zone) in some countries. Because of the special policy background of affordable housing, its residents are usually disadvantage groups in the city, the location choice of affordable housing relate to their ability to obtain opportunities (Oakley and Burchfield, 2009, Li *et al.*, 2013), there is need for affordable housing to be located inside advantage area. By mapping affordable housing in the city, one can find its relationship to the city, paving the road for spatial comparison.

When defining advantage area in each city, different strategies must be applied to identify the specific area. For Shanghai and London, the research area extend to the whole metropolitan boundary, thus showing a significant core in the city, both recognized as CAZ, while in Amsterdam and Singapore, considering the relatively smaller land area, property price acts as market tool to assess supply and demand, in this research we used it to identify advantage area in both country.

Existing literatures recognize spatial clustering of affordable housing as the cause of some negative social effects, such as segregation of minor social groups. Therefore, we adopted a tract-level analysis to identify the clustering of affordable housing clustering in the city. Anselin (1995) suggest that the value of certain attribute is not only significant in itself, but also related to the same attribute of nearby areas. This theory works as an extension of Tobler’s “first rule of geometry” (Tobler, 1970), and is extended to the Explorative Spatial Research Analysis (ESRA), in which LISA model and Local Moran’s I is used to identify the high and low value clustering(Oakley and Burchfield, 2009).

Spatial Pattern of Affordable Housing in Global Context

Global metropolis is faced with housing problems, normally in the form of declining social housing, rising price for urban housing and shortage for affordable housing, therefore most megacities pay special attention to housing affordability in the city.

Variety in global housing policy attached importance to the introduction of every city’s housing policy and advantage area. Based on introduction, the mapping of affordable housing is overlapped with advantage area. Moreover, we used spatial clustering model to examine whether there is congregation of affordable housing in tract-level.

Shanghai

Before 1990s, housing in Shanghai has not yet been commodified, citizens resided in government-owned or subsidized dwellings (Huang, 2013). Reform of urban housing scheme in 1990s posed severe impact on the role of affordable housing in China. During this period, Cheap Rental Housing was first announced. As the

commodification of urban housing intensifies, the status of affordable housing was lowered and did not returning to urban housing scheme until 2007 (Qu and Xiao, 2015) In China, central government issued the guideline of affordable housing, and local governments are in charge of construction and management.

Affordable housing in Shanghai started in the 1980s (Li,2011), while almost 40 years of development brought us to the result of diverse in housing types. According to Shanghai (2017), there are currently four types of affordable housing in Shanghai: Cheap Rental Housing (CRH), Public Rental Housing (PRH), Shared-ownership Housing (SOH) and Relocation Housing (RH). The former two types are for rentals, while the latter for sold, which is mainly aimed at residents with *hukou* (residency register status).

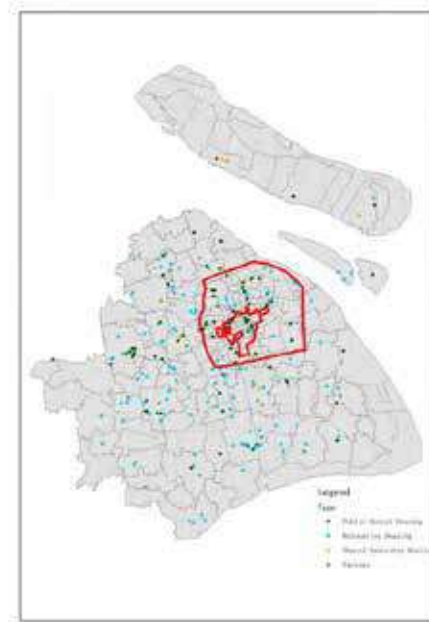

Figure 1 Spatial Pattern of Affordable Housing Points in Shanghai

The structure of Metropolitan Shanghai can be divided into three parts with central core area. The most inner part consists mostly historic district and is defined as CAZ, while between CAZ and the outer ring there is inner city of Shanghai, and the large peri-urban outer Shanghai. Metropolitan Shanghai is rather centralized, with the intensity of land use and infrastructure decay as the distance to city center increases.

Figure 2 Affordable Housing Ratio in Census Level

Figure 3 Spatial Clustering of Affordable Housing in Shanghai

Currently, there are 402431 affordable housing units in Shanghai, with Relocation Housing taking up the most part, who are mainly located in peri-urban area. By spatially joining to census level, its spatial pattern significantly marginalized, with almost no affordable housing units in CAZ. Few affordable housing units are situated in the inner city, most of which are Public Rental Housing, taking up 9.8% of total units, as much as single large-scale community distantly located takes. In spatial correlation, affordable housing in Shanghai shows low-low cluster in inner city and high-high cluster besides several large-scale communities like Pujiang, South Songjiang and North Jiading. The result show that affordable housing in Shanghai doesn't located in advantage area in the city, with construction focused on peri-urban area surrounding the outer ring.

London

London is faced with severe shortage of housing supply, with housing privatization leading to rising property price, urban housing become less affordable for citizen, the price of market-oriented rental housing is hard to control, it is in dire need for affordable housing (Mayor of London, 2018).

Aside from some minor projects, affordable housing in Greater London is supervised by Great London Authority (GLA). As London recognize variety as the fundamental aspect behind economy booming, there are no restriction on affordable housing applicants, open to London, Great Britain and other part of the world.

Figure 4 Spatial Structure and Property Price in London

Mayor of London (2018) suggest that the housing crisis could be solved by providing more housing for Londoners, therefore three types of affordable housing come up: homes based on social rent levels (which includes London Affordable Rent); homes for London Living Rent ; homes for London Shared Ownership, and is open to other affordable housing types. According to Ministry of Housing, Communities & Local Government (DCLG), as of 2018, Great London area possesses 310029 units of affordable housing, taking up 8.9% of all dwelling units.

Figure 5 Affordable Housing Ratio in Borough Level

Figure 6 Spatial Clustering of Affordable Housing in London

Affordable housing in London show its consideration with advantage area in the city, but failed to deliver fair amount of affordable housing in the highest priced borough in the city like Westminster. The spatial structure of London is similar to that of Shanghai, with CAZ in core area, ringed by inner and outer London. The concentration of housing price shows similar result, though slightly offset western in the core area. Spatially joined in borough level, we find that most affordable housing located in Inner London, the concentration pattern resembles property prices. In clustering aspects, Boroughs eastwards CAZ, such as Southwark, Tower Hamlets and Hackney shows high-high cluster, affordable housing units in these Boroughs take up much as 29.1% of total units.

Amsterdam

Affordable housing scheme in Amsterdam is different from any other country in our research. The supply of affordable housing construction stopped since 1990s, and since 2015, affordable housing units in Amsterdam are totally managed by Housing Association, without the intervention from government. Housing Associations are non-profit group that stress the importance of public rental housing in urban housing scheme, and is governed by AFWC (Amsterdamse Federatie van Woningcorporaties), housing units under their management mounting to 43% of all dwellings in the city. There is no solid affordable housing in Amsterdam, the price of rental housing is limited through a “threshold price”.

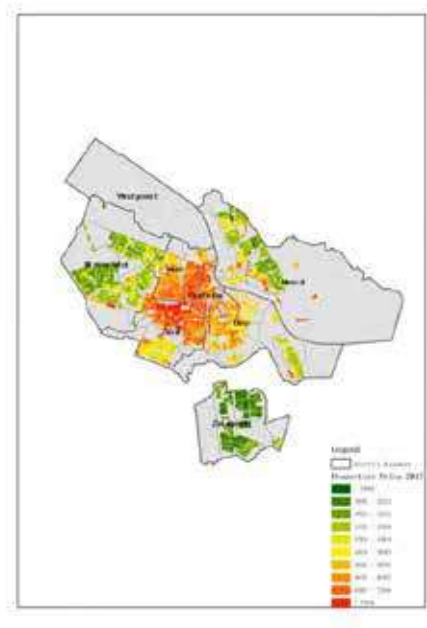

Figure 7 Figure 7 Property Price in Amsterdam

In 2017, there are 52% of total population in Amsterdam that is not Netherland background, with 53% of which are single-dwelled, and non-European residents shows clustering outside the core area (AFWC, 2017). Therefore, Amsterdam stress the importance of diversity in its affordable housing scheme.

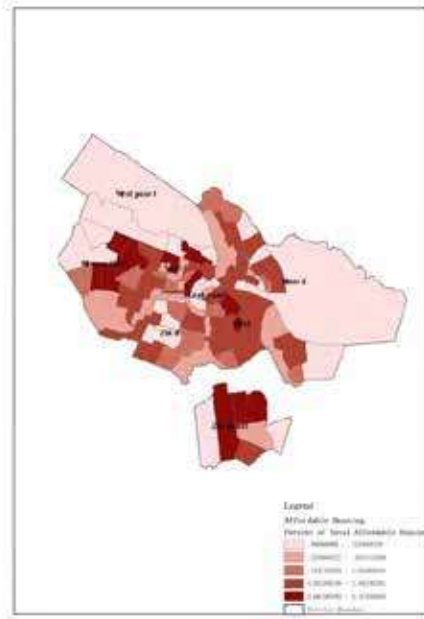

Figure 8 Affordable Housing in Quarter Level

Figure 9 Spatial Clustering of Affordable Housing in London

Amsterdam provides denser amount of affordable housing in the city, while maintain a decent number of affordable housing in advantage area, though not the highest-valued ones. With an area of 219 km², the city of Amsterdam is centralized in form of advantage area, as shown in the property price mapping, the highest priced properties located in central area. There are 192120 units of affordable housing as of 2017 in Amsterdam, the number of units in each area are inversely related, and a significant drop is detected in the highest-priced area, showed as low-low cluster.

Singapore

The reaction Singapore has to urban housing problems in a highly dense urban area is well-known. Faced with huge demand for urban housing and scarce land supply, Singapore's provision of HDB flats suggest an ideal way of government-oriented development of affordable housing (Jia *et al.*, 2019). According to HDB, as of 2018 there are 81% citizens of Singapore live in HDB flats, making it the affordable housing for the majority groups.

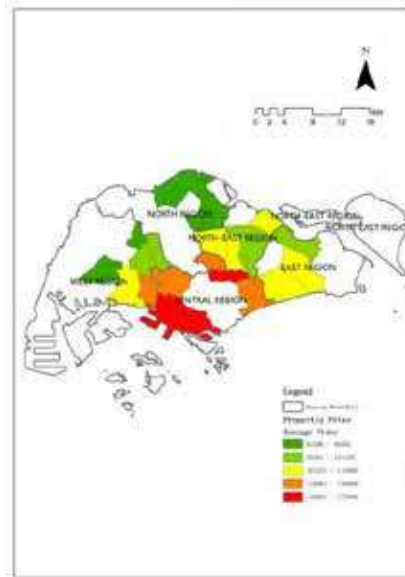

Figure 10 Property Price in Singapore

Housing and Development Board (HDB) is in charge of the planning, construction and management of all affordable housing in Singapore, with the help of land use control from government. HDB flats are constructed in towns, mainly aimed for sell, while a certain amount goes to rental market.

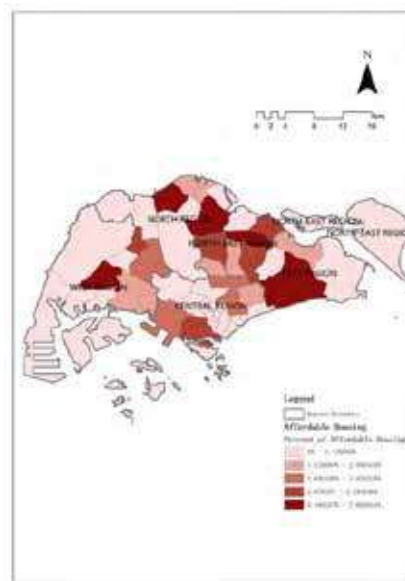

Figure 11 Affordable Housing Ratio in Town Level

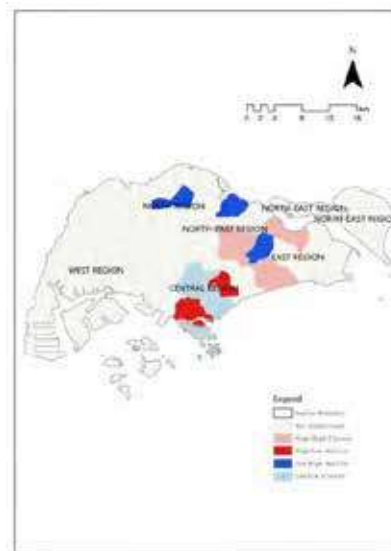

Figure 12 Spatial Clustering of Affordable Housing in Singapore

The amount of HDB flat in 2018 Singapore is, 1047695 and the largest researched countries. Due to the large scale of single HDB flat program, spatial pattern of affordable housing in Singapore is dense and clustered. Taking advantage area into consideration presented by resale price in each town, we find that the number of affordable housing units is usually higher where resale price is lower, though there has been an exclusion in Bukit Merah and Toa Payoh, where resale price is higher with greater number of HDB flats.

Result and Discussion

Table 1 Summary of Affordable Housing in Four Countries

Location	Shanghai	Amsterdam	London	Singapore
Municipal Area	6,340 km ²	219 km ²	1572 km ²	782 km ²
Population	26.32 million	1.6 million	8.83 million	5.80 million
Involvement of Government	Y	N	Y	Y
Affordable Housing Types	Sold & Rental	Rental	Sold & Rental	Sold & Rental
Affordable Housing Units	402431	192120	310029	1047695
Unit per km ²	63	877	197	1340
People Share One Unit (Average)	65.4	8.3	28.5	5.5

Table 1 shows an overall comparison of affordable housing in four researched countries. Judging only from the numbers, Singapore provides its citizens with most affordable housing units in a compact area, while Shanghai's supply of affordable housing is severely lacking compared with other countries.

Figure 13 Location of Affordable Housing and City Structure (Left: Shanghai, Right: Other Researched Area)

The spatial pattern of affordable housing shows a distinct picture in Shanghai and other researched cities, as most of Shanghai's affordable housing is located outside the inner city, into the peri-urban area, and away from advantage area in the city. However, there is no clear distinction between other three cities while London, Amsterdam and Singapore all located decent amount of affordable housing in advantage area. Furthermore, we find that all four cities failed to provide many affordable housing units in the most advantage area, such as the city core, as the historic city center is now compact and densely dwelled.

The distinction of affordable housing spatial pattern in the city is likely the results from difference in definition of affordable housing in China and global context. Global metropolis like London, Amsterdam and Singapore argue that a variety of social groups is fundamental to a vital urban development, by providing affordable housing with high quality and subsidized through policy-making process, they guarantee the opportunities for citizens less advantage in the city (Mayor of London, 2018, HDB, 2018). Therefore, affordable housing in cities of these countries provide fair amount of affordable housing open to various social group. However, the strict definition of affordable housing in Shanghai and China suggest that affordable housing aimed at disadvantage groups in the city, and the standards of affordable housing is lower than commodified ones (Shanghai, 2010). Poor location choice of affordable housing under the background of land-based finance could lead to the segregation and marginalization of certain social group.

Healthy City Planning: Food, Physical Activity and Social Justice

Emerging Places of Social Innovation (POSI).

The co-production of space between multilevel stakeholders: the case of productive urban green infrastructure

Nicholas Ardill*¹ and Fabiano Lemes de Oliveira²

^{1,2}*School of Architecture, University of Portsmouth, Eldon Building, Winston Churchill Avenue, Portsmouth, PO1 2DJ, UK*

**Corresponding author: nicholas.ardill@port.ac.uk*

Abstract: Social innovation is recurrently positioned as an important collaborative element in helping cities to transition and address human needs and societal challenges for the health, wellbeing and welfare of citizens. To address a call for more sector-specific research on the spatiality of social innovation and further understanding of the process dimension of social innovation, this article presents a conceptual framework of the process of socio-spatial innovation. By combining social innovation insight from process theories and urban spaces discourse the article indicates that socio-spatial innovation in the co-production of space can be grouped into four major processes: 1) Identification of human need or societal challenges to sustainable development; 2) Development of social relations in systems or structures; 3) Provision of opportunity for social empowerment; 4) Reflection of socio-spatial development practice. Applying this framework, the article examines how the case of productive green infrastructure emerges in the urban landscape as a Place of Social Innovation (POSI). The framework draws attention to the significance of partnership working and intermediation activities to improve access to urban spaces to contribute to socio-spatial justice and healthy orientated urban environments.

Keywords: healthy city, social innovation, co-production of space, productive green infrastructure

Introduction

Contemporary cities need to find more effective and efficient solutions to societal challenges of climate change, inequality and healthcare (BEPA, 2011, European Commission, 2013). The field of innovation studies is well-placed to contribute to debates on urban transitions to tackle such challenges, but only when it considers the role of human agency in transforming the built environment towards sustainable development (Geels and Schot, 2016). Consequently, there has been a renewed attention on the role of social innovation to sustainable development, especially around cooperation and participatory approaches to spatial development to develop new capacities (Ardill and Lemes de Oliveira, 2018).

Participatory forms of urban growing have been emphasised in the search for socially innovative solutions to social, economic, and environmental challenges of changing cities whilst civil society and institution instigated growing projects have multiplied in recent times (Cunk et al., 2017). This socio-spatial process is reshaping urban landscapes, experimenting with alternatives to capitalist formations of urban environment (Harvey, 2012) and co-producing public spaces as productive green infrastructure (Rosol, 2012). As a consequence, Places of Social Innovation (POSI) are emerging in the urban landscape in the co-production of space between multilevel stakeholders. The term is defined here as the place-based process of urban change in the collaborative planning, design and delivery of public infrastructure; physical and social, between bottom-up citizens, intermediate non-governmental organisations, and top-down government institutions.

The process of social innovation is argued to perform a significant role in helping to integrate participatory mechanisms into urban decision-making processes, increasing the social inclusion of disadvantaged groups, and enhancing the resilience of urban areas and communities (Moulaert et al., 2005, 2010, Mehmood, 2016). Nevertheless, there have been few studies on the process dimension of social innovation that investigate common patterns or aggregated learning (Mulgan, 2006), especially how it is 'designed, diffused and supported' (Caulier-Grice, Davies, Patrick, and Norman, 2012, p.33) with further research on social innovation spatiality required to comprehend dynamics in social and urban change (Moulaert and Mehmood, 2011). Therefore, this article seeks to contribute to the understanding of social innovation process in the co-production of urban spaces. The focus for the article is to consider the topic of social innovation, and how participatory and collaborative processes may support the development of planning principles linked to healthier, more equitable built environments.

The article now proceeds to review current knowledge on social innovation process. Then, it develops a process framework for understanding socio-spatial innovation in the co-production of space, considering the various cooperative inputs which are necessary or possible from innovation participants. Afterwards, the article presents an overview of an emerging POSI in order to illustrate the main characteristics of the proposed framework in the case of productive urban green infrastructure. Finally, the article ends with a summary and concluding remarks.

The process of social innovation

In this section a framework to investigate the social innovation processes in the co-production of urban space is proposed after reviewing three social innovation models found in the literature. Mulgan (2006) proposed a framework for the process of social innovation, later advanced with other collaborators from the Young Foundation and NESTA UK (e.g., Mulgan *et al.*, 2007, Bacon *et al.*, 2008, Murray *et al.*, 2010, SIX, 2010, Caulier-Grice *et al.*, 2012), identifying six stages: 1) Prompts, inspirations and diagnoses (which involves identifying and defining a need to be met); 2) Proposals and ideas (the stage of idea generation and designing ways to deal with the identified need); 3) Prototyping and pilots (where ideas get tested in practice through pilot projects with feedback from users and experts); 4) Sustaining (when the idea becomes everyday practice); 5) Scaling and diffusion (which involves developing a range of strategies for growing and spreading an innovation to a larger group or to other communities); and 6) Systemic change (so that it works on a broader scale by introducing entire systems). Sustainable

systemic change in redesigning society through changes in relations between institutions and stakeholders is positioned by policy advisors as being the principal focus of social innovation (Murray *et al.*, 2010, SIX, 2010, BEPA, 2011, Baturina and Bežovan, 2015). Caulier-Grice *et al.* (2012) highlight that the innovation process proposed is iterative rather than linear and the model be considered more like multiple spirals than straight lines. Therefore, it should not be assumed that initiatives will transcend all six stages as many will jump between or skip entire stages altogether. Some cases of social innovation ‘remain small in scale and locally based, rather than attempting growth and scale, and very few social innovations effect or reach the stage of systemic change’ (Caulier-Grice *et al.*, 2012, p.34). Social innovation is understood broadly as the production of societal value in meeting social needs and creating new social relationships or collaborations to enhance society’s capacity to act (Mulgan, 2006, Mulgan *et al.*, 2007, Murray *et al.*, 2010)

Another framework is the Alternative Model of Local Innovation advocated by Moulaert *et al.* (2005, 2010) to counter social exclusion dynamics experienced at various socio-spatial scales. The model conceptualises social innovation dynamics occurring in interaction with each other over time, beginning with the deprivation of human needs across four areas: economic or material basic needs, such as food, clothing, shelter and employment; social needs of health and education; cultural needs of self-expression, identity and recognition; and political needs of equal opportunity and active citizenship (Moulaert *et al.*, 2005, 2010). The deprivation of needs causes a reaction and the mobilisation of resources; recognised as human, social and institutional, organisational, and financial with mediation between stakeholders (e.g., civil society and state) in order to develop social initiatives to satisfy human needs that are currently not being satisfied. This agency fosters processes of ‘social changes in existing social and power relations’ towards inclusive and democratic urban governance systems to ‘increase the level of participation of all but especially deprived groups in society’ (Moulaert *et al.*, 2005, p.1976). Consequently, previously excluded social groups are empowered through ‘increasing the socio-political capability and access to resources’ needed to improve rights to satisfaction of human needs and participation (Moulaert *et al.*, 2005, 2010). Thus, social innovation is understood in a radical perspective as social and urban change that achieves conditions of empowerment, favouring bottom-linked governance initiatives and inclusive infrastructure development, and ‘therefore explicitly refers to an ethical position of social justice’ (Moulaert *et al.*, 2005, p.1978).

The third model reviewed in this article is the one drawn by Ayob, Teasdale, and Fagan (2016). Examining how the concept has developed over time they argue that the social innovation process has ‘five plausible routes through some or all of this process, all of which can be conceived of as social innovation. First, new forms of social relations lead to innovation; second, innovation leads to a restructuring of social and or power relations; third, innovation leads to utilitarian social value; fourth, new forms of social relations lead to innovation which results in the restructuring of power relations (and thus societal impact); and fifth, new forms of social relations lead to innovation, which creates utilitarian social value (and thus societal impact)’ (Ayob *et al.*, 2016, p.648). In doing so, the authors distinguish between two social innovation traditions and outcomes in social change. The first, seen as utilitarian, emphasises changes in aggregate individual utility. The second, considered more radical, ‘sees social (and political) change occurring as a consequence of innovations in social relations’ (Ayob *et al.*, 2016, p.648). The authors proceed to draw similarities between co-production and the five social innovation pathways outlined due to common themes of: 1) collaboration (new forms of social relations); 2) the generation of new ideas (innovation); 3-4) empowerment (utilitarian social value and/or new forms of power relations); and 5) societal change (societal impact). To conclude, the radical

approach, termed ‘strong social innovation’, is suggested in this model as strongly linked to co-production due to shared emphasis on shifting power influences as a key component of this approach, notably through the engagement and empowerment of previously disadvantaged individuals and groups (Ayob *et al.*, 2016).

The models outlined attempt to address different questions and develop their own viewpoint on social innovation process. Mulgan *et al.* is interested by how innovations in the social field progress, identifying six stages ‘that take ideas from inception to impact’ (Murray *et al.*, 2010, p.12). Whereas, Moulaert *et al.* (2005, 2010) examines what structural changes in social relations are happening, making the connection between urban governance, empowerment and socio-spatial justice. Finally, Ayob *et al.* (2016) explores how social innovation has evolved, linking pathways to co-production and shared actions in developing collaborative forms of social relations, leading to changes and societal impact. This article attempts to integrate these three models into a socio-spatial innovation framework that encompasses all three of these components: the progress of the innovation, changes in social relations, and collaborative agency. The article does this by defining a model of the social innovation process in the co-production of space involving four cyclical stages. Table 1 indicates how the stages of this model relate to the elements in the Mulgan *et al.*, Moulaert *et al.* (2005, 2010), and Ayob *et al.* (2016) models.

Table 1: Relationship between different stages of the social innovation process in models

Murray <i>et al.</i> (2010) <i>How innovation progresses?</i>	Moulaert <i>et al.</i> (2005, 2010) <i>What innovation in social relations is taking place?</i>	Ayob <i>et al.</i> (2016) <i>How do collaborative actions cause change?</i>	Ardill and Lemes de Oliveira, <i>What is the stage of the particular process?</i>
Prompts, inspirations and diagnoses	Deprivation of human needs	New forms of social relations	Identification of human need or societal challenges to sustainable development
Proposals and ideas		Innovation	
	Mobilisation of resources		Development of social relations in systems or structures
	Changes in social relations (and political relations)		
Prototyping and pilots	Empowerment	Utilitarian social value	Provision of opportunity for social empowerment
Sustaining		New forms of power relations	Reflection of socio-spatial development practice
Scaling and diffusion	Satisfaction of human needs and participation	Societal impact	
Systemic change			

Socio-spatial innovation framework

The traditional linear process of technological innovation postulated innovation always starts with research (Godin, 2006, Balconi *et al.*, 2010), then followed by development, and ends with production and diffusion (Balconi *et al.*, 2010). This model has been much criticised (Godin, 2006, Balconi *et al.*,

2010). It fails to recognise that ‘knowledge does not flow smoothly among different stages of the innovative process and among different organizations and institutions. Nor does it flow freely among geographical areas’ (Balconi *et al.*, 2010, p.7). Following Murray *et al.* (2010) this article therefore proposes a framework for social innovation process based on iterative innovation processes, allowing for overlap, interaction and nonlinearity, as ‘change needs to be understood through the iterative action of the processes and dynamics’ (Van de Ven and Poole, 2004, p.317). While stages are not necessarily linear or sequential, this article can identify four key stages based on theoretical knowledge to provide an analytical framework with which to think through all the activities taking place (Ardill and Lemes de Oliveira, 2018), the various agents involved, and patterns in the context of such innovation journeys (Rip, 2012). The proposed framework is illustrated in Figure 1 as a circular process with the implication that socio-spatial change is a constant activity. Key stages are described in following paragraphs and process dynamics and factors categorised at the end of this section in Table 2.

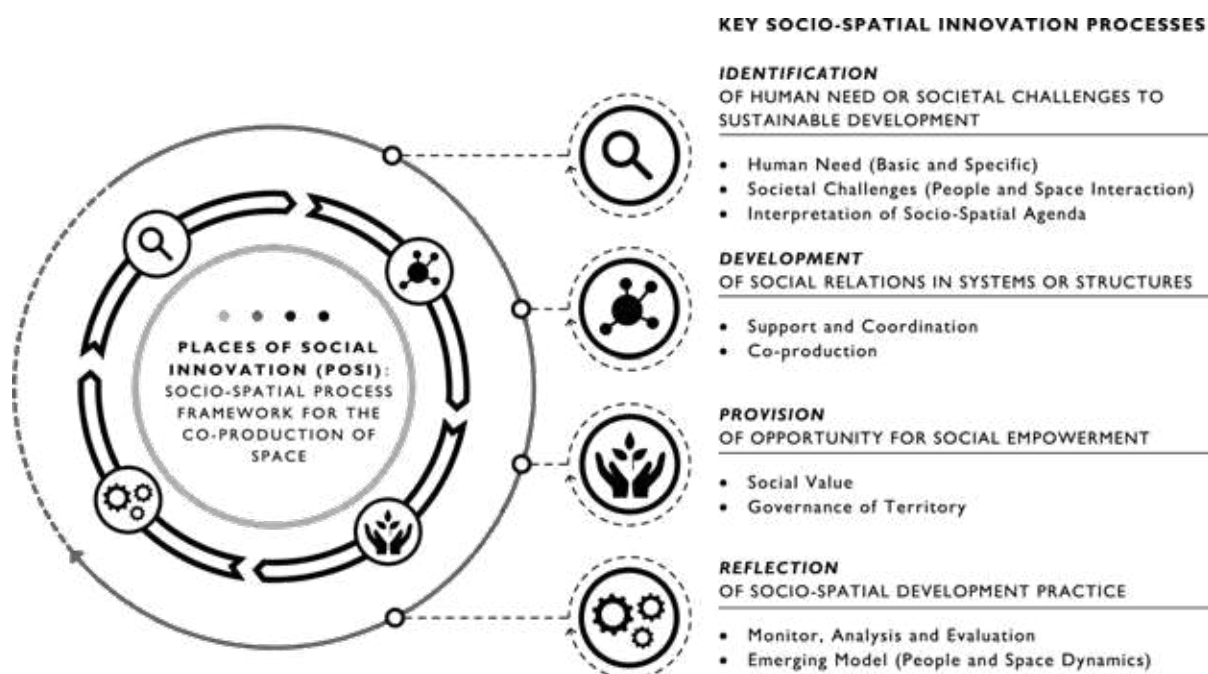

Figure 1: Proposed socio-spatial innovation process framework

The first stage: *identification of human need or societal challenges to sustainable development* involves prompts that highlight the need for innovation to address human need or societal challenges (Murray *et al.*, 2010, SIX, 2010). Human need may include the basic or specific needs of individuals and groups. Maslow (1954) characterises basic needs as physiological needs (e.g., food, clothing, and shelter), and safety needs of health and wellbeing, employment, and security. Whereas, societal challenges in a sustainable development perspective (BEPA, 2011, Baturina and Bežovan, 2015) are directed towards society as a whole and recognised as major concerns shared by all citizens, especially uneven development, health, and climate action (Grimm *et al.*, 2013). They are highlighted by people and space interactions (Smith, 1984). Long-standing and emerging urban problems are brought into focus by an experience or event or research and interpretation of socio-spatial agenda takes place (Murray *et al.*,

2010). This process involves diagnosing unmet need or challenges by understanding contextual dynamics affecting the situation in order to frame opportunities and constraints (SIX, 2010). From the identification of need an idea for a solution is generated to activate an initiative. Data gathered is synthesised as findings and made into a persuasive argument to immediate stakeholders that the solution proposed can be effective, and a defined brief with strategic objectives and directions is set out (Torres, 2017).

The second stage is the *development of social relations in systems or structures*. A multitude of stakeholders will be typically engaged on this stage (e.g., the stakeholder that has identified the need or challenge and other stakeholders that are interested in or might directly benefit from addressing the socio-spatial agenda). In this regard, generating cross-sectorial support and coordination will be valuable here to mobilise resources to work on the social innovation solution and the co-production approach presents a way of collaborative working (Boyle and Harris, 2009, Voorberg *et al.*, 2014, Ayob *et al.*, 2016). The setup of a coalition and supportive structures further develop the innovative solution (Murray *et al.*, 2010), and creation of a protected space for experiment are significant features of this process (Rip, 2012). This stage is aided by innovation intermediaries, such as agents and organisations (TEPSIE, 2014). Intermediaries create opportunities and spaces (e.g., social, economic, and physical) through facilitation, configuring, and brokering activities to create relationships to support innovation (Stewart and Hyysalo, 2008). Furthermore, the contribution of civil society through social entrepreneurship and social enterprise (Mulgan *et al.*, 2007, Phills *et al.*, 2008, Howaldt *et al.*, 2018) aligned with state steering to coordinate processes of social innovation creates the condition for hybrid partnerships to emerge (Baker and Mehmood, 2015, Nicholls *et al.*, 2015). New coalitions are comprised of public, private and social participants in the organisation of development (Noworól, 2013). These coalitions contribute to the rearrangement and restructuring of existing social relationships (Mumford, 2002, Moulaert *et al.*, 2005). As such, the use of embedded resources and assets is a way of engaging a range of stakeholders in the co-design and development of solutions (SIX, 2010, Caulier-Grice *et al.*, 2012, Manzini, 2014), and design-based approaches fusing design-thinking can progress and shape the idea (Brown and Wyatt, 2010, Manzini, 2015). To help ensure needs are met, collaboration amongst the stakeholders that contribute to the development of the social innovation solution through co-production activities, such as their planning, design and delivery with the active participation of citizens and beneficiaries is significant (Voorberg *et al.*, 2014).

The third stage: *provision of opportunity for social empowerment* is where a socio-spatial initiative is implemented and is about creating openings to enhance society's capacity to act in a changing environment (Murray *et al.*, 2010, BEPA, 2011, Grimm *et al.*, 2013). This involves generating social value, both to disadvantaged groups and society as a whole (Phills *et al.*, 2008, Ayob *et al.*, 2016), and through increasing participation in multilevel urban governance structures to increase access to resources (Gerometta *et al.*, 2005, Moulaert *et al.*, 2005, Evers *et al.*, 2014, Ayob *et al.*, 2016, Brandsen *et al.*, 2016). In this stage, opportunities for community development are enabled through inclusive practices and social engagement to encourage active citizenship to help meet needs (Davies and Simon, 2013, Mehmood and Parra, 2013, García *et al.*, 2015). In this regard, social learning activities, where people can learn from each other collectively rather than through the isolated activity of an individual (Reed *et al.*, 2010), increases community capacity through development of new skills to construct more resilient communities (Pol and Ville, 2009, Manzini, 2015). Moreover, building resilience will contribute to sustainable place making and the promotion of sustainable development (Mehmood and

Parra, 2013, Baker and Mehmood, 2015). In this process, improving access to urban resources helps to build capacities (TEPSIE, 2014), and changes in group-decision making and power relations creates new socio-political capabilities, enhancing peoples control over their own lives to support socio-spatial inclusion and justice (Moulaert *et al.*, 2005, 2010, MacCallum *et al.*, 2009).

The fourth stage connecting the process cycle is *reflection of socio-spatial development practice*. It involves consideration of measures of success of the initiative (SIX, 2010, Bund *et al.*, 2015), and the process of selecting, developing and prescribing a model of standardisation. The activity of demonstrating, refining and testing ideas to obtain feedback from users and specialists in order to evolve solutions and maximise impact is important to learning (SIX, 2010, Torresa, 2017). Through iteration, conflicts can be resolved and coalitions gather strength (Murray *et al.*, 2010), supporting ongoing infrastructuring and embedding of stakeholder relations, networks and resources (Hillgren *et al.*, 2011, Bjögvinnsson *et al.*, 2012). Here the adaption of the idea and the sustaining of the initiative through use of evidence and identifying further resources is necessary to carry the innovation forward (Murray *et al.*, 2010, SIX, 2010). In this stage, the spreading and sharing of the solution through diffusion and emulation of an idea or practice occurs (Murray *et al.*, 2010, SIX, 2010, Caulier-Grice *et al.*, 2012). As such, the provision of support and know-how from one organisation or place to another (Murray *et al.*, 2010) is significant to open knowledge advancement (Chesbrough *et al.*, 2014, TEPSIE, 2014). This is necessary to move innovation from a community level to a widespread solution (Torresa, 2017). It is important here to identify how an initiative can be imitated from a highly localised context to other contexts and will involve other agents adopting and implementing that solution in new situations and places (Windrum *et al.*, 2016).

Table 2: Key socio-spatial innovation processes, dynamics and factors

Key process	Process dynamics and factors
<i>Identification of human need or societal challenges to sustainable development</i>	<p>Human Need</p> <ul style="list-style-type: none"> • Basic Need (individual and collective): Physiological; Safety and Security in Environment (for Health and Wellbeing) • Specific Need of groups: Deprivation of Community and Locality; Disadvantaged Group and Vulnerability <p>Societal Challenges (People and Space Interaction)</p> <ul style="list-style-type: none"> • Built Environment (Physical and Social Dimensions): Access to Public Spaces and Equitable Environment; Urbanisation • Climate Action: Human Activity and 'the Environment' (Land Use and Resources); Ecological Resistance <p>Interpretation of Socio-Spatial Agenda</p> <ul style="list-style-type: none"> • Frame Opportunity or Constraint: Diagnosis of (Unmet) Need or Challenge; Context Dynamics (Locality, Politics, Economy) • Strategy and Brief Preparation (of Initiative): Idea for a Solution; Inception and Activation

Socio-spatial innovation: towards emerging Places of Social Innovation (POSI)

This section presents an overview of a case of emerging POSI in order to illustrate the main characteristics of the proposed framework. The section starts by introducing the organisation involved in the development of socio-spatial innovation presented. Then, key processes are distinguished through employing the analytical framework outlined in this article. Finally, a graphic visualisation of the analytical framework as applied to the case is presented at the end of the section in Figure 2.

Case background

The Brighton & Hove Food Partnership (henceforth the Food Partnership) formed in 2003 due to the identified need for a partnership approach to integrate sustainable urban policy, agency and change. It emerged as an umbrella non-governmental organisation within the local system connecting cross-sectorial stakeholders to form a participatory and strategic approach to developing a holistic food system. The organisation is embedded in the city with over 4000 members and links food policy with initiatives within public health, education, community development, land use, urban planning and sustainable development.

‘Harvest Brighton & Hove’ was an innovative citywide programme instigated by the Food Partnership from 2009 to 2013 to develop local food projects. Altogether, Harvest supported the development of 54 new growing projects across the city, transforming 1.19 hectares of urban land into productive green infrastructure. As a Harvest exemplar, the Racehill Community Orchard (henceforth Racehill Orchard) was the most significant community growing space to be developed with permission to grow to 1.30 hectares and is the largest orchard in the city. Contextually, the Whitehawk estate bordering Racehill Orchard in 2015 was the most deprived area in the city and the 331st most deprived area in the UK out of 32,844, placing it just outside the national bottom one percent (NHS Brighton & Hove, 2015).

Identification of human need or societal challenges to sustainable development

At the national level, the Cabinet Office Strategy Unit (2008) review into UK food policy emphasised societal challenges to meeting needs concerning economics and equity, health, safety, and environment. Previously, the Department of Health ‘Choosing Health’ (2004) report had identified local community food initiatives as an instrument to support behavioural changes and reduce health inequalities. The Food Partnership likewise recognised the social utility of community food initiatives to meet specific local needs whilst helping to address wider societal challenges. Within Brighton & Hove, there was a contextual need to reduce inequalities to help realise a more just city (Fainstein, 2010), especially in relation to health. The Annual Report of the city’s Director of Public Health (2006) highlighted challenges of growing health inequalities and deprived wards having a life expectancy of up to five years below more affluent wards in the city (Brighton and Hove City Primary Care Trust, 2006). Furthermore, geospatial data exposed a social equity divide between rich and poor within Brighton & Hove (OCSI, 2007); bringing to light a social injustice and prompting social innovation (Murray et al., 2010).

The Food Partnership interpreted the opportunity presented by the Local Food Fund (2007 to 2013) to develop an integrated citywide approach to make locally grown food more accessible and build material, personal, and cultural capacity to develop the overall capacity and resilience of communities involved (Local Food, 2012). In preparing their bid document, the Food Partnership organised meetings with

members and partners, including the City Council and Primary Care Trust, to jointly develop the aims, outcomes and delivery of initiatives. The specific need for community growing spaces was demonstrated by a strong interest in local food, and its impact on the environment and health. The collaborative project development, between the Food Partnership and Harvest partners within the local system representing the identified beneficiaries demonstrated a strategic approach to addressing needs. Here, consultations with those affected by development were significant to identifying a cohesive strategy to satisfy needs (Fainstein, 2010). Although Harvest aimed to benefit citywide residents the programme targeted areas of socio-economic disadvantage that would especially gain from interventions to address poor access to fresh food, high incidence of poor health or lack of access to urban resources (Harvey, 2009). As such, the Racehill Orchard Harvest exemplar was developed within the deprived Whitehawk neighbourhood of East Brighton because the high-density estate was identified as a location experiencing social need and would enable more residents to participate in urban growing (Murray *et al.*, 2010).

Development of social relations in systems or structures

Collaboration with other Brighton & Hove stakeholders through partnership working was central to the case, helping to strengthen and develop new or existing relationships within the local system, and aided by multilevel intermediation to network groups and people across issues and communities (Stewart and Hyysalo, 2008). For instance, a cross-sectorial advisory committee for the Racehill Orchard aided project partners in organising the co-production of space, ensuring interested parties were democratically represented (Fainstein, 2010). The participatory framework enabled a co-design process to promote a sense of community ownership and collectively develop a spatial and programmatic brief (Marcuse, 2009). To undertake linking, the Food Partnership operated across levels to broker top-down support from the City Council to access resources and develop strategies to ensure long-term support for Harvest's aims. They configured and multiplied their agency with other non-profit organisations through sharing resources and expertise in developing green infrastructure to realise more effective production than working independently, whilst engaging bottom-up residents with neighbourhood growing projects to embed social practices and behavioural changes.

As a Harvest partner, the City Council provided organisational support by facilitating land access and recognising the social value of citywide development (Baker and Mehmood, 2015), especially to deprived areas whilst adhering to strategic urban policy as part of its commitment to sustainable development. For example: The Sustainable Community Strategy (2006) aimed to increase land available for food growing; the City Food Strategy (2006) sought to increase growing opportunities (Brighton & Hove Food Partnership, 2006); and the updated Food Strategy Spade to Spoon: Digging Deeper (2012) targeted 'more food consumed in the city is grown, produced and processed locally using methods that protect biodiversity and respect environmental limits' (Brighton & Hove Food Partnership, 2012b, p.14). A 15-year land agreement for Racehill Orchard was also significant to the case. The implications were reflected in the agreement serving as informal governance model between the City Council and community groups for other Harvest growing spaces on public land later developed. As such, learning generated by Harvest enabled the Food Partnership to create a template for future community agreements with the City Council that outline roles and responsibilities for each partner, maintenance arrangements, and conditions for governing areas of public green spaces.

Provision of opportunity for social empowerment

Harvest increased the amount of food grown in the city by developing more community growing spaces and increasing the number of people involved, supporting community development to meet urban needs and address inequalities (Moulaert *et al.*, 2005; Murray *et al.*, 2010; TEPSIE, 2014). Material capacity was increased by developing physical infrastructure, improving public access to green space and complemented by educational opportunities to build personal capacity. Here, Harvest facilitated community development through training workshops, skills-sharing and open days delivered citywide to residents, often in community growing spaces, supporting engagement. Consequently, confidence was built in food growing and developing abilities in running growing projects to help embed productive green infrastructure.

The Racehill Orchard demonstrates how opportunities were provided to residents within deprived areas of East Brighton to contribute to personal development and social empowerment. Brighton Permaculture Trust, an organisation which promote sustainable development through design, trains residents in traditional agricultural techniques, including scything, tree and hedgerow planting, pruning and caring for fruit trees. The social value of these opportunities is demonstrated through enhancing capabilities (Fainstein, 2010). Volunteers can be trained in leadership skills through a session leaders' course, helping to devolve organisation and diffuse knowledge. This approach to social behavioural change supports community empowerment through enhancing the neighbourhood capacity to act (Bacon *et al.*, 2008). It improves resident access to skills and resources whilst helping growing projects become self-sustaining (Moulaert *et al.*, 2005, TEPSIE, 2014). The importance of increasing urban participation, especially amongst groups excluded from the built environment in some form was central to meeting Harvest aims (Madanipour, 1998). At Racehill Orchard, free activities and events target people living on the deprived estate. Regular 'Healthy Activity Days' involve health walks, foraging events, pick and cook sessions, and other activities promoting healthy lifestyles and behaviour. The production of green infrastructure in bringing new land into food production, providing community events to build capacity, and improving the access to resources of specific target groups is reinforced by enabling public access to urban space (Lefebvre, 1968, Mitchell, 2003, Harvey, 2012, Low and Iveson, 2016). Cultural capacity was developed through engagement and territorial appropriation to give residents a sense of connection with their urban landscape and is significant to the social production of space, where space operates as both a product and a producer of changes in the urban environment (Lefebvre, 1991, Soja, 2010).

Reflection of socio-spatial development practice

The citywide development was an archetype for practitioner based social innovation and the integrated approach across multiple levels helped diffused socio-spatial innovation, generating a territorial infrastructure in relations, networks and resources. The measure of social innovation success (Murray *et al.*, 2010) in terms of developing capacity (Fainstein, 2010) in Brighton & Hove was evidenced by community growing spaces tripling from 25 to 79, helping to diffuse ideas and behaviours and amplify the visibility of social practices. By undertaking Harvest, the Food Partnership helped to improve distributional justice by accessing new land for urban growing (Fainstein, 2010, Soja, 2010, Low and Iveson, 2016), with many projects located in housing estates, public parks, churchyards and railway stations to increase the visibility of community growing practices.

A central objective of the Harvest experiment for the Local Food programme was to share experience and knowledge of the project's approach to increasing food production to disseminate learning that could be replicated in other cities, both within the UK and internationally. This was undertaken in several ways: establishing a Reference Group to enable parties to learn from the experiences of nationwide projects; visits from other Local Food Fund Beacon Projects to demonstrate Harvest activities; attending international conferences on planning and food systems to exchange thinking; the Local Food 'Share and Learn' networking events and the national evaluation event 'More than just the veg' in 2012; and distributing reports on Harvest to influence policymakers by demonstrating outputs.

Locally, dissemination was supported by the innovativeness (Bund *et al.*, 2015) of the Food Partnership's intermediation between bottom-up to top-down levels of urban stakeholders (Stewart and Hyysalo, 2008). Grassroots working helped to mobilise an urban social movement of community growers and develop a network of growing spaces (Castells, 1983). Engaging local decision-makers helped to influence planning and development policy whilst attracting attention of national policy makers (Baker and Mehmood, 2015). To embed good practice into local planning, Harvest insight supported lobbying to include references within the Brighton & Hove City Plan Submission Part 1 for the City Council 'to support and promote local food growing', expressly in city wide policies: SA6 Sustainable Neighbourhoods, CP8 Sustainable Buildings, and CP16 Open Space (Brighton & Hove City Council, 2013), later developed in the City Sustainability Action Plan (2015) setting key actions to develop productive green infrastructure and support sustainable development.

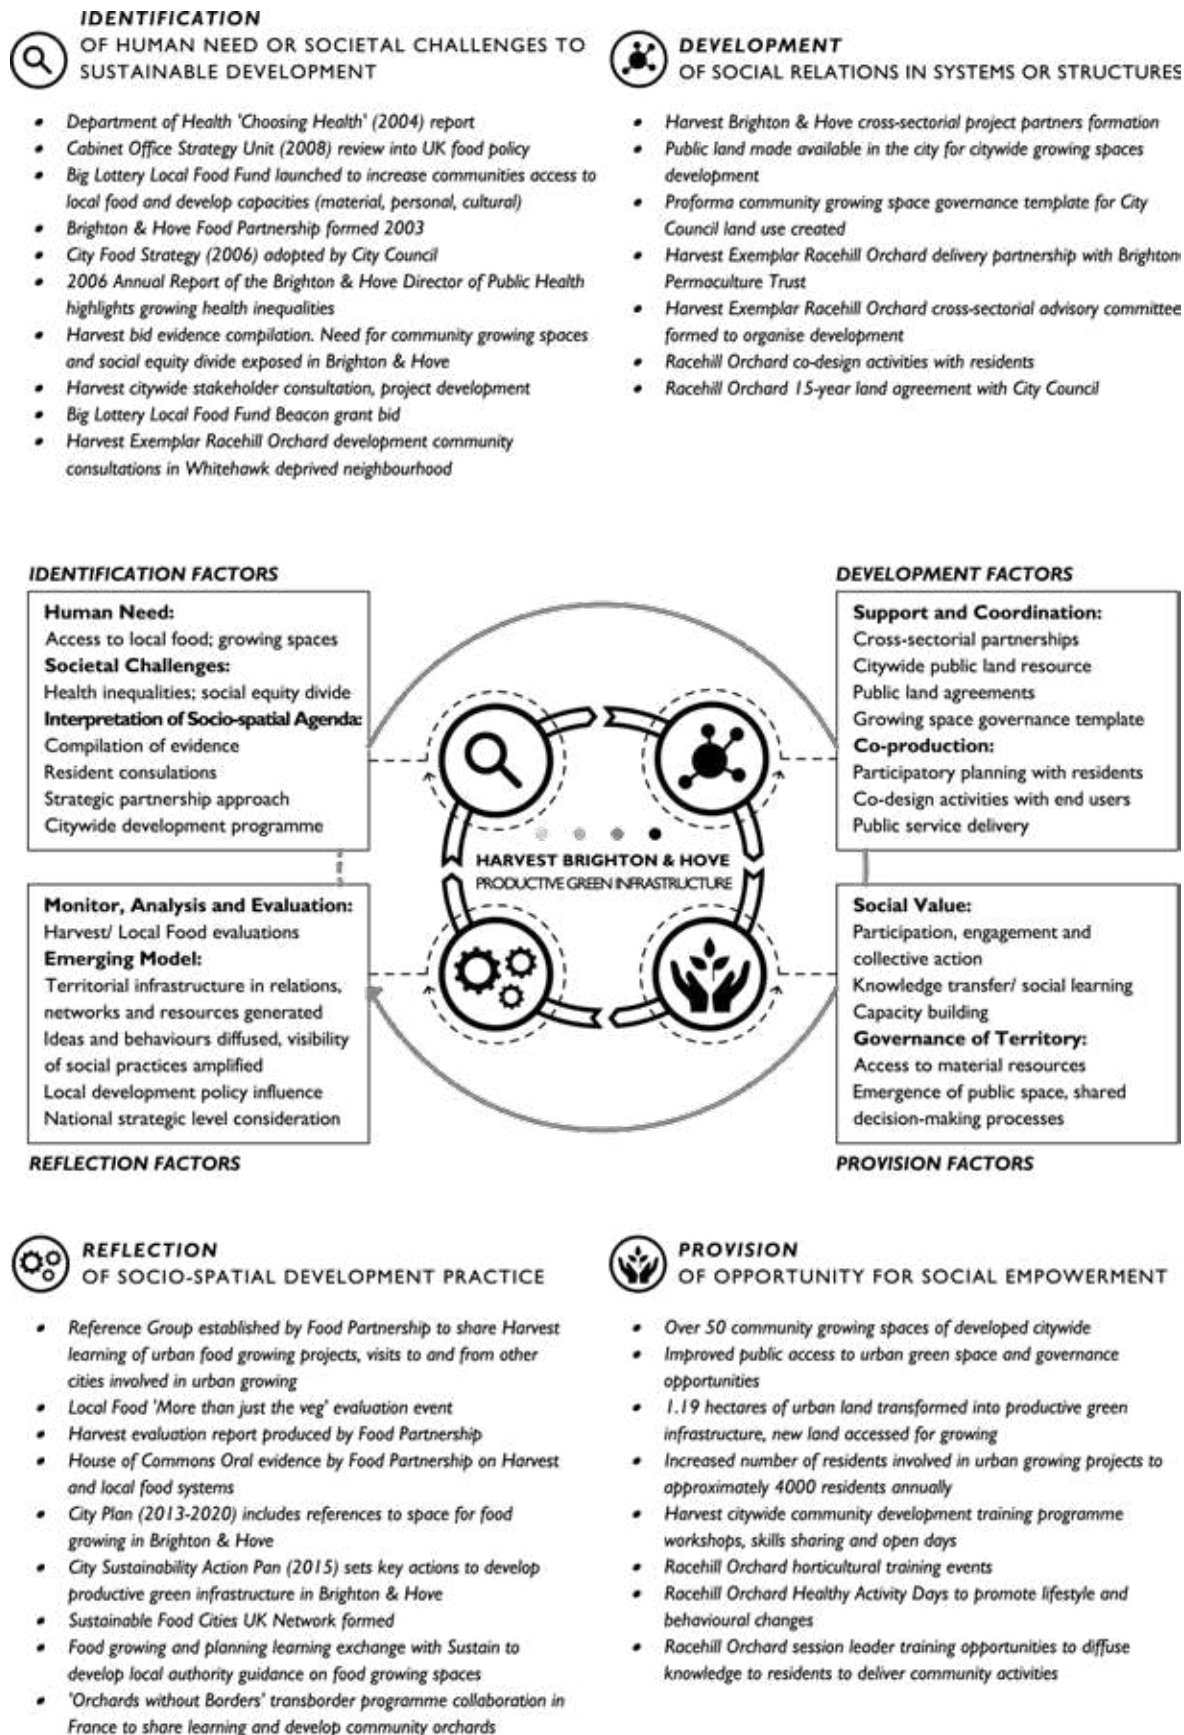

Figure 2: Application of socio-spatial innovation framework. Populated with Harvest Brighton & Hove urban growing programme. Key socio-spatial process factors highlighted in boxes and case dynamics bulleted.

Conclusion

This article was concerned with the role of social innovation as a way of contributing to a healthy orientated built environment and has taken the perspective of how socio-spatial innovation can contribute to the process of creating capacity to meet human needs and respond to societal challenges. Social innovation has gained attention in the promotion of active citizenship in sustainable development policy and practice, especially around collaborative service delivery and novel approaches to welfare (BEPA, 2011). The socially innovative development of productive green infrastructure is of interest as a participatory concept that can meet needs, create social relationships and form new collaborations. However, as a process this innovative approach does not end with the development of a growing space. Like cities, it needs to continuously evolve in order to meet the challenge of affecting changes in social structures and systems regarding the participation in decision-making processes, social inclusion, and sustainable urban development (Cunk *et al.*, 2017).

To understand social innovation dynamics in the co-production of urban space a conceptual framework of the process of socio-spatial innovation was proposed in this article. An advantage of proposing this framework is that it provides a basis for understanding how a change process occurred. Especially, in analysing how urban space is collaboratively produced by social interactions between multilevel participants throughout the social innovation process in a more just way to promote health and reduce built environment inequities.

To provide some insight on the role of socio-spatial innovation in the process of an emerging POSI an overview of a case study of productive green infrastructure was presented: Harvest Brighton & Hove. This comprised the collaborative planning, design and delivery of a socially innovative development programme in the city of Brighton & Hove, UK to deal with challenges of health inequalities and equity divisions. The problem found was a lack of urban growing projects to meet needs, training to build capacities and lack of coordination of community projects as networked infrastructure. The solution proposed was a citywide food growing project that would be co-produced through a partnership approach linking stakeholders. This would develop new community growing initiatives to improve access to local food, especially within deprived areas. The aim was to support communities to grow and eat more local food, by developing skills and confidence, and helping to find more land for food growing. As such, the integrated development model presented an approach that improved access to local food, increasing both the land available and the number of people involved in urban growing.

Notes on contributors

Nicholas Ardill is an architect and doctoral researcher at the University of Portsmouth. His research focusses on socio-spatial processes around urban change, especially related to emerging Places of Social Innovation (POSI) in the co-production of space between multilevel urban stakeholders.

Dr Lemes is a Reader in Urbanism and Architecture at the University of Portsmouth. His research expertise is in planning models aimed at balancing urbanisation with nature, in particular related to the green wedge idea; green and blue infrastructure; sustainable and resilient planning models and planning history and theory. He is the author of the book *Green Wedge Urbanism: History, Theory and Contemporary Practice*, published by Bloomsbury in 2017.

Healthy neighborhoods along an urban to rural gradient

Rial Carver¹

¹*Kansas State University, rtcarver@ksu.edu*

Abstract: Neighborhoods are fundamental units of planning. Over the past century, planners have presented theories on designing the ideal neighborhood. Many of these theories include recommendations for size, population, and orientation to community health needs like food stores and healthcare facilities. Neighborhood level research pays little attention to the contexts (urban, suburban, and rural) that neighborhoods are situated in. This research aims to explore the differences in neighborhood forms, characteristics, and access to community health needs (food and healthcare) in varying contexts along an urban to rural gradient. Specifically, this study (1) explores patterns in accessing community health needs and (2) identifies patterns in people's perceived neighborhood center and boundaries in neighborhoods along an urban to rural gradient in the Wichita, Kansas, metropolitan area. This study collects data using surveys and cognitive mapping and the data is evaluated using descriptive statistics, cross tabulations, Analysis of Variance and geo-spatial analysis. Results indicate that distances to food stores are generally smaller than distances to healthcare facilities. Variations in neighborhood access and perceptions exist. Neighborhoods along the urban to rural gradient are distinct, but suburban and rural neighborhoods appear to be more alike than suburban and urban.

Keywords: urban-rural, gradient, neighborhood

Introduction

Neighborhoods are fundamental units of planning (Keller 1968, Hester 1975, Park and Rogers 2015). Many planners have developed theories that attempt to define the ideal characteristics of a neighborhood. In America, neighborhoods occur in most any setting or context including urban, suburban and rural areas (Chaskin 1997, Park and Rogers 2015). Generally, a gradient of urban form has emerged where neighborhoods are more dense in urban areas and steadily less dense as distance increases from the urban core. Often this gradient follows a major arterial road that allows for easy access by car to a range of neighborhoods (Nelson 1992). This trend has been documented as a result of a multitude of policy decisions in the United States that encourage development outside of the urban core (Schwartz 2014).

An important component of neighborhood planning is siting services like food and healthcare to ensure access to basic needs (Stewart 1985). In particular, research on this topic reveals that sufficient access to basic needs, or lack thereof, directly impacts ones' quality of life (Davis 1991, The Reinvestment Fund and Opportunity Finance Network 2012, Widener *et al.* 2013, Schwartz 2014). As important as neighborhood level planning is for the planning profession, there are gaps in understanding how neighborhoods behave in varying urban contexts and, in turn, how the provision of basic community health needs differs among these varying contexts.

Background

Neighborhood Planning

Neighborhoods abound, but can be hard to define (Chaskin 1997, Park and Rogers 2015). They signify a subset of a larger area with a unique social fabric. Many agree that neighborhoods are comprised of two components; its physical and social dimensions (Hester, 1975; Keller, 1968; Morris & Hess, 1975; Rohe, 2009). Its physical characteristics are what distinguish a neighborhood from a community. Neighborhoods are inherently place-based. The boundary of a neighborhood is used to determine the geographic location of the neighborhood. Boundaries can be made up of natural or man-made features (Keller 1968, Chaskin 1997, Park and Rogers 2015). Social characteristics of neighborhoods are based on the behaviors and characteristics of its residents. Planners tend to focus on the physical elements of a neighborhood rather than its social characteristics (Hester 1975). This research aims to explore both.

Neighborhoods have often been studied within an urban context, but it is known that they exist within many contexts (Warren 1978, Chow 1998). A critical aspect of planning includes the provision of amenities and services (McLeod 1970, American Planning Association 2018). Planned neighborhood strategies attempt to guide neighborhood design in order to accommodate basic needs.

Neighborhood Planning for Basic Needs

One of the most notable planned neighborhood theories is Clarence Perry's Neighborhood Unit Concept. The Neighborhood Unit Concept prescribed 160 acres of land, no more than 5,000 people, an elementary school at the center no more than a 5 minute walk or ¼ mile from every residence (Perry 1929). In contrast, Jane Jacobs argued that a neighborhood in a large city could be up to 100,000 people (Jacobs 1961, Park and Rogers 2015). Other neighborhood planning theories have focused instead on retail or healthcare facilities at the neighborhood center rather than a school (Engelhardt 1940, Stein 1949, Calthorpe 1993, Spreiregen and De Paz 2005, Gibbs 2012). Most planning theories consider walking distance as an important measure of access, but Spreiregan and DePaz (2005) based their neighborhood on driving distance. While the planned neighborhood theories have their critics, the legacy of guidance that planned neighborhood theories provide regarding access to basic needs is a fundamental contribution to the planning profession.

Neighborhood planning theories begin to address the importance of planning for basic needs by discussing where basic needs should be located within a neighborhood. McLeod claims that, "the purpose of a community is to satisfy the needs of people" (McLeod 1970). Accordingly, one responsibility that falls under the purview of the planning profession is providing for access to basic needs (American Planning Association 2016). Basic needs can encompass many things and many scholars have attempted to define basic needs. From the infamous Maslow's Hierarchy of basic needs to more contemporary perspectives, most proposed definitions include some reference to food and healthcare (Corning 2000). Since the 1920s, the public health field has defined its profession with a focus on the provision of basic needs (Koplan *et al.* 2009).

The urban to rural gradient as an analytical tool

In 2002, Duany and Talen proposed the concept of transect planning as a method to eliminate urban sprawl. Duany and Talen's transect planning approach offered an alternative to Euclidean Zoning, zoning based on the separation of uses, which they felt was the crux of urban sprawl (Duany and Talen 2002). Since its introduction, rather than being used primarily as a planning and development tool, the transect planning approach has been modified to serve as an analytical tool by a range of professionals (Bell 1992, Sallis *et al.* 2006, Long *et al.* 2007, Yu and Ng 2007, Hahs and McDonnell 2008). For this research, the transect presents a methodology for evaluating differences in neighborhoods along the urban to rural gradient.

Development patterns happen on a continuum of urban to suburban to rural. In the United States, definitions of urban, suburban, and rural are not consistent or sufficient. The United States Census Bureau defines rural as, “what is not urban.” This simplified definition overlooks many variations within urban form, the most glaring omission being suburbia. As such, the census bureau, and other federal agencies have attempted to identify additional indicators to help paint a more accurate picture. The Census Bureau categorizes urban places into urbanized areas (population > 50,000) and urban clusters (population between 2,500- 50,000). The United States Department of Agriculture (USDA) Economic Research Service (ERS) uses their Urban-Rural Continuum which categorizes places based on population and metropolitan status (Quinterno 2014). Even still there is not a specific definition of suburban places. Public agencies and researchers have proposed alternative definitions for variations in urban form (Nelson 1992, Zhou *et al.* 2004, Kolko 2015). A sample of these naming protocols is shown in Figure 1.

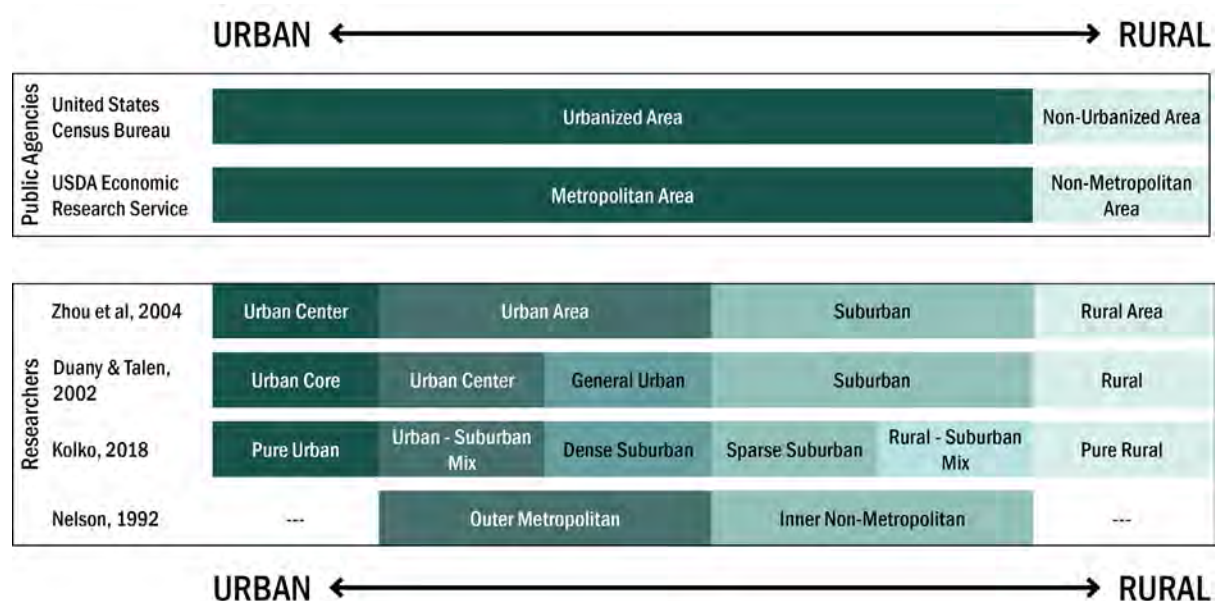

Figure 1. Examples of nomenclature of urban contexts

Methods

This research explores the differences in perceived neighborhood forms, characteristics, and access to basic needs (food and healthcare) in six neighborhoods along an urban to rural gradient outside of a representative metropolitan midwestern city (Wichita, Kansas). This study uses a mixed methods including geo-spatial data analysis. Cognitive mapping and mailed survey questionnaires were used to collect data regarding this study’s research questions and aims.

The study area was located in a representative midwestern United States city and spanned approximately 15 miles from the downtown core of the city. The selected transect was comprised of six zip codes, United States Postal Service (USPS) defined geographic units, which were used as proxies for neighborhoods and were situated in varying contexts. One mail route in each zip code was randomly selected to receive the questionnaire (Figure 2). This resulted in a stratified clustered sample. The questionnaire included two map-base questions. These questions asked respondents to identify their neighborhood boundary and center and also identify the locations where they access food and healthcare most frequently. The questionnaire also include questions about neighborhood characteristics and travel patterns to basic needs. Surveys were distributed and returned by mail. An incentive was provided for completed surveys in an effort to increase response rate.

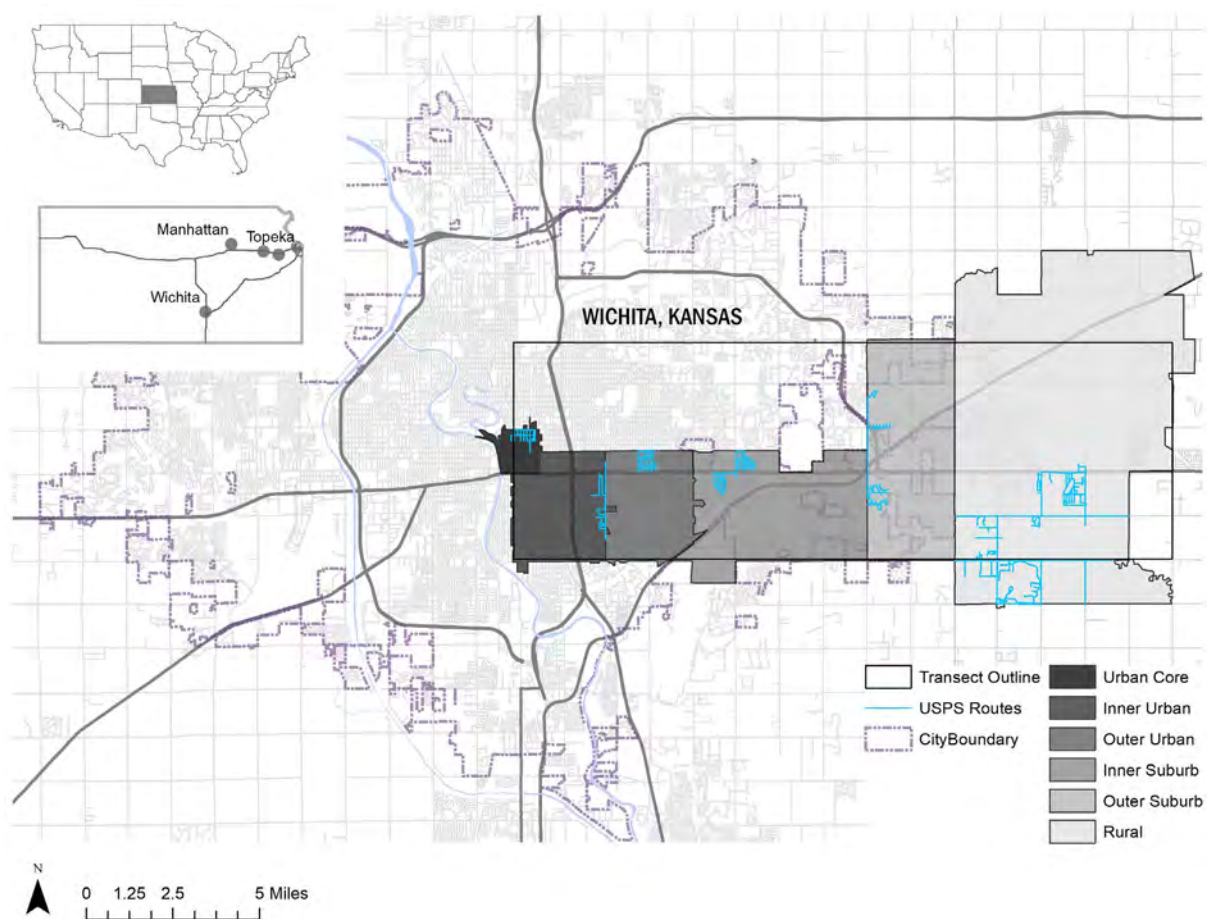

Figure 2. Map of Study Area showing neighborhoods, zip codes and mail routes

Results

Neighborhood Characteristics

The average size of neighborhoods identified by respondents was just under 1 square mile (0.95 mi²). The smallest neighborhood (0.05 mi²) was identified in the Urban Core neighborhood and the largest neighborhood (12.62 mi²) was identified in the Rural neighborhood, however, neighborhood size was not determined to be significantly different among neighborhoods.

Overall, neighborhood centers were identified as less than half a mile away from home (0.39 mi). The Rural and Outer Urban neighborhoods had the longest mean distance from home to neighborhood center (Figure 3). All other neighborhoods had a mean distance from home to neighborhood center that was about 0.25 miles.

Letters indicate significant differences at $p < 0.05$.

Figure 3. Neighborhood Characteristics by Neighborhood

In the Urban Core and Inner Urban neighborhoods, respondents were more likely to identify a neighborhood institution like a church as their neighborhood center. Few respondents identified a school as their neighborhood center (1.3%). Few overall residents identified shopping centers as their neighborhood center (7.7%), however, 1 in 5 respondents in the Outer Urban neighborhood identified a shopping center as their neighborhood center (Figure 4). In suburban and rural areas, residents primarily identified their home as their neighborhood center, but some also identified a recreation center or country club.

In terms of characterizing their own neighborhoods, generally, respondents identified their neighborhood along with its urban context. All the respondents in the Urban Core neighborhood characterized their neighborhood as “inner city or downtown.” Suburban residents tended to identify their neighborhood as “suburban.” In the Rural neighborhood, the majority of respondents identified their neighborhood as either “suburban” or “rural” (Figure 4).

A majority of overall respondents (77.3%) indicated that roads were a factor in determining their neighborhood boundary. In urban neighborhoods, one-third of respondents cited the use of buildings or commercial centers to delineate their neighborhood boundary. Natural features or parks were more likely to be used to draw neighborhood boundaries in urban and suburban neighborhoods. Residents in the Outer Suburb and Rural neighborhood identified neighborhood subdivisions or developments as their neighborhood boundary (Figure 4).

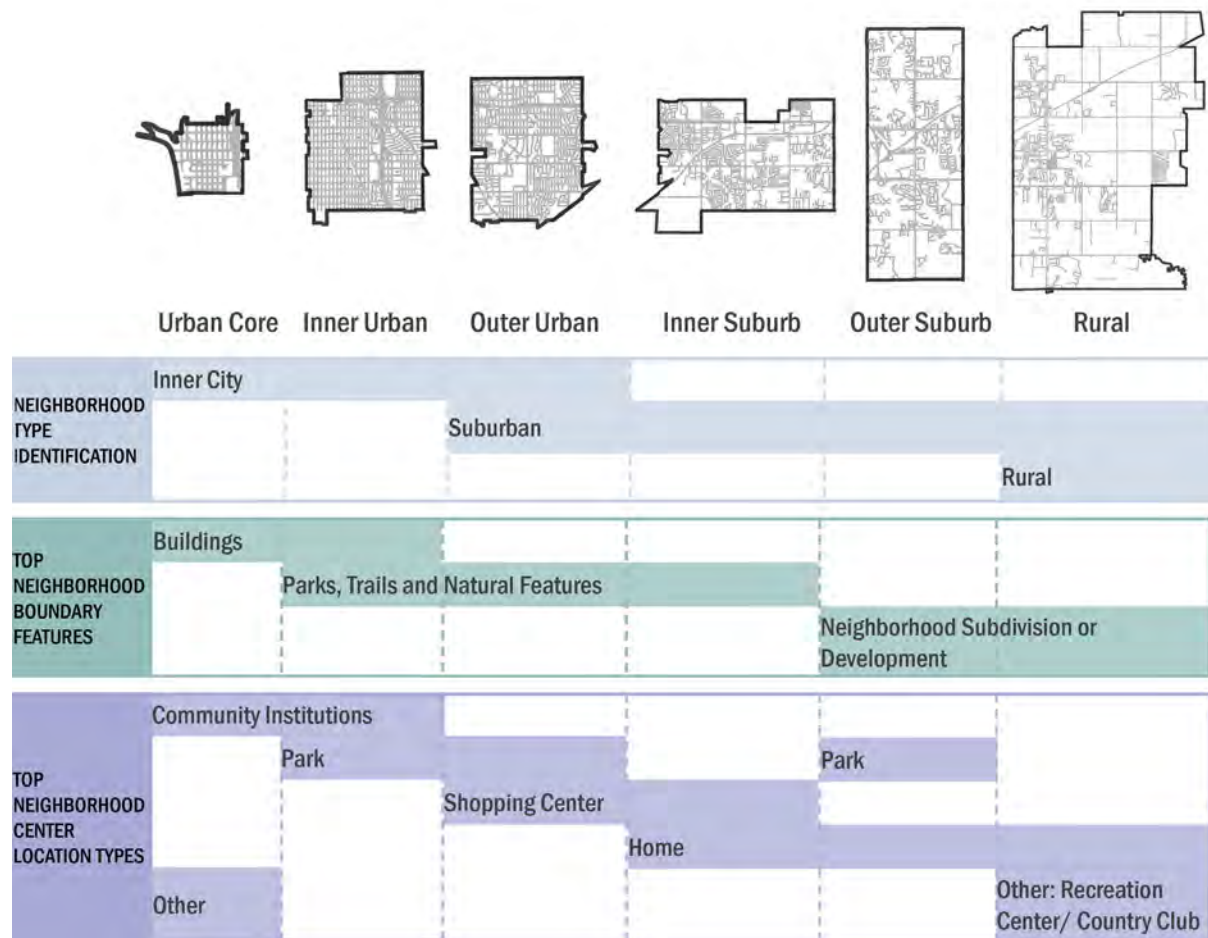

Figure 4. Neighborhood Characteristics by Neighborhood

Access to Basic Community Health Needs

Overall, a majority of respondents (87%) identified the food store that they visit most frequently. Fewer identified their healthcare facility (74%). Overall patterns of travelling to food and healthcare were similar in origin point, and satisfaction, but differed in mode, frequency of travel, travel companions, time, and distance. The most common type of food stores visited were supermarkets and the most common type of healthcare facilities visited were general practitioners. Generally, respondents travel to food stores and healthcare facilities from home, by themselves and by vehicle. Respondents were generally satisfied with their level of access to these community health needs. The majority of respondents travel to a food store at least once per week and travel to a healthcare facility a few times per year (Table 1).

Table 1. Travel Patterns by Type of Need

	Food	Healthcare
Type	Supermarket	General Practitioner
Origin Point	From home (88.2%)	From home (71.1%)
Satisfaction	Satisfied (87.5%)	Satisfied (83.3%)
Mode	Drive/ride in vehicle (96.3%)	Drive/ride in vehicle (96.6%)
Frequency	At least once per week (82.8%)	A few times a year (83.9%)
Travel Companion	Alone (75.1%)	Alone (74.4%)
Mean Network Distance	2.16 miles	3.33 miles

Access to Food by Neighborhood

Overall, the majority of respondents visit a supermarket or grocery store most frequently (92.4%), however, those in the Urban Core neighborhood were less likely to go to a supermarket or grocery store. Respondents generally use a vehicle to get to food stores, however in the Urban Core, respondents were more likely to bike, bus or walk (25.0%). Overall, travel time to a food store takes an average of 9 minutes, but in the Urban Core, the mean travel time to a food store was 20 minutes. Generally, respondents travel to food stores at least once per week (82.8%). Respondents in the Urban Core neighborhood were most likely to be dissatisfied with their food stores (50.0%).

The mean network distance to a food store was 2.11 miles. The Outer Suburb and Urban Core neighborhoods had the longest mean distances to food stores. The Inner Suburb and Inner Urban neighborhoods had the shortest mean distances to food stores (Figure 5). The longest individual distance to a food store was found in the Urban Core (7.69 miles) and the shortest individual distance was found in the Inner Urban (0.18 miles) neighborhood.

Letters indicate significant differences at $p < 0.05$.

Figure 5. Mean Network Distance to Food Store by Neighborhood

Access to Healthcare by Neighborhood

Overall, respondents indicated that they visit a general practitioner or family doctor (81.3%) most frequently. Respondents were most likely to have an ongoing or serious health problem in Urban Core (34.8%) and Inner Urban (40.6%) neighborhoods. Respondents in the Urban Core were more likely to bus, walk or bike to their healthcare facility than all other neighborhoods. Respondents were generally satisfied with their healthcare facility. Respondents in urban areas were more likely to travel to healthcare alone than respondents in rural areas.

The mean network distance to a healthcare facility was 3.33 miles. The Outer Suburb had the longest mean distance to a healthcare facility. The Urban neighborhoods had the shortest mean distance to a healthcare facility (Figure 6). Both the longest (12.56 miles) and shortest (0.35 miles) individual distances to healthcare were located in the Inner Suburban neighborhood.

Letters indicate significant differences at $p < 0.05$.

Figure 6. Mean Network Distance to Healthcare by Neighborhood

Patterns begin to emerge regarding overall neighborhood access to community health needs (Table 2). The longest distances to community health needs are located in the Outer Suburb and in the Urban Core (for food only). The shortest distances to community health needs are located in the Inner Urban and Inner Suburb (for food) and the Outer Urban neighborhood (for healthcare).

Table 2. Mean Network Distances to Community health needs by Neighborhood

Mean Network Distance (miles)	Urban Core	Inner Urban	Outer Urban	Inner Suburb	Outer Suburb	Rural
From Home to Food	3.42 ^a	1.61 ^c	2.15 ^b	1.34 ^c	2.87 ^a	2.21 ^b
From Home to Healthcare	2.58 ^{bc}	2.55 ^{bc}	2.30 ^c	3.85 ^b	5.45 ^a	3.51 ^b

Note: Superscript letters indicate significant differences at $p < 0.05$.

Discussion

Research on neighborhood perceptions show that residents in urban areas tend to identify their neighborhood as smaller than suburban areas (Haney and Knowles 1978, Haeberle 1988, Chaskin 1997). Additionally, certain demographics (minorities, older adults, long-term residents) have been known to perceive their neighborhood as smaller than others (Pebbley and Sastry 2009). In this study, however, the perceived size of each neighborhood did not vary significantly. Overall, little variation in racial and minority demographics were seen in this study, so little effects could be attributed to racial or ethnic makeup in the neighborhoods. While some neighborhoods showed higher percentages of older adults and longer tenure in their neighborhood, a relationship to neighborhood size was not found. This could be because the neighborhoods were being compared between urban, suburban, and rural instead of just urban to suburban as was the case in some studies (Haney and Knowles 1978). It could also be related to the type of cognitive mapping used in this study. Many studies that include neighborhood mapping provide residents with a blank canvas (Orleans 1973, Coulton *et al.* 2001), whereas this study provided a base map containing the information of street and location of community health needs for respondents to draw and identify what they perceive and use.

While the perception of size did not vary among neighborhoods, the distances from home to neighborhood center did vary significantly between neighborhoods. The distances to the neighborhood center in the Outer Urban and Rural neighborhoods were more than twice as long as the distance to neighborhood center for all other neighborhoods. This could mean that neighborhood size may actually vary, but not in a way that is perceived by residents. Still, in all six neighborhoods, the mean distance to neighborhood centers generally aligned with the recommendations of neighborhood planning theories of $\frac{1}{4}$ mile to $\frac{1}{2}$ mile distance to the neighborhood center (Perry 1929, Calthorpe 1993).

Neighborhood planning theories identify the types of community institutions that should be at the center of a neighborhood. These recommendations primarily include schools (Perry 1929) and shopping centers (Stein 1949, Spreiregen and De Paz 2005). Few residents in this study identified schools as their neighborhood center. In fact, the mean distance to school overall was nearly 3 miles. However, residents in the Urban Core and Inner Urban neighborhoods exhibited tendencies of a structural or institutional perspective, one that orients community institutions at the center. Whereas suburban and rural residents were most likely to exhibit tendencies of an egocentric perspective, one that situates home at the center of a neighborhood (Guest and Lee 1984, Lee and Campbell 1997). Demographic characteristics of these types of perspectives identified in Lee & Campbell's study (1997) were also seen in this study. For instance, in both studies, the residents with structural/institutional neighborhood perspectives were more likely to be male, single, and have shorter housing tenure (Lee and Campbell 1997).

Neighborhood boundaries are thought to be made up of visible or invisible features (Park and Rogers 2015). In Lynch's foundational work regarding elements of a city, an "edge" relates most closely to the idea of the neighborhood boundary. Lynch's work acknowledges that edges, or boundaries, can be composed of different elements (Lynch 1960). In all neighborhoods, a majority of residents noted roads as components of their neighborhood boundary. Residents in urban and areas also used buildings or parks/trails as references for drawing their neighborhood boundary. The use of buildings or landmarks to delineate neighborhoods is not uncommon. Buildings can represent a contrast in land use from residential areas, and can allow buildings to serve as effective borders (Alexander *et al.* 1977). In the outer suburban and rural areas, buildings were not often used to create neighborhood boundaries, rather residents identified their particular subdivision or residential development's boundaries. Residents in the rural neighborhood were more likely to draw their neighborhood irrespective of the elements on the map. Interestingly, residents in planned neighborhoods are typically found to have a clear understanding of their neighborhood boundaries (Park and Rogers 2015). Perhaps, in suburban and rural areas, boundaries are known, but residents have little say in the creation of them.

Residents generally categorized their neighborhood as its appropriate urban context (urban, suburban, rural). Respondents in the Urban Core were resolute in their characterization of their neighborhood as inner city or downtown, but all other neighborhoods were less unanimous. While the rural neighborhood studied in this sample included some subdivisions that could be considered suburban, residents in this neighborhood still identified as living in a rural area. The lack of clarity in defining urban contexts on a national level underscores the increased variation seen in neighborhood characterization in non-urban areas along this transect.

Generally, travel patterns to community health needs did not vary by neighborhood or urban context. However, the urban core was most likely to bike, bus, or walk to all three community health needs. The Urban Core also had the fewest mean number of vehicles per household. Residents in urban centers are known to make more trips on public transit than those that live a further distance from the urban core (Millward and Spinney 2011). Additionally, research shows that people living in urban areas are more likely to walk while residents in rural areas are less likely to walk (Frank *et al.* 2008, Kegler *et al.* 2015).

Distances to community health needs among neighborhoods varied. Overall, the Outer Suburb had the longest distance to community health needs. Generally, the distances to community health needs were longer in the suburbs and rural neighborhoods, but not always. Conversely, the urban neighborhoods generally had shorter distances to community health needs, but not always. The Urban Core had the longest mean distance to food stores, but some of the lowest distances to healthcare. Generally, the neighborhoods that had longer mean distances to community health needs also had fewer locations of community health needs identified in their neighborhood. Compact built environments, low residential population density in urban core due to concentration of businesses, and lower socioeconomic status of residents have been cited as challenges for sustaining retail food stores in downtown urban areas (Walker *et al.* 2010). Access to healthcare facilities, as measured in distance, has been shown to decrease as one moves further from the center of a city (Bissonnette *et al.* 2012).

This research finds that there are differences in ways that residents perceive their neighborhood boundaries and centers among neighborhoods along the urban to rural gradient. Connections to the recommendations of planned neighborhood theories exist in all urban contexts. Travel patterns along the urban to rural gradient did not differ among neighborhoods even though the distances did. This research found that more differences occurred along neighborhoods regarding neighborhood characteristics than access to community health needs. The imperative to access food and healthcare could imply that distance is not always the most important concern.

Future Research

Further research needs to be done to understand the underlying contexts that affect the patterns seen in this study. Additional external factors likely had an impact on the differences in neighborhood patterns and characteristics that were not explored in this study. Information related to household workplaces in relation to accessing community health needs would likely provide deeper context into the reasons that some drive further to access community health needs.

This study applied the transect methodology to understand differences among neighborhoods along a 15-mile transect. This methodology could be applied to an urban to rural gradient that spans a larger area, potentially 30-60 miles long which could confirm the patterns seen within neighborhoods in this study and illuminate patterns evident in neighborhoods of starker contrast.

Conclusion

Two main research questions were posed in this study:

Do urban, suburban, and rural residents classify their neighborhood centers and boundaries similarly?

This research identified patterns in perceived neighborhood characteristics like boundaries and neighborhood centers. Residents identified their neighborhood centers and boundaries differently among urban, suburban, and rural areas. Urban areas were more likely to identify landmarks outside of their home as the neighborhood center or as part of their neighborhood boundary, while suburban and rural residents were more likely to identify their home as the neighborhood center and use subdivision boundaries as neighborhood boundaries. Patterns found in suburban and rural neighborhoods resembled each other more than patterns in urban and suburban neighborhoods. This is important to note because of the way that suburban areas are typically considered part of urban areas.

Do neighborhood residents' patterns vary in accessing community health needs of food and healthcare?

This research identified patterns in accessing community health needs like food, healthcare, and education along the urban to rural gradient. Travel patterns in access community health needs were not shown to vary significantly except for in mode of travel in the Urban Core where residents were more likely to bike, bus, or walk to community health needs. Significant variation occurred regarding the network distance to community health needs. The Outer Suburb neighborhood had the furthest mean distance from all three community health needs while the Inner and Outer Urban neighborhoods has the shortest mean distance to community health needs.

The transect methodology approach was useful in identifying patterns and differences among neighborhoods along an urban to rural gradient. In some cases, differences were not seen; the perception of neighborhood size did not vary among urban contexts as was anticipated. Variation in density and urban form are evident along the transect, but neighborhood size perceptions are not. In other areas, differences occurred where expected; the differing characteristics of neighborhood centers in urban, suburban, and rural areas.

Perceived neighborhood characteristics were more likely to vary among neighborhoods than travel patterns to community health needs. While accessing basic need is an important component of day-to-day life, the community health needs appear to have less linkage to a residents' perception of a neighborhood.

Many of the identified neighborhood characteristics in this study relate to neighborhood planning theories and their range of possibilities for neighborhood characteristics. The lack of schools being cited as neighborhood centers, a foundational component of Perry's Neighborhood Unit Concept, raises the question of whether Perry's ideal neighborhood is as relevant as it used to be to the planning profession. However, programs like "Safe Routes to Schools" that encourage children and their parents to walk or bike to school could reinforce some of Perry's ideas moving forward.

Suburban and rural neighborhoods tended to behave similarly more so than suburban and urban neighborhoods. This demonstrates that the current definition of urban and rural are not sufficient. Planners are known to use established administrative boundaries when conducting neighborhood level plans. If planners are using the urban/rural designation to determine neighborhoods, this could lead to inappropriate planning recommendations. Instead of comparing strictly urban to rural, this study provides a framework for planners to understand and assess differences along a gradient that is relevant for future planning projects.

Abstract: The built environment encompasses the major physical spaces, including buildings, streets, homes, schools, parks, playgrounds and other infrastructure in which we live, work and play. In an ideal world, the built environment should support and promote physical activity across the lifespan. However, with increased mechanization and urbanization, physical inactivity and higher levels of chronic diseases such as obesity become common among urban residents. Pudong District covers an area of 1,210 square kilometers with 12 streets and 24 towns. With urbanization in China, it formed unique built environment that high levels of residential density and low-density township environment both exist in this District. Physical inactivity increases risk of chronic disease, this study examine relationships between built environment and chronic diseases using spatial models. We use gis-data to explore whether mixed land-use, high levels of street connectivity, and accessible facilities can reduce the incidence of urban residents' chronic diseases. The survey consists two parts: First, the public service facilities poi and road data are used to calculate the built environment feature in Pudong District. Second, the sample address information is re-encoded, and the spatial distribution characteristics of chronic disease patients are obtained through point density analysis of gis. We conduct follow analysis : 1) overlay analysis of high-density residential areas and high chronic disease incidence, to figure out whether supportive built environment may have lower prevalence of chronic disease. 2) Comparative analysis of the built environment characteristics between urban streets and township streets in Pudong District and the spatial distribution characteristics of chronic disease patients. Our analysis suggests there is an association between built environment and chronic disease.

Keywords: health city; built environment; type 2 diabetes; gis; linear regression analysis

1. Introduction

This study is based on the theoretical and empirical contributions of the health literature. The research data is based on the 2016 Diabetes Community Hospital credit card data of Shanghai Pudong District, with 26,687 records. The elderly patients with type 2 diabetes who were older than 60 years old were selected as the final study samples, and a total of 8246 samples were obtained. Since the impact of the built environment on physical health should be a long-term continuous effect, the household registration population of Shanghai Pudong district is selected as the research object to reduce the impact of environmental changes on its health. The samples are mainly distributed in 12 streets and 24 towns except. The address information is spatially encoded using gis to obtain the spatial distribution map of the research samples (Fig. 1). The calculation data of the built environmental factors in the study are the POI data of various facilities in Shanghai in 2016 and the GIS files of Shanghai Road Network. The data population used for calculating density in each street is the sixth census data in 2016.

Figure 1 Spatial distribution of type 2 diabetes patients over 60 years old in the study

2.Review

The study of the relationship between built environment and physical activity has always been the focus of academic research. Lack of physical activity has become a major cause of overweight, obesity, diabetes, heart disease and some cancers. Environmental and policy interventions have become an important means of promoting physical activity, and a large number of studies have shown that the supporting elements of the community environment are closely related to physical activity. (Ball et al., 2001) With the World Center for Disease Control and Prevention (CDC), the dynamic community environment (ACES) is able to promote the active participation of all ages people in physical activity. Since 2004, the research has covered the field of health, and a large number of literatures have analyzed the built environment. The correlation between physical health and good community environment can promote the physical health of residents, thereby reducing the proportion of obese people and chronic diseases caused by obesity and improving overall health. In recent years, planners have begun to think about the relationship between built environment and physical health, and hope to promote people's physical activity through reasonable planning. Through the study of the relationship between built environment and physical activity, there is sufficient research foundation to show that the built environment affects physical activity, so we have reason to believe that the built environment will affect people's body index to a certain extent.

2.1 Study on the relationship between built environment and type 2 diabetes

In order to better understand the relationship between the built environment and type 2 diabetes and clarify the intrinsic impact of the built environment on type 2 diabetes, this study's literature review that is based on the web of science database use the software citespace to process quantitative analysis, with the literature from 2000-2018 as a sample. The key words for literature screening were built environment, type 2 diabetes, body mass index (BMI), obesity, and sandentary lifestyle which are closely related with build environment and diabetes. 1,709 articles were finally obtained.

The citespace co-citation network mapping function was used to analyze the citations, and the co-citation network of the relationship between the built environment and type 2 diabetes was generated as a time interval (Fig. 2). Through the analysis of citations, we can see that each node in the figure represents the cited article, and the nodes are composed of different rings of some circles. The larger the radius, the higher the frequency of citations, and the connection between nodes indicates a total of The relationship between the two indicates the strength of the co-introduction. It can be seen from Fig. 2 that the literature co-citation network from 2000 to 2018 has obvious natural clustering, and the clusters are linked through 10 key documents (betweenness centrality ≥ 0.1). In 2018, the clustering is in the lower left, and in 2000, the clustering is in the upper right. Explain that the flow of knowledge is relatively clear and the links between knowledge bases are very close.

Figure 2 Citation analysis

At the same time, the keywords are clustered to generate Keyword Clustering Common Word Maps, and the 8 clusters represent the main research fields of international literature on international built environment and type

2 diabetes in 2000-2018, namely: children, walking , diet, participation, childhood obesity, community planning, intervention, effectiveness, and social environment (Figure 3).

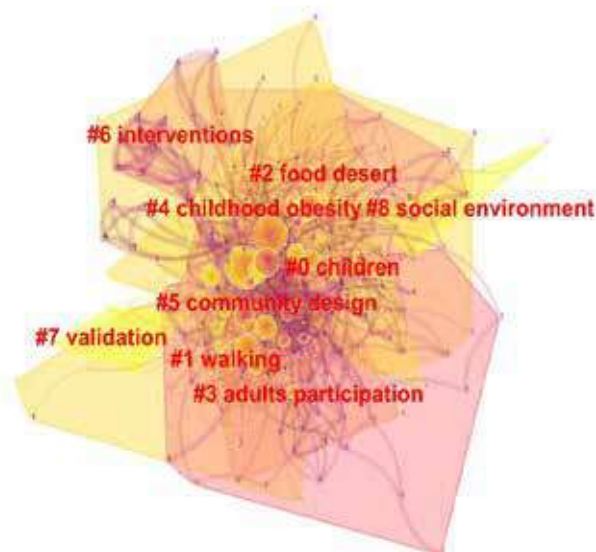

Figure 3 Keyword cluster analysis

Numerous studies have confirmed that the characteristics of the community or living environment may affect health and lead to social and ethnic inequalities in health. Cluster analysis can be seen that the built environmental elements associated with walking and diet are the focus of research. Over the past 15 years, research on the health effects of communities has grown exponentially, with increasing attention to chronic diseases (obesity and related risk factors) and mental health (depression and depressive symptoms). For each type of empirical research, it is divided into two layers: one is to use the census data to directly measure the built environment attributes for correlation analysis, and the other is to review the key concepts, core elements and methodological challenges that are affecting health, and try to clarify the field. Some knowledge gaps and promising new directions. (Auchincloss et al., 2013)

Figure 4 keywords timeline

2.2 Built Environmental Factors That Affect Physical Activity And Physical Health

1) Net residential density (Net residential density)

The net dwelling density is equal to the number of people per acre of land in the household census block. The census data is allowed to be used for population estimation in the calculations and is a more accurate source of data than the 1 kilometer buffer level data. Studies have shown that residential density can promote walking to a certain extent, so it is expected to have a negative impact on obesity. The role of net dwelling density in the study is often used as a control variable [3], or the stratification of the study sample based on the density of the dwelling density [4], and the density of dwelling as part of the evaluation of the walkable index (Smith et al., 2008).

2) Mixed use of land

Some studies have shown that the mixed use of land can promote people to walk, and the main four land uses for calculation are residential, commercial, office and educational facilities. The specific measures for the mixed use of land have the following types of methods in the study:

Entropy Scores: The entropy is obtained by predicting the walkability index through a series of predictors (such as residential density, street connectivity, etc.). The method used to calculate the entropy value was proposed by Lawrence Frank and colleagues. Through two different sets of data, the calculated results are fully correlated with body weight and walking. Entropy has the characteristics of including a wide range of land use categories, but this method also has some drawbacks, which obscures the contribution of individual land use categories. For example, in the calculation, the number of land use categories included will affect the entropy result, less The land use may have the same entropy value as for more land uses, and the land use that is not included in the calculation will also affect the calculation results to some extent (Frank et al., 2006).

$$Lum = - \sum_{i=1}^n p_i * \ln p_i / \ln n$$

Destination-Based Measures: The destination measure is mainly to mark the density of various destinations and the average distance to the place of residence by marking the walking destination around the place of residence. The choice of destination can include multiple types, including Parks, fast food restaurants, hospitals, schools, vegetable markets, shops, etc. [7] B. Brown et al. selected three types of facilities closely related to walking in the study of the relationship between land use mix and body mass index (BMI) and obesity: rail transit stations, bus stops, and parks. This method also has certain limitations and cumbersome measures. (Brown et al., 2009)

Proxy-Based Measures: This method uses substitute variable to measure the mix of land use. The first is the number of residents who walk to work in one block, and the second is the age of housing. However, this method is not suitable for large sample size calculations.

3) Street Connectivity (street Connectivity)

Street connectivity is measured by the number of road intersections in the residential buffer zone, more than three intersections per square kilometer are considered to have connectivity.

4) Facility accessibility and distance

This type of research is mainly divided into two levels, one is the built environmental factors related to walking, and the other is the body index and health-related facilities. Although the built environmental elements involved in the two types of research overlap, they also have different emphasis. The facilities related to walking are

mainly parks, open spaces, etc., and health-related facilities are mainly food-related, such as supermarkets, restaurants and other facilities(Nagel et al., 2008).

3.Spatial Distribution Characteristics Of Research Samples And Built Environment Elements

3.1 Analysis of spatial distribution characteristics of research samples

ArcGIS software is used for data acquisition and development, as well as subsequent spatial analysis. All residents in the study used address geocoding before calculating the environmental variables built by the GIS. The result of this geocoding process creates a spatial coordinate for each resident's home, allowing further analysis of the relationship of these locations to other GIS layers. Of the 8246 subjects, a total of 8211 were successfully address-matched with an accuracy rate of 99%. The map shown in Figure 1 shows the geocoded locations of the study samples within the study community.

The standard deviation ellipse analysis is performed on the sample data. The generated semi-axis of the ellipse represents the direction of the data distribution, and the short semi-axis represents the range of the data distribution. The larger the difference between the length of the long and the short axes (the larger the flatness). The short semi-axis represents the range of data distribution. The shorter the short semi-axis, the more obvious the centripetal force of the data presentation. Conversely, the longer the short semi-axis, the greater the degree of dispersion of the data. It can be seen from the standard deviation ellipse analysis of the overall sample data that the sample distribution has a certain directionality and centripetality. Generating the area representation range, we can see that the main morbidity range of the sample is concentrated in the northwest region. This area is mainly a high-density urban area. The flat rate indicates his direction clarity and centripetal force. We can see the incidence trend of Pudong district have a clear direction.

The point density analysis of the study samples can be seen: red is high prevalence, yellow is low prevalence, and high-risk areas of type 2 diabetes are high-density urban space along the Huangpu River, and expand with

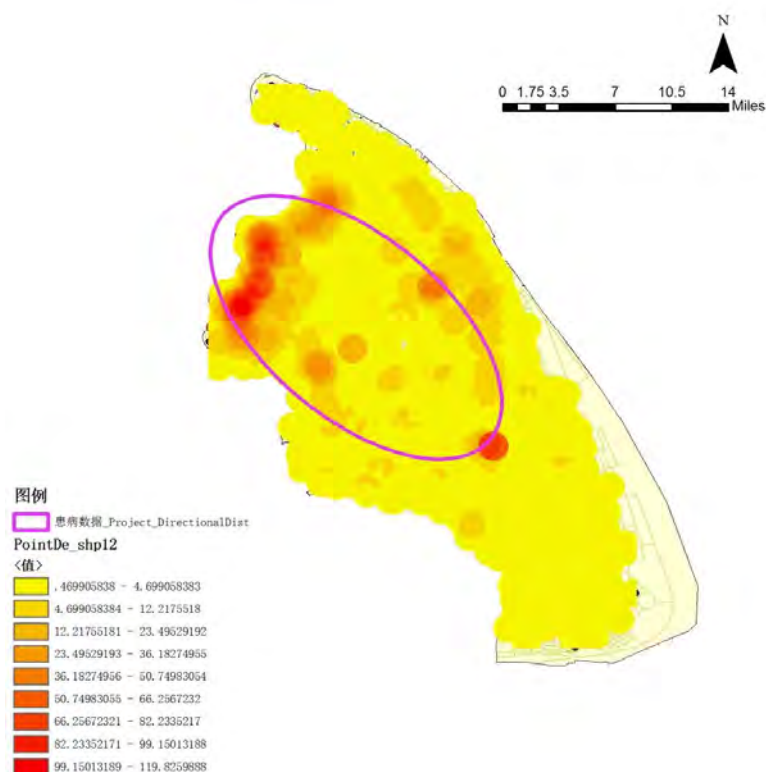

Figure 5 Sample point density and standard

the north-south direction of space.

3.2 Analysis Of Spatial Characteristics Of Built Environment Elements

ArcGIS is used to calculate the characteristics of the building environment in each block. The literature review shows that the built environmental elements that are most closely related to physical activity and health outcome are: (1) food-related facilities (supermarkets, restaurants) Facilities related to physical activity (fitness center, community center); (3) green open space and recreational space (including public parks, open area playgrounds, shopping malls, etc.). Based on the POI data of these facilities, the number of facilities distributed in each study street was calculated, and the density of each street facility was calculated according to the street layer (figure 6) .

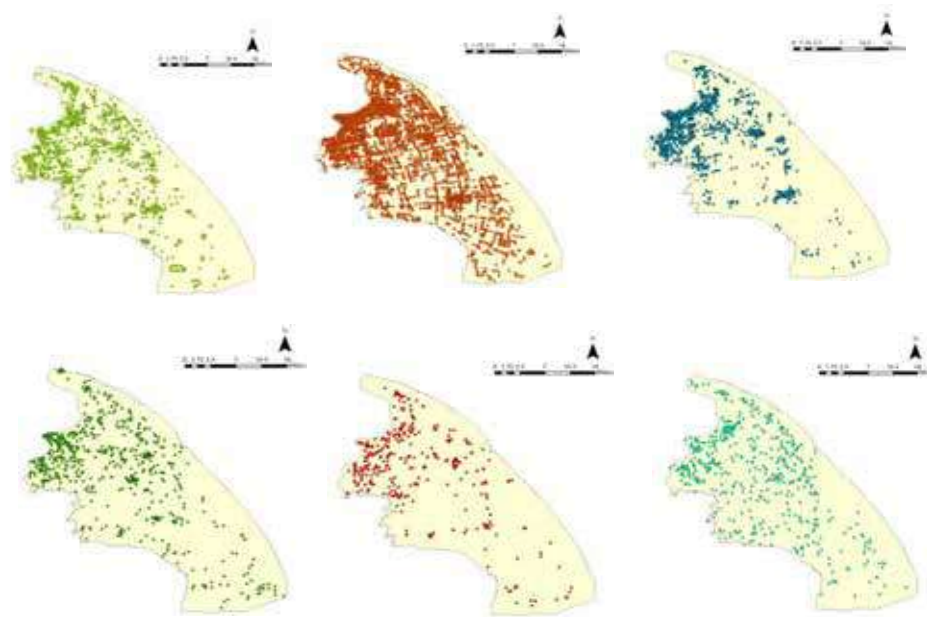

Figure 6 Spatial distribution of various facilities

The current measurement of the built environment focuses on the use of GIS for quantitative analysis, making the results more reliable. At present, some studies have suggested that previous studies have focused on the study of related relationships, and the results of the research are not very applicable. If epidemiological studies based on environmental exposure are used to investigate the effects of environmental density and quantitative levels on physical activity, the results of the study are The application has a better guiding significance. (何晓龙, 2017) In the calculation method of built environment index density, many current studies recommend the use of nuclear density analysis. The significance of the nuclear density equation is that the density distribution is highest at the center of each xi point and decreases outward. When the distance reaches a certain threshold range (edge of the window), the density is 0, and the nuclear density at the center x of the grid is (Cerin et al., 2006) :

$$f(x) = \frac{1}{nh^d} \sum_{i=1}^n K\left(\frac{x-x_i}{h}\right)$$

Here K() is the kernel density equation, h is the threshold, n is the number of points in the threshold range, and d is the dimension of the data. For example, when d=2, a commonly used kernel density equation can be defined as:

$$f(x) = \frac{1}{nh^d} \sum_{i=1}^n K\left(\frac{x-x_i}{h}\right)$$

Based on the nuclear density analysis method, this study geocodes the research samples to the nearest street, and uses ArcGIS10.3 software to calculate the indicators of each built environment (table 1) .

4.Analyse

The spatial research analysis is divided into two parts. One is to calculate the prevalence of each street by using the spatial distribution of the patient population, and obtain the spatial distribution map of the prevalence rate (Fig. 7).we can see the spatial differences in the incidence of type 2 diabetes in Pudong district, high-incidence streets and low-incidence streets. The second is to use the calculation results of the built environment elements calculated by gis, and compare and analyze the disease situation of each street in space, and use gis to normalize the environmental density and prevalence of each built environment, and obtain Figure 8. By comparison, it can be found that areas with low prevalence tend to have more homogeneous service facilities, and various facilities have higher density in spatial distribution; high prevalence is concentrated in urban high-density areas and central areas. Urban and rural areas combined with urban and rural characteristics. Although the high-density urban-type area has a perfect built environment configuration, due to the restrictions on land use and population, the per capita facilities use less land. For urban-rural areas, on the one hand, there are differences in the layout of facilities in urban areas, and on the other hand, The space environment is biased towards the street and the wide road network, which limits the physical activity of the residents to a certain extent. Therefore, the prevalence rate in these areas is relatively high.

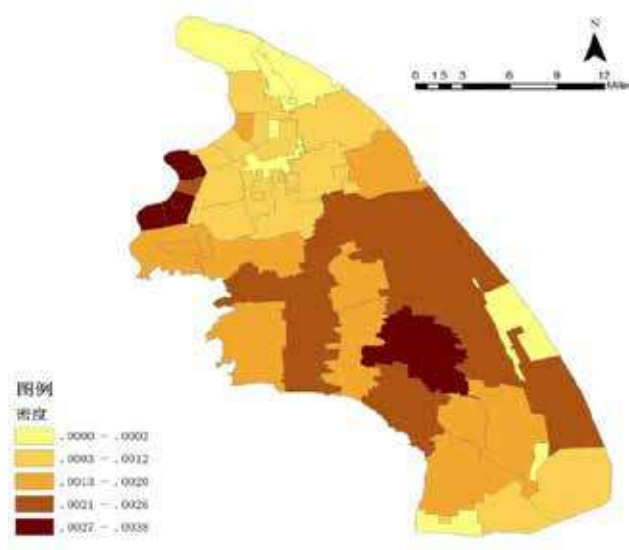

Figure 7 Disease density of each street

Figure 8 Comparison of disease density and density of various facilities in each street

In order to further analyze the relationship between the built environment factors and the prevalence rate, according to the area of each street, calculate the density of various facilities, and carry out regression analysis with the disease density of each street to quantitatively analyze the relationship between them (table 2) . Through the analysis of the regression results, we can see that the two variables of open space and surrounding leisure tourism facilities passed the significance test in the model, and the other variables failed the test in the model. By analyzing the statistical results of variables in different models, the stability of the relationship between the prevalence and the intensity of each street of the dependent variable can be judged. Model 2 reflects the variable relationship more comprehensively. The results show that the indicators that play a positive role in the physical health of residents include the open space area, that is, the number of physical activity facilities such as park green space and squares around the community. This shows that when the living space around the residents has a fitness park, it has a significant effect on physical activity, thereby promoting the physical health of the residents.

5.Results

As a space carrier for the daily life of the citizens, the urban built environment has shaped the lifestyle of the residents and affected the health of the residents. Since the 20th century, chronic diseases caused by lack of physical activity have attracted widespread attention from scholars at home and abroad. A large number of empirical studies abroad have clarified the factors that influence the urban built environment on the physical activity of residents by tracking observations and cross-section confidentiality. In order to further test the universality of the existing conclusions, this paper conducted a regression analysis based on the streets of Pudong District, Shanghai.

The study found that good community space structure and community outdoor activity space can have a positive and significant impact on residents' physical health. Outdoor activities such as parks in the living circle near the community can significantly stimulate residents' willingness to carry out physical activities and promote the physical health of residents. Therefore, in the future, for community planning in healthy cities, it is necessary to rationally set up community facilities and improve the environmental quality of facilities. In the future, this research can be further expanded to analyze the relationship between the built environment and physical health from the community and individual levels.

² *Centre for urban and rural planning support research, Huazhong University of Science and Technology, Wuhan, China*

Abstract: Improving greenness level is proved to have the potential to enhance green space use and outdoor physical activity level. However, high urbanization level and rapid densification process make green space - especially urban public green space - gradually lost and fragmented, which results in small or even no further land for public green space. Identifying such challenges, some planners and researchers suggest to connect existing urban public green space to encourage use and improve public health. Does it indeed work? Considering that, we research on the relationship between the connectivity of urban public green space and use in Wuhan inner city. In detail, we refer to the Integral Index of Connectivity in landscape ecology theory to calculate the connectivity of urban public green space by the unit of sub-district. Besides, Location Based Service (LBS) data - Tencent Yichuxing - is collected to measure the green space use of every study unit. Based on that, we make a further analysis between the two by Pearson correlation in SPSS. However, there exists in negative correlation between the connectivity of urban public green space and green space use, which is potentially due to the characteristics of public green space (such as quality and accessibility) weighing more than connectivity on promoting green space use.

Key words: urban public green space use, connectivity, LBS, Wuhan inner city

Introduction

Regular physical activity is proved to play a key role in avoiding and relieving chronic diseases –including diabetes, obesity, cardiovascular diseases, depression, etc.– and premature death (Warburton et al. 2006, Lee et al. 2012, de Rezende et al. 2018). As the evidence that physical activity contributes to improving public health gradually becomes well-grounded, increasing authorities and governments place the emphasis on promoting physical activity. For example, variety of relevant strategies and plans are proposed in the world to enhance public physical activity level, such as the Global Action Plan on Physical Activity 2018-2030 (WHO, 2018) and Physical Activity Strategy for the WHO European Region 2016–2025 (WHO Regional Office for Europe, 2016). Particularly, most of those policies stress the importance of open space especially urban green space on enhancing physically active, because study after study has demonstrated urban green space is a significant catalyzer in encouraging physical activity. For instance, it could conduce to improve frequency, intensity and duration of outdoor physical activity (Pate et al. 2008, Schipperijn et al. 2010, Coombes et al. 2010, Han et al. 2013, Kondo et al. 2009, Dadvand et al. 2014). Besides, taking physical activity within such natural environments could benefit more than that in non-green settings (Pretty et al. 2005, Taylor and Kuo 2009, Gidlow et al. 2016).

However, the process of urbanization and densification leads to open space, especially green space constantly decreasing and fragmenting in urban area (Xu et al. 2011, Kabisch et al. 2015, Haaland and van den Bosch 2015), which means that green space use and physical activity generated by green space might be discouraged by such built environment changes. On one hand, continually shrinking urban green space cannot meet residents' growing demands due to the inadequate and scarce provision; on the other hand, the disequilibrium of urban green space distribution potentially results in its unequal accessibility and availability. Indeed, series of studies have suggested that green space use and physical activity level within it are significantly and strongly influenced by quantity, quality as well as configuration of urban green space (Schipperijn et al. 2010, Thompson et al. 2014, Richardson et al. 2013, Vujcic et al. 2019), whereas it is almost impossible to largely build new green space in the intensively compact urban area or widely revise the structure of existing urban green space system to improve public green space use and physical activity. Considering that, several researchers argue that enhancing the connectivity of actual green space by referring to the principals of landscape ecological is probably the relatively economic and efficient way to handle with the forementioned challenges (Zhang et al. 2015, Jim 2013, Oh et al. 2011).

Based on the talked above, this paper aims to explore if the solution of improving connectivity of existing urban green space would be a useful way to promote green space use. Since public

green spaces are the accessible green infrastructures and free resources that can be available by all residents, therefore, we concentrate on the urban green space that is open to public in this study. In detail, the paper analyzes the correlation between the connectivity of urban public green space - calculated by applying the Integral Index of Connectivity in landscape ecology theory - and green space use through the empirical study in Wuhan inner city.

Data and Method

Study area

Wuhan, the capital of Hubei province and one of the China's megapolises, is located in the middle area of China and plays the roles of transportation hub and core of economic, technology as well as commerce trade logistics in those middle-area cities. The urbanization rate is 80.29% and approximately 647 million residents live in urban area in 2018 (Statistics Bureau of Hubei Province 2019). What's more, it is divided by Yangtze River and Han River into three parts of Hankou, Wuchang and Hanyang, which totally includes 13 districts. The scope of this study - Wuhan inner city - consists of 7 districts, namely Wuchang, Hongshan, Qingshan, Hanyang, Jiang'an, Qiaokou and Jianghan (depicted as Figure 1). Besides, each district contains several sub-districts/ *Jiedaos* (sub-district, also translated into *Jiedao*, is the lowest administrative unit in China) and 96 sub-districts are encompassed in total within the study area. In this study, we take sub-district as the basic research unit.

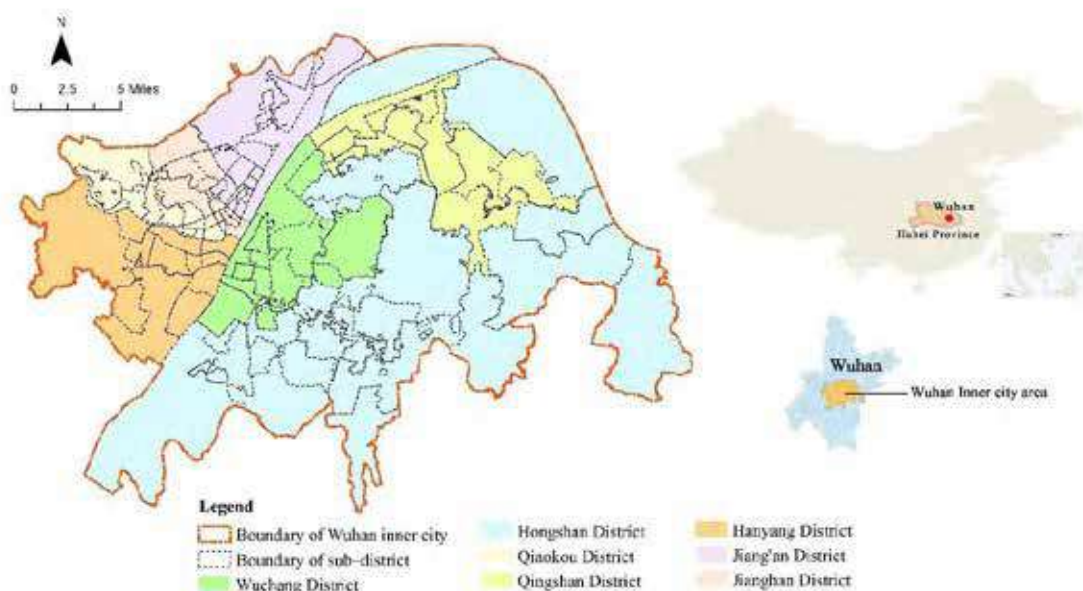

Figure 1 The location of Wuhan inner city area

Data collection

- Public green space

The distribution of public green space within inner city is extracted from the vector-graph of green space system provided by the official greening department in Wuhan. Public green space in this study consists of parkland (including comprehensive park, neighborhood park, theme park and pocket park), land for squares (green space proportion more than 35%), and parts of ecological green space as well as attached green space that can be accessible and used. Besides, according to the published studies, 1 hectare or more is proved to be the reasonable area for green space use especially for physical activity (Van den Bosch et al., 2016). Hence, that size is employed for the public green space selection (detailed distribution of PGS in Figure 2).

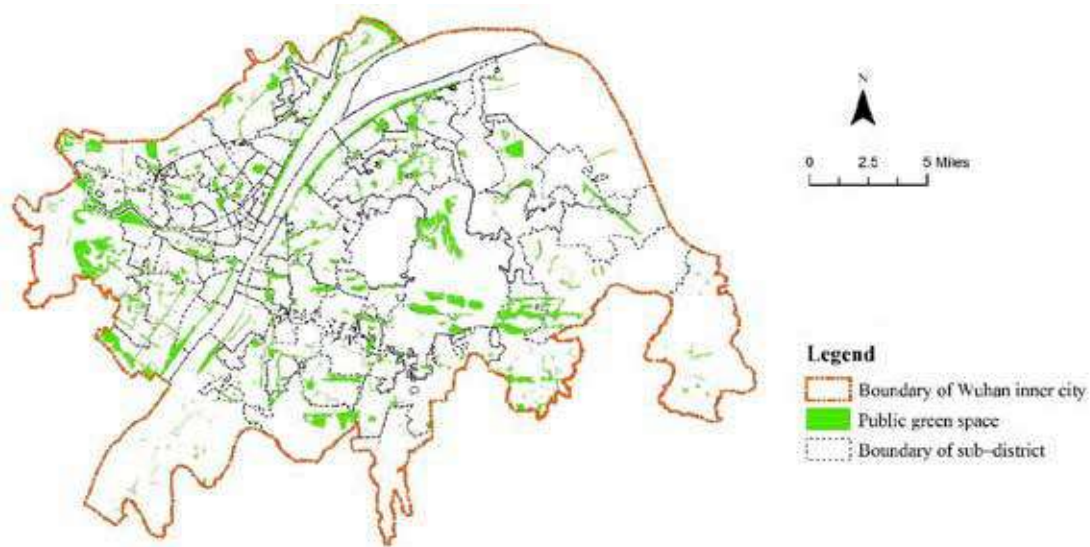

Figure 2 The distribution of public green space in Wuhan inner city

- Location Based Services data

Location Based Services (LBS) data in this paper is obtained from WeChat of Tencent company, which is the most popular social media app in China. Yichuxing is a function of WeChat to reflect population distribution by acquiring users' mobile terminal real-time position information (longitude and latitude), and the values of Yichuxing is the standardized data of actually being collected population. Therefore, it can be used to represent the relative population in a certain area. Here we apply it to calculate the relative use of public green space. Data acquisition time in this paper is a week (7 days) and the weather is non-rainy during this period. Further, it starts from 6:00 a.m. and ends at 22:00 p.m. every day with two hour-interval. In other words, there are 63 time points (9 time points/ day * 7 days) of such data acquired in total.

Variables calculation

- Public green space use

Public green space use of each sub-district is measured by relative population density within it. Since the values of Wechat - Yichuxing is the kind of real-time data, therefore, average relative population density of total public green space in each sub-district is calculated to reduce the impacts of data at different time points. The detailed calculation formulas are as follows:

$$P_i = \frac{\sum_{j=1}^n Q_{ij}}{d_i \sum_{j=1}^n G_{ij}} \quad (1)$$

Where P_i is the relative population density of public green space in sub-district i , d_i is the residential population density of sub-district i (This study takes it as a weight, when calculating the public green space use to reduce the influence of number difference of inhabitants in sub-district), Q_{ij} is the average relative population within public green space j that belongs to sub-district i , G_{ij} is the area of public green space j that belongs to sub-district i (in square meter), and n is the total numbers of public green space within sub-district i .

In particular,

$$Q_{j1} = \frac{\sum_{h=1}^w \sum_{t=1}^m X_{jht}}{wm} \quad (2)$$

or

$$Q_{j2} = \frac{\sum_{t=1}^w X_{jt}}{w} \quad (3)$$

Where Q_{j1} is the average relative population of public green space j per day, X_{jt} is the relative population within the public green space j at time t , m is the total time points per day (here is 9), w is the total days, and Q_{j2} is the average relative population of public green space j at time t . It is worth to note that for formulas (2), when w is respectively equal to 7, 5 and 2, Q_{j1} represents the average relative population of public green space j per day of a week (7 days), weekdays (5 days), and weekends (2 days) separately; for formulas (3), w is assigned as 7, which means that Q_{j2} measures the average relative population of public green space j at time t during a week. In order to explore if the time makes a difference in the impacts of public green space connectivity on green space use, we correspondingly calculate the relative population density of public green space in each sub-district at 9 time points as well as per day (separately based on a week, weekdays and weekends).

- The connectivity of public green space

The connectivity of public green space in each sub-district is measured by the Integral Index of Connectivity in landscape ecology theory, which has been developed maturely in ecology, and some researchers have applied it to study the connectivity of urban green space (Shi and Xu 2011, Mu et al. 2017). By referring to the relevant publications (Pascual-Hortal and Saura 2006, Saura and Pascual-Hortal 2007), the formula applied in our study is as follows:

$$IIC = \frac{\sum_{i=1}^n \sum_{j=1}^n \frac{a_i a_j}{1 + nl_{ij}}}{A_L^2} \quad (4)$$

Where *IIC* is the integral index of connectivity (ranging from 0 to 1), a_i and a_j respectively represent the areas of urban green space i and j (in square meter), nl_{ij} means the link numbers between public green space i and j (based on the topological distance), and A_L is the area of individual sub-district (in square meter).

Based on the analysis of distance (edge-to-edge Euclidean distances) between two arbitrary public green spaces in each sub-district by Arcgis extension, then we calculate the *IIC* in Conefor 2.6. It is worth to note that, considering on the issue focused on in this study is that the influence of public green space connectivity on its use, therefore, public green spaces within what distances can be taken into analysis is significant. According to the human's walking speed and the distance affecting users to access to public green space (Almanza et al. 2012, Kondo et al. 2009, McMorris et al. 2015, Catherine et al. 2013, Cohen-Cline et al. 2015), we separately take 500 m and 1000 m as the thresholds to decide which public green spaces are considered when calculating *IIC*.

Analysis method

Before correlation analysis, the process of data standardization (z-score) and descriptive statistics analysis (mainly inspecting outliers) is applied first to reduce the analysis error. Then the relationship between the connectivity of public green space and its use is analyzed by Pearson Correlation Analysis in SPSS 22. As mentioned above, we divide the average relative public green space use into two types by the unit of o'clock and day. In detail, the former includes 9 time points and the latter concerns 3 kinds of daily average. All of them are applied to test whether or not they correlate with *IIC* of public green space that is calculated based on 500 m and 1000 m respectively.

Results

Since there are some sub-districts that do not have the public green space meeting the requirements of area being more than 1 ha. What's more, even if some sub-districts satisfy that

standard, either the number of public green spaces within them is no more than 2 or the distance between the public green spaces within them is more than 1000 m. In a word, after neglecting those unfit sub-districts, there are 74 ones are taken into *IIC* calculation. Based on that, another two sub-districts are deleted due to the outliers, thus, only 72 units are left to be analyzed at last. According to the calculation results of *IIC*, we find that the connectivity of public green spaces within each sub-district is relatively low no matter it is based on the 500 m or 1000 m. For 500 m, the threshold of *IIC* is between 0.195 and 0 while for 1000 m, the one is from 0.202 to 0 (shown as Figure 3 and Figure 4).

Figure 3 The connectivity distribution of public green space (distance threshold: 500 m)

Figure 4 The connectivity distribution of public green space (distance threshold: 1000 m)

Depicted as Figure 3 and Figure 4, it is obvious that relatively high connectivity of public green space is almost in the small-scale sub-districts which locates in the old town of Wuhan, especially in the center of old urban areas, whereas low connectivity mainly lies in the large-scale sub-district, especially near the peripheral of the inner city.

Intriguingly, after visualizing the calculation results of green space use in different time, the sub-districts with high public green space use are not accompanied with high connectivity of public green spaces simultaneously. On the contrary, most high green space use distributes in low *IIC* areas, which are relatively new and near the periphery of inner city. Considering the words length of the paper, two types of public green space are selected to illustrate the detailed distribution (presented as Figure 5 and Figure 6).

Figure 5 The distribution of public green space use (during weekends)

Figure 6 The distribution of public green space use (on 20 o'clock)

The results of correlation analysis are shown as Table 1 and Table 2. Different from what we expect is that the *IIC* of public green space is negatively related with green space use no matter is statistically significant or not. From the perspective of distance threshold impact, the Pearson Correlations are almost same in both ranges. In other words, as long as the distance between two public green spaces is no more than 1000 m, the generated *IIC* might not make an apparent difference in the role of green space use. While when taking time into considering, there exists several variations in that relationship. In detail, *IIC* has a statistically significant correlation (within a 95% confidence interval) with the average public green space use during weekends and a week as well as on different time points (namely, 6 o'clock, 10 o'clock, 18 o'clock, 20 o'clock and 22 o'clock). That is to say such relationship is likely to be influenced by the characteristics of residents' daily behaviors.

Table 1 The correlations between relative public green space use (daily average) and *IIC*

Correlations						
Relative public green space use (daily average)	500 m_ <i>IIC</i>			1000 m_ <i>IIC</i>

*. Correlation is significant at the 0.05 level (2-tailed).						

Discussion

As mentioned above, the measurement of public green space use is based on the data of Yichuxing, which is obtained from WeChat users. Additionally, more than 90% of them, according to the Wechat Data Report in 2018, are less than 55 years old (WeChat Team, 2019). Public green space use (deriving from that data) during work and school hours or weekdays, therefore, might differ obviously from that during off-work and after-school hours or weekends, which indirectly mirrors the user group of public green space from single (mainly the elderly, during work and school hours or weekdays) to relatively diverse (during off-work and after-school hours or weekends). Moreover, series of studies have proved that various groups prefer and require different characteristics of green space, and take different types and levels of physical activity in it (Cohen, 2015, Mytton, 2012, Douglas, 2017). For example, Kaczynski et al. (2009) find that the area of neighborhood parks within 1000 m of individual's home could contribute to improving the level of physical activity for women as well as the younger (between 18 and 34 years old) and elder (more than 55 years old) groups. Similarly, Leslie et al. (2010) conclude that when local parks are safe, attractive and well-maintained, groups with high socioeconomic status have more park use and recreational walking. That is to say, the influences of public green space characteristics on use may vary with the user groups changing. Hence, off-work and after-school hours as well as weekends makes a difference on the correlations between *IIC* and public green space use likely due to the variation of user groups at different time.

Seemingly, the negative correlation generated in this study is unreasonable and opposite to the expectation that enhancing connectivity contributes to promoting green space use. After all, some scholars suggest that high connectedness among urban green spaces is good for the movement of both wild animals and human as well as public health (Tian et al. 2017, Selim and Demir, 2019, Zhang et al. 2015). However, it is worth to note that there is a basic difference of such movement between wild animals and human beings, which is that the former originally lives in the nature environment (that is a way of green space use per se) without need of considering the accessibility of those green spaces (Moving from one patch of green space to another is oriented by survival need for them), whereas people have to access to those nature places first if they want to use them and the activities happening within or inter green spaces are decided by many factors, such as the recreational demands and green space quality. That is to say good connectivity among green spaces is significant for biodiversity protection but not necessarily encouraging green space use for human beings.

Indeed, according to the analyzed results in this study, high connectivity- that represents good accessibility between green spaces but not equals to being accessed easily from other places

(like the residence, school and workplace)- locates in the old town where the quality of green space within it is poorer than elsewhere in Wuhan inner city, while high green space use primarily exists in the areas with relatively good accessibility. What's more, in the light of the characteristic evaluation of health-oriented green space in Wuhan inner city (Dong and Liu 2018), the distribution of green space use in this paper is roughly corresponding to the locations with good greenness, quality and accessibility. That indirectly reflects the characteristics of green space (including quality, accessibility, etc.) are more likely to play a significant role in promoting use than its connectivity, which aligns with the confirmed conclusion that quantity, quality and accessibility of urban green space (especially quality and accessibility) should be emphasized to improve green space use (Haaland and van den Bosch 2015, WHO, 2016). Therefore, the negative coefficient of the Pearson Correlation Analysis in this paper does not accordingly mean the higher connectivity discourages green space use. On the contrary, such results can be considered as the old town existing poor characteristics that weighs more in the role of hindering green space use than the promoting role of connectivity. However, attention should be paid when applying it, because this underlying factor is inferred from the qualitative comparison with the conclusions previous research. Quantitative analysis will be necessary in the future to improving its credibility.

Conclusion

In order to explore if improving the connectivity of public green space contributes to promoting green space use, we apply Pearson Correlation Analysis to test the relationship between them, whereas the analysis results are opposite to what we expect. Negative correlation is found between the connectivity of public green space and green space use whatever the time and distance threshold is. Moreover, this relationship differs in statistics significance with the variation of user groups of public green space at different time. Instead of superficially explaining the results as simple promotion-inhibition relationship between two variables, the paper identifies the underlying factor influencing the correlation between connectivity and green space use. That is the characteristics of urban green space (including quality, accessibility, etc.) playing more significant role in improving green space use than connectivity. Hence, putting more emphasis on the quality and accessibility of the existing public green space is potentially the useful way to promote its use when there is no large space left to build new public green space in the intensively compact cities.

Abstract: In high-density cities, large scale public spaces are becoming more and more precious and scarce. As a complement, micro-public space is an important indicator to measure the quality of urban lives because of its flexible location and convenient accessibility. The geometry prototype enclosed by architectural groups and texture elements as important urban morphology factors are extracted and simplified in this paper to analyze the interrelationship between micro public space morphology and the microclimate. Through the simulation of actual research projects in Shanghai, the accuracy of the simplified model is verified. The spatial and temporal distribution of microclimate is directly related to outdoor thermal comfort. It means that the correlation analysis can not only achieve multi-objective optimization to reduce urban design uncertainty, but also can provide design strategies for healthy urban environment.

Keywords: urban micro public space, urban morphology, microclimate, reactive factors

1. Introduction

With the depletion of urban land resources, activity space is gradually decreasing. The concept of micro public space has increasingly received people's attention. The idea of the miniature public spaces is a broader and richer concept developed on the basis of the notion like pocket parks, mini parks, small squares etc. which were put forward in the 1960s. Unlike other urban public spaces, micro public space is specifically produced in the centre of the city or around the community and is a place for residential daily activities. Beyond this, it also has followed features: 1. small in scale; 2. strong in accessibility; 3. high in usage rate and humanized; 4. Simple in function and human scale. Due to its small size and flexible site selection, it is mostly embedded in residential, working and commercial area. It can not only alleviate the impact of the large-scale park green space lacking caused by the acceleration of urbanization, but also promote rational utilization of street blank spaces and even corner wasteland in urban central areas.

2. The Definition of Urban Micro Public Space

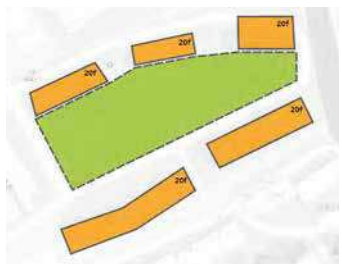

“Micro” or “small” is a relative concept of dimension relationship. The microscopic space in field of environmental psychology discipline refers to an invisible space around the human body while in the perspective of geography it is defined as a concrete space closer to daily life practice. 25m is considered as the most appropriate size in the social environment in Site Planning and it has been pointed out that spatial scales over 100m scarcely emerged in cities (Obuyoshi, 2017). In accordance with above analysis, this paper defines

the concept of “micro-space” in terms of scale, functional attributes and interaction relationship. Consequently, the micro-space refers to the public space in small measurement that mainly served for urban resident daily life in the perspective of human settlements.

Micro public space is defined as a type of space in relation to the large and medium-sized public space in the city, including small parks, small squares, community parks, stadiums and so on. "Small area" is an important feature of micro public space. According to the Hong Kong Planning Standards and Guidelines, the open spaces are categorized into three grades: Regional Open Space (at least 5 ha in size), District Open Space (at least 1 ha in size) and Local Open Space (at least 500 m²). Furthermore, the American Park Association considers the size of the pocket park to be 0.13-2ha and the service radius to be 400m. The Tokyo Park City Park green space construction target determinates the area of the neighbourhood park to be 0.25ha. China's "Park Design Code" (CJJ48-92) stipulates that the area of the residential community should be more than 5,000 square meters.

This study investigates the relationship between urban morphological characteristics and microclimate. The urban forms under various scales of public space are very different. It is determined that the scale of the micro-public space is controlled at 300-15000m², and classified into three categories basing on the size of the area: 300~3000 m² for S-Space, 3000-6000 m² for M-Space, 6000~10000 m² for L-Space (*Table 1*).

Table 1. Micro Public Spaces and Area Distribution in Shanghai

S			
Area	Xuhui Mall—2500 m ²	ABC Square—2400 m ²	Union Square—3000 m ²
M-			
Area	Xinyi Park—5000 m ²	Zhonghe Square—3800 m ²	Lanxin Square—3000 m ²
L			
Area	Boyang Park—6500 m ²	Huimin Park—6000 m ²	Songhe Park—9500 m ²

The classification methods of micro public spaces overlap with each other to some extent. For example, according to the function, it can be divided into public activity space mainly for public communication; the recreation space for the public to carry out leisure and recreation activities; the community open space mainly composed of urban communities. In terms of the positional relationship between the site and the main road, it can also be classified into following three types: 1. the open space with the total length of the adjacent side of the main road is greater than the depth; 2. open space with the total length of the adjacent side of the main road is less than the depth; 3. closed space where the main road is not adjacent.

3. Literature Review and Research Methodology

The study first identified urban form factors and key environmental parameters through literature review. And then the geometric prototype and texture elements of the miniature public space enclosed by the building group was simplified. The simulation was to performed analyse the simplified model of the urban form factor to study relationship between city shape and microclimate. Finally, the simplified simulation was validated by the actual project simulation.

In the field of environmental climate science, the research of urban microclimate involves three levels: Urban Boundary Layer, Urban Canopy Layer and Urban Street Canyon (USC). Urban Street Canyon studies urban space enclosure pattern such as streets and squares. The literature research on this point is mainly divided into the following aspects: architectural orientation, urban texture characteristics, street aspect ratio, building density, and building enclosure. The urban form factors selected in this paper include building density, building envelope, street aspect ratio, urban texture characteristics, Sky View Factor(SVF), etc. By controlling a single variable during the study the reliability of the simulation can be improved. It is shown that urban block and street space have an impact on the micro-environment in Urban Street Canyon, involving local temperatures, sunshine, wind and air quality in the space. In this article, the main performance indicators for the microclimate environment are the average radiant temperature (T_{mrt}), Universal Thermal Climate Index (UTCI) and wind speed. With the continuous revision and development of the thermal comfort model, the UTCI model has been increasingly used by researchers. Compared with the traditional empirical model, UTCI pays more attention to the human body's heat balance and can directly calculate the equivalent temperature. Compared with the complex experienced model, UTCI pays more attention to the objectivity of the model, which is the most comprehensive and widely used in human fitness indicators.

In 2013, Maro Sino et al. (2013) found that the requirements of residents in different climate zones for micro-public spaces varied greatly. In London, the most considerable factor in designing a successful park is tree and green surface, while in Athens it refers to the ample shade. The highest temperature in Shanghai is 36.8 °C and the lowest temperature is -4.5 °C. The annual average temperature is approximately 16.7 °C. July is the hottest month in one year and June 29 to July 5 is the hottest week. A typical week in summer start from August 24 and end in August 30. Contrarily, January 6th to January 12th is the coldest week and the coldest month is January. February 17th to February 23th is the typical winter week. The purpose of the microclimate design is to encourage users to participate in the local region frequently. Nevertheless, too many activities should be also avoided in maximum degree.

4. Microclimate Analysis According to Space Morphology Factors

4.1 Building density

The building density is the ratio of the sum of the floor area to the base area. The greater the building density, the narrower the air tunnel, and the greater the building's outdoor wind environment is affected by the building density. The public space forms in the building group, and the base scale has a great influence on the simulation results. In order to guarantee the precision, the layout of the “1” type building is estimated as the standard type in terms of setting building simplified model. During simulated period, the base scale remains constant and the

number of buildings randomly reduces. When the number of buildings is the least (5 buildings), the density is 4.30%. As the number of buildings increases by a factor of 5, the building density is 8.59% (10 buildings), 12.89% (15 buildings), and 17.19% (20 buildings) respectively (Table 2). The public space will also be randomly divided into smaller from 8000 to 600 m² by enlarging the building density.

Table 2. Model of building density change (Site : 125m*125m)

			
4.30%	8.59%	12.89%	17.19%

Table 3. Wind Map and Average Wind Speed According to Building Density (Site : 125m*125m)

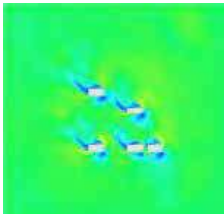

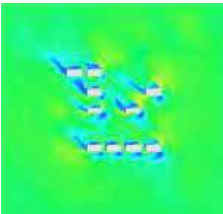

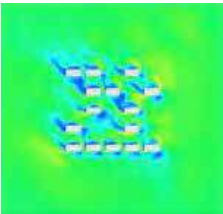

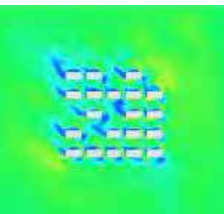

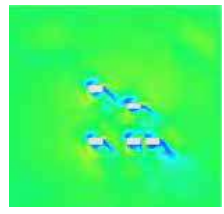

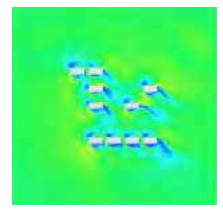

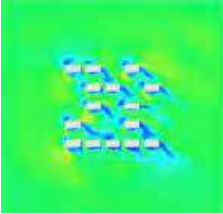

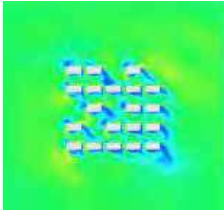

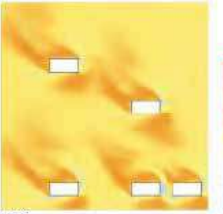

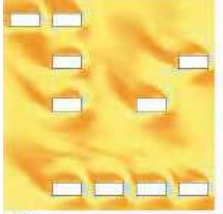

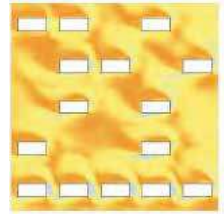

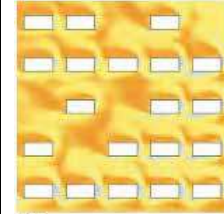

Summer					
Speed	1.933m/s	1.761m/s	1.636m/s	1.530m/s	
Winter					
Speed	2.038m/s	1.798m/s	1.629m/s	1.569m/s	

Table 4. UTCI Simulation According to Building Density (Site : 125m*125m)

			
32.805°C	32.914°C	32.911°C	32.921°C

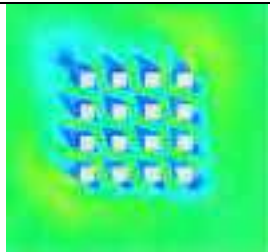

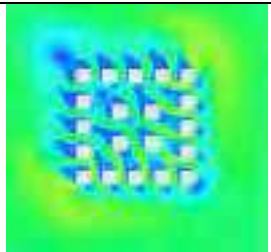

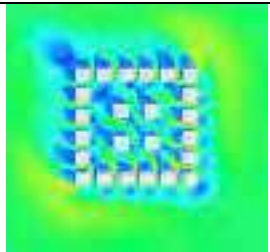

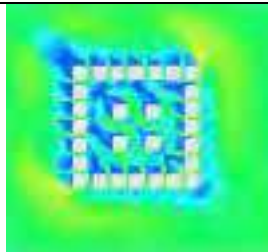

As the building density increases, the overall wind velocity in summer has dropped, and generates easily local high wind speed area (*Table 3*). Moreover, the ventilation performance of the micro public space in the high-density urban area is highly susceptible to the surrounding buildings as the increase of the static wind zone in the enclosed square. Especially if there is a building blockage in the wind coming direction, it may cause the site to be in a wind shadow area. In summer, this is unfavorable for the wind environment. In winter, this can be used to avoid the cold airflow and improve the thermal comfort.

It can be observed from the UTCI simulation that the change in UTCI is very similar to the wind contour graph and presents a negative correlation with each other (*Table 4*). That is to say, the UTCI in the static wind zone will be relatively high, and the UTCI in the well-ventilated area will be relatively low. As the density of buildings increases, the shadow area increases, the outdoor thermal comfort decreases as the enlargement of wind shadow area.

4.2 Building Enclosure Degree

In 2012, the Stephen Siuyu Lau et al. (2012) has focused on the guidance of designing small and micro-public open spaces in Hong Kong's high-density urban centers. Stephen Siuyu Lau conducted a comparison research for climatic parameters of different measurement points and relationship with the morphological and greening characteristics and a regression analysis was performed to verify the influence of building geometry and vegetation on outdoor temperature. The results show that wind conditions and building geometry apparently affected outdoor Temperature (T_a). The shading effect of a building may be more important than the shade and evapotranspiration of plants.

Table 5. Wind Map and Speed According to Building Enclosure Degree Variation

0.4	0.5	0.6	0.7
			
0.48m/s	0.47m/s	0.463m/s	0.46m/s

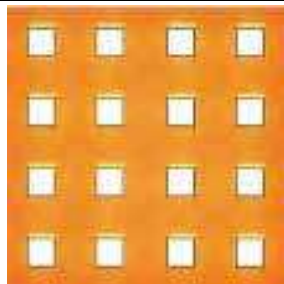

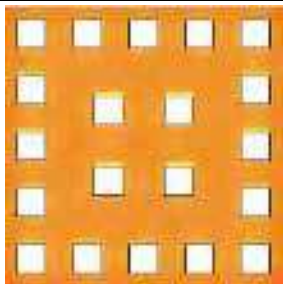

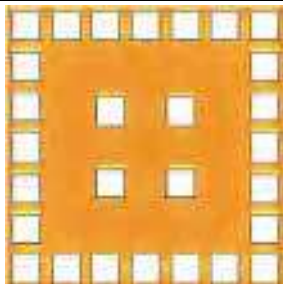

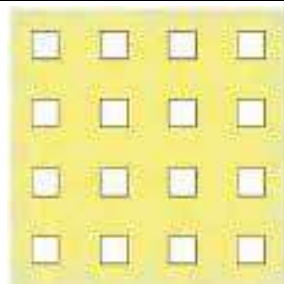

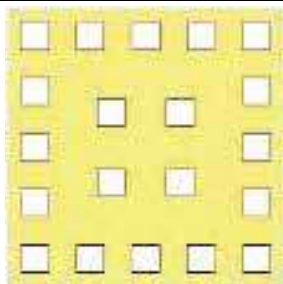

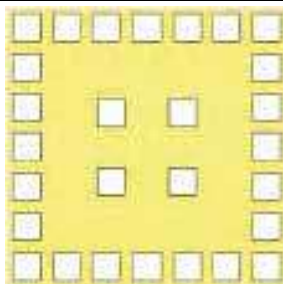

The degree of enclosure refers to the ratio of the length of the building facade along the street to the total extent of the base line, reflecting the openness of the street space. It has a greater impact on solar radiation and ventilation, but more effect on ventilation. The smaller the degree of enclosure, the more open the neighbourhood. The height of the experimental building model for enclosing degree is fixed at 20m, and the outer periphery of the buildings is arranged equidistantly with 4*4, 5*5, 6*6, 7*7 body blocks with same central plot. Simulated wind speed and T_{mrt} with variations of enclosure are shown in *Table 5* and *Table 6*.

By enhancing the degree of building enclosure, the airflow increasingly difficult to penetrate into the interior of the block. On the other hand, the local high level of wind velocity is easily formed. In this experiment, the enclosure extent has negative influence on the wind speed at the pedestrian height of 1.5m above ground level.

By comparing the average T_{mrt} of the summer solstice day through experiment, with the large level of encirclement the mean T_{mrt} is the highest at noon during the day and the lowest is achieved in the night. When the degree of encirclement is small, this T_{mrt} condition indicates contrary performance totally with the large enclosure level. It is indicated that in hot summer and cold winter regions, the variation of the enclosure has negligible effect on the thermal environment inside the block regardless of flow. The relationship between the

dominant wind direction and the degree of enclosure should be properly considered to effectively adjust the microclimate of the plot.

Table 6. Tmrt Change under Different Enclosure Degrees

0.4	0.5	0.7	
			 12:00
24.24°C	24.12°C	23.67°C	Tmrt
			 20:00
20.95°C	21.05°C	21.23°C	Tmrt

4.3 Street Aspect Ratio

Street aspect ratio refers to the ratio of the average building height on both sides of the street to the width of the street (H/W). According to the aspect ratio, the street canyon can be divided into three types: shallow canyon when $H/W < 0.5$; standard canyon when $H/W = 1$; deep canyon when $H/W > 2$. Street aspect ratio has the most significant impact on the specific linear micro public spaces. The most famous Nanjing East walking street in Shanghai is a linear urban public space with a total area of about 3ha. In addition, Shanghai has a number of linear miniature public spaces such as the 550m long Duolun Pedestrian Street (Figure 1) and the 200m long Wujiang Road Pedestrian Street (Figure 2).

Through wind tunnel experiments, Oke (1981) found that when the dominant wind direction is perpendicular to the block canyon and the height and width are relatively small ($H/W < 0.5$), there is no excess airflow exchange between the vortex area on the canyon side and the adjacent buildings. The airflow pattern is similar with that around isolated buildings which is called isolated rough flow. As H/W increases to 0.5~0.65, the airflow between the downward of the layer canyon-side vortex zone and the upward face of the adjacent building forms a secondary circulation which is called the wake interference flow. When the H/W enlarges more than 0.65, the airflow over the building gradually separates from the airflow in the layer canyon, forming a stable circulating flow in the layer canyon, called taxiing airflow. Therefore, the appropriate street aspect ratio can be applied to make the airflow pass through the street and improve the street wind environment.

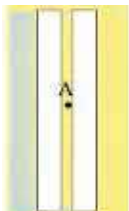

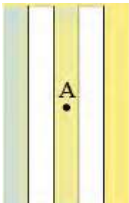

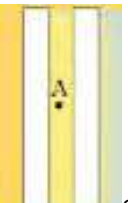

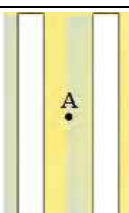

Figure 1. Duolun Walking Street

Figure 2. Wujiang Walking Street

In this experiment the block and building model was simplified into a long strip and performed in a 100m*200m site. The block width is 10m, 20m, 40m, and the aspect ratio (H/W) is 2, 1, 0.5 respectively with 20m building height. *Table 7* shows the measurement point locating the centre of the block. It can be observed from the simulation that as the aspect ratio of the block increases, the average radiant temperature decreases during the day. Meanwhile, the temperature is also reduced significantly. The phenomenon is basically consistent with other scholars' conclusions. On the other hand, with the aspect ratio of the block becomes larges, the visibility of the sky becomes smaller, which is not conducive to heat dissipation at night. Therefore, the average Tmrt at night is positive to the aspect ratio, but the effect on long-wave radiation at night is relatively weak.

Table 7. Tmrt Change Tendency Under Different H/W

Time	8:00	12:00	16 : 00	20:00
H/W=2	 21.02°C	 22.72°C	 21.81°C	 22.00°C
H/W=1	 20.69°C	 23.26°C	 21.28°C	 21.65°C
H/W=0.5	 20.20°C	 24.07°C	 20.50°C	 21.13°C

4.4 Urban texture element

Urban texture elements can be divided into two types: different textured protrusions and variant textured ground surfaces. Protrusions include isolated building, building group, urban forests and sky garden that has developed in recent years. The variant textured ground surfaces refer to urban greening, squares and water. Urban buildings can be regarded as hard elements, and urban greening can be considered as soft mass elements, which are the main factors that interfere with urban microclimate.

Studies and observations have confirmed that urban forests can play a positive role on urban microclimate. Jauregui (1990) reported that the influential range of a large urban park (525 ha) in Mexico City reaches one park's width away from the park and the green area is 2–3.8°C cooler than outside the park. At the smaller scale, even a park as small as 60m*40m can lead to a Ta reduction of 3.8°C inside the park compared with the surrounding area (Saito, Ishihara and Katayama, 1990).

Shashua-Bar and Hoffman (2000) observed the cooling effect of 11 wooded sites with various geometric configurations in Israel and developed an empirical model for predicting the cooling effect of green areas based on the observations. The areas range from 450 to 10000 m². He concluded that the shading effect by tree canopy and the Ta of non-wooded surroundings were most important for the Ta variance inside the sites. In Chang et al.'s (2007) research about 61 Taipei city parks (ranging from 0.1 ha to more than 20 ha), results showed that urban parks were on average cooler than their surroundings.

The temperature can be diminished by the vegetation function of shadowing, evapotranspiration and photosynthesis. However, more vegetation may not cause a temperature drop because it also blocks wind flux and thus affects the heat exchange process, which may be the main strategy for relieving UHI intensity in tropical climate zones. Further research should be performed on the optimal design of greening and the strategic design of the spatial layout.

4.5 SVF

SVF means the area ratio of the visible area of the sky at a position to the entire sky hemisphere. It is one of the important parameters reflecting the geometric shape of the city mainly ranging from 0 to 1. The height, shape and layout of elements such as buildings, structures and green plants in the city will have an impact on the surrounded SVF value. For example, SVF value is small in a dense urban centre while it is large in a flat and open suburb. Therefore, SVF reflects the degree of closure of the block space, and the SVF value is small, which means that the block space is relatively closed. The SVF value can be calculated in terms of the building density, height, spacing and other indicators, and is also a crucial indicator reflecting the urban fabric morphology.

In recent years, Hong Kong scholars (Grimmond, Potter and Zutter, 2001) have concluded based on field measurement research in Hong Kong that when the SVF of a city's street space is larger than 0.5, the probability of generating UHI is negligible. While the heat island effect can be obviously induced under SVF value smaller than 0.35. This indicates that the urban design or the combination pattern design of the construction could optimize the city space condition under specific constant SVF value.

This paper investigated SVF in 6 public spaces including S-Space, M-Space shown in *Table 8*. The result suggests that the public space with an area greater than 6000 m² has a large SVF value and basically does not generate urban heat island effect. When the area is between 3000 and 6000 m², a slight UHI may be produced. Note that surrounded building enclosure and height should be pay attention to controlled to avoid significant UHI with the area less than 3000 m².

Table 8. SVF Changes Under Different Areas

500~3000 m ²	3000~6000 m ²	6000~10000 m ²
		
Tongji Union Square	Xinyi Park	Boyang Park
		
ABC Square	Zhonghe Square	Songhe Park

5. Case Analysis of Micro Public Space

As the spatial form in the actual project is much more complicated than the simplified model, this paper verifies the reliability of the simplified model by investigating the five actual projects and wind simulation. The size of selected 5 actual project areas are similar with each other in the range of 2000~4000m², so as to eliminate the influence of the area factor (Table 9). The surrounding cities varies diversely in form, and Huoshan Park has a high degree of openness where one side is adjacent to the road, and one side is only obscured by the buildings on the corners, forming a very small static wind zone. Other areas are under good wind flow condition and can bring thermal environment improvement. Zhonghe Square and Tongji Union Square have a weakness airflow environment as the blockage of surrounded buildings and high level of enclosure degree. The businesses around Tongji Union Square are mainly catering, causing a large amount of waste heat to be discharged into the square. It is difficult for residents to stay in it for a long time because of the poor ventilated performance resulting in a hot thermal environment. (Figure 3, Figure 4) In the narrow gap between the buildings, an obvious blast jet zone was formed, which adversely affected the surrounding pedestrians. Tongji Mall and ABC Square are close to linear narrow spaces, which are closely related to street aspect ratio and direction. When the orientation of ABC Square and the wind direction are close together, cross-ventilation condition is formed leading to a better airflow environment. Moreover, as the narrow space of Xuhui Mall and the wind direction are under an angle, wind calm area is formed at the entrance and the high air velocity zone is generated at the exit. It can be predicted that as the angle further increases, the wind environment will continue to be exacerbated.

Table 9. Wind Map of 5 Actual Cases

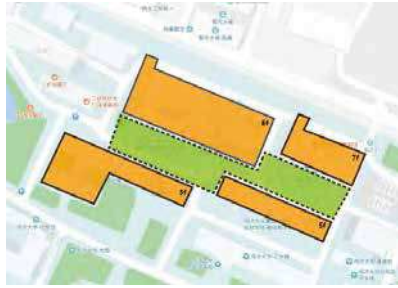

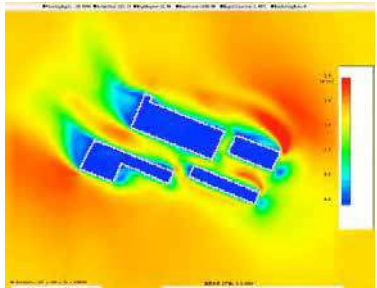

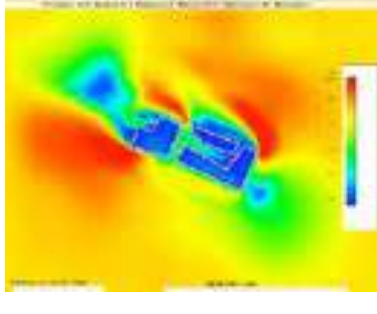

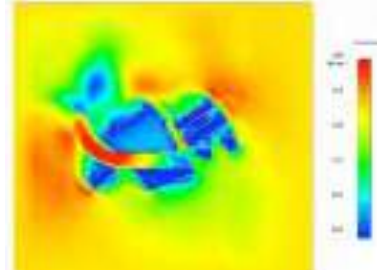

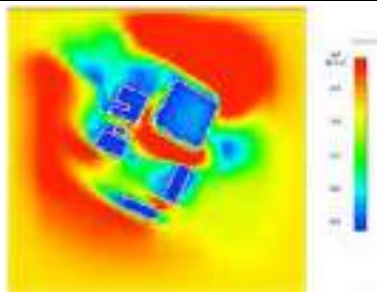

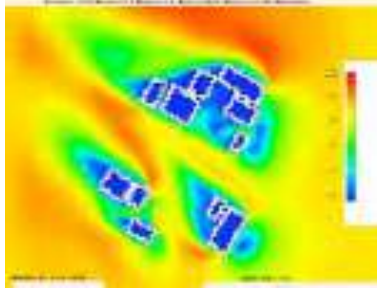

Location	Area	Site Plan	Wind Simulation
ABC Square	2400 m ²		
Tongji Union Square	3000 m ²		
Xuhui Mall	2500 m ²		
Zhonghe Square	3800 m ²		
Huoshan Park	3000 m ²		

Figure 3. Tongji Union Square

Figure 4. Tongji Union Square

It can be observed from the wind simulation comparison between the actual case and the simplified model that although the urban form of the actual project is much more complicated, using simplified model simulation shows a good agreement with the practical cases. In other words, the conclusion of the simplified model can help us to optimize the design of the wind environment in the micro public space. Therefore, simplifying model is an available tool in the process of conducting preliminary design of urban space and qualitative judgment of urban microclimate.

6. Conclusion

The essence of micro-public space is a special functional urban public space created by the designers, scattered or hidden in the urban structure to serve the public directly, could indeed stimulate the social interaction of the crowd. Consequently, urban renewal in high-density central city concentrated on the vitality of public life, especially the updating of small and micro-open spaces is becoming increasingly considerable. Especially with the increase of urban density and mental stress, people need this kind of rest space to get mind relaxation. The present study has provided much useful information for conducting more valid research for future study by refining research methods. It is hopeful that based on the implication from further study in future, a design guideline for policy-makers, urban planners, urban designers and architectures can be formed to create a more energy conscious and comfortable urban environment.

Abstract: Climate has a significant impact on public health. In the context of severe cold climate, severe cold regions have high incidence of cardiovascular diseases. Combining the health problems with regional climate and urban spatial elements, to study the impact of urban space has on public health and planning regulation strategies will help deepen research of healthy urban planning. In this paper, with the analysis of the correlation between severe cold climate, urban space and cardiovascular, we discuss the research significance on urban spatial planning regulation based on cardiovascular health. We try to develop a research framework of urban spatial planning regulation in severe cold regions, through two pathways including reduction of incidence of cardiovascular diseases and promotion of physical activities favorable to prevention and rehabilitation of cardiovascular diseases. With the pathways analysis, preliminary planning regulation strategies are put forward, aiming at providing some support for healthy urban planning in severe cold regions for reducing the risk of cardiovascular diseases.

Keywords: severe cold region; cardiovascular health; urban space; planning regulation

Introduction

Cardiovascular health is the important cornerstone of human health. World Health Organization has reported that about 17.1 million people die of cardiovascular diseases in the world each year, accounting for 29% of all deaths. Chinese Cardiovascular Diseases Report (2017) showed that China had 290 million cardiovascular patients, and cardiovascular disease death ranked the first place of total death of urban and rural residents, higher than that of cancer and other diseases, causing over 40% of residents disease death (Chen W. W. *et al*, 2018). In addition, the elderly are the main sufferers. Relevant studies propose that the elderly have as 2~4 times incidence as non-elderly in hypertension, ischemic cardiovascular disease, atrial fibrillation and coronary heart disease (Geng J.C. and Jian H., 2009; Chen L. *et al*, 2018). According to the statistics published by National Office for Ageing, having stepped into an aging society, China had about 240 million aging population, accounting for 17.3% of the total population in 2017 and the proportion is predicted to reach 34.1% by 2050. In face of the significant public health problem threatening life and health and healthy aging, it is urgent to promote the prevention and treatment of cardiovascular diseases.

Climate has a close relationship with health. The significant impact on public health caused by climate should not be ignored. A large number of studies have found that cardiovascular disease morbidity and mortality are higher in high latitude and cold regions and in winter (Bhatnagar A., 2017). According to the International Association of Cold Cities, there are at least 30 countries located in the northern hemisphere, and more than 0.6 billion people have the life experiences in winter (Jiang C. Y. and Leng H., 2017). How to overcome the influence of climate factors to promote public health in the severe cold regions where cardiovascular health problems are more serious is a key point for prevention and treatment of cardiovascular diseases with regards to both China and the vast cold cities of the world.

A core content of social–ecological models published by World Health Organization is that urban space is an important factor influencing public health through affecting human behaviour, which reveals that reduction of the risk of illness in a larger population may come true by optimizing urban space (Sarkar C. *et al*, 2013). Applying this content to urban space and cardiovascular health, research by Diez-Roux A. V. has showed the correlation between neighbourhood environment and coronary heart disease (CHD) (Diez-Roux A. V., 2001); approaching green space has a significant influence on reducing cardiovascular mortality (Mitchell R. and Popham F., 2008; Shen Y. S. and Lung S. C., 2016); Gan proposed automobile exhaust exposure has a link with the arising of incidence of coronary heart disease (Gan W. Q. *et al*, 2010). Relative studies also show that there is a relationship between residential environment, such as sports facilities as well as quality of leisure activity area, and physical activities; thus residential environment may influence physical activities, further having impact on cardiovascular health (Kohl and Harold W., 2001; Humpel N. *et al*, 2002). Previous studies have revealed the potential relationship between urban space and cardiovascular health.

In this paper, focusing on cardiovascular health problems in the context of severe cold climate, we expect to explore urban spatial planning regulation strategies. On the basis of the analysis of correlation between severe cold climate, urban space and cardiovascular, we illustrate the significance, pathways and methods of urban space planning regulation research based on cardiovascular health in the context of severe cold climate, aiming at providing some theoretical basis and practical guidance for healthy urban planning in severe cold regions for reducing the risk of cardiovascular diseases.

1. Severe cold climate, urban space and cardiovascular health

1.1. Severe cold climate and cardiovascular health

Medical studies support the evidence that severe cold climate affects cardiovascular health. There is a u-shaped relationship between air temperature and cardiovascular mortality- for every one-degree decrease in air temperature in cold regions, cardiovascular mortality increases by 1% (Liu Z. X., 2013). The effects can be illustrated to be direct and indirect. In terms of the direct effects, the outdoor low-temperature environment and the sudden change in temperature between indoor and outdoor space are the key factors influencing cardiovascular health. Low-temperature exposure can result in vasoconstriction, spasm, hypoxia, blood viscosity increase, and increase the burden of the heart. The sudden change in temperature between indoor and outdoor space easily lead to rapid expansion and contraction of blood vessels in the process of indoor and outdoor transformation, resulting in increased vascular resistance and brittleness, which is the key cause of hypertension, coronary heart disease, stroke and other cardiovascular diseases (Hasegawa F. X., 1985). In terms of the indirect effects, severe cold climate can exert effects on cardiovascular health through its influence on urban environment and residents' behavior and activity patterns. In relationship with the long period of coal-burning heating as well as the ascending proportion of vehicle out-driving in severe cold regions in winter, the frequent occurrence of haze and the increase of atmospheric pollutants can cause damage

to human cardiovascular system. Meanwhile, the severe cold climate makes the residents in these regions develop dietary and living habits which are different from those in other regions, such as high-salt diet, less outdoor activities and physical exercise, and overweight or obesity resulting from excess fat metabolism. A number of key risk factors lie in the regional environment and residents' lifestyle in the severe cold regions. On the other hand, it should be noted that medical studies have shown the importance and necessity of appropriate outdoor exercise in winter for the prevention and rehabilitation of cardiovascular diseases, which indicates that severe cold weather has a dual effect on cardiovascular health.

1.2. Urban space and cardiovascular health

According to existing research, urban space is associated with cardiovascular risk factors (such as obesity and lack of exercise) and cardiovascular rehabilitation factors (such as heart-healthy walking activities). For example, more than 60 studies suggest the relationship between urban space and obesity; a number of features of communities in urban space have been proved to relate to BMI; communities with more physical activity resources are associated with lower insulin resistance levels (Li J. and Siegrist J., 2012).

In addition, specific to the impact mechanism, studies have shown that urban space may have an effect on cardiovascular health by affecting air environment, physical activity, social interaction, food intake and so on. In terms of air environment, studies have confirmed that urban space is related to the reduction of air pollution (Alonso R. *et al*, 2011; Rao M. *et al*, 2014), and several studies have linked air pollution to an increasing incidence of cardiovascular diseases (Metzger K. B. *et al*, 2004; Feng J. and Yang W., 2012). In terms of physical activities, lots of studies have shown the correlation between spatial elements such as green space and physical activities, while the correlation between physical activity level and cardiovascular risk has been widely confirmed (Li J. and Siegrist J., 2012). In terms of social interaction, some studies have shown that urban space is positively correlated with social support level, and a large number of studies have found that low social support level is one of the risk factors for cardiovascular diseases. In terms of food intake, the consumption and supply distribution of food in urban space will also affect residents' diet, which is closely related to cardiovascular health (Chum A. *et al*, 2013). Therefore, air environment, physical activity, social interaction and food intake mediate the impact of urban space on cardiovascular health, and the differences in urban space are important factors leading to the differences in cardiovascular health status.

1.3. Urban space and cardiovascular health in the context of severe cold climate

Under the direct effects of severe cold climate on human cardiovascular system and the indirect effects on urban environment and residents' lifestyle, residents are at higher risk of diseases due to factors consisting of the stimulation of cold air, increasing air pollutants, insufficient physical activities and social interaction in winter, as well as high-salt diet. Research from Huang Likun *et al* indicated that under the influence of urban 6-month-heating period in winter, cities in severe cold regions of China have higher concentration of suspended particulates and extremely serious air pollution (Huang L. K. *et al*, 2011). Introducing the existing survey, Yang Baofeng proposed that due to the long winter in northern China, residents have less time for outdoor activities, and almost 80.5% of them never exercise (Yang B. F., 2015). A statistical survey conducted by the Food and Nutrition

Advisory Steering Committee of Heilongjiang Province showed that the average daily salt intake of urban and rural residents aged 18 years and over was 10.6 g per person in the province, which exceeded the recommended daily intake limit of 76.7% in the Dietary Guidelines for Chinese Residents (Chen K. *et al*, 2015).

In view of the mediating factors of the impact of urban space on cardiovascular health, existing studies have provided evidential support and realistic plans for optimizing urban air quality in winter and promoting residents' physical activity in winter through urban space variously. For instance, Kong Fanqiu *et al* studied urban space optimization in cold regions based on air quality analysis in winter (Kong F. Q. *et al*, 2018). Tucker P. and Gilliland J. reviewed the literature about the participation of people in different age groups in sports activities in cold regions (Tucker P. and Gilliland J., 2007). Leveratto J. and Maria studied the morphological scale of buildings surrounding the open space, aiming at improving the comfort and utilization rate (Leveratto J. and Maria, 2002).

Previous studies provide a theoretical basis to clarifying effects of severe cold on cardiovascular health, and revealing the possibility of optimizing intermediate factors through urban planning and design for reducing risk of cardiovascular diseases. However, research combining climate, urban space and cardiovascular health remains to be explored; the correlation between urban space and cardiovascular health in the context of severe cold climate requires to be understood. Here, the specific impact of urban spatial characteristics on cardiovascular health in winter and the role that urban space can play in resisting the threat to cardiovascular health posed by severe cold climate need to be further clarified.

2. Significance and theoretical framework construction of urban space planning regulation research based on cardiovascular health in severe cold regions

2.1. Research significance

Focusing on specific diseases to improve the quality of urban space planning, the research of urban space planning regulation help to promote healthy city planning in severe cold regions for reducing the risk of cardiovascular diseases. As for the severe cold cities in China with more harsh winter weather, more aging population and more higher risk of cardiovascular diseases, the research has more special significance. Taking Heilongjiang Province (a typical province located in severe cold regions) in China as an example, clinical data shows that hypertension, heart failure, coronary heart disease, arrhythmia and thrombotic diseases caused by severe cold climate are quite common in the province. Among the diseases, the prevalence of hypertension is 25.69% in the province, while that of the nation is only 18.81% averagely. Research from Harbin, a typical severe cold city in China, shows that cold temperature is responsible for 2.7 percent of deaths, especially for coronary heart disease patients who are affected by cold stimulation most (Liu Z. X., 2013). At the same time, Harbin has entered a fast development period of population aging. At the end of 2016, there were 1.924 million elderly people, accounting for 20 percent of the total population in the city (the 13th Five-Year Plan for the Development of Harbin Aging Cause, 2017). With significant high-risk population gathering characteristics, the city is facing a very serious situation of cardiovascular diseases. Therefore, it is of great significance to explore how to carry out urban planning for promoting cardiovascular health in the context of severe cold climate to improve relevant theoretical research and practical development in the field of healthy urban planning as well as healthy aging.

2.2. Theoretical framework construction

Based on the analysis of the relationship between severe cold climate, urban space and cardiovascular health as well as the illustration of the research significance, we intend to establish a theoretical framework of urban space planning regulation research based on cardiovascular health in severe cold regions. We aim at adding the content of urban space planning regulation research focusing on specific diseases- cardiovascular diseases in the context of regional climate to the existing research on healthy urban planning, with emphasis on the potential impact of urban space in severe cold regions on cardiovascular health, thus to enable the urban space to play a role in reducing the cardiovascular disease risk and promote cardiovascular disease rehabilitation to a certain extent.

The theoretical framework, shown in Figure 1, illustrates two pathways of urban space planning regulation research based on cardiovascular health in the context of severe cold climate. The first pathway in the framework is achieved by the protection of urban space for cardiovascular health, namely through urban space planning and design, to reduce the damage resulting from the adverse environmental problems on cardiovascular health, including reduction of cardiovascular disease risk from the low temperature, temperature change between indoor and outdoor space and air pollution. The second pathway in the framework is achieved by the active intervention of urban space for cardiovascular health, namely through urban space planning and design, to promote the occurrence of overall daily physical activities and exercise beneficial to cardiovascular disease prevention and rehabilitation.

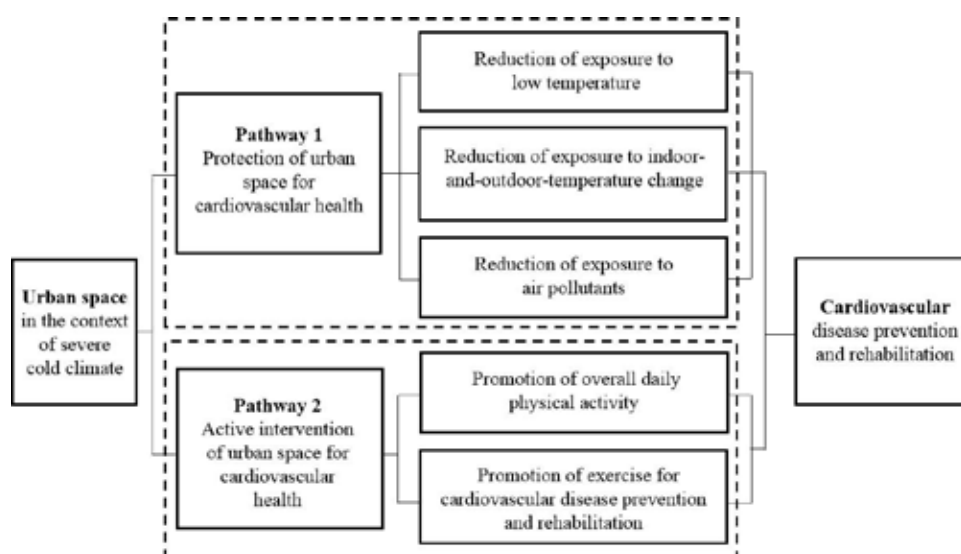

Figure 1 Theoretical framework of urban space planning regulation research based on cardiovascular health in the context of severe cold climate

In combination with these two pathways, the analysis of the situation and planning regulation in the urban space planning regulation research based on cardiovascular health in severe cold regions can be done from two perspectives. From the perspective of the protection of urban space for cardiovascular health, the research should emphasize on cardiovascular disease risk factor analysis, including the content of exposure analysis of low temperature environment, indoor-and-outdoor-space temperature change and air pollution. By identifying regions and nodes where cardiovascular health is faced with greater climate impact and the disease risk is higher, key regulatory areas will be determined, and then

corresponding planning regulation can be carried out. From the perspective of the active intervention of urban space for cardiovascular health, the research should emphasize on the analysis of supportive elements of overall daily physical activities and exercise beneficial to cardiovascular disease prevention and rehabilitation, including the content of daily public service facilities and public space. By analyzing the correlation between supportive factors and the promotion of physical activity for cardiovascular disease prevention and rehabilitation, the regulatory objectives of public facilities and public space will be determined, and the corresponding planning regulation can be carried out.

3. Urban space planning regulation based on cardiovascular health in severe cold regions

3.1. Cardiovascular disease risk factors analysis and planning regulation

There may exist risk factors with potentially negative effects on cardiovascular diseases in severe cold regions. We suggest to analyse and clarify the potential types and spatial distribution of pathogenic risk factors in planning schemes or projects, and then carry out targeted planning regulation on this basis. It can be carried out from the low-temperature exposure, indoor-and-outdoor-temperature change exposure, air pollutants exposure and other factors that have influence on cardiovascular health.

Reducing the low temperature exposure level of residents in urban space is conducive to improving the safety and comfort of urban space, so as to mitigate the severe impact of low temperature environment on human cardiovascular system properly. Low-temperature exposure is distributed in various places of residents' outdoor where people participate in travel, leisure, exercise, entertainment and other daily activities. Given the restriction of natural meteorological conditions, the low-temperature environment of these places is difficult to be changed significantly. Therefore, it is advisable to focus on key areas for regulation, especially where winter activities are particularly threatened by low temperature, such as traffic waiting area, leisure and exercise-oriented public space and so on. First of all, the waiting node can be designed to defend the climate. For example, the heated waiting hall, connecting corridor, underground passage, overpass bridge and gray space of eaves corridor can be set up at the transitional space between traffic and buildings. Secondly, the physical environment of public space can be designed and optimized. For instance, the form of streets and the layout of public space can be optimized and adjusted based on the analysis of sunshine and wind environment. Thirdly, the capacity of indoor activity space in winter can be expanded, such as the sharing of indoor activity space with school or office at different time.

Given the impact of indoor-and-outdoor-temperature change on the intensity of human blood vessel contraction and diastole, the adaptive design of indoor-and-outdoor-temperature difference is favorable to alleviate the human blood circulation obstacle resulting from it. The indoor-and-outdoor-temperature change exposure mainly exists in the boarder area between indoor and outdoor space, such as the area between the indoor space of residential houses, daily activity facilities and outdoor public space. The variation of temperature difference between indoor and outdoor space mainly exists in the area between the indoor space of residential houses, daily activity facilities and outdoor public space. In the process of planning regulation, combining medical research and methods of the temperature test and simulation of the boarder area, the thermal comfort survey and so on, indoor-and-outdoor-temperature range for reducing the degree of vascular contraction diastole can be confirmed. With regards to planning regulation strategies, the temperature environment of outdoor entry space,

the temperature gradient design of transition space, and the temperature design of the indoor space can be considered, achieving the gradual buffer and transition of indoor-and-outdoor temperature.

Air pollutant exposure is another important factor that causes cardiovascular diseases. Analyzing the types and spatial distribution of air pollutant exposure and proposing targeted planning regulation strategies are helpful to reduce the concentration of pollutants and thus to weaken their harm to the human cardiovascular system. The main types of air pollutants that affect cardiovascular health include haze and automobile exhaust. The exposure of pollutants is mainly distributed in the travel path, road intersection, traffic transfer waiting area, and the adjacent area between the activity area and the road among the daily activity space of residents. With regards to planning regulation, methods such as layout adjustment, shape optimization and pollution source isolation can be adopted to reduce the exposure of air pollutants. The specific ways include adjusting the pollution source land, optimizing the block form, setting up the greening-isolation belt of fitness ground and configuring the dust plants.

3.2. Cardiovascular disease prevention and rehabilitation resources analysis and planning regulation

Combined with the concept of health resources proposed by Wang Lan et al (Wang L. *et al*, 2018), from the perspective of active intervention of urban space for cardiovascular health, the supporting factors of the urban space for physical activity for cardiovascular disease prevention and rehabilitation will be analyzed here. Taking the promotion of overall daily physical activity as well as exercise for cardiovascular disease prevention and rehabilitation as two goals, we propose three aspects involving analysis and planning regulation, consisting of accessibility and proximity of daily public service facilities and public space, convenience and connectivity of facilities combination, the support of physical fitness facilities for cardiovascular disease prevention and rehabilitation.

The accessibility and proximity of daily public service facilities and public space is an important precondition to attract residents to the facilities and space for physical activity, which plays an important role for people to develop daily exercise habits and form exercise compliance-both for the healthy people and patients with confirmed cardiovascular diseases and those with potential risk of cardiovascular diseases such as diabetes, hypertension and hyperlipidemia etc. The accessibility and proximity can be analyzed by GIS to identify the overall fairness of the planning area and the supply and demand matching, on the basis of the distribution of the elder or patient population. Then planning regulation can be implemented focusing on the areas with higher risk of cardiovascular diseases, with regulatory elements such as road network structure, pedestrian space, barrier-free facilities, site layout and so on (Zheng C. Y. *et al*, 2017).

The convenience and connectivity of facility combination play a role in cardiovascular disease prevention and rehabilitation mainly through residents' daily use of facilities to promote traffic walking physical activities, so that residents can improve their physical activity level to some extent even if without deliberate exercise. Taking an old man suffering from cardiovascular disease as an example, the combination and connectivity optimization of facilities such as the market and the physical fitness facilities with high frequency of daily use can provide convenient walking travel options for him, so that he can complete daily travel more on foot. In addition, enhancing convenience and connectivity of facility combination can also help reduce prolonged low-

temperature exposure in winter, with dual protective and intervention effects for the prevention and rehabilitation of cardiovascular diseases. The analysis of convenience and connectivity of facility combination can be carried out through questionnaire, interview and other survey methods to investigate residents' and patients' use frequency and demand for daily public service facilities and different facilities combination, and to combine or set up facilities with high use frequency and demand nearby (Li M. *et al*, 2017). Apart from that, the spatial environment of the connection path of facilities can be investigated and analyzed through field survey and other methods, and also the targeted regulation strategies can be brought forward, such as adjusting the connection path of facilities used frequently and connecting the interruption path, so as to enhance the connectivity of the path.

The support of physical fitness facilities for cardiovascular disease prevention and rehabilitation means to analyze and planning regulate the physical fitness facilities according to medical research and exercise prescription for cardiovascular disease prevention and rehabilitation. Medical research indicates that exercise is essential for cardiovascular disease prevention and treatment, which should be regarded as significant as diet control (Chinese Guidelines for the Prevention and Treatment of Type 2 Diabetes, 2018; Joshua J. J. *et al*, 2019). The contents of exercise prescription for the prevention and rehabilitation of cardiovascular diseases include exercise items, intensity, time and frequency. In terms of exercise items, according to the research from Lancet, the top three exercises that are most beneficial to cardiovascular health are swinging, swimming and aerobics (Lee I. *et al*, 2012). In addition, as a safe, simple and easy exercise to adhere to, walking is considered as the first choice of exercise for elderly diabetic patients. Then the demand of walking and aerobics for physical fitness facilities in winter can be analyzed, such as the layout and design of anti-skid track in the community, as well as the composite use with the residents of lower age groups. In terms of exercise intensity, middle-aged and elderly patients should take low-intensity exercise due to more complications, while young people or individuals with better physical quality can take shorter and higher intensity or interval training (at least 75 minutes/week). Then the preference features of medium and low intensity exercises for physical fitness facilities can be analyzed, such as the site size, facility preferences, so as to adjust the site design and facilities configuration. In terms of time and frequency, for most people, the general recommendation is to exercise at least five days a week for at least 30 minutes a day, or 150 minutes a week. Then the thermal comfort environment of physical fitness facilities in the ideal time of exercise in winter can be tested and simulated to obtain the differences of the thermal comfort status of different positions in the public spaces. Based on that, the site selection and layout adjustment for different exercise prescription items can be carried out to extend the exercise time. The environmental factors that attract residents to stay can also be investigated and analyzed, such as winter ice sculpture, snow sculpture, and night lighting, so as to set up corresponding spots to enhance sports frequency and cultivate sports compliance by enhancing the attraction of physical fitness facilities.

4. Conclusion

With the comprehensive analysis of the relationship between the severe cold region, urban space and cardiovascular health, this paper introduces the significance of urban space planning regulation research based on cardiovascular health in severe cold regions. Then a theoretical framework is established, illustrated as two pathways, one path is to reduce the pathogenic risk factors in the urban space, the other is to promote the physical activities for cardiovascular disease prevention and

rehabilitation. In addition, we propose corresponding planning regulation strategies on the basis of pathway analysis. This paper has made a preliminary discussion in theory, in order to provide a basis for subsequent empirical research, and to provide new ideas and methods for healthy urban planning for reducing the risk of cardiovascular diseases in the context of severe cold climate.

^{*2} College of Architecture and Urban Planning, Tongji University, sty@tongji.edu.cn

Abstract: In the past decades, the urbanization of China has developed faster. The pedestrian accessibility of large old residential areas with new village-style becomes worse due to the large scale and few entrances and exits for residents. Simultaneously, the closed communities seriously affect the development of urban areas induced by poor urban living atmosphere, incomplete pedestrian system and traditional public space node setting. The public spaces where walking is the mainly activity need optimization urgently. This paper took Anshan New Village as an example and applied spatial syntax to analyze spatial accessibility and integration based on the current investigation. The study demonstrated that the network system should be established to improve the pedestrian environment in large urban blocks and the measurements of construction of pedestrian network were also suggested. Dredging the pedestrian path and increasing public space nodes can better build the urban pedestrian network and realize the balance between privacy, publicity and security. The conclusion of this paper can provide reference for building a good pedestrian environment in the process of urban renewal in Shanghai.

Keywords: pedestrian network; large old residential areas; public space node; spatial syntax

Introduction

In recent years, building green architecture and sustainable cities have become important in all sectors of society. The WELL standard of the United States puts forward seven core systems, i.e., air, water, nutrition, light, fitness, comfort, spirit. It pays attention to the impact of urban environment on human health. The ultimate goal of urban sustainable development is to create a healthy living environment of high quality for human beings. As the most basic mode of transportation in a city, Walking not only plays a key role in alleviating traffic pressure, creating a green city, energy saving and emission reduction, but also promotes interpersonal communication, contributes to health and is conducive to the construction of a healthy city. Currently, construction of walking environment has become a major direction of healthy cities. However, with the rapid development of urbanization, population agglomeration and modern transportation, motor lanes are gradually eroding the traditional pedestrian space. Vehicle lanes, automobile exhaust, dust, haze and other factors affect our walking environment in varying degrees. Poor air quality and lack of exercise seriously affect people's health. Therefore, a good walking environment is the foundation of building a healthy city.

In the early days, industry developed rapidly and the working class population doubled due to the influence of Soviet. In order to solve the problem of accommodation for the working class, a new construction model for

workers villages emerged all over the country. The construction process of Shanghai Workers New Village had spanned from 1949 to 1978. During this period, about 11 million square meters of newly added housing area in Shanghai were workers new villages, accounting for two-thirds of total newly added housing area. In the past decades, the workers new villages have always been the important component of figure ground in Shanghai. However, the construction of workers new villages such as Anshan New Village has been existed more than 30 years and the surrounding urban areas are becoming mature. Residents in the new villages need more diverse daily life and demand higher quality of space. There is a huge contradiction between the old physical space and the needs of residents. How to change the current situation and improve the quality of space has become a top priority (Song, 2018). Currently, many studies have been addressed on this kind of urban phenomenon for more healthy pedestrian system.

Since Perry put forward the theory of Neighborhood Unit, this model has been used in residential areas, i.e., transit traffic avenues are arranged around the border, and the internal road system does not connect with the external. Although the latter traditional neighborhood units add other living facilities to create rich community life, centralized living has been developed under the guidance of the idea of neighborhood units resulting in the inadequate function of residential areas. In addition, the closed residential mode in China induces the split of urban pedestrian transportation system and brings great inconvenience to our daily life. Domestic research on the openness of residential areas begins with the criticism of closed residential areas. A large number of scholars criticize the closed residential areas and residential areas under the traditional planning theory mode. With the continuation of relevant research, the focus of research on the openness of residential areas has shifted from the criticism of closed residential areas to the practice of solving the closed problems. In recent years, the government has increasingly encouraged and supported the construction of open residential areas. Xinhua News Agency proposed that in principle, new residential areas should no longer be built in closed residential areas, and residential areas and unit courtyards that have been built should be gradually opened. It is pointed out that community opening can alleviate traffic pressure, stimulate community vitality, promote urban harmony and improve urban ecology, and can effectively solve urban diseases (Xinhua News Agency, 2016).

Streets have always been an important area of urban research. Jacobs compared hundreds of streets around the world and lists the best street models in the world. A great street should contribute to the formation of neighbourhood relations, be safe and comfortable in the physical environment, encourage the participation of the public, imprint on people's minds, and become a representative model (Jacobs, 2009). Lu discussed how to explore the visual order law in the design of building layout from the natural characteristics, aesthetic laws and humanistic characteristics of streets (Lu, 2006). Gail suggested the public communication in the street and emphasized the study and evaluation of the quality of public space in cities and residential areas from the perspective of the requirements of people and their activities on the physical environment. When social behavior and incidental behavior occur, it is necessary to create suitable space for social interaction for these behaviors (Gehl, 2002). Jacobs argued that street safety cannot be achieved by public security, but by street eyes, that is, people's conscious (subconscious) supervision. It challenges the traditional urban planning theory, deepens our understanding of the complexity and development orientation of the city, and provides a basic framework for evaluating the vitality of the city (Jacobs, 1961). In recent years, Street guides have been made around the world considering the importance of urban streets. The United States has put forward complete street guides, which are designed to make them safe for all users, regardless of age, physical condition or mode of transportation. More emphasis is placed on safe walking environment (Chen and Liu, 2017). The Guidelines for Shanghai Street Design emphasizes the construction of street interface, street pavement and the size of street space to create safe streets, intelligent streets, vigorous streets and green streets for Shanghai citizens.

This paper took Anshan New Village in Shanghai as an example and aimed to optimize the internal pedestrian structure of the old and new residential areas in Shanghai New Village and build a walking environment

conducive to people's health. Based on spatial parsing, this paper evaluated the original walking system of Anshan New Village and put forward corresponding solutions to the problems of the original walking system. The finding shows that the network pedestrian system of Shanghai blocks can be well constructed and the urban renewal of Shanghai can be promoted according to dredging pedestrian paths and adding public space nodes.

The study area

As shown in Figure 1 and Figure 2, Anshan New Village is located in Yangpu District, Shanghai, within the boundaries of Jiang-Controlling Road, Dalian Road, Siping Road and Zhangwu Road. This area was founded in the 1950s. In the past decades, Anshan New Village has been expanding continuously and has eight residential areas currently. Anshan New Village was once one of the largest and earliest workers new villages in Shanghai. The interior of the community is mostly a six-storey determinant slab building. Because of the long construction time, the social background and the main body of the construction are more complex.

Figure 1. Macrolocational map of Anshan New Village, Shanghai

Figure 2. Microlocational map of Anshan New Village, Shanghai

As shown in Figure 3, Anshan New Village has a larger neighborhood scale and dense buildings than the residential areas built in recent years. The figure ground of the buildings is arranged in parallel in determinant form, which retains the characteristics of low-rise and high-density construction in the old worker's residential areas. There is a thick wall between the residential area and the city, which severely separates the connection with the urban environment. The scale of eight residential districts in Anshan New Village is different. The main structure of residential districts is large and severely fragments the urban pedestrian road system. There are Tongji University Station, Siping Road Station of Metro Line 10, Siping Road Station of Metro Line 8 and Anshan New Village Station in Anshan New Village District. The dense distribution of bus stations and rail transit system has become the barrier for the pedestrian environment in the area. In addition, since the residential areas are close to the main roads of Siping Road, Dalian Road and Zhenjiang Road, the internal pedestrian environment and accessibility are poor and public space is scarce. The relationship with the surrounding urban environment is very negative due to lack of reasonable pedestrian system. As shown in Figure 3, Anshan New Village only has one direct pedestrian road between Siping Road and Fuxin Road and the region only has four entrances and exits along Siping Road for people living in the community. The street interface is closed and the

relationship with the city is weak. Usually, people have to go around reaching Siping Road from the residual area due to the unreasonable pedestrian system.

Methodology

Space Syntax theory was first put forward and used by Hillier and the study object is spatial ontology (Hillier, 1984). The method applies quantitative analysis to describe the spatial structure of cities and buildings and abstracts the spatial relationship through modeling. Additionally, the theory explores the relationship between spatial ontology and other non-spatial factors, such as the accessibility of space, the relationship between space structure and human activities. Spatial syntax has been widely used in various aspects of urban space, i.e., urban land use, urban morphological development and road accessibility.

This paper firstly extracted the central line of pedestrian path in Anshan New Village area based on spatial syntax and draws the axis map. Thereafter, integration, selectivity, global depth, connectivity and comprehensibility were analyzed and the existing pedestrian system in Anshan New Village was evaluated. In general, when the travel radius is less than 1000 meters, it is completed by walking (Xia, 2018). Therefore, this paper took 10 minutes walking distance, namely 800 meters, as the travel radius to study Anshan New Village. Then, a new scheme to build a more efficient walking system was proposed and the new walking system was presented based on the existing walking system problems.

Problem analysis of current pedestrian system of Anshan New Village in Shanghai

Through field investigation and spatial syntax, the problems existing in Anshan New Village are analyzed and summarized as follows.

1. As shown in Fig. 4, Fig. 5 and Fig. 6, the large size of neighborhoods results in inadequate pedestrian links between urban roads. Fewer entrances and exits along Siping Road and closed interfaces induce unobstructed pedestrian links between urban roads. The area is located between Siping Road Station of Metro Line 10 and Tongji University Station. Although the traffic volume is large, the routes to subway station, bus station and other public facilities in the district are more circuitous. The larger scale of closed unit causes the situation of pedestrian bypass;

Strategies for construction of new pedestrian system of Anshan New Village in Shanghai

For large new village residential areas with long construction time, it is a challenge to upgrade the spatial quality of urban renewal. According to the analysis of actual cases and results of spatial parsing, it is necessary to build a network system of pedestrian system and public space nodes to effectively update large-scale new village residential areas. When the pedestrian system and public space are connected into a network, the residual area will have higher connectivity and more route choices. The network space system can effectively guide people's travel and increase people's walking movement. To establish the network system of pedestrian system and public space nodes, the following principles should be met first.

1. Increase pedestrian path density. Based on comparing the areas with good walking experience, i.e., Puxi people's Square, Tianzifang, the Bund, Wu Kang Road and the areas with poor walking experience, i.e., Pudong Oriental Pearl, Shanghai science and Technology Museum and Lian Yang community, we found that when the length of the road in each square kilometer is about 10 kilometers, it is the most suitable way to create a pleasant walking environment. As shown in Figure 10, for better increasing the accessibility of internal roads in large residential areas, it is important to open up the broken roads in large-scale new village residential areas, build new path links relying on the original path, divide the large-scale plots into small plots with moderate scale and convenient access;

Figure 10. Comparison of route density in different areas in Shanghai (Sun and Xu, 2017)

Figure 11. Enclosed unit of residual area

2. Increase public space nodes, i.e., add urban public space nodes at the junction of blocks, street corners and the center of public space structure, add community public space nodes between districts and districts, and add neighborhood public space nodes within groups. Public space nodes and walking paths form a tensioned network of public space network structure, which constructs a pedestrian space environment for urban people. There should be functional interface support around public space nodes, and the interface should be open to the public;
3. Create a reasonable open neighborhood size to achieve a balance between public and private. Closed residential district has the characteristics of quiet and safe, but it is difficult to meet the growing demand for physical space due to the lack of public facilities. People hope to open up enclosed residential areas and create open blocks. However, it is easy for the idle and miscellaneous people to enter after the opening of

the community, which challenges the security of the residential area. So we should create a new mechanism and reasonable size of the neighborhood to provide a small range of privacy for residents and meet the requirements of openness. As shown in Figure 11, the original determinant slab dwellings are partially enclosed by increasing the volume of the edge buildings. The interior is a private space, while the exterior is a public space. At the same time, the underlying functions will be replaced into commercial space, and businesses will become "street eyes" to ensure the safety of the community;

4. Improve the quality of walking space. Along the pedestrian path, trees can be planted, seats and other urban furniture can be placed, public facilities, business interfaces and public places for daily life can be increased, and water-permeable hard pavement can be laid on the pedestrian road. Through a series of detailed considerations, we can improve the quality of walking space and provide a good walking experience for travelers and create a vibrant urban living place.

Under the basic principles of pedestrian system and public space node network system, aiming at how to carry out effective urban renewal and build high-quality pedestrian space network in Anshan new area, this paper uses spatial syntax to assist specific urban renewal strategies, which are summarized as follows.

1. Increase the path density. According to the design principle of 10 kilometers per square kilometer of land in pedestrian area, the pedestrian path is added to the interior of Anshan New Village to optimize the way of path connection. The pedestrian path in the original community will be opened as an open urban pedestrian path. As shown in Figure 13 to Figure 15, through the spatial syntax analysis of the integration and connectivity of pedestrian roads in Anshan Xincun area, Fuxin Road, as the only street in the area that can directly connect Zhangwu Road and Dalian Road, has the highest integration, selectivity and connection value. Tieling Road, Jinxi Road and Sujiatun Road have higher integration, and Jiangpu Road, Anshan Road and Tieling Road have better connectivity. However, the internal road network of large-scale residential areas is not fully opened and the integration degree and connection value of pedestrian roads is extremely low. The main roads to Siping Road of the city are few and the integration degree is low, so the pedestrian system network has not been formed. Fuxin Road, Zhangwu Road, Tieling Road, Fushun Road, Anshan Road, Jinxi Road and Sujiatun Road are all the main roads with large traffic volume, but the interior of the district is closed and deep. So we should increase the density of road network in places with low integration and open the urban pedestrian path system in places with high connection value. The new road network system was shown in Figure 16 and the measurements were summarized as follows.
 - Chifeng Road will be connected with Fuxin Road. Three axes in series will be built between Dalian Road and Zhangwu Road, along Siping Road. Break the barrier between Fuxin Road and Siping Road. These strategies will increase the opening degree of the interface along the street. According to increasing the entrances and exits along Siping Road and opening the interface, people can easily and quickly reach the main road of Siping Road. The opening of the interface improves the integration of the road network system and increases people's choice of roads.
 - Connect Jinxi Road with Dalian Road and Yanji West Road. Connect Sujiatun Road with Jiang-Controlling Road. Connect Tieling Road with Jiang-Controlling Road. Fuxin Road and Tieling Road will be extended northward to intersect the central node space in the new bus village. Meanwhile, the north-south, East-West of the new bus village will be connected to form a cross-axis pedestrian road network system. Finally, create open blocks and dredge the city capillaries.

Figure 12. Integration

Figure 13. Choice

Figure 14. Total depth

Figure 15. Connectivity

2. Add public space nodes. The places with high integration degree should be active, but some areas with high integration degree are crowded and have poor quality. It is necessary to expand public space and form node squares. Fuxin Road, Anshan Road, Sujiatun Road and Dahushan Road have a high degree of integration, which makes them easy to gather traffic. Simultaneously, they are also places where people have a strong understanding of space and a high degree of comprehension. They are suitable to construct public space nodes. The new pedestrian public space was shown in Figure 17 and the measurements were summarized as follows.
 - Focus on building Jinxi Road, Fuxin Road, Anshan Road, Sujiatun Road and Tieling Road and make them become pedestrian streets. Widen the pedestrian roads on both sides of Sujiatun Road and Dahushan Road and remove the fences on both sides of the road. Increase the openness of the interface. By replacing the functions of the bottom floors of the buildings on both sides into commercial shops, residents are allowed to declare functional replacement so as to provide merit for the pedestrian roads. Jinxi Road and Sujiatun Road will be built to pedestrian roads and Fuxin Road will be built to a pedestrian priority road. Fuxin Road before and after two sections can allow motor vehicles to pass and the middle part can be used as a pure

pedestrian road. Fuxin Road, Jinxi Road, Zhangwu Road, Anshan Road and Sujiatun Road have become the main spatial topological structures, and the public spaces along them will be strengthened.

- Public node squares are built at new openings along Siping Road. City squares are constructed at TOD nodes between Tongji University Station and Siping Road Station. The turning points of Jinxi Road, Anshan Road and Fuxin Road form public space nodes. The core node square is set at the junction of Jinxi Road and Tieling Road.
- When the building is densely textured and there is no public space reserved, the buildings with poor living conditions and suitable transformation will be dismantled through functional replacement. the bottom part will be removed and public facilities will be increased to form public places of activity.

Figure 16. New road network

Figure 17. New public pedestrian space

3. Build a reasonable neighborhood size. The largest, smallest and average neighborhood size in Anshan New Village are 600*500 meters, 100*200 square meters, and 400*300 meters, respectively. Via segmentation of existing neighborhoods, about six determinant buildings are partially enclosed to form a private unit. The new size is about a quarter of the size of the current neighborhood and there is a branch between 80 and 100 meters. The inner part of the private unit is a community garden, which is only for the leisure and enjoyment of the people in the unit. Private units become public space outside through the replacement of the underlying functions into shops to create street eyes. Retail stores not only support pedestrians purchase needs, but also play the role of community safety monitoring, which is conducive to the formation of community atmosphere. According to the enclosure of small blocks, the unit is more private inside and has commercial function support outside. The specific measurement was summarized as follows.
 - The five villages in Anshan, six villages in Anshan and seven villages in Anshan are re-divided to form three residential groups. The plots along Siping Road are re-divided for high-intensity development. At the same time, the four villages in Daanshan will be re-divided to create a reasonable size of the neighbourhood.
4. Improve the quality of walking space. As shown in Figure 18 and Figure 19, the synergy between global and local integration of Anshan New Village is 0.56. Current road synergy is relatively general, indicating that it is difficult for residents to recognize the whole through local. The degree of synergy between connectivity and integration is 0.25. In the pedestrian road, there are many broken roads, T-shaped roads and so on. The comprehensibility of the pedestrian road is very poor. It is difficult for the pedestrian to feel the surrounding space environment. The lack of highly identifiable node space in the regional road network

system leads to the lack of perception of the overall form of the city. Therefore, we must rely on several main development axes to complete the subjective perception of urban form. The vision of city life was shown in Figure 20 and the specific measurement was summarized as follows.

- In the places with higher integration, the node public space with perceptible urban intentions is arranged. On the main spatial topological structures along Siping Road, Fuxin Road, Jinxi Road, Anshan Road, Sujiatun Road and Tieling Road, the main development axes and urban intentions are formed by expanding public space, increasing commercial interfaces, setting up external swing areas and planting street trees to improve the quality of pedestrian space.

Figure 18. The synergy between global and local integration of Anshan New Village

Figure 19. The synergy between connectivity and integration of Anshan New Village

Based on spatial syntax analysis, it is proved that after the formation of pedestrian space network in Anshan New Village area, the integration of internal roads, Fushun Road and Sujiatun Road along Siping Road has been significantly improved, and the accessibility of internal pedestrian roads in large old residential areas has been enhanced. Especially, when the 10-minute walking distance, namely 800 meters, is used as the travel radius calculation, the regional center integration degree has been significantly improved, and the global integration degree has also been improved to varying degrees. Fuxin Road is still the most selective street. However, under the 800 meters travel radius scale, residents obviously have more choices. In addition to the main roads such as Jinxi Road, Zhangwu Road and Tieling Road, there are more roads with the potential to attract cross-traffic. People can go through the interior of super-large-scale residential areas, and travel efficiently and conveniently. Many large-scale plots also have high traffic attraction after being re-divided. Additionally, the connection value of pedestrian structure roads in residential areas has also been significantly improved and the clear pedestrian network has been formed. The degree of synergy between local integration and global integration has also been significantly improved, and the system has good comprehensibility.

Figure 20. The vision of city life

Conclusion

Walking is the most basic mode of transportation in a city. Walking not only alleviates traffic pressure, saves energy and reduces emissions, but also promotes interpersonal communication and health. Walking is conducive to the construction of a healthy city. In the future, metropolitan cities will face the trend of more dense population and more dense buildings. Many cities will face severe environmental pollution and lack of resources. We should pay more attention to the friendly environment and create comfortable and natural urban pedestrian traffic space.

This paper studied the current network of pedestrian system in Anshan New Village and built a more friendly and healthy urban pedestrian system through increasing the density of pedestrian paths, optimizing the way of path connection, adding public space nodes, and dividing reasonable open neighborhood size. The results can provide a reference for how to establish a good pedestrian environment in the process of urban renewal in Shanghai.

THE REPOSITIONING AND URBANISATION OF HEALTH: NEW HEALTHY PLACES ALONG HOSPITAL-CITY-CONTINUUM AND ITS IMPLICATIONS FOR HEALTHY CITY PLANNING

Magdalena Maierhofer

TUW, magdalena.maierhofer@tuwien.ac.at

Abstract:

The role of health in our cities and in planning is radically changing. Aaron Antonovsky's concept of the Healthsease-Disease-Continuum brought the dichotomy of disease and health to an end. Consequently, the differentiation between a place for the ill (hospital) and one for the healthy (neighbourhood) is outdated and rather moves towards into a Hospital-City-Continuum. While the World Health Organisation (WHO) identified the city and the urban environment as the main setting for health promotion, health infrastructures are gradually losing their insulated positions and turn into integrated elements of the neighbourhood's everyday life. Considered systematically the borders between hospital- and urban areas are blurring. Resulting from this, new fields and places for health infrastructure, health promotions and urban health evolve. At the same time, health promotion and health care increasingly penetrate the everyday spaces in the cities. Digital Health, individualized care, personalised (or stratified) medicine and mobile medical devices are no longer banded to health institutions. On the contrary, they can turn a private bedroom into a temporary patient room. The paper identifies and describes these (new) healthy places, positions them along the Continuum and enquires into their possible futures.

Introduction

The borders between the hospital and the city blur as the first assumes traits of the neighborhood while in the latter health is increasingly playing a distinctive role.

The compact and sealed off hospitals were a result of the last century's new technological and medical achievements. Patients flocked to the clinics for an increasing number of examinations and treatments; stationary admissions became quite common thereby marginalising the outpatient sector. Today, the medical wind is changing. Many devices lost their former size and increased the mobility, a gadget on our wrist monitors our physical functions, telemedicine enables the physician to treat a patient without requiring his direct presence and thanks to minimally invasive surgery patients leave the hospital on the same day of the intervention. Medicine is pushing back into the city and people's everyday life. This development raises the question as to how the nexus of hospital, health and city acts on each of its components. How do we handle the re-urbanisation of health and hospitals?

Historically, the form of a hospital was always a reliable indicator for the importance of health in the city. Every change in opinion gave birth to a new (or at least transformed) image of both the hospital and the city. Consequently, only a joint analysis of the city and the hospital on the one side, and urban planning and public health on the other side, can explain the on-going re-urbanisation. Against this backdrop I will conduct a comparative analysis of historical tendencies regarding the conjunction of the hospital and its (urban)

neighbourhood asking what can be learned from the organisation of the latter for the planning of the first. Opening up these closed or semi-closed entities can only prove beneficial when merging one into the other.

Starting from this assumption, the paper will introduce a new notion of explaining these areas along the lines of Aaron Antonovsky's (1979) idea of the health-ease / dis-ease continuum (HEDE). Differentiating between a place for the ill (hospital) and one for the healthy (neighbourhood) is both exclusive and out-dated as they clearly develop into a hospital-city-continuum (HCC).

Figure 1: The hospital as an egg (Tracing of Cedric Price's original 1982 diagram, "The City as an Egg.")

The erosion of the "big hospital"

The design of hospitals is radically changing. The number of beds is being reduced, patients get redirected into primary care units or the like, as ever-improving medical engineering contributes to the erosion of the "big hospital". Large specialised and monofunctional central hospitals, the ancient "palaces of medicine" if you like, obviously fail to meet today's demands. While medical care is pushing its way back into the city's heart, the hospital is increasingly requested to take in "urban qualities". Borders between city and hospital are continuously blurred. Once the 20th century's behemoths of medical care, hospitals now seem to morph (back) into the surrounding quarters – a trend which I see as the "re-urbanisation of the clinic". (Wagenaar, 2006)

Hermetic super-hospitals like the Cornell Medical Centre in New York, or the University Hospital Aachen, or the Vienna General Hospital have a quite short history. Their de-urbanised concept, which seemingly disregards the outside world, does barely count a hundred years. Keeping in mind which spirit gave birth to these anti-urban clinics helps to the understanding of their present demise. (Foucault, 1973) Now and then, a wide-ranging repositioning of both the hospital and public health changed their interrelated connections to the city.

From the healing environments of Pavilion Hospitals to medical functionalism

Pavilion hospitals came up as the 19th century's solution to the quest for the ideal conditions of healing environments. Bright, sunny, well aerated and dry rooms were the non-plus-ultra of the time. Physicians were eager to use the results of the freshly blossomed medical empiricism and translate them into scientifically founded building types for hospitals. As measured by the standards of that time, we could read the resulting architecture as evidence-based design.

At the beginning of the 20th century, the medical disciplines change radically. It started to turn into a science, which necessitates ever more and ever bigger apparatuses – most of them immobile. Technical progress forced medicine into stationary treatment and assigned hospitals a hitherto unknown importance. (Corburn, 2009)

At the same time, the doctors' interest pivoted from the patients' living circumstances to their "inner life", the functioning and condition of their organs. (Rodensteiner, 1988) Improved microscopes and, even more importantly, the invention of the X-ray machine changed the idea of human health. Previous concepts of hospital planning appeared to be overcome, the creation of healing environments lost importance. Healing architecture had to make way for highly-specialised, compact and ever-growing buildings – medical functionalism had prevailed. The new "monuments of medicine" follow their own inner logic; they seem to ignore the urban environment just as a purely biomedical perspective on illness (and health) disregards environmental aspects. Clearly, the enclave-character of the institutions mirrored the constructed reality of the contemporary concepts of health. The de-urbanising of the hospital is a consequence of the institutionalisation of the associated de-normalisation of the clinical space. Health disappeared from the public sphere and was relegated behind the impenetrable hospital walls. This observation is significant as the motives that led to de-urbanisation are no longer valid; even more, they have attracted fierce criticism.

The Re-Urbanisation of the Hospital

Today, current hospital concepts seem to have reached their limits as they fail to answer to concerns of public health and planning. New developments such as telemedicine arise, medical devices get smaller and more mobile. Thanks to keyhole surgery and the like, the duration of hospital stays decreases. Specialised hospitals lose their monopoly over healthcare provision and it's not heretical to ask whether in the future we will need them at all. (Wischer, 2007)

Over the last decades, hospital planning has earned the reputation of a "secret science" as of its high complexity and unique character. Only genuine specialists could develop a true understanding of the mysterious matters inside. Hospital planning drifted away from the general discourse and sealed itself off from not-specific trends. Many prominent topics such as the critique of functionalism, inclusiveness or flexibility, which changed urban planning and architecture, seem as if they never really entered the sphere of hospital planning. (Nickl-Weller/Nickl, 2013)

However, it became clear that a hospital's rapidly varying professional focus, organisation and procedures couldn't provide for a reliable basis for sustainable design. As a result, medical functionalism is no longer the legit foundation of hospital planning. Its tasks undergo an important

"normalisation". This development must not be misinterpreted as mere simplification. On the contrary, previously ignored qualities like urban integration gain in importance. Subsequent approaches advocate hospitals that are no longer recognizable as such, as their sheer immensity is said to represent the inhumanity of "health machines". Henceforth, values like the human, the normal and the urban shall prevail. Urbanity is the word, the promise of salvation in a world of institutionalised cold-heartedness of shuttered clinics. The building, for instance, should contribute to public life on its site. At the same time, normalisation alters the image of the hospital, which loses the aura of a closed and solitary monument. The implication is clear. The hospital itself morphs into the city becoming an integral part

of the city and the neighbourhood. As we overcome the duality of city and hospital, the latter turns out to be both an important exercise and tool in urban planning. We shall take a closer look on three levels:

- Level 1: The hospital in the city (location of the hospital)
- Level 2: The hospital in the neighbourhood (blending with the environment)
- Level 3: The hospital as city (as urban space)

(Maierhofer, 2016)

Figure 2: Levels of the hospital-urbanisation

The hospital in the city

Together with other institutions, such as an university, the city hall or a market, the hospital constitutes the basic framework of the urban fabric, the city.

The Viennese hospital master plan (Wiener Spitalskonzept 2030) displays the multiple ways a hospital may influence its urban surroundings and the city. 32,000 employees on seven locations are going to be reorganised. 10,000 beds, 400,000 stationary admissions and 3,500,000 ambulatory services per annum add to this figure. These vast numbers of permanently working, temporarily dwelling and repeatedly visiting people draw an impressive picture of how the location of such crowds and the associated visitor frequency affects the whole city and the specific site or neighbourhood. The numbers clearly point out that projecting a hospital means shaping, building and developing a city.

The crucial question of hospital planning concerns the selection of an appropriate site for the hospital. Only on rare occasions, the planner will effectively be able to choose the location. Rarely the planner may effectively choose the site. However, in this seldom case this decision has both large and long-ranging effects on healthcare provision and the city. This is why this choice must always be understood as a tool for urban development and has to anticipate future developments. The choice may change the city from within, can be part of the development or expansion of the city or may be used as a starting point of a new city.

The planner's goal shall be to link city and hospital in order to lift the veil of exclusiveness from the latter and finally overcome the not-so-invisible barriers to the neighbourhood. The city, on the other hand, has to embrace closer to the hospital and allow for its development on the urban ground. This can only be achieved through common planning of both structures.

The hospital in the neighbourhood

The strict division between structures for the sick and for the healthy can no longer be maintained. Health science has replaced this dichotomy by the “health-ease versus dis-ease continuum” (HDC). (Antonovsky, 1979) Many people live with their medical conditions, some more, some less severe. Preventive healthcare is and shall be part of everyone's quotidian live, another reason for finally bringing down the walls parting institutionalised medical care in hospitals from daily business in the urban context. The notion of functional separation is seen as obsolete for many aspects of urban organisation and hence must be reassessed also in the view of healthcare buildings.

Figure 3: Integrated hospital planning

The hospital needs to blend into its surroundings and must intermesh with it on the functional, structural as well as special developments. Hospital planning must learn to see beyond the end of its stonewalled nose. In rare cases the qualities of the quarter will may prove harmful to the hospital, and vice versa. People who work at the hospital, who make a visit or receive treatments all need everyday things, that define a well-functioning town centre, a shopping street or the like. Still, the job is only half done by incorporating qualities of the quarter into the hospital: the hospital itself has to spread over into the neighbourhood. Neither are health, its provision or its promotion exclusive to hospitals, nor are they strange to the city. While integrated healthcare allows for a smoother transition between “healthy at home” and “sick in stationary care” than it used to be, it also demands closer cooperation and communication between primary care in the city and the inpatient sector.

The location in city is of distinct significance regarding the wards. While historic hospitals used to be organised as huge wards with a small number of adjacent rooms, state of the art organisation puts examination and treatment areas at the core of the hospital. The number of beds is diminishing whereas outpatient units gain importance. New flexible types of care emerge, either provided by the hospital

itself (on- or off-site) or in cooperation with the outpatient sector. This shapes the transition from fulltime care to discharge as a multi-stage process, which is reflected by both the spatial aspects and the distance to the core facilities. This form of integrated care blurs the lines between primary and secondary care. (Stapf-Finé/Schölkopf, 2007)

In the first scenario, patients are bed-bound and depend on the total surveillance of intensive care units. These are contrasted by practically healthy patients who, concerning their accommodations, have only moderate demands. For instance, it is appropriate to plan units which require less or little attention according to the logic of the city rather than to that of the hospital. The result is a continuum of hospital and city, which - in parallel to the HDC - accompanies the patients to the hospital gates and back to their quotidian life.

The hospital as a city

It is impossible to derive the immanent form of the hospital from its functions. One reason for this is in wide range of functions which all require different formal and spatial solutions. In addition, technological and medical know-how progress at an immensely fast pace acting as constant drivers of change. Every tailor-made solution, akin to a fashionable suit, would become obsolete after a couple of years.

Building a hospital is a costly affair, but running (and adapting) it will make your expenses skyrocket. It's virtually impossible to predict the challenges and requirements it will have to manage in 20 years. Hospital construction is a highly complex matter and subject to permanent transformation. Its sustainability depends on its adaptability. (Wischer, 2006)

Regarding on the hospital site, the building structure is the most important aspect of sustainability – and this, in turn, is an argument of urban design. Therefore, it is necessary to differentiate between hospital construction as long-term structure and hospital construction as „designed function“. This “designed function” describes the architectural and functional development of single hospital tracts or facilities such as stations, an emergency department (ED) or a specific department.

On the other hand, the “long-term structure” guarantees a spatial arrangement that is not only focused on present duties but allows for future adjustments – without having to question the whole organisation. This applies to both the hospital and its environment. (ibid.)

Hospital design becomes less specific as it moves towards more “normal” shapes. By virtue of this “normalisation” the planner can develop qualities independent from the building tasks. But, what are these “long-term conditions of health promotion” and what do they imply for the hospital as health promoting surrounding.

Figure 4: The element of the hospital ((Tracing of Kevin Lynch's original 1960 diagram, "The elements of the city")

If it holds true: A house, a hospital, a city; what's the difference?

It also must hold true: A good house, a good hospital, a good city; what's the difference?

So, we will be called upon to be good urban planner. (Driesen, 2006)

The city-like hospital includes tiny alleys and large streets, a variety of pathways, circular roads and axes, calli and campielli, small yards, large squares, landmarks, monuments and residential districts, houses of every size; it encloses shops, restaurants or caf  s, hotels, schools, a cinema, churches, workshops and offices. People work here, dwell and shop and celebrate here. Here they are born and here they die.

The apparent resemblance with urban spaces isn't just the result of a re-urbanised view but reveals a new understanding of looking at the conjunction of health, the city and hospitals. While the hospital adopts more and more city traits, the urban space assumes greater responsibility in healthcare provision. The compact, big hospital is to lose its importance, predictions say. It seems obvious, that the hospital's insulating walls will be torn down. The frontier between the space for the sick and the space for the fit dissolves as the dichotomy of health vanishes in the haze.

However, the impetus for this development isn't coming from the hospital alone. The second important driver of change is a new perception of the healthy city, which is born out of a novel notion of health itself.

Healthy, healthier, urban

Although urban development and medicine are mostly seen as two distinct disciplines, this hasn't always been like that. Just like their built manifestations, the fields drifted apart in the 19th century and are now slowly re-approaching each other.

Especially at the beginning of the 19th century – against the backdrop of rapidly growing cities and on the onset of modern natural science - the two disciplines lived through a quite intense love affair. Their mutual key issues consisted of the establishment of a healthy environment; this lasted until biomedical foundations of medicine were discovered and modern urban planning devoted itself to rational

functionalism. They lost interest in each other and embarked on two different academic roads. (Corburn, 2004)

Today, the glance at the city has become holistic again – everyday life is gaining ground. Urban planning concentrates on subjective experience and strives for understandable and customisable cities with empowerment and participation being the hot topics. Now that the total refusal of the city has been abandoned, urban sentiments are booming - again.

At the same time the paradigms of health are shifting. In 1948, the WHO's founding declaration adds subjective feelings to the definition of health which is described as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity". Both this conceptual realignment and the re-embrace of the city lay the foundations for the re-invigorated alliance and hence for mutual strategies of action in shared action fields. Both disciplines start to take interest in particular living worlds, quarters and neighbourhoods.

While urban planning dwells on the discovery of the micro plane, the medicinal disciplines revive their interest in the big picture: the human being in its habitat. As a result, research interests and action levels overlap once again in the second half of the 20th century. Bluntly put: while urban planners zoom into the city, physicists zoom out of the body. City and health meet each other in the living worlds of the people and open up a new, joint area of activity.

Along with the resuscitated concordance also methods and strategies come to a change. Planning becomes an integrating, coordinating and moderating purpose. Similar terms appear in the public health discourse as the WHO declares participation, empowerment and intersectorality as the principles of action for health promotion. Still, against the backdrop of all the similarities listed above, it astonishes how little the planning discourse of that time refers to health topics. It surprises even more as no such reservations can be observed in healthcare debates. On the contrary, beginning with the 1960s health scientist pounced on the city and started to discover it in quite an euphoric fashion.

The WHO's setting approach encourages health promotion at its origin, namely "where they learn, work, play, and love", within the settings of their everyday life. In this context, cities are the arguably most important setting. The programme aims to place health high on the agendas of decision makers and to endorse health promoting general policies. So called Health Impact Assessments (HIA) help to evaluate the policies' influence on health. All this serves the purpose of integrating health topics and measures in city planning and development.

Parallel to our analysis of hospital urbanisation, the WHO equally proposes three settings for urban health promotion: the healthy city, the healthy quarter and the healthy hospital. Urban health promotion does not only deal with the city as a whole. Many concepts take into account the quarter and the district – the hood, if you like. Since the quarter comprises a variety of spheres and hence of health afflicting factors, numerous (quotidian) risks can be reduced while health potentials can be fostered.

The idea of health promotion follows a remarkably all-embracing approach. As of its immersion into constructional and physical, social, political, administrative and symbolic topics it seems nearly impossible to separate it from other fields, especially from neighbourhood development. At a first glance, the term health-promoting hospital may appear slightly redundant but it actually does make sense in the logic of general health promotion. Taking into consideration the size of hospitals, the

amount of employees, patients and visitors and the impact of the institution on its environment, the inherent potential for health promotion becomes apparent.

The hospital plays a particular role that can be compared to universities. While the latter provide access to science and education (as institutions for research and teaching) the first carry responsibility for urban health. A health-promoting city stays a mirage without health-promoting hospitals, whereas the creation of health-promoting environments constitutes an integral part of the health-promoting hospitals. The most powerful tool of health promotion is THE health care institution itself: the hospital.

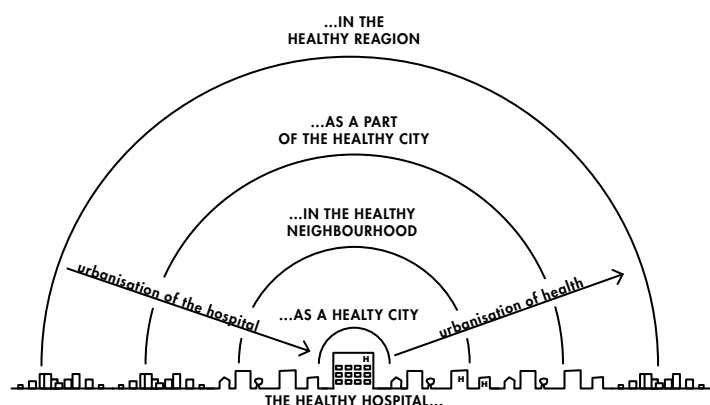

Figure 5: The healthy hospital in the healthy city

So the hospital shall become a health-promoting environment and subsequently contribute to raise the level of health promotion in the neighbourhood and the city. Bearing this spill over in mind, we can understand the correlation between the form and urbanisation of the clinic. Simultaneously, physicians re-focus on a patient's health on its whole, instead of exclusively examining the sick body. Aron Antonovsky and his description of the sense of coherence bring back the peoples' reality of life to health science. Once more, borders are overcome between health and disease as well as between pathogenic and health-maintaining spaces. City and hospital converge as more and more health arguments pop up in urban planning and hospital architecture ponders everyday properties.

The hospital-city-continuum (HCC)

In the past, the location and form of a hospital expressed the respective understanding of health and their place in urban society. Also today we may question into the current definition of health to understand the re-urbanisation of hospitals.

The duality of illness and health has been superseded by Aron Antonovskys's (1979) concept of salutogenesis, replacing it with the HEDE. In consequence, we can no longer discriminate between spaces for the sick and the fit, namely between the hospital and the city. Health promotion is no longer happening behind hospital walls, but is becoming an integral part of urban life. Simultaneously, the hospital gets increasingly integrated into the urban tissue. So it's not a mere re-urbanisation we are describing but the birth of the hospital-city-continuum (HCC). Like before, observations can be made on various levels.

Private apartments turn into hospital rooms while visiting the clinic means daily business for many city residents. A fluent transition between the two worlds implies that the “day of admission” loses the nimbus of a hard rupture between two lives (in or out, sick or healthy, etc.). The patient biography describes a gradual path; preliminary examinations and follow-ups are held in the city, the night prior to an operation is spent at the patient hotel while the procedure takes place in the core hospital. After a short time in the actual patient bed one progressively moves back to the city via patient hotel, patient apartment, day clinics and finally care at home (hence “normalising” one’s situation and condition). So we could assert that every patient passes through the HCC.

The HCC’s second implication considers the planning and building of hospitals, their physical aspects. Just as in any good community, the borders between “in” and “out” must be torn down. When the medical service spreads over the neighbourhood, the physical structure has to follow. We do not need an intermediate space between two worlds helping to comfort patients, relatives and staff. The solution for the modern hospital lies within an analogous continuum of treatment structure (both physical and organizational), from primary care at the rim to the hot floors at the core. With a shrinking hospital, the neighbour (the city) is ready to take over and reanimate the abandoned structure. – the spatial HCC.

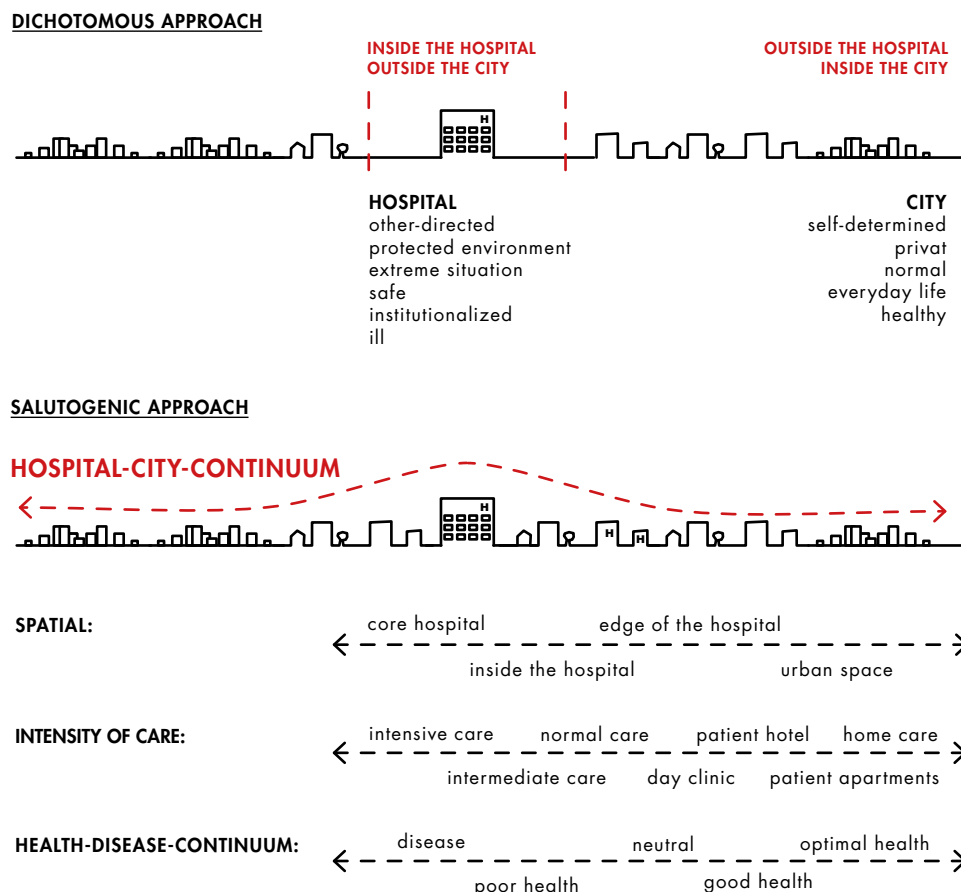

Figure 6: Hospital-city-continuum

This process will not take place abruptly, but gradually. Structures that are developed as hospitals today may be part of the “normal” neighbourhood in 40 years. Having been planned for surgery and intensive care, the core hospital might be recycled as administrative facility and thereby be moved towards the

rim before eventually merging into the city finding its built fate as university, residential complex or the like. Therefore, a genuine challenge is the planning of structures that allow for future adaptations along the lines of the HCC and repositioning therein. This process will not take place abruptly, but gradually.

Cunclusion

The disintegration of the hospital does not imply the disappearance of health infrastructure, but solely its relocation into the city, the neighbourhood, to a private apartment or the digital world. Frontiers between disciplines are brought down - no longer can be clearly distinguished between public health, urban planning and hospital architecture. Hospital planning as an isolated field will cease to exist giving way to new strategic and integrated approaches, which are needed to shape the urbanisation of health. While a hospital must always be the responsibility of urban planning, the three disciplines shall not disintegrate but maintain continuous distinctions. Neither urban nor hospital planning can be responsible for the application of health concepts for the city. On the other hand, health science won't take on the task of exploring the "goodcity" and how to plan it. Therefore, architects and urban planners must proactively develop the HCC. It has to be designed and planned like a city – like a good city.

Abstract: Having as case study the parish of Rio de Mouro, a suburb of Lisbon, in this work, we try to verify in what extent the practice of physical activity fits into the daily life of the families. For this, surveys were carried out on resident families whose results show not only the existence of asymmetries in the practice of physical activity due to the socioeconomic characteristics of the population, but also due to the means of transport used in the commuting movements. A more in-depth reading shows that physical activity practice requires a framework that follows the activities of individuals and their families throughout the day (understanding the life cycle and types of families: young people, active with or without dependent children, retirees, among other modalities), so it is often the case that greater practice of physical activity arises associated to the use of the car as a mode of travel.

Keywords: Health determinants; Physical activity practices; Daily life; Means of transportation

Introduction

Lifestyles are one of the major determinants that affect the health of populations. One of the areas linked to it is physical activity practices (Dahlgren e Whitehead, 1993; Warburton et al, 2006; World Health Organization [WHO], 2008), that emphasizes that the lack of practice of physical activity is not only a problem of individuals, but also has social, economic and environmental repercussions (Kohl *et al.*, 2012). Nevertheless, the practice is generally limited to a small part of the population (Miles, 2007). As reasons for this phenomenon are: socioeconomic characteristics of the population, distance and time-consuming in daily commuting movements and the use or not of the own car or public transport (Bauman *et al.*, 2012; Franco, 2017; Franco and Marques da Costa, 2017). The availability of time and the squeeze time are factors that affect the practice of physical activity, depend largely on the mobility and the relation between working and non-working time (Marques da Costa, 2007, Marques da Costa and Louro, 2010).

In this work, we try to verify in what extent the practice of physical activity fits into the daily life of families, while also understanding if the use of private vehicle is a permissive factor in that. For this purpose, it was used one case study, the parish of Rio de Mouro, a suburb of Lisbon Metropolitan Area [LMA]. In order to assess socioeconomic characteristics, lifestyles and habits, physical activity practice, time use patterns and means of transportation preferred surveys were carried out on resident families. Those were later worked, and the results are based on statistical analysis and crossed information retrieved from them.

Theoretical framework

The correlation between physical activity, health and quality of life is strong (Warburton et al, 2006, WHO, 2008). Physical activity is seen as a decisive behavior for the individual's health and functional capacity (WHO, 2007). However, it awakens and promotes behavioral changes in society, therefore is a public health issue, increasing the well-being felt in communities, not just the individual health (WHO, 2011).

Only a small part of the population practices physical activity (Miles, 2007). This is not only related to their socioeconomic characteristics, but also the way the individual moves in his daily life - using his own vehicle or public transport - or the duration or distance of commuting itself (Bauman *et al.*, 2012). The availability of time time squeeze conflicts are a factor in the practice of physical activity. The structures of mobility and the relation between work and nonwork time are rather complex (Marques da Costa, 2007, Marques da Costa and Louro, 2010). The struggle of families against the 24 hours a day is a constant, it is necessary to make time available for paid work and for domestic work and also for family and leisure. It is usually necessary to abdicate of some activity to fit the practice of physical activity in the individuals' daily schedule, which consequently brings repercussions in family everyday life. This has implications for the practice of physical activity, due to the lack of time and framing of everyday activities, these type of activities are relegated to the background, resulting in time squeeze problems (Naegele *et al.*, 2003). These confrontations are even enhanced by the socio-geographic context, that is, the space problems and the mobility and means of transportation problems.

The lack of physical activity practice in today's society is becoming a problem, as it is implicated in a more or less direct way in many causes of death (Pate *et al.*, 2008; Barnes *et al.*, 2012). However, the inexistence of physical activity is not only a problem of individuals, it also has social, economic and environmental repercussions (Kohl et al, 2012). Hence, assessing the population practices and habits in this aspect, has large significance in health planning and in the composition and implementation of policies and programs.

Methodology and study area

The work was developed using statistical analysis of general indicators taken from the INE (national statistics) database and from information obtained through surveys. These surveys were applied to the population living in the parish of Rio de Mouro (in Sintra municipality, LMA), the data obtain referes to a total of 154 respondents. The survey intended to retrieve information about the socioeconomic characteristics, daily time use and physical activity practices. For this it was considered various types of physical activity: open air activities (like running, biking, group sports); gymnasiums; swimming

(pool). Also, with the survey data we created different family typologies that address the sample reality.

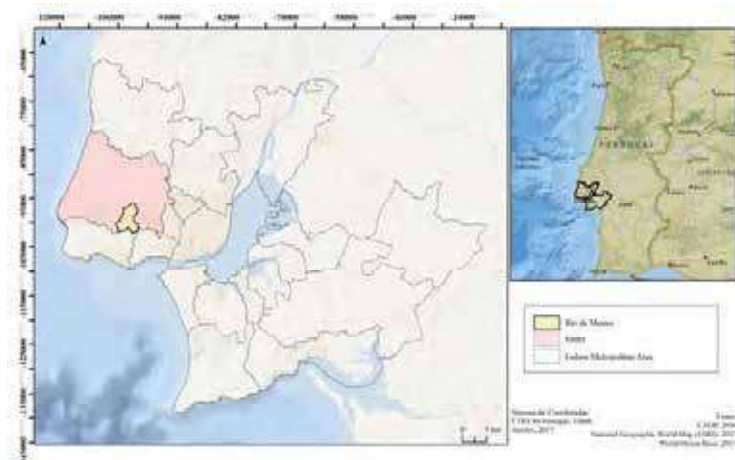

Figure 1. Territorial contextualization of the study area. Source: own execution.

Figure 2. Structuring axes of urban occupation. Source: Marques da Costa et al. (2009).

Rio de Mouro is a parish of Sintra municipality and is situated in the first suburbanization crown of LMA. As it can be observed in Table 1, LMA is a heterogeneous region with some very different realities, even its municipalities possess traits of heterogeneity inside. Sintra ranks in the bottom half of LMA – except in the demographic aspect, as its inhabitants are younger than the average –. The majority of Sintra parishes are dependent of Lisbon municipality (in which Rio de Mouro is included), because a large part of its population works outside the municipality (normally in Lisbon). So, the daily movements are an important part of the individual's daily life. Therefore, Rio de Mouro is a good case study for an evaluation like the one we are doing in a suburban area.

Region	Youth Dependency index	Elderly Dependency index	Population Density (hab/km2)	Medics per 1000 inhabitants	Monthly mean earnings	Transition / completion rate secondary education

Results and discussion

The practice of physical activity is, in general, quite reduced, with 38% of the sample saying that practice it and 62% that does not practice it. It is a rather strong prevalence of unhealthy habits that goes along with the rest of the country reality, in fact, according to data from WHO, these values seem to be slightly better than those concerning the whole country.

In the analysis we have found many asymmetries among the resident population regarding physical activity practices. Some of those are related to socioeconomic characteristics and others linked with the means of transportation.

Physical activity is mainly practiced by men. Actually, there is little difference between those who practice and those who do not do it (pending to the last one), this in men. When we observe the women, it is not the same, the values for those that do not practice any physical activity more than double those who do it. So, sex is clearly a differentiating factor in physical activity practice in the territory analysed.

Age is also a preponderant factor for physical activity practice. Looking to these activity habits by age groups, it is possible to notice that the population that falls in the age groups of 6 to 12 years old and the two groups that comprise the ages between 18 and 49 years of age, are those that practice physical

activity the most, however the class from 6 to 12 years and from 18 to 29 years old are the only ones in which it is verified that the practicing individuals exist in greater number than the non-practicing.

This demonstrates the importance of physical activity in school context, helping to create and maintain healthy habits and lifestyles. But not only, the reduced physical activity practiced by the elder groups, mainly the 66 or more years old, emphasize the lack of effective strategies for active aging.

Figure 3. Practitioners of physical activity by age group in the suburban studied area, in percentage. Source: inquiry.

In none of the education levels – ranging from illiteracy to tertiary level – the number of individuals practicing physical activity is higher than the non-practicing ones. Is in the group with a higher educational level that the highest proportion of population practicing is observed, followed by individuals with lower secondary and lower primary. In fact, there is a differentiation between persons with higher level of schooling and the remaining ones, nevertheless, the smaller proportion between practitioners and non-practitioners is found in individuals with the 2nd Cycle completed and not with the illiterate level.

The educational level does not seem to evolve around some major rule, nevertheless, the highest values are detected in the highest educational level.

Figure 4. Practitioners of physical activity by educational level, in percentage. Source: inquiry.

The lowest levels of income correspond to those with the least physical activity. The highest incomes – with the exception of the highest echelon – demonstrate about 63% (€ 1000-1500) and 73% (€ 1500-2500) of practicans. This translates into the fact that, to some extent, there is a level of income in which below it there are considerable less (or none) population practicing physical activity.

The means of transportation used by most of the reporting population to travel to the place where they practice their physical activity are the car (especially this one) and the trip on foot, without any competitors. Among the other modes used are the bicycle (mainly used by regular cycling practitioners, both for physical activity and for others) and the train. In terms of transport used by household income levels, a greater propensity to use the car is perceived as incomes increase. In fact, from the income bracket 1000 to 1500 euros, car use becomes predominant in these journeys. Also, in the general context of mobility, from this income level and upwards that the car is most used.

Means of transportation and household income are correlated; bigger incomes translate to higher use of private transport, in contrast, smaller incomes result in higher use of public transportation.

Whilst regarding the relation between the constituency of households and the means of transportation, the families with children under the age of 15 years are the ones who use the car. This can be partly explained due to the almost unavoidable use of this type of transport in order to the individual be able to carry out all the daily tasks of caring for him and his family with a normal working day.

Practically two-fifths of those practicing physical activity use the car in commuting, followed by the combined use of their own vehicle and public transportation and the use of public transport. However, there is a more important information to retain, whereas amongst private vehicle users physical activity practice is doubled when compared to non-practitioners, in public transport users, non-practitioners are superior to practitioners, but when both types are used, practitioners are superior to non-practitioners. It should also be noted that all those who move on foot to and from work are too practitioners of physical activity.

What is verified is the existence of a greater number of practitioners when the individuals use the car, because this mode of transport is (a real) factor in providing greater independence to individuals.

Figure 5. Practitioners of physical activity by family income, in percentage. Source: inquiry.

Figure 6. Means of transportation used to the place where the physical activity is practiced by type of aggregate and household income, in percentage of practitioners. Source: inquiry.

Although it is observed that the greater use of automobile in the daily movements increases the number of practitioners of physical activity, the reality is that individuals who show more regularity in physical activity practice are users of a mixed typology, followed by those who use public transports and lastly the ones who utilize the car. In this situation, it can be seen that the lower frequency is not related to the greater or lesser ease of integration of the physical activity in the day-to-day schedule, since this is already inserted in the daily life of the individual.

However, when analyzing the mode of transportation used in the commuting movements by the most active physical activity groups, a distinction is made between the existence of dependents – that in this study are viewed as the households that have one or more individuals with 15 years or less – and those without such dependents, it is noticeable that the majorities of families with dependents and practitioners of physical activity at least 3 times a week use the car at some point in their daily life, while the others use more public transport. Between car and mixed transport, those with dependents account for more than 75%, on the other hand, those who do not have dependents register just under 45%.

Figure 7. Weekly frequency of practice of at least one physical activity, as a percentage of the means of transportation used in commuting movements. Source: inquiry.

It is imperative to understand if the same happens to individuals who do not engage in any type of physical activity, understanding if they do not do it due to lack of time, or because they use different means of transportation or a simple matter of disinterest in the activity.

It was assessed that most individuals not practicing any type of physical activity work or study outside the parish of Rio de Mouro. Besides, these individuals, in their vast majority, spend large amounts of time outside their households doing their quotidian activities. It is interesting to note that, although there is a wide use of the car itself in commuting, especially in the typology of families with children under 15 years of age, these persons do not engage in any physical activity. It should also be noted that elderly individuals, although not practicing any kind of physical activity, make their daily commutes on foot. In this way it is perceptible that, in most cases, a time squeeze phenomenon is observed, individuals spend much of their day away from home in their daily activities and cannot find the time necessary to practice physical activity. Even with the use of the automobile itself, individuals are unable to integrate extra activities into their family quotidian life.

The possibility of conflicts between the time available for family and leisure activities with that of practicing physical activity is quite evident. There seems to be a relationship between the family routine and the practice of physical activity. However, there is no connection between the greater or lesser practice, that is, the difficulty lies in creating space in the daily life for practicing activity. In fact, the aggregates that practice it most are also those who denote certain family obligations, let alone the existence of minor dependents.

Therefore, the existence of such time-activity conflicts is reduced by the use of private transportation, but not extinct, since many families continue to be unable to put an end to these conflicts. This is a corroboration that the automobile is a weapon in the fight against time. When using the car in daily commute, the individual has access to a panoply of opportunities that can take advantage, something that could not happen and generate conflicts of time squeeze when used only the public transport, however, the vehicle itself is only a weapon in the fight against such conflicts, is not a sure and "miraculous" response.

Figure 8. Means of transportation used in the daily life by non-practitioners of physical activity, in percentage.
Source: inquiry.

Conclusion

This study allowed to understand the relationship of families with physical activity, considering their socioeconomic characteristics, mobility and the use of time in their daily lives. It was verified that these characteristics play a major role in the physical activity habits, which reiterates the bibliography on the subject. We found that certain aspects, like sex, age and the family budget impact significantly the practices observed.

About the transportation aspect, when only public transport is used the propensity to practice physical activity is lower, however, once the private vehicle element is added to the equation, or when it is the only used, the trend is much higher. This is much more evident in cases which the families have a dependent, here the use of a private vehicle has the ability to enhance the execution of certain activities, in this case physical activity, due to its capacity to coadunate (in a greater extent) the family duties, work requirements and leisure and personal time.

Although not being the one true reason for activity the car arises as an enabler for individuals' practices, even more when the household has one or more dependents.

All in all, there is a close relation between physical activity practice and the family's daily life, because for there to be practice is needed a quotidian activities framework prone to that. Nevertheless, there is no relation between that and frequency of practice.

Track 12 Healthy City Planning: Food, Physical Activity and Social Justice

(Draft)

Healthy city of tomorrow

Lucia Nucci

¹*Departement of Architecture, University of Roma Tre, lucia.nucci@uniroma3.it*

Abstract: In London the 32+1 Boroughs are testing methods, in terms of physical environment's and urban design, to respond to Healthy City model starting from urban open space design. The investigation field is supplied by the different Open Space Strategies OSS written by each Borough giving specific solution in term of design parameters to increase physical activity, elevate air and water quality, play and sport activities, open space deficiency and accessibility. The paper will discuss all sets of innovations introduced which have the potential to reshape the lifestyle and working patterns of urban residents, and to assure sociospatial justice. In UK they start again, using urban design, to interlace open space with services and residence at the local level, as was the local planning and urban design Anglo-Saxon tradition

Keywords: Open Space strategy, London, Boroughs

Introduction

A recent study on the latest regeneration projects in London (Nucci, 2012) proposes few guidelines on planning and designing urban green networks. The hypothesis presented in this London case study states that conceived as a design characterized by integration and continuity the system of urban open spaces can be a primary component of a city with a more consolidated form. The study analyses the possibility of re-using residual or abandoned areas as part of the urban settlement process with consolidated urban open green spaces. These spaces logically form part of continual and integrated green networks, in terms of environmental quality, of creating new uses and of greater social integration. Furthermore, they provide a unified design and quality to the whole city and its parts. The actual efficiency of this hypothesis is often viewed as a principal line of criticism for urban regeneration in terms of its operative, social consensus, economic and administrative feasibility.

The example provided of Great Britain's green networks and in particular the new London Plan has the notable advantage of simultaneously proposing government objectives and strategies for a green space system as an integral part of a proposal for the regeneration of the city (urban renewal) and some operational experiments conducted at a local level¹. The experience must be examined in relation to the Anglo-Saxon tradition of green

¹ In Great Britain, more specifically in London, the government (Department of Environment, Transport and Regions) has implemented a cultural and administrative reform in favour of urban transformations and green policies. In 1999 the *Urban Task Force* proposed guidelines to regenerate cities and London in particular. These

open space, the contractual and pragmatic planning system respectful of local authorities. The research has combined theoretical proposals with practical local experiences examining the feasibility of green theories, the debate between specialists, urban planners, administrators, workers and locals, highlighting both successes and failures. Documents, case studies and various positions emerged has been possible to single out and suggest several guidelines, together with significant issues still being debated. These can be used as theoretical reference and planning strategies for the debate on the regeneration of European cities.

The guidelines at a European level pertain the opportunity:

- to ensure the continuity of the green systems as a common objective for urban regeneration, whilst maintaining the diversity of solutions in relation to the character of the urban and territorial structure;
- to consider the realisation of green networks as an opportunity for the morphological reorganisation of the overall city form and the design of its parts and for the functional reorganisation to create new relations between the parties;
- to think and manage continuity by co-ordinating and moving across different levels (principal, secondary and local networks);
- to consider green network projects as a component of an integral urban project based on the standard used by the urban planners;
- to give preference, in the construction of a continuous network, to the use of residual spaces as elements which insure the capillary articulation of green space in residential zones;
- to reassess the relationship between private, semi-private and public green spaces;
- to re-evaluate and improve the collective uses, social and economic, of green spaces in relation to the new urban local and daily demands of residents;
- to adopt planning procedures which ensure through contractual and participative process the consensus of citizens and actors most directly affected by the interventions.

The objective of constructing a continuous green network within the contemporary city is to obtain multiple gains of urban, social and ecological order that are geared towards a greater integration and quality of urban life. More precisely, the green network from a planning perspective is an opportunity for the morphological reorganisation of the overall form of the city and the design of its parts. From a functional perspective it offers a new system of relations (renewed urban polycentrism, a new relationship between centre and periphery) linked to leisure time and low mobility which support largely saturated public spaces and mobility infrastructures.

At the level of local interventions, the realization of the green network is occurs under: an ecological profile, guaranteeing environmental conditions and biological diversity (drainable surfaces, green areas, tree cover, lakes, presence of water) in relation to the density of residents; a social perspective, to improve integration, security, increase collective uses; from a planning perspective, it becomes a salient element in the organisation of space between built-environment and open spaces, nature and architecture, public and private space.

Green space helps to create a more balanced functional organisation for new services and leisure activities, complement to living space, binding them together within a low mobility. Moreover, a highly organised open space which carefully considers accessibility and functionality helps to reduce the conditions for marginality, social risk and abandoned areas.

guidelines provoked a serious debate and many administrative changes at all government levels. In response, the Department produced the *Urban White Paper* (2001), with the government program on urban regeneration. In London, with the Greater London Authority's restructuring in 2000 a new Plan was adopted (*The Draft London Plan* 2002-2004). At the same time Boroughs put into practice certain proposals made by the Urban Task Force in poor neighbourhoods of the city centre (Southwark, South Bank) and in a brownfield site (the Dome in Greenwich Peninsula and the Greenwich Millennium Village).

The London case demonstrated how the green network project should be built along two levels following two interrelated strands, one urban-metropolitan and the other local.

The urban-metropolitan level of the project is drawn up by the Greater London Authority, a new, unique government structure, presided by the mayor and a decision making assembly for the whole of the London metropolitan area. It has transverse authority over urban projects, transport, economic regeneration and development, environment, security and public order structures, culture and public health.

On the local level, the project is promoted by each Borough and drawn up for the most part by specialists in the administration who bear responsibility for the decisions brokered in talks with private parties to guarantee the realisation of the network.

The partnership, institution bringing together the concerned public and private parties, has an important role on both levels. She has in charge of promoting for a specific area socio-economic development programmes and other financial initiatives (administering public and private funds, managing together with borough specialists, the economic planning with the owners, social planning with residents and monitoring of projects).

In regards, to the tools and the form of the project for the urban-metropolitan scheme, the planning documents for a new development clearly propose the need for the administration to have an “overall spatial design of the city” and of green networks (refer The London Plan).

The construction of a green network is carried out with a draft local urban project (masterplan) and must first be referred back to standard procedures (general plan, unitary development plan), before verifying the feasibility of the project. This will prevent the separation of green spaces from other components of the city project. The project evaluates the specialised planning (environmental, transport, technology) in conjunction with the assessment of social, environmental and economic feasibility.

It is commonplace in the UK for the plans and the local projects to be binding in contractual terms and in terms of policy; they represent the administration’s vision and strategy. In local projects, they serve as a flexible point of reference in negotiations with private parties and can remain internal documents without being formally recognised within the Local Plan. In the case studies examined, a masterplan (1:2000) summarises the structure of the local project, the relationship between the various networks and amongst other elements. Subsequently, the agreement being concluded and the executive operations begun, this agreement will be received in the local plan. In addition to the masterplan a selection of draft-phase illustrative designs of the spatial and structural elements and database for project elements in relation to properties and zone projects allow for a direct and autonomous implementation of the individual interventions. Nevertheless, the studies examining the UK’s green network projects currently in progress have revealed an approach on several different levels and a progressive reconciliation between the strategic dimension (objectives, directives, contracts) and the design dimension and formal outcomes of the project.

The continuity of green networks is realised by putting in place traditional urban project typologies (parks, gardens, river parks, tree lined avenues) within the wide variety of residual spaces left by the sprawl of contemporary cities. It is in these spaces where the large part of city transformations are taking place today (opportunity areas, areas for regenerations, areas for intensifications). Natural (woodland, streams, lakes) and artificial (urban parks, district parks, villas, tree lined avenues, canals) elements are included in a green projects. On an metropolitan level, the London Plan indicates the types of areas which compose the green system (Green Belt, Metropolitan Open Land, Blue Ribbon Network, Green Corridors, Green Chain, local green spaces). The plan indicates metropolitan and urban green systems, the areas in which the main transformations will take place and require local authorities to indicate which areas are available to realise the green networks. The decision to select areas at a local level gives an understanding of local reality, which allows more insight into problems, needs and opportunities so that the construction of a continuous network may respond to two fundamental

requirements: the first of a general nature that is regarding the connection of large metropolitan residual natural areas and parks, and the other local, regarding the resolution of environmental habitat problems.

Residual spaces are fragments of urban construction which have lost their original use or never had an allocated usage. They have not been designed and are characterised by a extreme uncertainty. Furthermore, they have what could be termed as a “fragility” of use, making them key areas for the construction of continuous green space akin to “a fluidity of space” and for the recuperation of socially and environmentally sustainable urban habitat conditions.

In the UK initiatives various types of residual space have been used for the construction of green networks from the core of the city and peripheral areas. These were classified on the basis of form, dimension (punctual, linear, areal) and former use. Amongst the areal elements selected are large abandoned areas (derelict, vacant land) in proximity of urban centres often with contaminated soils (brownfields), which have direct access to transport networks (public transport and railway lines). The linear elements chosen are obsolete infrastructures (routes, electric lines) abandoned railway tracks, throughways, artificial canals once used for the transportation of merchandise, abandoned lanes, road embankments, crossroads, the stumps and roots of felled bushes and trees, the arches of viaducts, the tracks of old tram lines, the spaces around the city walls. The punctual elements used are public and semi-private condominium spaces often with tarmac surfaced courtyards and raised walls, tarmac surfaced play parks, the spaces surrounding public buildings (schools, health centres, clubs and cultural centres, religious buildings, indoor sport structures), spaces surrounding private buildings (entrance halls and exteriors of multinationals and businesses, open spaces of research institutes), squares and various other public places where people gather.

For several reasons, many larger areas are not used to their full potential: large agricultural land owners obstruct possible intervention; areas with contaminated soils and serious environmental problems caused by industrial misuse remain too costly to repair; and unofficial political will to let land lie barren for speculation purposes. As for areas of smaller dimensions, their abandon is often due to technical design errors (irregular agricultural fragmentation, vacant expropriation areas). They are real problems but entirely solvable with government acquisition policies, attaching remunerative uses for fractions of these spaces or by providing exchanges or re-localisation of building rights.

T. Turner created an innovative way of designing green networks with the concept of green chains (Turner, 1991). They are a continuous system of public spaces set within and merging with the built-up area (parks, offices, shopping centres, town squares) to create a circuit of “environmentally pleasant” pedestrian paths and cycling lanes (drainable soil, vegetation, sustainable microclimate) to be used by citizens on a daily basis. It is innovative in that, unlike other green networks, it makes use of abandoned spaces within the built-up area. These additions aim to improve the environmental quality within the city, provide new functional uses and encourage social integration. It will also ultimately provide for a more unified urban design within the city and the component parts.

Green chains are a circuit of “environmentally pleasant” interconnecting footpaths and bicycle lanes to facilitate movement between various destinations (origin-destination survey): from one’s residence to the park, from the office to the park, from a station to the park, from one’s residence to the office. They must incorporate the existing parks, river banks, canals, shopping centres, footpaths, playgrounds and abandoned spaces. The land can be public or private, open or closed to the public, hard or soft, single or multiuse. The green chain is also a support system for transport, creating a secondary network between longer travel distances, helping to create a more effective network between various destinations (city centre, train station, underground, shopping centres, schools).

...Railway networks and abandoned areas inaccessible to the public can become part of the construction of an ecological network within green chains. In the city centre the green of the Green Chain is made up of elements that are environmentally pleasant (permeable soils, vegetation, sustainable microclimate)²...

In spite of the diverse character of residual spaces it is easy to conceive how this kind of space can be regenerated in all European cities. The space chosen to build a green chain within the typically dispersed European model needs to be carefully considered, taking into consideration sprawl or coastal settlements of Mediterranean countries, where there is an overabundance of vacant space in the absence of systems which provide structure, with the exception of basic infrastructure systems.

Continuity and integration models progressively linking minor residual spaces, private and semi-private spaces in private properties and urban public parks and natural green spaces (parks along waterway) are most frequently cited in plans and design models.

The most frequently used reference models are: a grid pattern: an interwoven green space, which guarantees the continuity and a relative homogeneity without excessive diversity in dimension or specificity of use; a tree model: the continuity of green, through the hierarchical organization of spaces, built with a gradual transition between the smallest to larger urban and regional parks; consolidated island model: built using the densification of existing residential areas to provide smaller green spaces secure, easily equipped and well delimited.

The grid pattern and tree models have the quality of combining the concepts of continuity and system, allowing for creation in phases. They are also geared towards low mobility and the creation of pedestrian walkways and cycling lanes for a better integration between spaces for social and public service uses.

Functional use and green element design are two other criteria proposed for the planning of green networks in an attempt to give a sense of identity to the various components of the green network. The reorganisation of these spaces changes their nature, image and function. They are reconsidered with a design that integrates the various demands expressed by residents and other users who make use of these spaces on a daily basis. The design is modified to suit various lifestyles with greater flexibility in use by offering a variety of green spaces, including natural open fields (crop land, pasture), Italian style gardens, local parks.

In addition to naturalistic and ecological functions provided by large parks and corridors with direct access to the countryside there are another set of functions included for social usage, such as leisure activities, sport and other events, which are compatible and in different ways characterize each green node. On a local level, every element and minor green space, often related to residential areas, presents supplementary integrated uses (recreational, sports, cultural) to render spaces more occupied, attractive and secure in the 24 hours.

Landscape, water, vegetation, morphology and historical aspects are all essential to design the city's identity. Local authorities in London conducted a green heritage census to get a better understanding of the historical significance, the singularity, the design and the state of green areas (urban parks, small local gardens, private gardens, tree lined streets etc.) in terms of dimension, range of influence, characteristics, functions. The end objective being to recuperate the historical typology of green spaces in future projects.

Using residual spaces (frequently of unusual shapes and dimensions) has allowed to experiment with new designs, open system typologies, and services, to distinguish temporary places of transience and others to hang around. The results of the most significant experiences are gathered in brief manuals.

² [Turner, T., 1991, *Op. cit.*, Green open space strategy for London, pag. 12-13.](#)

The results achieved in England demonstrate that even small changes in residual spaces with the use of few trees, to provide a place for people to stop and talk, can greatly enhance the quality of settlements (re-appropriation of these spaces by citizens, new perception of lifestyle with alternative means of transport, innovative way of experiencing daily life in a green surrounding. Space is also dedicated to hydraulic and technological efforts, to prevent energy and water waste and to restore polluted land.

Finally, the necessary measures and requisites for the operation to be a success, based on UK experiences: appropriate top-down strategies, vision and political incentives for the regeneration of the entire city and the metropolitan context; a bottom-up approach to planning, in order to increase social consensus, consent amongst actors, and resources in relation to shared local objectives; a communicative and open approach to objectives strategies and planning indications which is developed progressively in the course of the design of green spaces and through the representation of plausible end scenarios; an exhaustive analysis of the environmental, economic and social aspects in the drafting of a final proposal; a contractual and participatory method, with private parties and local authorities to define by means of consensus, a system and courses of action to carry out implementation and management.

Open Space Strategy (Oss)

The Open Space Strategy (Oss) is the document that the Government and the New Plan of London have asked all the administrations premises, Boroughs, to achieve the continuity of the green. To make this document both the government and the GLA have provided guidelines. The Open Space Strategies ... help all those responsible of open space to provide parks and open space well-designed and well gestiti61. The Strategy proposes a shared vision for improve the open space that meets the needs of the community and become a reference point for utilizing resources and detailed plan azione62. Through ... a creative and collaborative approach, the Strategies may be the way to equip cities with safe and attractive public spaces as proposed from urban renaissance: - By involving the community to create a shared vision;- Protecting the future of green spaces;- Improving the quality of Neighbourhoods;- Promoting the well-being of the residents; - Attracting resources for management. These objectives promote an integrated approach to green space that supports the guidelines of the borough to increase the value of areas and buildings and to attract external funds. In the construction process of the Strategy must be actively involved key users and stakeholders to meet the needs and the desired community. To integrate the open space in the local plan and to find safe funds, it is critical support Interdepartmental involving the offices of the Borough that involved in urban design, environment, transport and residence, both for the preparation that for the implementation of this. The Strategy must give real benefits and improve green space and must contribute directly to propose the local community strategy through:- The creation of a vision for the future of parks and green spaces; - A precise knowledge of the typological and the status of existing green space; The definition of compatible uses in accordance with the needs and aspirations of the community; The promotion of local qualitative and quantitative standards; The choice of actions and timescales to achieve these standard; The creation of a system of monitoring and updating the action plan. Each strategy should have a thorough evaluation of existing spaces and their use actual or potential, in line with the demands of government policy Government's Planning Policy 17 Guidance PPG 17, including parks, play areas, allotments, community gardens and other green spaces. In the propositional must choose their own goals, balancing the different functions of green space, integrating into a "green network" functions sports, educational, recreational and ecological preference, define actions and targets for improvement, sources of financing that need to be mobilized to achieve this vision. Finally, the strategy needs to be regularly assessed and appropriate to be sure that it can meet the needs of the community. For the part of investigation and evaluation of the paper considers the other: the structural aspects (demographic, socio-economic, ...); environmental and landscape aspects (characters idrogeomorfologici, parks, gardens, areas of flooding, environmental goods protected, strategy for biodiversity, historic and protected landscapes, ...); aspects urban, families eligible for types of uses of space; investigations seeking to ascertain the demand of the

residents. In the proactive response to the issues raised in the evaluation, the issues of greatest attention include: the types of open space, the integration between different uses; Facilities of open space per resident and pedestrian accessibility; models the network. The indications of the strategy proposals have no value prescriptive, to exemplify the will of the administration, initially evaluate the consent and feasibility of the proposals and then, once implemented in the instrument of plan UDP, express the aims and directives that intends to pursue the administration in the implementation phase, particularly in the negotiations with individuals.

Shaping cities for health to contrast the effects of climate change: the CCHURE proposal

Rosalba D'Onofrio¹, Ilaria Odoguardi², Elio Trusiani³

Abstract: Regenerating the existing city and placing health at the center of policies, plans, and projects represents an effective response to contrast the effects of climate change that impact cities and the health of inhabitants. Convinced of this need/opportunity are the World Health Organization (WHO), eminent international researchers, and public administration representatives in many European cities. However, a consolidated "silo approach", which is common to the sectors of scientific research and public administration, does not allow common objectives to be defined, especially in small-medium cities, or integrated design proposals to be formulated. The CCHURE Research (Climate change and urban health resilience) aims to define a transdisciplinary methodology to evaluate the effects that climate change produces on urban health, to direct policies for adaptation/mitigation through the contribution of many scientific disciplines, interaction with municipalities and local health agencies, and the involvement of local communities. This will be done with the support of new IoT (Internet of Things) technologies and mobile crowdsensing techniques in order to expand knowledge to measure/assess the effects of climate change on health, to involve communities in designing shared plans for development, to empower them when dealing with urban health and wellbeing, and to support public administrations in making decisions.

Keywords: Urban regeneration; urban health and climate change; community participation; IoT and crowdsensing;

1. Introduction

Climate change is often addressed in terms of risk for infrastructures, energy reliability, and ecological concern. Growing evidence shows that the impacts on people's health/well-being are also urgent. The report "Healthy as the Pulse of the New Urban Agenda" (World Organizations Health, WHO 2016) introduced the idea of urban health resilience as the need to promote resilient urban policies to reduce the risk of climate change with respect to human health. The Fifth and Sixth Ministerial Conferences on Environment and Health from 2010 and 2017 declared their commitment to protect health and well-being, natural resources, and ecosystems; and to promote health equity, health security and healthy environments in a changing climate. The commitments made at these two conferences were the result of research activities in recent years (Patz *et al.* 2000; McMichael, 2002; Confalonieri *et al.* 2007; Barata *et al.*, 2011; Smith KR *et al.*, 2014; Watts *et al.*, 2015) and calls by international bodies (IPCC, 2013; WHO, 2015; etc.). All of these studies agree that cities are exposed to the greatest risks, both due to the effects of climate change (Ispra, 2014) and for the social imbalances that these effects can generate (UN-HABITAT, 2010; Hughes BB, Kuhn R, Peterson CM, *et al.* 2011).

The European "Health 2020" strategy recognizes the important leadership role of cities in developing health urban policies. Reorganizing the existing city by placing health at the center of policies for

urban regeneration represents an answer to contrast the effects of climate change as it impacts cities and the health of inhabitants. Many researchers from different disciplines are convinced of this, although they are accustomed to a silo approach that does not permit common objectives to be defined (e.g., the 2013 “Helsinki Statement” on “Health in all policies”).

Medical science alone is insufficient to address the theme of social and environmental determinants of health, which are explicitly present in the WHO's vision of health (WHO, 1948). Other disciplines must be involved, those dealing with the places where most people live: the cities (Urban Age Hong Kongdel 2011/London School of Economics and Political Science). First among these disciplines is urban planning and design, which is called to respond to the needs of health in cities, in delivering health improvements through reshaping the urban fabric of cities, in the creation of new healthy urban environments, in the sustainable organization of mobility, land use, and green areas. These principles were reiterated by the WHO through the UCL–Lancet Commission of 2012 and the Healthy City Europe Movement (VI Phase 2014– 2018: theme: “creating resilient communities and supportive environments”), in close relation with one of the priorities in the European Health 2020 Strategy. Some research has begun in this field in Europe (UK/ Barton, Tsourou), America (Corburn at UC Berkeley, Columbia University, Mailman School of Public Health), Canada (Canadian Urban Environmental Health Research Consortium-Canue, McGill School of Urban Planning), and Australia (RMIT University, Melbourne with NHMRC Centre of Research Excellence in Healthy Liveable Communities directed by Giles-Corti). In current research, there is a strong focus on the neighborhood scale, which is the most appropriate for involving communities in designing/creating environments favorable to health (D’Onofrio, Trusiani, 2018). London, Rotterdam, Copenhagen, Bratislava, and Almada are being activated with climate-change adaptation plans, beginning to make use of the new information technologies of sensors and mobile apps to monitor phenomena such as the urban heat island (Rotterdam), traffic, atmospheric pollution and respiratory illnesses (Barcelona), the effects of atmospheric precipitation, etc.

What emerges is the need to break down disciplinary fences in research and among the different sectors of public administration; expand knowledge to measure/assess the effects of climate change on health; and involve communities, empowering them with respect to health. Sustainable, low-cost tools to monitor health equity on the local scale are essential to make decisions, allocate resources, and guide interventions for transformations/adaptation (Vlahov D, *et al.* 2011). One aid may come from the Urban Internet of Things (IoT), low-cost technologies capable of real-time collection of information to understand the complex interactions among the urban ecosystem, climate change, the health of inhabitants, and social conditions (Yick, Mukherjee and Ghosal 2008, Kontokosta *et al.* 2016).

2. Materials and Methods

The CCHURE (Climate change and urban health resilience) Research¹ intends to take up the

¹ CCHURE is a research funded in 2018 by the University of Camerino. The members of the group are researchers from different subject areas of the University and some Italian and international researchers. Research UNIT 1: Rosalba D’Onofrio School of Architecture and Design - UNICAM (Italy); Michele Talia School of Architecture and Design - UNICAM (Italy); Chiara Camaioni School of Architecture and Design - UNICAM (Italy); Ilaria Odoguardi PhD Student School of Advanced Studies - UNICAM (Italy);

challenges mentioned above in a transdisciplinary approach, with greater knowledge of the impacts through new technologies, involving local populations in identifying the needs of health and co-designing their neighborhoods.

The research, in particular, aims to define a methodology to evaluate the effects that climate change produces on urban health, to direct policies for adaptation/mitigation through the contribution of many scientific disciplines (urban planning, architecture, medical science, computer science, social science, legal science), the interaction with municipalities and local health agencies, and the involvement of local communities with the support of the new IoT (Internet of Things) technologies and mobile crowdsensing techniques.

A small-medium size city of 50,000 inhabitants, Ascoli Piceno, was chosen for the research as being representative of small and medium European cities with greater criticalities due to the lack of qualitative and quantitative data on the risks for health and the lack of sufficient economic resources. The field of comparison is the neighborhood, where the local community is most present and participatory, specifically the Monticelli Quarter (Figure 1). In addition to involving researchers from different disciplines, CCUHRE also involves local entities, neighborhood associations, local health agencies, and experts. It aims to identify a working method that can be exported to other cities in which traditional means of gathering information on health, the environment, and their interrelationships are combined with collection via IoT devices and mobile crowdsensing techniques. Citizens are called to intervene in the process of gathering data, identifying/resolving problems, and building design hypotheses.

3.1 Features of the Monticelli district

The Monticelli quarter is one of the most populous in the city of Ascoli Piceno, with about 10,000 inhabitants. It is located only a few kilometers from the historical center, but “... you can’t get to Monticelli on foot”, as the local news reported a few years ago. Until the beginning of the 1970s, the land where the quarter is located was practically open country. In 1972, the city was endowed with its first local plan. This called for linear development along the east-west expanse of the city and defined a broad area to the east of the city (Monticelli) where the greatest residential volumes, built new, would be concentrated, in order to house 21,600 inhabitants (compared to the roughly 75,000 inhabitants expected in the entire municipal territory for the year 1975). It was quickly realized that the forecast for an increase in population from 50,000 to about 75,000 inhabitants was entirely unlikely, and that the nucleus of expansion in Monticelli was oversized in relation to the effective demographic trends. Despite this, the city administration proceeded to partially realize the housing and main roads as established by the plan. This was done in consideration of the fact that the earthquake of 1972 had caused serious damage to the building heritage in the historical center, with the consequent abandonment of uninhabitable buildings and the fact that the zones for social housing in Monticelli could take advantage of significant economic subsidies. Today, the quarter contains the hospital, a supermarket, offices, various types of shops, two churches, and, until a short time ago, a fast-food restaurant. Today, for most of Ascoli Piceno’s residents, Monticelli is simply a dormitory, a quarter situated between a road axis and the Tronto River, a small town in and of itself with respect to the rest of the city of Ascoli Piceno (Figure 2). The quarter lacks infrastructure and equipped green areas, it lacks meeting points and places that identify the quarter, and some residential buildings are degraded. The city news reports stories of drug addiction, aggression, and accidents due to dangerous cross traffic — both on the central axis and the internal streets — smog, and noise. Despite this, there are signs of liveliness and action by the local population in the presence of sports associations, social gardens, and a very busy senior center. Attention for the quarter has re-emerged in recent years

following urban regeneration projects financed with national public funds and local interest holders, such as the Neighborhood Contract 2 – Extraordinary Program for Peripheries (Contratto di Quartiere 2- il Programma Straordinario per le Periferie-PRASI), which establishes a budget of €86 million, of which €18 million is financed by the State with some interventions on the roads, green areas, and degraded buildings.

3.2 Objectives and products expected

CCUHRE, in particular, proposes to:

1) Build a methodology to investigate the relationships between the impacts of climate change and the health/well-being of inhabitants on the urban scale of the neighborhood, which contributes to selecting actions and combinations of actions for mitigation and adaptation with citizens' active role.

Outputs:

a) Climate and Health Profile (CHP): to construct the neighborhood CHP, reference will be made to qualitative/quantitative indicators that assess the effects of climate change on the health and well-being of the population. These indicators will be selected based on existing public health data, as products of international research, and with the contribution of inhabitants by administering questionnaires and activating focus groups.

b) Climate and Health Actions (CHA): the selection of actions and combinations of actions for adaptation and mitigation, already present in international best practices, with reference to the "fundamental themes" of urban design — land use, mobility, housing, open spaces, and meeting spaces, the natural environment — and some themes of technological design — temporariness and flexibility, etc.

2) Proposing a methodology for public administration to select scenarios for adaptation to/mitigation of the effects of climate change, through the use of real-time analytics and data feedback mechanisms and non-instrumental interaction with local communities. Outputs:

a) Climate Health Lab (CHL): construction of a platform of sensors and automation technologies (Urban Internet of Things, IoT), which will provide real-time information/measurement of the physical/environmental conditions of the neighborhood and its inhabitants. This platform will be implemented with citizen contribution through the use of mobile crowdsensing techniques, which will allow smart-phone users to interact with IoT devices.

With the CHL, it will be possible to:

- analyze and assess the difference between subjective and objective measurements of quality-of-life indicators to understand how the perception of different environmental conditions varies across the neighborhood;
- verify and compare, with the help of researchers, technicians, and citizens, the "health" performance of the scenarios identified and their evolution in time, thereby assisting public administrations in the decision-making process.

The research objectives will be measurable: 1) in the number of citizens involved in the experimentation in the field and in the focus groups; 2) in the number of planning proposals for adaptation/mitigation that will be designed with the support of IoT technologies and citizens and from which the administration can choose based on the quarter's needs.

3.3 The current phase and the next steps of research

The research started at the beginning of 2019 with the presentation of the theme and objectives to the local community. Up to date, the research group is involved in construction of the methodology to investigate the relationships between the impacts of climate change and the health/well-being of inhabitants on the urban scale of the neighborhood, which will help to select actions and combinations of actions for mitigation and adaptation with citizens' active role. At the base of this methodology there is an approach that foresees the fundamental involvement of the community and the preparation of preliminary data with particular reference to: a) The construction of the Community Health Profile and b) the identification of Climate-Health Actions.

In order to construct a meaningful Community Health Profile and the consequent Climate-Health Actions, some indicators were highlighted to assess the families' quality of life in the Monticelli district. The indicators have been grouped together in a questionnaire; It has been distributed to families, intercepting an average age range between 30 and 55 years, with the help of primary school in the neighbourhood. The questionnaire is organized in 9 sections: demographic data, area where the family lives, security, accessibility to services, social cohesion in the neighbourhood, daily travel, characteristics of the dwelling, quality of life in the dwelling, outdoors.

Simultaneously and in close collaboration with ASUR (Regional Healthcare Company), for a complete and significant construction of the Health Profile is begun the administration of the PASSI questionnaires (Progress of Health Services for Health in Italy). Promoted and financed since 2006 by the Italian Ministry of Health, this questionnaire aims to carry out a full-scale monitoring of the population's health status. The administration of the questionnaire is in progress; it was being

administered on a sample of 250 people in the neighborhood and it gathers information on lifestyle and behavioural risk factors of the Italian adult population (18-69 years) related to the occurrence of non-communicable chronic diseases. Among the many topics investigated by PASSI are: smoking; physical activity; obesity; excessive weight, cardiovascular risk, state of physical and psychological well-being, and other aspects related to quality of life related to health.

From the results that will emerge from the administration of these two questionnaires, the Community Health Profile will be drawn up, which will allow to the research group to select indicators that will assess the possible impacts of climate change on the inhabitants' health and well-being of the neighborhood. Moreover, these additional indicators, selected by international literature and with the citizens' contribution, will be administered within focus groups and through the contribution of new information technologies. Simultaneously, it will be conducted a survey of best practices, that many European and world cities have and are promoting, which link urban plans and projects with the objective of combating climate change and health impacts. The fields of investigation to carry out this survey will cover: *Housing and buildings; Neighbourhoods; Social environments; Connectivity, density and land use mix; Accessibility, amenities and decision-making processes; Greenspace, etc.*

To simplify this activity, a reconnaissance of the district was carried out through the analysis of the planning tools in use, and then specifically considering: demographic data, urban standards, organized for green areas (type of green areas surveyed, type of green areas of public utility, etc.) (Figure 3); services (primary services, parking areas, commercial activity, etc.) (Figure 4); mobility structure (pedestrian path's survey, bicycle lane's path, bus routes, etc.) (Figure 5). Starting from the end of 2019, the next steps will concern the activities described in the previous paragraph.

4. Conclusions

The innovation of CCUHRE regards the possibility of beginning a system of knowledge shared between the public administration, scientific community, and local community to assess projects and plans for mitigation of and adaptation to climate change and to choose the most advantageous in terms of their effects on health. This will occur through the use of IoT technologies and low-cost mobile crowdsensing. The results of CCUHRE will impact the research in the field of urban health in two ways: 1) the front-line participation of interested populations confers validity and concreteness on the research and the assessment of policies and the plans for adaptation to and mitigation of climate change, maximizing the impact of the solutions identified; 2) going beyond the concept of "urban design" guided by a top-down approach, which is strongly debated today, towards "human centred design" focusing on the knowledge of individual behavior, collaboration with the community, which makes use of contributions from various disciplines and the use of modern IoT technologies.

Citizens become providers and assessors of data regarding health and well-being, simulators and evaluators of scenarios for mitigation and adaptation, joining in the design of their living environments at risk due to climate change. This will favour:

- dialogue among the public administration, citizens, and researchers;
- citizens' participation and awareness regarding city governance/decision-making;
- an understanding of the need/opportunity to adopt an integrated, transdisciplinary approach, the only one capable of responding to the complexity of the effects of climate on health in urban areas;
- the fundamental role of the "urban project" in ensuring "equitable" access to health.

In imagining recourse to a methodology centred on people's knowledge of their living environment and the contribution that they can make in evaluating the quality of the mitigation and adaptation projects it is essential to earn their trust. It is therefore necessary to dialogue and establish collaborative relationships between citizens and the public administration by sharing information and ensuring:

- a) quality control of the data collected (which should be made known to the interested parties (ref. website of reference) and made available on an appropriate level of aggregation);
- b) assessments of mitigation and adaptation scenarios should occur through direct interaction between experts, technicians in the public administration, and citizens.

Supply-demand analysis of park services for different age groups in Community life Circle: a central district in Shanghai as a case

Ming QIU¹, Min WANG*

¹*College of Architecture and Urban Planning, Tongji-university, ming.qiu@foxmail.com*

**College of Architecture and Urban Planning, Tongji-university, wmin_tj@qq.com*

Abstract: Parks prominently contribute to the healthy lives of urban residents at all ages in their community life circle(CLC), however, it is rarely discussed what distinction in different age groups' personas exist and furthermore whether the supply and the demand of park services for them are matched. This results in socio-spatial injustice of urban parks and inefficiency of park services in terms of healthy city planning, design and governance. propose an enhanced method that takes both sides of supply and demand into account to reflect the authentic budget of park services in the CLC. At the same time, age plays a weighting factor in the evaluation progress so that the outcome could be more adaptive to specific groups of residents and thus support a targeted decision making in constructing CLC. A central district in Shanghai was taken as a case and the result suggests that in 177 out of 304 community units of this area, the elder and children's demand for park services could be basically or even better, while the young face a better situation. The service budgets also depict different spatial agglomeration. Some improvement strategies are thus proposed to assure a better healthy-oriented built environment.

Keywords: park services; demand-supply analysis; community life circle; two-step floating catchment area

Introduction

The master plan of Shanghai 2035 proposes the notion of the 15-minute Community Life Circle(CLC) as the basic unit for organizing community, which ensures basic service facilities and open space within the residents' walking accessible range so as to create a comfortable community space(Li, 2017). As a result of that, the number of researches focusing on improving service of open space in the CLC increase rapidly in recent years(Huang et al., 2019, Sun and Chai, 2017).

Urban parks, as a pivotal component of urban open space, serve residents in recreation, sightseeing and some other ecological regulating services like air purification, rainwater absorption and so on. To optimize parks' spatial pattern and to improve their service quality therefore necessarily contribute to the construction of the CLC. Nowadays the most common approach is to ameliorate the accessibility of parks, with multifarious methods in hand, for instance, provider-to-population ratios, travel impedance to nearest provider, average travel impedance to provider and gravity model(Guagliardo, 2004). The principle of them inherently bases on the assumption that

park services could be consumed only when residents could reach them. That is to say, it emphasizes parks' role as supplier of the services and services are distributed to each life circle.

Meanwhile people demand various park services according to their features. David Crawford found out the public open spaces in high socio-economic neighborhoods possess more features relating with physical activities amongst children (Crawford et al., 2008). The investigation of Jiang Haiyan suggests the more localized residents are, the more park services they would consume (Haiyan et al., 2010). Also park services are mainly consumed by children and the elderly and the young and middle-aged people only carry out community activities after work and on weekends, of which visiting a park is not inclined to be their preferred one (Li, 2017, Wang and Wang, 2016, Huang and Zhu, 2018). In that case, with personas of consumers of park services we should segment some specific needs of groups of various features in ages, income occupation and so on, furthermore judge whether or not service supply accordingly meet those demand. However, pertinent researches are still relatively rare.

Two-step Floating Catchment Area (2SFCA) method is a reasonable approach to integrate supply and demand of services. It considers population-to-provider ratio twice in turn in terms of supplier and demander: firstly, for each service supplier, all populations which falls within a threshold distance should be determined and then, for each service demander, the objective is to determine all available services that fall within a threshold distance. In the end a final outcome of population-to-provider ratio would be calculated out (Luo and Wang, 2003). This method has been applied mainly in spatial accessibility evaluation of health care facilities (Delamater, 2013, McGrail and Humphreys, 2009) (Nakamura et al., 2017) and also recently more inclined to other services like urban green space (Dony et al., 2015, Wu et al., 2018). However, the 2SFCA method manifests as a reflection of service supply in the end, since the population-to-provider ratio could be considered as a ratio of supply which is filtered twice by threshold distance. When it comes to demand, it's only possible to know how much services have been provided, rather than how much needs have been met.

Based on 2SFCA method, this paper aims to propose an enhanced method that takes both sides of supply and demand into account to reflect the authentic budget of park services in the CLC. At the same time, age plays a weighting factor in the evaluation progress so that the outcome could be more adaptive to specific groups of residents and thus support a targeted decision making in constructing CLC.

Materials and methods

Study area

The study area is located in a central city of Shanghai, with a total area of 54.76 km². There are a household-registered population of about 920,000 in the area, among which children (under 12 years old) account for 6.31%, young and middle-aged (13-59 years old) for 73.62%, and the elderly (over 60 years old) for 20.06%.

In contrast to other central districts of Shanghai, the study area owns an insufficient total green space and its park area per capita in the study area is relatively low, which drives it urgent to improve the budget of parks service. As Figure 1 shows, the parks in the study area are classified into 4 levels according to *Shanghai Park Classification and Classification Management Standards and Assessment Methods* and *Shanghai Controlled Detailed Planning Technical Guidelines*, namely district park, community park, street park and pocket park. Parks have a specific service radius which corresponds to the class (details in Table 1). The Shanghai Botanical Garden is excluded since it is not an ordinary residential park.

The research involves four types of data: (1) road network, which is extracted and topologically corrected from the road center line in the land use map 2011. (2) parks data, including information of name, location, area, entrance location and so on, which are derived from the land use map and complemented with google earth and other related materials. (3) population, which refers to the 6th National Population Census of China. (4) results of

questionnaire survey which was conducted on the working days and weekends in the summer of 2017. 13 parks, from district parks to pocket parks, were surveyed and the respondents were residents around the parks. Except for the basic profile information, the questionnaire mainly focused on the frequency of visiting parks.

All the data were loaded into ArcGIS 10.3 and edited in the Gauss Kruger Xian 1980 120E projection coordinate system. The neighborhood committee is chosen to be the spatial statistical unit, with the number of 304 in total.

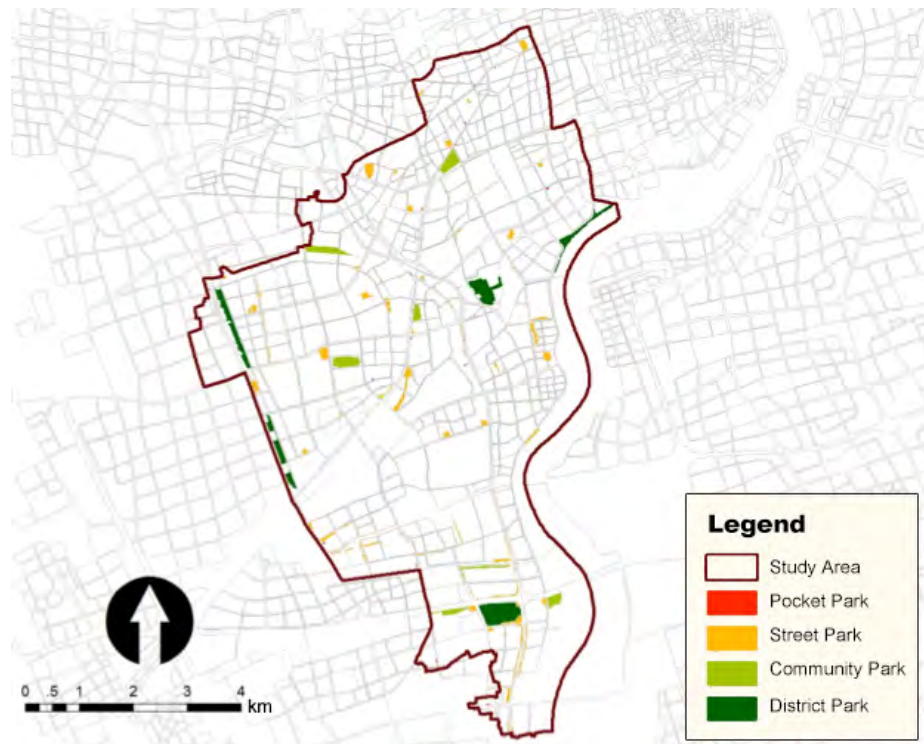

Figure 1. Parks in the study area

Table 1. Statistic information of the parks in the Study Area

Class	Threshold (hm ²)	Service Radius(m)	Number	Area in total (hm ²)	Percentage of Study area
District park	≥10	2,000	5	85.88	1.57%
Community park	≥4	1,000	6	45.77	0.84%
Street park	≥0.3	500	97	89.53	1.64%
Pocket Park	<0.3	250	82	9.91	0.18%
			Total:	227.49	4.23%

Framework of evaluation

This research takes consumption count of park services as the measurement for service supply and demand. On the one hand, for service supply evaluation, determine the ratio of park services that each park provides to the spatial units in its service catchment and then calculates available consumption count, which could interpret the level of park service supply. On the other, service demand could be measured in the way that required consumption count is calculated with the frequency of different age groups' visiting parks per week. At last, both separate evaluations are integrated to reflect the budget of the supply-demand. Compared with 2SFCA, this method

supplements the evaluation with the consideration of the demand side, which is independent of the evaluation of the supply side, so it can realize an integrated analysis. At the same time, the features of service consuming of different age groups are taken into account in terms of range of CLC and service-consumption frequency. Details of each step are as follows.

Firstly, determine the ratio of service supply. Each park is reclassified and has a service radius d . The service catchments of each park are generated with the network analysis tool in ArcGIS. Each catchment covers a plurality of spatial statistical units and then with the equation(1) we can calculate out the supply ratio of each park for each spatial statistical unit. The ratio correspond to the size of the park(larger parks have a larger service catchment and thus cover more spatial units) and the principle of equitable geographical distribution(larger spatial units should obtain more services from the parks). The equation of calculating the ratio is below:

$$W_j = \frac{S_{k_i}}{\sum S_{k_i}} \quad (1)$$

where W_j means the ratio for park j , S_{k_i} is the area of the i th spatial statistical unit k located in the service catchment and $\sum S_{k_i}$ is the sum of all S_{k_i} .

Secondly, determine the level of supply with available consumption count. The CLC of each age group has different range, thus take 15-minute walking distance as its radius(Li, 2017). In this study, according to the walking speed, the radius for the elderly and children is 1.2km and 2km for the young and middle-aged population. Usually children are accompanied by guardians (mostly the elders in China) to the park, so the study has included children and the elderly into the same group to simplify the discussion. With the network analysis tool can ArcGIS generate CLC catchments for each age group. After that calculate the ratio of effective service supply by each park in the CLC catchment and then available consumption count for each age group with the equation as below:

$$X_{k_p} = \sum (W_{k_j} \times M_{k_p}) \quad (2)$$

where X_{k_p} is available consumption count for age group p , which reflects how many people could ideally speaking be served by a park. W_{k_j} is the ratio of effective service supply by park j in the CLC for the spatial unit k and M_{k_p} is the population of age group p in unit k .

Thirdly, determine the level of demand with required consumption count as the equation below:

$$Y_{k_p} = \sum (\alpha \times M_p) \quad (3)$$

where Y_{k_p} means required consumption count, which reflects how many people would like to consume services of a park, M_{k_p} is the population of age group p in unit k , and α is the frequency of visiting parks of different age groups, which is determined by a questionnaire survey.

Finally, determine the budget Q of demand and supply for each spatial unit with the equation below:

$$Q_{k_p} = X_{k_p} - Y_{k_p} \quad (4)$$

When Q_{k_p} is greater than or equal to 0, that indicates the budget for park services of age group p manifests moderate or good in the spatial unit k . On the contrary, when Q_{k_p} is less than 0, that indicates the budget not satisfactory and a larger absolute value suggests a worse situation. We could furthermore propose adaptive strategies and carry out targeted approaches for each park and spatial unit.

Results

Supply level

As shown in Figure 2 the spatial distribution of the services supply for the young and middle-aged people and the children and the elderly is roughly the same. Abundant supply area is concentrated in the central part of the study area and the riverside area, while scarce supply are in the north and west. Overall speaking, the level of service supply for children and the elderly differentiate amongst each spatial units is more than for middle-aged people and apart from that in most spatial units is in the upper-middle class.

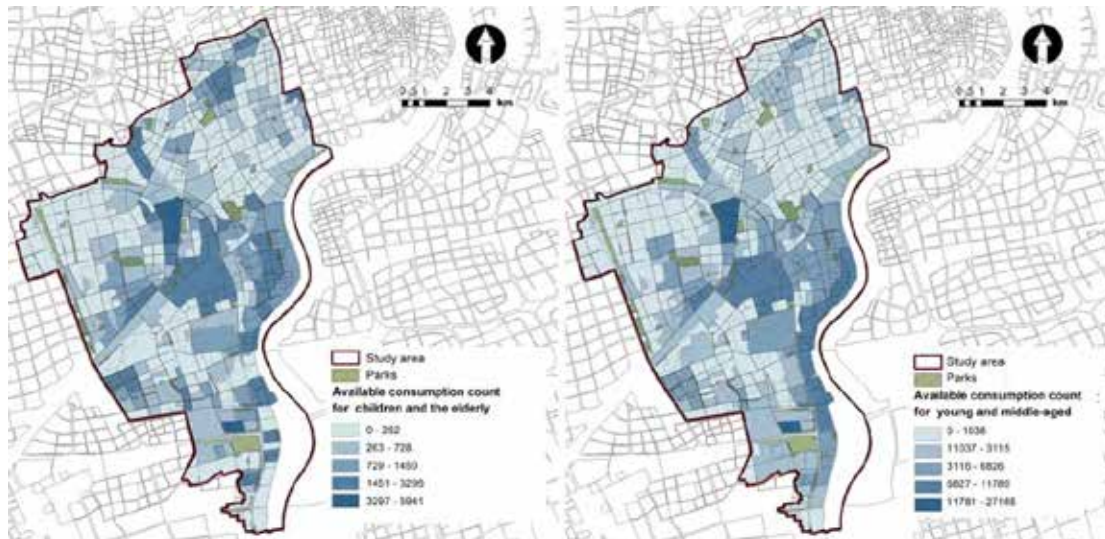

Figure 2. Supply level of park services in each spatial unit for two age groups

Demand level

In the end, a total of 280 valid questionnaires were collected, among which 171 were young and middle-aged respondents, 90 the elderly and 19 children. If the respondents visit a park every day, it is counted as 1. Then 3-4 times a week as 0.75, 2-3 times a month as 0.5, 2-3 times a season as 0.25, other lower frequency as 0. The average frequency of each age group is calculated out afterwards and the result suggests that the frequency of young and middle-aged people's visiting a park is 0.59, while children and elderly is 0.85.

As shown in Figure 3, the middle-aged and young people who demand for more park services concentrate in the middle of the study area. In contrast to that, the group of the elderly and children own much stronger demand for park services. The number of spatial units with higher demand is more amongst them than amongst young and middle-aged people and distribute wilder in the spatial dimension. On the whole, each age group's high demand areas have less spatial overlap. For example, the demand for children and the elderly in the northern part of the study area is moderately high, but the demand for young and middle-aged is on the contrary low. This indicates that parks in different parts of the study area have different target visitors.

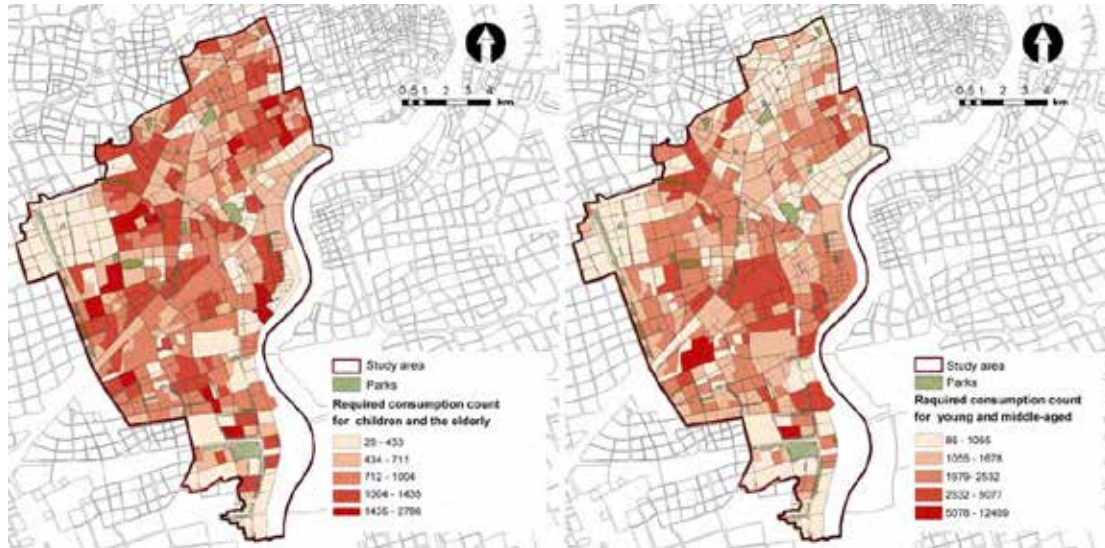

Figure 3. Demand level of park services in each spatial unit for two age groups

Budget level

The result of overlapping the demand and supply level suggests that as far as the elderly and children are concerned, as shown in Table 2, 177 out of 304 spatial units have a moderate or even ideal budget, but for the other 127 units the supply could not meet the demand. In contrast, the group of young and middle-aged enjoy a better service budget. In over two thirds of the spatial units, the supply could meet the demand or even oversupply. However, Figure 4 all in all indicates that the spatial distribution of budget for different age groups is somehow consistent with each other. The oversupply area is all concentrated in the middle and the supply shortage area is all in the northern part.

Table 2. Budget of park services for two age groups in all neighborhood committee units

	Young and Middle-aged		Children and the elderly	
	Number of Units	Percentage	Number of Units	Percentage
shortage	17	6%	21	7%
moderate shortage	86	28%	106	35%
matched	115	38%	120	39%
moderate oversupply	38	13%	25	8%
oversupply	48	16%	32	11%
Total	304	100%	304	100%

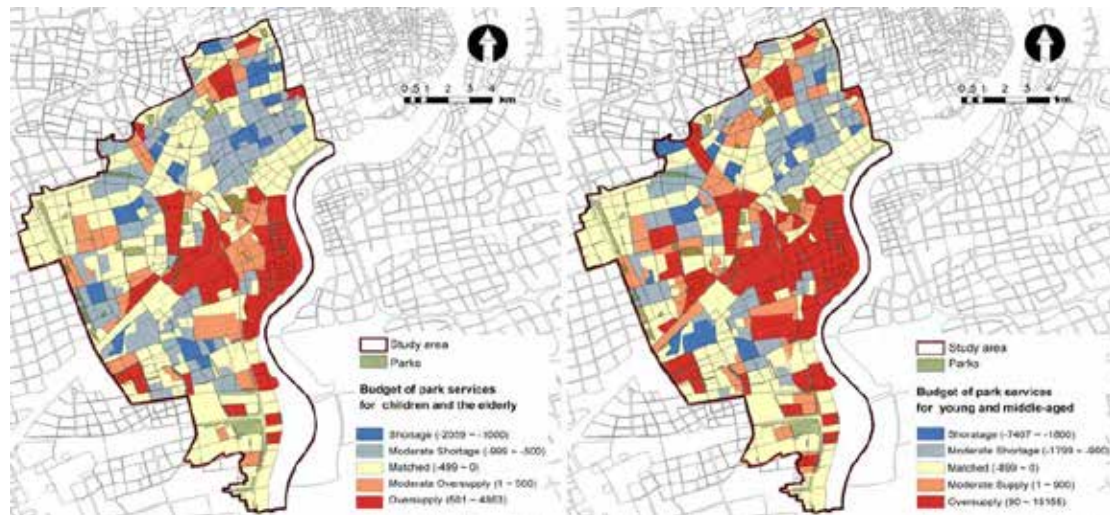

Figure 4. Budget level of park services in each spatial unit for two age groups

Discussion

As the spatial correlation analysis of park service budget in CLC for different age groups illustrates the Moran I index implies positive spatial correlation between supply and demand for all the age groups, which is significant at the level of $\alpha=0.01$. That is to say, there is spatial agglomeration of service budget and we could identify the areas which are oversupplied or in huge shortage on the basis of Hot Spot Analysis (Figure 5) and afterwards propose the improvement strategies.

As far as those oversupply areas are concerned, it would better emphasize shaping characteristics of parks and provoke their differentiated development. Supplying surplus only means the delectable number of park services rather than the quality. The next step to construct CLC, we could identify the recreational preferences in each CLC through some robust and comprehensive surveys. Then it's possible to initiate a bottom-up differentiation of park system and improve the quality of park services.

To improve insufficient supply areas, one simple but effective way is to raise the budget level of those parks surrounding the weak budget areas. Since China steps into the urban development stage of stock renewal now, it is difficult to meet the intensive demand for park services by constructing new large parks in the central urban area. That highlights therefore the importance of the existing parks. In that case, to expand recreational space and to supply more recreational facilities in parks come first when we try to take the opportunity of urban renewal to alleviate the mismatch between supply and demand of park services.

One another way to ameliorate weak budget areas is to excavate idle space and construct pocket parks. Pocket parks can be scattered in urban areas to serve residents and feature in superior accessibility and highly frequently visited. Though small scale for each, the total performance is impressive when there are numerous pocket parks. To build a sharing recreational parks in residential area, open attached green space and other kinds of pocket parks, could it benefit not only in raising the efficiency of space, but also in promoting park service budget by forwarding with breakthrough points.

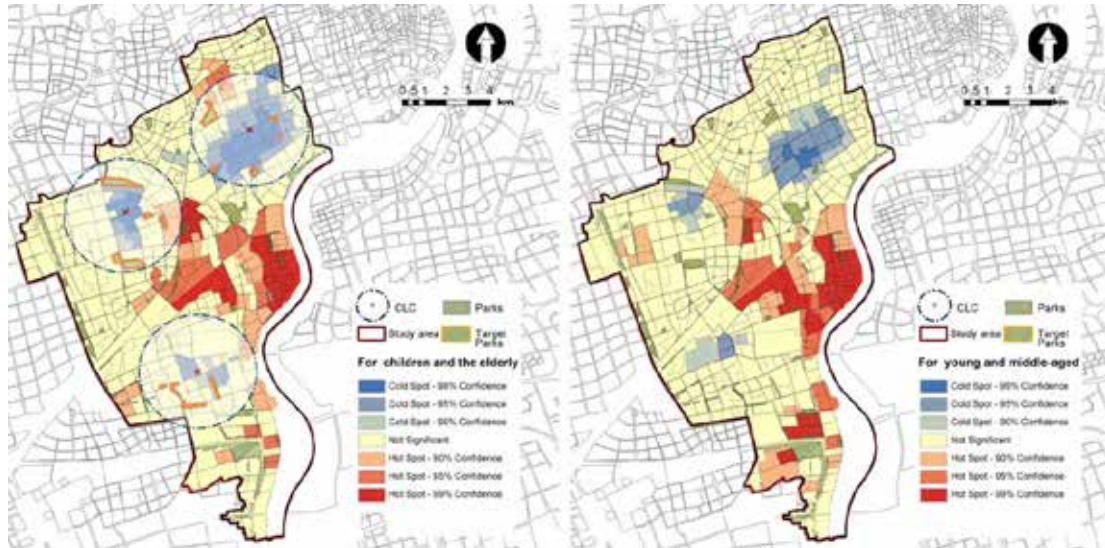

Figure 5. Identification of hot and cold spot of service budget within CLC

Conclusion

This paper proposes an method to evaluate and analyze the budget of park services in constructing CLC. In the case of a central district in Shanghai, where the method has been applied and practiced, the results indicate that the method has advantages in simple operation, especially comprehensively depicting the supply, demand of park services in term of different age groups. This method promises to promote the efficiency of urban green space in the context of urban renewal. However, the study assumes that the possibility of enjoying park services within the CLC is equal, which leads to a distorted cognition, since residents who live closer to parks are more likely to consume park services. Otherwise, it's not sufficient enough to support the improvement decision-making when evaluating park services without other criteria apart from accessibility. These shortcomings ought to be corrected in the future.

Well-being, social interaction and physical activity: encouraging healthy behaviours through quality urban design

Marichela Sepe

IRISS CNR - DiARC Università Federico II di Napoli, marisepe@unina.it

Abstract: In recent years, the healthy city topic has become more and more present in both research studies and urban actions. According with many principles declared in the Quito New Urban Agenda, the centrality of this topic is due to many important factors, including the climate change; the lengthening of human lifespan; the necessity of a wider accessibility in social, physical and environmental sense. Although the recognition of the importance of liveable spaces for keeping people in good health and improve social interaction, it is difficult to demonstrate that good urban design is capable to reduce hearth and other kinds of diseases. However, the increasing in the number of people who spend time, walk and cycle on the streets can be shown easily and this is a first measure to demonstrate the success of the environment from the healthy point of view.

Starting from these premises, this work will illustrate the principal definition of healthy city mainly related to public spaces and propose the Charter of urban health, liveability and happiness with 25 principles. The principles – following an holistic approach - should be considered as dynamic, in keeping with the increasingly rapid rates of change in a place and are both a check-list and guide lines for sustainable spaces.

Keywords: healthy city; well-being; urban design; public space

Introduction

In recent years, the healthy city topic has become more and more present in both research studies and urban actions (Burns, 2005; Florida et Al., 2013; Friedmann, 2010; Gehl, 2010; Montgomery, 1998-2013; Sepe, 2017). According with many principles declared in the Quito New Urban Agenda (NUA), the centrality of this topic is due to many important factors: the climate change; the lengthening of human lifespan; the necessity of a wider accessibility in social, physical and environmental sense.

The Agenda, adopted during the Habitat III Conference in 2016, represents “a shared vision for a better and more sustainable future”.

Many principles that are contained in the NUA concerns topics related to public spaces, liveability, healthy, networks, and many arguments, which are illustrated in this study.

In the following, a selection of these principles are reported, in order to clarify the general framework in which the paper is presented.

13. We envisage cities and human settlements that:

(b) Are participatory, promote civic engagement, engender a sense of belonging and ownership among all their inhabitants, prioritize safe, inclusive, accessible, green and quality public spaces that are friendly for families, enhance social and intergenerational interactions, cultural expressions and political participation, as appropriate, and foster social cohesion, inclusion and safety in peaceful and pluralistic societies, where the needs of all inhabitants are met, recognizing the specific needs of those in vulnerable situations.

36. We commit ourselves to promoting appropriate measures in cities and human settlements that facilitate access for persons with disabilities, on an equal basis with others, to the physical environment of cities, in particular to public spaces, public transport, housing, education and health facilities, public information and communication (including information and communications technologies and systems) and other facilities and services open or provided to the public, in both urban and rural areas.

37. We commit ourselves to promoting safe, inclusive, accessible, green and quality public spaces, including streets, sidewalks and cycling lanes, squares, waterfront areas, gardens and parks, that are multifunctional areas for social interaction and inclusion, human health and well-being, economic exchange and cultural expression and dialogue among a wide diversity of people and cultures, and that are designed and managed to ensure human development and build peaceful, inclusive and participatory societies, as well as to promote living together, connectivity and social inclusion.

50. We commit ourselves to encouraging urban-rural interactions and connectivity by strengthening

sustainable transport and mobility, and technology and communications networks and infrastructure, underpinned by planning instruments based on an integrated urban and territorial approach, in order to maximize the potential of these sectors for enhanced productivity, social, economic and territorial cohesion, as well as safety and environmental sustainability. This should include connectivity between cities and their surroundings, peri-urban and rural areas, as well as greater land-sea connections, where appropriate.

53. We commit ourselves to promoting safe, inclusive, accessible, green and quality public spaces as drivers of social and economic development, in order to sustainably leverage their potential to generate increased social and economic value, including property value, and to facilitate business and public and private investments and livelihood opportunities for all.

67. We commit ourselves to promoting the creation and maintenance of well-connected and well distributed networks of open, multipurpose, safe, inclusive, accessible, green and quality public spaces, to improving the resilience of cities to disasters and climate change, including floods, drought risks and heat waves, to improving food security and nutrition, physical and mental health,

and household and ambient air quality, to reducing noise and promoting attractive and liveable cities, human settlements and urban landscapes and to prioritizing the conservation of endemic species.

97. We will promote planned urban extensions and infill, prioritizing renewal, regeneration and retrofitting of urban areas, as appropriate, including the upgrading of slums and informal settlements, providing high-quality buildings and public spaces, promoting integrated and participatory approaches involving all relevant stakeholders and inhabitants and avoiding spatial and socioeconomic segregation and gentrification, while preserving cultural heritage and preventing and containing urban sprawl.

99. We will support the implementation of urban planning strategies, as appropriate, that facilitate a

social mix through the provision of affordable housing options with access to quality basic services and public spaces for all, enhancing safety and security and favouring social and intergenerational interaction and the appreciation of diversity. We will take steps to include appropriate training and support for service delivery professionals and communities in areas affected by urban violence.

100. We will support the provision of well-designed networks of safe, accessible, green and quality streets and other public spaces that are accessible to all and free from crime and violence, including sexual harassment and gender-based violence, considering the human scale, and measures that allow for the best possible commercial use of street-level floors, fostering both formal and informal local markets and commerce, as well as not-for-profit community initiatives, bringing people into public spaces and promoting walkability and cycling with the goal of improving health and wellbeing.

109. We will consider increased allocations of financial and human resources, as appropriate, for the upgrading and, to the extent possible, prevention of slums and informal settlements, with strategies that go beyond physical and environmental improvements to ensure that slums and informal settlements are integrated into the social, economic, cultural and political dimensions of cities. These strategies should include, as applicable, access to sustainable, adequate, safe and affordable housing, basic and social services, and safe, inclusive, accessible, green and quality public spaces, and they should promote security of tenure and its regularization, as well as measures for conflict prevention and mediation.

114 (d) Urban freight planning and logistics concepts that enable efficient access to products and services, minimizing their impact on the environment and on the liveability of the city and maximizing their contribution to sustained, inclusive and sustainable economic growth.

118. We will encourage national, subnational and local governments to develop and expand financing instruments, enabling them to improve their transport and mobility infrastructure and systems, such as mass rapid-transit systems, integrated transport systems, air and rail systems, and safe, sufficient and adequate pedestrian and cycling infrastructure and technology-based innovations in transport and transit systems to reduce congestion and pollution while improving efficiency, connectivity, accessibility, health and quality of life.

149. We will support local government associations as promoters and providers of capacity development, recognizing and strengthening, as appropriate, both their involvement in national consultations on urban policies and development priorities and their cooperation with subnational and local governments, along with civil society, the private sector, professionals, academia and research institutions, and their existing networks, to deliver on capacity-development programmes.

This should be done by means of peer-to-peer learning, subject-matter-related partnerships and collaborative actions, such as inter-municipal cooperation, on a global, regional, national, subnational and local scale, including the establishment of practitioners' networks and science policy interface practices (<http://habitat3.org/the-new-urban-agenda/>).

Although the recognition of the importance of liveable spaces for keeping people in good health and improve social interaction, it is difficult to demonstrate that good urban design is capable to reduce hearth and other kinds of diseases. However, the increasing in the number of people who spend time, walk and cycle on the streets can be shown easily and this is a first measure to demonstrate the success of the environment from the healthy point of view.

Starting from these premises, this work will illustrate the principal definition of healthy city mainly related to public spaces and propose the Charter of urban health, liveability and happiness with 25 principles carried out in the framework of the IRISS CNR research project "Contemporary urban landscape design: place identity,

happiness, liveability, health and sustainability” (Responsible: M.Sepe). The principles – following an holistic approach - should be considered as dynamic, in keeping with the increasingly rapid rates of change in a place and are both a check-list and guide lines for sustainable spaces.

Well-being, social interaction and physical activity

The relationship between healthy, liveability, happiness and urban design are the complex result of multiple elements which play different roles in the city system. Improving these factors with sustainable urban design, and preserving place identity as well, is a great challenge (Carmona, et Al., 2010; Lynch, 1960; Madanipour, 2003; Porteous, 1977; Relph, 1976; Sepe, 2013-2015). To suitably understand this complex system, in the following the topics are illustrated separately.

With respect to the health theme – which is strongly connected with liveability and happiness -, recent studies (AAVV, 2017) report that firstly it is important to identify reasons why people who live in cities have greater risk to have health problems because of different factors. These include: disparities; crowding, noise, pollution, which can produce stress and encourage people to avoid social relationships that are important for mental well-being; low presence of green, which results in possible reduction of leisure time, security and privacy; the increasing use of the Internet followed by a decreasing in the use of public space; the demand of always more specific types of food; the increasing in metropolitan, street and city sports of different kinds.

Urban design and planning can contribute to decrease mental health problems and improve happiness in the city by reducing those risk factors. The Mind the Gaps frameworks created by McCay (AAVV, 2017) identify four topics to make tangible the urban planner help, even though no one city still embodies all of them. Topic 1 is, as affirmed in different theories, access to urban green places, which can have many good factors including encourage exercise and social interaction; Wilson affirms that the good effect of green space stands in the fact that humans have biological need satisfied by the contact with other species; Ulrich states that the good effect is due to the contemporaneity of experience with aesthetics of nature and distance from every day problems; the Kaplan (Rachel and Stephen) theory proposes that natural sites take the attention of people more than the non-natural because these last need contemporary concentration on many elements.

These theories can help to understand the positive effect of green space in mental health but are not enough to assume that the design of green space in a site can assure improvement in mental health. There are other factors which can influence negatively benefits in green space such as inaccessibility, bad management, a feeling of threatening that can discourage its use. Green spaces should be designed to be welcoming to different kinds of people and not monopolized by certain groups. Indeed in some cases, green spaces can encourage behaviours, which are anti-social and discourage their use, because people feel unsafe in those spaces.

Successful green spaces should be walkable and have a suitable both physical and visual accessibility, which improve people’s wellbeing. Accordingly, small presence of green in small space, streets or workplace is important as well.

Another important factor is to create different options of transport such as paths for pedestrians and bikes, which help to reduce sedentary habits. Furthermore, it is important to design public spaces with flexible use which are capable to create a sense of belonging and community, providing streets furniture for both resting and chatting and other elements which contribute to social activities and the general perception of wellbeing.

The perception of safety also contributes to a better quality of life and public spaces, and those that are capable to contribute to this feeling are successful. Some features, which can help this feeling, include suitable lighting and clear landmarks.

As Lucy Saunders (AAVV, 2017) affirms people in the last decades are living longer than ever and so it is necessary to have healthier places to allow healthier life to all. This is because the daily activities such as work, travel and leisure are directly or indirectly connected to the place where these occur requiring suitable spaces.

Elements such as air pollution, noise, road dangers and social connectedness can influence our health in different ways. The question is to understand what of these factors influence in a wider ways health and how to address them. Sauders suggests to address all of them at once and implementing good practice in urban design at the largest possible scale.

Indeed, places which are good for people are often healthy as well. In public realm, this often means the diminishing in motorised transport, which is used for carrying people who could instead walk or cycle. Motorised transport impacts in non-positive ways on air pollution and physical inactivity, transforming public spaces in noisy and unwelcoming areas. And these also increase the problems deriving by poor access and road danger, which are particularly important for the most disadvantaged people. Putting people at the centre of the urban design and decision potentially reduce the inequalities. Accordingly, Healthy streets, as Lucy Sauders suggests, identify 10 indicators, which indicate how design urban spaces and transport policies which make people first (AAVV, 2017).

The most two important indicators - pedestrians from all walks of life and people choose to walk and cycle - have the aim to create places in which all people can participate in public life and both healthy and friendly environment design are considered in priority way.

The other eight indicators - People feel relaxed, Easy to cross, Clean air, Not too noisy, Places to stop and rest, People feel safe, Things to see and do, Shade and shelter show –clarify what is necessary to do to create inclusive, appealing and healthy places. Places, which do not have these characteristics, discourage people in using them. All professionals – transport professionals, landscape architects, community groups, artists, planners and developers - are involved in the realization of Healthy streets and all the indicators are necessary for creating them.

A big challenge is to meet the demands of the different stakeholders in order to put in practice the principles, all often in limited spaces. Streets can be contested spaces and every street requires different approach according with social, physical, political or financial questions, which can weight in the general design not always in the same way. The important, as declared by Sauders, is that the general objective is to create public space which work better for people and are healthy and liveable for all.

Furthermore, there exist important factors which create good interactions between places with behaviours, including: the promotion to daily activities such as walking or cycling which help people in having a healthy weight; the facilitation to easy access to healthy food; and the promotion of connected neighbourhoods and economic development.

Finally, the Richard Crappsley' (AAVV, 2017) approach to healthy design is mainly focused on streets and includes: reducing on-street parking and reallocating road space for vehicles, while adding space for walking and cycling; improving both the quality of footway zones and furniture and making easier for all age people to cross the streets; making bicycle infrastructures safer and more comfortable also introducing suitable separation with busy roads; slowing traffic, using different kinds of visual elements and tight corners; improving environmental elements, such as trees, sustainable drainage, shades streets and reduction of traffic noise; adding on-streets activities with both formal and informal activities which encourage people to use the space for social interaction or spend more time there; making safer the streets dissuading crimes and sense of insecurity, improving suitable lighting, natural surveillance; and making streets welcoming for all, improving accessibility.

Encouraging healthy behaviours through quality urban design

The factors described in the previous sections shows that healthy and liveable urban design are capable to influence urban happiness in many ways, contributing to sustainability and the preservation of place identity. Accordingly, in the following, the principles of the Charter of urban health, liveability and happiness will be

proposed. The principles are the results of the experiments carried out with the original Ecolivable+ Design Method (Sepe, 2019). The aim is encouraging healthy behaviours through quality urban design promotion.

1. A healthy, liveable and happy place is a space which can transmit feelings of healthy, liveability and happiness to everyone who uses it.

Accordingly, it is important:

2. To encourage the use of the place by people of different age groups, from children to the elderly
3. To eliminate architectural barriers which might discourage people from frequenting that space
4. To create a suitable balance between the elements of nature, landscape and equipment in the composition elements of the space
5. To have both in streets and public spaces natural lighting during the day and artificial at other times, avoiding artificial light in daily hours.
6. To retain an adequate state of cleanliness and maintenance
7. To create suitable spaces for dogs and domestic animals
8. To create a sense of security and safety to those who walk, cross, rest, and so on in the public spaces
9. To minimise or eliminate the noise generated by public transport
10. To improve suitable cycle lines
11. To fully perceive naturally occurring smells - e.g. wood, grass, sea
12. To have direct contact with natural materials, preferably local, used in the design of the space
13. To have the presence of water in different shapes (e.g. fountains) which promotes the vitality of the place.
14. To have the possibility of doing actions – such as walking, watching, etc.. - with a moderate or slow pace, promoting opportunities to take breaks in the space
15. To have the possibility of using the space in different weather conditions and seasons, contributing at the same time to its good state of maintenance
16. To preserve both the place identity and the intangible characteristics of the site and its surroundings
17. To both allow and promote different types of functions such as games, breaks, walking, etc..
18. To facilitate gymnastic activities – also slow - with the presence of small equipment or a designated space.
19. To have the possibility of doing actions that normally are not permitted – such as walking barefoot in the water or in designated public areas -, improving a feeling of freedom and joy.
20. To encourage the presence of art in its different forms.
21. To promote sculptures, games, or other elements and amenities which can bring a smile to a person's face promotes a state of liveability and happiness.

22. To promote participation, namely the feeling of being able to contribute to the life of that place increasing the sense of belonging.
23. The consideration of the place as symbolic of the neighbourhood improves the perception of its identity.
24. To promote the educational function which a place has – e.g. clearly displayed information about history of the place etc. or suitable ways to use it - increasing its intrinsic value.
25. To facilitate the use of new technology to increase the knowledge of its intangible values and history, offering a more profound experience of the place.

The principles – following an holistic approach - should be considered as dynamic, in keeping with the increasingly rapid rates of change in a place and are both a check-list and guide lines for sustainable spaces.

Conclusion

The work illustrated the principal definition of healthy city mainly related to public spaces and the Charter of urban health, liveability and happiness with 25 principles. The New Urban Agenda, adopted during the Habitat III Conference in 2016 was used as a framework and the study concerning urban liveability and healthy were the scientific framework. The *file rouge* of the study presented in this paper is the idea that people have to be considered the centre of any design of place and that a quality urban design is able to strongly improve well-being, social interaction and physical activity encouraging healthy behaviours.

The paper identified the reasons why people who live in cities have greater risk to have health problems because of different factors, including: crowding, noise and pollution, which can produce stress and encourage people in avoid social relationships that are important for mental well-being; low presence of green, which results in possible reduction of leisure time, security and privacy; the increasing use of the Internet followed by a decreasing in the use of public space. Urban design and planning can contribute to decrease mental health problems and improve happiness in the city by reducing those risk factors.

The principles of the Charter of urban health, liveability and happiness – result of the experiments carried with the original Ecolivable+ Design method - which were proposed represent both a checklist and guidelines, which the project has to satisfy in order to enhance the three factors – health, liveability and happiness - of the place in question. As mentioned in the NUA section, the Agenda promotes civic engagement, engender a sense of belonging and ownership among all their inhabitants. Furthermore, it supports the provision of well-designed networks of safe, accessible, green and quality streets and other public spaces that are accessible, promoting walkability and cycling with the goal of improving health and wellbeing.

Accordingly, aim of the Charter of urban health, liveability and happiness is encouraging healthy behaviours through quality urban design promotion. The principles should be considered as dynamic, in keeping with the increasingly rapid rates of change in a place, which lead to continually expanding the concepts of health, liveability and happiness (Taylor et Al.,1998, Zelinka et Al., 2001; Zidansek, 2007).

Next steps of the present study – currently in development - are devoted to identify and create suitable indexes to measure urban health, liveability and happiness or other indexes derived from a combination of these elements. These indexes could be used in a more comprehensive calculation of the sustainability meant in social, environmental and economic meaning of an urban project both in the initial and final phases.

Abstract: Under a rapid-unplanned urban transformation of Indonesian cities, which brings more pressures to already marginalized urban farming/agricultural practices in this country, the future of food security of Indonesian cities is in a big question. As already predicted by Central Bureau of Statistic/BPS, two-third of about 250 million Indonesian people would reside in cities in the next two decades and therefore their welfare including their basic needs particularly food would be depended how the country guarantee food security for the whole nation. The fact that many productive-agricultural areas in the urban and rural fringes, which are under pressures of unplanned-organic-scattered pattern of urban growth, suggests that there is a crucial need of reforming the existing urban policy and planning system which are not supported and protected to urban farming ideas and practices. The paper discusses this issue and documents the practices of urban farming in two creative cities of Indonesia, Bandung and Yogyakarta, and evaluates how the existing urban policy and planning guidelines support urban farming initiatives. This paper argues that it is crucially important to reform the Indonesian urban policy and planning guidelines and practices to accommodate the new paradigm of cities and urban areas as productive sources for sustaining food security for the whole nation.]

Keywords: urban farming, community, policy challenges

Introduction

It has been predicted that two-third of about 250 millions Indonesian people would reside in cities in the next two decades and therefore their welfare including their basic needs particularly food would be depended how the cities guarantees food security for their inhabitants (Bakti Setiawan, 2000). This rapid urbanization affects agricultural lands in suburbs. Most of them have been converted to housings and commercial buildings. This condition may affect food production in the future. Even though land is not the only aspect to enhance food production, farmland is still essential in food production and it needs to be expanded to meet the demand of the future population. Converting vacant lands within urban area for urban farming is one example of strategies to expand farmland. It has been predicted that more than half of global population will live in cities. There will be less people living in rural area and less labour for rural agriculture. So, integrating food production and urban development may address this issue.

In terms of nutrition and access to food, urban farming activities enhance food security by enabling urban dwellers to produce fresh produce in limited lands. In the era of rapid urbanisation, people living in urban area are relatively more vulnerable to food insecurity than rural population due to lack of access to agricultural land. Poor people living in a village can survive and maintain their health by growing their own food in their gardens or paddy fields. However, people living in cities depends on grocery stores and supermarkets to get food. Even in some cities in developed countries, there are some areas defined as food desert because of low access to fresh produce (vegetables and fruits) (Jettner, 2017). Food prices in cities are also relatively high and fluctuating because of transportation cost and unexpected weather events (Gaballa & Abraham, 2007). These problems rising awareness of urban communities in many cities in the world, to develop urban farming. For example, urban farming has been developed by low income communities in Indonesia since 1990s and a study found that urban farming in six cities in Indonesia was able to reduce communities' food expenditures (B Setiawan & Rahmi, 2004).

Unfortunately, urban farming has been relatively neglected in urban planning policies and literatures (Cohen, 2014; Morgan, 2014; Pothukuchi & Kaufman, 1999). Studies regarding urban farming are relatively limited in Indonesia and there is no recent study that specifically analyses Indonesian cities' planning policies in terms of its support for establishing urban food security. Therefore, this paper aims to discuss urban farming practices in two Indonesian cities, Yogyakarta and Bandung. These two cities are quite different in terms of population. Yogyakarta with population of 412.704 represents Indonesian small city. Bandung which has more than two million population, is one of big city in Indonesia (Central Bureau of Statistic, 2015). However, both two cities are famous of their innovation and creativity, including their urban farming movement.

The main inquiries of this study are: (1) What are types of urban farming initiatives in Yogyakarta and Bandung? (2) How did urban farming initiatives grow in Yogyakarta and Bandung and how do they manage their organisation? (3) How do government and spatial planning policies support these initiatives?

This study may raise awareness of urban planners and local government to redevelop the link between urban land use planning and food security. Food system is a part of urban system which is not less important than other urban elements such as water and air (Morgan, 2014). There is a need to reconnect urban land use planning and zoning regulations to agriculture activities. Most Indonesian cities are naturally blessed with tropical climate, fertile soil and plenty of water which enables people to grow various types of vegetables and fruits all year long. These resources must be managed through urban farming.

Methods

This study used qualitative approach and embedded multiple case study design. The case study cities are Yogyakarta and Bandung. This research design enables comparison between two cases and discussion of contrasting findings. Yogyakarta and Bandung are two cities in Indonesia that are famous of its creativity. These cities currently have a lot of communities including urban farming communities which were developed from the initiatives of the young generation. However, Bandung's urban farming community is relatively more well-known than the ones in Yogyakarta because the Mayor of Bandung, Ridwan Kamil, was the initiator of national scale urban farming

community namely *Indonesia Berkebun*. The members of this community communicate by using social media. Any kinds of information and invitations are posted to its followers (Ardianto, Aarons, & Burstein, 2014). Unlike Bandung, urban farming initiatives in Yogyakarta are developing with limited exposure to national media. Therefore, it is interesting to compare contrasting findings from these two different cities.

Data was collected from various sources such as semi structured interviews, field observation and some documents from different sources such as websites of urban farming communities, land use planning authorities, ministry of agriculture and Central Bureau of Statistics/ BPS. Interviews were conducted to eight participants who represent leaders of seven urban farming communities, four of them are in Bandung and three of them in Yogyakarta. The samples were chosen to represent different approaches and types of organisation. Some samples are initiated by government and some of them are a kind of grass root movements. Some of them run as a business, while some of them focuses on food security, social empowerment and environmental sustainability.

The data collected from interviews was transcribed, coded by using NVivo software and analysed by using thematic analysis. The coding was based on the major patterns appeared in participants' responses across interview questions. These codes then grouped into several broader themes. Additionally, data from government's websites (land use planning authorities and ministry of agriculture) was also collected for analysing policy challenges of urban farming development in these two cities. The documents collected are Urban Sustainable Home-yard Food Garden (Kawasan Rumah Pangan Lestari) Program and Report, Detailed City Spatial Planning (RDTR) and Zoning Regulation of Yogyakarta and Bandung.

Urban Farming in Indonesian Planning Literature

Several studies have been done to explore urban farming in Indonesia. Some articles relate urban farming with food security issue. For example, an article by B Setiawan (2000) provides a literature review discussing urban planning best practices in various cities in the world and draw a conclusion regarding the potential role urban farming in establishing urban food security in Indonesia. This study followed by an empirical research examining the role of urban farming for urban poor household in six Indonesian cities (B Setiawan & Rahmi, 2004). This study suggests that urban farming does not only enhance food security, but also improve households' economy through business opportunities and reducing food expenses. However, this study also mentions several problems and challenges for development of urban farming in Indonesia, such as lack of access to financial support, limited gardening skill and knowledge, and limited support from government. In this study, the authors recommend an urban land use planning that accommodate urban farming activities in the zoning regulation. Similar study has been done to specifically explores urban farming in several Green Kampongs in the City of Yogyakarta (Pasha, Widyaningsih, & Rijanta, 2013). The findings of this study depict that urban farming has been spontaneously implemented since a long time ago in Yogyakarta. Various types of simple verticulture (vertical agriculture) and container gardens even has been implemented in these Kampongs to deal with limited vacant land available for gardening. Another study in Jakarta that also suggest that urban farming has been implemented since 1990s by migrants who utilising vacant non-agricultural land in peri-urban areas for producing leafy green vegetables (Siregar, 1999).

Other studies specifically discuss the community aspect of urban farming. Puriandi (2013) explored urban farming activities of a farming community in the City of Bandung namely *Bandung Berkebun* (farming Bandung). This study suggests that *Bandung Berkebun* has a critical role in assisting and empowering the urban community to manage their gardens and sustain their farming activities. A recent study by Adinurani & Wuryantoro (2015) emphasises the role of a community in enabling people to share gardening experiences and knowledge as well as exchanging seeds and seedlings.

Based on the studies mentioned above, although urban farming may not be a new theme in Indonesian urban studies, it is still considered as a new issue in urban planning. There are still relatively limited studies that links urban farming and planning in Indonesia. The existing studies mostly explores urban farming from the side of food security and community development. However, only a few discussions regarding land use planning and urban zoning regulation for urban farming.

Types of Urban Farming Initiatives in Bandung and Yogyakarta

Yogyakarta

Although rarely exposed by national media, urban farming and local food communities in Yogyakarta (Jogja) are growing rapidly in the last five years. Each community has different approach, but they have a similar goal which is establishing more sustainable urban food system. Their activities are not limited to gardening and harvesting, but also includes discussions for raising awareness, sharing seedlings and selling products in organic farmer market. This study discusses three examples of prominent urban farming initiatives in Yogyakarta, *Pemablitz Jogja*, *Jogja Berkebun* (Farming Jogja) and *Kawasan Rumah Pangan Lestari/ KRPL* (Urban Sustainable Home-yard Food Garden).

Permablitz Jogja is one example of urban farming initiatives in Yogyakarta. This community was initiated in 2012, by a group of young people who are inspired by permablitz movement in Melbourne, Australia. Permablitz comes from words Permaculture, which is a kind of gardening approach developed by an Australian biologist, Bill Mollison (Mollison, Slay, Bourguignon, & Bourguignon, 1991) and Blitz, which means a project that is done in a short time. So, permablitz means a gardening project that involves a group of volunteers (community members) to create an edible garden in a kind of idle land (usually backyard/residential garden) in a short time. Unlike other urban farming community, permablitz Jogja implement sustainable agricultural method that focus on maximizing the use of natural resources and energy for gardening and ensuring no damage to the ecological system. The technological innovation in permaculture is similar with biomimicry, imitating what has been established in nature. This community has its own website and social media to post their activities (DALEY, 2015). In 2016, this community assisted students of Undergraduate Programs at Department of Architecture and Planning (DETAP), Universitas Gadjah Mada to develop an edible garden in the inner court of the campus building. A group of students in this undergraduate program formed a student community called *Perma DETAP* which aims to be a place for students to explore further and practice permaculture design trough urban farming.

Figure 1. Urban Farming Activities of *Permablitz Jogja* (left) and *Perma DETAP* (right)

Permablitz Jogja has converted several private residential gardens to permaculture gardens and there is no obstacle in terms of land use regulation so far. In terms of social side, there is also no significant social problem due to the development of these permaculture gardens. This may be because the projects were implemented in private lands. A small problem may occur when this project implemented in a public land such as the one in the university. *Perma DETAP* had to ensure that the garden design is agreed by all the academic staff and students. This was done by inviting the lecturers and students in the design process and accommodating comments and suggestions from the attendees.

Another urban farming community in Yogyakarta is *Jogja Berkebun (Jogbun)* that was developed in 2013. Similar with *Permablitz Jogja*, this community also converted vacant lands to edible gardens. However, unlike *Permablitz Jogja*, this community does not work alone. It is part of national movement in urban farming, *Indonesia Berkebun*, and it usually engages with private companies, state owned enterprises and government institutions in conducting gardening activities. Moreover, this community does not only manage private lands, but also utilising lands owned by some government institutions. Currently, this community is managing a vacant land owned by the department of forestry of Yogyakarta Province (Jogja Berkebun, 2017; Petani Muda, 2017)

Figure 2. Community Garden site of *Jogja Berkebun*

In terms of organisational arrangement, the membership of these communities is open and the members are free to join, contribute and even go out from this communities. *Jogbun* has an organising committee, but its formation is often reshuffled due to its open membership. *Permablitz Jogja* even does not have a fixed organising committee. This was designed to enable each of its members to

contribute similarly in this community. Each member is a leader in this community. In this kind of organisation, members can be more flexible to run these communities, but this condition is also vulnerable in terms of its sustainability. Some communities fail to maintain their sustainability due to this kind of membership and leadership management. People are free to come and go, so there is no fix organisational succession to ensure the continuity of urban farming movement. Learning from *Jogbun* and *Permablitz Jogja*, *Perma DETAP* combines formal and informal organisational structure. It was started from an informal initiative of the undergraduate students in Gadjah Mada, but its organisation was developed under the existing student organisation to ensure its continuity. *Lintang Panglipuran* also has fixed organisational committee that is divided into several divisions with specific responsibilities and duties. People are free to join, but once joined this community, a member has responsibility to contribute based on his division duties. Although it was recently formed in 2016 and still considered small and young, this community has a quite good informal organisational arrangement that may maintain its continuity and development.

Slightly different from *Permablitz Jogja* and *Jogja Berkebun*, *Kawasan Rumah Pangan Lestari/ KRPL* (Urban Sustainable Home-yard Food Garden) was initiated by a government institution, The Ministry of Agriculture. This program is a national program and was developed in almost every cities and villages in Indonesia. This program aims to bring agri-food production close to people and to increase agricultural land by utilising vacant spaces in residential areas. In the City of Yogyakarta, Kauman, a kampung located in the city centre, is one of successful model of Urban Sustainable Home-yard Food Garden.

Figure 3. KRPL in Kauman, Yogyakarta.

Bandung

Another urban farming initiative in Bandung is *1000 Kebun*. This community is relatively young because it was founded in 2015. Slightly different with other urban farming communities mentioned before, the members of *1000 Kebun* comes from different islands in Indonesia. So, it was initially founded as a local community, but then grow as a national movement. *1000 Kebun* does not only focuses on converting urban vacant lands to edible gardens, but it also manages a farmer market called *Pasar Sehat 100 Kebun* (Komunitas Indonesia, 2017).

Similar with *1000 Kebun*, *Agritektur* is a social enterprise in Bandung that concerns in both production and distribution of local produce in Bandung. This community is similar with POJOG in Yogyakarta which aims to cut food supply chain by meeting the consumers directly with the producers or farmers. However, *Agritektur* was not initiated by the producers. This community was founded by five young people with various education backgrounds who followed sociopreneurship competition in 2012. Two of the founders are an architect and a bachelor of agriculture. That is why the name of this community include *agri*, which is part of agriculture and *tektur* from *Arsitektur* (Architecture). The founders of this community engage with local farmers and help them to market their products to urban dwellers. The activities of this community are not only running a farmers' market, but it also has activities that enables people to experience growing vegetables such as table to farm, camp on farm and farming Kampong (*Kampung Berkebun*). Some restaurants in Bandung are interested to engage with this community to get vegetables, fruits and herbs from local producers (Agritektur, 2017; Bekraf, 2017).

Figure 4. Activities of *Agritektur* (left & middle) and *1000 Kebun* (right)

Some urban farming activities in Bandung were initiated by non-urban farming communities. For example, Yayasan Pengembangan Biosains dan Bioteknologi (YPBB)/ *Bioscience and Biotechnology Development Institute*, is a non-profit organisation developed in 1993 that aims to develop sustainable communities. This organisation focuses on assisting urban communities in Bandung to manage their solid waste. This activity enables people to recycle their waste including recycling organic waste into compost. Producing compost leads people to start thinking about growing veggies around their houses. The same approach occurred in Maleer, a district in Bandung that is a model of sustainable Kampung developed by the municipal government. Maleer is considered as a waste free Kampung in Bandung. Similar with YPBB, People living in Maleer started urban farming activities after being successful in composting their organic waste.

Missions, Management and Dynamics of Urban Farming Communities.

Missions illustrate perceived benefits of urban farming

Based on the interview, some urban farming initiatives began from awareness of the quality of food. The interviewees assert that urban farming enables people to care about and reconnect with their food. Urban agriculture initiatives enable people to grow their own food or engage with others who grow or make food for them. For example, one interviewee said,

“Nowadays, many food available in cities, but we do not know that they may contain chemicals that can harm our health. People do not care where their food comes from, how it was produced and how it was cooked. Therefore, this community was developed to address this issue. 1000 Kebun often brings our members to visit the organic farmers and educates our members how to make compost and grow their own food. (Interviewee 1).

Furthermore, urban farming initiatives also encouraged by low access to organic food which is considered healthy. This kind of food is much more expensive than non-organic ones because of the cost of organic certification. Therefore, not all people can afford to eat organic food. An interviewee said, “Organic vegetables are usually consumed by rich people because it is expensive, but actually we can grow our own organic vegetables”. (Interviewee 8). In terms of accessibility, urban farming brings food close to people, so they can reduce time and money to travel to markets. Urban farming also helps people to deal with spiking prices of some food commodities. One interviewee explained,

Growing food at home has several benefits. Firstly, we can grow our own organic food. This is cheaper than buying it at supermarkets. Secondly, we can save time and money. We do not need to go to the market every day to get fresh vegetables and herbs because we grow them at home. So, we can reduce our expenditure on food. Moreover, sometimes food prices are spiking, for example the price of chili that was more than doubled recently due to flooding. Actually, growing chili at home is very easy. You can see over there, I have plenty of chilies at the front yard. (Interviewee 3).

Most of interviewees also showed that their missions are related with awareness of conserving urban natural environment is a critical aspect of their initiatives. One interviewee from Bandung commented that urban farming provides urban greening and integrates waste management into urban food production. This interviewee said,

Nowadays, every neighbourhood in the City of Bandung is encouraged to be waste free by implementing sorting, reusing and recycling solid waste. Sorting is a process of separating the waste into organic and non-organic waste. In my neighbourhood, there is no waste sent to landfill because the organic waste is composted and used as fertilizer in our residential gardens, and the non-organic waste is sold to junk dealers to be recycled. (Interviewee 7)

So, urban farming is not just about producing food but also reducing waste by composting organic waste. This process is like recycling of nutrition within an urban area. Food consumed and generated food waste, then the waste is composted to grow food again.

Most interviewees also mentioned that there is no use of chemical fertilizers or pesticides in their gardens. Conventional agriculture usually uses synthetic fertilizers that can create pollution to the natural environment. Therefore, most of urban farming initiatives in Yogyakarta and Bandung stick to the use natural pesticides and fertilizers. However, some of them still use chemical fertilizers in low dosage to boost the production. One interviewee said, “This garden used fertilizers from cows’ urine, compost and a little bit of low dosage chemical fertilizers” (Interviewee 3).

One interviewee with a permaculture background commented that urban farming is just one part of sustainable living. This depicts that urban farming creates benefit for broader natural environment. This interviewee said, “Permaculture is not just about growing food with no chemical, but more broadly, it gives guidance to how to create sustainable living” (Interviewee 4).

Even though these initiatives have serious missions in food security and sustainability, most of them were started from informal meetings of a group of people. People with similar interest and hobby met and initiated urban farming communities. Urban farming become a leisure activity for them. For example, one interviewee said,

In this community, we usually spend our leisure time on weekends to meet, conduct discussions and gardening together. These programs become positive leisure activities for us especially the stay-at-home mothers. Finally, mothers can develop their neighbourhood, not only meet for shopping and gossiping. (Interviewee 7).

Management

In terms of internal organisation, all urban farming communities were initiated by people from non-agricultural background, except KRPL program which was initiated by the Ministry of Agriculture. The community members consist of people from various backgrounds, even in KRPL. They are interested in urban farming and get gardening skills from self-learning or investing their money in non-degree training programs like permaculture design course. Only KRPL that get training and 3-year community outreach program provided by government. One interviewee said,

“At that time, the members did not have any gardening skill at all, but they participated in various trainings provided by BPTP (Assessment Institute for Agricultural Technology). The trainers also came to visit the gardens and help community members to deal with gardening problems. This program last for 3 years and now the community is independent enough to manage their gardens.” (Interviewee 6).

Furthermore, almost all communities have a clear organisational structure although some of them are considered informal community with no strict or paid membership. Everyone are welcome to join with no membership fees. At least these community has a leader and members. Some communities have more complex structure with defined divisions. For instance, 1000 Kebun has four divisions: community, commercial, research and organic certification divisions. However, Permablitz Jogja is the only one which implement fluid structure with no leader. This community defined itself as a movement not community and want its members to be the leaders, so there is no hierarchy in this community.

These communities varied in terms of program developed. Some of them focus on gardening. They sell some of the produce directly to consumers or share the produce among the members or neighbours. One interviewee said, “The produce is usually sold to [informal] food vendors. However, the members are free to take veggies from the gardens, as much as they want. [Then, the rest will be sold].” (Interviewee 6). Another interviewee said, “We prefer not to sell our produce. We consume it for ourselves or give it to our neighbours. It is too valuable to be sold.” (Interviewee 8). These communities see urban farming not as business but as a self-satisfaction. One interviewee expressed this,

We do not see benefit as monetary value. We enjoy gardening. We are happy and feeling satisfied seeing the veggies grow. Sometimes, we sell the produce, so that we can raise fund for the community (Interviewee 7).

In my opinion, a community [in Yogyakarta] may survive without money. For example, the program we run last August was succeed without money. That program was developed based on volunteering. Participants contributed through their actions, time or thoughts. (Interviewee 5).

However, a few communities developed complex programs that deal with production and marketing. For example, 1000 Kebun mainly works as a food hub focussing on connecting organic farmers to consumers. This community also developed a certification board that based on trust. So, people can get affordable organic products. Agritektur even has more varied programs, including community supported agriculture (CSA) and designing urban farms for offices. However, this community currently focuses on developing urban agriculture for tourism purposes. This kind of communities see urban farming as a business, as described by one interviewee as follow,

“We have developed various programs. However, this kind of business need process and serious maintenance [to be developed]. We have created a good business plan and framework, but it seems that this business is still less interesting for young generations who prefer to work in big companies. So, we currently prefer to focus on developing Camp on Farm program because it is more [economically] prospective. We hope agriculture in [Indonesia] can sustain and to sustain it needs money not just altruism. Therefore, [in this community,] the programs were designed based on monetisation, but also implement justice, fairness and transparent. So, both farmers and consumers will benefit [from our programs]. We have to be patient to achieve that.” (Interviewee 2).

Some urban farming communities received or seek for external funding such as from government, donor or private institutions. They get external funding, then tried to sustain by selling produce or processed products. However, some of them have no external funding because they are based on volunteering. One interviewee expressed this, “We are not a kind of NGO that received fund from donors or sponsors. We depend on our own money which is limited.” (Interviewee 4).

In terms of inter-community network, some communities already reached international network. Agritektur has ever partnered with Hivos, Netherland, to develop a CSA. Permablitz Jogja was initiated through informal partnership with members of Permablitz Melbourne, Australia. It was the first permaculture community developed in Indonesia. Based on the interview, Jogja Berkebun (since 2011) is also considered as the first urban farming community in Indonesia and it becomes a part of national movement, Indonesia Berkebun (since 2013). These communities are usually supporting each other as described by an interviewee, “We have ever helped other urban famring communities in Bandung, such as Bandung Berkebun and 1000 Kebun. However, we only designed the garden.” (Interviewee 2). A community even become a member of a more formal community. An interviewee explained, “We have participated in Bandung Agri Market (BAM) three times and our community is a member of Green Farmers Group that is listed at the Department of Agriculture.” (Interviewee 7).

The management and community dynamics

In terms of continuity, some communities are struggling to sustain their activities due to low commitment. One community is struggling to conduct regular meetings and programs in the last 2 years, because their members are busy with their work or study. For example, one interviewee said, “Our community has no activity in the last 1.5 years. We were initially met because we love urban

farming. However, [we also have to work], we cannot earn money from this community.” (Interviewee 2). Another interviewee added,

The last program was in 2016. It is hard for us to arrange a meeting because many of our members are very busy especially the key members who master gardening skills. One is studying overseas, one moved to another city, one went back for good to Australia, and other members are busy working or running their business. (Interviewee 4).

Nonetheless, some other communities can maintain their sustainability may be due to the characters of their members. One community has members that mostly students. Other communities are mainly followed by stay at home moms. These groups of people have relatively more time to spend in communities than working people. Furthermore, some communities do not only sustain, they even expanded or spread urban farming activities to neighbouring areas as described by an interviewee, “Urban farming was firstly developed in RW 11 (an administrative division), then people from RW 11 helped people in RW 9 to develop their urban farming.” (Interviewee 7).

Interviewees commented that the key success of urban farming community are organisation management, varied members, support from government and commitment. An interviewee argues, “The key success of a community is organisation. With good organisation, a community can run any kind of program with little [or even no] stimulation from government.” (Interview 3). In terms of variety of members in terms of age. An interviewee commented,

A good community is the one that has members from different ages. In my opinion, 1000 kebun can be a good example because its members range from older people to youngsters. For example, when the young members are busy working or studying, the older members can fill the gap. When the older members have less creativity, the young members can help by providing plenty of creative ideas. (Interviewee 2).

Another key aspect is support from government. One interviewee explained, “Our community got 3-year support from government, and now we already know gardening skills needed. So, we can be independent now, but government is welcoming us to ask help if needed.” (Interviewee 6). Another interviewee added, “Government support is important for us. We got 1-year funding support from city government. Green kampong competition [arranged by city government] also raise eagerness in developing this community.” (Interviewee 7). Lastly, it seems that commitment is the most important aspect as described as by an interviewee, “The key is our consistency and commitment [to develop this community] no matter we get award from government or not. If we focus on getting awards [or grant], we cannot sustain in long term period.” (Interviewee 6)

Policy Challenges

Based on interview, there is no conflict emerged between urban farming and land use planning policies or other government policies. However, this does not mean that there is no problem regarding this issue. This part discusses several policy challenges that may be faced by urban farming communities in Bandung and Yogyakarta. Urban farming activities may be limited with no support from land use planning and zoning regulation. Furthermore, without support from formal organisation, these urban farming communities may face problems to sustain, expand and develop their activities.

Land use planning policies

According to the existing spatial planning policies, Detailed Spatial Planning of the City of Yogyakarta does not mention a regulation regarding agricultural activities or land uses (Yogyakarta City Council, 2015). This may be because no agricultural lands lefts in this city. Unlike Yogyakarta, detailed Spatial Planning of the City of Bandung (Bandung City Council, 2015) has a regulation regarding lands for sustainable agricultural zones (*LP2B*). These lands are in three districts of Bandung: Madalajati, Ujungberung and Cibiru. However, this plan only focuses on preserving the existing agricultural land and does not mention any strategies in expanding agricultural land or integrating agriculture in the residential lands. The programs regarding green open space and residential zone do not mention urban farming as a part of urban open space strategies or residential facilities. This depicts that although urban farming activities have been developed in grass root level, it has not yet been accommodated in the land use planning both in Bandung and Yogyakarta.

Even though urban farming is not acknowledged in the existing urban planning strategies, it has been included in a national program of the Ministry of Agriculture, Republic of Indonesia. Ministry of Agriculture has developed an urban farming models called *Kawasan Rumah Pangan Lestari/ KRPL* (Urban Sustainable Home-yard Food Garden) in several Indonesian cities in 2012. The examples of this neighbourhood models are in *Bener* and *Kadipaten*, Yogyakarta and *Astana Anyar*, Bandung (Indonesian Ministry of Agriculture, 2012; Nurnayetti & Sadikin, n.d.). However, this national program is less famous than *Indonesia berkebun* because it is slightly exposed to popular media. This program is funded by the government and engage with the residents and agricultural authorities. Coordination between KRPL and city spatial planning policies is needed to support the existing urban farming initiatives and the growth of new urban farming community innovations in the future.

The absence of urban farming in urban land use policies does not only occurs in Yogyakarta and Bandung. This issue is also emerging in cities in developed countries. Some urban planning scholars such as (Morgan, 2014), Pothukuchi & Kaufman (1999) and Budge (2012) suggest that most of the existing planning policies in global north has not explicitly accommodate urban food strategies. However, many cities in global north already have specific urban food strategies. For instance, City of Melbourne Food Policy includes a strategy regarding sustainable and resilient food system which aims to enhance urban farming within the city boundary (City of Melbourne, 2012). The City of Yarra and the City of Darebin, a municipality in inner suburbs of Metropolitan Melbourne, even have a specific urban agriculture advisory committee under the municipal government that developed urban agriculture strategies (Darebin City Council, 2014; Yarra City Council, 2014). In New York, the city government already created several planning policies and zoning regulation that aim to ensure all of the city dwellers have good access to fresh, local and healthy food (Ackerman et al., 2011; Morgan, 2014). Furthermore, some cities in Europe even have developed and implemented a food-sensitive urban design concept called *Continuous Productive Urban Landscape (CPUL)* which integrates green open space design, storm water management and urban farming (Bohn & Viljoen, 2011). These sort of planning policies particularly zoning policies are needed to be developed to support urban farming activities. Government policies should provide permit for urban farming in a residential zone and provides more facilities for urban farming and farmers markets (Cohen, 2014). This may support the continuity and the growth of urban farming movement in the future.

Local government policies

Interviewees commented that many local government policies developed to support urban farming especially in Bandung. Media reported that Ridwan Kamil, the city mayor of Bandung, created several policies to support urban farming development in his city. However, in reality, there are several drawbacks of these policies. An interviewee from Bandung said,

[Local] government donates fertilizers, seeds and other types support to every village [or kampung] that develop urban farming in Bandung. This is a very good policy, but in practical, the procurement of the donations is not as we expected. For example, we have ever submitted a proposal to government to get donations of [vegetable] seedlings, but we finally get donations of seedlings of big trees. The programs look good only in the beginning, in pictures and reports, but they cannot sustain and are usually not right on target. (Interviewee 1)

In the beginning, this community was supported by the city mayor, when he was nominated as the city mayor. We get several helps from him as a person and as a city mayor. We partnered with Bandung Agrimarket which is a government initiative. However, lately I feel that this initiative is not in line with our expectation. We tried to criticise this program, but then it is hard for us to contact the government for further partnership” (Interviewee 2).

Another flaw is related to hydroponics. Government provide grants and supports for the development of hydroponics farming, but some urban communities sees that hydroponic is not organic method and requires advanced technology and electricity. An interviewee said,

Hydroponics method does not suit to our community because it needs significant amount of water, electricity and we must buy special fertilizers for hydroponics. However, we get a donation of [a set of] hydroponics system from government. We do not benefit from this donation program. Moreover, many donations from government that came without any community outreach program. So, people cannot use the donation and benefit from it. The money is wasted through this program.” (Interviewee 8).

Conclusion

To sum up, urban farming initiatives in Indonesia has been rapidly spread over Indonesian cities in the last five years. More than five local urban farming communities was founded in 2012 in Yogyakarta and Bandung. The use of social media has significant role in spreading this green movement virus to urban population. Each community develops its own social media page to post its activities and inspire others to replicate or modified its urban farming initiatives. Even though it seems that each community has different urban farming approach and work separately, these communities are working together to greening the city and bringing back food production close to urban dwellers. However, this movement has not been supported formally by the existing land use planning and zoning regulation. This condition may be a drawback for the continuity of this movement. This kind of community initiatives may be diminished and soon changed to a profit-oriented corporate’s business ideas if there is no protection and support to legalize this urban farming activities.

This study may be considered as an initial study in Indonesia, that briefly examines the local land use planning policies in terms of its support for urban farming. Further studies that thoroughly analyse urban farming aspect of different types of Indonesian urban planning policies are needed. Besides, a study regarding the development of food sensitive planning theories is also interesting to

accommodate this current issue in urban planning theories. In terms of planning practice in Indonesia, it is also needed to develop urban planning and urban design concepts that includes urban farming as a part of urban landscape elements.

Abstract: Health profile is becoming more significant in Developing country such as China.

Research into the effects of the built environment on health has increased dramatically in recent years. Researchers are trying to understand and research explores the role of the built environment and transport system on an individual's health. Data from recent reviews have shown associations between environmental features, such as presence of sidewalks, proximity to parks and presence of certain types of food outlets, and outcomes such as physical activity. However, results from many studies conducted have been non-significant. A primary cause of these non-significant is due to how neighborhood areas are defined, which directly affects how the built environment variables are calculated in geographic information systems.

In this paper tests to what extent the potential impacts on regression analysis resulting from different data aggregation methods are well documented in spatial studies by varying the initial geographical scale of analysis which is primarily referred to as the modifiable aerial unit problem.

As explained earlier, the focus is on reducing the error caused by the modifiable aerial unit problem by introducing a data aggregation method.

Individual health and lifestyle data are obtained from the survey of income, and labor dynamics in census figures of China, and the relationship between the built environment and health profile is evaluated by using a discrete choice model.

The intended results is identify which variable is more closely related to health status by the proposed aggregation method is evaluated across three spatial scales

Keywords: built environment, spatial, geographic, health profile, regression analysis

Introduction

Health outcomes have been a central concern in evaluations of quality of life (Brazier, Ratcliffe, Saloman, and Tsuchiya 2017). Obesity prevalence has increased at a unhealthy rate over the last three decades in industrialized countries. This sudden increase in unhealthy is more likely to be related to environmental changes than to biological changes. Several empirical studies document a relationship between built form and obesity in adults (Frank et al., 2004; Lopez, 2004; Lopez-Zetina et al., 2006; Xu et al., 2005). Green infrastructure has

emerged as a topic of significant interest in urban and regional planning. A lot of scientists and public health experts determine that environmental change could help health—for example, by restricting the number of fast-food restaurants in a neighborhood (Minkler, Wallerstein, and Wilson 2008). Different population and urban form factors also have an impact on walking and weight. Other studies have shown that store density is related to physical activity (Atkinson et al., 2005, Besser and Dannenberg, 2005, Handy et al., 2005, Frank et al., 2005). Then researchers are trying to understand the environmental variables that affect health. Land use change and urbanization have changed the architectural pattern of metropolitan areas. Studies have found land use, plot size and health-related variables (Amir Samiz, Abolfazl Mohammadian, Seyedali Madanizadeh 2009). One related growing stream of research explores the role of the built environment on physical activity (Samimi, A., A. Mohammadian, and S. Madanizadeh 2009) and the individual's health (Coffee T. N 2005). However, results from many of the studies conducted have been contradictory (Zhang, M., and N. Kukadia 2005). One of the primary causes of these contradictions can be attributed to the way the neighborhoods are defined, which directly affects how the built environment variables are calculated in geographical information systems (GIS). Spatial analysis is the foundation of many studies within the transportation field. Spatial analysis implicitly defines some of the underlying assumptions of a study. A typical spatial analysis is the aggregation of data within geographic boundaries. The distribution of data can be clearly seen through aggregation.

Materials and methods

Study population

This section describes the study area, data source, and processing procedures used in this study. The study area is defined by the Shanghai Statistical Division, which is a large administrative zone that encompasses the city of Shanghai, China. The study area includes 2,253,525 participants who responded to the survey (referred to here as “respondents”) within 5432 census collection districts (CCDs).

The health used in this study came from the Shanghai Statistical Division (SSD) survey, which began in 2010 and surveyed the Shanghai population. The data were subsequently processed in ArcGIS and spss to calculate a number of environment variables (introduced in the next section) that represented the urban characteristics of Shanghai, China

Health outcome assessment

Survey respondents were asked: “Would you say that in general your health is excellent, good, fair or poor?” SSD used this measure of self-rated health -- used extensively in the literature, and shown to be a good marker of combined physical and mental health (Idler and Angel, 1990, Idler and Benyamini 1997) -- as a continuous measure, coded such that increasing values denote better self-rated health.

Built Environment Variables

The “six Ds” principle, which accounts for the main ways in which the built environment is expected to influence travel behavior, was used as a guideline for the selection and development of the built environment variables included in this study. The six Ds principle is composed of density, diversity, design, destination, distance to transit, and demand management (Ewing, R., and R. Cervero 1998).

The destination principle was considered by using the variable “quantity and distance to supermarket” A code was developed in Python to obtain the walking distance and quantity to the grocery stores and sports facilities closest from Gaode Maps. These are the two major points of interest affecting health. In order to convert these two variables to the CCD zones, overlapping two layers and CCD layer for range segmentation to calculate the number of shops and sports facilities in each CCD range. Greenland data from Shanghai Surveying and

Mapping Department. The green space is divided according to each CCD range, and the green area of each CCD range is calculated.

.Method

The purpose of this study is to evaluate the association of urban environment characteristics and health in Shanghai, China, and to examine the importance of spatial aggregation methods in the significance of this association. The residential location of individuals is preaggregated to CCDs in the data used in this study. Although CCDs are relatively small zones (resident committee management), it is not possible to define the neighborhood area for each individual by using a road buffer from the address of each individual. Thus, the only link between the data and the built environment variables is the CCD. The CCDs were defined for the purposes of data collection during the census.

The ideal aggregation methodology would define the neighborhood area on the basis of how each individual interacts with the physical environment surrounding his or her place of residence; this method would remove the associated MAUP errors. This problem is referred to as the uncertain geographic context problem, which requires that the travel trajectory of each individual represent the urban area of influence within which an individual would have interactions (Kwan, M.P 2012). Using the self-assessment health data of the sixth census for spatial clustering, we can know the relationship between health status and built environment through clustering results. Many studies have shown that the more points of interest (POI) and green spaces and health facilities near the place of residence have a stronger link to health outcomes (Crawford, Thomas W 2014). The following steps are used to calculate the built environment variables using the suggested aggregation method:

1. Overlapping CCDs and land-use layers containing green spaces;
2. Remove the protective green space next to the road;
3. The green map layer is overlapped by the CCD range line for regional division;
4. Calculate the green area near each neighborhood committee;
5. Overlay the layers aggregated with the self-assessment health survey;
6. Calculate whether there is any correlation with self-assessment health data;

Statistically, correlations between multiple variables (statistics) are detected by correlation analysis. For example, rice yield is usually related to soil fertility. If the statistic of the analysis is the same attribute variable of different observation objects, it is called "autocorrelation". Therefore, the so-called spatial autocorrelation is to analyze these spaces by statistically studying the spatial degree of autocorrelation between a spatial unit and its surrounding units in space. Characteristics of unit space distribution phenomena. Therefore, the local spatial autocorrelation of health data is first self-assessed to understand the spatial distribution of health. The regional Moran's I measures the degree to which each i is related to each j within the range of distance d . The formula is as follows:

$$I_i = \frac{(x_i - \bar{x})}{S^2} \sum_j w_{ij} (x_j - \bar{x})$$

X_i , X_j are observations of spatial positions i and j , and w_{ij} represents the neighborhood of spatial positions i and j .

Statistical analyses

Within each areal neighborhood definition, we calculate Pearson correlations among the four environmental variation. This relation is because the defined neighborhood area is more likely to reflect the area in which an individual had direct interactions as compared with an administrative boundary or a straight-line buffer (Duncan, M. J., E. Winkler, T. Sugiyama, E. Cerin, L. duToit, E. Leslie, and N. Owen.). To measure the association between the built environment and health, a logit model is developed. To measure the association between the built environment and obesity, a one-dimensional logit model was developed. Four sets of environmental variables were modeled and saliency calculated, taking into account the potential relationship between individual variables and health. Healthy input - output model.

Results

Characteristics of survey population

A majority of participants reported at least good self-rated health: 151019 reported 'excellent' self-rated health, 150675 reported 'good,' 31248 'fair,' 12930 'poor,' and 1907933 unfilled.

Associations with self-reported health, environment variable

In each dataset, Pearson correlations were lower for green area (Table 1). The number and health status of sports facilities are significant, with the highest correlation between the two variables. Although the number of health and stores is significant, the two variables are negatively correlated. Table 1 shows the results across the four models as discussed previously. From the green area variables not has a association with health, which may seem counterintuitive at the first glance (since green area is considered healthy). From the built environment variables, the number of Sports Facilities has a positive association with health. In general, the area of green space has no significant impact on health, but the number and distance of sports facilities have an impact on health.

Table 1. Pearson correlations of health by environment variables.

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.

a. Dependent Variable: Health						

Cluster analysis of self-rated health

This study proposed, applied, and tested an aggregation methodology for anonymous surveys in which the self-rated health of individuals is preaggregated to an existing administrative boundary. 151019 of participants reported at excellent self-rated health that use localized spatial autocorrelation analysis(Figure 1).The low-low

clusters are mainly concentrated in the central area of Inner Ring Line of Shanghai. Residents living in the city centre are particularly bad at their health, and than it can be seen that green space has no effect on health.

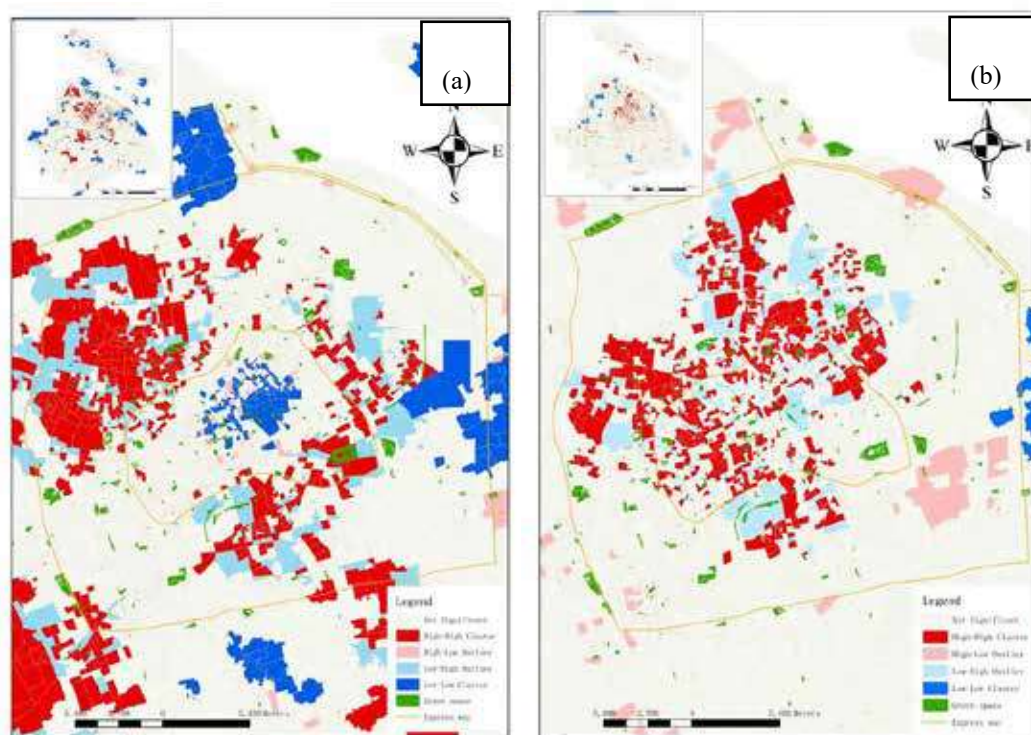

FIGURE 1 Aggregation clustering:(a) 'excellent' self-rated health within CCD boundary; (b) 'poor' self-rated health within CCD boundary

Discussion of results

The study assessed the association between built environment and health in Shanghai, China. A significant data collection and processing effort was conducted to obtain GIS data necessary for the evaluation of the built environment variables. The variables were selected on the basis of the six Ds principle, which considers how the urban environment may affect travel behavior. Results from the study indicate that there is an association between built environment and health, particularly when the number of Sports Facilities. But residents living in the city centre are less satisfied with their health than those living outside the city. There may be three reasons,(1)More demanding for your health; (2)The way to go out is mostly negative travel; (3) Getting food is more convenient. Through the aggregation clustering of health self-assessment data, the results show the distribution of residents' health status in Shanghai.

Conclusion

Our study aimed to understand the importance of: (1) know what environmental variables affect the health of residents in the city; (2) aggregation of vegetation data into the same areal units when seeking to evaluate potential effects of neighborhood greenness exposure on health. Using individual-level data obtained from a survey of Shanghai residents, we compared associations between self-rated health and greenness exposure.

The size and shape of neighborhoods as perceived by each individual (i.e., self-defined) could differ due to demographic characteristics of different subgroups within a population. Anonymous surveys tend to aggregate the residential location of survey respondents to predefined zones. These zones are typically not designed to capture the urban characteristics of a neighborhood. The issue associated with defining the spatial aggregation

boundary is referred to as the MAUP and has been shown to have dire consequences, particularly in regression analysis. In this study a variety of data sets describing the urban characteristics of Shanghai, China, are collated, processed, and analyzed. And contrary to expectations, we found not associations between green space and self-reported health, And the number of sports facilities significantly affects health. A previous US Study found that areas around home contained more fitness facilities than non-home areas(Hurvitz PM, Moudon AV.2012). It can be considered that the health status of residents outside the city center is better, because the residential area is mostly outside the city center, and the sports facilities are located near the residential area, so the residents living in the center of the city have a higher health index.

The current study has some limitations. Due to the cross-sectional nature of our research, reverse causality is possible, and it is impossible to truly identify all the variables that affect the state of self-health, and only actually reflect the distribution of health status of the city.

The space-time relations between pedestrians and street vendors: a case study in Suihua, China

Ziwen SUN¹

¹*The University of Edinburgh, Ziwen.Sun@ed.ac.uk*

Abstract: This paper is set in a broad scope of urban walkability research related to street vending practices. How are urban streets temporarily re-calibrated by mobile street vendors and dynamically used by the presence of pedestrians? The empirical basis and temporary data are lacking at a micro-scale. Using on-site observation and behaviour mapping, this study incorporates both social and physical elements to provide a fine-grained picture of human activity in urban spaces where street vendors operate. This compares the space-time patterns of street activities during four daily periods of three urban street spaces in the smaller Chinese city of Suihua. The empirical evidence produced reveals two co-operations of environment-behaviour interactions (e.g. micro-climates and street characteristics) and socio-spatial relations (e.g. the presence of street vendors and pedestrians). This study interprets a notion of flux in patterns of vending-walking relations, which could reveal an alternative understanding of Chinese urban walkable space via the temporary practices of street vendors. This knowledge and its application of designing active street spaces could benefit future policy-making and urban design practitioners.

Keywords: transient walkable space; urban walkability; everyday street activity; street vending

1. Introduction

1.1 Brief

This paper provides an alternative way of understanding urban walkability through dynamic street vending practices (Sun et al. 2016). Fan et al. (2018) indicate that street vendors as an interesting factor can impact walkability in contemporary Chinese cities, but there are no empirical studies. This research is an attempt to fill some of the emerging gaps. The aim is to be able to link who are they, what they do, where and when they do it. Golcinik et al. (2010) note the value of behaviour mapping and GIS techniques in producing detailed mappings of urban park spaces, which could help to understand the relationships between the built environment and human behaviour. This paper reflects on the development of the methods having collected empirical evidence in three urban street spaces, with a view to understanding the space-time relations between heterogeneous uses of pedestrian groups and street vending types.

1.2 Walkability and pedestrians

In light of the multiple benefits of walking (e.g. promoting public health, enhancing social interaction, increasing land value and reducing environmental pollution), improving walkability is becoming increasingly significant among urban designers and public health researchers (e.g. Saelens et al. 2003, Kashef 2011, Speck 2013, Duncan et al. 2015, Sun et al. 2016, Brookfield et al. 2017). The relevant studies on walkability have covered numerous different aspects, especially in developed countries: 1) The influence of urban fabric and spatial configuration on walking behaviours, such as the Walkability Index (Frank et al. 2010) and Space Syntax (Hillier et al. 1993, Koohsari et al. 2016), which could be applied in order to quantitatively evaluate cities and regions; 2) Walkability has been studied via ecological models and environmental factors, such as the Context-specific Behaviour Model (Giles-Corti et al. 2005) and Neighbourhood Environment Walkability Scale (Cerin et al. 2013), which attempt to explore correlations of perceived environmental attributes with walking behaviours; 3) Walkability could also be subjectively studied in relation to sense of place and experience of environment, such as Ewing & Handy's (2009) Urban Design Framework and Gehl's (2010) Three Types of Outdoor Activities, which present spatial meanings in terms of human-scale design guidance.

Despite the complexity of approaches to the concept of walkability, some studies have focused on specific aims, for instance, pedestrians on urban streets. Mehta (2008) notes three street characteristics (physical, social and land use), which simultaneously impact pedestrians' attitudes and perceptions. Whilst in most instances street features are relatively fixed, pedestrian behaviours are dynamic and difficult to determine. Hall (1966) defines the intimate, personal, social and public distances, which might relate to different sizes of pedestrian group. Furthermore, several studies indicate that sensitive pedestrians (e.g. older people, children, women, people with accessibility support needs and low-income groups) should be considered differently in the same environment (e.g. Unt et al. 2014, Brookfield et al. 2017, Jensen et al. 2017). However, it could be argued that street design generally focuses only on one human type (i.e. the "average person") (Jacobs 1961). Inspired by the idea of environmental affordances (Gibson 1986, Heft 2010), this study contends that pedestrians need to be more variously defined in specific urban streets.

According to the Oxford English Dictionary (2018), the word "pedestrian" is a noun, which means "a person who is walking rather than travelling in a vehicle". Therefore, pedestrianism could be defined as a transportation mode distinct from other such modes (e.g. driving) in streets. However, the word can be traced back to the early 18th century, from the French *pédestre* or Latin *pedester* "going on foot", which expands the definition of pedestrian to walking for non-transportation purposes, such as recreation, leisure, exercise, shopping, parades and social interaction (Lo 2009). The status of stationary pedestrians is also ambiguous regarding walking or standing. As such, pedestrians could be regarded as undertaking various street-based physical activities. The ambiguous activities of pedestrians could be further distinguished related to a specific purpose, population and behaviour.

1.3 Chinese cities and street vending phenomenon

The rapid urbanisation in China has led, in most cases, to urban developments, which ignore the everyday life for urban residents and the need for walkable neighbourhoods. Decreased walkability and its multiple consequences have emerged during the past few decades. For example, since China's economic reform in the late 1970s, the number of people walking and cycling has declined (Su et al. 2017). From 1992 to 2002, the increasing number of overweight and obese people in China reached

approximately 100 million (Chinese Academy of Sciences, 2009). In recent years, the Chinese scholars have begun to outline the various negative consequences of fast urban development and to undertake research into walkable environments (e.g. Sun et al. 2015, Zhou et al. 2017, Su et al. 2017, Fan et al. 2018). However, the majority of published research in this field is mostly quantitative, especially at a large-scale, and based on the study of western urban models.

Returning to the idea of distinguishing pedestrians via a specific purpose and behaviour, street vendors are a common feature of numerous streets in residential neighbourhoods, dynamically occupying space where many people regularly walk (Sun et al. 2016, Flock et al. 2016), leading to alterations of street layout and spatial use in contemporary Chinese cities. Although some Chinese scholars note that street vending can improve public vitality, its inherent mobility is considered problematic from the management perspective, such as trying to govern, control or manage the phenomenon or considering it as a necessary conflict (Huang et al. 2014, Xue et al. 2015). According to the Lefebvrian proposition that “(social) space is a (social) product” (1991 p.26), walkable space is not a pre-existing or a timeless container which pedestrians fill up and move around in, rather it is temporarily co-produced by street vendors and pedestrians. In other words, the inherent mobility should not be viewed as an “issue” but could be a positive approach to understanding a transient walkable space via ontological forces of local everyday life (e.g. habit, demand, culture and socio-economic situation), which can be further used to comprehend dynamic pedestrian behaviours.

1.4 Research aims and objectives

The challenge, therefore, is to explore the space-time patterns of street vendors and pedestrians by empirical studies of three specific urban street spaces in Suihua, in order to understand how these relations operate and how they in turn influence the walkable space at different times. The research aims and questions are:

Investigating activity types: the everyday street activities can be further distinguished via the paired types of street vendors and their clients (i.e. pedestrians), specific walking behaviours and populations, in order to identify detailed correlations across heterogeneous pedestrians and street vendors or other co-existed activities;

Understanding everyday uses in flux: how the space-time patterns differ at the three sites, periods and days; how the correlations between temporary street vendors and ever-changing pedestrians operate.

2. Methodology

This methodology included four phases: pilot study, workshop data collection, GIS database archive and analysis. A pilot study was undertaken by the researcher to develop a detailed protocol for the following workshop. Its tasks were selecting observation sites and times, drawing site plans, analysing site contexts, and summarising presence of activity types. The workshop was designed to collect data from three selected sites simultaneously, to refine the previous tasks (e.g. the activity types), and to discuss potential results or reasons, with 9 observers together, thereby ensuring inter-rater reliability and being more comprehensive when reflecting on the findings.

2.1 Developing behaviour mapping

This development has been presented in a working paper (Sun et al. 2019). The behaviour mapping method is an objective tool to study the relationships between the built environment and human behaviour through observing different activities in selected surroundings with minimal intervention by the observer (Golicnik et al. 2010, Unt et al. 2014, Ghavampour 2017). Behaviour mapping juxtaposes subject-related behaviours with the properties of space, making it possible to ascertain environment-behaviour interactions. This study has further distinguished the subject-related behaviours (i.e. Chinese everyday street activities) at specific times of the day.

The original method has five important steps: an initial site survey to collect the characteristics of the selected sites via photographs and notes; a symbolic coding system for the types of existing activities with demographic characteristics; a method of mapping the symbols or codes (e.g. activity, age, and gender) to the spatial characteristics (e.g. site plan) during a survey; iterative site surveys and recording of the microclimate at different periods (e.g. times and days); combined mappings and comparative analysis. However, this pilot study has identified the following limitations of the foregoing method:

- It is only valid for implementation in places of relatively fixed behaviours. Such streets and markets contain numerous pedestrians and changing behaviours that are impossible for observers to record.
- Observers must use the symbolic coding system creating mappings by hand. The low efficiency leads to a challenge for simultaneous recording in different streets.
- The data/mappings could not be repeatedly checked due to the activities disappearing shortly after the recording.

2.2 A workshop for data collection

This study proposes further development of the method, to include a fieldwork workshop dealing with the limitations in urban street spaces with plentiful everyday activities. The workshop entitled “Walking Practice” recruited 9 observers from various subject areas, who were studying at different Chinese universities. The multiple perspectives and interdisciplinary knowledge were significant in enriching the findings. Due to local residents were most likely to spend their time outdoors during the warmest month of the year, the workshop was held between 23 and 31 July 2017. The first day of data collection was designed for an initial practice (i.e. a weeklong survey).

Considering higher pedestrian movement and density of the selected urban street spaces, the on-site mapping by hand was replaced by taking panorama photos from high spots by observers with an average approach. 13 photos per hour were taken at each site (i.e. on average one photo was taken every 5 minutes). The date and time of each photo were archived. Furthermore, the micro-climate (i.e. approximate temperature, rainfall, cloud and wind) and special annotations (e.g. impression, light, and noise) were noted separately.

The data were simultaneously recorded from three selected sites during four different hours of the day, to have the maximum sampling of the various uses of spaces regarding the rhythm of everyday life. The four selected hours (i.e. 07.00-08.00, 11.00-12.00, 16.00-17.00 and 18.30-19.30) could be summarised as “morning commute to work”, “high temperature and lunchtime”, “commute to home after work” and “recreational phase”. The remaining hours and dates would comprise theory lectures, mapping practices, critical reviews, discussions and reflections. Three observers’ spots were selected in a higher position enabling observers to visually record a given observation area (around 1500 m²).

With the aim to create a GIS database, gender and twenty-six activity types (Table 1), were identified or refined during the workshop and discussed twice with the on-site observers. Paired activities were not only regarding street vendors and their clients, but also included some specific population groups and behaviours. For instance, children most often emerged with adults in urban street spaces. Therefore, a filtrating system was developed to distinguish all activities from explicit behaviours to ambiguous behaviours. It included five layers (Table 1): selling, buying, specific population (e.g. street cleaners), specific behaviour (e.g. dog walking) and common behaviour (e.g. walking).

2.3 Database creation and analysis techniques

The seven days’ data (i.e. the panorama photos) was recorded in digital form onto a GIS system using ArcMap 10.5 (ESRI, USA). From 13 photos taken per hour, 7 were input to the GIS database (i.e. an average of ten minutes per photo). Other 6 redundant photos were retained in case of needing to replace blurred photos systematically. The inputted photos were archived and used to repeatedly check the GIS database (i.e. spot checks). Moreover, some supplementary elements for training subjective judgment were used to refine age, gender and activity from the photos (e.g. clothes’ style or colour, schoolbag and hairstyle). The individual locations would be referred to the site settings (e.g. pavement crack, building façade, curb, tree, public furniture and private stall). The completed GIS database included 84 hours and 588 photos from three sites.

The sophisticated recording of individual spatial location, activity type, gender, time and date, created an explicit GIS database that could then be analysed through different hours, days and sites. There was no clear boundary of street vending spaces, so comparing the proportions (e.g. of percentage and mean) is more appropriate for this study. Furthermore, the database allows cross-comparison with other factors (e.g. micro-climate, spatial feature and on-site observation). The three sites were analysed separately, then the space-time patterns were compared and discussed with social relations together.

2.4 Introduce the selected sites

Site 1 is situated in Xishi street (Guangming Hutong). Figure 1 shows the spatial fabric, settings and observation area. The spatial fabric represents a high-density residential area and a feature of shortcut. There are two influential amenities around the selected site – 93 Market and Suihua People’s Hospital. The market engages numerous vendors (e.g. farmers and peasants) and pedestrians. The selected observation point is in the middle of the alley (i.e. a less integrated and narrow road), with

less vehicle movement but a higher pedestrian flow. According to the latest master plan (2012-2030) in Suihua, the alley will be removed in the future.

Figure 1: Urban fabric and spatial settings at Site 1, Suihua

Site 2 is situated in Guangsheng Street. Figure 2 shows the fabric, settings and observation area. The spatial fabric represents a high-density residential area, but a main street feature (i.e. a wider pavement with a roadway). There are many street vendors and pedestrians. The selected observation point is in front of the school and focusing on the corner (i.e. around the intersection). In addition, this site might attract many games players together (e.g. poker or Chinese chess).

Figure 2: Urban fabric and spatial settings at Site 2, Suihua

Site 3 is situated in Zhifu Street. Figure 3 shows the fabric, settings and observation area. The spatial fabric also represents a high-density residential area and a secondary street feature (i.e. an inconsistent/incomplete pavement and relatively wide roadway). The selected observation point is in the middle of the street (i.e. a relatively less integrated area). Due to the abundant street vendors having appropriated the pavement in various ways, vehicle movement and pedestrian flow are mixed on the roadway.

obviously higher than of boys. Compared to Sites 1 and 3, males playing at Site 2 was extremely noteworthy and its mean was higher at weekends.

3.2 Temporal vendors and pedestrians in numbers

Table 2 shows the observation period, temperature, proportion of people, correlation and number of street vendors and non-vendors (i.e. various pedestrians) during the four periods at the three sites. The lowest average temperature was 20.6 °C (a range of 18-23°C) at 07.00-08.00. The highest average temperature was 24.3°C (a range of 21-27°C) at 16.00-17.00.

At Site 1, the highest proportion (32.1%) was at 07.00-08.00 and the lowest proportion (15.2%) was at 18.30-19.30. The correlations between street vendors and pedestrians during the four periods were strong and fluctuated slightly - the weakest (2.9) was at 18.30-19.30 and the strongest (2.2) was at 11.00-12.00. *At Site 2*, the highest proportion (37.7%) was at 16.00-17.00 and the lowest proportion (19.1%) was at 07.00-08.00. The correlations were generally week - the weakest (17.1) was at 18.30-19.30 and the strongest (6.3) at 11.00-12.00. *At Site 3*, the highest proportion (39.4%) was at 16.00-

17.00. The lowest proportion (16.6%) was at 07.00-08.00. The correlations fluctuated slightly - the weakest (3.0) was at 07.00-08.00 and the strongest (2.1) was at 16.00-17.00.

Table 2 Period of observation, number of days, times, temperatures, total people, vendors and non-vendors

4. Discussion

Returning to the two research questions in this study, the first question has been answered through the activity filtering method (i.e. twenty-six street activities within five layers at four periods of the day in three urban street spaces). Based on the specific activities, sites' characteristics and periods, the answer to the second question is multifaceted. Examination of the space-time patterns across the three sites revealed two crucial co-operations of environmental affordances (Gibson 1986) and socio-spatial practices (Lefebvre 1991) at different times and sites. The findings are further discussed at specific sites.

Figure 4: Correlations between vendors and non-vendors at four period of the day

Site 1, an alley connecting a popular market and hospital in the city centre, could engage many pedestrians. In this sense, the walkable environmental characteristic was less influenced, such as the thermal comfort and street design (Ewing et al. 2009, Gehl 2010, Speack 2013). Based on the field observation, the market generated numerous people in the early morning since 04.00, leading to the highest percentage of people at 07.00-08.00. Compared to the two periods of 11.00-12.00 and 16.00-17.00 (i.e. the comfortable temperature), the numbers of street vendors were similar, but the number of pedestrians dramatically increased in the afternoon during the recreational time. Also, at weekends, the number of people increased obviously (Table 1). However, at the recreational period of 18.30-

19.30, the cold temperature might result in the lowest number of pedestrians. After a whole-day selling, the vendors decreased dramatically, leading to the weakest correlation in the evening.

Site 2, an intersection connecting central urban areas, has a high accessibility (Figure 2). However, this space overlapped with another system of older people playing (Table 1), unlike Sites 1 and 3. As such, the correlations between vendors and non-vendors were significantly weak (Figure 4). The temperature and street elements play a significant role to influence when people occur and where they stay. For example, the percentage of adult playing (26%) was high (Table 1) and many pedestrians emerged during the recreational periods, particularly at 16.00-17.00 with a comfortable temperature (Table 2). Compared to Sites 1 and 3, this reveals two distinct systems (i.e. vending-walking space and playing-walking space), producing different walking behaviours and socio-spatial meanings in Chinese urban streets, which deserves to be further studied.

Site 3 is situated in an ordinary residential neighbourhood connecting central urban areas. The correlations between vendors and pedestrians were strong during the four periods, similar to Site 1. Due to this area does not have a market, the pedestrians were hurried to go to work or school and most vendors did not appear yet in the early morning, unlike Site 1. However, the highest and lowest percentages of people at different periods were similar to Site 2 (Figure 5), closely related to the two periods of the highest and lowest temperature (Table 2).

Figure 5: Changing proportions during four periods of the day at the three sites

Returning to the gender equity of everyday activities (Jensen et al. 2017), this study shows the “real life” in Chinese street space. Other studies have considered walking and cycling together as a mode of active travel (e.g. Saelens et al. 2003, Giles-Corti et al. 2005). The results show that walking females and female buyers were statistically high at Sites 1 and 3, as they still generally take care of their family. At Site 2, the number of male playing was extremely high, indicating a different family role. The most important result is that girls tended to be more linked to their guardian’s short-term movement at an intimate distance (Hall 1966, Gehl 2010) at the three sites, revealing that gender behaviours in Chinese public street space have been unconsciously formed since childhood.

5. Conclusions

This study has three main contributions. First, most previous studies show that neighbourhood walkability (determined by population density, land use diversity and street connectivity) significantly impacts physical activities. However, this study further explored the two co-operations of environmental affordances and socio-spatial practices at specific street spaces and times. Second, this

study distinguished different walking behaviours and time-related variations between the market street (Site 1) and everyday street (i.e. Sites 2 and 3). For instance, the numbers of urban pedestrian unexpectedly decreased during the recreational times (i.e. weekends and evenings) in the ordinary streets. Third, the correlations between street vendors and pedestrians existed and simultaneously changed at different periods (i.e. Sites 1 and 3). Although the correlations at Site 2 differed, this provided another system about adults playing.

This study shows how the detail of dynamic street activities was temporally related to environmental affordance, temperature variation, human feature and time characteristics. In short, the method incorporates both social and physical elements to provide a fine-grained picture of Chinese street activities, going beyond a general narrative of street vending itself or common studies on walkability, towards a precise empirical study in specific urban spaces at specific times. Although all three street spaces in Suihua are walkable, the socio-spatial practices differ, producing distinct walking behaviours and space-time meanings. This is a dynamic system of spatial uses and social practices, which possibly operates at all urban scales from the city to the street corner, recalibrating urban street spaces at different times of the day and night. This recalibration itself was also dynamic according to ever-changing or alternate demands of emerging pedestrians, and nuanced by development situations of a neighbourhood, commuting or recreational periods. Street vendors occupy marginal street spaces as transient and mobile amenities that could dynamically improve walkability via heterogeneous tactics of mixed land use.

Acknowledgements

This research has been fully funded by the China Scholarship Council (No.201608060149) and supported by the Tweedie Exploration Fellowship, Henry Lester Trust and Great Britain-China Educational Trust. I would like to thank Simon Bell, Iain Scott, Chengrun Li, Xi Chen, Junchao Qian and the 9 workshop participants who contributed fruitful discussions and/or parts of the GIS database in this study. I would also like to express my gratitude to Yang Yu, Ruyue Zhao and the 13 students at Harbin Institute of Technology who supported this methodology development in the early stage.

Abstract: Insufficient physical activity is a key factor for noncommunicable diseases such as cardiovascular diseases, different cancers and diabetes type II. According to the World Health Organisation more than half of the European population does not meet physical activity recommendations. International studies have shown that living in high-walkable neighbourhoods is associated with higher physical activity levels. A clear understanding of the geographical variation of the walkability within a region is necessary for effective spatial interventions promoting physical activity. However to date in Europe no analytical spatial tool at a regional scale exists to provide such an evidence base. Our research mapped walkability at a high resolution for the entire region of Flanders. Analysis of the spatial distribution at a regional scale reveals only a few distinct areas showing a higher walkability score in comparison to other Flemish neighbourhoods. At a local scale differences between neighbourhoods or districts are apparent and can be addressed. The tool provides support in making more evidence-based healthy spatial policy decisions. Based on the resulting map an easy accessible open-source online tool was developed which can be used to assess the walkability and to compare neighbourhoods within a municipality or in reference to other towns and cities.

Keywords: Walkability, Physical activity, Analytical spatial tools, Urban environment and health

Introduction

Insufficient physical activity is a key factor for noncommunicable diseases such as cardiovascular diseases, different kinds of cancer and diabetes type II. Evidence shows, in Europe more than half of the population is not active enough to meet health recommendations. (World Health Organisation, 2018) Therefore increasing the average amount of physical activity is paramount to ensure a healthy population. According to The Lancet (Das and Horton, 2016) only raising awareness to the issue is not sufficient to ensure a significant long-term health outcome. Only a limited group of people will feel addressed and accordingly respond by doing more physical exercise. Moreover the effects are most of the time not long lasting and people tend to soon return to their old habits.

To profoundly embed physical activity in our daily routines, other policy fields such as spatial planning, housing and mobility should also incorporate health concerns policy initiatives or interventions. A structural way to ensure more physical activity is to shift from a motorised means of

transportation to walking or riding bicycles where possible. At some locations this is of course easier to achieve than at other locations, depending on several parameters (e.g. availability of high quality public transport, cycle or pedestrian infrastructure, proximity of jobs, schools or commercial facilities) This article focuses on exploring the geographical variation of spatial characteristics associated with high levels of physical activity, applied to the Flemish region in Belgium, situated in the centre of Western Europe.

The recently adopted strategic vision document of the ‘Spatial Policy Plan for Flanders’ (Flemish Government, 2018) expresses the ambition to develop healthy urban places as an overall policy goal, and stresses the importance of enhancing environmental conditions that favour active mobility. The aim of our research is to develop an analytical tool to assess the geographical variation in walkability in Flanders in order to support the expressed ambition to incorporate health concerns in spatial policy, and planning practice.

Walkability

Intuitively what is meant by ‘walkability’ is clear. However in literature, research and planning practice different definitions are being used, mostly based on related yet sometimes divergent spatial concepts, assumptions or empirical evidence. (Forsyth, 2015) The term is for instance often associated or intertwined with concepts of liveable and sociable placemaking at a human scale (Jacobs, 1961, Gehl, 2010, Montgomery, 2013). These concepts link walkability to other positive outcomes regarding the quality of life for people living in these neighbourhoods, not only improving their physical health but also their mental and social well-being. Still not all neighbourhoods with a large amount of people going on foot is necessarily liveable or is designed to foster pedestrians. Furthermore not every neighbourhood providing a sound, safe and pleasant pedestrian infrastructure will therefore always induce a higher rate of active mobility or be able to grow into vibrant living environments.

Research in human movement sciences (Frank et al., 2006, Owen et al., 2007, Sallis et al., 2016, Van Dyck et al., 2010) indicate a significant positive correlation between the observed amount of people’s physical activity and specific objective spatial characteristics. The evidence shows people will more likely choose for an active mode of transportation (going on foot or by bike) for functional travel in neighbourhoods characterised by a high residential density, a high amount of different destinations and a high street connectivity. Other possible determinants such as a high amount of motorised traffic, a higher risk of injuries for pedestrians, or a lack of high-quality pedestrian infrastructure or urban greenery seem to have less influence on the amount of active mobility in a neighbourhood (Van Holle et al., 2012). This insight clarifies why urban design efforts will not necessarily increase the average amount of physical activity in a neighbourhood, but also why some environments which intuitively are not considered to be walkable still attract a fair amount of pedestrians.

In this article ‘walkability’ is used to indicate spatial characteristics of a neighbourhood associated with high levels of physical activity.

Methodology

Walkability is operationalised and computed by making use of the following formula: $\text{Walkability} = 2 \times (\text{z-connectivity}) + (\text{z-residential-density}) + (\text{z-land-use-mix})$. The calculation method is based on

earlier research by Frank *et al.* (2010), which has been modified and tested by Van Dyck *et al.* (2010) to suit the specific Belgian spatial context.

In our research walkability is computed for every neighbourhood in Flanders and visualised on a high density grid (100 by 100 meters) . ‘Neighbourhood’ is defined as an area consisting of adjacent hectare-cells reachable on foot within a 1 km radius from a cell over the road network. This method is preferred over a Euclid buffer to determine the neighbourhood size because it takes physical barriers (for instance railways, highways or canals) into account. Unreachable cells are not considered to be part of the cells neighbourhood. However using this methodology the walkability index is not computed for cells not accessible by the road network, although these cells could be part of a larger adjoined area (for instance the core of a public park) which in some occasions could be reached on foot.

Connectivity for active mobility (pedestrians and cyclists) refers to the directness, or the ease, to walk from one location to another (Saelens et al., 2003). Pedestrians tend to switch to other modes of transportation if the detour to their destination is too large. A high density of intersections provides pedestrians the opportunity to choose for short walking distances. Connectivity is calculated for every neighbourhood by the ratio of the number of true intersections (by 3 or more streets) to the neighbourhood size. Only those true intersections that can be crossed by pedestrians were selected from the Flemish road network register. (<https://overheid.vlaanderen.be/producten-diensten/wegenregister>, accessed on 30/05/2019)

In the prior research by Van Dyck et al. (2010) residential density is computed by the ratio of dwellings to the area designated for housing in zoning plans. Unfortunately this data is not available for the entire territory of Flanders. As a proxy our research made use of the population density (for the year 2017), being the ratio of the total amount of people living in the considered neighbourhood to the neighbourhood size.

Land use mix indicates the diversity of different kinds of land uses in the considered neighbourhood. To assess this feature an entropy index is computed which represents how homogenous or heterogenous the usage of a neighbourhood is. The higher the entropy index, the higher the diversity of land use. Following Frank *et al.* (2010) and Van Dyck *et al.* (2010) the entropy index is calculated by using following formula:

$$\text{Land use mix} = \frac{-\sum_{i=1}^k [(p_i) \cdot (\ln p_i)]}{\ln k}$$

p_i = area of a considered land use
k = total amount of different land uses

A selection of the land use data (for retail, offices, public services, leisure) collected in the research of Verachtert *et al.* (2016) provided a solid basis for the calculation of the land use mix in Flanders.

The eventual walkability index consists of z-scores for each cell, normalised in regard to other cells of the grid.

Results

Figure 1 shows the resulting map indicating the walkability index for every cell accessible on foot by the road network. The map also includes cells that are part of agricultural or natural areas. Considering the three spatial characteristics associated to active mobility, it is more interesting only visualising cells that are part of the built environment or for which urban development is made possible in zoning plans (figure 2).

As to be expected the map (figure 2) clearly shows the neighbourhoods with the highest walkability (indicated in dark blue) in Flanders are located in the urban centres of the most important cities. The historic centres have both a high street connectivity and population density. Also the land use mix in these neighbourhoods is high, due to an abundance of retail, offices, leisure accommodation and public services (schools for instance) serving not only the local neighbourhood but the larger city agglomeration. The map also shows the effects of *urban sprawl* on walkability. Overall neighbourhoods in the centres of smaller cities or villages (indicated in light orange) score better on the walkability index than neighbourhoods characterised by scattered spatial patterns or ribbon development (in brown). The latter more peripheral locations are very monofunctional (designated residential areas, retail ribbons or industrial areas), which also have a low population density and a very car-oriented street pattern resulting in less connectivity.

Comparing the scores of all neighbourhoods in Flanders (figure 3) it is notable that only a distinct number of locations score high on the walkability index. The majority of neighbourhoods in Flanders score very low in comparison to the city centres of Ghent and Antwerp (highest scores). Using the classification introduced by Pisman, Vanacker, Willems, Engelen, and Poelmans (2018) the differences in walkability in urban, suburban and rural areas in Flanders can be assessed (figure 3).

Figure 1: Walkability in Flanders, natural breaks (Jenks)

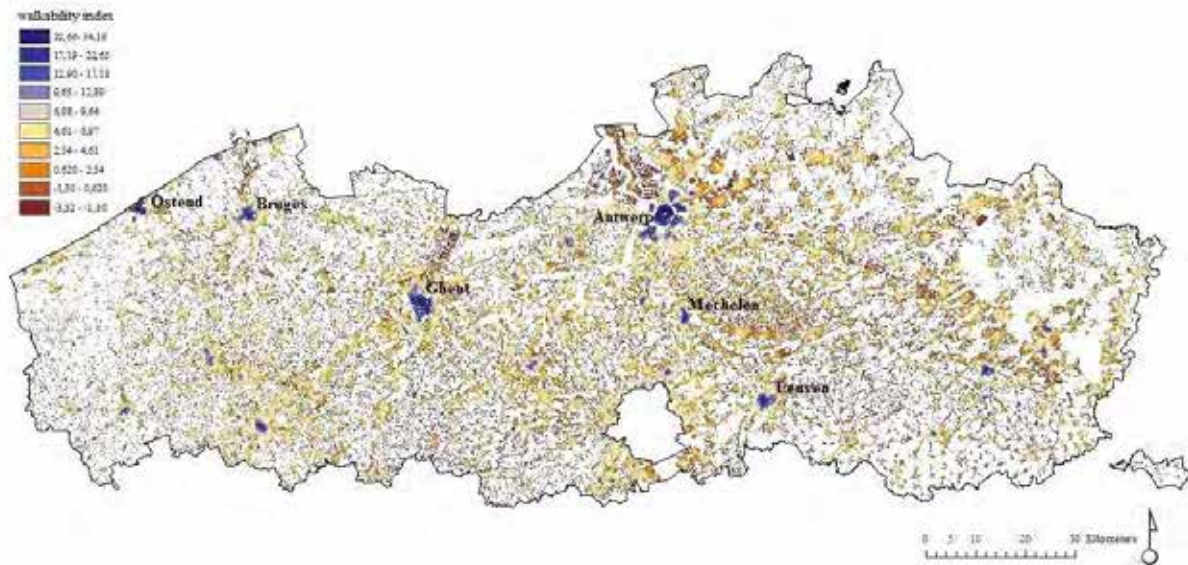

Figure 2: Walkability built environment in Flanders, natural breaks (Jenks)

Figure 3: Box-Whisker-plots walkability index built environment in Flanders

In particular the urban areas score high on walkability. Although suburbs seem to score slightly better than rural neighbourhoods, the walkability in both categories is rather low. Nevertheless, there are also urban locations that remain below the Flemish median. Furthermore also some rural or suburban locations score as high as the most walkable neighbourhoods in the urban category (third quartile, walkability index above 8.95). Most of these high scoring suburban or rural neighbourhoods are actually situated in the centre of small historic towns and villages developed from a medieval dense spatial pattern which to date still have a local importance in terms of retail, jobs and public services.

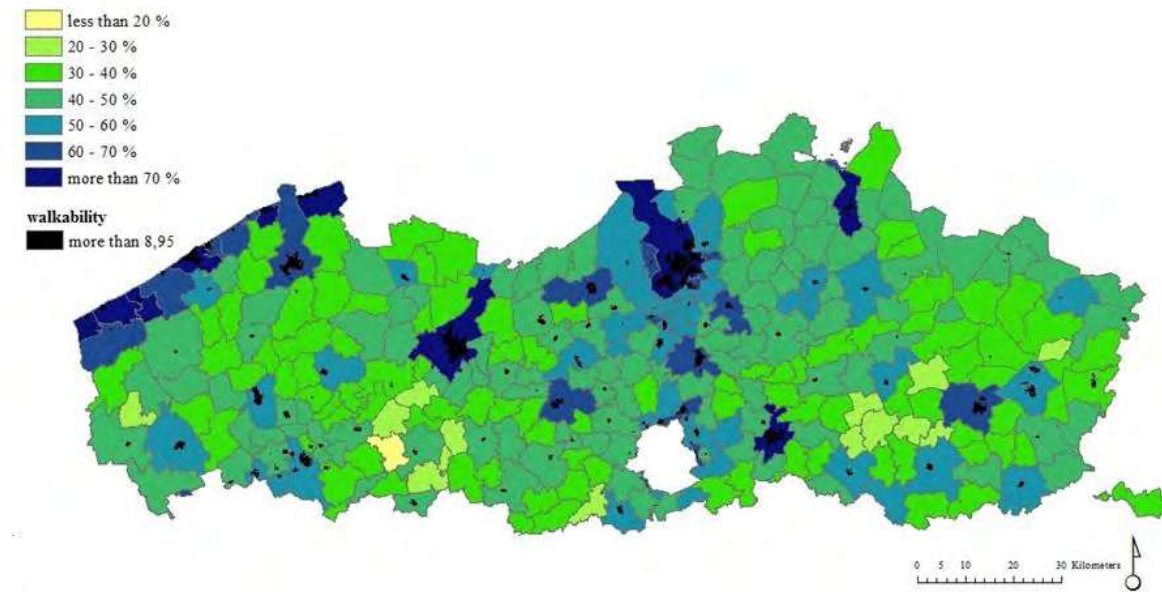

Figure 4: Neighbourhoods scoring more than 8.95 on the walkability index versus percentage of inhabitants per municipality reporting going on foot at least once a week, based on survey data retrieved from Agentschap Binnenlands Bestuur (2018).

Figure 4 shows the highly walkable neighbourhoods (walkability index over 8.95) compared to the reported active mobility in the municipality based on survey data retrieved from the Flemish Agency for Domestic Administration (Agentschap Binnenlands Bestuur, 2018). The largest clusters of highly walkable neighbourhoods are located in municipalities with a high percentage of inhabitants reporting going on foot at least once a week. For smaller clusters the relationship is less clear. In some municipalities there appears to be a higher rate of active mobility than expected based on the walkability index, at other locations the opposite is noticeable. More in-depth research can provide more insight into this. There may be other (spatial) characteristics influencing active mobility such as the urban design, the condition of pedestrian infrastructure or proximity of public transport. Also the different resolution (i.e. a survey aggregated at municipal level versus a walkability index based on a 1 km radius) can explain differences. Furthermore it is not inconceivable that a minimum size of "high walkability clusters" is required to effectively convince people to walk. Finally, it is probable that also non-functional journeys (i.e. walking for leisure) were reported in the survey, since all coastal municipalities (West on Figure 4) score high.

Walkability and spatial policy

It is probably for the first time in Europe that walkability is being mapped for a large region. Previous exercises were limited to a city or city region. Nevertheless, mapping on a regional scale also provides added value for *regional spatial policy*. It indicates places that already favour active mobility today. Our research proves the number of locations in Flanders scoring high on walkability is rather limited. Furthermore except for highly urbanised city centres the existing locations are also very limited in terms of size. The strategic vision document of the Spatial Policy Plan for Flanders (Flemish Government, 2018) focuses on public transit oriented development. Furthermore it emphasises future spatial developments have to enhance liveability, reduce health hazards, ensure more social inclusiveness, *favour active mobility* and provide a higher amount and quality of urban green spaces.

Recent research (Verachtert *et al.*, 2016) indicated high potential locations for future transit oriented development (TOD) in Flanders. These locations are close to high quality public transport hubs and have a high level of facilities in the vicinity, figure 5 shows a clear overlap with locations of high walkability. Nevertheless most of the indicated high potential locations for transit oriented development lack a high score on the walkability index.

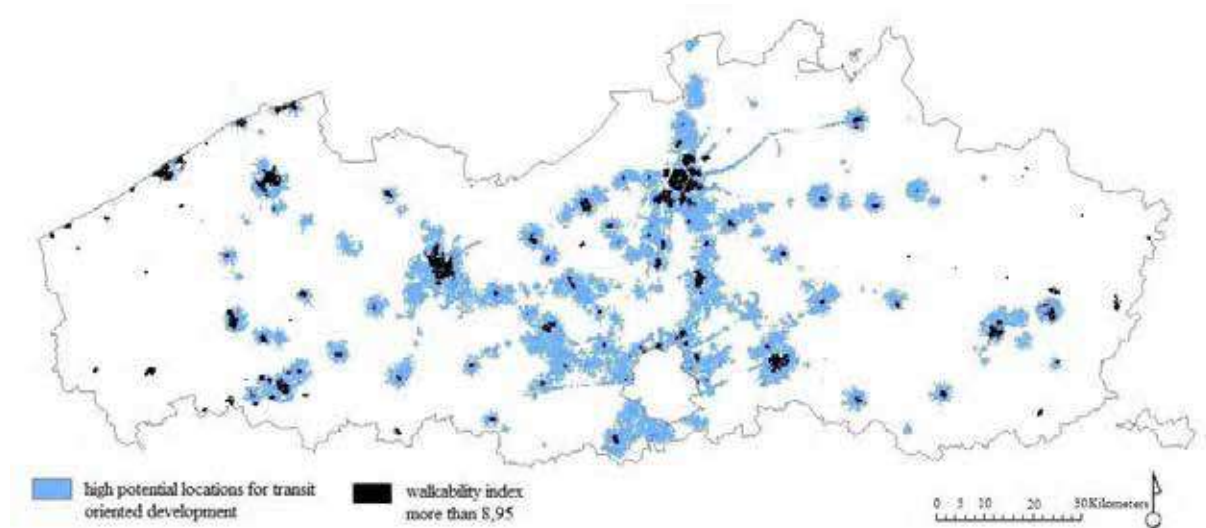

Figure 5: High potential locations for transit oriented development in terms of proximity of high public quality public transport and a high level of facilities – ‘A-Quadrant locations’ in Verachtert et al. (2016) versus highly walkable neighbourhoods.

For sustainable and healthy urban policy in Flanders walkability evidence is an added value to guide strategic development. Within the high potential locations for transit oriented development a focus on locations with a decent walkability score, or locations of which the score could be significant enhanced, will result in more active mobility. As mentioned before a walkable neighbourhood is not necessarily a liveable or sociable neighbourhood. It is however an excellent spatial condition for further spatial developments at a human scale. Moreover it will decrease car dependence, which will also have a positive effect on the use of public transport for the longer distances. At the regional scale (Flanders) this means the transformation of the urban sprawl pattern to a more dense and concentrated development at specific strategic locations must be placed central and high on the future spatial policy agenda.

Also at a *supra-local or local policy* level (e.g. a city-region, city or municipality) insights in the geographical variation of walkability provides a basis for a differentiated spatial policy for sustainable and healthy urban development of neighbourhoods. Locations characterised by a sufficiently high residential density, street connectivity and land use mix are less car dependent. Densification should therefore in the first place be considered in neighbourhoods that already have a substantial level of walkability while ensuring the improvement of other important conditions for liveability (e.g. high quality public space, safety, urban green space, absence of environmental nuisance,...). In addition these neighbourhoods are the best locations for investments in pedestrian friendly infrastructure as more active mobility is to be expected.

For example examining the walkability within the municipality of Mechelen, (a medium sized city located in the centre of Flanders, South of Antwerp, North of Brussels – figure 6) clear differences

between the city centre (dark blue) and the surrounding villages are visible. The city centre, but also the neighbourhood Spreeuwenhoek, score high on walkability. But there are also differences in walkability between the surrounding villages. Muizen, Hombeek and Walem have a larger central more walkable cluster than Heffen or Leest. Very low walkability scores are noticeable in the residential ribbons surrounding Heffen, Leest and Hombeek. Urban policy promoting active mobility should be well aware of these differences, concentrating developments foremost in the central blue or light orange areas and to a lesser extent in the more walkable centres of the surrounding villages. Also investments in pedestrian friendly public spaces should in the first place be considered in these distinct areas. High quality public transport or bicycle connections from the villages to the city centre could be introduced or enhanced. In the darker brown areas, which have a very low walkability, a cautious assessment of the desirable spatial development perspective is appropriate.

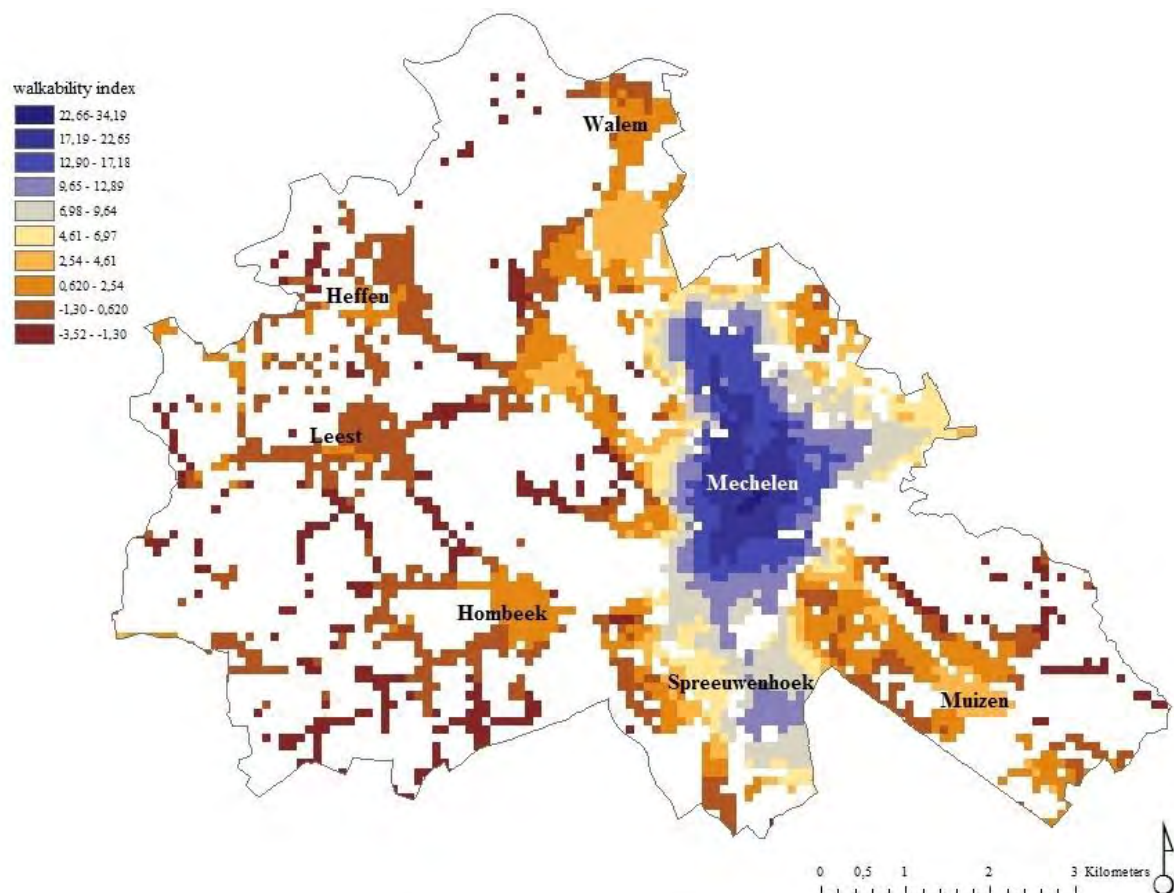

Figure 6: Walkability index for the built environment in the municipality of Mechelen, natural breaks (Jenks)

Another consideration from a health perspective to guide local spatial planning initiatives improving walkability is an assessment of the socio-economic status (SES) in different neighbourhoods. People of lower socio-economic status are more vulnerable to several health hazards (i.e. because of budget restraints which affect their diet, housing quality or access to drugs and medical advice) (Pampel et al., 2010). Increasing the walkability in low SES neighbourhoods will increase possibilities for active mobility, thus effectively improving health conditions for a vulnerable group.

Governance and dissemination

Achieving the policy goal to develop healthy urban places (i.e. neighbourhoods with increased levels of physical activity) in Flanders relies very much on the capacity of the local policy level to address the issue. The Flemish policy level outlines guidelines for spatial planning, is responsible for policy interventions in areas of regional importance and supports the local institutional level achieving policy goals, but the lot of planning initiatives and spatial projects in Flanders are carried out at the municipal level. There are 300 municipalities in Flanders: larger cities like Antwerp (over 515.000 inhabitants) and Ghent (over 255.000 inhabitants), but mostly smaller towns and cities. The administrative capacity and resources of these municipalities are unevenly distributed. To enable all local governments to access the walkability data for their municipality an easy accessible open-source online tool was developed based on the resulting maps (<https://walkability.marvin.vito.be>). The tool can be used to assess the walkability and to compare neighbourhoods within a municipality or in reference to other towns and cities. It gives insight in the underlying three environmental features (connectivity, residential density, land use mix) of a neighbourhood providing evidence to improve the local walkability. The data is also made available enabling municipalities with more technical resources a more thorough analysis possibilities using their own GIS-system. The tool was tested and adjusted in cooperation with civil servants in five municipalities of different scales.

The walkability evidence and the online-tool is actively disseminated and promoted by the Flemish Institute for Healthy Living, the Department of Environment and Spatial Development Flanders and the Flemish Agency for Public Healthcare to policy makers, civil servants, private organisations and citizens as part of a larger project on healthy public spaces.

Conclusion

Based on prior evidence (Frank et al., 2010, Van Dyck et al., 2010) linking neighbourhood characteristics to increased levels of physical activity our research succeeded in mapping a walkability index for the entire region of Flanders (Belgium). Overall the research reveals walkability throughout the region is rather low. Nevertheless clear contrasts between more walkable centres of small villages and towns and peripheral scattered spatial patterns or ribbon development with a very low walkability level is noticeable. Neighbourhoods scoring best in terms of walkability are mainly located in urban city centres. The number of neighbourhoods in Flanders scoring very high on walkability index however is limited. Except for highly urbanised city centres these highly walkable neighbourhoods are also very limited in terms of size. The high resolution map also enables analysis of walkability at a municipal level, as a basis for a differentiated spatial policy for sustainable and healthy urban development. Urban policy promoting active mobility should be well aware of the spatial differences throughout the territory, concentrating developments foremost in the more walkable neighbourhoods or actively enhancing walkability conditions at locations selected for densification.

Acknowledgements

The authors would like to thank Tomas Crols, Guy Engelen, Wim Peelaerts, Lien Poelmans and Els Verachttert at the Flemish Institute for Technological Research (VITO) for their technical help computing the walkability index and developing the online walkability tool. This research is funded by the Government of Flanders.

Abstract: The compact city theory develops different connotations in different eras. In the information age, the way people live has changed, which leads to the reconstruction of urban functions and forms, and therefore it is necessary to develop the compact city theory accordingly. This thesis firstly reviews the development history of compact city theory in different eras, and then explores the impact of information age on urban functions and forms, and considers that living space of people has changed from real physical space to physical space integrated with virtual network space in the information age. Finally, it is concluded that function division in the future city will be more blurred, land use will be more compatible and mixed, and the city's structure develops from single center to multi-center or homogeneous center network, based on which new measurement index for compact city is proposed to measure compactness of city in the information age.

Key words: compact city, virtual network space, urban form, Internet

1.Introduction

China has a huge population of Internet users. The 43th Statistical Report on Internet Development in China issued by China Internet Network Information Center (CNNIC) shows that as of December 2018, China has 829 million web users, with the penetration rate of 59.6%, and has 871 million mobile-phone subscribers, with internet access rate by mobile phone of 98.6%. The rapid development of Internet and related information technology industry has brought new changes and experiences to the life of citizens. Working is not limited in physical space and video conference becomes quite common. Due to rapid development of e-commerce, citizens can directly buy goods and meals in any store in the city through APP, and these goods and meals can be delivered to them within half an hour. In addition, citizens can directly pay the phone bill, Internet access fee, and water and electricity charges online with mobile phone, and it is unnecessary to go to the business office. Information network technology helps citizens

to break through the constraints of physical space and influences the distribution of traditional urban functions. Since urban form is undoubtedly the most direct reflection of social conditions in urban space, exiting study of urban form is not suitable to cities in the new era and new explorations should be proposed.

2 Development History of Compact City Theory

2.1 Origin and Development of Compact City Theory

2.1.1 Origin of Compact City Theory: Industrial Revolution

After the second industrial revolution, internal combustion engine fueled by gas and gasoline occurred and automobile became popular vehicle for the public. Convenient traffic has greatly changed the way people live, promoting communications between people and enlarging the scope of activities of people. After the 1950s, automobile became the popular vehicle for the public and cities developed into transport-oriented pattern from small, crowded classical city. It also brought negative effects, such as sprawl and blind expansion of city, low-efficient land use in suburb, decline of downtown, repeated construction of municipal facilities such as roads and plumbing pipelines in new area. People began to learn how to face and solve these new problems.

In 1973, George B. Dantzi and T.L.saaty wrote Compactcity: Aplanfora Liveable Urhan Environment, and in the same year, he explained the theory of compact city in the lecture of The ORSA New Orleans Address on Compact City. He proposed to achieve concentrated construction of urban infrastructure by controlling the size of city and increasing population density and reduce the use of cars by automatic transport system covering the whole city, which can be considered as pioneer of compact city theory.

2.1.2 Development of Compact City Theory: Impact based on Sustainable Development Concept

Since the middle of the last century, urban environmental problems have been worsening, and a series of problems such as resource crisis and land desertification began to threaten human survival. In 1987, the world commission on environment and development first elaborated the concept of sustainable development in its report "our common future", which has gained broad consensus from the international community.

Under the background of sustainable development, the European Community Commission issued the Green Book of Urban Environment in 1990, which regarded compact city as "a solution to residential and environmental problems" and considered compact city as a sustainable urban form (European Commission,1990). After that, "compact city" has become the focus of many western urban planning and research of scholars, gradually changing from a vague idea to a theoretical system with certain depth, and is regarded as the thought and principle of urban planning by many cities and scholars.

2.2 Connotation and Framework of Contemporary Compact City Concept

The theory of compact city is an urban planning theory of urban sustainable development strategy and a systematic urban space construction method proposed in the process of

contemporary urban development aiming at a series of environmental, economic and social problems caused by urban sprawl (Jun JIN,2017). Up till now, unified definition of compact city hasn't been proposed. From the understanding of domestic and foreign scholars of the concept of compact, mixed-used urban functions (Chuanglin FANG,2007), intensive urban form (Wei LANG,2017)and high urban density (Lin LI,2012) are the consensus of domestic and foreign scholars about the compact city theory, also the study of compact city is mainly conducted around the functional structure of city and spatial form.

3 Urban Space under Impact of Information Age

In the context of the information age, the influence of the Internet on cities can be roughly divided into the following two aspects. (1) the rapid development of Internet information technology and related industries has changed the lifestyle of urban residents. As the main carrier of human activities, the huge changes in urban residents' production and life will inevitably lead to the reconstruction of urban functions and forms. (2) the "virtual space" formed by the Internet is interwoven with the geographical space of the real city, which influences and promotes each other and forms an informationized city under the background of the new era.

Figure 1 Concept map

3.1 Impact of Internet on Lifestyle of Urban Residents

The biggest impact of network information technology to the lifestyle of urban residents is that the "virtual space" which is formed by it is distinctly different from traditional physical space defined by entity, distance and the boundary. It specifically refers to the online virtual information space built by human by virtue of information media internet based on integration of many technologies, and its virtuality, instantaneity and interaction is transformative (Yaoyu LIN and Jiaming WU,2010). The impact on the life and work of urban residents mainly includes the following two aspects:

3.1.1 Substitution of Urban Real Space

The virtual network space has intense substitution effect to partial reality spaces in cities. Namely, partial of original pedestrian flows may realize through the virtual network space. The substitutable pedestrian flows have the inevitability of non-face-to-face communication and the network performability of behavior activities. In real life, a lot of pedestrian flows can be realized through virtual network spaces. For example, WeChat group and QQ group can be

regarded as the transfer of physical space for friends to meet and chat in the real world into the virtual space. Internet shopping platforms such as Taobao and JD can be regarded as the transfer of real shopping malls and supermarkets into virtual space. Similarly, the opening of online payment for urban public services such as mobile phone bills and utility bills can also be regarded as a substitute for the traditional public service spaces.

3.1.2 Enhancing Functional Compatibility of Urban Real Space

Traditional urban physical functions are divided into four major categories: residence, work, recreation and transportation. Under the background of informatization, hidebound classification and layout are abandoned by traditional physical functions in cities, which develop towards mutual compatibility and function integration. Production domain and current domain blend gradually, and living space and working space are compatible. For example, integrating working and living, SOHO (home office) mode rises mainly due to the development of network information technology. Further mixing of various leisure and entertainment spaces in cities is also the trend of urban development in the information age. For example, a large number of complex buildings integrating retail, leisure and culture appear in cities.

3.2 Reconstruction of Urban Functions and Forms

3.2.1 Reconstruction of City Center

Functions of traditional city center are mainly concentrated on retail, entertainment and office. Basically, difference of center level could be regarded as difference of commodity and entertainment quality and level. However, with rapid development of e-commerce and improvement of commodity and service capability provided by e-commerce, daily demands of citizens are beginning to be gradually replaced by internet, and their travel purpose will also be changed. Initially, internet weakens citizens' demands for going out to purchase daily articles and clothes. Later, they purchase home appliances and mobile phones at home. Now, they are even able to book three meals a day, nail beauty and physical therapy services at home. It means that certain demands that could not be replaced by internet, such as sports, education and outdoor activities, will become main travelling purposes of citizens. Functional focus of city center will shift towards personal experience program. Proportion of traditional retail and entertainment programs will be decreased, and such programs shall be shifted to high quality experience program, such as brand flagship stores, large stadiums, theaters, and large park green spaces that pay attention to personal experience.

3.2.2 City Developments From Single Center Towards Homogeneous Center Network Layout

Considering that great increase of compatibility of urban functional spaces leads to mutual mixing and complementation of residential district, business district, office district and sci-tech park, city layout tends to present multi-center network form and city expansion towards peripheral areas also presents multi-polarization composite development trend. With support of advanced telecommunication and transportation network, business activities in the city will be more scattered spatially in information age, and urban space structure will be gradually

developed towards balanced and scattered direction, and be shifted from single center to multi-center and later networked open space structure.

3.3 Duality of City in Information Age

Original urban physical space is interwoven with virtual space formed by information network. However, there is a certain degree of separation between the two types of spaces. The people therefore have dual identities, namely the citizens and the netizens, and the city itself has many expressions of the two different forms, namely street network and internet, physical store and online store, physical bank and online bank, hospital and remoted medical service platform, stock exchange and electronic transaction system, physical site work and online work. New information network space, and physical urban spaces formed by bricks, concrete and rebar coexist and complement with each other, presenting unique “dualized city” feature of information society.

4 Adaptation of Compact City Theory to City in Information Age

According to the influence of the Internet on cities in the information age, the theory of compact city should be developed and optimized accordingly.

4.1 Adjustment of Urban Compactness Measurement Mode

From the perspective of city planning, functional compactness of city is to configure and organize urban functions stipulated in master plan of the city. In current city development, scientific and reasonable planning requires arrangement of main city functions in different zones as per master plan of the city. Different urban area undertakes certain main city function. Previous functional compactness of compact city mainly refers to overall functional mixing in city level or highly functional compactness in certain urban area, such as downtown area.

Internet increases functional compatibility of urban spaces and obscures original functional zoning concept of city. Compatibility of production and logistics areas (retail space) of the city will become more and more prominent. Boundary and spatial concept of work, entertainment, living and leisure areas will be more obscured. Most urban functional spaces will be shifted to present interdependence and integrated development relationship (Zhongwei SUN,2007). Highly functional compactness of the city and blocks will be developed towards more micro direction, viz. create one space that could satisfy multiple demands, such as living, work and leisure demands at the same time.

4.2 Add The Measure Of The Virtual Space Of The Internet

The city under the information age is composed of real space and virtual space. The transformation of urban residents' lifestyle from traditional reality mode to reality and virtual integrated mode is the root of change. The virtual space breaks the concept and connotation of the traditional urban space, and complements and competes with the existing material space piled up by bricks, concrete and steel to form a new urban space, replacing some cities and their building space. The urban area is expanded in an intelligent way, with higher space efficiency and stronger comprehensiveness (Le CHE and Zhiqiang WU,2015).

The virtual space formed based on information technology saves a lot of physical space, but makes the city more compact and efficient. In the real world, the virtual space is not visually expressed and is imperceptible. However, in the study of the compactness of the city, this part of the “space” has a great impact on the city, particularly, the relevant measure of the city compactness. .

4.3 Preliminary Assumption on Measurement Index of Compact City

4.3.1 Mobile 2-dimensional Code Transaction Volume Per Unit Area

According to the 2018 Mobile Internet Payment Security Survey Report issued by China UnionPay, 570 million people in China use mobile phones to pay at present. Of the 100,000 questionnaires, 82% respondents have used mobile payment, which is much higher than fast payment and E-bank payment. Therefore, it is reasonable to use the relevant data of mobile payment as the coupling point between the virtual space of the Internet and the real world. The report also shows that 2-dimensional code payment has accounted for 70% of mobile payment, covering almost all types of mobile payment. By analyzing the transaction volume big data of the 2-dimensional code payment, it can indirectly reflect the usage amount of the Internet virtual space in a certain area, and provide basic data support for the compactness measurement of the virtual space.

The calculation formula is

$$D = \frac{Qc}{A}$$

D—Density of qr code trading volume

Qc—Qr code trading volume

A— The area of the area to be measured

4.3.2 Mobile APP Downloading Volume and Diversity Per Unit Area

Different APPs can provide different types of Internet services, which indirectly reflect the impact of virtual space on the real world. For instance, by analyzing the downloading volume of instant delivery and meal delivery APPs (such as Ele.me, Meituan, etc.), it can reflect the compatibility of catering and other functional spaces in urban commerce; by analyzing the downloading volume of online shopping APPs (such as Taobao, JD, etc.), it can reflect the compatibility of urban commerce and the other functional spaces; according to the downloading volume of real-time communication APPs (WeChat, mobile QQ, etc.) that breaks through the interpersonal isolation of physical space, it can reflect the real-time communication degree of the urban residents of certain areas in the Internet virtual space.

The calculation formula is

$$I = \frac{Ains}{A}$$

I—A certain type of APP installation density

Ains — *A certain type of APP installed*
A — *the area of the area to be measured*

$$V = \frac{\sum_{x=1}^m x}{N} \quad (m < x)$$

V — *The diversity of APP*

m — *Types of apps owned by a single user*

x — *Total APP type*

N — *Total number of respondents*

5 Conclusions

In the information age, the post-human living space has realized the transformation from the real physical space to the spatial mode of the virtual space of the network and the real physical space integrated. The thinking mode of the researchers, planners and managers also needs to change from reality to semi-realistic and semi-virtual mode. Moreover, we shall also pay close attention to the development trend of modern information technology, so as to control the direction of urban development and planning.

The compact city theory has developed under the different background of different times. As Castells (2001) said, "the expression form of architectural space changes with the rise of informational cities. In the next few years, architecture and design are likely to be redefined in terms of form, function, process and value. " The advancement of information technology and the popularity of Internet have changed the lifestyle and give us new insights and reflections on the changed urban spatial form and the virtual space that cannot be directly observed in real space. Therefore, the adaptive development of compact urban theory is a matter of course.

Abstract: In the process of rapid urbanization, urban traffic emphasizes the development of motorization and neglects the important health effects of non-motorized transportation systems. The impact of automobile traffic on urban ecological environment and walking environment cannot be ignored. This not only causes serious air pollution, but also leads to a decline in the health of residents. Before the car became popular, walking was the most important way for city residents to go out. Residents walk not only to reach their destination, but also to socialize and exercise on the road. Improving the walking environment will enable people to choose more green ways of travel. It allows them to communicate with others while walking, which helps the residents' mental health and enhance community cohesion. This paper explores the importance of walking ability to improve the health of urban residents, and points out that walking cities are an important part of building a healthy city. By studying the practice and design guidelines for improving the walking environment in Europe and the United States, and using Shanghai as a case, explore how to transform an international city into a livable and healthy city. And what are the shortcomings in Shanghai's current street design guidelines.

Keywords: walkability; healthy city planning; walking environment

Introduction

In 1987, the World Health Organization (WHO) established the "Health Cities Project" for the first time. The researcher of this project suggested that, "Where people live affects their health and chances of leading flourishing lives. Communities and neighbourhoods that ensure access to basic goods, that are socially cohesive, that are designed to promote good physical and psychological wellbeing, and that are protective of the natural environment are essential for health equity."^[1]

In Europe, the Healthy City Project has a five-year development phase and has consistently achieved the goals and outcomes of each phase. This project has changed the traditional urban planning to focus only on the concept of urban economic, social and cultural construction. People are beginning to realize that planning should also target health promotion. Planners should strengthen their focus on public health, integrate healthy development into urban construction, and achieve a healthy built-up environment and promote public health as a foothold for healthy urban planning.

The rapid advancement of industrialization and urbanization has brought rapid economic growth to the world's major cities, and has also brought about increasingly severe urban environmental pollution, motor vehicle traffic pollution, and urban ecological imbalances. Whether a city is healthy depends not only on the medical and

health fields, but also on the urban ecological environment, the transportation environment and the social environment.

The urban walking environment is the most basic environment for people's lives, but it suffers from the imbalance of serious damage and development. How to improve the quality of urban walking environment, how to coordinate the relationship between urban pedestrian built environment and public health has become an urgent question to answer. At present, developed countries in Europe and America have produced many excellent walking environment practice and design guidelines, which have good guiding significance for developing countries. Comparing the current situation of Shanghai's walking environment with the implementation of the "Shanghai Street Design Guidelines" and the experience of Europe and the United States, it will be able to further guide the pedestrian environment in Shanghai to further deepen and improve, and to explore the construction of a healthy international metropolis.

Methods

This paper adopts literature research method and inductive method to collect and study a large number of literature materials and scientific research results, and conduct comprehensive analysis and in-depth summary of the theoretical and practical progress of pedestrian environment planning and construction at home and abroad. Then use the method of comparative analysis to judge the characteristics of Shanghai's walking environment and study the feasibility and operability of the Shanghai Street Design Guidelines. The guidelines are supplemented and revised by the evaluation results to further deepen and improve the guidelines.

Text format

The contradiction between motorized traffic and healthy cities.

Among the factors affecting the urban environment, motor vehicles occupy a high weight. Since the German engineer Carl Benz has invented the world's first car, the car has been on the planet for more than 100 years, and the number of cars continues to grow. Taking China as an example, in the past five years, the annual increase of motor vehicles has increased by more than 15 million, and the average annual increase of drivers has reached more than 20 million. The number of motor vehicles in the country has reached 264 million, including 154 million vehicles. 300 million people, including more than 246 million motorists.

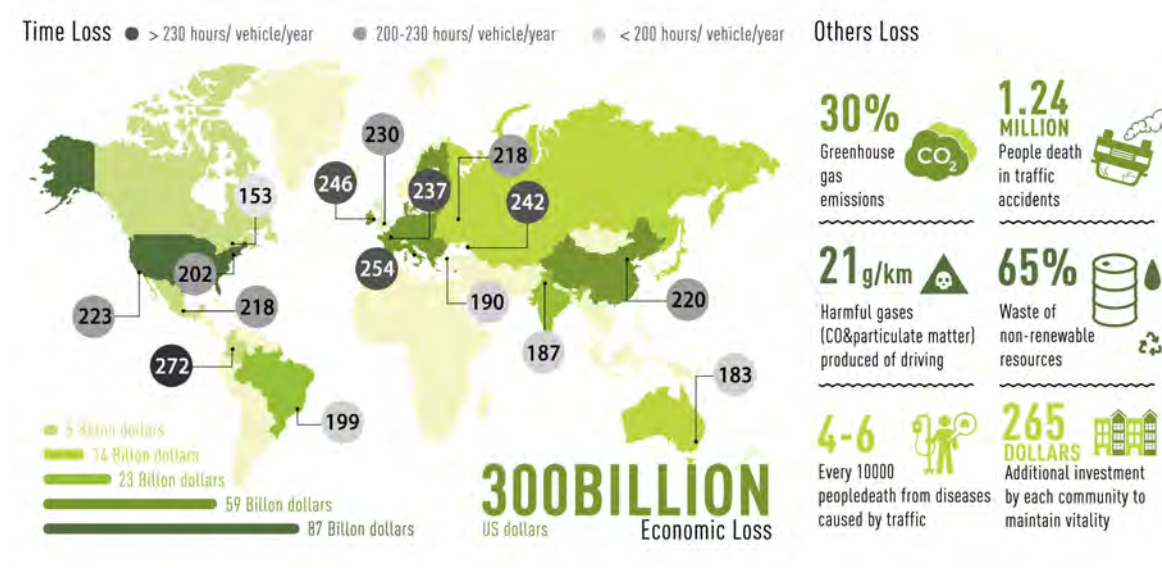

Fig1. Loss caused by traffic jam

The huge impact of such a huge number of vehicles on the city is terrible. The most intuitive negative impact is the waste caused by congestion. According to statistics, citizens in big cities around the world spend more than two hundred hours a year on congestion. At the same time, congestion also brought high economic losses. The United States loses about \$87 billion a year, and the United Kingdom loses about \$5.5 billion a year. In other countries, about 2% of the gross national product is wasted on congestion.

Compared with obvious congestion, the negative impact of motor vehicle traffic on urban health is even more serious.

70% of urban air pollution comes from automobile exhaust. Of the car's emissions, 90% come from diesel exhaust particles, DEP. These pollutants are mainly caused by incomplete combustion of automobile fuels. The main components are carbon monoxide, hydrocarbons, nitrogen oxides, carbon dioxide, lead, fine particles and the like. Among these pollutants, particulate matter that can enter the lungs has the greatest impact on human health. In the past 100 years, the incidence and mortality of airway allergic diseases have increased significantly.^[2]

Researchers have observed PM2.5 in 185 countries. By assessing the link between particulate matter emissions and average life expectancy in each country, researchers can speculate on the impact of air pollution on the global average life expectancy. They confirmed how air pollution drastically shortens the life expectancy of the global population and draws the conclusion that humans have lost their lives on average for about one year. The study also highlighted the benefits of improving air quality for older people. For most Asian countries, if air pollution is no longer a risk of death, the likelihood of a 60-year-old person living 85 years or older will increase by 15% to 20%.^[3]

At the same time, motor vehicle traffic has also had an indirect negative impact. The first is that most of the motor vehicles are driven in densely populated areas of the city. Considering that the pollutants in the exhaust gas are mainly spread through the ground through mechanical diffusion and thermal turbulence, pollutants in the traffic micro-environment, such as inside the vehicle and on both sides of the road. The concentration is much higher than the environmental background concentration, which greatly increases the health risks of residents exposed to high concentrations of pollutants.

The second is because the changes brought by the car to the street are subversive and systematic, and the traditional urban space and street structure are gradually being disintegrated. Streets lack human participation and applicability, and urban residents are increasingly prone to health crises such as tension, anxiety, depression, and insecurity. People are no longer willing to stay in the city street space. This has led to a continuous decline in the mental health of urban residents.

Benefits of a good walking environment

The shaping of the walking environment is an essential part of building a healthy city, which is embodied in the three aspects of society, economy and environment.

In terms of environment, pedestrian-preferred urban construction can reduce motor vehicle travel, reduce road congestion, and reduce carbon emissions. Despite all kinds of technical means, walking priority is still a cheap, operational, and important way to cope with energy shortages and climate change, reduce pollution and noise, increase safety and mobility.

On the social front, walking priority can reflect social equity. Walking is an integral part of many people's lives. The walking system can meet the needs of all sectors of society. The most vulnerable groups benefit the most from the construction of the walking system. Although the middle and lower classes cannot participate in the planning process, policy makers should still look at walking. Walking can also enhance the vitality of the

community, which is more beneficial to people's mental health. Walking can be cheap, convenient, and thief-lower to reduce the risk of obesity and promote physical health [4], and the World Health Organization also recommends replacing some medications by walking every day. Related studies have shown that the reduction of walking will increase the risk of chronic diseases such as obesity, arteriosclerosis and arrhythmia, which directly affect the health of urban residents. Corrective analysis showed that people walking or cycling to work were significantly less likely to have obesity, high blood pressure and diabetes than those who commuted to work by private transport. Walking to and from work is positively correlated with the health of men and women, and negatively correlated with male body mass index (BMI), obesity, triglyceride, blood pressure and insulin levels.

On the economic front, the relevant research shows that the same amount of money, invested in the construction of the walking system is far more helpful than the other places to the health of people [5], can bring long-term financial benefits.

Fig2. Comparison of differences between cars and walks

Actions and guidelines to improve the walking environment

Motor vehicle-oriented traffic planning has caused such a bad negative impact, and walking has so many health benefits. In Europe, a series of practices to correct mistakes began. Urban builders provide a healthy lifestyle by improving the walking environment, thereby alleviating the health challenges of urbanization.

In 1978, the Austrian capital of Vienna began construction of new motor vehicle lanes to alleviate traffic congestion in the city. At the same time, it also introduced a free policy for parking lots in the city center. This erroneous policy led to a deterioration in urban air quality, a significant increase in traffic accidents and peaked in 1994. Some residents moved out of the city center due to the deteriorating living environment. After realizing the seriousness of the problem, the municipality of Vienna began to pay attention to the impact of non-motorized traffic on urban health. The new car-free zone is set in the city centre, and the expensive parking costs

have also brought about a fundamental change in the way the citizens of Vienna travel. 60% of the citizens began to use the green way to enter the city center, the air quality and the urban environment have been improved, and Vienna has regained its charm and vitality. The Vienna government proposed that in 2025, the proportion of citizens using public transport, bicycles or walking will reach 80%; personal car travel will be reduced to 20%.

Not only Austria, France, the Netherlands, Germany, the United Kingdom, India and other countries have proposed plans to reduce the use of motor vehicles. In 2017, the world's major cities planning to build car-free cities at the World Economic Forum reached 12, including Oslo, Madrid and Chengdu, China. In 2018, the Mayor of London clearly stated in the transportation strategy to reduce motor vehicle traffic on London roads, improve air quality, and achieve urban goals of zero carbon emissions; more importantly, roads must be designed to promote people's health. activity.

The United States has also proposed design guidelines for promoting walking, and "health promotion" as one of the important goals of urban planning, and released a series of guidelines for space design actions to promote health. Among them, New York's "Active Design Guidelines: Promoting Physical Activity and Health in Design" and Los Angeles's "Design a Healthy LA" are two representative design guidelines.

The Active Design Guidelines believe that promoting the use of transportation and related activities (such as walking and cycling will give commuters the opportunity to perform physical activities. Due to differences in social status and economic level, different groups of people have gymnasiums, gymnasiums, etc. Site accessibility and use are different. Sometimes this limits people's choice of physical activity and thus has a greater impact on health. But physical activity depends mainly on the design of walking, cycling and public transportation systems. It is possible to push people to choose these healthy ways of travel.

In the Active Design Guidelines, the principles of health-oriented include increasing the density of roads from a macroscopic level, creating as many pedestrian passages as possible, and setting up isolation zones (trees, etc.) between motorways and walkways as much as possible. reducing the impact of traffic exhaust and noise on human health.

Based on the Active Design Guidelines, major cities in the United States have developed transportation and public space designs that promote active lifestyles. For example, the "Play Streets" project in New York in 2010 used urban roads to provide public space for the public, for low-income people and lack of Community residents of the recreational venues provide an activity venue for physical exercise.

Design a Healthy LA was released in 2013 by the Urban Design Studio of the Los Angeles Urban Planning and Development Department. It is the basic construction manual for the authorities to improve the health of residents by creating environmental space design. From the perspective of urban design, the manual proposes interventions in the three spatial latitudes of buildings, streets and blocks. Because the designer believes that people of all ages and people with different activities can participate in the walk, it is proposed to establish a continuous and rhythmic walking facilities and provide benches. This is especially important for older people or pedestrians who need frequent breaks. The safety of travel is also an important factor in promoting travel. Implementing measures to reduce vehicle speed has created a safe street for pedestrians. Configure pedestrian lighting facilities and road signs to help pedestrians identify where they are heading and improve safety. "Design a Healthy LA" also pays attention to the environment and culture of the neighboring units, and hopes that walking can stimulate the vitality of the neighborhood.

Shanghai's walking environment practice and design guidelines

Shanghai is an international metropolis with a blend of history and modernity. Before the opening of Shanghai, it was a meteorological situation in Jiangnan Water Town. The staggered rivers and streets together constitute

the transportation system of the time. Since the opening of Shanghai in 1843, the Anglo-American legal concession has been established and expanded. The public concession streets are mainly square grids, which conform to the original terrain. The French Concession incorporates radial roads and straight lines in the road network.

Fig3. Historical picture of Shanghai walking environment

Beyond the concession, in 1930, the Shanghai Municipal Authority compiled the "Greater Shanghai Plan" and built a central area in the Jiangwan area. The use of narrow streets and dense road networks in the city center is an important practice in the construction of modern Chinese cities. The "Shanghai Metropolitan Plan" compiled from 1945 to 1949, the Shanghai government carried out a systematic road planning for the city's road network. After the liberation to the beginning of the new century, the Shanghai Central City road network system was adjusted several times. Its planning concepts and guiding ideology are not the same, reflected in the constant and repeated changes in the red line of the road. Especially after the reform and opening up, the road network construction focuses on improving the traffic capacity of motorized transportation. After 1980, with the rapid expansion of urban form, isolated high-rise office buildings, large commercial complexes, access control communities, and centralized office parks became common forms of construction. Urban activities were transferred to the interior of the plot, causing lack of vitality in some areas. .

In 2007, Shanghai Municipal Engineering Management Office compiled the "Guidelines for Shanghai New Town Road Planning". In 2016, Shanghai promulgated the "Shanghai Street Design Guidelines", stating that the street design should be changed from car to person. The subsequent White Paper on Shanghai Transportation Development will be planned to build a slow-moving system as an important traffic strategy and target task. The "Shanghai Urban Master Plan (2017-2035)" further clarified that the city's slow-moving traffic accounts for no less than 50% of all-way and full-purpose travel, of which pedestrians and non-motor vehicles are respectively no less than 25%. In 2018, Shanghai issued the "Street Space Design Fans for Opinions", hoping to establish safe streets, green streets, vibrant streets, and smart streets.

Like other big cities in the world, Shanghai's road network has basically been shaped. The method of increasing road density cannot solve the problem of Shanghai walking environment. Therefore, Shanghai set out to develop relevant plans to improve the slow-moving system and improve the environmental quality of the street space. Shanghai divides all roads into 15 categories, each of which presents a typical representative street. In Huangpu District, Hengfu District and Taopu Science and Technology Smart City, a large number of street quality improvement work has also been carried out, and historical roads have been rehabilitated and new district roads have been completed. Some achievements have been made in high quality construction.

Fig4. Classification and current situation of Shanghai streets

Although the "Shanghai Street Design Guidelines" proposed four major street design concepts, the street design guidelines mainly focused on the creation of environment and space, and did not directly solve the macro mobility problem. Compared with the two manuals in the United States, the Shanghai Street Design Guidelines contain less content on management and evaluation, but only put forward the principled content: "Need government departments, owners along the line, designers, enterprises and the public to participate and cooperate together. ", did not propose specific implementation rules, does not have practical guidance and operational. This also reflects the flaws in China's planning on how to specifically conduct street assessments and implement public participation.

Less concern for people's mental health is also a problem in the "Shanghai Street Design Guidelines." The guidelines propose a number of recommendations that are conducive to traffic efficiency and the ecological environment, but ignore the positive effects of the street on the community and have major drawbacks in this regard.

Conclusions

This article takes the negative impact of motor vehicle traffic and the importance of the walking environment to the city as an entry point, summarizing the efforts made by countries around the world to establish a good walking environment. Taking the walking design guidelines in New York, Los Angeles, and Shanghai as examples, analyze the design principles of health orientation and explore the shortcomings in the Shanghai guidelines. Walking environment

It is an important part of urban health, and the compilation of the Shanghai Street Design Guidelines is a useful attempt in this regard. However, the transformation of ideas, methods, techniques, and evaluations will be a long-term gradual process. It still requires the joint efforts of management departments, designers, and the general public to promote the establishment of healthy cities through continuous practice.

Abstract: Children's health and outdoor activities are closely related, with the increasing of childhood obesity and the improvement of people's health consciousness, urban planning and spatial design promoting children's outdoor activities will become increasingly important. Selecting children and teenagers of 6-18 years old in Shanghai as the object, this research conducts a network questionnaire survey to obtain the data and quantitatively analyzes the spatial-temporal characteristics of their health and outdoor activities. A relationship model between the children's outdoor activities and cognized neighborhood environment is established, using the logistic regression model. Results show that children in shanghai have a high incidence of obesity and are lack of outdoor activities. The time of outdoor activities is concentrated in the daytime of weekends, and the activity venue is concentrated in the green lands and exercise fields in the community or the parks nearby. Children's vigorous activities tend to happen with high time consumption and frequency in the vacant street space and sidewalks along the street. At the city level, some parts of Shanghai can see remarkably high concentration or low concentration of children's outdoor activities, and the frequency and time consumption of children's vigorous activities within the Inner Ring is significantly higher than that in other rings. Neighborhood environmental factors have significant associations with children's health and outdoor activities. Curb parking, environmental harmony and civilization, neighborhood relationship, and the quality of children's activity facilities have a significant correlation with children's outdoor activities, especially with their activity frequency.

Keywords: Children; Health; Outdoor activity; Neighborhood environment; Shanghai

Introduction

The origin of modern urban planning and health began in 1986 when the World Health Organization (WHO) first established the Healthy Cities Project, and then the Healthy Cities Engineering Network was established in Europe. After 30 years of development, Healthy City has become a worldwide movement (XU Congbao, *et al.* 2005). It has gone through four stages of development, and is now in the fifth stage (from 2009 to now). The core theme of this stage is supportive environment, healthy lifestyle and healthy urban design (XU Congbao, *et al.* 2005). At present, the change of life style has become one of the main reasons that endanger residents' health (MA Guansheng, *et al.* 2006). The traditional methods of urban planning to protect residents' health (such as functional zoning, sunshine spacing, green space rate, etc.) can no longer meet the growing health needs of people. Planning needs to re-recognize the direction and path of healthy city construction.

The static lifestyle formed by housework, work, commuting and leisure activities has a significant impact on residents' health, but also has a close relationship with urban spatial environment. Commuting and leisure activities are directly related to urban spatial environment (Lee C, et al. 2004). One of the most serious problems caused by static lifestyle is childhood obesity. In the Draft Final Report on Ending Child Obesity, WHO pointed out that the rapid increase of childhood obesity has become an urgent global public health problem, especially in cities of low- and middle-income countries (WHO. 2004). Existing studies generally believe that lack of adequate physical activity is an important cause of obesity and overweight in children (Fredriks A M, et al., 2005, Wang Wenyuan, et al., 2008). A large number of studies have proved that urban built-up environment has significant effects on children's outdoor physical activity, body mass index (BMI) and health perception. For example, barren open space can reduce children's outdoor activities and health evaluation value (Lestan K, Eržen I, Golobič M., 2014, Janssen I, Rosu A., 2015); low residential density and road density can increase children's obesity rate (Duncan D T, et al., 2014); neighbourhood safety has accumulated for children's outdoor activities. Extremely affect and reduce the incidence of obesity in children (Nogueira H, et al., 2013, Janssen I., 2014); leisure facilities such as parks have a positive impact on children's outdoor activities (Babey S H, et al., 2008), which will reduce the incidence of obesity in children (Wolch J, et al., 2011). In contrast, the relevant research in China focuses on the design of micro-activity sites, plant allocation, environmental construction and facilities arrangement, aiming at enhancing the safety, comfort and independence of children's outdoor activities (Zhan Yan., 2005, Xu Xuefang., 2010, Yan Tingting., 2013). It lacks the research on the relationship between built environment and children's outdoor activities from the perspective of larger-scale neighborhoods and even cities (Zhang Yi, Dai Shenzhi., 2011). Only Han Xili (2012) adopted the research on the relationship between built environment and children's outdoor activities. The perceptual map method qualitatively explores the factors affecting children's outdoor physical activity in neighborhood space environment (Wang Dong, Han Xili., 2012).

At present, the problems of high population density, land shortage, deterioration of traffic environment, prominent contradiction between supply and demand of facilities, and severe public security environment prevail in large cities in China. Additionally, the concept of children's education, such as "can't lose at the starting line", may become the cause of restraining children's outdoor activities and causing diseases. Taking Shanghai as an example, the problem of childhood obesity is particularly prominent. The detection rate of overweight and obesity among children is close to that of developed countries in the world (Zhu Meihong, et al., 2011). At the same time, the level of economic and social development in Shanghai is relatively developed, and people pay high attention to health issues. Therefore, the study of children in Shanghai is of great practical significance to solve this problem from the perspective of urban built environment. Shanghai is also a metropolis with high heterogeneity. Its built environment is rich and its population and social economic background are diverse. It provides an ideal sample space for exploring the material and social factors and mechanisms affecting children's outdoor activities. Therefore, this study takes Shanghai as a case study. The goal of this study is to grasp children's physical health and outdoor activities as a whole, to explore the characteristics of time and space, and to explore the relevant elements, so as to provide a basis for further exploring and understanding the mechanism of urban construction affecting children's health and outdoor activities, and to provide urban planning for promoting children's outdoor activities and reducing the incidence of childhood obesity. Provides the basis for the design.

Data collection

Questionnaire Survey

Questionnaire survey was used to collect data. Because the cognitive and expressive aspects of young children are not enough to complete the survey alone, at the same time, similar studies abroad mostly use the method of investigating parents, and the credibility is also recognized (Tappe K A, et al., 2013). Therefore, the subjects of this study are parents of children and adolescents aged 6-18 (hereinafter referred to as children). The goal of this

study is to collect data on children's health and outdoor activities, built environment and family background from the perspective of parents. In terms of health, the self-assessment of children's overall health and BMI index were investigated; in outdoor activities, the frequency, time consuming, activity time and activity venue of children's moderate and vigorous activities were recorded; in the aspect of building environment, 15 types of built environment indicators affecting children's outdoor activities were collected by parents in the form of structure scale, including population density. Degree, land mixing, pavement facilities, traffic volume, environmental safety, accessibility of activity facilities, neighborhood relationship environment, etc. The background information of children's family includes two levels: children and family. Children collect information on gender, age and number of children. Family level collects monthly family income, education level of parents, household registration and location information of residential quarters.

The questionnaire was distributed to the resident residents of children aged 6-18 in Shanghai in November 2015 through the "Questionnaire Star" network survey platform. A total of nearly 700 questionnaires were collected, and 403 valid questionnaires were obtained after screening and screening. Screening conditions include excluding the answers other than the age of the target children, setting trap questions to exclude the randomly filled answers, excluding Shanghai users according to IP address, excluding the answers that are incomplete and invalid, etc.

Sample characteristics

Children aged 6-7, 8-10, 11-14 and 15-18 accounted for 44.9%, 29.1%, 13.9% and 12.1% respectively. The sex distribution of the sample children was fairly uniform, with boys accounting for 59% and girls 41% respectively. The highest educational background of parents is undergraduate, accounting for 65%; 15% and 20% respectively are below undergraduate and above undergraduate. The distribution of household monthly income is not very different. 43% of household monthly income ranges from 10,000 yuan to 20,000 yuan, 34% of household income is below 10,000 yuan and 23% of household income is above 20,000 yuan. Ninety percent of the households in the sample had only one child and 10 percent had more than one child. The sample families consist mainly of nuclear families, accounting for 54.6% of the sample; 42.2% of the families living together with three generations; and only 3.2% of the single-parent families.

The spatial distribution of sample residences at Shanghai regional level is shown in Figure 1. Except for 2.7% of the cases, the residences of the remaining samples are not located, accounting for 19.6%, 25.1%, 21.3% and 31.3% respectively within the inner ring, between the inner ring and the central ring, between the central ring and the outer ring, and outside the outer ring. The number of cases and the socio-economic attributes of children and families in the four circles are more balanced in space, which lays a foundation for comparative analysis.

Children's Health

The physical health of children is measured from both subjective and objective aspects. Subjectively, the children's parents'evaluation of their children's physical health was divided into five grades: very good - good - General - poor. The results showed that most parents rated the children's physical health highly: 34% of parents thought the children's health was very good, 36.7% thought it was good, 23.6% thought it was good, only 5.7% thought the children's health was normal, and No parents think their children are in poor health.

Objectively, the body mass index ($BMI = \text{weight divided by the square of height (kg/m}^2\text{)}$) is used to measure the obesity of children. Himes suggests defining obesity in the 95-point group with BMI greater than the same age and sex, and overweight in the 85-point group(Himes J H, Dietz W H., 1994). Because of the differences in race, level of economic development and lifestyle, different countries have used different BMI screening criteria for obesity (Ji Chengye., 2006). In this paper, we selected the WGOC standard for children and adolescents of China Obesity Working Group (Chen Chunming., 2008), which was proved to be the most suitable criterion for screening the incidence of overweight and obesity among children in China (Chen Lei, et al., 2010). According

to WGO standard, children's overweight is defined as body mass index (BMI) between 85 and 95 in a specific age and sex group, obesity is defined as BMI greater than 95 in a specific age and sex group, and low body mass is defined as two standard deviations lower than the average BMI of the same age and sex group, and the rest is normal. The results showed that more than half (55.5%) of the children in the sample had normal BMI, 22.9% had obesity, 12.9% were overweight and 8.7% had low BMI.

The objective indicators reflect the serious physical health problems of children in Shanghai at present. However, the health status of children reported by parents is generally good. This shows that parents have not paid attention to the hidden dangers of children's obesity, overweight and low physique, which are harmful to children's health. It also highlights the importance of correctly recognizing children's physical health and the necessity of promoting children's physical health by building an environment.

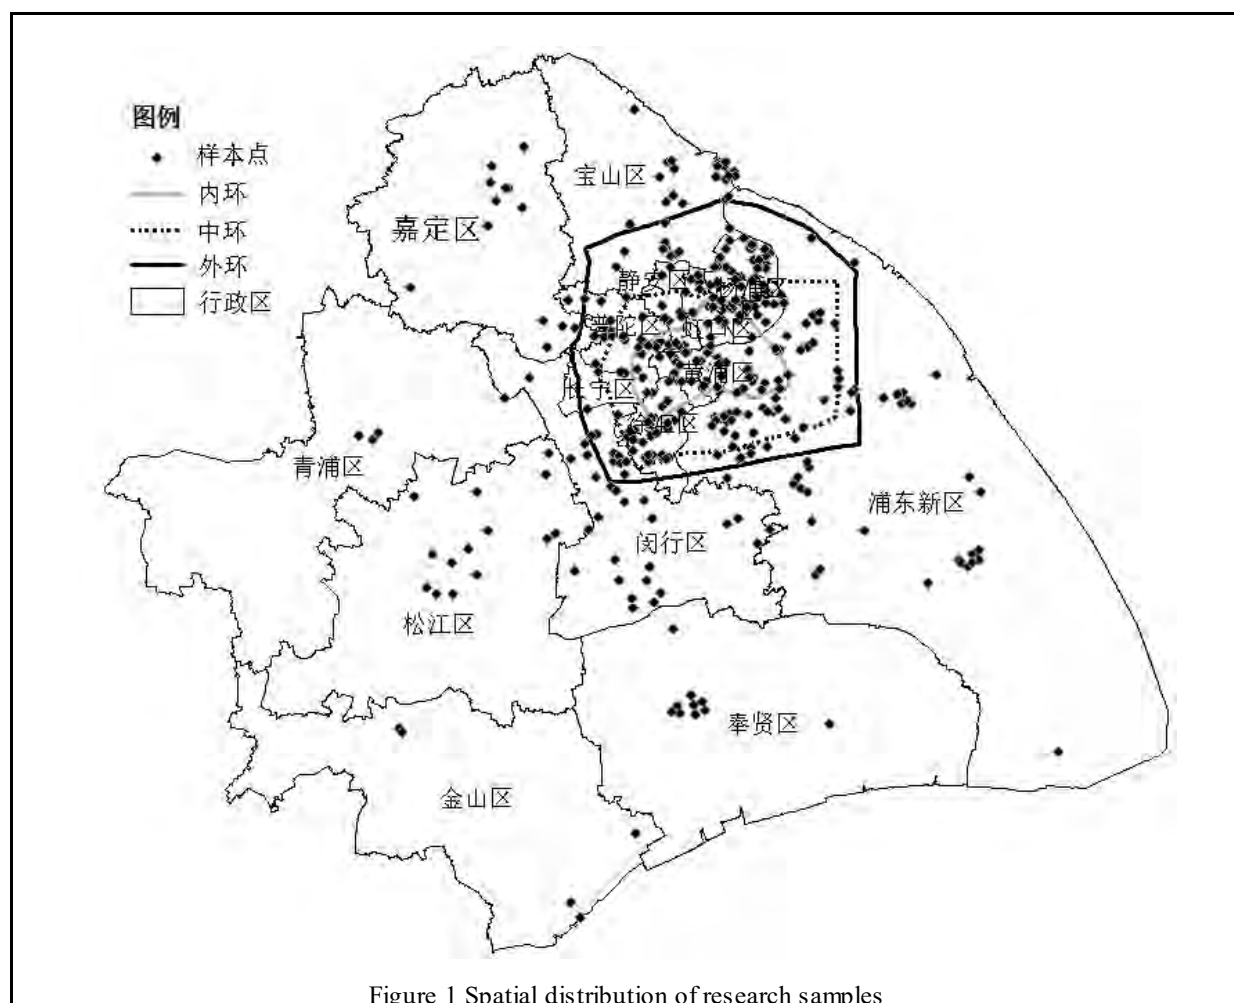

Figure 1 Spatial distribution of research samples

Children's Outdoor Activities

Existing studies have shown that children's physical health is closely related to the amount of activity (Xue Hongmei, et al., 2015). In this paper, the frequency, time consumption and intensity of children's outdoor activities are used to measure the amount of activity. According to the degree of energy consumption, children's outdoor activities can be divided into moderate activities and vigorous activities. Moderate activities refer to physical activities that require moderate exercise but do not cause shortness of breath and significant acceleration of cardiac rhythm. Vigorous activities refer to physical activities that require a lot of exercise and cause shortness of breath and significant acceleration of cardiac rhythm(WHO, 2017).

Most of the children in the sample had outdoor activities. The time and frequency distribution of activities were shown in Figure 2 and Figure 3. Among them, only 5% of children do not engage in moderate outdoor activities, and 15% do not engage in vigorous outdoor activities. The frequency distribution of moderate and intense activities is similar to that of time-consuming activities. The frequency of activities mainly concentrates on 2-5 times per week, and the time consumption of a single activity concentrates on 10-30 minutes. The frequency of moderate activity of children is slightly higher than that of vigorous activity, and the time spent within 40 minutes is also longer.

Figure 2 The distribution of time consumption of children's outdoor activities

Figure 3 The frequency distribution of children's outdoor activities

By synthesizing the frequency and time of activities, the intensity index of children's outdoor activities is constructed, which is the total time consumption of children's outdoor activities every week. Because the energy consumption of vigorous activity is different from that of moderate activity, the intensity of vigorous activity is equal to about twice that of moderate activity by using the conversion method of WHO (WHO, 2017). Finally, the intensity of children's outdoor activities is calculated as Figure 4, showing an obvious exponential distribution. With the increase of activity intensity, the number of children's cases decreases; the average intensity of children's outdoor activities is 238 minutes/week, mainly within 250 minutes/week, and the number of children whose activity intensity exceeds 250 minutes/week decreases sharply; the standard deviation is 210 minutes/week, which indicates that the intensity of children's outdoor activities decreases dramatically. There are a few cases with high activity intensity. The physical activity of children and adolescents aged 5-17 recommended by the World Health Organization is greater than 420 minutes/week (WHO, 2017). Only 9.4% of the children in the sample had more than 420 minutes of outdoor activities per week, which indicated that the intensity of outdoor activities of Shanghai children was far from meeting the requirements of WHO.

Figure 4 The intensity distribution of children's outdoor activities

The influence of built environment on children's outdoor activities

The survey asked parents to evaluate the built environment near their residence. The questions were expressed positively in terms of environmental factors affecting children's outdoor activities. The answers were divided into four levels: very disagreement - disagreement - agreement - very agreement. The statistical evaluation mean is shown in Figure 5. The higher the evaluation mean is, the more reasonable or perfect parents think the present situation of environmental factors is. It shows that the evaluation of road connectivity, traffic accessibility and neighborhood relationship around residential areas is higher. The current situation of environmental factors such as traffic volume, facilities accessibility, roadside parking and driving speed is worse.

Figure 5 The mean value of parents' evaluation of the built environment affecting children's outdoor activities

Non-parametric tests were used to verify the relationship between 15 built environment factors and children's outdoor activities and health (Table 1). It is found that most of the environmental factors are closely related to children's health assessed by parents. Specifically, in the built environment with mixed land functions, harmonious neighborhood relations, perfect pavement facilities, high road accessibility, low road speed, less roadside parking, traffic safety, convenient activities and good quality, children's health assessed by parents is obviously better. In contrast, the correlation between these environmental factors and BMI health index is weak. Only road speed and traffic accessibility are significantly correlated, but interestingly, they are all traffic factors.

For children's outdoor activities, the relationship between built environment and intense activities is more closely than moderate activities, and the relationship between frequency and time is more closely. In terms of activity time consumption, in the urban environment with uncivilized phenomena (such as garbage, dog dung, graffiti) and poor road connectivity, moderate activity time consumption is significantly lower. In terms of activity frequency, children are more likely to engage in outdoor vigorous activities in urban environments with low road speed, less parking on the roadside, beautiful and harmonious built environment, civilized outdoor environment, harmonious neighborhood relationship, convenient children's activities facilities and high quality; in urban environments with less traffic, harmonious neighborhood relationship and high quality children's activities facilities, children's outdoor activities are moderate. The activity frequency is high. In terms of total activity intensity, the urban environment with less parking, beautiful and harmonious built environment, civilized outdoor environment, harmonious neighborhood relationship and high quality of children's activity facilities corresponds to children's high-intensity outdoor activities.

Table 1 Cross analysis of children's outdoor activities and health and social economic attributes

Built environment	Health rated	BMI health	vigorous activity			moderate activity			Total activity intensity (minutes / week)

Conclusion

With the prominence of children's health problems and the enhancement of social health awareness, children's outdoor activities will be paid more attention. Urban planning and space design for promoting children's outdoor activities are of great significance to improve children's health. Taking Shanghai as an example, this study summarizes the characteristics and related factors of children's outdoor activities in big cities from the dimensions of time, space and family attributes, which can provide a basis for relevant planning, design, decision-making and in-depth research. The study found that the incidence of obesity among children in Shanghai is high. Most children's outdoor activities are not up to the World Health Organization standard.

However, parents do not know enough about children's health, which indicates the urgency of measures to promote children's outdoor activities, including urban planning. The analysis shows that children's outdoor activities are highly heterogeneous. Although this study has obtained the overall impact direction of significant related factors to children's health and outdoor activities, more precise impact mechanism must be further explored in order to provide a clearer theoretical basis and methodological means for planning. The analysis at the municipal level finds out the hot spots of children's health and outdoor activities, which provides clues for in-depth regional case studies or interregional comparative studies to find out reasonable explanations. Some findings also prompt reflection on traditional planning concepts and methods. For example, although children's outdoor activities mainly focus on community green space, exercise venues and parks, high frequency and long time-consuming activities mainly occur in some "informal" activities such as sidewalks and street empty spaces on both sides of the road; the reasons for this phenomenon need to be more systematically examined. If space forms do have an impact, then the focus of planning and design may need to tilt towards creating safer, continuous and comfortable street children's activity space.

Abstract: Physical inactivity is a significant public health problem in cities. There is a growing consensus that physical activity results in a plenty of positive health outcomes. Therefore, finding a way to promote physical activity has the potential to improve public health as well as to control health care costs. More and more studies have proved that green infrastructure strongly affects physical activity carried out in our daily life. Urban parks eagerly visited by city dwellers are believed to promote walking and routine exercise, thus influencing population health. Based on the above assumptions, studies are conducted in three historical parks in Beijing (the Summer Palace, Beihai Park, Xiangshan Park) aiming at determining how well urban historical parks serve and influence public health for local residents, and developing recommendations for urban historical parks management and revitalization. This paper mainly researches 1) park users' physical activities, 2) community members that parks serve, 3) space size, facilities, historical and cultural atmosphere, attractiveness in parks as well as surrounding environment of the parks. Questionnaire are developed to collect park users' view of the role that they feel parks play in their physical activity. Semi-structured interview are used as complement for collecting information. We conclude that activity undertaken in the park is primarily associated with the land cover structure of the park and its location within the city. And physical activity is significant positive especially in mental health. These findings suggest that urban historical parks play a critical role in facilitating physical activity even beyond the neighborhood, and the needs also arise to conduct active maintenance and spread cultural knowledge to improve the benefits.

Keywords: Physical activity; Urban historical parks; Public health; Beijing

1. Introduction

Well-designed urban parks strongly that people are willing to visit affect the quality of human life in cities. Urban parks are good for physical health via promoting outdoor physical activity (Rydin et al., 2012). Many health problems can be prevented or alleviated through routine physical activity. It is widely acknowledged that the environment in which we live helps determine how physically active we are on a daily basis (Cohen et al., 2012). Some historical gardens in Beijing which serve as urban parks now play an important part in local people's life and urban sustainable development. Understanding the determinants of physical activity undertaken in urban historical parks and health benefits can promote the management and valorization of historical parks. Thus, those parks could attract the permanence of the resident population while keeping their historical and cultural asset/values intact (Nocca, 2017).

Existing studies have discussed relationships between park benefits, park characteristics, park use, physical activity levels and health (Bedimo-Rung et al., 2005, Agata et al., 2018, Abdullah, 2016, Bonnie et al., 2019). However, few studies have focused specifically on historical and cultural context which may affect physical activity and health. Besides, most researches on green open space use focus on North American, European, and Australian contexts (Özgüner, 2011, Sreetheran, 2017) so far.

Therefore, this research chooses historical gardens in Beijing including one cultural heritage which symbolize Chinese culture as object in order to find relationship between cultural context, physical activity and health. By focusing on Beijing, this research adds cases in Asian cities except for Hanoi (Thi-Thanh-Hien et al., 2019), Kuala Lumpur (Sreetheran, 2017) and so on.

We investigate three urban parks in Beijing which are also historical gardens in the context of the following characteristics: a) intensity and duration of activity of park users and frequency of park visits; b) plant, paths, facilities, attractiveness, cultural atmosphere in parks; c) physical and mental health condition of park users; and d) location of the parks within the urban structure. The goal of our research is to determine how urban historical parks promote physical activity for individuals and how well they serve local people in national and regional cultural context. This research serves in the pursuit of balancing people's needs and cultural landscape protection, and improves the management and preservation plan of urban historical parks. We hope that this research could develop recommendations on protection and valorization of urban historical parks adjusted to Asian cities and populations, thus achieving urban sustainable development.

2. Methodology

2.1 Study area

The research is conducted in Beijing (39° 56' N; 116° 20' E), capital of China. It is located in northwestern of the North China Plain, surrounded by Yanshan Mountain in the west, north, and northeast. It is a megacity with an area of 16410.54 sq. km. Beijing has a predominantly warm temperate continental monsoon climate. The annual frost-free period is about 186 days, the annual temperature of 10°C, and the average annual precipitation is 600 mm (Xie et al., 2015). Beijing has experienced rapid demographic urbanization and urban land expansion with the rapid economic growth during the past three decades and the urban area has increased from 801 to 2,452 km² during 1980–2010 (Wu et al., 2015), and its population increased from 8.72 million in 1978 to 19.62 million in 2010 (Beijing Municipal Statistics Bureau [BMSB] 2011). Beijing is a famous historical and cultural city in the world. There are more than 200 historical gardens with long history, high popularity and Chinese traditional garden design principle in Beijing, some of which serve as urban park and integrate into contemporary society.

2.2 Description of parks

We choose three famous historical gardens served as urban parks now differently located in Beijing. These parks are also different in size, landscape characteristics and surrounding areas which could lead to different physical activity features.

The following parks are analyzed: the Summer palace, Xiangshan Park and Beihai Park. We choose those parks for the following reasons.

As shown in Figure 1.a, the Summer Palace (290ha) (Figure 1.a) is located in north-western of central districts in Beijing, center area of Haidian district. It was built in 1750 in Qing dynasty. It was an imperial garden (temporary imperial palace) belonged to Qing imperial family. Since 1928, it has become a national park. In 1998, the Summer Palace was awarded World Cultural Heritage which meets the criteria (i) (ii) (iii). Surrounding the Summer Palace are Qinglongqiao subdistrict, Wanliu subdistrict and part of Sijiqing subdistrict which respectively had a density of 3572 inhabitants/km², 3695 inhabitants/km², 1790 inhabitants/km² in 2006. It also includes a research institution, three universities and several cultural relics.

As shown in Figure 1.b, Beihai Park (71ha) (Figure 1.b) is located in Beijing central district, northwest of the Forbidden City. It was also an imperial garden which dates back to the 13th century. Since 1925, it has become a national park. Surrounding Beihai Park are

As shown in Figure 1.c, Xiangshang Park (188ha) (Figure 1.c) is located in northwest of central districts in Beijing, north-western of Haidian district that urbanized after 2000. It dates back to Yuan dynasty. It was also an imperial garden (temporary imperial palace away from inner city). Since 1956, it has become a national park. Population densities around Xiangshan Park tend to be lower, with 428 inhabitants/km² in 2006. And there are two large botanical gardens around the park.

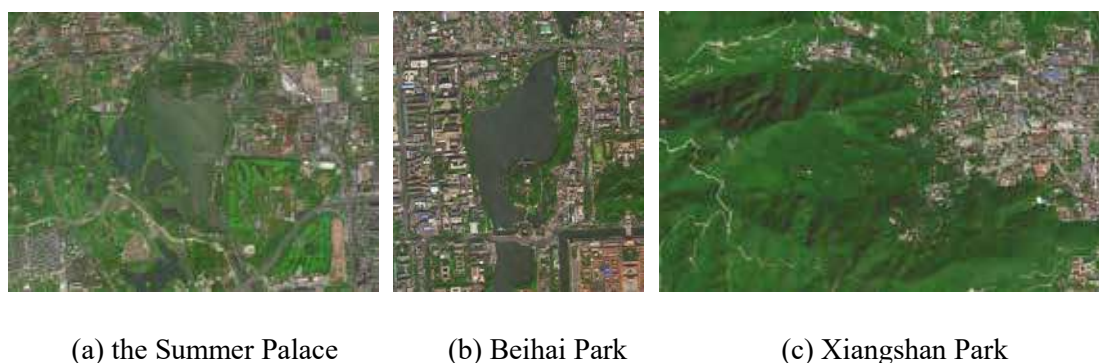

Figure 1. Location of three historical parks

2.3 Data collection-questionnaire and semi-structured interview

We applied structured questionnaire and semi-structured interview (Bonnie, 2019), to survey people's activities undertaken in parks.

A quota sampling method was applied to collect opinions from questionnaires. Quota sampling follow three rules. First, we aimed mainly to local people who undertake physical activity regularly. Second, at each research park, gender and age ratio of respondents we sought is in accordance with demographic characteristics in Beijing. Third, we carried on the survey in each park two times a week, once in weekdays and once in weekend from morning to evening. All questionnaires were self-administered on paper during multiple site visits in May, 2019. The refusal rate was quasi-null.

The questionnaires survey was conducted on a face-to-face basis, in order to collect data more sociable and enlist respondent cooperation more effective (Sheskin, 1985). Most questionnaires were

filled inside the parks such as attractive sitting-out area and other open space, and the rest were filled at park entrances, It took about 6 minutes to complete a questionnaire. Each collected questionnaire was checked afterwards to ensure their completeness and accuracy.

The questionnaires administered to respondents include: i) respondents' characteristics (gender, age, education, occupation, yearly income, transportation mode, travel mode to access the park, time cost on the way to the park, habitual companion); ii) activities undertaken in the park (physical activity frequency, physical activity duration, physical activity types, place most frequently go to for physical activity); iii) respondents' health condition (physical health through the question 'How often do you have the following physical illness over the past month?', physical illnesses include fatigue, headache, neck pain, cold, insomnia, cardiovascular diseases, respiratory diseases, mental health through the questions 'How often do you feel happy over the past month?', 'How often do you feel down over the past month?'); iv) respondents' perception of the park through the question 'Which areas of the Park do you like taking physical activities?' and impacts (including attractiveness, strong historical and cultural atmosphere, good maintenance, enough public space size, many shades, quietness, good air quality, convenient service facilities) on choosing those areas, each of which are measured on a 7-point Likert scale ranging from 1=Strongly Disagree to 7=Strongly Agree. We suppose that respondents' perception of the park represent park's characteristic. At last, the respondents were asked to suggest how to improve the park to add comfort and convenience for use.

2.4. Statistical analysis

Multivariate linear regression analysis was used to analyze questionnaire data. We investigate the associations between characteristics of the park (e.g. attractiveness, strong historical and cultural atmosphere, good maintenance, enough public space size, many shades, quietness, good air quality, convenient service facilities) and frequency, duration, intensify of physical activity. Second, the associations between characteristics of the park, frequency, duration, intensify of physical activity and physical health, mental health were investigated. And it needs to be explained that physical intensify was calculated according to Compendium of Physical Activities which has been used as important criteria and reference basis for the determination of metabolic value and intensity division(Ainsworth et al., 2000).The results are presented as unstandardized coefficients (and SE) with 95% confidence intervals (CI). A p-value of .05 is considered to indicate statistical significance. R was used for all statistical analyses.

3 Results

3.1 Socio-demographics traits of visitors

During the survey, 72 visitors agreed to answer the questionnaire. Among them, 36 were male(50%) and 36 were female(50%). According to the 2010 Beijing Municipal Bureau of Statistics data, the percentage of men and women in Beijing is respectively 51.6% and 48.4%. About 51.4% of the respondents were over 60 years old; the youngest was 21 years old and oldest was 92. Majority of the respondents were retired (68.1%), a quarter of the respondents were full-time workers (20.8%), some were students (6.9%) and the rest were freelance or waiting for an employment (4.2%). Over half of the respondents' education level were associate or bachelor degree. Most respondents were low and

middle income groups. Majority of them received CNY0-50,000 (47.2%) or CNY50,000-100,000 (33.3%) per month.

3.2 Visit-related preferences

Most of the respondents visited the park by public transportation including bus and subway (79.2%). Almost half of the respondents cost 30 minutes to 1 hour to go to the park by public transportation (45.8%), and over one third of the respondents cost 1-2 hours (34.8%). The rest of the visitors cost less than 30 minutes (19.4%), and some of them go to the park on foot. For transportation, most of the respondents thought convenient.

Most respondents visited the park with family or friends because they enjoyed themselves in group. Over half of the respondents took physical activities in the park most frequently (65.3%), the second most of respondents took physical activities at home (18.1%), students usually took physical activities at school (8.3%), and the rest took physical activity in gymnasium (4.1%) or other place (4.2%).

According to semi-structured interview, some of retired respondents participate in scheduled events such as square dancing group, social dancing group and chorus group in certain area every day or on weekdays. And they feel very delighted spend time in the park.

3.3 Relationships between park characteristics, frequency, duration and intensify of PA

To investigate relationships between park characteristics, frequency, duration and intensify of PA (Physical Activity), we carried on a series of multivariate linear regression analyses. As shown in Table1, covariates (gender, age, education attainment, occupation, yearly income level) control for the result. In the multivariate regression analysis while controlling for the covariates, the findings indicate that PA frequency was positively associated with transportation convenience. Most of respondents visit the park by public transportation that they are content with which leads to higher frequency of PA. PA duration was positively associated with shades. PA intensify was positively associated with gender, education level, the place for physical activity, and historical and cultural atmosphere. Male take more intensive activities than female. Respondents with higher education level tend to take more intensive activities. The place for physical activity is also a factor influencing intensify of physical activities. Respondents who take physical activities in park most often take more intensive activities than others. Feeling strong historical and cultural atmosphere also causes more intensive activities in the park.

3.4 Relationships between park characteristics, frequency, duration and intensify of PA and health

Relationships between park characteristics, frequency, duration and intensify of PA and health were presented in Table 2. The analysis shows that physical health was positively related to habitual companion. Mental health was positively related to PA frequency, PA duration, gender, education level, transportation mode, historical and cultural atmosphere, and space size.

4. Discussion

The findings of the present research reveals that those famous historical and cultural parks are so attractive that local people living a little far away come to spend leisure time. According to Sihui G.'s(2019) study, the average service radius of historical parks is the largest among all types of parks in Beijing (Sihui, 2019). Those parks provide high-quality place for local people taking physical activities. There are also scheduled events organized by residents for taking activities in group

regularly which attractive dozens of people. Owing to a large amount of visitors coming to visit those famous parks on weekend, weekdays were the period when respondents came more often. In addition, respondents usually chose areas with fewer visitors to take physical activities.

Convenient transportation is a significant factor affecting frequency of physical activity. There are many bus stops and subway stations around those parks now. Most residents are satisfied with the transportation, while a few visitors think Xiangshan road—the road to the gate of Xiangshan park is a bit chaotic. Therefore, surrounding environment around the park needs to be focused on and improved.

Park characteristics especially shades is associated with duration of physical activity. For example, Xiangshan Park which possesses 0.27 million trees provides many shades and sitting areas in the mountains. According to semi-structured interview, visitors also prefer to run, walk or sit around the lake because of wide vision. Beihai Park and the Summer Palace both possess large lake that attract many runners and walkers. Thus, natural environment is important to stick to physical activities. Those historic parks relied on superior geographic environment which stick out from numerous parks in Beijing, attracting many local people.

Gender, education, place for taking activities and attractiveness are positive related to intensify of physical activity. According to our result, male is positive related to the intensity and frequency of physical activities. Previous studies also found that male is significantly positive in the frequency of physical activities in both Western and non-Western cities (Thi-Thanh-Hien, 2019, Baran, 2013, Özgüner, 2011, Sreetheran, 2017, Wang, D., 2015, Wright Wendel, 2012). Generally, men's physical capability is more stronger than women. This may explain that gender affects intensify of physical activity. As for frequency of physical activity, men had on average slightly more leisure time than women in China (Wei, Monika 2015) so that they can take physical activities more frequently. People with higher education level including associate and bachelor degree tend to take more intensive physical activities. This may be explained by location of the park. Those parks are all located in Haidian district, where universities, research institutions, and high-tech park are concentrated. Residents around are mostly from those institutions and more likely to get higher degree. Attractiveness is also a significant factor affecting intensity of the physical activity. Respondents were willing to spend time in place with attracting scenery. Those well-designed famous parks embodies the highest level of Chinese traditional garden art which attract plenty of local residents to take physical activities.

Physical health is significantly positive in habitual companion. Respondents who came to the park in group were in better physical health. Parks are charming places for them to spend time with family, friends and partners, to socialize, to participate in scheduled events, thus improving quality of life and well-being.

Mental health is positively associated with the frequency and duration of the physical activity, education level, and park characteristics (space size). Higher frequency and duration of the physical activity leads to better mental health. This finding was the same as previous studies indicate that higher frequency of physical activity was related to improve mental health (Abdullah, 2016). In addition, reviews reported that self-reported PA is associated with health-related quality of life (Bize et al., 2007). Respondents with higher education level also causes better mental health. This result was the same with the previous study finding marked association between educational status and the

likelihood of having sought mental health services (Leah et al. ,2007). Space size is also positively related to mental health. Large space with wide view may keep respondents pleasant mood and leads to better mental health.

However, historical and cultural atmosphere is not significantly related to the frequency and duration of physical activity and physical health. According to semi-structured interview, some of local residents did not feel strong historical and cultural atmosphere in those parks owing to lacking of historical knowledge and being accustomed to ancient architecture and gardens in Beijing. This means historical and cultural atmosphere are not primarily used for physical activity by respondents.

Based on the results of this research, it is recommended that future research could devote on different age of people such as teenagers. In addition, future research could compare historical parks to other types of parks. By doing this, more objective and specific strategies could be proposed for improving social value of historical parks.

5. Conclusion

This research explores relationships between park characteristics, physical activities and health in historical parks in Beijing, China. Some limitations are worth mentioning in this respect. The survey sample need to be more to improve the accuracy.

Our results confirm some tendencies of physical activity, characteristics of parks and health indicators observed elsewhere, but also revealed cultural and place-specific particularities. In contrast with western cities, safety is not a problem in Beijing. All areas are supervised. And because of crowded Asian cities' contexts, local residents taking physical activities need to avoid plenty of visitors which affects time and activity zones for physical activities in historical park. Such cultural and context-specific differences should be considered in theories of park use, park planning and historical park management (Thi-Thanh-Hien ,2019). Historical park and its surrounding environment need to be improved for more people to use. For example, in Beihai Park, more benches, toilet and navigation card need to be set in order to enhance convenience for park users, and some temporary architecture and surplus grass need to be changed into open space for people to take physical activities. In addition, historical parks need to disseminate history and culture to park users including local people, and closed area need to be open to make people get close to traditional culture as well as adding activity space, thus inheriting culture and making them more attractive.

China have experienced dramatic demographic urbanization and urban land expansion with the rapid economic growth during the past four decades (Sun, Zhao,2018, Zhao et al.,2015). Historical parks are part of urban green space and the symbol of Chinese culture. Urban historical parks play an important role in rehabilitating and revitalizing urban areas, and in strengthening physical activity of citizenship (United Nations, 2016). It is necessary to protect and revalorize historical park, and integrate culture and memory into social life, thus achieving the goal of cultural sustainability in the city.

Abstract: Research on the correlation between physical activity such as walking and cycling and the built environment has received extensive attention. Based on how the built environment causes travel, most of the existing research focuses on spatial features such as land use, scale, density, and location on different geographic scales. The street networks is the largest and most obvious global space that affects the movement of residents. However, few studies pay attention to the influence of the structural characteristics of the street network on physical activity, thus ignoring how individuals are affected by the surrounding space elements in the process of movement. According to the theory of spatial syntax, the individual movement in the urban space network is caused by the space network itself under the same conditions, which means that the spatial configuration of the street network is a decisive factor for the movement pattern. Therefore, this paper, taking Yangpu District of Shanghai as an example, uses Mobike (a biking sharing service provider) location data to analyze the impact of urban spatial morphological characteristics on cycling. Firstly, the spatial network model of street space, which is based on the notion of a 'segment map' is established by spatial syntax, and the variables such as connectivity, integration and depth are used to characterize the spatial topological features of networks. Then, the time-space characteristics of the distribution of residents' cycling activities are analyzed by using Mobike location data. Subsequently, a spearman correlation analysis was used to assess the correlation between cycling activity and street network morphological characteristic. Interestingly, this paper finds that the local morphological characteristics of the street network have more correlations with the use of bikes than the global features. The space syntax variable that is most strongly associated with bicycle use appears at a search radius of 700 meters.

Keywords: cycling; Mobike; space syntax; spatial networks analysis

Introduction

There is clear evidence that cycling has substantial benefits for both physical and mental health. Studies have shown that regular physical activity has substantial health benefits (Warburton and Bredin, 2006, Janssen and Leblanc, 2010). People who lack adequate physical activity are at higher risk of chronic diseases such as overweight, obesity, hyperlipidemia and hypertension (Katzmarzyk et al., 2009). Cycling, as a low-carbon, environmentally friendly way of travel, has received great attention in urban research and planning practices in various countries (Moudon et al., 2005a). Cycling activities are affected by many factors such as age, gender, natural and built environment, and there

are great differences in the habits of cycling in various countries(Wang et al., 2016, Stewart and Moudon, 2014). There is growing evidence that some characteristics of built environments are closely linked to the level of cycling activities. Among many factors in built environment, lower density housing, single land use, lack of health and recreational facilities, limited public transport systems and public open spaces usually act as the barriers to physical activities, including cycling(Giles-Corti and Donovan, 2002, Saelens et al., 2003, Sallis et al., 2012, Troped et al., 2011, Van et al., 2013).

Since 2016, bike sharing, featuring “ on-demand” have begun to appear in the streets of some major cities in China. Compared with the traditional “pile-oriented” public bikes system, bike sharing can be more flexible and distributed in various angles in the city(Zhang and Mi, 2018). Although it brings certain difficulties to urban management, its flexible layout a provide great convenience to residents in cities. In some megacities such as Beijing and Shanghai, the number of sharing bikes has exceeded 3 million. Not only that, the popularity of bike sharing has also changed the daily traffic habits of residents. According to the White Paper on Bike Sharing and Urban Development released by Mobike in 2017, after the emergence of bike sharing, the proportion of urban cycling travel increased from 5.5% to 11.6%. Furthermore, 81% of bikes in Beijing are active around the bus station; 44% of bikes are active around the subway station. And these two figures are 90% and 51% in Shanghai, respectively. This shows that the emergence of bike sharing can not only effectively alleviate urban traffic congestion, but also change the traffic habits of urban residents. At the same time, under the background of bike sharing, residents' cycling activities will present new time and space characteristics. For this new cycling service provider in China, whether the relationship between cycling and built environment presents new features remains to be studied

Based on how the built environment causes travel, most of the existing research focuses on spatial features such as land use, scale, density, and location on different geographic scales. These researches are based on the assumption that space is the container of socio-economic activity and that the link between socio-economic activities results in movement. However, few studies pay attention to the influence of the structural characteristics of the street network on physical activity, thus ignoring how individuals are affected by the surrounding space elements in the process of movement. The quantitative description of urban spatial structure by space syntax theory makes it an important tool for urban planning and design decision-making. The theoretical basis of the "natural travel principle" is that the main factor shaping the urban user movement model is not the specific land use, but the spatial structure of the street network. Space syntax is a set of theories and techniques for measuring the spatial configuration of street networks. By focusing on street networks rather than buildings or parcels to describe the built environment, space syntax analysis considers spatial properties of physical space(Hillier et al., 1993). Therefore, this paper aims to use space syntax tool to identify the impacts of the relative characteristic of networks on cycling activities.

Cycling and built environment

In the identification of built-in environmental factors for cycling activities, most researches are based on the “3D” theoretical model of traffic and environment, and the environmental variables are selected from the three dimensions of Density, Diversity and Design(Cervero and Kockelman, 1997, Cervero et al., 2009, Moudon et al., 2005b). The density dimension mainly includes population density: per acre, employment density, and employment accessibility. The diversity dimension mainly includes the number of land types used in each grid of hectares, the average entropy of various types of land, vertical mixing degree, and land development intensity: residential, commercial, office, etc. Business intensity, proximity to commercial retail. Design dimensions include street design, support for walking and cycling activities, and site design elements. Among them, street design elements include street type, connectivity, street width, speed limit, number of blocks, highways, street green coverage,

street lighting, etc. Supporting elements of walking and cycling activities include the proportion of sidewalks, signals, etc. Number of intersections, average length of street blocks, width of sidewalks, interval between street lights, slopes, length of acar lanes, stay and rest facilities, shelters, etc.; site design elements include commercial retail services The design of sexual and landscape fountains. In the subsequent research, according to the development level of different countries and regions and the behavior characteristics of residents, research has increased the distance from traffic stations and the accessibility of destinations on the basis of 3D(Lee and Moudon, 2006). Moudon added "R" on the basis of 3D, that is, the environmental characteristics of the travel path are equally important for walking or cycling. In addition, in another study, Moudon proposed a spatial element that influences physical activity in the environmental-behavior theory model, which she believes should be derived from the origins and destinations of the individuals' walking or cycling trips, and the surrounding areas of the travel path(Moudon and Lee, 2003). The primary spatial object that identifies the environmental impact factor. From this point on, urban streets have become the main target for identifying the impact factors of cycling activities. More and more research has begun to pay attention to the physical form of the road and the impact of the perceived environment on physical activity.

Spatial variables in urban models in existing studies are often measured by distance. This approach comes from the observation and assumption that economic and social forces shape matter and distance is a measure of economic costs. Another perspective in existing research is to build urban models through people's complex perceptions. The main spatial variables include safety, social environment, visual quality and maintenance, and perception of sports destinations or facilities. The presence of parks, sports facilities, trails and bikes lanes, the perception of the existence of walking obstacles, and the capture of walking support conditions in the neighborhood. And this perspective tends to be a partial vision to observe the urban space. Therefore, the urban modeling method in the urban planning field should focus on the overall and local level, the residents' perception of urban space during the travel process.

Previous studies for the measurement of built-in environmental characteristics within a spatial unit at a certain geographic scale. This type of research has a natural assumption that urban space acts as a container for the influencing factors of physical activity. However, urban forms are characterized by self-organization. The original research design ignored the influence of the structural features of urban form on physical activity. Therefore, the study aims to explain the initial application of this emerging travel mode through a quantitative model of urban morphology. Hillier pointed out that in fact people's movement in the urban street network is based on the minimum number of turns rather than the shortest distance, and is a city street network, rather than attraction points, shaping the travel activities in the network(Hillier et al., 1993).What is still unclear is whether the structural characteristics of this urban form still have an impact on bike sharing in China and what is the theoretical explanatory power.

Methodology framework

The case study and data

Taking Yangpu District of Shanghai as an example, this paper attempts to analyze the influence of topological features of street networks on the distribution of cycling activity based on spatial syntax theory by using the location data of bikes sharing on a rest day, trying to explore the applicability of space syntax theory to emerging bike sharing travel mode. As one of the first cities to share bikes and the largest number of bikes in Shanghai, residents have become more stable in terms of the number and habits of bike sharing. As an old industrial base in Shanghai, Yangpu District is transforming into a knowledge-based innovative city centered on colleges and universities. Wujiaochang is a sub-center

of Shanghai City. The research area is mature and rich in function types, and it is representative of the relationship between the spatial structure of the city and the distribution of cycling activities.

Cycling behavior is greatly affected by the weather, and poor weather conditions can result in a significant reduction in cycling travel(Wang et al., 2016). In addition, cycling behavior has obvious differences in the use of working days and rest days. In order to reduce the impact of weather and commuter traffic on the research results, the study selected the rest days with good weather conditions to analyze the characteristics of cycling behavior. The date is November 18, 2017.

The research data in this paper obtains the location data of the use of bike sharing in Yangpu District of Shanghai through crawlers, and the space vector data such as POI and road acquired through open source map. Among them, the bike sharing data is crawled through the network to obtain the unlocked bikes information available in the research area. The daily data covers 48 time-and-half-hour time points throughout the day, covering approximately 327,539 locations in November 18, 2017 (rest days) in Yangpu District, Shanghai, including: bikes ID, location information, time information, etc. . These data are based on the user's completely spontaneous riding behavior, which can more objectively reflect the space-time characteristics of the residents' cycling behavior.

Space syntax modeling based on the segment map

From the existing research, more urban travel activities are attributed to the results of being attracted by travel destinations and being perceived by distance. Space syntax theory holds that when people move linearly in the city, the land-use will tend to remain the same, but when you turn a corner and move from the front of the same plot to the back, you will enter another world. Hillier called this transition through two topological depths one of the historical mysteries of urban planning. Therefore, in the urban model of spatial syntax, the basic unit of the city is not a land, but a straight line. Thus, Hillier proposed the principle of “natural travel”, that is, when other factors are not considered, the distribution of traffic flow in the city is only related to the topological form of the street network. On this basis, he believes that it is not the store that attracts the crowd, but in the process of urban evolution and development, the choice of location of commercial land use will make full use of the advantages of people flow caused by the characteristics of pure space organization, thus making “natural movement” has a multiplier effect(Hillier et al., 1993).

The classical research tool of spatial syntax is the axial map. At the beginning of the spatial syntax applied to the spatial study of urban scale, the axis model dominates. However, as research continues to expand, the axial map gradually shows its limitations. Ratti pointed out that the axial modelling only considers the characteristics of the dual network, while ignoring the typical network features such as distance(Ratti, 2004). Since 2005, space syntax has developed a second-generation model: line segment angle model(Hillier and Iida, 2005, Turner, 2007). In addition to the topological relationship, the new model can accurately reflect the geometric properties of the street network (ie, the turning angle of the street segment), showing a more accurate description of the urban spatial structure. The basic element of the line segment model is the street segment between road intersections. It is essentially based on the improvement of the axial map.Reflecting the line segment angle map in addition to capturing the topological properties of the street network, it can also reflect the geometric relationship of the network, including Concepts in Euclidean geometry such as line angle, distance, etc. The improved integration value essentially reflects the minimum number of turns from one road to another within a certain radius.

In view of the extensive research that has proved the applicability of segment map to large-scale urban space research , this paper uses segment map as the network analysis model of space syntax.

(networks analysis models). Identify the spatial group effects that influence and shape sharing bikes and their importance. As a kind of analytical tool for quantitatively describing the topological features of urban spatial structure, spatial syntax reveals the complex relationship of urban spatial form through parameters such as connectivity, control, depth and integration. Its calculation method mainly inherits the centripetal analysis method in social network analysis. Connectivity primarily represents the number (k) of other spatial units in the network that are directly connected to spatial unit i.

Integration reflects the degree of agglomeration and dispersion of a certain space and other spaces in the city. If the integration of a point is higher, the other points within the analysis range are easier to reach. Its calculation formula is as follows :

$$\text{Integration} = \frac{D_k(k-2)}{2\left(\frac{\sum_{j=1, j \neq i}^N d_{ij}}{N-1} - 1\right)}$$

Where i, j represents a spatial unit, k is the number of other units in the network, and N is the total number of spatial units in the network. Depth is the reciprocal of the integration. Choice is used to measure the probability of traffic flow in space (Hillier, et al., 1987). All axes are linearly related to each other and must pass through other axes. The degree of selectivity can be measured as the number of passes. That is, the degree of selection can reflect the importance of the axis within the scope of analysis. Its calculation formula is as follows :

$$\text{Choice}_i = \frac{1}{(N-1)(N-2)} \sum_{j=1; k=1; j=k=1}^N \frac{n_{jk}(i)}{n_{jk}}$$

The modeling method is to create the axis model by hand-drawing, transform the axis model into a line segment model by Depthmap software (version 10, UCL) and calculate the relevant space syntax variables. Then the segment map is imported into the arcgis and registered, and the attribute connection is used to connect the calculation result to the registered segment map. Cycling data analysis and visualization are done in ArcGIS (ver. 10.2) software. It should be pointed out that in order to avoid the "edge effect" in network analysis, it is necessary to set a buffer of a certain distance around the analysis area as the base area of drawing the segment map. Therefore, the study area of this study is Yangpu District, Shanghai. According to the speed of cycling activities and the actual urban space composition, base area is set up around Yangpu District, west to north-south elevated road, east to Huangpu River, north to outer ring highway. South to Yan'an elevated road.

Fig 1 the base area and the study area

Results

Since the acquired bike sharing data is the position information of the unlocked state, the bikes that have never been moved throughout the day, it is ensured that the counted bicycles have been used.. The activity of bike sharing in the study area is known by counting the number of bikes that have been moved throughout the day according to a 30-meter grid. As can be seen from Fig. 2, the use of bikes on the off day is still closely related to the subway station.

Fig 3 the results of integration, choice and depth in segment map modelling

Finally, the segment map in the Depthmap is imported into ArcGIS 10.2 and georeferenced. Then, in terms of line segments, count the number of moved bikes within 30 meters around the line segment. Spearman correlation analysis was performed in SPSS 22. Table 1 shows the spearman correlations between the global spatial syntax parameters and the use of moved bikes, important topological characteristic variables such as choice, integration, depth and connectivity pass the significance test ($p < 0.0001$). However, although the level of significance is higher, the correlation coefficient is generally lower, and the highest correlation coefficient is 0.203 (connectivity).

Table 1 Spearman correlations between the number of the moved bikes and the global space syntax parameters

	Global choice	Global integration	Global depth	Connectivity
R^2	.124**	.134**	-.134**	.203**
Sig.	.000	.000	.000	.000

Interesting findings are found in the correlation analysis of local spatial syntax variables and cycling volume from different scales, as shown in Table 2. When only the same variable is concerned, it will be found that the most relevant variable always appears on the 700m scale, and this total situation occurs simultaneously in these three set of variables. As the spatial scale becomes larger, the correlation coefficient decreases and the significance test is not passed at the 3500 m scale. Second, when compared with global variables, global integration and global choice are positively correlated with the number of bike sharing used, while these two variable show a negative correlation at with the number of bike sharing used 1600m and 700m scale. This change in the direction of correlation caused by the different scale does not appear in depth. The global spatial syntax variables represent the importance of spatial units in the overall spatial configuration. The local space syntax variable is related to how the residents perceive the local environment. It can be seen from the above analysis that the overall spatial structure of Yangpu District is related to the use of shared bicycles, and the influence is very limited. However, the spatial characteristics of the Yangpu District show few support for cycling activities. Comparing the two correlation analyses, it can be seen that the correlation coefficient of the local variable is generally higher than the global coefficient, and as the search radius continues to expand, the correlation coefficient begins to decrease.

Table 2 Spearman correlations between the number of the moved bikes and the local space syntax parameters

Choice_R700	Choice_R1600	Choice_R3500	Integration_R700	Integration_R1600	Integration_R3500	Depth_R700	Depth_R1600	Depth_R3500
-------------	--------------	--------------	------------------	-------------------	-------------------	------------	-------------	-------------

R ²	-.349**	-.126**	0.048	-.265**	-.122**	0.019	-.372**	-.193**	-.072*
Sig.	.000	.000	0.103	.000	.000	0.527	.000	.000	0.014

Unlike previous studies, the spatial syntax variables of this study did not show a strong correlation with shared bicycle use. There may be two reasons for this explanation. One is the existence of more access control street districts in Chinese cities. In Shanghai, shared bicycles are usually forbidden to enter the interior of residential areas and unit complexes. This is also why in the southern regions where road network density is high, the use of shared bicycles is very low. For further explanation of the less relevant correlation, the spatial structure of Yangpu District and the calculation result of segment map should be combined and analyzed. The result of spatial syntax also reflects the relationship between function and urban form. Fig. 4 shows the integration calculation results of the segment map in study area. It can be seen that, as Hillier said, the local road network encryption phenomenon brought by the integrated core appeared in the southern part of the region near the center of Shanghai. The inner center of Yangpu District is located at Wujiaochang area. As shown in the figure, the current commercial center and integration center are misplaced. In other words, the attractiveness of the Yangpu District Commercial Center has yet to be further enhanced. Secondly, through field research, it was found that non-motor vehicles were prohibited from entering the Wujiaochang area. In other words, due to the lack of support for the cycling activities in Wujiaochang, the high traffic is more from the subway station.. This is another potential reason why the relationship between integrated cores and shared bicycles is not strong. The results show that the overall explanatory power of networks features at the overall level is weaker than the local level. For integrated values, when the spatial scale of the analysis is large, it is positively correlated with the cycling activity. When the spatial scale is small, it is negatively correlated with the cycling activity and the depth value is always negatively correlated with the cycling activity regardless of the spatial scale. As is shown in Fig 4, the distribution of the high integration is more correlated to the subway station than local integration.

Fig 4 local integration distribution at 700 m, 1600 m, 3500 m radius

Discussion and conclusion

Based on the spatial syntax theory and model tools, this paper explores the influence of spatial fabric characteristics on the use of bike sharing in Yangpu District, Shanghai. This paper uses the location data of bikes among one day in weekend in Yangpu District of Shanghai, and analyzes the space-time characteristics of the bike sharing use on the rest day in Yangpu District by using ArcGIS and other

analysis tools, and the number of bike sharing and the parameters of space syntax at different scales. A spearman correlation analysis was performed. The study found that although there is a lack of strong correlation factors, integration, choice and depth in urban network analysis still shows a significant correlation effect with bikes use. Moreover, from the comparison of three different spatial scales, the correlation coefficient of choice is increasing as the spatial scale becomes larger. This shows that road density has a strong correlation with cycling activities at local scales. However, when the spatial scale is gradually increased, the correlation between the integrated value and the cycling activity begins to change positively and negatively. The larger the spatial scale, the stronger the positive correlation. Because the distribution of global integration values is more relevant in metro lines and site distribution. That is to say, compared with the “constant speed transportation system” of the traditional city, the actual “integrated nuclear” brought by the “differential transportation system” of the modern city is the shaper of the cycling, and is also the current resident’s habits to use bike sharing. Yangpu District used to be an old industrial base in Shanghai. Compared with Jing'an and Huangpu, the neighborhood has a large scale and low road density. There are more “access control” communities and unit complexes. With the deepening of the transformation process of Yangpu District to the knowledge-innovated urban area, the road network encryption phenomenon of the local integrated core will appear in the future, and the correlation between urban spatial form and function will be further enhanced.

Compared with the existing research on the correlation between cycling and built environment, the urban model based on spatial syntax can simultaneously measure the influence of global and local spatial fabric features on cycling activities, and thus shape the spatial factor of cycling activities at different scales. The lack of trajectory data for cycling activity is the reason for the lack of explanatory power of the integrated value based on the minimum angle weighting. This research is not enough to answer the question of whether people move at the smallest or shortest distance.

Of course, there are many limitations in this study. For bike sharing data, since the python returns the location of the bikes every half hour, the bike sharing usage within half an hour will not be recognized, and it is difficult to eliminate the interference caused by human factors such as bikes company internal dispatch. Secondly, this paper only attempts to analyze the space syntax theory to explain this new way of cycling in China, and has not yet thoroughly analyzed the built-in environmental factors affecting cycling activities. So, in the background of bike sharing, is the space configuration still the shaper of the cycling activity? The answer to this question requires further research in the next step. In the follow-up study, other built-in environmental factors such as land use, spatial form, and road traffic conditions will be included as control variables, , so as to explore the causal link between cycling activity and the built environment more deeply and comprehensively.

Abstract: In the last decades, urban river regeneration (URR) has been increasingly adopted to solve environmental issues, especially in China. The prevalence of this trend is due in part to the fact that, besides solving water pollution problems, urban rivers are a potential new source of open public space for contemporary cities. Due to the extremely rapid urban development, available public space in these cities is shrinking and becoming more and more inadequate. In this context, URR can enhance the quality of the built environment, social life, and public health. This study aims to investigate the influence of URR on social life by analyzing people's behavior and perception of space. Due to its geographical location and its urban context, Futian River in Shenzhen has been chosen as a case study. Methods adopted include direct observation, interview, and survey research. The study is expected to explore the influence of urban river regeneration on social life, adding new knowledge for future healthy city planning in contemporary urban environments.

Keywords: urban river regeneration, open public space, human interactions, urban life

Introduction

Urban rivers as Linear Parks

After the 1950s, in China, the provision of urban green spaces started to be increased (Xiao-Jun, 2009). By 2000, China's green space ratio, green space coverage, and public green area reached 27.4%, 23% and 6.52%, respectively. However, these percentages are still relatively low. As noted by Xiao-Jun (2009), theories and methods for the planning of the urban green space system are still lacking. These issues are due to a lack of knowledge about biological processes and natural spaces in relation to urban form development. Moreover, administrative zoning limits green space development, as natural spaces and urban processes do not evolve along the same timeline (primarily due to biological principles). In their critique of the 1989 City Planning Act of the People's Republic of China, Ng and Wu (1995) explain how long-term city planning in China (20 years) is not effective in guiding urban development. In response to this critical situation, the Chinese Government over the last two decades adopted new planning strategies to increase the provision of green spaces in urban contexts (Zhao et al., 2013, Chen and Hu, 2015). Green spaces are usually public, and provided by the government (You, 2016). However, there is still an unequal distribution of green space in urban contexts due to the high-density built-up development (You, 2016). Specifically, in cities that are becoming denser, the often-adopted infilling approach produces compact urban areas, which threaten the ability to provide open green spaces accessible to the public (Haaland and Bosch, 2015). As Haaland and Bosch (2015) point out, there is growing evidence of the decrease of urban green space due to urban densification processes, especially in Asian cities. In this context, urban rivers emerge as a potential source of urban green open space, providing continuity within the green infrastructure and bringing more advantages than the sporadic green infill that is normally adopted in high-density cities.

One of the main advantages of URR is to provide the city with a new continuous greenway. In fact, the space generated by URR is typologically a linear urban open space, very similar to a linear park. While the positive role of urban green space in improving social and mental health is well-known (Grahn & Stigsdotter, 2010; Wolch et al., 2014), there is also a growing body of literature on the advantages of having urban green space

distributed along linear spaces in the form of greenways. As an example, Brown et al. (2014), indicated that urban parks of various shapes offer different opportunities for people and influence both physical activities and the distribution of social and environmental benefits. To confirm this study, Liu et al., (2016), demonstrated that in the case of Shenzhen, green and well-developed areas strongly support physical activities such as walking, jogging, and cycling. In addition to facilitating physical activities, linear parks provide many more benefits compared to other types of urban parks. In fact, linear spaces may have a greater impact on urban neighborhood environments and social interactions because of their narrow and long shape, which can provide more access to diverse neighborhoods. Accessibility is especially important for children, the elderly, and the unemployed, in other terms, vulnerable groups (Shen et al., 2017). In addition to accessibility for vulnerable groups, the linear typology can also provide access to different social groups, with a wide range of income and social status. In this regard, since linear shapes can cross continuously different districts in the city, urban rivers appear as a collector of social and urban life. Moreover, Park and Kim (2019) provided evidence that linear space has strongly influenced surrounding economies. To summarize, newly developed linear green space has frequently served social, environmental, and economic purposes.

As extremely rapid urbanization over the last few decades in contemporary cities has caused the available public space to shrink and become more and more inadequate, river regeneration has increasingly been adopted to improve ecosystems, enhance the quality of urban environments, or to gain economic benefits (Palmer et al., 2005). In fact, URR has become a worldwide tendency (Holmes, 1998; Henry et al., 2002; Ormerod, 2003). The common objectives of URR include controlling the quality of the natural environment (Gordon, 1996), improving accessibility, and improving the urban landscape along rivers. Given differences in national policies, geographical conditions, climatic conditions, and cultural backgrounds, every country has its own strategies and methods for river regeneration. The US, Canada, and Europe all have policies and legal requirements to encourage RR, such as the US Water Act (1972), the Canadian Water Act (1985), and the EU Water Framework Directive (WFD), (2000), (Morandi et al., 2014). However, in these countries, river regeneration is more oriented towards solving ecological and environmental issues and is mainly adopted in sub-urban or peripheral contexts. On the other hand, in China, several river restoration projects were undertaken from the 2000s as part of a national effort to improve mostly urban environments (Zhao et al., 2013). Compared to western countries, URR in Chinese cities is a relatively recent practice, but the pace of URR development in China is faster.

River Regeneration impact assessment

Although river regeneration projects are frequently executed around the world, there are relatively few studies to assess their success. Bernhardt et al. (2007), concluded that only 10% of RR projects in the United States over the last 30 years have had their progress monitored. In Japan, Nakamura et al. (2006) also emphasized that while these projects have been growing rapidly since the 1990s, it was rare to evaluate them at that time. In China, there are thousands of rivers that have been regenerated in recent years, but the knowledge of how to evaluate the results of URR is weak. It is crucial to assess whether any restoration project has successfully reached its objectives (England et al., 2008). Indeed, for Bradshaw (1983), the conclusion of the evaluation of restoration projects is an acid test of our understanding, and it is crucial for future studies.

According to Palmer et al. (2005), the success of URR projects can be explicitly evaluated along three axes, as shown in Table 1. Ecological success is the primary axis: URR achieves this success by enhancing the quality of the environment, mainly by solving water pollution issues and improving urban microclimates. Many studies that analyze bioremediation technologies for the natural and ecological environment have been conducted with the hope of improving the quality of remediation and control of urban rivers pollution (Qu and Fan, 2010; Wang et al., 2012). However, despite a growing body of knowledge on the ecological success axis, few researchers have investigated the social impact of URR.

Table 1. Axes of success in RR (Palmer et al., 2005).

Success	Evaluation Guidelines
Ecological Success	Guiding image exists Ecological improvement Self-sustaining No lasting harm done Assessment completed
Stakeholders Success	Aesthetics Economic benefit Recreation Education
Learning Success	Scientific contribution Management experience Improve methods

Social Impact of Urban Rivers Regenerations

The regeneration of urban riverfront space, which always combines natural and social resources, provides more public open space for urban residents. It is believed that the new space generated after URR can both improve a population's relationship with the river and provide new space for different kinds of social groups. In fact, the new riverfront space is an important part of urban open and green space, which is increasingly recognized as a recreation-oriented part of an urban landscape (Kienast et al., 2012).

Achieving both ecological and social success has increasingly been acknowledged as among the most essential parts of URR (Palmer et al., 2005; Petts, 2007). Baschak and Brown (1995) demonstrate that riverfront space brings not only ecological benefits to the city but also social benefits. The assessment of social impact is not clear because, compared to ecological impact, social impact is generally of secondary importance (Eden and Tunstall, 2006). Yang et al. (2013) believed the waterfront area to be a golden zone that brought new opportunities to developers. In addition, they believed riverfront space to be a new place for improving the urban living environment. The social impact of public green space considers how people use the new riverfront space, how people experience new human interactions along the river, and whether the new space truly caters to people's daily needs. Diverse recreational facilities and well-planned landscapes within public open spaces can encourage people to visit and thus promote human interactions between people (Gehl, 2011). Much research has focused on the human dimension of urban greenways (Gobster and Westphal, 2004), classifying them in categories such as cleanliness, aesthetics, safety, appropriateness of development, naturalness, and access. Other studies have related human interactions to the connectivity concept (Kondolf and Pinto, 2017), but little research has investigated the influence of rivers regeneration on human interactions.

Human interactions, in particular Face-to-Face (FtF) interactions, are intense and pervasive along urban reaches of rivers and along with these interactions come the communication and movement of different people, cultures, and ideas (Kondolf and Pinto, 2017). As time has passed, human interactions around rivers have been changing. Kondolf and Pinto (2017) identified that rivers can, depending on their size, have different social impacts. In ancient time, interactions occurred along rivers given their importance for transportation and agricultural use. With the development of society, however, urban rivers have become multi-functional spaces that can provide ecological and social benefits to the urban environment. An important aspect of social life, FtF human interactions are fundamental to people's well-being. In fact, it has been demonstrated that human interactions have positive benefits on public health, especially mental health (M. Leyden, 2003, Bernstein et al., 2012, Francis et al., 2012). In some cases, increasing the number of human interactions can even prevent premature mortality (Holt-Lunstad, 2018). Relevant studies have demonstrated the relative importance of FtF human interactions compared to online interactions; these studies have shown the association of the symptoms of depression with time spent online (Kraut et al., 2002). Caplan (2003) confirms this theory, relating psychosocial well-being to online communication rather than to FtF. Moreover, human interactions play a fundamental role in the definition of social life and social capital (M. Leyden, 2003), both of which are features very relevant to one's well-being. Finally, human interactions between different social groups can blunt the

effects of segregation in urban contexts. For example, Cattell et al. (2008) observed that in public open spaces, people of different backgrounds could join each other in the same recreational activities and learn from one another. Rasidi et al. (2012) indicated that urban green space could enhance human interactions between different communities. The research also revealed that the vegetation density, biological diversity, landforms, and water bodies provided favorable conditions for human interactions.

The paper will focus on recreational use along the river to investigate the impact of URR on urban life, mainly focusing on human interactions as a relevant aspect of social life. The study attempts to answer the following questions. (1) Who are the frequent river users? (2) From where do they come? (3) How frequently do they visit? (4) What is their level of satisfaction with and perception of the riverfront space? (5) What is their level of human interactions and with whom are these interactions occurring?

Methodology

Case study: Futian River, Shenzhen

Due to its extremely rapid urbanization and its massive demographical development, Shenzhen is here chosen as a case study. Having evolved for only around forty years, Shenzhen is located at the border of Hong Kong, 100 km south from Guangzhou and part of The Greater Bay Area and is one of the major high-density financial centers in southern China. In 2014, with its 50 million inhabitants, Shenzhen overtook Tokyo in terms of population and territorial expansion. Shenzhen, the first SEZ (Special Economic Zone) in China, is a leading city in economic reform. Moreover, Shenzhen territory is characterized by a dense urban fabric, so there are obstacles to providing green spaces and to introducing new green elements. Due to its dynamic evolution, history, and urban morphology, Shenzhen appears as a relevant testing site to proceed with data collection and analysis for investigating the impact of URR on social life. Special emphasis will be focused on the role of urban rivers as potential sources of new green space in high-density cities.

From north to south, Futian River runs through Bijiashan Park, Central Park and finally joins Shenzhen River; the flow pattern follows a linear distribution. Futian River is a 6.8 Km long urban river, and it crosses the main urban neighborhoods in Shenzhen. In 2008, due to severe water pollution issues and the need to improve waterlogging areas in the city, the Shenzhen Government renovated the river space. The Government hoped not only to solve the pollution issues and to increase flood control and prevention but also to improve the urban landscape and the equality of the areas crossed by the river. Furthermore, the government aimed to enhance public open space. Moreover, accessibility to the rivers has been improved, promoting the connection between people and the waterfront space (Shenzhen Water Conservancy Planning and Design Institute, 2008).

Survey Research Design and Interviews

Whether or not the regenerated riverfront space is actually promoting communication and interactions among different users around the river needs to be verified. The methods typically adopted to investigate people's perceptions of space and demographics include both quantitative and qualitative approaches, such as surveys and interviews. These methods are applied here to answer the research objectives. Demographics data must be collected, as the percentages of human interactions and social activities along the river have to be calculated. Moreover, people's satisfaction will be investigated, combined with accessibility and frequency of visits to the river. Questionnaires were distributed randomly along Futian River on weekdays and weekends between 7.00 a.m. – 7.00 p.m. At the same time, in-depth interviews were conducted. People who showed interest in being interviewed on the topic of the social impacts of URR would be asked explorative questions about social interactions along the regenerated river.

Results and Discussion

Demographics

The results of the survey analysis are based on 220 questionnaires. Data were coded into IBM SPSS for the descriptive statistical analysis. The general information in Table 2 shows that the sample of the respondents is 49.1% male and 50.9% female, and that most respondents are aged between 31 – 42, which accounts 30.9% in total. The results also showed that users of Futian River are very diverse, with different ages, educational levels, and income levels.

Frequency

The first part of the survey questionnaire aims to understand the frequency of visits to the Futian River. It includes three questions, which are how often, for how long, and when people visit the river waterfront. Table 3 shows descriptive statistics of these frequency related questions. As we can see from Figure 1, in the total sample, around 30% of people visit Futian River daily, making this the most common of five frequency

choices; the second most common frequency (24.5%) are those who come to the Futian River three or four times a week, and only 6.8% is the first time to visit Futian River.

Table 3. Descriptive Statistics of Frequency Questions

			First time	Less than 1 day per month	Once per week	3-4 days per week	Everyday	
How often		N	15	47	38	54	66	
		Percent	6.8	21.4	17.3	24.5	30

		Percent	85.9	8.6	3.2	1.4	0.5	

Figure 1. The Frequency of people visit Futian River

Accessibility

On the accessibility dimension, the main purpose is to find out from where people have traveled, what kind of transportation they use, and how long it takes for them to reach the Futian River. Table 4 gives an overview of accessibility-related questions. The results indicate that most people come to Futian River from their homes, with walking the most common means of transformation. As shown in Figure 2, most people (37.3%), can get to Futian River in between 10 and 20 minutes, and 33.2% travel within 10 minutes. The results show that Futian River has relatively high accessibility in terms of walking distance from the riverfront space.

Table 4. Descriptive Statistics of Accessibility Questions

			Never	Rarely	Sometimes	Often	Always
Where	Home	N	11	10	19	78	102

Figure 2. The Travel time to Futian River

Human Interactions

One of the most critical parts of the survey questionnaire consists of investigating whether people have human interactions in the riverfront space. The third and fourth part of the questionnaire is designed to collect information about the usage of riverfront space and people's interaction habits. The collected data in these two parts can help to find out the relationship between human interactions and the use of the space. As shown in Figure 3, around 60% of people indicated that they sometimes, often, or always having social interactions with others along Futian River. Only 13,6% of the survey replies affirmed that they never have human interactions along the riverfront, but a further 25% acknowledged that they rarely have such interactions. The majority of responses (40%) stated that human interactions occur sometimes. The percentage of people interacting compared to people not interacting is therefore relatively high.

Figure 3. The number and percentage of people's social interactions along the Futian River

After analyzing human interactions percentages, Pearson correlation has been applied to verify if human interactions are related to some activities happening on the riverfront space. People's activity preference is based on Likert scale 1 to 5 (where one means never, and five means always do these kinds of activity along with riverfront space). In Figure 4 the mean and standard deviation of all activities observed are shown; at a higher level of mean, a higher number of people involved in the activity. Preferred activities are walking, relaxing, or resting in the riverfront space. Further correlational analysis results show that among all activities relaxing, resting, waiting or killing time, and dancing have a positive correlation with the percentage of human interactions.

Figure 4. People's Activity Preference along Futian River

Finally, in order to understand people's perception of the riverfront space, some questions were asked to investigate and measure satisfaction and importance of the riverfront space, the variables investigated are as follow: safety (SA), activities (ACT), cleanliness (CL), facilities (FAC), public service (PS), spatial features (SF). Importance and satisfaction rates were expressed on Likert scale 1 to 5. Table 5 shows the average rates of people's perception. It appears that users of riverfront space consider relevant all variables, but with satisfaction rates are relatively lower than importance rates. The correlational analysis between people's satisfaction rate and human interactions shows that the satisfaction of the cleanliness and maintenance of public toilets, distribution of rubbish bins, and playground for children have a positive effect on human interactions. At a higher rate of satisfaction of these four factors, a higher number of human interactions is happening on the riverfront space. This type of analysis is relevant in assessing which are from users perspectives the most important variables. By associating with which factors people are not satisfied, further improvements can be arranged to increase frequency index, consequently the number of users, number of people participating in social activities and finally the percentage of human interaction.

Table 5. People's Satisfaction and Importance Rate of Futian River

	Satisfaction rate	Importance rate	Satisfaction std	Importance std
(SA) Personal safety	3.89	4.57	0.82	0.64
(ACT) Public events	3.69	4.26	0.85	0.74
(CL) Cleanliness of public toilets	3.70	4.32	0.77	0.69
(CL) Distribution of rubbish bins	3.54	4.19	0.90	0.70
(FAC) Bicycles parking	3.20	4.05	0.86	0.73
(FAC) Facilities for disabled	3.04	4.08	0.94	0.74
(FAC) Playgrounds for children	3.16	4.11	0.90	0.76
(FAC) Sport facilities	3.26	4.09	0.82	0.76
(FAC) Water disposals	2.83	3.93	0.95	0.79
(PS) Distribution of public toilets	3.26	4.20	0.97	0.75
(PS) Maintenance of public toilets	3.41	4.22	0.87	0.70
(PS) Service areas	3.45	4.10	0.80	0.70
(SF) Shadow areas	3.91	4.34	0.72	0.64
(SF) Lawns	3.85	4.40	0.78	0.70
(SF) Benches	3.84	4.41	0.79	0.71

A critical aspect of human interaction mentioned before concern the importance of facilitating interactions among different social groups, helping to heal segregation in urban environments. To investigate this aspect, besides statistical analysis, in-depth interviews have been conducted to understand people's attitude towards experiencing human interactions with strangers. The three most frequent answers reveal the fact that they generally do not care who are the people they are interacting with. Most people have interactions with other individuals with the same hobbies such as dancing, playing chess or fishing; kids are also seen as a bridge for interactions; usually, if kids are playing together, parents have communication with each other.

These were the most popular answers to the question regarding who are the people they are interacting with. In these statements, people show that they do not care about the social status of others. Another prevalent answer was related to the fact that human interactions happen on some specific occasions, such as asking others necessary information. This answer provides support to the fact that people feel safe to ask instant information to strangers, still not caring about social status or provenance.

To summarize, from the results, people on the riverfront space are in percentage inclined to experience human interactions. Moreover, most users did not care about social status, income, level of education, or provenance. Therefore, it can be assumed from this study that the riverfront space has a positive impact on people's behavior in terms of social life and human interactions, even between different social groups.

Conclusion

As an indispensable part of urban development and green space provision, rivers are getting more and more attention nowadays. In this context, URR emerges as a potential source of new green space well-distributed in the city, allowing residents of different communities to easily enjoy social resources, experiencing human interactions, and improving their social life. URR has developed rapidly in China, but few studies have assessed the social impact of URR on urban life. This paper discusses whether the regenerated river as a linear public open space in the city promotes human interactions as an aspect of social life, providing more public activity opportunities for urban population. Methods applied to evaluate the regenerated riverfront space are both quantitative (survey research design) and qualitative (direct observations and interviews).

The results show that the regeneration of Futian River promotes the advantage of its linear characteristics and provides more public open space for the surrounding residents within the linear range. Accessibility and availability of the riverfront linear space promote a well-distributed use of social resources and a high frequency of visits. Moreover, findings from survey and in-depth interviews also indicate that the improvement of the riverfront space quality increases people's satisfaction of Futian River, leading to a high frequency of visits and consequently increasing the chance to experience human interactions. People of all ages, all levels of education and income showed interest in the riverfront space, and a relatively high percentage of human interactions generally occurs in the riverfront of Futian River regardless the social status of users.

Eventually, this study has several limitations and offers room for future improvement. Firstly, data collected should be benchmarked against a sample of other case studies with different morphological characteristics in order to rise the evidence of the social impact along the regenerated riverfront. Secondly, the sample size can be enlarged in order to increase the accuracy of data results and decrease the margin of error due to calculation processes. In conclusion, this study can be considered as a preliminary research aiming to demonstrate the effectiveness of URR on the improvement of social development and provision of public green space in a Chinese high-density city such as Shenzhen. Besides, it contributes to the current knowledge on the assessment of URR success.

Acknowledgments

The work described in this paper was partially supported by a grant from the City University of Hong Kong (Project No. 7005042). We would also like to thank the Shenzhen Water Bureau for providing detailed information about the Futian River. Moreover, we thank the students of Shenzhen University who helped in distributing questionnaires along Futian River.

Abstract: International organizations promote the equitable provision of open public spaces (OPS) as a strategy for healthy cities planning. In the context of high-density Asian cities, the densely built environment, constraints generated by mobility infrastructures and the limited distribution of OPS pose challenges to the implementation of equitable OPS provision. Pedestrianisation –the conversion of a vehicular street for pedestrian uses– is emerging as an effective policy to increase the supply of OPS. Nonetheless, the temporary or permanent space conversion strategy –from mobility infrastructure to OPS– lacks a comprehensive implementation framework. This paper reviews the governmental policies for the supply of pedestrianised streets (PS); it investigates the *tactics* of PS appropriation drawing upon the case of Hong Kong, one of the densest and more socially polarized Asian cities. The unconventional use of the short-term OPS can provide insights into *tactics* of informal use of OPS and it can contribute to evaluating the need for pedestrianisation and for additional planning measures. This study comprises documentary analysis and primary data collection and analysis. The method adopted for policy review is content analysis. The methods adopted in fieldwork involve unobtrusive observations. Results are presented in the forms of policy review and Structured Direct Observations.

Keywords: open public space, planning, pedestrianisation, stationary activities, Hong Kong

Introduction

The equitable provision of urban open public spaces (OPS) is increasingly recognized as a strategy to promote social wellbeing in the form of social interaction, communal sharing and cultural expression in cities (Carr *et al.*, 1992; UN-Habitat, 2015). As OPS has become a further contested resource among different uses and ownership-domain in cities, current academic research, international organizations, urban planning, and public discourses give particular attention to the function of urban streets as public space (UN-Habitat, 2013). Specifically, academic research urges to incorporate the mobility uses (pedestrians, bicycles and motorized vehicles) as well as stationary uses (as social functions and cultural expression) in the planning of urban streets (Agyeman and Zavestoski, 2015; Von Schönfeld and Bertolini, 2017). In addition, research on the variety of temporary, planned or unplanned uses of urban streets by organization of citizens and small-scale entrepreneurs suggests the need for a more flexible approach to planning of urban streets to accommodate these uses (Hou, 2010; Bishop and Williams, 2012; Lydon and Garcia, 2015). Pedestrianisation, a transport planning measure for the temporary or long-term conversion of a vehicular street for exclusive pedestrian uses (Hass-Klau, 2015), epitomizes this dynamic struggle to incorporate a multiplicity of uses (pedestrian, cyclist

and partially vehicular mobility and pedestrian stationary uses) and the need for a flexible approach to planning of urban streets (Von Schönfeld and Bertolini, 2017).

The objects of this study are the planning framework for long-term and temporary pedestrianisation, and the stationary uses -consolidated over time- of the first pedestrianised street-space in Hong Kong. In this high density and compact urban environment, the quantity and quality of OPS are severely limited, and the issues related to the competing uses that public space needs to fulfil are exacerbated (Tang and Wong, 2008; Siu and Huang, 2015). A recent measure to re-open a pedestrianised street to vehicular traffic after 20 years over complaints about long-term stationary uses (Hui, 2018; Transport Department, 2018a), suggests there might be the need to reconsider the pedestrianisation planning framework and to integrate the stationary uses in the planning for pedestrianisation.

Drawing upon De Certeau's theory of strategies –policies generated by the government– and *tactics* –the powerless individuals' creative act of negotiating strategies to meet their needs– the paper revisits the conflicts between formal pedestrianisation planning and the informal stationary use of space (De Certeau, 1984). This paper first discusses the need of seeking a balance between mobile and stationary functions in planning for pedestrianisation, by illustrating the rationale behind competing and complementing roles of mobile and stationary functions in pedestrianised streets. Secondly, it discusses the logic underlying pedestrianisation policies and planning in Hong Kong. The question investigated in this second part is: to what extent planning for pedestrianisation in Hong Kong considers mobility and stationary uses? We sought answers to this question through the content analysis of the purposes and objectives of pedestrianisation policies and planning strategies. In the third part, this article focuses on the evidence of consolidated stationary uses within the first implemented case of temporary pedestrianisation in the central business district (CBD). The final section of the paper focuses on how the limitations of the pedestrianisation policy and planning strategies could be overcome by considering the empirical evidence emerging from behavioural research. It also sets indications for further work.

Pedestrianised streets: stationary and mobile uses

Urban OPS play a vital function, they contribute to social inclusion, communal sharing, cultural integration, democratic and political expression in cities (Carr *et al.*, 1992; Gehl and Gemzøe, 2004; Cattell *et al.*, 2008; Madanipour, Knierbein and Degros, 2013). They have a role as well for environmental and economic sustainability of cities (Chiesura, 2004). OPS can be places for exchange and interaction with a great variety of population (Bertolini and Dijst, 2003). So that the equitable provision of accessible and varied OPS is considered a strategy to promote the health determinants (facilitating social cohesion, supportive social networks, healthy lifestyles) that relate to the physical environment of cities, under the WHO Healthy Urban Planning Initiative (Barton and Grant, 2013).

OPS refer to different spatial forms that include public parks, squares, space between buildings, markets, transport stations, streets and sidewalks (Jacobs, 1961; Bertolini and Dijst, 2003; Chiesura, 2004; Mehta, 2013). These spaces integrate a wide variety of mobility flows as flows of pedestrians, bicycles and increasingly of personal mobility devices. At the same time OPS play the vital contribution of enabling a wide variety of stationary activities in urban environments as allowing people to linger, stand, sit, socialise, read and share food (Cattell *et al.*, 2008; Mehta, 2009; Gehl, 2011). Urban planning research and practice is increasingly showing how these activities can be

encouraged through temporary, flexible, planned or unplanned initiatives as in Copenhagen (Christiania occupation and Stroget Street pedestrianisation), London (Camden Lock pop-up market), Bogotá (Ciclovía, Highway pedestrianisation) and Hong Kong (temporary seating in urban neighbourhoods) (Bishop and Williams, 2012; Lydon and Garcia, 2015; Rossini, 2019).

OPS in the form of urban streets accommodate wider mobility functions. Urban streets are at the same time networks for private, public and shared means of transportation of people and goods, this constitutes a significant part of the functioning of urban environments. So that urban streets are often only associated to this mobility function (Von Schönfeld and Bertolini, 2017). The contribution of streets to the function of public space is equally important. Jacobs (1961) argues that “Streets and their sidewalks, the main public spaces of the city, are its most vital organs. Sidewalks, their bordering uses, and their users, are active participants in the drama of civilization...” (Jacobs, 1961, pp. 29–30).

Pedestrianised streets might represent an extreme case of these mobility and public space dynamics. Pedestrianisation is one traffic control policy that is devised to reduce the environmental and safety drawbacks of the motorized vehicles, to reallocate space for non-motorised vehicles and pedestrian mobility and activities, and, more essentially, to improve the urban environment as a place in which to stay (Brambilla and Longo, 1977; Yuen and Chor, 1998). Research on the benefit shows that pedestrianisation can lead to a significant increase (20-40%) of pedestrian flow (Hass-Klau, 1993) as well as stationary activities (sitting, strolling, socialising) (Gehl and Svarre, 2013). Pedestrianisation can involve the closure of one street or one entire precinct to motorised traffic.

Most of pedestrianisation planning have been established as a strategy to reduce automobile congestion in city centres or to stabilise downtown commercial activity, in the theory of De Certeau to “impose order” (De Certeau, 1984). According to De Certeau the “strategies” are the act of systematizing and ‘imposing order’ (idem). Strategies are imposed by structures of power- as institutional bodies- and produce a space “the city” (idem). Similarly, pedestrianisation policies and planning, promoted by the government and relevant departments produce the pedestrianised space according to specific rules.

Individuals act in the environments that are set by strategies performing “tactics”. “Tactics” are the powerless individuals’ ways to disrupt and negotiate the strategies that are imposed to them (De Certeau, 1984). These imply a creative effort to negotiate the environment in order to meet individuals’ needs. The pedestrian that takes a shortcut in the imposed rational grid of the city is an example of tactic (idem). Similarly, in the case of the pedestrianised space produced by strategies of traffic control or commercial revenue increase, pedestrians apply “tactics” to meet their needs. Specifically, through *tactics* of pedestrianised space appropriation pedestrians negotiate the environment to perform their stationary activities that otherwise cannot find spaces elsewhere.

Pedestrianisation planning in Hong Kong

In Hong Kong road infrastructure occupies the 3.7% (compared to 2.3% for private housing) of the 270 km² of the city built-up area, serving a population of more than 7 million. In comparison to other high-density Asian cities as Tokyo and Singapore, in Hong Kong the public transport modal share is high (about 90% of journeys) and the car ownership is low (74 per 1000 people). At the same time because of its high density, Hong Kong’s roadway system is the world most heavily used (Murakami and He, 2018). The

planning of urban streets as high-circulation or car parking infrastructure, the functional segregation of the urban environment (Siu and Huang, 2015), and the privatisation and the commercialization of public space heavily impact on both quantity and quality of the OPS (Tang and Wong, 2008; Xue, Ma and Hui, 2012). The OPS standard is set by the Planning Department to a minimum of 2 m² per person. On average the quantity of OPS is 2.7 m², compared to the 7.4 m² per person in Singapore (Lai, 2017).

Hong Kong transport policy goal is to ensure the efficient, safe and environmentally sustainable mobility of people and goods. The railway is set as backbone of the transportation system and road safety and traffic congestion and related vehicle emissions reduction are high priorities. Since the late 1990s, a range of strategies has been implemented -including pedestrianisation-in the attempt to mitigate the conflicts between pedestrians and vehicles. Pedestrianisation is promoted at the government level as a traffic planning policy. The department involved in planning is the Planning Department or in some cases, the planning is directly initiated by the Transport Department (Planning Department, 2001). The implementation is carried out by the Transport Department and Highways Department. Other than one pedestrianisation project in the CBD, most of the pedestrianisation projects were completed by the second half of 2000. These are of three types (Transport Department, 2019):

- Full-time pedestrianisation: In these streets, pedestrians have absolute priority. Vehicular access is restricted to emergency services only, but service vehicles may be allowed in specific periods, for selected locations.
- Part-time pedestrianisation: In these streets vehicular access is only allowed in specific periods. In these streets there is no on-street parking space.
- Traffic Calming Street: In these streets there is no restriction to vehicular access, but vehicles are slowed down, and sidewalks are normally widened.

The purposes and objectives of pedestrianisation changed through time, the next section examines the pedestrianisation policies and planning strategies of the last twenty years since pedestrianisation was first introduced.

Policy review: Purposes and objectives of pedestrianisation planning

Since the late 1990s, the Hong Kong Government started a city level study on pedestrianisation planning. The analysis of twenty years of policies shows a gradual change in the planning approach, from safety and mobility oriented to a commercial and later accessibility focus. In order to have an in-depth review of the relevant pedestrianisation planning approaches, this section will examine the purposes and objectives of the governmental planning policies in Hong Kong through content analysis (Gaber and Gaber, 2007). The data sample consists of policy addresses, planning strategies and legislative council papers from 1997 to 2016. The main intended function, the purposes, and objectives of pedestrianisation are summarised in Table 1.

The *Third Comprehensive Transport Study* (CTS-3) (HKSAR Transport Department, 1999) conducted by the Transport Department (TD) is the first planning strategy to put forward the concept of pedestrianisation at the city level. The planning approach of CTS-3 (HKSAR Transport Department, 1999) and later of 1999 *Chief Executive Policy Address* (HKSAR, 1999) shows a major focus on the mobility objectives of pedestrianisation. The purpose of CTS-3 is to update Hong Kong's transport infrastructure policy framework upon considerations of population increase and traffic-related air pollution increase. Pedestrianisation, increase in access to public transport and grade-separated pedestrian links are considered measures to promote walking as a short-distance transport mode. This significantly influences the mobility function in the planning for pedestrianisation. In addition, the purpose of pedestrianisation is a purely

traffic control resolution, that is to improve road safety by minimising the conflicts between vehicles and pedestrians. The three types of pedestrianisation (permanent, partial and traffic calming) are firstly here delineated. The decision on the implementation of a specific type of pedestrian scheme is linked to traffic management requirements, assessed by a study on the impact on local district traffic. The suggested implementation of part-time pedestrianisation is supported by a traffic management motivation: the unavailability of loading and unloading alternative access routes. This makes evident that the mobility function (concern about the access of vehicles in specific time periods) is a main issue.

These directions are represented in the 1999 *Chief Executive Policy Address* (HKSAR, 1999) where three streets in high priority urban areas (Causeway Bay, Mongkok and Tsim Sha Tsui) are selected. Russell Street, one of the most crowded streets in Hong Kong, is also set for pedestrianisation implementation in the same year. This selection of high priority streets is based on heavy pedestrian flow and pollution levels. The 2000 *Legislative Council panel on transport* further developed the pedestrianisation implementation plan in three phases: trial, traffic impact assessment and, eventually, in case of positive result the scheme would become permanent (HKSAR Legislative Council, 2000). From 2000 to 2005, the TD has extended pedestrian schemes to seven urban locations (Central, Wan Chai, Jordan, Sham Shui Po, Stanley, Yuen Long and Shek Wu Hui) other than the three priority locations. The mobility function as main objective of pedestrianised streets can be here observed in the traffic impact assessment as the only evaluation tool before implementation.

In 2001 *The Study on Planning for Pedestrians* was commissioned by the Planning Department (PD) (HKSAR Planning Department, 2001) and marks a shift in the approach to pedestrianisation planning. The objective is to formulate a more comprehensive planning and development framework for pedestrian planning at different levels (HKSAR Planning Department, 2001). In this document the concept of public space explicitly includes streets, footpaths and pedestrianised streets. It promotes planning for pedestrian mobility and safety purposes (linkage, safety, accessibility), but also for social gathering and leisure activities (stationary activities), stressing the possibility of commercial purposes and private sector involvement. In existing urban areas pedestrianisation is envisioned as a strategy to provide open public spaces. The new purpose of pedestrianisation is “[t]o provide pedestrians with a safe, healthier and more convenient street environment by giving more sympathetic consideration to pedestrians over vehicles” (HKSAR Planning Department, 2001). The objectives of pedestrianisation are widened and focus on the enhancement of the shopping environment and the provision of open public space in congested urban areas. Although this document envisions pedestrianisation planning for stationary uses, the main purpose of pedestrianisation planning is related to the additional commercial opportunities and retail viability given by pedestrianisation. These directions are embraced and updated in the *2016 Hong Kong 2030+: Planning and Urban Design for a Liveable High-Density City* (HKSAR, 2016), that promotes planning and urban design directions to enhance the quality of living and sustainability of Hong Kong. In this planning strategy, the purpose of pedestrianisation is shifted to the accessibility of the walking environment. Location of pedestrianisation projects should be explored in station precincts and walking environment enhancement plans should be part of a broader district-wide urban design plan. Drawing from Singapore covered passageways near transportation nodes, a further objective is to emphasize the provision of shading facilities and public seating. The focus shift on the accessibility of the walking environment through traffic calming streets (instead of pedestrianisation) can also be seen in the higher number of traffic calming projects implemented from 2005 to 2011 (HKSAR Transport Department, 2018b).

The analysis of twenty years of pedestrianisation policies shows that there was a gradual change in the planning approach, from safety and mobility to a commercial and later accessibility-oriented objective. Therefore, pedestrianisation objectives were mainly related to two aspects: mobility function and

commercial viability opportunity of pedestrianised streets. At the planning level, the increase of stationary activities in public space has never been highlighted as the main purpose of pedestrianisation, as this measure is mainly conceived as a traffic planning measure and implemented by the Transport Department. Therefore, pedestrianisation was initially planned to promote the mobility function of pedestrianised urban streets recognizing walking as a transport mode. The focus on the mobility function in the planning of pedestrianised urban streets can also be seen in the selection criteria of priority locations (focus on pedestrian flow), the type of scheme to be planned (based on vehicles loading access), the assessment criteria for implementation (traffic management requirements). All in all, the pedestrianisation strategy of the governmental bodies is related to the mobility function of pedestrianised street.

Table 1: Summary of main information related to Pedestrianisation planning in Hong Kong

Title	Type	Year	Function	Purposes of Pedestrianisation	Objectives of Pedestrianisation

Chater Road pedestrianisation and public space appropriation

The analysis of the temporary pedestrianisation of Chater Road aims to provide an in-depth investigation into stationary uses practices-the *tactics*- in this pedestrianised street and shed light on the spatial characteristics as shape, shading facilities and seating availability that will generate insight for further discussion. Chater Road was the first implemented temporary pedestrianisation project, the precursor of the pedestrianisation schemes planned in the late 1990s and is a widely recognized cultural meeting space for migrant workers in Hong Kong (Law, 2002; Constable, 2007; Lorenz, 2009). Chater Road is located in the Hong Kong CBD (Figure 1), linked to a network of streets, parks, square and elevated walkways in one of the most accessible areas by public transportation in Hong Kong. The part-time pedestrianisation at Chater Road (between Pedder Street and Jackson Road) and the perpendicular Ice House Street (between Des Voeux Road Central and Connaught Road Central) was implemented on trial between 24 January and 27 January 1982 and permanently from 7:00 a.m. to midnight on every Sunday and Public Holiday starting from 31 January 1982 (Transport Department 2019, personal communication, 30 April).

Figure 1: Location of Central and Western District and Chater Road

In 1982, Hong Kong Land, the leading central district landlord, proposed the closure of Chater Road to vehicular traffic during general public holidays. The strategy of pedestrianisation was related to commercial viability opportunity. In fact, the aim of the proposed project was to attract pedestrians to the high-end retail area and promote it as a shopping destination, organising concerts and cultural events attracting a wealthy public (Constable, 2007). While during the working days the walkways system provided greater accessibility to the connected Hong Kong Land's office and commercial properties, the CBD was empty at weekends, when offices were closed (Law, 2002). Once this street was pedestrianised, it attracted among others, migrant workers that found in Chater Road an accessible and well-served meeting point, near commercial facilities with shops (World Wide Plaza) and religious institutions (Law, 2002). During the weekly closure to motorised traffic in the pedestrianised streets emerge sedentary occupations as socializing, sharing food, sleeping, dancing, reading or praying (Figure 2). This temporary pedestrianisation in Chater Road and the perpendicular Ice House street has been going on since 1982 and gradually the area has become a form of open public space during vehicle-restricted hours. The experimental character of Chater Road use marks one high-density district in Hong Kong, with an average open public space quantity (2.1 m²) per person that is lower than the average city level (2.7 m²) (Lai, 2017). The stationary activities that take place in the pedestrianised streets can be conceptualised as *tactics* of space appropriation.

Figure 2: Chater Road temporarily pedestrianised street

Spatial characteristics of the pedestrianised street

Chater Road and Ice House Street were originally planned mainly for mobility functions (of motorized vehicles and pedestrian flow). The strategy of pedestrianisation planning enacted by the governmental bodies produced a space that is analysed in this section. The *tactics* -stationary uses- that emerge once the streets are closed to traffic suggest that the spatial characteristics of the streets might accommodate both mobility uses and stationary uses. The data here presented on the spatial features, design, land uses and establishments fronting the streets of the Chater Road pedestrianised area were collected through the on-site survey. This inventory was then recorded on geographic information system (GIS) and integrated with a dataset drawn from the Outline Zoning Plans. This plan is prepared by the Town Planning Board and the Planning Department and illustrates the designated land-use (commercial,

open space, road) and transportation patterns in every planning area (Chapter 131, Laws of Hong Kong).

The pedestrianised area consists of a 300m long by 22m wide street (Chater Road) and a 140 m long by 15m wide street (Ice House Street) that are closed to vehicular traffic during general holidays from 7 am until midnight. The area consists of two to three one-way traffic lanes plus loading bays in Chater Road and one-way traffic lane plus loading bay in Ice House Street. The street space is allocated for about the 53% (4558 m²) to motorized vehicle mobility with a concrete surface, while the remaining 47% (4095m²) is planned for pedestrian mobility with a paved surface. When no motorized vehicles move through this area, a total of 8653 m² (more than a football pitch) become a space that unites functions of non-motorized mobility and public space.

The function of non-motorized mobility is determined by the pedestrian flow generated by and from the three-mass rapid transport (MTR) exits located in the area and the bus stops and taxi stand in the streets surrounding the pedestrianised area, as well as street-level pedestrian flow from the surrounding area. The entrances to the commercial buildings and the luxury retail shops fronting the streets are additional pedestrian flow generators. During the motorized access times, this is channelled through the sidewalks and constrained by railings that do not allow pedestrians to randomly cross the roadway. When the area is closed to motorized traffic, pedestrians can potentially walk in any location of the street, making the railings lose their primary function. Similarly, the curb that separates the elevated sidewalk from the roadway loses the primary function of discouraging vehicles from driving on the sidewalk and makes this step open to multiple functions, other than mobility ones.

The pedestrianised area is characterised by two additional spatial characteristics that once motorized traffic is not allowed in the street, might contribute to the emergence of multiple uses of the streets (as stationary uses). The trees and landscaped areas that are planted in the pedestrianised streets can create shading and this condition can create favourable settings for sitting eating or any other stationary uses. In addition, the 621 m² elevated walkways that connect the commercial buildings, the MTR exit and bus stop canopies can provide shading and protection under adverse weather. These elements were purely planned with the aim of facilitating mobility functions, in one case to facilitate the pedestrian flow between commercial buildings and in the second case to ease the transition from a mobility area. Eventually, once the streets are closed to motorized traffic the shading and weather protection created by the skywalks and transport stop canopies can create wide weather protected areas for multiple uses.

Stationary activities in the pedestrianised street

In order to examine the *tactics*, stationary uses that emerge in the pedestrianised area, the purpose of this part of the study is to investigate the space occupation pattern of people in the street. The method applied is behavioural mapping, this links the design features of the setting with the behaviour of the occupants in both time and space (Bechtel and Zeisel, 1987; Mehta, 2009). This was based on three phases: on-site Structured Direct Observations, on-site video recordings of stationary activities along the full length of the area and geolocation of the activity points on Geographic Information System (GIS). Stationary activities data are information on the location where people gathered and socialized. All data were geolocated on GIS maps as points and added to the pedestrianised area dataset described in the previous section. Data were collected for one pilot study on Sunday, as pedestrianisation in-

place day, for one time-slot (1 pm) on January 2019. Observations were made during a day with moderate temperatures and climate conditions.

The Structured Direct Observation allowed to identify multiple stationary activities emerging in the pedestrianised streets (Figure 3). The main activities are socializing, sharing food, playing, talking on the phone, dancing or singing, taking a selfie, sleeping, reading, eating individually or using the phone. The average population density of 0.1 people per m² in the entire area is not quite indicative of the clustering of activities in a specific setting.

The Structured Direct Observation allowed to identify some general pattern of use of the space. Firstly, the street space is mostly dedicated to active behaviours as singing, dancing or distributing flyers. Secondly, the sidewalk area is appropriated by people that occupy the space, sometimes sitting with cardboards and gathering in groups. The specific area of the sidewalk where stationary activities are observed is in the area near the railings and the area near the curb. It is observed that the railing is used as a seatback while the curb is used as seating space. These two specific areas might be used as incidental seating space when the street is closed to traffic and they lose the primary function of directing a (pedestrian or vehicle) traffic flow. Stationary activities cluster in a few main areas of the street. These correspond to the shaded areas created by the three elevated skywalks and the public transport canopies. This suggest that when the access to the street is closed to motorized vehicles, the shaded space under the walkways or under the public transport canopies can accommodate stationary uses.

Figure 3: Stationary activities in Chater Road pedestrianised area

Discussion and conclusion

Based on current academic research this article set out one key question for pedestrianisation planning in Hong Kong: to what extent does planning for pedestrianisation consider mobility and stationary uses? we tried to answer it with the content analysis of the purposes and objectives of pedestrianisation policies and planning strategies. This highlighted that the increase of stationary activities in public space has never been considered as the main purpose of pedestrianisation. This was initially planned to promote the mobility function of pedestrianised urban streets recognizing walking as a transport mode. In the pedestrianisation policies the selection criteria of priority locations based on high pedestrian flow, the type of pedestrianisation to be planned based on vehicles loading

access and the assessment criteria for implementation based on traffic management requirements are parts where the focus on mobility function is evident.

Drawing upon De Certeau theory of strategies and *tactics* (De Certeau, 1984) this article presented Chater Road temporary pedestrianisation as a case study. It highlighted how the strategy of the pedestrianisation policy and planning are related to the commercial viability of the area and the mobility function in the design of the street. These strategies are negotiated through *tactics* based on the needs of users. This article shows the empirical evidence of stationary uses emerging from behavioural research of Chater Road temporary pedestrianisation. This area unites the function of moving through the pedestrianised streets as well as lingering and interacting between user. Although the spatial characteristics of the area have not been planned to encourage public stationary use, once the streets are closed to motorised vehicles, these becomes setting of multiple *tactics*, stationary activities as socialising, dancing, sleeping or sharing food. In particular the behavioural mapping shows that activities cluster on the curb of the sidewalks, near railings and mostly under the skywalks that become shading devices. Through the evidence of this case it is possible to inform how pedestrianised streets can be potential spaces where people can move through the city as well as have social interactions, communal sharing and cultural expression, in one-word social wellbeing.

This study reported one pilot-study observation of the pedestrianised area. Further research needs to extend the analysis to a wider number of pedestrianised streets cases. In addition, the total occupancy and the observations that emerged from Structured Direct Observation investigation can be further integrated analysing the occupancy related to specific spatial attributes of the pedestrianised streets (for example curb area occupancy and shaded area occupancy). This can highlight some directions for a planning agenda aiming at increasing the social wellbeing in similar contexts.

Planning for accessibility and sustainable mobilities

Comparing Implementation Approaches in Mobility Innovations: The ECCENTRIC Project in Madrid

Ángel Aparicio¹

¹*Universidad Politécnica de Madrid (UPM), angel.aparicio@upm.es*

Abstract: Innovation is often considered as a mostly linear process, piloted by visionary researchers, technicians and decision-makers to get new concepts implemented. This linear concept collides with much of contemporary thought on public policies, social action and collective thinking or knowledge creation. This paper illustrates this by analysing the planning and implementation processes of eleven measures in Madrid between 2016 and 2019, in the context of the EU Horizon 2020 *ECCENTRIC* project. The experience can be seen as a real-life experiment: different teams were charged with the implementation of each measure; although the territorial, political and social context was the same in all cases, the contents of the measures were different and each team had to find its particular route, sometimes getting momentarily lost, and sometimes arriving to unexpected destinations. The experiences of these teams offer an excellent basis to identify the essential traits that innovative measures have, and the alternative methodologies that planners and professionals may mobilise; not to get innovations implemented as initially planned, but to put innovations at the service of transformational public policies. Taking a wider understanding of their context, planners can embrace innovation critically and contribute to strengthen the local democratic discussion.

Keywords: Sustainable mobility; innovation; decision-making; planning theory

Introduction

The understanding of innovation processes in transport relies largely on Geels' (2012) description of socio-technical systems through a multilevel perspective (MLP). In accordance with this concept, changes in transport are mostly incremental, based on innovations produced by the incumbent stakeholders (mainly the transport industry), and only exceptionally of a disruptive nature, based on innovations produced by niche stakeholders challenging the dominant position of the incumbent industry and decision makers. In both cases, implementation of innovation is seen as a mainly lineal process in which research results move forward to pilots, full-size demonstrations and finally reach the market, eventually failing to move from one of these stages to the next one and perishing. Whereas this model can rightly describe wide technological developments (e.g. electro-mobility), it does not seem to capture the complexities of innovation implementation in particular contexts, such as cities.

In practice, the innovation process is far from linear, and this is particularly obvious at the demonstration stage in urban environments. The experience of large European Union's (EU) demonstration projects in cities show the lack of linearity of the innovation process, as many

innovations do not follow the simple stages of design, implementation, operation and upscaling. Along any of these stages, many innovative measures fail to move forward, and others undertake substantial changes. This can be the consequence of the interaction of the measures with their local context (Hodson et al, 2017). They can also be the consequence of the adaptation of the measure at stake with the elusive concept of *public interest*: transport is not a stand-alone, isolated policy sector but a part of a broader set of public policies serving the political agenda and priorities of those in charge.

From a public policy perspective, demonstrations become not only a critical stage of the innovation process, but also of a broader knowledge-creation process. A process that moves away from the rigid, external hierarchies of the Porphyrian tree, but which is also elusive to be described through the Deleuzian concept of rhizomes. The pragmatic tradition can be useful in this particular situation: an idea agrees with reality, and is therefore true, if and only if it is successfully employed in human action in pursuit of human goals and interests, that is, if it leads to the resolution of a problematic situation (Westbrook, 1991). In the context of innovation in urban transport, demonstration actions are asked to address a concrete challenge; however, this challenge is not the one defined by the researchers and experts that developed the original idea; the challenge has to be so in the terms defined by the particular political context in which the demonstration takes place; in other words, the idea has to be embedded within the larger perspective of the identification of the public interest in each particular local context.

The paper is organised in three sections, besides this introduction. The next section provides an overview of ECCENTRIC, a European Union's (EU) demonstration project running between 2016 and 2020, concluding that the demonstrations carried out by the project in Madrid can be classified into three different categories, with specific challenges in terms of implementation and with different knowledge creation processes and potential: the "means-focused", "market-focused" and "values-focused" measures. It is followed by another section analysing the knowledge creation characteristics for each category, suggesting that values-focused measures can be better understood along the lines of neo-pragmatic epistemology. The last section concludes providing considerations to streamline the implementation of research results, and particularly those of a "values-focused" ambition by taking into consideration the political context since the initial steps of urban transport research, rather than postponing it to the demonstration stage.

The ECCENTRIC demonstration project

CIVITAS stands for "City Vitality and Sustainability". It is a brand name grouping most of the research projects on urban transport within the European Union's Framework Programmes on Research and Development. The idea of branding urban transport research under this name started in the late 1990s, and was formalized in the 6th Framework Programme, in 2002. Since then, five generations of CIVITAS projects have followed: CIVITAS I, CIVITAS II, CIVITAS PLUS, CIVITAS PLUS II and the current CIVITAS H2020. Key elements of CIVITAS are (1) a focus on demonstration, (2) strong participation of cities and cities leadership in its flagship demonstration (also called living lab) projects, (3) strong top-down monitoring of projects, (4) focus on dissemination and replication, including annual conferences (CIVITAS Forum) and a diversity of

networking and dissemination tools (official website, newsletter, social media, publications with common guidelines...). CIVITAS has become to the European Commission (EC) “an engine of urban mobility innovation” (EC, 2013). Although formally financed by the EU’s Research and Development budget, its demonstration focus makes it closer to the instruments the European Commission manages to support the objectives of the Common Transport Policy as defined in the various White Papers on Transport (EC, 2011). CIVITAS is also loosely connected with most of the EU’s initiatives on urban issues, like the broader EC’s urban mobility package (EC, 2013).

The freedom of cities for defining their own projects (including the measures to be implemented and their particular characteristics, location, goals...) and the accompanying measures for public participation and integration within the cities’ plans are constrained by an increasingly stringent monitoring and reporting framework, largely predefined by CIVITAS. The framework favours quantitative metrics, which is helpful for benchmarking and for encouraging replication in other cities, but this comes with a risk to reduce the debate to transport technicalities, and to divert attention from the broader picture of the cities’ vision and priorities.

It is worth noting that CIVITAS is not targeting particular social groups or urban areas within cities. CIVITAS builds upon a simplified vision of citizens as individual users, rather than as members of social groups and particular communities. The same can be said about the CIVITAS’ concept of *city*. The ECCENTRIC project is a good example of a concrete effort to overcome these limitations. ECCENTRIC was selected under the 2015 CIVITAS call. Its basic hypothesis is that mobility needs in high-density districts in the urban periphery are different from those in city centres, and that innovative measures must be tailored to the specific needs of each community and place (ECCENTRIC Consortium, 2016). ECCENTRIC in Madrid intended to move away from the traditional approach in the design and implementation of mobility measures, although it was unclear at its conception to what extent the expectations of traditionally marginalised social groups could be met by the project.

ECCENTRIC (Innovative solutions for sustainable mobility of people in suburban city districts and emission free freight logistics in urban centres) is one of the three demonstration projects funded by CIVITAS within Horizon 2020. ECCENTRIC started in September 2016, and includes the cities of Madrid, Munich, Ruse, Stockholm and Turku. These cities have in common previous experience in the implementation of sustainable mobility policies and measures, and a rising demand to implement high quality and viable solutions for neighbourhoods outside the city centre. Briefly described, the challenge for these cities is to demonstrate innovative sustainable urban mobility solutions in peripheral city districts, serving as living labs.

The living lab in Madrid is Vallecas, a district at the south-east of the municipality, with 328,000 inhabitants. The area consists of several well-defined neighbourhoods, all of them with a population that has consistently decreased in the last 10 years (1.23%). The only exception is the neighbourhood *Casco histórico de Vallecas*, which almost doubled its population (+96.7% or 38,218 inhabitants), due to a newly developed area known as *Ensanche de Vallecas*, which started to materialize in the past decade.

The project in Madrid includes eleven measures. Their main contents are presented in Table 1. The measure code in the table will be used to refer to the respective measures throughout the remaining of

this paper. The link of the measures to the living lab is very different. Only four measures (measures 2.8, 4.6, 4.7, 5.1) are clearly targeting Vallecas. Another three measures (measures 2.3, 4.1, 5.8) refer to technological innovations, which could have been demonstrated in any other part of the city. Finally, four measures are taking place at a city-wide level (measures 3.3, 6.2, 7.1, 7.6).

Table 1. The ECCENTRIC measures in Madrid.

Code	Measure name	Main contents
2.3	Adaptive parking management based on energy efficiency and occupancy	A smart parking management scheme to be tested in the demonstration area. The system will include priority for HOVs and clean vehicles.
2.8	Mobility management strategies for vulnerable groups with a gender approach	A focus on vulnerable groups (children and elderly), identifying actions through a collaborative process and building upon inputs from recent psychology research. For children's mobility, the methodology will build upon the successful results of the previous project STARS. The actions focused on the elderly will be based on the projects implemented in Madrid regarding health and active life for them.
3.3	Open platform for multimodal mobility information and services	An open mobility data portal with multimodal information from different sources (public and private transport, traffic, public bicycles, air quality, etc.) will be created as a basis for the development of new mobility information services and products by interested companies, institutions and individuals.
4.1	Innovative and participative approach to traffic safety at neighbourhood level	A comprehensive road safety study, supported by the analysis of key urban parameters serves as a basis for the development of a GIS-based application collecting road safety incidents. Residents' safety perception is also analysed through a systematic review of social media and other sources of information.
4.6	Pedestrian friendly public space outside the city centre	Improving walking conditions in one of the car-oriented areas in Vallecas. A high quality pedestrian itinerary (<i>Paseo Miradores</i>) is created, improving the quality of the public space.
4.7	Enabling cycling outside the city centre	Prioritising the shared use of road space in the demonstration area. Bike ownership will be fostered through the implementation of innovative parking solutions for residents and for users of public transport hubs in the demonstration area.
5.1	High-level public transport service corridors in peripheral districts	The objective is to improve the quality of the bus service and increase the bus patronage on a tangential corridor in the eastern districts. The study will assess different solutions, and one 3-km pilot section will be built, including the rearrangement of crossings, parking facilities, new signals, bus stops, etc.
5.8	Electric and hybrid buses for public transport	Service needs will be analysed to select the electric and/or hybrid bus solution. The new buses will be assigned to serve the pilot PT corridor. Buses' performance will be monitored and assessed to support future renewal plans of the city's bus fleet.
6.2	Test fleets, policy incentives and campaigns for the uptake of electric vehicles	The municipality will foster the use of electric vehicles within its own services and also by local private companies, and will expand the electric charging network in the city. Based on the monitored performance of the electric vehicles in the pilot, new strategies will be designed to promote a wider uptake of electric vehicles.
7.1	Consolidation centre with EVs and local regulations for clean urban freight logistics	Based on a detailed analysis of the urban logistics sector in Madrid, a pilot urban consolidation Centre for last mile distribution will be implemented. The pilot will include the implementation of regulatory reforms to encourage the use of cleaner delivery vehicles.
7.6	Prototype for an ultra-low emission cargo vehicle	Development and demonstration of a 5.5-ton electric truck prototype, adapted to the specific needs of Madrid's urban delivery sector. It will be tested under real conditions in order to fine-tune its design and performance, and to promote its commercialisation.

Considering their relationship with the local context, the measures above can be classified into three different categories. The first one would include measures 2.3, 4.1, and 5.8: all of them are measures of a technological content, aiming at improving the management of existing public policies (parking access control, road safety and public bus emissions); they are likely to be pushed forward mainly by civil servants working in the related technical services, and are not expected to raise much interest from the side of citizens or decision makers. They are expected to provide incremental improvements,

of a medium to long-term range, as the measure is expanded from the demonstration site to the whole of the city.

The second cluster consists of measures providing technological solutions, usually implemented by private stakeholders. Although these are mature technologies, they still need a favourable environment or context to become fully competitive compared with incumbent solutions. This is the case of measures 3.3, 6.2, 7.1, and 7.6. The third cluster refers to measures of a more political character, highly sensitive to the local context, and requesting strong leadership from local authorities. They need to mobilize a variety of stakeholders, to gain sufficient support, and to move through administrative procedures poorly fitted to support them. Furthermore, the mobility components within each measure have to be combined with a variety of other considerations of a social, urban, or economic nature. For good or bad, they are likely to gain a prominent political profile and even to generate keen political discussion. This is the case of measures 2.8, 4.6, 4.7, and 5.1.

Demonstrations as knowledge-creation experiences

All the processes leading to the demonstration of the measures were reviewed in the first half of 2019. The results of the process evaluation suggest that those in charge of the implementation of demonstration measures follow different strategies in accordance, *inter alia*, with the particular profile of the measure they are responsible for. These strategies reflect how the technicians in charge are acquiring knowledge from their experience. In the case of measures within the “means cluster”, the process is lineal, and tends to follow the taxonomies characteristics of the traditional Porphyrian tree: the most often barriers these measures encounter are described as of a *planning*, *organisational*, *financial*, *technological* and *spatial* nature, and can be addressed through minor adjustments, without requiring significant diversions from the initially established path. The knowledge acquired is shared at the conclusion of the pilot in the form of recommendations and lessons learnt to streamline future implementation. The knowledge acquired is typically of a management nature, and is applied in the form of better suited structures within the institutions dealing with innovation (through autonomous agencies, horizontal services or other solutions), earmarking resources or providing incentives for technical services to innovate as a way to gain access to additional funds or to strengthen the relationship with the research community (e.g. May, 2015). Recommendations may also include a call to tailor measures to their specific spatial contexts, introducing methodological changes in the process e.g. to include more ambitious participatory and co-creation processes, participatory budgeting and other actions.

The recommendations above are not adequate to deal with the barriers implementation processes face in the case of measures within the “market cluster”. To be successful, these measures require to put in the market competitive alternatives to the existent options, to reach final users, and to get the support of committed private or public stakeholders eager to take these innovations to the market and make them widely available. Much has been discussed in terms of how public action can speed up the access to market of innovative technological solutions: financial support and incentives during the deployment stage, supportive regulatory frameworks, public stakeholders as early adopters, risk-sharing between the public and the private sectors... (TRB, 2015). The experience from the ECCENTRIC project in Madrid merely confirms these recommendations, and the difficulties (counter-balanced by the significant potential) to establish the appropriate cooperation framework that

can lead to successful implementation. The process of knowledge creation is no longer linear, based on choice between mutually exclusive alternatives. On the contrary, the knowledge-creation process can evolve at any moment following unexpected directions as a result of the power interactions among the variety of stakeholders participating in the market. As in the powerful image of Deleuze and Guattari (1980), the path of knowledge creation evolves like a rhizome; not only because the relations of power among the stakeholders (the industry, the innovator, the regulator, the governmental decision-maker...) are not stable, but also because the knowledge acquired at a certain moment is likely to change the relative position and power of some stakeholders vis-à-vis the others. The process is not completely anarchic, though: as it goes, moments of change and reposition alternate with more stable stages, at which stakeholders take stock of the knowledge acquired. These knowledge-building stages (*plateaux* in Deleuzian terms) provide the necessary stability for stakeholders to further cooperate, increasing the likeability of moving successfully from innovation and demonstration to the market stage.

The knowledge acquired from demonstrations within the “means-focused” and the “market-focused” categories is scarcely useful for the implementation of measures within the “values-focused” group. The difficulties for implementation of these measures primarily rely neither on rigid, inappropriate or underfunded public bureaucracies nor on the reluctant involvement of private partners. They face a more substantial obstacle: a public policy model inconsistent with such measures, and that cannot accommodate them without getting into trouble and instability. Public policies, including urban mobility policies, remain dominated by the values of responsibility and efficiency. Public bureaucracies select measures on the basis of their efficiency (e.g. cost compared to benefits or targets achieved), and public action is justified by its ability to empower users to choose alternative options to the undesirable ones. Sustainable mobility measures under this cluster do not fit well within this paradigm: their impact is of a long-term nature, and it is spread over a wider range of sectors. Consider, for example, a measure to improve the quality of pedestrian networks in a neighbourhood, such as ECCENTRIC measure 4.6. If successful, it can modify travel patterns, increasing short-distance trips and changing modal split, but these impacts will affect people’s behaviour and become significant only in the long-term; furthermore, their main impacts may be of a completely different nature, for example, increasing liveability and social bonds within the neighbourhood, or be of a more dubious character, like increasing real estate prices and displacing low-income residents and small businesses. This does not mean that we should oversize our repertoire of indicators; on the contrary, it will probably be wiser to move away from the efficiency approach to a more nuanced monitoring and assessment framework.

The relevant knowledge acquired through this category of “values-focused” measures is of a transformative nature. It relates to the ambitions to act politically, to review and challenge the traditional understanding of the public interest and to build up a stronger citizenship. Knowledge acquisition becomes relevant to the extent that it allows to effectively address this wider conversation. Borrowing the wording of James and Dewey, knowledge is validated through its ability to move forward along the path of a radical democracy (Westbrook, 1991; Dewey, 1925).

Measures within the “public policy cluster” are consistent with a long-term vision of the city, which includes but is not limited to mobility issues. They contribute to create the conditions in which alternative behaviour is not only possible, but is actively supported by public institutions. They do not primarily attempt to provide alternatives to users, but rather to empower citizens to gain ownership of

their physical and political environments, by creating the conditions to increase social bonds, and to access to the public sphere regardless of the particular personal circumstances. They cannot really be legitimized by their ability to increase the options available to people, so that they can responsibly make sustainable choices; on the contrary, they are legitimized on the basis of solidarity: they provide more balanced conditions to all, decreasing inequalities. Their impact evaluation could be assessed, if necessary, not in terms of efficiency, but in terms of their effectiveness in improving social equity. As it is well known (e.g. Nagel, 1986), the cost of these measures increases with the ambition in terms of solidarity.

These measures are not likely to be successfully implemented within the framework of mobility projects like the ones promoted by CIVITAS. They need to be embedded within urban policies based on the principles of solidarity and effectiveness, which are occasionally promoted by local leaders in some cities to address major city challenges. It is only in a context of transformative change that mobility measures can yield the expected results in terms of sustainability.

This is not to say that these measures cannot be implemented autonomously. In fact, this is the way many cities are dealing with pedestrian areas, bike expansion or children, elderly and other social groups' mobility. The point is that (1) the implementation of these measures remains, at best, at the fringes of the local bureaucracy, requires enormous resources and political leadership to move forward, and cannot be streamlined within the municipality, and that (2) the actual impacts of these measures remain uncertain, sometimes generating gentrification and displacements, or increasing motorised mobility elsewhere in the city.

The living-lab approach is consistent with a vision of public policies from the values of solidarity, effectiveness and equity. It offers an opportunity to build up a shared and integrated vision among stakeholders, and to gain their involvement (Niitamo, 2006). But a living-lab approach cannot be narrowly limited to mobility issues. With its sectoral approach to urban mobility, the CIVITAS initiative (in the case of Madrid and, probably, in most of the participating cities) is successfully developing more favourable institutional and regulatory environments for the implementation of technological innovation in cities. This is positive for the implementation of measures within the “means” and “market” clusters. But it cannot successfully support the implementation of measures of a transformative nature. For doing so, it would be necessary to get out of the “mobility bubble” and reach out to broader urban policies based, not based solely on the values of responsibility and efficiency.

Knowledge creation and innovation implementation

Geels became aware of the weakness of its *socio-technological* paradigm to understand innovative processes in highly contextual, local environments like cities. In his recent publication with Hodson et al (2017), a complementary concept is presented: innovation in the case of urban transport would be a reconfiguration process of the socio-technological system, in which besides technological changes, the transition is characterised by reforms in the governance framework and by political and technical discussion and revision of the shared vision to be attained through the transition, i.e. the sustainable transport paradigm. To better understand the reconfiguration process, it is necessary to take into consideration the governance and institutional arrangements shaping it. They will help to explain

which innovations are selected for demonstration and how they are tailored to the particular conditions in each living lab. Innovation becomes closely linked to the spatial traits of particular local contexts, such as a city, a region, a social group or an industry.

The governance framework becomes particularly relevant. Whereas the original multilevel perspective, as initially presented by Geels (2012) is strongly influenced by neo-institutional analyses (DiMaggio et al, 1983), and emphasizes the homogeneity of institutions, the living lab approach takes into account the various ways in which institutional and social interests are organized through governance processes that seek to shape transitions. In the re-organization of governance processes within living labs, concrete configurations of technologies and social interests are assembled and experimented in a particular place, and provide contextualised lessons. This does not mean that the configuration process is autonomous, and that the landscape level defined in MLP becomes irrelevant. On the contrary, exogenous processes of a global (in space) or of a modal (within the transport system) nature also intervene in the configuration of the living lab experience, and in the eventual scaling-up of the innovation from the living lab to a wider area (Kivimaa, 2014).

As social and institutional interests compete to shape the reconfiguration processes, they provide revised- and usually competing- conceptions of the sustainable mobility vision they are aiming at. Indeed, the definition of the concept remains ambiguous in the EU policies on transport and research, which can be interpreted as a recognition at the EU level of the necessity to contextualize the concept in particular spatial, temporal or social circumstances. This ambiguity facilitates its adaptation to the contextual circumstances in which each living lab takes place. In short, there would be no single way of reconfiguration in transport innovation.

Is the sustainable mobility paradigm a sufficiently bold and values-charged concept to sustain such a comprehensive reconfiguration process? If so, this would provide an excellent argument for those claiming that each relevant sectoral policy should look for its own values, and generate consistent visions of fairness or equity in accordance with those values within their own spheres of influence (Walzer, 1983). Two main arguments can be opposed to this position, notwithstanding its strong appeal. On one hand, the short-sighted scope of the sustainable mobility paradigm; on the other hand, the insufficiency of reforms in the transport sector to advance on its own along the path towards radical democracy.

In spite of its widespread acceptance within the transport community (or precisely due to this wide acceptance), the sustainable mobility concept does not provide a sound-enough basis to build up the sort of citizenship envisaged by Dewey in its radical democracy vision. Banister (2008) provides a widely-accepted description of the sustainable mobility paradigm, in which citizen participation mainly plays a users' educational, awareness and acceptance perspective. The sustainable mobility paradigm moves away from the utilitarian perspective by providing a balance among social, economic and environmental objectives. But one thing is to broaden the scope of the objectives, and another one to promote values such as better informed and educated citizenship, transparent and factual-based public deliberation or providing for minimum quality of life standards. Transport can certainly contribute to that, but should not do it on its own, without getting embedded in the wider effort of the public policies implemented by the local government. In this sense, claiming that transport innovation has the potential to reconfigure local governance seems naïve, to say the least.

To provide useful knowledge, in the neo-pragmatic sense, transport innovation rather needs to take into account the political context in which it is operating and identify whether the basic contextual conditions are present. This means, that a certain innovative demonstration of a “values-focused” content should only be implemented where the local government is engaged in a political vision consistent with these values: otherwise, the demonstration will be unable to provide the expected knowledge, and will not provide any relevant progress in the search for stronger local democracies. An innovative transport measure cannot be an isolated event: it should be understood within the wider global processes strengthening democracy beyond place-specific contexts.

Conclusions

The ECCENTRIC project in Madrid has successfully proved the ability of the municipality to implement measures within tight deadlines. The local bureaucratic and technical machines have been able to successfully deal with the challenges of adaptive management to implement actions that did not fit with the usual profile of municipal actions. However, in a few cases, adaptive management may have gone a little too far, eviscerating some measures of their most innovative contents and embedding them within actions already in progress in the city. This has been the case for the measures on the improvement of pedestrian and cycling conditions (4.6 and 4.7), on the implementation of clean buses in public transport (5.8), on the expansion of electric car fleets (6.2) and on the implementation of a freight consolidation centre (7.1). Measure 5.1 was the only one that had to be abandoned. It aimed at implementing the first section (some 3 km) of a bus corridor linking several neighbourhoods in the east periphery of the municipality, and its failure was due not only to the lack of sufficient political support from the local government, but also to the complex needs of the affected area: residents preferred that the municipality’s investments were dedicated to actions outside the mobility realm. There was a technical focus on bus priority that left aside critical issues regarding the public’s priorities and preferences, as well as funding availability. When the preparation of the construction project had been completed, decision makers realised that the concept provided little value for money and would not be backed by a majority of residents.

The project in Madrid also showed the difficulties to actively engage some of the stakeholders initially envisaged. This concerned stakeholders at the decision-making level (who tended to see their participation as unnecessary in the absence of critical problems), and residents (as the transport actions undertaken by the project, although relevant for them, were not of first priority compared to more urgent, non-transport related issues in their agendas). The central role played by the local civil servants involved in each measure became even more relevant to navigate the local bureaucracy, identify opportunities and take the actions to reasonable completion.

In general, the implementation of most measures was facilitated by its inclusion in a CIVITAS project: the project mainly served to provide the “manpower” needed to dedicate the necessary effort to actions that otherwise would have hardly been seen as a priority by the technical departments involved. The project also served to check the adaptive capacity of the local government and bureaucracy to cope with the needs of innovative actions. For example, it showed some contradiction between the top-down approach in CIVITAS (in which participation is limited to the “how”, and not to the “what” of the measure) and the general trend of the local government to foster participatory

budgeting for the selection of actions (in all policy areas) in the neighbourhoods. It also showed the tensions between the long procedures for project design, budgeting and construction in the city (fully justified by public control procedures and by the need to establish rigorous selection of public investments) and the tight deadlines established by the CIVITAS initiative within the four years envisaged for the project.

The suitability of the CIVITAS concept to the project in Madrid also showed some shortcomings. CIVITAS has a strong mobility and technological focus, not fully consistent with the particular conditions in Madrid: the focus of the project in Madrid was a large low-income peripheral district, whereas CIVITAS is usually targeting city centres with high visibility; secondly, there was a strong interest on equity and social impacts in Madrid, whereas the social focus of CIVITAS is limited to the public acceptance of new concepts. The contextual conditions in Madrid were challenging, with a new local government fighting with strong financial shortages due to the overspending of its predecessors, among others, in a multi-billion urban motorway project. It could be said, at the very least, that CIVITAS is poorly adapted to intervene in such kind of complex social, financial and political contexts. It is worth pointing out that the CIVITAS approach did not suited well the local government effort on participatory democracy. Participatory aspects were relevant only in some of the measures included in the project, and the involvement of decision-makers was not reviewed in detail in the project proposal. CIVITAS technological priorities could have at best a minor impact on the living conditions of the residents, and were unlikely to raise high interest among them. A more profound mismatch can be pointed out: the CIVITAS focus on innovative technologies and its deployment in the mobility market is far away from the political priorities in many cities, and it is not likely to induce any substantive process to strengthen local participatory democracies or to increase local cohesion.

**Sustainable and connected infrastructure networks and
urban regions – transition towards integrated planning
of urban nodes on TEN-T corridors
- WORK IN PROGRESS -**

Abstract: Achieving a smart, green and integrated transport system is essential for the (social)-economic and environmental vitality of European urban regions. In order to better integrate urban nodes into TEN-T corridors, the challenges of multimodal connections between long-distance and last-mile transport have to be tackled from both freight and passengers' perspective. Different spatial scales, modalities, sectors and stakeholders have to be taken into account when improving mobility, infrastructure and spatial development in both urban nodes and corridors. To tackle these challenges a research programme has been developed, supported by EU's Horizon2020 (Vital Nodes), which analyses best practices, experiences and opportunities in various urban nodes in Europe. This paper addresses the approach deployed by the Vital Nodes-project to integrate investments in mobility, infrastructure and urban development from (inter)national/corridor, regional and local perspectives. To this end, the paper discusses results from case studies in urban nodes as Gothenburg, Vienna, Rotterdam, Genova, Strasbourg, Turku, Hamburg, Budapest and Mannheim and related TEN-T corridors, including an analysis addressing their main challenges. The paper concludes by exploring the main elements of such transition that will improve the integration of urban areas into the TEN-T corridors and the vitality of the urban regions of tomorrow.

Keywords: integrated spatial and infrastructure planning, multi-modal infrastructure, multi-level governance, urban nodes

1. Introduction

The worlds of transport and spatial planning are in a major transition, coping with a large number of changes and (the need for) related innovations. This relates to global challenges related to climate change, energy transition, environmental pollution, globalisation, ageing infrastructures as well as densification, urban growth, liveability and growing passenger transport and freight volumes. Transport and logistics provides vital functions to the European society, enabling economic growth and access to jobs and services, but also create issues of CO2 emissions, environmental pollution, fragmentation and land-take. *Urban nodes* are crucial for the effectiveness of the core network of Trans-European Transport Network (TEN-T), as they are the origin and/or destination of most long-distance transport flows, for both passengers and freight. Several trends and major developments can be seen that influence the relation between the TEN-T (core) network and the urban nodes – e.g. changing freight flows via the New Silk Route between China and Europe. Developments that (may)

affect spatial-economic growth, mobility and freight flows in and between metropolitan areas, thereby impacting infrastructure networks and liveability, especially in urban areas. Important trends and transitions in the field of transport include (Linden and Linssen, 2018b):

- Growing urbanization and densification;
- E-Commerce, 24/7 delivery and access to multiple distribution channels;
- Urban and logistical sprawl and development of micro and midi hubs;
- Agglomeration, e.g. development of XXL warehouses (economics of scales);
- Growing demand of flexibility in freight transport and logistics;
- Increasing number of cities with low-emission transport policies and sustainable transport modes (related to Sustainable Urban Mobility Plans, SUMPs);
- Conflicting transport flows between freight and logistics, and person transport.

These trends are coinciding with a transformation in Europe's transport system as discussed in the Transport White Paper by the European Commission (COM, 2011) focusing on e.g. limiting transport emissions and contributing to accessibility and liveability in cities. In this regard urban nodes specifically are major areas in which public and private parties and society should join forces to cope with transitions and related challenges. The local context and characteristics of a specific place are however making an effective integration of a node in the TEN-T network more complex. As urban logistics and freight transport grow, innovate and increasingly impact socio-economic development in urban areas, accessibility and spatial-environmental quality of urban regions, there is need for a transition towards integrated planning approaches. An integrated planning of spatial, mobility and infrastructure that takes into account different spatial scales, sectors, modalities and stakeholders.

Currently infrastructure development, mobility and spatial planning are mainly separate worlds, which have not yet been integrated although the many challenges which call for an integrated and innovative approach. For an integrated approach of effective and sustainable incorporating urban nodes on the European transport corridors, a variety of actors need to collaborate early on in the decision making process, such as urban planners, freight and logistic operators, infrastructure operators and coordinators and financiers. This allows not only integrated perspectives and solutions, but also integrated investments in mobility, passenger transport, freight and logistics and infrastructure from local, regional and (inter)national/corridor perspectives. Funding is key when implementing integrated solutions and improvements. However, the conventional shaped worlds of infrastructure, urban mobility and spatial planning are often funded within their own sector. An integrated approach needs integrated funding. A (sustainable) integration of urban nodes into the TEN-T network requires coordination in public funding at European, national and/or local level but also with private funding.

This paper aims to explore how the transition towards an (sustainable) integration of urban nodes into the European TEN-T corridors can be stimulated. To this end, we build upon the results of the European Horizon 2020 project *Vital Nodes* (<https://vitalnodes.eu>). First, the paper discusses the approach of the Vital Nodes project, which has been applied during workshops in a series of urban nodes in 2018-2019, including Vienna, Rotterdam, Gothenburg, Budapest, Hamburg, Genoa, Turku, Strasbourg, Mannheim. Next, we discuss a specific case – the urban node Vienna – addressing good practices and tools that support tackling the occurring challenges. The paper concludes with a discussion of the Vital Nodes' project results and recommendations for integrated planning of urban nodes on the TEN-T corridors.

2. Integration of the worlds of spatial and infrastructure planning

To cope with current challenges, a focus on innovative technical solutions alone, will not be enough. There is need for a transition in planning connecting between the worlds of infrastructure, mobility, freight and logistics, and the world of urban and spatial development. An approach in which there is attention for soft innovations, addressing the multiplicity of the challenges by integrating different spatial scales, sectors, modalities, stakeholders, funds and levels of governance. This need for integration has been acknowledged by key stakeholders such as National and Regional Infrastructure Authorities and DG MOVE, as well as the Coordinators of the TEN-T corridors, who stress the importance of integrated strategies, platforms for exchanging experiences and multi-level governance approaches (Philips et al., 2016). Meaning a need to combine policy objectives as promoted by the Commission in the 2013 Urban Mobility Package (UMP) of the TEN-T regulations and the Sustainable Urban Mobility Plans (SUMP) (EC 2013, COM 2012, 2013). This asks for forward-looking practices and integrated approaches, which both enhance transport solutions and stimulate synergies with other urban functions (Balázs et al., 2016). Viewing the complexity of the current and future challenges, there are no ‘silver bullets’ (CEDR et al., 2018; Broesi et al., 2018).

The Vital Nodes project is funded as part of the EU Horizon 2020 programme, to investigate integrated planning approaches. The main objectives of the Vital Nodes project are (Vital Nodes Consortium, 2017; <https://vitalnodes.eu>): to deliver validated recommendations for a more effective and sustainable integration of all 88 urban nodes into the TEN-T corridors, focusing on freight and logistics; and, to establish a long-lasting European expert network for safeguarding long-term continuity in knowledge and implementation. As part of the Vital Nodes project challenges, drivers and barriers, good practices and opportunities are analysed in various urban nodes and TEN-T corridors. To this end, Vital Nodes has brought existing networks together and has been working on ensuring long-term engagement and recommendations for research and funding needs as well as input to adapt the TEN-T and CEF (Connecting Europe Facility) guidelines.

3. Approach: analysis of multiple dimensions of practical cases

The approach applied in Vital Nodes is based on the Networking for Urban Vitality (NUVit) concept (see Arts et al., 2015, 2016; www.nuvit.eu) that comprises various dimensions (see Figure 1). The spatial and network dimensions regard the linkages between transport infrastructure, freight logistics and land-use. This includes innovative solutions for freight logistics. Combining spatial and network dimensions results in potential synergies that have to be considered, at which the time and value dimensions are important to analyse and discuss. Finally, to become effective integrative planning, it is needed to develop an adequate institutional approach and dealing with implementation issues. Subsequently, transport infrastructure can be carefully coordinated with spatial developments resulting in tailor-made solutions to the local situation (landscaping, context sensitive design), enhanced vitality of regions (at the level of a Daily Urban System) and well-functioning (inter)national transport corridors and networks.

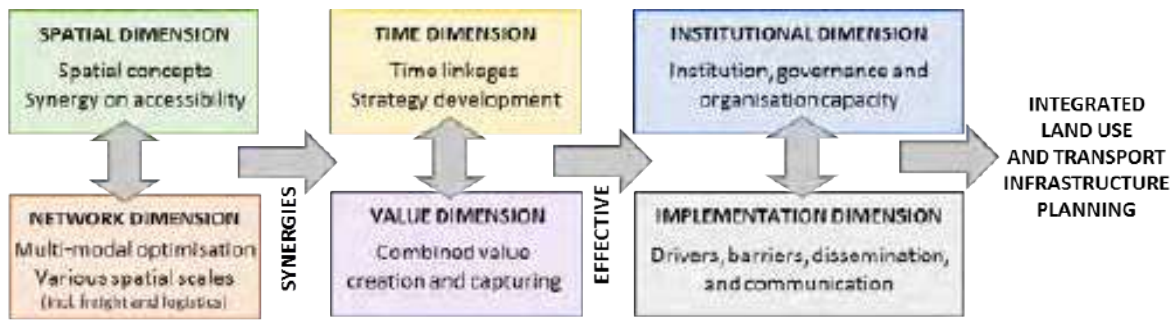

Figure 1: Linkages between different dimensions (based on Arts et al., 2016).

During 2018 and 2019 the Vital Nodes project has conducted numerous workshops throughout Europe in urban nodes such as: Vienna, Rotterdam, Gothenburg, Budapest, Hamburg, Genoa, Turku, Strasbourg, Mannheim, Ljubljana, Munich, Duisburg, Venlo, Tallinn, Bilbao, Antwerp Cologne, Piraeus and Gdynia. Within these workshops, (local) challenges have been identified, drivers and barriers discussed and good practices with potential impact presented (Poppeliers et al., 2018a; Linden and Linssen, 2018a). By bringing together results of the workshops, knowledge and information and make them available for European stakeholders, infrastructure providers, investors and urban nodes a solid basis has been developed to formulate recommendations to the European Commission for stimulating an sustainable and efficient integration of the transport network in Europe.

An important aspect of to the Vital Nodes project for planning practice proved to be bringing together stakeholders from different disciplines and backgrounds to discuss challenges of the specific urban nodes. Stakeholders present at the workshops included a variety of stakeholders: national government representatives, road and waterway authorities, railway infrastructure managers, environmental agencies, representatives of the airport, provinces/regions, service providers, urban/spatial planners, city representatives regarding spatial planning, mobility and environment, port authorities, hub operators, public transport operators, representatives of the chamber of commerce, company representatives and research institutes. In addition, external experts were also participating in the discussion to share good practices from elsewhere in Europe and to reflect on the discussions. While widening their own knowledge the participants in the workshop often came to a real understanding of each other's issues and worked together towards integrated solutions (see Figure 2).

Figure 2: Vital Nodes workshop in Gothenburg, April 2018, participants discussing the challenges of the urban node Gothenburg, while using maps.

An important issue proved to be raising awareness amongst stakeholders on the role of the urban node in the European TEN-T network and the role of freight, logistics for the urban region. In order to create this understanding a set of tools was used and developed (van der Linden and Linssen, 2019) – such as the use of ‘research by design’ and mapping the functional urban area – which proved helpful in developing possible solutions addressing the specific circumstances of an urban node.

During the discussions, participants showed their interest in the linkages between the different geographical scale levels (of (inter)national corridor, urban region and local neighbourhood) and the role of ‘their’ urban node in the context of the TEN-T corridors. Based on the objectives of the participating stakeholders and the Vital Nodes project, the data and information provided, the Vital Nodes appraisal methodology and urban node typology (Poppeliers et al., 2018b), discussions focused on the specific challenges of the urban node regarding infrastructure, freight and logistics and spatial planning. The data and information collected on forehand in a so called ‘Fingerprint’ (Linden and Linssen, 2018b; Poppeliers et al., 2018b) provided insights in – and common understanding about – the characteristics of the node, similarities and differences between nodes that might specify drivers or barriers for challenges, impacts and solutions, and good practices usable for other nodes.

The introduction of one or more European good practices, to help the stakeholders in the urban node to make a mind shift from thinking in barriers and obstacles towards (potential) solutions and options, has shown to be an effective method. Besides, several good practices connect local, regional and corridor level, so stakeholders will get concrete input and inspiration from other European cities and regions on how the relation between the urban node (local, regional) and the corridor level might be improved (Poppeliers et al., 2018c). Cases across Europe show that coordinated optimisation of infrastructure and spatial development at the level of the Dialy Urban System (DUS) can be key to safeguard corridor interests while solving local spatial conflicts. Moreover, the other way around, small measures at local scale may help to solve bottlenecks at the DUS level and the corridor level. For instance, at urban ringroads often up to 30% of the traffic is local. ‘Shaving off’ some of this share by relatively small local mobility measures (which may regard other modalities; e.g. public transport, biking) may reduce traffic sufficiently to (partly) solve congestion bottlenecks at the urban ringroad. If such a ringroad is part of the an (inter)national corridor such ‘acupuncture’ measures can be of importance to the (inter)national transport network (see also Arts et al. 2016).

Following a discussion on solutions, drivers and barriers, the different scale levels are again related to each other while discussing the added value for the local, regional and European level. The added value for Europe relates to the integration of the urban node in the TEN-T network. Special attention is given to drafting business cases with potential win-wins for both the urban node (local, regional scale) and the corridor (European scale). Identifying this (potential) European added value that can be realized in the urban node (city and region) will be direct input for the recommendations of the Vital Nodes project to the urban node and the European Commission.

4. Case study urban node Vienna

As an example of the urban nodes workshops conducted in the Vital Nodes project, the case of Vienna is described in more detail below. Among the participants were a variety of representatives of the national and regional government, municipality, railway infrastructure manager, road administration, waterway administration, airport, chamber of commerce, research institutes and the

private sector. Thereby knowledge was brought together from the fields of infrastructure, freight and logistics, spatial planning, environment, economy and finance.

The Austrian capital of Vienna with around 2.6 million inhabitants is located on three core network TEN-T corridors – the Baltic Adriatic, Orient/East-Mediterranean and Rhine-Danube corridor – including road, rail, aviation and waterways for both freight and passengers (see Figure 3).

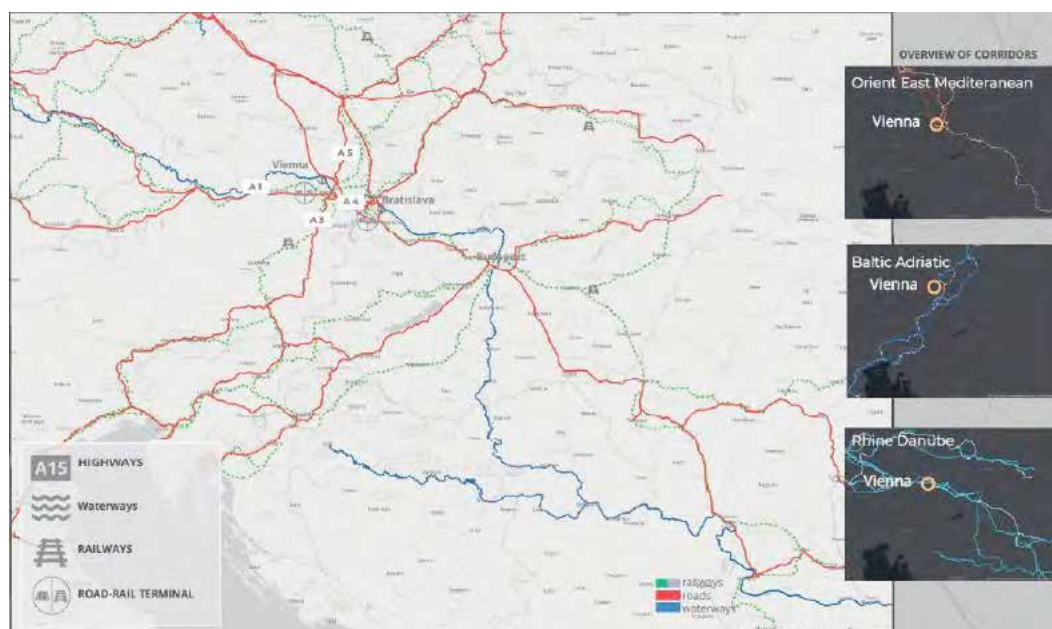

Figure 3: Vienna's location on three TEN-T corridors (van der Linden and Linssen, 2018b).

On each of the corridors Vienna is located mid-way, heightening the urban node's importance to enable well performing transit flows. It is noted that the Baltic-Adriatic flows by road are mostly transferred along Bratislava, with which Vienna has a strong relation. As a border cohesion region future investments in road and rail infrastructure are foreseen between Vienna and the Czech border, which might draw the North-South flows over Vienna instead of via Bratislava (van der Linden and Linssen, 2018b; Poppeliers et al., 2018a).

The urban region of Vienna is fast growing and major urban developments are planned (Vienna City Administration, 2014; van der Linden and Linssen, 2018b, 2018c) on Vienna's East in Aspern, Vienna's Urban Lakeside (Aspern Seestadt) and through various mixed-use urban development zones like the inner city housing projects such as the Sonnwendviertel in the central station district and the development of the Nordwestbahnhof. Impacting the regional level are: a railway connection between Hütteldorf (western side of the city) and Meidling (southwest), and the development of an additional runway of the airport. Also cross-border links are discussed such as the link between the airport and Budapest via the Eastern Rail line, an upgrade of the Pressburgerbahn between Hainburg (on the border with Slovakia) and Bratislava. At a higher spatial scale many investments are done in improving the TEN-T links at the corridors. All these developments are undeniably influencing the transport flows of passengers and freight on different levels, having its effects on the needs for consolidations centres, and hubs at different scale levels as part of logistics oriented development.

With these developments issues of multi-level governance and integrated planning becomes pressing related to the scattered responsibilities of the surrounding municipalities (local planning), the Vienna city administration with coinciding borders of the Bundesland Vienna, the neighbouring Bundesland Lower Austria, and the nearby national borders.

5. Challenges of urban nodes

Through discussions amongst all participating representatives, challenges related to the urban regions have been discussed, using maps on local, regional and (inter)national/corridor level as tools to guide the discussion and clarify specifically mentioned aspects. From the discussions in the urban node Vienna, three challenges were identified that proved to be exemplary for the urban nodes in general (van der Linden and Linssen, 2018c; see also Figure 4):

- (Lack of) logistics oriented development;
- Spatial planning at functional urban area level;
- Robustness and vulnerability of the network.

5.1. (Lack of) logistics oriented development

Vienna is centrally positioned on TEN-T corridors. However awareness of this position amongst the stakeholders in the region proves to be rather limited. However, the position on the TEN-T corridors shows the importance of the urban area for neighbouring areas and countries regarding freight flows. Multiple corridors (road, rail and waterway) are crossing the Austrian capital, meaning that the impact is substantial. Therefore the urban region has to deal with logistics in its development to be a vital node in the European network accommodating liveable housing areas and facilitating freight transport. Rethinking ‘functions’ of urban areas is essential.

5.2. Spatial planning at functional urban area level

Because of growing population, urbanization and increasing transport flows of persons and freight/logistics, a real challenge of space occurs. Many different functions are fighting for space and their place in the city. There is need for mixed land uses and attention for socio-economic relations to maintain a liveable city. This relates to both central city and peri-urban areas, urging for multi-level governance and integrated planning at the level of the Daily Urban System (DUS, for persons transport) and the Functional Urban Area (FUA, for freight transport). In other urban nodes such as Budapest similar challenges have been identified. NB: the workshop results indicate that the FUA is larger than the DUS which is usually the focus of attention in policy-making.

5.3. Robustness and vulnerability of the network

One of the main challenges discussed during the workshops is that persons and freight transport compete for limited infrastructure capacity at national, regional and local level. In Vienna the network proves to be vulnerable, especially the crossings of the Danube via road and rail. This asks for alternative routes, e.g. via a South-East bypass. Optimizing the use of the network and looking for opportunities to use the river Danube for inland waterway transport could be possibilities to find multimodal solutions. This vulnerability and robustness of the network is also a major challenge in the urban region of Mannheim in Germany.

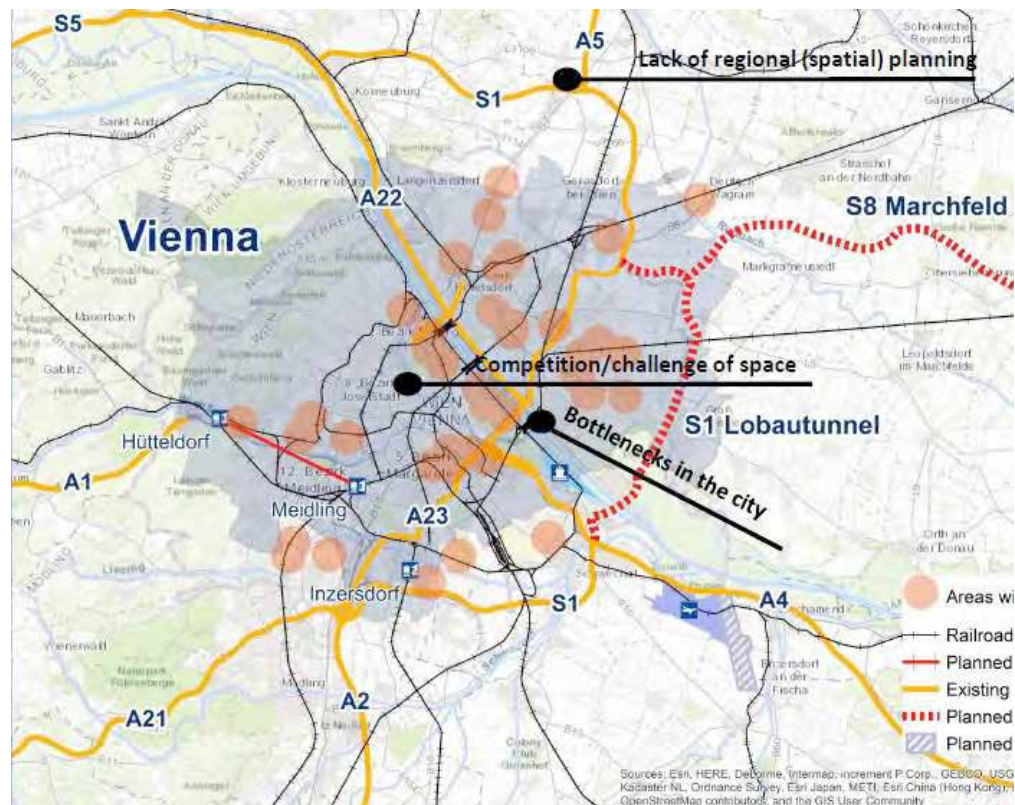

Figure 4: Challenges within and around the urban node Vienna.

6. Good practices for creating impact

Much effort has already been done in Vienna and other urban nodes to tackle the challenges identified, resulting in some *good practices* with (potential) impact that might even be of inspiration for other urban nodes throughout the (European) network (Poppeliers et al., 2018c). A few examples, related to the challenges mentioned are discussed hereafter.

6.1 (Lack) of logistics oriented development

Dealing with the (lack of) logistics oriented development has led to the search for hubs on different scale levels, including the development micro and midi hubs in the city centre of cities, accommodating supplies for last-mile logistics. An example of such approach is Vienna's HUBERT project (<http://hubert.stadtlogistik.at>). Another example can be found in Budapest where empty buildings within the city are used as micro and midi hubs for last- last-mile logistics and distribution.

6.2 Spatial planning at FUA level

To face the complexity of multi-level spatial planning, including the peri-urban areas, the city of Vienna together with other stakeholders, thought about the claim of space already in an early phase and developed a vision named the 'Produktive Stadt' (Stadt Wien, 2017) as part of its long-term strategic vision STEP2025 (Vienna City Administration, 2014). Within this vision interesting and innovative directions are introduced such as the reservation of brownfield spaces within the city centre for possible future development – not only for housing, but also for logistics, transport, industrial development. In this way authorities aims to make preservations of these areas for e.g. handling goods and prevent huge increase of land value causing future impossibilities.

The discussions during the Vital Nodes workshops in Vienna made clear to the participants that multi-level governance and cooperation in their urban region is needed to address the planning issues resulting from the highly dynamic transport and spatial developments such as urban growth and logistic sprawl in the Functional urban Area that go beyond administrative borders.

6.3 Robustness and vulnerability of the network

Developments at corridor level, focusing on multimodality could stimulate the robustness of the network and decrease the vulnerability. This is currently done in the Netherlands in the *East/South-East Freight Corridor programme in the Netherlands* that regards the corridor between Rotterdam and the Rhein-Ruhr area (Germany) consisting of a highly developed network main highway, railway and waterway (and pipeline) connections (see Faith Ell et al., 2019). This cross-national corridor is not only vital to the Netherlands' transport system and economy but also to the EC (being part of the TEN-T Rhine-Alpine Corridor). The Freight Corridor programme currently investigates what is needed to maintain and optimize this highly important multimodal corridor with the ambition of being a "topcorridor in 2030", which should result in a coherent package of measures at which national, regional and cities collaborate together with private companies. The programme focuses explicitly on the optimization of 6 major nodes. The programme strives for new economic development with specialisation in the major nodes in order to prevent unwanted competition between nodes and cities. This proves to be a complex multi-level governance issue, as it requires on the one hand that local and regional government think at corridor / network level (as many local terminals and hubs were developed, competing with each other) and on the other hand that national government reaches out to local and regional spatial-economic development issues. The programme has increased the awareness of being on a corridor, and the importance of the corridor to the country, regions and cities. Attention points for the programmatic approach prove to be issues of: multi-level governance, creating multimodality, balancing freight and persons transport, and developing a scope for cross-border issues and measures – to Germany and Flanders (Faith-Ell et al., 2019).

Another interesting development is in the Swedish city of Norrköping (130.000 inhabitants) situated 165 km southwest of Stockholm, which is transforming fast due to the building of a new high-speed rail line linking the Swedish capital with Gothenburg and Malmö including a new railway station in or nearby Norrköping (CEDR et al, 2018). At this moment the existing rail link is heavily used by both passenger and freight transport. The new high-speed railway connection will create conditions for improving freight transport and activities at both the corridor and the local level. At corridor level the new high-speed rail link will leave extra capacity at the existing rail link for freight trains (also causing less mixing of freight and passengers traffic). At local level, harbour and logistics activities will be concentrated on a 'Harbour Island' that will be developed North of the city at the former harbour area, while a new harbour extension is created to the east in seaward direction. Several smaller distribution centres that are currently scattered in the city and thereby disturbing the city life will be relocated to the Harbour Island. A new, consolidated logistic centre will be developed in the new harbour area as well (Broesi et al 2018).

7. Recommendations

Based on two years of bringing together knowledge throughout Europe – such as the Vienna experiences – recommendations can be drawn from the Vital Nodes project. Within this paper we focus on recommendations regarding the network, spatial and implementation dimension (Linden and Linssen, 2018b; Böhler et al., 2019). As In addition, some first directions are provided regarding funding mechanisms and needs (Van der Werf, and Smit, 2018).

7.1. Network dimension

Explore Functional Urban Areas (FUA), such as Vienna-Bratislava, Rotterdam-Venlo. Possible solutions for bottlenecks within urban nodes can be found elsewhere on the wider TEN-T corridor, including the comprehensive network. E.g. multimodal terminals in Venlo (NL) and Lauterbourg (FR) to relieve pressure in the urban regions of respectively Rotterdam and Strasbourg (“second order effects”).

Stimulate network resilience and infrastructure fitness. Currently local, regional and long-distance people and freight flows come together on two Danube bridges in Vienna. Realizing a new link across the Danube can free the city from the long-distance transport flows. This is also true for other nodes such as Mannheim.

Renovation and renewal of infrastructure. For instance, bridges across the Rhine is a major challenge in Germany, as has been discussed in Mannheim. This task should be organized in a broader regional perspective to prevent cutting off communities west and east of the Rhine and to offer alternative transport options for inhabitants and companies. Renovation and renewal need a more prominent position on the TEN-T agenda.

Develop the potential of urban nodes, as the main hubs for connecting the local and regional network to the TEN-T core network corridors, as *forerunner for distributing and deploying alternative fuels and other innovative technologies*. They can be centres for new inter- and multimodal logistics concepts and structures along the corridors.

7.2. Spatial dimension

Combine Transit Oriented Development (TOD) and Logistics Oriented Development (LOD) concepts (Vienna, Budapest, Hamburg, Strasbourg). Policies for densifying cities should not only relate to housing and offices but also to ‘blue collar’ production and logistics activities.

Midi and mini hubs should be implemented to stimulate sustainable inner-city freight flows and modal shift to cargo bikes and other cleaner vehicles for the last mile delivery and construction-related freight flows.

Careful design of interfaces (via integrated planning) of trans-national network and local transport. For instance, in Vienna two major Urban Consolidation Centres (Wien-Süd and Port of Vienna) are the main entrance and exit points between the corridor (rail, road, waterborne) and the city.

7.3. Institutional dimension

Development of regional SUMP including strategy on freight and logistics for preventing ‘Logistics Sprawl’ regions across city borders. E.g. in Vienna the Logistics Oriented Development strategy ideally comprises surrounding municipalities.

Stimulate regional collaboration beyond classical government borders, multi-level governance and cooperation should be required when applying for EU funding for infrastructure/regional development. Develop TEN-T related *cross-border strategies and operations* for urban nodes. For example, there is a strong connection between Vienna and Bratislava in terms of freight and logistics. The Port of Rotterdam has an important link with Duisburg and Strasbourg with the port of Kehl. These cross-border collaborations have many economic benefits for both urban nodes, but because of differences in legislation, permits, etc., the economic possibilities are often not fully utilised and can be strengthened.. To this end, cross-border collaboration is to be established.

Raising awareness for freight/logistics issues in urban, regional, and infrastructure planning. Increase the involvement of the urban nodes into the coordination of the nine TEN-T core network corridors under the lead of the European Coordinator. This could include actively involving the (main) urban nodes in the core network corridors coordination, for example by having a dedicated urban node working group, closely linked to corridor coordination. And in addition, assigning a dedicated urban node European Coordinator (in addition to the already existing ‘horizontal’ coordinators on European Rail Traffic Management System (ERMTS) and Motorways of the Sea (MoS). Establish an urban node information exchange and lobbying network, playing an active role in integrating urban nodes in the TEN-T corridors, lobbying for the urban nodes interests regarding the interface between the FUA and the TEN-T corridors.

Other recommendations relate to the focus of current TEN-T policies which focuses heavily on the core network. *Smaller nodes are also important to the functioning of the (core) TEN-T network corridors* (e.g. Venlo and Lauterbourg), this is especially true in poly-nuclear urban regions such as The Netherlands, Rhein/Ruhr and Rhein/Neckar. Include incentives for *public-private and private-private cooperation schemes* on the regional ("transit regions") and node level. Support cooperation between the public and the private sector to develop innovative logistic concepts for e.g. capacity sharing in terminals.

7.4. Funding

The current TEN-T guidelines (article 30) recognise and formalise the important role of urban nodes on the TEN-T network to connect and facilitate flows of people and goods while mitigating the negative effects. Funding of integrated solutions is complex, but also might provide ways forward to deal with this multi-level governance situation.

Awareness of complexity and importance of urban nodes. TEN-T Funding policies should be more aware of the complexity and liveability issues of urban nodes in TEN-T project development. As discussed before, urban nodes are the places where many different networks, actors and demands come together and interconnect. One stretch of TEN-T infrastructure might for example be used by both passenger- and freight transport, for different modalities, for both long- and short distance. For one single type of transport the network might seem robust, if transport grows at all these types at the

same time. Bottlenecks in the overall transport network as well as the urban spatial fabric might quickly occur (as has been observed for Vienna in the (near) future). TEN-T policy and investments should be aware of this. Sectoral, uni-modal investments along TEN-T corridors may create (especially) new bottlenecks in urban nodes, not only regarding transportation issues but also environmental issues, spatial and socio-economic development. To realize sustainable integration of the urban nodes on the TEN-T networks and increase liveability of these urban nodes at the same time, in TEN-T policy more awareness is needed of these complex environments and environmental challenges for the success of CEF and TEN-T investments in cities and regions. Sufficient funding should be set apart for mitigating measures or even alternative investments that might give the same results as the planned TEN-T investment, e.g. measures to reduce transport needs.

Integrated (metropolitan) governance and funding as key element for successful urban nodes. Given the complexity in urban nodes, the quality and architecture of metropolitan governance has a major impact on the sustainable development of urban nodes. Here awareness that the functional-spatial relationships of the DUS and FUA spread beyond (municipal) administrative borders is crucial. Through its funding, the EC has a leverage to stimulate integrated metropolitan governance. In the European Cohesion policy a certain budget is reserved for sustainable urban development. Cities can only have access to this funding if they have integrated sustainable urban development strategies (such as a SUMP). Some Member States have added the requirement for their cities that such a strategy is designed at metropolitan level. If such a requirement would become European policy, this could be an important incentive for cooperation at urban-regional scale. In practice, however, urban nodes (regions and cities) are often consulted at a late stage, when critical planning decisions have already been taken. A stronger involvement of the various governmental levels in urban nodes can significantly improve the coordination, the added value of investments, liveability and development of TEN-T projects, maximizing the potential benefits of the projects implemented on the ground.

Better integration of different types of EU funding. CEF grants are a vital part in the realization of the TEN-T networks and the TEN-T objectives. While maintaining the CEF funding for urban nodes, added value could be created by a better integration of different types of EU-Funding. Sustainable integration of urban nodes is not only a matter of increasing the capacity of infrastructure but also a matter of lowering environmental impact of logistics and transport in and around an urban node. An integrated approach of spatial and mobility planning seems the only way to make infrastructure investments acceptable to citizens and local authorities and to capture added value, e.g. for environment, liveability and property. But such an approach is expensive. Here European funding can contribute to achieving a business case for integrated infrastructure and spatial development. The European Fund for Strategic Investments (EFSI) may offer alternative means and instruments to invest in high-risk (infrastructure) projects. While national, regional and city authorities recognize and make use of the potential of Public Private Partnerships (PPPs) to support many essential urban transport projects, there are fundamental infrastructure projects that are relevant to the overall transport network structure but that cannot attract private finance because of their low financial returns. Nevertheless, these projects have a high European added value and a wide socio-economic return, bringing benefit to overall society. In order to be able to facilitate an integrated approach, proper use of financial instruments is important. A sound mix of public and private investors and long-term commitment are critical factors. Long-term commitment is a challenge for both the public and private investors and focus is often on the short and medium term. When using financial

instruments for an integrated approach, a wide range of private investors should benefit from the investment. Private investors not only include banks and pension funds, but could also include real estate companies and logistic and transport companies.

On basis of the experiences gained in the Vital Nodes project some first indications of funding needs might be given. As discussed, funding for integrating urban nodes on TEN-T corridors is financial more challenging because of the complex nature as it regards: multiple transport modes, multiple and connected infrastructure networks, multiple sectors, multiple geographical scales and multiple governance layers – see also above. As a consequence of this multiplicity nature, a first step could be that different funding sources (e.g. CEF, EFSI, ERDF, Horizon2020/Horizon Europe), are combined in order to create a shift towards integrated infrastructure and spatial development in practice. Regarding the absolute magnitude of funding needs: a comparable amount of budgets as the current funds comprise can be considered to be needed. To create a fundamental shift towards integrated planning, that at least 20% of these budgets should be combined and devoted for integrated development – and ensure that only proposals that address integrated development are eligible for this. In a stepwise approach, the percentage of funds devoted to integrated development could be raised (e.g., 50% in the subsequent period). NB: In various member states (such as the Netherlands) infrastructure and spatial development funding has already been combined over the last years (currently, in the Netherlands national infrastructure funding is in effect for some 80% devoted to integrated infrastructural and spatial development). The results of the Vital Nodes project suggest that such 20% of CEF-funding should be reserved for:

- investments in infrastructure, mobility, spatial and environmental measures enhancing the integration of urban nodes on the TEN-T Network;
- investments that focus on the peri-urban networks (the interface of long-distance, inter-urban, and short distance intra-urban mobility), on intra-urban networks in economic core areas (strengthen agglomeration effects, conform ‘borrowed size’), and on coordination with spatial development to strengthen socio-economic benefits (creating multiplier effects) of EU funding;
- investments that enhance integrated spatial and multimodal transport development and that increase coherent development of innovation, sustainability and liveability.

On basis of earlier experiences with integrated planning, it can be expected that such integrated investments in urban nodes and the peri-urban networks in economic core areas may lead to less costly planning processes (as development is directly coordinated between governance levels), less costs of mitigation and compensation measures (because of integrated spatial and environmental design), and less societal costs related to noise, air pollution (health effects) and safety (because of combined planning of (multimodal) infrastructure and spatial development).

In addition, the Vital Nodes project results suggest that more focus could be given on measures with a smaller investment volume (around EUR 50 million), which can be invested in coherence with other small initiatives and deliver an interesting proposition. And, that more funding is needed to invest in infrastructures and urban nodes that are resilient against climate change, natural disasters and catastrophes. This could include such measures as the construction of bypasses in the network, in multi-modal connections, or investments in innovative and green shipping logistics.

6. Conclusions

The Vital Nodes project discussed in this paper shows that urban nodes are often not yet an integral part of the TEN-T and comprehensive network. On the one hand, urban nodes are often important transport bottlenecks on the TEN-T network corridors, while increasing traffic at corridors is causing much environmental and spatial pressure in urban nodes. On the other hand, urban nodes profit socio-economically from their central position in the transport network, while the importance of urban nodes in terms of logistics and passengers transport at the TEN-T network will increase in the future. Urban nodes (and urban areas in general) seem to change faster than the network can keep up. To cope with these developments, a focus on innovative technical and sustainable solutions alone, will not be enough, as the challenges in integrating urban nodes into network corridors have a multi-dimensional character. Therefore, a transition towards sustainable integration of urban nodes into the TEN-T network requires an integrated a planning approach as has been discussed in the previous sections. This need for integration has been acknowledged by key stakeholders (see Philips et al., 2016) such as National, Regional Infrastructure Authorities and DG MOVE, as well as the Coordinators of the TEN-T corridors, who stress the importance of integrated strategies, platforms for exchanging experiences and multi-level governance approaches. A careful mix of interventions – regarding network, spatial, institutional and funding dimensions – seems to be the way forward to strengthen the connections between urban nodes and TEN-T corridors, and to achieve an efficient and sustainable transport system and vital urban regions.

Cargo Hitching as a tool to transform the urban mobility system. Integrating passengers and goods transportation towards a more sustainable, desirable and efficient mobility

Francesco Bruzzone

¹*Università IUAV di Venezia, Santa Croce 191, Venice (Italy)*

Abstract: Mobility in cities is facing growing challenges. Urbanization trends, growing complexity of stakeholders scene, e-commerce and increasing fragmentation of freight transport all have negative impacts on congestion, safety, environment and quality of life in general. Authorities have developed uncoordinated policies and regulations in an effort to tackle such issues, often resulting in minor or even counter-productive effects only. The *Green Paper on Urban Mobility*, issued in 2007 by the European Commission, first explicitly mentioned the integration between passengers and freight mobility as a solution for increasing attractiveness and efficiency of the overall mobility system in urban areas, starting a new research branch. This paper presents passengers and freight transport challenges and regulation attempts and further discusses Cargo Hitching, that is the combination of people and cargo flows (cargo that hitches a ride on a vehicle transporting persons or persons hitching a ride on a vehicle transporting cargo), as an approach to promote sustainable, efficient and socially desirable passengers and goods mobility in both dense cities and shrinking peri-urban and rural areas. The potential and some limitations of Cargo Hitching will be discussed and results of a modeled application in Venice (Italy), case-study city in the Novelog project, will be presented. The focus will specifically be put on achievable operational, socioeconomic and environmental benefits and on the need of a fully renewal of governance and of the normative approach, key to the management of the mobility system as a whole in compliance with sustainability and efficiency objectives imposed on the one hand by market requests and on the other by the growing sensitivity of the various authorities and stakeholders.

Keywords: shared mobility, public transport, urban logistics, sustainable mobility

Introduction

Passengers and goods mobility is facing growing challenges: urbanization trends, growing complexity of stakeholders scene, e-commerce and increasing fragmentation of freight transport all have negative impacts on congestion, safety, environment and quality of life in general. Authorities have come up with uncoordinated policies and regulations in an effort to tackle such issues, often resulting only in

minor or even counter-productive effects. This paper first shortly discusses urban mobility and logistics challenges, both in dense urban cores and in rural or peri-urban areas with lower densities, and hints at strategies which have been pursued with little or no positive results. It then introduces a new paradigm for integrating passengers and goods transportation, referred as “Cargo Hitching” (CH), according to concept that was first mentioned by the European Commission in its “Green Paper on Urban Mobility”. The work, published in 2007, suggested how strong integration could improve mobility and logistics efficiency and sustainability (from environmental, operational and socioeconomic perspectives) while at the same time promoting a socially acceptable approach, responding to authorities’ needs and indications. Basic principles, best practices to explore the origins, and the potential of CH are presented and drivers for both success and failure are discussed, focusing in particular on achievable operational, environmental and socioeconomic benefits and improvements, as well as on regulatory and operational constraints that currently interfere with the promotion of the management of the mobility system as a whole. The last section of this work is dedicated to the presentation of results of a CH simulation for the North Lagoon of Venice (Italy), case-study city in Horizon 2020’s Novelog project. The area was chosen because of its peculiar mobility system and because, as it configures itself as a low-density semi-rural area located in between powerful attractors (Venice, Mestre and Marco Polo Airport) and relevant mobility and logistics flows, it is a perfect test terrain for CH. Despite the introduction of various constraints, reflecting operational reality, the simulation has proven to have high potentials in both obtaining environmental and operational benefits and in improving the socioeconomic situation of peri-urban shrinking, remote and scarcely populated islands, thus highlighting how CH, a solution originally designed for relieving pressure on congested urban cores, can ease long-term issues in suburban transport as well.

Logistics and mobility: challenges and hindrances to coexistence

It is important to be familiar with current challenges of logistics and passengers mobility to understand the need of growing integration and innovative practices. With decreasing densities, therefore in peri-urban or rural shrinking areas, public passenger transport faces increasing spare capacity and significant anti-economical operations, often resulting in poor service offer or no service whatsoever and therefore in transport-related social exclusion. Similarly, goods carriers might experience higher costs as demand is low and therefore offer limited service, increasing the areas’ isolation (McDonagh, 2006; Jansen, 2014). Dense urban cores, on the other hand, suffer from congestion and negative externalities generated by city logistics operations, as it will be discussed more in detail. As the world is seeing a growing urbanization trend (e.g. Taniguchi et al., 2001; Savelsbergh and Van Woensel, 2016) which will result in an urban population of around 9 billion in 2100, both urban dense areas and shrinking rural or peri-urban areas will grow in number and size, bringing whole new challenges in many sectors, including that of urban logistics (Taniguchi et al., 2001). City logistics is therefore a complex systems which operates in a complex environment, involving many active (impactful) and passive (impacted) stakeholders, such as authorities (national, regional/state and city level), carriers (transporters and warehouse companies), receivers (shopkeepers and retailers, consumers, intermediaries), residents (consumers), shippers (manufacturers, wholesalers, retailers) and traffic participants, all of which make use of the same scarce resources available in the urban areas (Kant et al., 2016; Taniguchi et al., 2001). The phenomenon of city logistics is not new and has actually been tackled at various levels, as can be seen in the Law of Caesar on Municipalities, ever since 44 BC (Savelsbergh and Van Woensel, 2016). As the world has

changed since roman times, so has city logistics, which is in fact a very dynamic sector, operating in the constantly mutating urban environment, on which it has both positive effects and major negative effects, such as contributing to congestion, creating safety concerns, participating in lowering the environmental quality of the city. The most recent major change happening to urban freight transport is the rapid development of e-commerce, which on one hand emphasizes the fundamental role of city logistics for the economic development of urban areas but on the other hand contributes to enlarging its impacts on social and environmental qualities of cities (Taniguchi et al., 2001; Anderson et al., 2005). City logistics is facing various challenges, which can be attributed to three major “channels”:

- Market requests: the conformation of today’s dynamic market leads to challenges for the urban goods distribution system, which has to respond to stimulations such as just-in-time requests, a high fragmentation in space and time of retailers and consumers, corporate policy such as the choices to only use company-owned and branded delivery vehicles (e.g. Coca Cola Company and soft drink producers in general). All of this adds constraints to the city logistics flow, often resulting in partial inefficiency due to low vehicle load rate, high mileage per vehicle, longer working shifts, higher number of deployed vehicles, etc.) (e.g. ENCLOSE Project Report, 2014).
- Policy and regulation: many authorities, particularly at local level, have come up with policy regulations that try to tackle some of the most invasive impacts of freight transport, such as noise, pollution, and usage of space (both for loading/unloading and while driving), sometimes even generating counter-productive effects due to forcing vehicles to take long detours, idle for longer times, etc. Such initiatives include time windows, restrictions for polluting, noisy or heavy vehicles, spatial restrictions, and so on (Munuzuri et al., 2004).
- Physical constraints/real time urban situation: congestion, pollution, noise are both partially generated by freight traffic and are affecting freight traffic, especially in terms of social acceptance by residents and, even more, by ruling authorities (which might lead to the adoption of some of the above mentioned measures) and in terms of inefficiency generated by extended operational time and related costs increases.

Starting from the described challenges, it becomes clear how the ultimate goal of urban logistics is (or should be) to reduce the clash between the interests of logistic companies and those of other stakeholder groups involved in urban mobility (Munuzuri et al., 2004), so that future policy and regulation on the topic can meet the interests of all parts and pick up the opportunities that are offered by technology advances. As it has been pointed out, though, it is increasingly difficult to provide “good service”, meaning managing to get the right product at the right time and at right place, at a low cost. It is also not possible to invest in transportation (infrastructure) capacity, either because of lack of space for expansion or because of the prohibitive costs that the operation would imply (Savelsbergh and Van Woensel, 2016). What is therefore needed is coordination of flows of goods, consolidation of freight volumes, and multi-organizational cooperation. It is needed to promote and inject innovative concepts at all levels: design, planning, execution, remembering that no pre-designed theoretical model can fit to real-life city logistics (Savelsbergh and Van Woensel, 2016). The solution to this has been approached in different ways from various authors, but it is recognized that cooperation between public intervention and company-driven efforts, a locally based strategy and a mix of technical/technological solutions (such as alternative fuel vehicles, use of real-time fleet management

data, etc.), logistical solutions (such as supply chain collaboration etc.), and policy solutions is needed (Kant et al., 2016; Savelsbergh and Van Woensel, 2016). Besides exploring the theory of policy and planning, many authors provide numerous examples of possible policy and physical interventions to tackle the issues of urban freight transport, which will not be extensively reported here for synthesis reasons but which in short have as keystone the creation and support of consolidation facilities and practices to achieve Joint Delivery Systems, aided by normative and economic pushes towards cleaner operations and innovative practices. For more details and examples see among others Van Binsbergen and Visser (2001), Munuzuri et al (2004), ENCLOSE Project Report (2014), Taniguchi (2014), Savelsbergh and Van Woensel (2016). It must however be said that despite a discrete amount of available literature on the weaknesses of urban logistics not much has been written on measured impact of radical improvement strategies, and this is mostly because those strategies often fail to take off (e.g. because of their complexity) while independent measures that have been promoted and tested have repeatedly proven ineffective (such as, for example, investments in urban consolidation centers). All reviewed sources, however, stress how only an increasing capacity to integrate freight transport and other urban activity and to cooperate among stakeholders, regardless whether public or private and whether impacted or impacter, can lead to a more economically and environmentally sustainable urban logistics system. The following section of this written work concentrates on CH as a way to put in practice this stated level of integration and coordination, while improving the urban mobility system from the perspective of economic stability, user acceptance, environmental performance and resilience.

Cargo Hitching: definition and basic principles

Cargo Hitching, or the combination of people and cargo flows, is a newly explored research and activity field in what regards urban freight transport and its relationship with the urban mobility system in general and with the key stakeholders in city management and economy: public administrations, those involved in the trading system (such as shopkeepers, carriers, manufacturers, etc.), residents. CH is “the combination of passengers and goods transport flows so to increase efficiency and efficacy of operations in both central and peripheral areas” (Bracale, 2016). Its main objective is “to design integrated people and freight synchromodal transportation networks and related planning and scheduling policies to enable efficient and reliable delivery of each parcel and retail delivery” (Jansen, 2014). Both definitions allow to reason on basic principles of the CH model: first, as discussed it is an integrated system, in which passengers and goods share vehicles, infrastructures, urban space or more than one of these at the same time. Both reported definitions concentrate on efficiency and efficacy (or reliability) of the proposed model: the idea is that CH, despite implying some investments, is more efficient than current business models and more effective in operations. This means lower costs for all stakeholders, more care for environmental issues, high social value. A following paragraph will discuss CH’s potential in terms of social value, discussing dynamics in central areas as well as in peripheral situations with shrinking population issues. Jansen’s definition provides other fundamental sparks: the first one is that CH is about building a network. It can’t therefore be said that it is just a modal quota shift to other means of transport: it’s a proper turnaround of the business model of both transit agencies and operators and of stakeholders of the cargo sector. The second key point that Jansen highlights is that the creation of the “network” must be accompanied by consistent policy and coherent planning. As it will be seen, regulatory and policy aspects are crucial in determining success of CH projects and currently constitute the biggest barrier to its

diffusion. Before discussing the potential of Cargo Hitching it is important to underline that is not a completely new phenomenon. The idea of outsourcing part of the delivery process, in this case using public transport with a surplus in capacity, has already been around for decades for what concerns – for example – long-haul air and rail operations, where mixed usage of one aircraft or train is nothing unusual (Bakker, 2015; Ghilas et al., 2013). The innovative aspect of Cargo Hitching lies therefore in the fact that it studies and proposes the usage of overcapacity of public transport to carry freight for short-haul operations, mainly in urban or peri-urban areas but without forgetting the potential for areas with shrinking population (Bakker, 2015; Jansen, 2014). The first hints about a shift towards a shared passengers and freight urban transport system was given by the European Commission in 2007, when they made the following statement: “Urban freight distribution could be better integrated within local policy-making and institutional settings. Public passenger transport is usually supervised by the competent administrative body while freight transport distribution is normally a task for the private sector. Local authorities need to consider all urban logistics related to passenger and freight transport together as a single logistics system” (European Commission, 2007; Bakker, 2015). Trentini and Mahene (2010) quickly reacted to this by producing a comprehensive list of ongoing or past projects that have been focused on sharing “public transport services, public road space or existing urban areas”, which can be considered as precursors of the CH model. CH in fact requires, for its implementation, a complete change of the operational model, including the way scheduling works, the fare system, the whole pickup, transfer and delivery process, and last but not least physical changes to assets (vehicle and infrastructure). Before deciding to implement such a complex and resource-taking strategy it is therefore important for local administrations and for public and private companies (goods manufacturing and delivering companies, passengers transport authorities, service management agencies,...) that the local context is carefully and exhaustively studied. The next paragraphs will first highlight CH’s theoretical potential in both central and peripheral areas and then discuss drivers which could bring the model to a failure at current state.

Cargo Hitching’s drivers for success in urban vs rural areas

CH, as said, has been developed to allow shared goods and passengers transport in short haul operations. In dense, urban areas, benefits from such a model are clearly perceivable. In shrinking, peripheral areas, the discourse is more complex and expands a bit from transport operations only. In central areas, benefits from CH are mainly financial (minor expenses), environmental (less pollution and more efficient fleet use), and related to governance (more acceptable policy and regulations). In peripheral areas, however, a new fundamental tile joins in: the intrinsic social value of CH. Cost reductions to provide transit services and goods deliveries, in fact, makes desirable or anyways possible the provision of services otherwise considered anti-economic, such as for instance additional, more frequent bus or postal services, thus interrupting or relieving the feeling of growing isolation which many shrinking areas face. this kind of dynamics increase areas’ attractiveness, allowing the retention of existing population levels and fighting growing isolation and alienation. This aspect is specifically important for the case study that will be discussed later in this work. Available literature, despite the topic having developed only recently, undoubtedly demonstrates through the analysis of real or simulated business models the potential of CH. Ghilas et al. (2013), Jansen (2014), Spoor (2015) and Li (2016) coherently present results from different studies that show how the freight sector as a whole (manufacturers, shippers and carriers, and receivers) generally gains economic advantage from loads consolidation and CH. They moreover agree in saying that public transport

operators, both fixed-schedule (typically transit agencies) or not (typically taxi and cab companies), also obtain economic advantages when making their spare transport capacity available for transporting parcels and/or small goods units. Finally, analyzed literature sources underline that public authorities can benefit from increased sustainability of transit operations, which will need lower subsidies. Absolutely not secondary are benefits related to the social sphere: as hinted, less onerous transport operations pave the way for additional, otherwise anti-economical delivery and passengers services, better serving shrinking areas and therefore increasing their attractiveness for current and future inhabitants. Those aspects are discussed in details by, among others, Jansen (2014) and Bakker (2015).

Cargo Hitching: drivers for failure. The inadequacy of the regulatory setting

CH, however, implies a significant change in today's operations and theoretical approach to urban mobility. Among the drivers which are keeping its diffusion to a hold, Jansen (2014) stresses that in most cases the regulatory and legislative systems (at all levels, from European to local) are not shaped to incentive such advanced sharing initiatives. Cargo and passengers transport are not only considered by governments and separated systems, but they are also referred as this by the law, they are regulated by different authorities, they are subject to different rules and guidelines, different work contracts etc. Spoor (2015) notes that regulatory constraints contribute to elevate the costs of the delivery chain. Ghilas et al. (2013) recognize the system as a very complex one, in which many stakeholders interact – namely “passenger door-to-door transportation, package transportation and public fixed line services,, - and produce different scenarios considering different integration levels, thus underlining that capacity to establish profitable cooperation is a necessary condition for the success of a Cargo Hitching process, but takes time and lots of political effort to achieve. The co-operation process becomes even slower due to the indecisiveness of corporation which are reluctant to “drop” their identity in delivery operations while consolidating deliveries. This phenomena is easily observable, according to literature, in the case of soft drink companies, for which the delivery with branded trucks is part of the marketing strategy. Many different constraints, moreover, complicate both the research phase and the physical application of Cargo Hitching theories. A different set of issues has to be included in research models and then transposed into practical operations, with obvious time and cost-related effects. Timing-related issues, like for example the fact that passengers are very sensible to travel times and must therefore have priority over goods, the time-limited availability of stores for receiving delivery, just-in-time deliveries and the management of just-in-time orders through web platforms, are a significant constraint to worry-free Cargo Hitching implementation. All read authors - and among those which have not yet been cited are Ghilas et al. (2013), Trentini et al. (2012) and Fatnassi et al. (2015) - have included time constraints in their research, even though they all have looked for a balance between relevance to reality and feasibility of the study. Other relevant constraints are related to spare transport capacity during certain times of the day or periods of the week, to flexibility of scheduled transportation, and to reverse logistics. None of the authors has included reverse logistics operations in their research to avoid excessive complexity of models, but it is clear that in real-life operations the problem is relevant and should be considered. This involves both waste management (which though could be outsourced to a different authority) and the return of empty rollers and containers, which is usually dealt with by shippers. A further slowing driver is the strong necessity for both public and private investments and adaptation: starting a Cargo Hitching project requires to make available at least one consolidation facility and pick-up and delivery

locations at selected transit hubs, to purchase new low impact vehicles for last mile delivery (e.g. tricycles or more sophisticated solutions such as electric light vehicles, which then introduces the problem of charging facilities), to strongly intervene on the existing public transport fleet to make it usable for easy and quick (especially in loading/unloading operations), reliable, safe for goods transport. All considered authors present this aspect as a big challenge, also considering that no regulation at the moment determines which investments should lie in the responsibility of the public sector and which should be covered by private stakeholders. One last significant braking factor for Cargo Hitching's success is the necessity of constant monitoring and adaptation of the running integrated system, so it can be kept attractive for passengers and effective for goods operators, while being in the meantime socially acceptable for residents and administrations. This involves facing problems related to ITC costs and to research costs and timing. Literature has not really widely discussed this aspect yet, because there is still no fully implemented system to analyze. To sum up and conclude, it can be said that future research should take as primary objective that to propose an acceptance model for Cargo Hitching (addressed to public administrations, private and public companies, stakeholders part of the transportation and logistics systems in general) to be merged with an integrated and broad business model, which should take into account all phases of the innovation process (from theorization and planning, to implementation, to monitoring and evaluation). The main point is – to be clear – to find a way to make the transition to the integrated system happen smoothly, thus solving regulatory issues in the first place while taking into account all other discussed aspects as well. Funding by public authorities and the design and implementation of pilot initiatives are fundamental elements in the development strategy for Cargo Hitching: small-scale applications (e.g. in a restricted sector of an urban agglomeration or in a limited-size rural area) could be the key to test proposed models thus allowing to build an appropriate and reliable set of indicators and operational model to facilitate future broader diffusion of Cargo Hitching which – as it must be reminded – available research identifies as a key process to build a more economically and environmentally efficient integrated transportation system not only in dense areas but particularly in more rural areas suffering phenomena like shrinking population and service quality decrease, thus entrusting a strong social value to transport operation.

CH for the Lagoon of Venice. Setting and business model.

This paragraph summarizes the setting and most notable results of a simulation of a Cargo Hitching shared transport system in the Venice area, Italy. The chosen area is set in the North Lagoon of Venice, and was chosen for multiple reasons: first, Venice is case-study city for the Novelog Project, meaning that some scientific contributions have been developed on the topic, including the one which is here synthetized. Second, the North Lagoon has two main itineraries, which are easily identifiable and which are used for both goods and passenger transport, carrying in both cases significant volumes. Those two main itineraries are coincident with the vaporetto/waterbus (ACTV) routes 12 and 13, from Fondamente Nove (Venice) to Murano, Burano (line 12) or Sant'Erasmo (line 13) and on to Treporti (connection with the mainland) (Figure 1).

Figure 1: ACTV lines 12 and 13, chosen for CH implementation. Own elaboration

In order to limit the overall complexity of the case study and to produce a realistic model, capable of immediate acceptability from sectorial stakeholders (of both goods and passengers transport), from the workforce and from the public, it is necessary to fix some constraints and starting hypothesis. Whereas some of these constraints have been set in the academic environment, most depend directly from the results of a confrontation with the abovementioned categories, where different scenarios were proposed for the study of CH system and the most realistic possible situation was outlined. The most important fixed constraints include:

- the choice of the study area, limited to the itineraries of ACTV routes 12 and 13, due to service frequency and volume and to its overlapping with major freight transport axes, as recognized by COSES (07/2002 report);
- the decision to simulate the worse possible scenario, using winter transit schedule (lowest offered level of service) and meanwhile the highest yearly recorded freight volumes. Moreover, prudent correction factors have been applied for loading capacity and spare capacity of ACTV waterbuses;
- the limitation of freight categories to include in the simulation to “Conto terzi” of the most frequent categories, as defined by the Chamber of Commerce, due to excessive unpredictability of transport demand of other categories;
- the decision to maintain a goods delivery window from 4 am to 11 am, corresponding to current delivery times. Public transport schedules were therefore only considered in this frame.

Table 1 synthesizes the results of data collection and elaboration regarding public transport offer, freight transport demand, and number of circulating vessels. It moreover presents the sizing of freight loads onto transit vessels, in both square and cubic meters and in percentage of available volume and surface, calculated according to the process of overlay of offer and demand. Figure 2 graphically shows the impact of goods loads into cabins of transit vessels in service on lines 12 (capacity: 325 passengers) and 13 (capacity: 218 passengers). As Table 1 and Figure 2 have helped to graphically

show how volumes could be redistributed, it is now useful to describe the functioning of the proposed CH system. Two consolidation hubs would be needed, one west , intercepting freight fluxes from Venice-Tronchetto and the mainland- San Giuliano (in Murano or F.Te Nove) and one east (in Treporti). Those facilities would serve as consolidation of goods deliveries into standard-size rolls (715x805x1800 mm) and for their transfer on ACTV's boats. The design of those facilities was not in the scope of this paper, however it must be said that current volumes do not impede to basically use standard ACTV floating pontoons, part of which could be dedicated to goods. Loading and unloading, as well as last-mile goods distribution on the islands, would occur in line with today's operational model.

Table 1: offer, demand and freight volumes on public transit vessels according to the proposed CH system.

Own elaboration.

Offer	Line 12 (carrying capacity: 325 passengers)				Line 13 (capacity 218 pax)	
	Murano-Burano	Burano-Murano	Burano-Treporti	Treporti-Burano	S.Erasmo-Treporti	Treporti-S.Erasmo
# runs before 11am	15	12	12	11	6	6
# vessels in service	4				2	
Capacity pax	4875	3900	3900	3375	1308	1308
Sqm offered before 11am	1218.8	975	975	893.8	327	327
Maximum declared usage (%)	35	35	35	35	37	37
Security factor (%)	10	10	10	10	10	10
Spare capacity (%)	55	55	55	55	53	53
Sqm used	548.4	438.8	438.8	402.2	153.7	153.7
Sqm available	670.3	536.3	536.3	491.6	173.3	173.3

Cubic meters available (security factor 10%, height=2m)	1072.5	858	858	786.5	277.3	277.3
Demand						
Freight volumes	556	366	237	163	140	87
# vessels used	22	21	13	12	6	7
Real-size freight loads						
Cubic meters on each service	37.1	30.5	19.8	14.8	23.3	14.5
Sqm on each service (height=1.8m, with security factor 20%)	20.6	16.9	11	8.2	13	8.1
Load size (side 1)	4	4	4	4	2	2
Load size (side 2)	5.1	4.2	2.7	2.1	6.5	4.0

CH in Venice. Open critical issues.

The proposed system leaves some critical aspects open; aspects which is necessary to highlight for both future research and for next on-field operative steps in the context of the city's mobility policy and practice evolution towards further integration. A first set of criticisms is represented by CH's intrinsic limits, as hinted already. In particular, it must be reminded that as today freight transport on vehicles – vessels in this case – designed and type-approved for public transportation is hardly frameable in the classic regulatory set nor in the competences which the law recognizes as proper of

public transit agencies and/or operators or in sector contracts for their employees. It would therefore be necessary to strongly act on the local, national and European regulatory structure in all interested sectors, on contracts and labor deals, on plans and strategies, with the goal of allowing and even promoting, if not enforcing, goods/passenger integration. This is a first relevant issue, which has been brought to interested stakeholders in the case of Venice and is currently under discussion in the parts of competence of local institutions and enterprises. A second critical aspect is the acceptance of CH by usual transit customers. In this particular case commuters on ACTV routes 12 and 13 might experience minor schedule dilations due to longer dwell times and higher load of vessels (meaning lower cruise speeds). Passengers could moreover experience less comfort due to higher intensities in the use of PT vessels capacity. Before implementing the CH system, therefore, further studies on social acceptability should be conducted in the interest of the public administration and of ACTV. It must however be noted, on the other hand, that in the context of the Lagoon of Venice transit is in the unique position of being in most cases the only available alternative to move. In this sense, it would be easier to force the implementation of the CH system – in case the public administration would decide so – even in case of mixed feelings from the users' side. Some more critical aspects are related to the constraints which have been introduced in the model: future research should include reverse logistics operations and additional goods categories, and should further discuss consolidation hubs.

Caro Hitching for Venice: performance evaluation

This paragraph is dedicated to an evaluation process of the proposed CH system for the venetian lagoon. This is an innovative element not only for the specific geographical context object of study, but for the whole literature body about CH. Only recently, in fact, the problem of evaluating mobility performance rose, and such an approach was, to the author's knowledge, never applied to real or simulated CH operations before. The evaluation process is conducted through a set of performance indicators (KPIs) which until now, outside of the Novellog project, have never been used with reference to the transport sector.

CH for Venice: evaluation results

Before describing the chosen indicators and the results of the evaluation process, it is necessary to highlight that in the process itself all constraints which have been set during the description of the case study have been maintained. Moreover, compared to the originally considered time window (4 to 11 am), the indicators have been calculated for a restricted time window of 3 hours only (7 to 11 am), as PT offer during those hours revealed itself to be sufficient to deliver the totality of considered freight while at the same time minimizing economic, operational and environmental impacts. The first analyzed evaluation dimension is that of operational impacts, considering efficiency and efficacy of the combined transport system and confronting obtained values with the current situation, in which the two systems are run independently. Part of this category are indicators concerning total operating hours, covered distances and load factors. A second group of KPIs investigates environmental impacts. This is an extremely important field of evaluation also for what concerns social acceptability of the integrated system: environmental benefits could be a persuasive tool to increase stakeholders' consent on the project. The third and last evaluation dimension concerns economic impacts, specifically related to costs of energy and costs of workforce. Aggregated results from each calculated KPI are available in Table 2.

Table 2: evaluation through KPIs and results. Own elaboration.

Indicator (code + name)	Description (if needed)	Evaluation results
A1 – Traffic variation	Traffic variation (# of boats)	Traffic drops from 323 to 242 daily operating boats. Average reduction is therefore -25%
A2 – Distance variation	Distance variation (kms operated)	Compared to today's 640 daily kms, with CH a reduction of 432 kms would occur. -67.5%
A3 – PT load factor	Public transit vessels load factor	CH would rise load factor to max 78.2% , still leaving spare capacity to absorb unusual peaks
A4 – Frequency/Level of service		There is no change in level of service from PT users' perspective.
A5 – Engines operating hours	Hours of total operations of vessels' engines (PT+freight)	Reduction from 50,6 hrs/day to 16,3 hrs/day. -68%
B1 – Carbon Dioxide Emissions		A daily saving of over 1.5 Tons of carbon dioxide is allowed, which means -38%
B2 – Energy consumption		Energy consumption reduction -38%
C1 – Cost of energy	Includes fuel costs	Cost of energy drops: -42.5%
C2 – Cost of workforce	Includes all human resources	Cost of labour is reduced by -38.1%

The evaluative process has highlighted incentivizing results, especially when considering that it was conducted with several limitations as to better adapt to the context's reality. According to the findings, therefore, CH proves to be a suitable solution for the discussed case study and it would be meaningful to continue the already started discussion with the various involved stakeholders so to identify common guidelines to first produce needed policy/regulatory changes and then implement the shared system. The inadequacy of the regulatory framework is, indeed, the biggest slowing driver towards high integration, in Venice more than elsewhere. It is of absolute priority to identify appropriate strategic and operational instruments to legitimate and promote integrated passengers/goods transportation. In Venice in particular the strategic reference plan could be the SUMP (Sustainable Urban Mobility Plan) which has not yet been prepared but will need to be discussed soon. From a tactic perspective, instead, the most interesting instrument for the context of study seems to be that of the tender or bid. Practically speaking, the administration should prepare a tender which includes and regulates the integrated transport system, establishing clearing rules and giving all operators time to organize and compete accordingly to their competences. In this scenario, the implementation of the CH system would be on one side supported by a powerful strategic planning instrument (the SUMP)

and on the other side promoted by the operators which would compete to affirm their role within the new system, thus lowering the risk of otherwise likely protests.

Conclusion

This paper has discussed some of the issues related with short-haul logistics, particularly in dense and congested urban environments. Given that current trends show growing urbanization and an increasing fragmentation of goods deliveries, it is obvious that the situation will grow worse. Authorities and governments have at times tried to tackle major issues (congestion, noise, pollution) by promoting restrictive and punctual measures, which have proven not effective or even counter-producing. Based on the EU Commission push for further integration between goods and passengers transportation, this paper presents Cargo Hitching, namely the combination of people and cargo flows, as a possible solution for achieving higher efficiency and sustainability standards for the overall transport system in both dense urban areas and in peripheral or rural shrinking contexts. After discussing the basic principles of CH and some of its main success and failure drivers, this article reports the setting and results of a CH simulation conducted for the venetian lagoon within Novelog Project. The evaluation process, conducted using KPIs for the first time for a CH application and innovatively for the whole transport sector research, has highlighted incentivizing results, with major operational, environmental and social obtainable benefits. Taking advantage of the participation of Venice into the Novelog project, next steps towards an integrated transport systems have been identified and discussed with the sectors' operators and other involved stakeholders. In this regard, a major issue has been highlighted in the inadequacy of the governance and regulatory systems and a proposal for a two-folded legitimation strategy (strategically, through the Sustainable urban mobility plan, and operationally, through a tendering process) has been prepared. Such a strategy should, according to the simulation's results, strongly be promoted in order not to waste the innovative push and the undoubtable potential which a CH system has with regard to themes which are or should be keystones in the political debate, particularly in the venetian area, as for instance the reduction of environmental impacts (on the lagoon itself as well), the necessity to maintain attractiveness and competitiveness not only of the historic city but of the islands as well, the will to make economically competitive and sustainable public transport and the mobility system in general, and the requirement to lighten the pressure on the lagoon generated by transport operations.

An On Demand Transport in a Low Density Region of Portugal - Alentejo

Carmen Carvalheira¹

¹*Vice President of CCDRA, carmen.carvalheira@ccdr-a.gov.pt*

Abstract: ON DEMAND TRANSPORT IN A LOW DENSITY AREA OF PORTUGAL - ALENTEJO

Mobility and accessibility to services in low density areas is a concern of municipal management policies in the Alentejo. Alentejo is the least populated region in the country, representing over one third of national territory but only 7.1% of its population. It is also the region with the oldest population, 22.9% being 65 years of age or more (while the national average is 17.5%). The CCDRA (Coordination Commission of Alentejo) has proposed, working with the municipalities, to model an on-demand-transport, based on a suitable selection of route centres and itineraries, with the objective of increasing coverage of the existing public transport network (providing an offer in areas and / or periods of the day or year where this offer does not exist or is in deficit). The project will start soon with five municipalities and, in a second phase all the remaining 40 municipalities can be added according to their will. In a first stage, routes, schedules and frequencies are established depending on health needs, supply needs, weekly markets, access to administrative and financial services or for linking with other means of transportation, and serving mainly elderly people living in distant places not served by public transport. Vehicles only make the routes if, in advance, the service has been requested and only go to the stops that have reservations.

Keywords: on demand transport; flexible mobility; low density regions

Introduction

The project "On Demand Transport for Alentejo" will cover, in an initial stage, five municipalities of the Alentejo Region (Reguengos de Monsaraz, Moura, Beja, Mértola and Odemira). The main objective is to increase the coverage of the existing public transportation network, providing an offer in areas and/or periods of the day or year where this offer does not exist or is deficient.

Like regular public transport, there are circuits, stops and schedules initially defined. However, on-demand transport services are distinguished from regular transport because the customer is the one who triggers the journey, through a previous request to a reservation center. In this way, the vehicles only make the service if, in advance, the service has been requested and only go to the stops that have reservations.

The five municipalities associated to this project has defined the stops, according to the objectives of the project, namely places where there are possible clients and where the offer of public transport is low or non existent.

All the movements and schedules of existing public transport were identified, and the on-demand transportation project does not overlap with existing services, aiming at eliminating gaps in the existing network transportation in each municipality, and complementing with existing services.

It is the municipalities that make the service available. CCDR Alentejo only intends to facilitate and guarantee management availability, being responsible for modeling of the routes and programming of the platform that receives the orders. Both platform and geographic information system need to be linked in order to produce three outputs:

- travel information for the customer
- travel information for those taking the vehicle (public or private operators)
- information on the cost of travel for those who provide the service (municipality)

Each municipality made a deal with the transport operators (mainly taxis) in order to invite them to join the project and to present conditions. In the next stage, the Social Entities that the municipality can define, should also be invited so that trips can be made available for disabled people (in particular wheelchairs, since some of these entities have properly equipped vehicles for this type of transportation).

The decision to start the project

Demand Responsive Transit (DRT) systems (also called dial-a-ride systems) have emerged in the last decades as an attempt to satisfy the dynamic nature of users' demands. They rely on flexible services able to provide almost 'door-to-door' transportation in small vehicles, with the possibility of pre-booking. DRT systems are nowadays mainly implemented as services for small groups of persons (e.g. elderly or handicapped persons). However, massive and on-demand services are far from being considered as a possibility or an alternative to the conventional public transportation system. (Archetti *et al*, 2016)

In neighboring Spain these on-demand transportation experiences are working well namely in Castilla and León and are based on on-line technologies of Advanced Vehicle Monitoring. The testing phase began in May 2004 in peripheral areas, raising quickly the number of municipalities which participated in the project as well as its number of passengers, thanks to the loss-leader effect. This system has benefited firstly users who may have access where scheduled lines do not arrives, granting the speed and provision of service by removing unnecessary stops being reported in real time by terminals; secondly the operator due to route optimization, cost saving, the increase in the number of passengers and the easiness to adapt the type of vehicle to specific requirements; finally to the Administration, which is able to control the service quality. This has enabled the reduction of displacements by private cars, family spending, accidents and the CO2 emissions. (Urrecho and Fernandez, 2016)

But, the first decision of project in Alentejo was to adapt a similar project already in operation since 2013 in another region of the country with characteristics not very different from Alentejo, the region of Médio Tejo. (Portal Regional do Médio Tejo, 2019). The past experience of these projects has allowed an evaluation of sharing problems in order to create efficient solutions. It was possible to understand that on average, ondemand travels cover around 7% of the km that would be required with a regular basic service. Furthermore in the same project it has been identified that 67% of travels

are made for health reasons. The Medio Tejo community presented the conclusion that this mobility solution allows them to give a qualified answer to mobility needs of the population living in areas of low population density, particularly for disadvantaged groups, thus giving the project a social relevance. As well it reveals a more economical solution and greater environmental sustainability compared to the regular network. High levels of satisfaction (greater Comfort and shorter travel times than regular service) are presented by users of the Médio Tejo municipalities.

With this information and also according to governmental decisions to support more sustainable mobility solutions, CCDRA decided to start working with some municipalities in order to define a pilot project that could accommodate a number of municipalities whose routes and decisions could be used as models and then later export to the rest of the territory. Figure 1 shows the five municipalities of Alentejo region that belong to this pilot project.

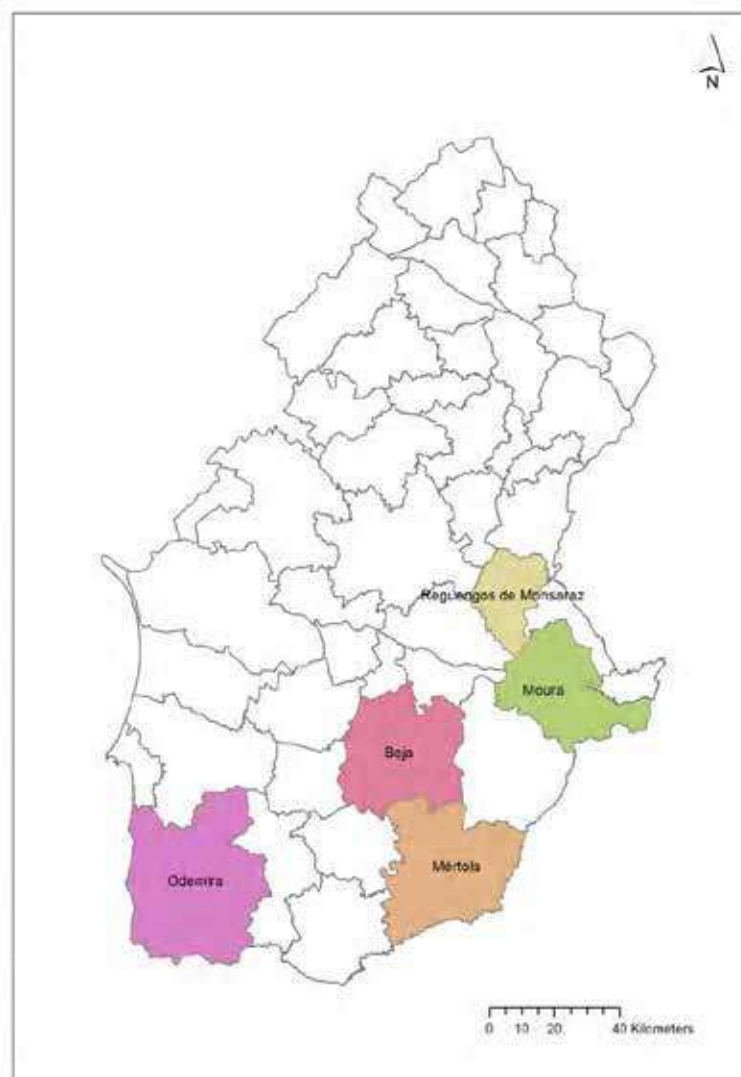

Figure 1 - Municipalities that are starting OnDemand Transportation

The road network

Each municipality was invited to define stops, suggesting that it could be in any place where there are possible users and where the offer of public transport is low or non existent. Also there can be an existing offer but in a different time of day or day of week.

Once defined the stops and having associated routes, a different color was defined and associated to each route, as shown in Figure 2, the on-demand transportation network for the municipality of Beja (7 routes with 68 stops).

Figure 2 – On-demand Transportation Network for the Municipality of Beja

Travel prices

All prices were defined by the municipalities, according to travel distances and the normal price rate for regular trips. The prices are about 1.5 x regular route prices that correspond roughly to the taxi trip value divided by 4 passengers (echelons depending on distance 1,60€ to 5,10€). For more frequent travels a book of 10 pre-purchased tickets is available, with 30% discount. Figure 3 shows the image on line and in paper flyer to illustrate the different prices according to distances.

Figure 3 – On line different prices according to distances

Travel requests – the service user

Besides the site information (soon on line and shown in Figure 4 as it will be on line), each municipality has a paper flyer with all the information needed to request the service:

1. The customer contacts the service through the phone number up to 12:30 the previous business day of the trip;
2. The caller performs the reservation according to the request. Until 16h00 / 18h00 on that day, a call is made to the client to confirm the time and cost of the trip;
3. On the day and time scheduled by the passenger, the transport will be at the default stop.

Figure 4 – Image on line to show all steps of travel request process

The travel requests – additional frequently asked questions

In order to ensure that no user has doubts and is easy understand every moment of the service, the FAQs - frequently asked questions - have been set on each paper flyers, as well as on the website and they are as follows:

What is On-Demand Transportation? It is a public transport service where the passenger has to pre-book a trip. It is a service provided by your municipality that intends to get transportation to places where it does not exist or is deficient. On-demand transport does not overlap with the existing offer, but only complements it.

How can I book? Reservations can be made until 15:00 on the business day prior to the day of travel, by calling the telephone number 300 079 000.

Does a booking request have costs? The phone numbers beginning with 300 are called nomadic numbers, and their usage is charged as a call for a fixed service according to their tariff.

What information should I give of my reservation? Name, Phone number, Stops and hour of origin and destiny.

What happens if you do not make a reservation? If a reservation is not made until 15:00 on the previous business day, the transport service is not guaranteed. Late reservations may be allowed, but only for stops that already have reservations.

After booking is the trip guaranteed? No. You must wait for the confirmation of your trip, so you will be contacted by an operator who will give you the confirmation of the trip, as well as the information about the time and associated costs.

How far can I go with on-demand transportation? There are pre defined circuits of the on-demand transportation service operating in the counties of Beja, Mértola, Moura, Odemira and Reguengos de Monsaraz. There are stops, routes and pre-defined times in each municipality. You should consult this information in the brochures available in your local authority or parish.

What kind of vehicle is included by the service? The services are carried out by taxis (of 4 or 7 places) or by vehicles of the respective municipality.

Will the vehicles collect the passengers at their houses? No. Although the shuttle service is also made by taxis, it is not a taxi service. There are stops (properly identified with the Symbol of the Transport on-Demand), schedules and defined circuits.

Where can I buy the ticket and how much? The ticket can be purchased at the premises of the town hall, the parish headquarters or the driver, and each trip corresponds to a ticket.

How can I get more information? For more information you can call the phone number 300 079 000, running every working day, from 09:00 to 12:30 and from 14:00 to 17:30.

The travel requests – the platform proceedings

The "Call Center Operator" registers the reservation request by the "User", indicating to the platform:

- County
- Name, Tax identification number, Phone number and Email
- Origin and destiny

The platform processes the various booking requests of the day and evokes the Geographic Information System for optimization. According to this optimization it generates work orders and notifies the "Local Service Manager" (a person defined by the municipality and working there) that validates service orders (validates vehicles and associates drivers) according to availability and notifies the "Call Center Operator". Then, the "Call Center Operator" confirms the reservations with the "User" according to the processed Service orders.

The platform aggregates service orders confirmed by municipality and notifies by mail the following stakeholders:

- Municipal Manager and Local Service Manager, with all the orders that are to be carried out by that municipality
- Transport Operator, with the work orders that were assigned to their vehicles
- Driver, with the work orders assigned to him.

This information allows all those involved in the process to keep track of all the trips as well as the financial costs of each trip attributed to the municipality.

The near future work

On May 30 the CCDRA developed a public presentation event for the project. The objective of this event is that municipalities of the pilot project as well as the managers of the Middle Tejo project can share the strategies and the experience of the definition of routes and tariffs. Each of the remaining forty municipalities can thus begin to prepare the possible association to the platform and begin the procedures that precede this association.

Before the project goes into operation it is still necessary that "Local Service Manager" in the municipalities as well as "Call Center Operators" receive specialized training for the operation of the platform.

At the same time a monitoring plan is being set up for all procedures from the reservation to the final destination of each trip. In this plan there are also surveys of satisfaction to the users that allow later to indicate the needs of updating each network or specific services.

The long term future work – second stage of the project

The first major objective for the future work is to accommodate all other municipalities that intend to be associated to the platform.

The platform is already being prepared to evolve from a project of On-Demand Transportation to a project of Mobility as a Service. In this second stage, all types of public transport should be associated

and users can book a trip that has more than one type of transport and therefore for travel between different municipalities. Since it will be at a time when users are already familiar with the project, online travel reservation as well as a mobile application will also be available.

Cycling to School: Exploring Key Factors Influencing School-Going Children's Mobility Choice to Cycle in Tallinn, Estonia

Õnne Kask¹, Wendy Tan²

¹*Wageningen University & Research, onne.kask@wur.nl*

²*Wageningen University & Research, wendy.tan@wur.nl*

Abstract: Cycling and other active travel modes have dominated sustainable transportation policy agenda of many cities worldwide. Cycling is deemed beneficial for individuals' health and well-being while contributing to liveability. While Amsterdam and Copenhagen are considered frontrunners in cycling, others are only taking their first steps. Tallinn, Estonia belongs to the latter category, setting up their first Cycling Strategy in 2018. Amongst other measures, the strategy aims to make cycling safer and more attractive in the vicinity of schools in order to increase the share of cycling to school to 25% by 2027. This demographic group are seen as a crucial to influence the potential future of Tallinn's cycling culture. Despite the abundant literature on cycling, there is little to no focus on children in aspirational cycling cities. This research explores factors that influence cycling to school in Tallinn among children in the ages of 13-16. The research includes street observations, a survey (n = 511) at various schools and focus groups sessions with children, parents and mobility experts. The findings support the need for comprehensive strategies including cycling infrastructure modifications and convenient cycle parking facilities together with promotional campaigns designated for children and parents.

Keywords: school-going children; school travel; cycling culture; sustainable mobility

1 Introduction

Cities are increasingly investing in active mobility strategies encouraging walking or cycling in place of private car travel (European Commission, 2016; Johansson, Laflamme, & Hasselberg, 2012). The expected benefits associated with active mobility are predominantly for increasing health and well-being. The attraction here is twofold. Firstly, cycling is considered the most sustainable transport mode in cities, also suitable for longer trips usually taken by car or public transportation. As Pucher and Buehler (2017) state: "Cycling is environmentally, socially and economically sustainable" (p.689).

Next, children are increasingly performing sedentary activities and child obesity is a growing health care concern. Walking and cycling to school offers children higher levels of physical activity, but also psychological gains such as having more social interactions. Simultaneously, a reduction in the number of parents driving their children would make active transportation safer, but also benefit the environment (Easton & Ferrari, 2015; Ermagun & Samimi, 2015; Helbich et al., 2016; Larouche, Stone, Buliung, & Faulkner, 2016; Mitra, 2013).

Most existing literature on cycling among children focuses on the USA, Canada and England, but also Denmark and the Netherlands which are more advanced in cycling. In comparison, Tallinn, Estonia where approximately

1% of all trips is done by bicycle (Maanteeamet, 2017) seems to not be addressed. This could be expected in a city where car dominate, public transport is free of charge and snow is predicted in winter months (Cats, Susilo and Reimal, 2017; Hess, 2017; Poltimäe and Jussi, 2017, Leesment, 2018). However, weather considerations aside, in comparable cities such as Helsinki or Gothenburg 11% and 8% of all trips are done by bike respectively (City of Gothenburg, 2015; Maanteeamet, 2017).

Tallinn adopted the Tallinn Cycling Strategy in 2018 which aims at 11% of cycling of all mobilities, and 25% of cycling of all mobilities for travelling to and from school (Jüssi et al, 2018). School children are an important focus of the strategy as they are seen as the future of Tallinn's cycling culture. However, as there is such a low percentage of cyclist, it becomes important to understand what the barriers to cycling for school-going children could be. These insights can offer valuable information for drawing up comprehensive measures for reaching the goals set in the cycling strategy.

In collaboration with the Tallinn Cycling Coordinator, this research therefore aims to understand which key factors influence school-going children's mobility choice for cycling to and from school in Tallinn. Through a mixed methods approach, this research discovers the factors influencing cycling to school in Tallinn, including a survey of 511 school-going children, focus groups with pupils, parents and experts to isolate the factors and observations of the current conditions in Tallinn in relation to these factors.

2 Theoretical framework

In order to understand children's mobility choice to cycle, this chapter first explains travel behaviour in boarder terms and then narrows it down to children. This research is based on the model of school transportation by Mitra (2013) which is explained here. Finally, the key factors that have found influencing children's mobility choice in other studies, are shown.

2.1 Travel behaviour & children's travel choice

Before making school travel choice explicit, first an understanding of general travel behaviour has to be established. The NOA model identifies needs (N), opportunities (O) and abilities (A) as determinants of travel behaviour. Needs describe motivational factors, social factors and emotions. Opportunities include available transportation modes and travel distance, and abilities looks at monetary and time resources, but also skills and capacity to use different travel modes. Needs, opportunities, and abilities are influenced by societal developments, such as economic growth and changes in values and norms. For instance, economic growth enables more people to own a car (Dijst et al, 2013).

In contrast to adults, children's mobility is largely determined by their independence from their parents or caregivers. *Children's Independent Mobility* (CIM) is a concept that tries to capture the extent of this independence by looking at the freedom children have to leave their home on their own (O'Brien, Jones, Sloan, & Rustin, 2000). CIM includes activities that children can do independently, such as crossing main roads, travel to places aside school, travel home from school, travel by public transport, bicycle and go out after dark (Carver *et al.*, 2014).

Children's independent mobility is linked with *Active Travel to School* which means walking or cycling to school instead of taking the car or public transport which are passive transportation modes (Easton & Ferrari, 2015; Lee, Orenstein, & Richardson, 2008). Active school travel has many benefits for the child, including higher levels of physical activity and psychological gains such as potentially having more social interactions. On the contrary, children who are chauffeured are more likely to perform sedentary activities and have weight issues (Easton & Ferrari, 2015; Ermagun & Samimi, 2015; Helbich, 2017; Larsen, Larouche, Buliung, & Faulkner, 2018; Oja et al., 2011; Schoeppe et al., 2013).

Researchers who have studied active travel to school, agree that no single factor can determine active school travel. However, factors that have more prominent influence on active school travel are similar across studies. These key factors are:

- distance to school (Broberg & Sarjala, 2015; Ermagun & Samimi, 2015; Mitra & Buliung, 2015);
- road, traffic and perceived safety (Broberg & Sarjala, 2015; Carver, Timperio, & Crawford, 2013; Johansson et al., 2012);
- street connectivity (Broberg & Sarjala, 2015; Helbich et al., 2016).

Nevertheless, experience from various countries has shown that investments in infrastructure alone have not brought the desired outcomes and thus educational programmes are also essential in influencing children's travel behaviour (Deka, 2013; Mitra & Buliung, 2015; Pucher et al., 2010).

Factors influencing active school travel also vary between younger children and the adolescences. Both Mitra (2013) and Johansson et al. (2012) agree that active commute to schools decreases as children get older. While younger children generally prefer to walk to school or use the walking school bus, the youth tend to prefer public transport (Mitra & Buliung, 2015; Hinckson, 2016). Hinckson (2016) also found that both younger and older children enjoy traveling with their peers, although they use different modes of transportation.

2.2 A behavioural model of school transportation

This research adopts Mitra's model of school transportation (2013) and uses the four domains of *external factors* (1), *urban environment* (2), *household* (3), and *child* (4) (Figure 1) to identify factors influencing active school transportation in Tallinn. However, in its simplicity, it excludes socio-demographic and economic indicators for travel behaviour.

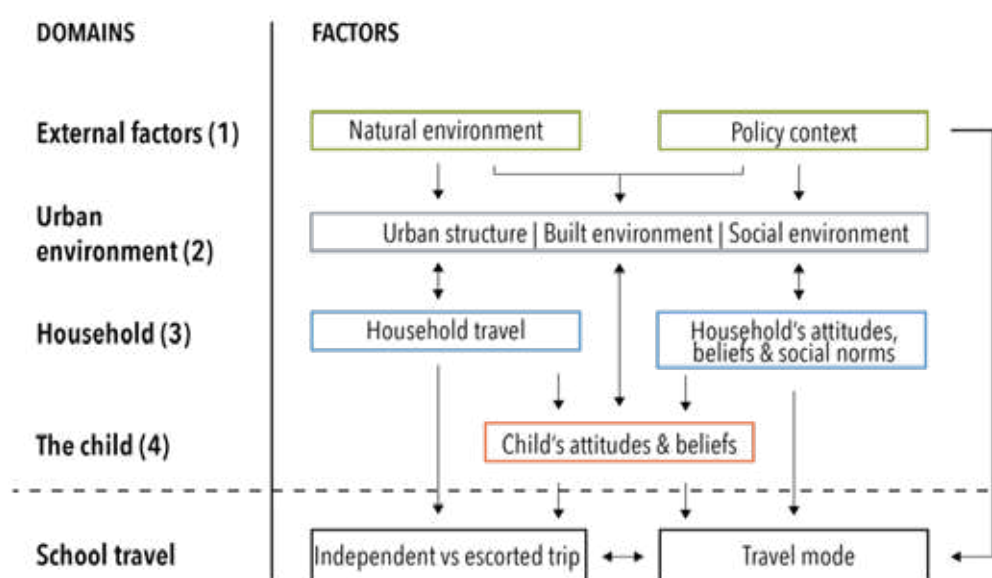

Figure 1: A simplification of Mitra's (2013) model of school transportation.

The first domain – *external factors* - include the natural environment and policy context. A city's topography, weather and climate, influence active school travel (Mitra, 2013). Studies from the Nordic countries report a

decrease in cycling rates in winter months (Larouche et al., 2016). However, if children are used to cycling on a daily basis, they are less likely to change their habits due to the change in season (Helbich et al., 2016; Larouche et al., 2016). Policies such as the possibility to use a school bus and provision of bike parking at school, can encourage or discourage cycling.

The second domain - *urban environment* – includes the urban structure, built environment and social environment. Here, Mitra (2013) identifies five links between neighbourhood characteristics and school travel outcome – proximity to school (1), traffic and personal safety concerns (2), connectivity of streets suitable for active travel (3), comfort and attractiveness of active travel modes (4) and opportunity to produce and maintain social capital (5), such as cycling together with other children.

The third domain – *household* – says that social norms and values, and the travel options contribute to school mode choice. Children are more likely to engage in active transport if they live in a car-less household. Relatives, friends and even teachers may disapprove parents' choice for active school travel (Bennetts et al., 2018; Mitra, 2013). General household activity, such as driving to work in the morning makes it convenient to drive the child to school (Mitra, 2013), but if parents are confident about their child's physical and cognitive capabilities, and aware of the benefits of active transport, they are more likely to encourage active school travel. plays a role.

The fourth domain - *the child* – says that children themselves have an opinion about their transportation options and consider their cycling capabilities and efficacies. These attitudes also change over time as they become more independent in their teenage years and make their own decisions about their mode of transport (Mitra, 2013). Veitch et al (2017) found that if children enjoy cycling, it contributes largely towards their traveling behaviour.

3 Methodology

The research requires both quantitative and qualitative methods to understand what factors influence school travel (quantitative/qualitative), and how and why they influence school travel (qualitative) in Tallinn.

3.1 Ethics approval

This research is concerned with children who are considered vulnerable groups according to the European Commission. A research protocol was submitted to and approved by the Wageningen University and Research Social Sciences Ethics Committee who declared the research satisfactory in terms of dealing with ethical issues and its compliance with the Netherlands Code of Conduct for Research Integrity.

3.2 Observations in Tallinn

Observations were carried out around three schools in Tallinn in the morning before the start of the first class. Observation forms were used to note down the weather conditions, number of cyclists entering school premises, other active modes besides the bike, location of bicycle parking and number of bikes at the bicycle parking. Photos were taken of the cycle parking and infrastructure surrounding the school. See Figure 2 for overview of school locations.

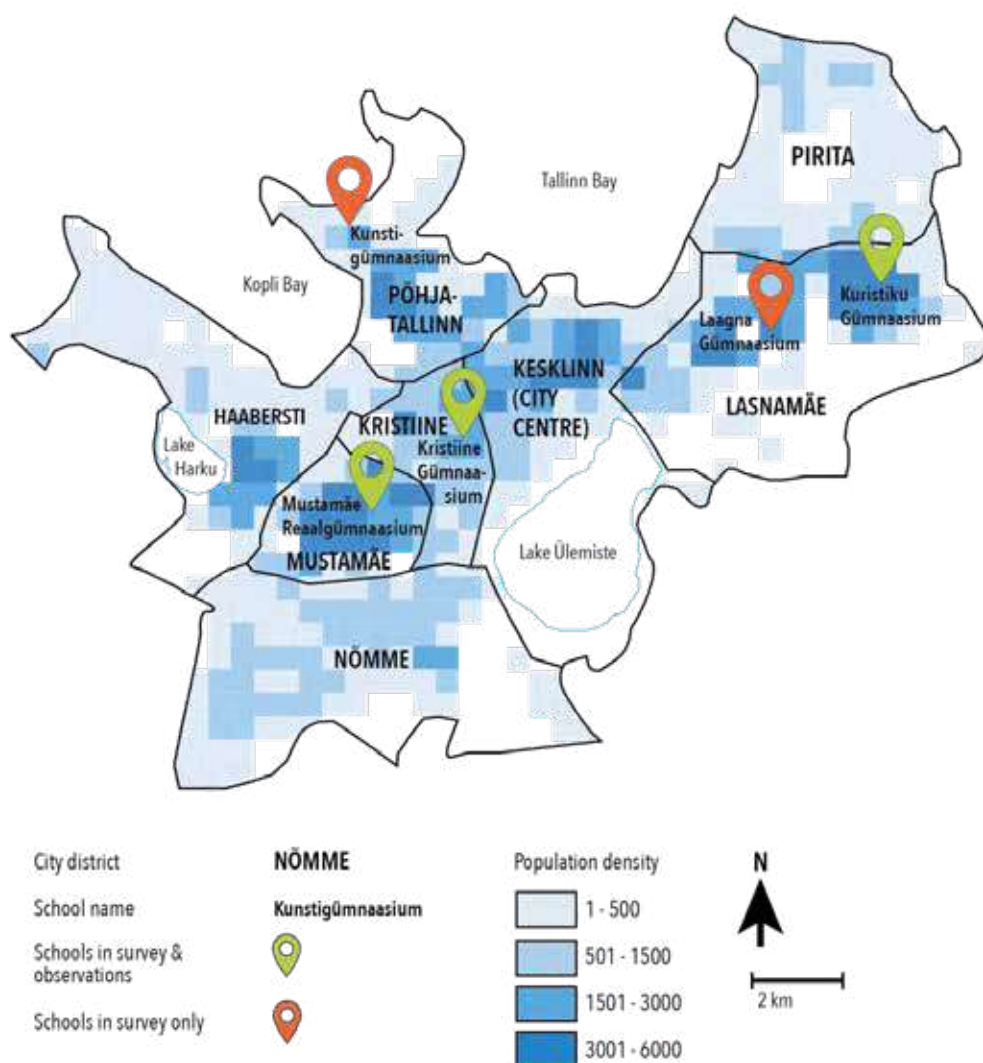

Figure 2: Tallinn – location of schools included in observations and survey

3.3 Survey among school-going-children in Tallinn

A survey was carried out among 13-16-year-old (forms 7-9) school-going children to gain a general understanding of pupils' attitudes and beliefs about cycling and barriers for cycling to school. The survey was carried out at five schools, resulting in 511 responses. This represents 5% of school-going children in Tallinn in forms 7-9 (Tallinn Education Department, 2018).

Topics covered in the survey included bike ownership, usual school transport mode, distance to school, uptake of cycling to school and different barriers to cycling. The survey was carried out as part of a promotional activity offered to schools by the Tallinn Cycling Coordinator. The interactive survey used Kahoot™ as a survey tool, included 9 multiple-choice questions and lasted about 10 minutes.

3.4 Focus groups in Tallinn

Once the surveys had been completed, three focus groups were carried out to gain in-depth information about additional barriers to cycling, and how and why these barriers influence cycling to school. Focus group participants were identified via tutors of grades 7-9 at various schools and through the network of the Tallinn Cycling Coordinator.

The three focus groups included:

1. School-going children aged 13-16 (6 participants);
2. Parents of school-going children (3 participants);
3. Tallinn's mobility experts (6 participants).

5 Results

The observations, survey and focus group sessions allowed to gain a comprehensive understanding of factors that influence cycling to school in Tallinn.

5.1 Cycling to school in the cityscape (observations)

The school observations showed that the majority of cyclists were younger children. Next to cycling, the smaller children also used the kick bikes which is a more common mode choice than the bicycle. Mountain bikes dominated in the cycle parking. Cycle parking is provided at all schools; however, the location, size and security level of each facility varies (see Figure 3 for overview of cycle parking facilities). All facilities only allow front wheel parking, which at one school meant that more bikes were parked at a wheelchair rail where bikes could be locked from the frame. Around the schools, speed limitations are put in place.

Figure 3: Impressions of cycle parking at schools in Tallinn

Observations were made about the cycling infrastructure while cycling in the school's neighbourhoods (see Figure 4). First, existing cycling paths are almost always shared with the pedestrians. However, in many places these paths are narrow which mean that there is little room for cyclists to pass pedestrians. When these slow mode paths pass bus stops, there is virtually no space left for cyclists.

Second, when crossing large intersections, in most cases it is necessary to stop at least twice to cross the street because the traffic lights are not synchronized. In these situations, the cyclist has to stop in the middle of the street on an island which is often just narrow enough for the bike to fit.

Figure 4: Impressions of cycling infrastructure in Tallinn

Third, many of the cycling paths are in poor condition and in some places signage on the roads has faded. Also, in some cases when crossing a street, the cycling path continues, but the curb stone is so high that it is not possible to get on the path while on the bike. Cycle paths can also be found ending suddenly, which proves the lack of connected cycling network in Tallinn.

Finally, no bikes were seen parked outside apartment buildings. Cycle parking facilities outside of apartment buildings were not spotted, although bikes were seen parked on balconies.

5.2 Cycling trends among school-going children (survey)

The survey resulted in 511 responses from five schools in Tallinn. Among the children, 66% have a bike, 13% do not have a bike and bike ownership is unknown for 20.4% (question was not included for one school) (Figure 5). When asked how they usually go to school, the majority of 47% says they go to school on foot, followed by 34% who take the public transport. 11% are taken to school by car and only 35 children (7%) have chosen the bike as their mode of school transportation (Figure 5).

Figure 5: Bike ownership and share of transport modes in school travel

Combining data about distance to school and transport mode (Figure 6) shows that pupils living closest to school are most likely to walk while the ones living furthest away are most likely to take the car or public transport. Meanwhile, the ones cycling to school live anywhere from less than 10 minutes away to more than 30 minutes walking away from school.

Figure 6: Journey length vs transport mode

The final part of the survey focused on different factors that hinder pupils cycling to school. Figure 7 presents ranking of these factors for two groups – for all pupils who participated in the survey and for potential cyclists (have a bike; would like to cycle to school; currently use other modes). The top three factors are the same for both

groups, stating that the weather, bike storage at home and the fact that car or public transport are more comfortable are the most chosen factors. The least chosen factor for both groups is social influence by their friends and peers.

Figure 7: Ranking of factors hindering cycling to school

Overall, the data shows that the potential cyclists are more concerned about cycling facilities and are constrained by their parents, while all pupils are more concerned about safety and comfort of cycling. This could mean that the potential cyclists have more knowledge about the actual cycling conditions and are less worried about the safety issues and would like to have better parking facilities both at home and school.

5.3 In-depth exploration on cycling to school (focus groups)

In order to gain further insights into cycling and expand the information gathered through the survey and observations, focus group sessions with parents, children and Tallinn mobility experts were held. The results of the sessions were categorized according to Mitra's model (2013) and divided into external factors (1), urban environment (2), household (3), and the child (4).

External factors

The weather conditions in Tallinn prove to be a crucial barrier for cycling to school. Parents admit that cycling is unlikely during winter months and rainy days. However, for children it could be more the perception of unsuitable cycling conditions than the actual weather of the day. Experts add that weather can be an even bigger barrier for adolescents than younger children, because it could imply wearing different clothing. The children themselves state that they would only cycle to school in warmer months.

"People already have attitudes about the weather, especially in the teenage years. Smaller children wear rain clothes, but in that age, you still want to wear jeans and white sneakers, so how can you go by bike."

- Tallinn Mobility expert 3-

The cycle parking facilities provided by the school influence cycling to school. The parents state that a child should feel confident about leaving their bike at the cycle parking. Three experts add that the location of the parking facility is crucial - preferably at a visible spot right next to the school's entrance.

Cycle parking is considered a major issue for people living in apartment buildings. Since most apartment buildings do not have cycle parking facilities, bikes are kept in the basement or inside the apartment. However, the basements are small and narrow which makes getting the bike out difficult, and also unsafe. Parents and experts agreed that it is likely that pupils prefer to walk to school instead of cycling if getting the bike out and locking it at school takes more time than walking.

"The one who is going to school on foot lives so close that there's no point to go by bike. Our aim is not to make children who walk one kilometre to cycle. But taking the bicycle out of storage and locking it (at school) takes proportionally too much time."

- Tallinn mobility expert 1 -

The three parents agree that a prevailing issue in Tallinn is the lack of cycling infrastructure and cycling culture. Although the infrastructure exists, many bike paths are not connected to each other or end suddenly. Cycling on the road is not favoured by any of the parents and it is a shared opinion that cycling smoothly is not possible due to multiple road crossings and traffic lights. Lack of cycling culture and lack of continuous paths could be the reason why pedestrians do not walk on their side of the shared paths and thus make it more complicated for cyclists to pass.

"Usually there's a mom with a buggy on one hand and a dog in the other, walking all over the shared path. You can see for yourself how you pass them."

- School-going child 1 -

Regarding infrastructure around schools, two experts stated that attractive and well-maintained school cycling routes are essential. The main cycling routes leading to school in the first 200 metre radius from the school should be inspected and retrofitted since that is the area that is used by most children.

Two parents add that arriving to school by bike in the morning is dangerous because many parents bring their children to school by car and drop them off right at the school's front door. The same issue comes up also at the experts' session. A "drop-off" zone further away from the main entrance would be helpful to improve the safety situation according to the parents and experts.

"At the same time, there are a lot of cars. Estonian schools have effectively avoided a so called „kiss and fly“ zone where you could say bye and go, there's no place for that. The area in front of the school is full of cars and it is dangerous to go through by bike."

- Parent 1 -

Household

Two parents state that they are not bothered that their children do not want to cycle to school. One of the parents said her children would be too distracted on a bike. Another one mentions that she knows exactly how her daughter behaves in traffic, and thus feels comfortable with her cycling alone. The parents do not actively encourage their children to cycle to school.

"It's very important that (cycling to school) seems safe for the parents. Even when a child wants to (cycle to school), then if for a parent the journey doesn't feel safe, the child will not be allowed to cycle."

- Tallinn mobility expert 2 -

All parents agree that if a parent does not cycle, their perception of traffic safety is low. This statement is also supported by four experts. The experts conclude that working with parents on their attitudes about cycling is crucial in getting more children to cycle to school.

Children say that none of their parents have permitted them from cycling to school due to unsafe conditions. However, their parents would not allow them to cycle to school because they have expensive bikes. The ones cycling to school use cheaper bikes for the purpose. The parents agree with this reasoning.

Parents' willingness to take their children to school by car influences children's mobility choices. One of the parent states that she used to chauffeur her children since school was on her way to work. However, all parents are aware that it is a major issue for safety in the morning and wish the parents would drop off the children a bit further away.

The Child

While parents can influence the child's mobility decision, it is clear that the children themselves, especially in adolescent years, have an opinion about how they go to school. One of the parents says that his daughter does not acknowledge cycling in the cityscape although she does like to cycle for recreation. The reason for this could be that children are not aware of the fun benefits of cycling.

My 15-year old does not bike to school because she does not like it. She likes to go on longer bike hikes, but does not consider the bike as a mode of transportation in the city, even though we as parents are an active example.

- Parent 1 -

When reflecting on the outcomes of the survey, the experts have difficulty believing that children are not influenced by their peer. Instead, they suspect that the pupils cannot objectively assess their behaviour.

The experts agree that all kind of supportive information and campaigns could lead to more children cycling to school, but especially in reducing the number of pupils being brought to school by car. They propose that a campaign similar to the on-going "smoke-free classroom" could be implemented either in warmer school months

or at the same time with the Tallinn's Sustainable Mobility month. "Car-free classroom" would entail that it is up to the child to choose which mode of transportation they choose, because the aim is not to get everyone to cycle, but simply move more.

6 Discussion

External factors

Adolescence in Tallinn consider the weather as the main barrier for cycling to school. This is explained as Tallinn does experience harsh winters and a lot of rain in autumn. However, parents and experts are certain that children may associate cycling only with sunny weather. Although Mitra (2013) and Helbich (2016) state that changes in season have little effect on changing mode choice, weather is indicated as a key factor for active mode choices in Czech Republic (Hollein et al., 2017) that has comparable weather patterns to Estonia.

As distance to school is considered the most prominent barrier to active school travel, policies on parental choice for schools (Easton & Ferrari, 2015) and the school's catchment area (Mitra, 2013) can determine how far children live from their schools. This study purposely opted for schools in Tallinn with a local catchment area and thus a high share of active travel was found in the survey. Different results would be expected if the survey included schools located in the city centre that attract pupils from across the city.

Public transport is free of charge for school-going children in Tallinn. Therefore, it is common for the youth to opt for this more comfortable option as they become more independent (Mitra, 2013; Mitra & Buliung, 2015). Although generally taking the public transport allows some walking, experts believe that pupils opt for public transport even on shorter distances that would be suitable for both walking and cycling. Similar findings have been discussed in Finland (Broberg & Sarjala, 2015).

Cycle parking facilities at schools was a much-discussed topic. Pupils in Tallinn generally regard cycle parking not sufficient and thus opt for other modes. Observations showed that in all schools locking the bike was only possible from the front tire. According to Mitra (2013), provision of cycle parking is part of the schools' mobility policy. Hinckson (2016) found that in schools where active mobility initiatives were not implemented, pupils found cycle parking limited and not appropriate for use. Together with low security measures, these conditions prevented pupils from cycling to school.

Urban Environment

A prominent issue in cycling in Tallinn is the lack of cycle parking facilities in apartment buildings where taking the bike out of storage takes too long for daily use. Previous studies have not elaborated on parking facilities at home. However, Kaplan et al (2016) found that in Denmark children living in an apartment are less likely to cycle and more likely to walk. Similarly, active commute was found more prominent in children living in an apartment in Sweden (Johansson et al., 2012). Contrarily, Broberg & Sarjala (2015) report that children living in private houses in Finland are more likely to take up active transport, because the smaller blocks provide a more suitable environment for walking and cycling.

In Tallinn, pupils living in less dense neighbourhoods are expected to cycle more, consistent with the Finnish study. This could be related to having an easy access to a bike, but is likely linked with the reduced availability of bus stops in such neighbourhoods similarly to Finland (Broberg & Sarjala, 2015). This research did not ask pupils to specify their living condition in the survey. Nevertheless, the findings indicate that one of the reasons cycling uptake may vary between private housing and apartments is the availability and quality of cycle parking.

Next, the survey in schools clearly indicated that most children travel to school actively if they live within a 30-minute walking distance from the school, while cycling is more likely in the 10-30-minute range. This corresponds

to findings of many studies that report that distance between home and school is the key barrier for active school commute (Broberg & Sarjala, 2015; Carver et al., 2014; Deka, 2013; Helbich et al., 2016; Hollein et al., 2017).

Regarding cycling infrastructure, this research found availability of connected and safe cycling paths, and its strict separation from pedestrians crucial for enabling cycling to school. Connectivity and traffic safety aspects have been reported as significant variables in many studies (Broberg & Sarjala, 2015; Helbich et al., 2016; Hollein et al., 2017). Strictly separated cycling paths from the pedestrians are described important by findings of Pucher & Buehler (2008) yet similar findings have not been discussed in studies about children.

Household

Low percentage of chauffeuring to school was a surprising finding in this research. The share is believed to be higher by experts and was also reported higher in an earlier study (Eesti Uuringukeskus, 2017). However, congestion in front of schools in the mornings could also be caused by parents of younger children. This would be in line with Carver et al (2013) who found that primary school children are more likely to be chauffeured. Such explanation is consistent with studies indicating that young adolescents are more likely to travel independently (Helbich, 2017; Mitra, 2013; Mitra & Buliung, 2015). Estonia's limited policies regarding car use may also lead to more parents driving children to school. This is in keeping with the findings of Deka (2013) and Helbich (2016), who state that policies aimed to reduce car use will have an influence on car chauffeuring in school transportation.

As children in Tallinn primarily have mountain bikes, parents may not allow their children to take this bike to school. This is related to the low safety measures of school's parking facilities. Such findings have not been discussed in earlier studies.

The child

Children who cycle are primarily younger school children, as found through the observations. This is consistent with findings of Potoglou & Arslangulova (2017), who add that active travel to school peaked at age 12 and decreases from there. Considering that increasing age of children is related to improved cognitive abilities and independence (Carver et al., 2013; Mitra & Buliung, 2015), more active travel could be expected among adolescents. However, as taking the public transport is free for school-going children and most of their peers take the public transport, opting for this mode is understandable.

The choice for public transport is also reported as a comfortable option for the youth (Hollein et al., 2017). In a qualitative study in New Zealand (Hinckson, 2016), the adolescence found taking the bus a convenient, cool and fun option that allows them to hang out with friends. Thus, as discussed in the focus groups, mode choice is influenced by friends' opinion on mode choice and their actual mode choice. Additionally, at the age of 13-16, the children have formulated their own opinion about different mode choices (Johansson et al., 2012; Mitra, 2013; Mitra & Buliung, 2015), which corresponds to the results of this study. For instance, adolescence in Stockholm said that they would avoid cycling in traffic if possible (Johansson et al., 2012).

7 Conclusions and Recommendations

Physical activity among children has rapidly decreased in the past decades as children perform more sedentary activities and are often driven to school. Enabling active school travel would introduce some extent of physical activity back into children's lives. Among active travel modes, cycling allows commute on longer distances than walking and is thus a suitable alternative to motorized daily travel in a city.

Tallinn adopted its first cycling strategy in 2018 and is gradually retrofitting the city for cycling. Among other aims, the strategy aims to develop safe cycling infrastructure around schools to enable cycling to school. In

collaboration with the Tallinn Cycling Coordinator, this research identified key factors that influence cycling to school in Tallinn.

The key factors that influence cycling to school in Tallinn are safety on school travel routes, parking facilities both at home and schools, and the availability safe, smooth, connected and separated cycling infrastructure. The Tallinn Cycling Strategy already provides a variety of measures that can improve safety of cycling in the city which will be implemented step-by-step.

Additionally, in order to increase safety on school routes, the city should take a comprehensive approach which would allow both infrastructure improvements in collaboration with children and parents, but also include campaigns that influence travel behaviour. As parking facilities are currently a major constraint to cycling in the city, the city could provide parking guidelines that help dwelling owners and schools to choose for a parking facility that is convenient and safe.

This research sheds light on a capital city in Europe that is taking its first steps to allow for more cycling. The findings here support the understanding that simple adoption of measures from a city such as Amsterdam would not result in the desired benefits because of the lack of a cycling culture. Instead, upcoming cycling cities should focus on measures that the inhabitants deem important. Additionally, upcoming cycling cities can learn from each other and avoid implementing infrastructure measures that other cities are now starting to correct, such as lack of separation between cyclists and pedestrians.

8 Limitations

The extent and quality of the survey and the focus group sessions in this research has to be considered carefully due to financial and time constraints posed for this research.

First, the survey had to be short and concise, which lead to a 10-minute time frame and the use of the Kahoot™. This tool only allowed multiple-choice questions, which left no room for children's personal views if they differed from the given answers.

Second, the focus group sessions were held with less participants than originally planned. The parents' session only included three parents of which two are active cyclists themselves. Although the parents seemed to be able to offer a broad view on cycling to school, conversation with a larger group of parents could have offered more insights into the opinion of parents who are less likely to allow their children to cycle. The children's focus group was limited to participants who participate in cycling training, thus eliminating pupils who, for example, feel uncomfortable when cycling.

Acknowledgements

This research was funded through the kind contribution of the EFL Foundation – a foundation that preserves the legacy of the prominent 20th century Dutch urban planners Cornelis van Eesteren and Theodor van Lohuizen. The Tallinn Cycling Coordinator, Erik Sarapuu offered much assistance throughout the study, by carrying out the surveys at schools, and also providing contacts for the focus group sessions.

Abstract: We explore how home parking quantity affects households' choices of car ownership and commute mode in the Greater Wellington Region (GWR) in New Zealand. We consider socioeconomic characteristics of commuters from the New Zealand Household Travel Survey between 2003 and 2017, as well as commute time, and characteristics of the residential location. The research makes two important contributions to parking literature. First, we consider commute time for different modes instead of distance. Time better represents perception of commute length. Second, our work is regional in scale, including several urban and rural areas. Almost all current studies focus on urban areas. Results of this study show the significant impact of home parking quantity on car ownership and commute mode. Households with more parking at home tend to have more cars and drive to work. Wellington downtown is surrounded by sprawl suburbs with high residential parking supply. Therefore, spatial structure of the GWR and parking quantity encourage car trips to the downtown. More car trips mean greater demand for parking at the city centre. Hence, there is a relationship between home parking and work parking which is rarely studied in parking literature. This is the focus of our future research.

Keywords: home parking, commute mode, sustainable mobility, Conditional Logit.

Introduction

Commuting can be viewed either as making trips between home and work or as changing parking (i.e. from home parking to workplace parking and vice versa). The first approach has dominated commuting studies (see for example, Beige & Axhausen, 2017; Ding, Liu, Zhang, Yang, & Wang, 2017; He & Zhao, 2017; Hu & Schneider, 2017; Melo & de Abreu e Silva, 2017; Moreno-monroy & Posada, 2017; Rüger, Pfaff, Weishaar, & Wiernik, 2017). However, commuting includes both travelling and parking. Every trip ends at a destination (i.e. home or workplace) where commuters typically spend one third to a half of their day, while their cars are parked. Considering commuting as a combination of flows (trips) and places (parking), cars are most likely to stay in places rather than flow between them.

There is little literature on the relationship between commuting and parking. In the small parking literature, most studies focus on parking downtown (Amer & Chow, 2017; Arnott & Rowse, 2009; Franco, 2017), however, parking at home is also important. Cars are usually parked at home longer than they are in the workplace. Many trips begin, and eventually end,

with the car parked in a residential suburb. Moreover, access to suitable home parking is often one of the factors commuters consider in deciding where to live and how to commute. Access to more car parks at home may encourage a household to have more cars, and consequently, drive to work more often.

Therefore, according to the dominant demand-oriented approach in urban transportation, the main question regarding parking is whether home parking is one of the areas of policy intervention to control transportation demand? If home parking is a significant factor, policy makers can use this knowledge to set appropriate regulations.

In this study, we provide empirical evidence on the impact of residential parking on households' choices of car ownership and travel mode. First, our study is also novel in the regional scale examined. Instead of considering one city, we consider the Greater Wellington Region (GWR) in New Zealand. The GWR has high density suburbs in Wellington city (the main city) and sprawling suburbs surrounding it. We then explore the effect of different residential locations or parking. Second, in contrast to most studies in this area, we consider households' choices of residential location. Commuting is a multi-dimensional issue including a consideration of housing in addition to travel and demographic characteristics. This approach also removes the problem of endogeneity between home parking and car ownership. Finally, we consider travel time instead of distance as proxy for commute length.

Literature

For residential parking, most studies concentrate on the cost of residential parking (Groote, Ommeren, & Koster, 2016; Z Guo & McDonnell, 2013; Seya, Nakamichi, & Yamagata, 2016). The impact of free on-site home parking on households' choices of commute mode and number of cars is neglected outside of Guo (2013a and 2013b). Guo (2013a) who poses three questions. First: does residential parking supply have a causal influence on car ownership and usage? If so, the second question is that is the parking effect large enough, compared to other factors, to justify policy intervention? The impact needs to be both strong and statistically significant to be considered in policy intervention. Third, what is the relative importance among the different residential parking types, such as garage, driveway, and on-street? In Guo's work, households are divided into two different groups in terms of type of parking: households with off-street parking and households with only on-street parking. He applies a nested logit model to capture the causal effect of parking supply on car ownership. He concludes that (in contrast to the dominant literature, which considers household's income and demographic characteristics as important factors affect car-ownership), parking supply has a significant impact on car ownership.

Guo (2013b) focuses on parking convenience and its impact on car usage. He defines parking convenience as parking "certainty" and parking "ease".¹ Different parking types have different levels of certainty and ease. Parking convenience's effect on car usage is measured using a regression model. In this model, variables like mode choice, car usage and Vehicle Mile Travelled (VMT) are dependent variables and explanatory variables are parking convenience and control variables. The percentage of households using each type of parking (garage, driveway and on-street) and the average time of use for each type is measured. He found that households with off-street parking drove considerably more than others. In addition, when two parking types (off-street and on-street) are available, households parked on-street made more trips by car.

¹ Parking certainty is the convenience to find a parking space at a desired place and a desired time and parking ease is the convenience to move the car in and out of the parking place (Guo, 2013b).

Methodology

This study employs a conditional logit model to estimate the impact of explanatory variables on a categorical response variable. Explanatory variables are factors that affect households' choices of car ownership, commute mode and residential location (e.g. parking quantity, income). The dependent variable is the households' choices observed in the data. The estimation process with conditional logit is:

1. Measure utility (preference) that each commuter achieves from each choice using equation 1 (Greene, 2003, P.719):

$$U_{ij} = \sum_n \beta_n X_{ijn} + \varepsilon_{ij} , \quad (1)$$

where individual "i" gets utility from choosing option "j" based on the set of observables "X". The coefficient vector is given by " β " and ε is the error term (which is logistically distributed).

2. Given the error distribution, calculate the probability that each commuter chooses option "j" as follows:

$$P_{ij} = \frac{e^{\sum_n \beta_n X_{ijn}}}{\sum_l e^{\sum_m \beta_m X_{ilm}}} , \quad (2)$$

in which P_{ij} is the probability that person i chooses choice j. From equation (2), the probability that each individual chooses the actual choice observed in data can be estimated.

3. To find coefficients, we choose coefficients that maximize the probability that each person chooses the choice that is observed in data. we maximize the following Log likelihood function:

$$\text{Log } L = \sum_i \text{Log } P_i(j(i)) , \quad (3)$$

where $P_i(j(i))$ is the probability that individual i chooses the actual choice (j(i)) observed in data among all his/her alternative choices. We use the Maximum Likelihood (ML) method to estimate the coefficients (β) and their variance.

Case study

The Greater Wellington Region (GWR) includes several urban and rural areas with a diverse range of socio-economic and spatial characteristics. As shown on figure 1, GWR is in the South of the North Island of New Zealand and includes 8 districts with population of 513,900 in 2017 (Greater Wellington Regional Council, 2017).²

² <https://profile.idnz.co.nz/greater-wellington>

Figure 1: Greater Wellington Region³

In Wellington City, space available for off-street residential parking and on-street parking is restricted. However, in other council areas, low-density suburbs with plenty of space available for parking, parking is mostly free of charge and without time limits. Figure 2 shows two examples of home parking supply in the city and outside. Hence, Wellington City is quite different than other areas in terms of home parking quantity and regulations.

Survey data

The New Zealand Household Travel Survey (HTS) was conducted by Ministry of Transport (MOT) from 2003 to present. A number of MeshBlocks (MBs) are randomly selected and then, across consecutive years households within these MBs are interviewed on two consecutive travel days until all households in that MB have been surveyed.⁵ Our sample includes commuters with fixed workplace in the GWR (2155 commuters in 1540 households).

Data and explanatory variables

- **Home parking quantity**

Home parking quantity is defined as two variables in our model. First is a dummy variable indicating whether the household lives inside Wellington City (D_{city}). Second is the interaction of this dummy variable and the percentage of households in each MB with home parking ($D_{city} * Parking$).

- **Travel time:**

We use an adapted transport network based on a road network from Kim Ollivier and Co and updated by Daglish *et al.* (2015) in ESRI's ArcMap.⁶ This network measures travel time and cost based on road restrictions (e.g. one-way roads) and costs (including traverse time and fuel consumption for each edge of network). In measuring travel time for walking and cycling, the network considers speed based on the slope of each edge in the network, particularly suitable for the hilly terrain in Wellington. Cyclists are assumed to follow similar road rules to drivers. An amended network considers Public Transport (PT). A journey to work by PT accounts for walking or driving to a PT stop and walking from the last stop to work.

- **Household Socio-economic characteristics:**

We control for the following characteristics based on the HTS data. Household's income is classified in table 3.

Table 3. Household income

Income range (\$)	classification	Measure
0	No income	0
1-20,000	Low income	1
20,001-50,000	Middle-low income	2
50,001-70,000	Middle-high income	3
70,001-100,000	High income	4
100,000 ⁺	Very high income	5

In the model, we use this measure as a variable for income. We also include the following covariates:

⁵ A MeshBlock (MB) is the smallest geographic unit for which statistical data is reported by Statistics New Zealand. "Area Unit" (AU) is the next smallest census area.

⁶ Kim Ollivier and Co network is described at <https://koordinates.com/supplier/corax/>

- Number of driving licence per household
- Commute mode of each commuter
- Ethnicity
- Age and gender
- Number of cars per household
- Households with children
- Number of people in household working in Wellington CBD
- **Built environment features:**
 - Market house value in each MB:

“A Rating Valuation is a three-yearly assessment of a property's value in relation to current market values” (Wellington City Council, 2019). We take the median of RV in each MB to avoid very high or low values. As MBs are small and few houses in them are sold each year, we calculate the ratio of median sale price over median RV of sold houses in each MB and for each year. This ratio gives an idea of the difference between market value and RV. We multiply this ratio by the median RV of that MB for that year to calculate our measure of market house value. Homes.co.nz provided median RV, median sales prices and median RV of sold houses in each MB for each year for all the GWR for the period of 2003 to 2017.⁷
 - North-facing (sunlight):

Sunlight is a key factor in Wellington housing demand. As a proxy, we use North-facing houses as this study is conducted in the southern hemisphere. Our measure is the percentage of residential area in each MB that is North, North-east and North-west facing.
 - Proximity to commercial areas: Close proximity to shopping centres and supermarkets is attractive. We measure drive time from residential locations (MB centroid) to commercial centre of the neighbourhood.

Results

As shown in figure 3, in Wellington city, home parking quantity varies considerably among MBs. Residential blocks in the CBD are dominated by apartments where, on average, only half (55.9%) have parking on the property. This value increases to 60.86% in suburbs surrounding the CBD, and to 77.22% all of Wellington City.

⁷ Homes.co.nz is one of the institutions in New Zealand presents information about properties' features.

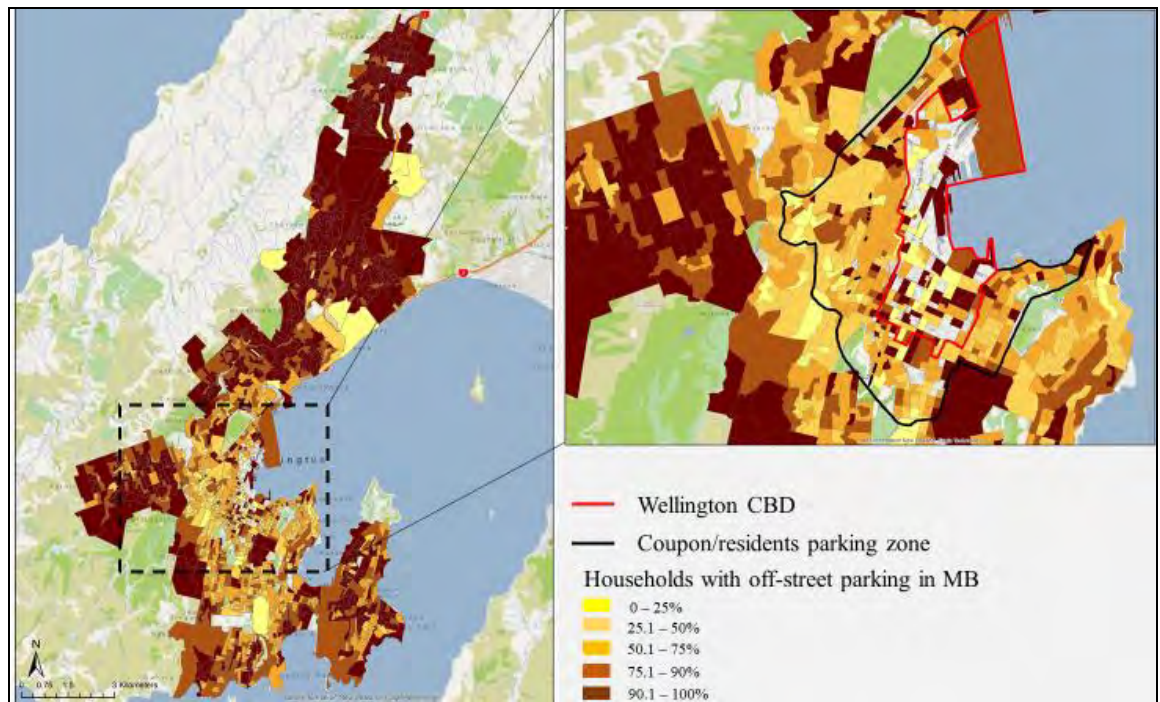

Figure 3. Home parking quantity in Wellington city

Closer to the downtown, households are less likely to live in a suburb where all houses have parking.

The difference between Wellington City and outside in terms of home parking quantity generates a considerable difference in car ownership and commute mode. According to figure 4, preference of households living in the city for having only one car or not to have a car is more than households outside. However, two or more cars are more popular outside Wellington City.

Figure 4. Number of commuters in the sample in Wellington City and Outside in car ownership categories

Figure 5 shows that although Wellingtonians are more willing to walk or cycle to their workplace, driving is much more popular among residents of urban and rural areas outside of the city.

Figure 5. Number of commuters in the sample in Wellington City and Outside in commute mode categories

According to figure 6, in Wellington city, suburbs with more off-street parking at home are more attractive for households who like to have at least one car. It is mostly the case of sprawl suburbs outside coupon/residents parking zone where more than 75% of houses have either a garage or driveway. Home parking provides a certainty and safety that may make commuters willing to have more cars and drive to work. Therefore, many daily trips to Wellington CBD from suburbs are car trips which may create a congestion delays travelling with public transport.

Figure 6. number of commuters in each home parking quantity and car ownership category (figure a) and mode category (figure b) in Wellington city

Car ownership and mode choices also depend on other factors (e.g. income). In the logit model, we control for important socio-economic characteristics and built environment features that might affect commuting choices. Then, we predict the impact of home parking on commuters' choices for the full study area (commuters in the Greater Wellington Region).

Estimation results

The results of our Logit model, shown on table 4, are consistent with our hypothesis about parking and commuting choices. Having cars is popular among households outside Wellington city. However, in the city, these choices are less popular.

Table 4. Logit model results

<i>Variable</i>	<i>Coefficient</i>	<i>T-stat</i>	<i>Variable</i>	<i>Coefficient</i>	<i>T-stat</i>
<i>Dcity</i>	0.42	0.50	<i>AT</i>	-2.27	-9.07

<i>DcityParking* three or more cars</i>	2.91	2.23			

More parking at home is generally attractive for households. Residential parking supply in the city is not as much as outside, therefore, people with at least one car prefer to live outside Wellington to benefit from high residential parking supply.

Driving is a popular choice among households living outside Wellington city where almost all houses have parking. However, limited home parking and congested streets in Wellington city encourage households to walk, cycle or take public transport to work.

Therefore, higher parking quantity at home means more car ownership which means a greater proclivity to drive. More car trips could be translated into more demand for parking at the downtown (which contains most of workplaces). Hence, there is a mutual relationship between home parking and parking at the CBD and we should consider them simultaneously in urban transport planning.

Residential location is another important choice. People usually like to live closer to their workplaces but there is a trade-off between commute time and house price. The ratio of the coefficient of log(time) to the coefficient of log(price) gives us an idea of how much more a household is willing to pay to get closer to the workplace of the household's head. The ratio of 0.49 means that household is willing to live in a house worth 0.49% more to reduce head's commute time by 1% (0.01 hour). For example, imagine a household rents a NZ\$ 500,000 house which is one hour from the head's workplace. They are willing to live in a

house costing $500,000 * 0.0049 = \text{NZ\$ } 2,450$ more to reduce commute time by 0.6 minutes. In the other word, this household might move to a NZ\$ 622,500 house to live 30 minutes closer to work, keeping all other features constant.

Income also plays an important role in this trade-off. Low income households prefer to save money by living in cheaper houses and as close to work as possible. On the other side, well-paid commuters who can easier afford monetary costs of commuting with fast travel modes (e.g. fuel, parking) care more about quality of house and residential neighbourhood.

Conclusion

This research sheds light on commuting in a network of cities and rural areas. Wellington City, as the capital of New Zealand, includes many governmental, commercial, cultural and educational businesses mostly in its CBD. However, high supply of home parking in sprawl suburbs encourage commuters to drive to the CBD. It means that urban spatial structure and home parking quantity are two important factors that help increase traffic congestion in peak hours. To improve use of AT and PT, the suggestion here is to put active and public transport in the highest priority and develop their routes and improve their efficiency. Another suggestion is to prevent spreading the city and instead, develop low-rise and high-rise buildings in the suburbs close to downtown.

Alternative discourse and narratives for institutional change in transport planning

Muhammad Imran¹

¹*School of People, Environment and Planning, Massey University, New Zealand*
i.muhammad@massey.ac.nz

Abstract: Mega transport infrastructure is increasingly resisted by local communities throughout the world. Community resistance becomes successful if alternative discourses and narratives have been developed and linked with a wide range of like-minded actors and are advanced during the transport planning process. This paper explores discourses argued and presented by various stakeholders to advance and resist the Basin Reserve Bridge (BRB) proposal in Wellington, New Zealand as a part of the Roads of National Significance (RoNS). This paper critically reviews planning and policy documents, media reports and submissions to uncover distinctive arguments and narratives within five main storylines: economic storylines, safety storylines, environmental storylines, traffic and access storylines, and heritage storylines. The influence of discourses is discussed at political, institutional and social levels to provide a greater understanding of community resistance. This paper concludes that alternative discourse has the potential to break a path dependency in transport planning and create a foundation for a new policy path.

Keywords: Alternative discourse, transport planning, Basin Reserve Bridge, Wellington

Introduction: Mega transport projects, community resistance and discourses

Transport planning literature documents high-density urban development as an indicator for providing a high quality sustainable urban transport system. Wellington, the capital of New Zealand, relatively fulfils the requirements of this indicator. However, Wellington's transport planning over the last fifty years has been focused on private vehicles and building-wide and better roads, motorways and tunnels. Main stream politicians, as well as transport professionals, present these projects as urban transport achievements. These projects were based on the narrative that traffic congestion, occurred due to increasing population and economic growth, would be relieved, and Wellington's quality of life would be improved. However, these narratives were resisted in the case of Basin Reserve Bridge (BRB) in Wellington CBD. The purpose of this paper is to critically review BRB proposal, and alternative discourse communities have developed and advanced to resist this road project.

A statutory document, the Government Policy Statements (GPS) on Transport under the National (conservative) party led government (2008-2017) have aimed at promoting economic growth and productivity by building high-quality roads known as the Roads of National Significance (RoNS). There is political recognition of the scale and number of RoNS necessary to accelerate economic growth and the creation of jobs. Politically, there is a firm belief that a strong economy and consequent prosperity is linked with road infrastructure investment which relieves congestion and promotes business. This belief is especially appealing in a country where over 85 per cent of people drives to work by car.

The Basin Reserve Bridge (BRB) proposal is part of the Wellington Northern Corridor RoNS project that aims to construct, operate and maintain a one-way two-lane bridge on the north side of the Basin Reserve Cricket Ground in Wellington. The Basin Reserve is a cricket ground located 2 km south of the Wellington CBD. The ground has officially been used for test, first-class and one-day cricket since 1866 make it the oldest test cricket ground in New Zealand. Currently, the Basin Reserve is used as a large roundabout with signals. It is estimated that over 25,000 vehicles enter into the Basin Reserve roundabout each day, 20,000 of which head towards Mount Victoria Tunnel (NZTA, 2015). These levels of traffic are producing congestion through high traffic volumes, which are affecting the State Highway one (SH1), local and freight traffic, pedestrians and buses. Without intervention, these congestion levels are projected to continue to rise by approximately 75% by 2021 due to Wellington's increasing population.

Unlike other RoNS projects, local communities resisted the BRB which is due to the gap between perceived benefits and personal and local cost such as decreased values of residential properties, personal safety and neighbourhood changes, related to the project. One way of addressing this issue is to involve the public in a meaningful way in the planning process, which reduces uncertainty and improves acceptance of such projects (Booth and Richardson 2001). In New Zealand, the Land Transport Management Act (2003) and the Resource Management Act (1991) provide a clear mechanism for public involvement in various stages of the planning process for roading projects. The consultation process includes information provision, consultation meetings, submissions, social media dissemination, and workshopping. In general, the number of people actively participating in this process seems to be limited, and any mild opposition to roading projects is dealt with during this process. Moreover, this process broadens people's understanding of the project and improves their satisfaction.

According to Dear (1992), the intensity of public resistance depends on the type of project, location of the project and community characteristics, along with other factors. For example, new roading projects are perceived as increasing car use and have safety and environmental impacts (North 1998). The location of the project is important because people relate the type, size and appearance of the project with the surrounding site. Several studies show that resistance to roading projects is higher in cities and suburbs where high-income and educated professional people to live and use an alternative mode of transport and have an interest in the environment (Dear 1992). They are more likely to receive information from multiple sources and attend consultation meetings and make submissions. Therefore, road infrastructure project advances based on economic growth and a car superiority agenda are contested beyond NIMBY in different cities around the world, including recently in Melbourne (Legacy 2016). Schwanenetal (2012) argues that contesting roads projects are more likely to become successful by developing alternative discourses, focusing broaden the criteria for road infrastructure investment. In recent years, decision makers recognise border social and environmental agenda and promote roading project with social and environmental discourses. Therefore, it is important to develop alternative discourses that encompass contextual details and focuses on promoting smarter choices that appeal to people and mobilise the community. Moreover, alternative discourses should be advanced and propagated them during the planning process.

This paper explores the Basin Reserve Bridge project's history, decision-making process, and the discourses argued and presented by NZTA, GWRC, WCCC and local communities and stakeholders. The paper addresses two broad questions. First is the question of whether there is community resistance of mega roading projects of BRB in Wellington. Second, if there is such resistance, what alternative discourse has been developed to make that resistance successful?

This paper applies the concept of path dependence on the development of the BRB proposal in Wellington. Path dependence explains the process of how a particular policy and solution becomes stable over time in an institutional context (Arthur, 1988; North, 1990). Transport policies and projects emerge from the norms, values, perceptions, mental-models and beliefs that decision-makers

use to discuss, interpret and solve problems (Denzau and North, 1994; Hajer, 1995). These soft dimensions of transport policy can be named ‘discourse’ directly contributing to how problems are perceived and approached, creating coordination and coalitions of like-minded organisations (ibid). It is, therefore, important to question beliefs and explore alternative discourse in urban transport planning. A theoretical framework based on the discursive form of path dependence examines soft factors or discourses that justify and advanced resistance of BRB. In terms of method, the paper critically reviews planning and policy documents, media reports and submissions to uncover distinctive arguments and narratives which tried to break path dependency.

2. Wellington Basin Reserve Bridge (BRB) – History and decision-making process

New Zealand is a small country. According to the 2013 census, 4.3 million people reside in New Zealand. Despite a rural heritage and economy, approximately 87 per cent of NZ’s population resides in urban areas. Collectively, three metropolitan cities Auckland, Wellington and Christchurch account for one-half of the country’s population. Wellington is capital of New Zealand and divided four distinct geographic parts: 1) high rise CBD and inner suburbs 2) post-war suburbs in Hutt City and Upper Hutt City 3) regional centres of Porirua and 4) rural towns, coastline and hills. The steep hilly topography and coastline of Wellington dictate the urban form and transport infrastructure in the city. The population of the Wellington region is approx. 500,000 in 2019. The city has a highly developed and compact Central Business District (CBD) due to constrained by the physical space available for development (see Figure 1). According to the 2013 census, professionals and managers comprised nearly half of the total workforce in the region mainly employed in the CBD.

Transport planning in Wellington is the responsibility of the NZ Transport Agency (NZTA) who is managing state highways, Greater Wellington Regional Council (GW) who look after public transport services and eight territorial (city or district/rural) councils who managed local roads and public transport infrastructure. Land Transport Management Act (LTMA) 2003, Local Government Act (LGA) 2002 and the Resource Management Act (RMA) 1991 provide the frameworks enabling authorities at different levels to undertake transport planning activities.

The Basin Reserve Bridge (BRB) proposal can be traced back to the 1963 De Leuw Cather Transport Plan, followed by the debate carried on in the 1970s when an extension to the Wellington Urban Motorway was considered. However, it was not until the early 2000s that the idea of the Basin Bridge was properly explored. In 2000 a study of transport options around the Basin Reserve, prepared by Transit NZ and titled the Meritec Interim Scheme Assessment Report, was completed. This study identified ten options to relieve congestion at the Basin Reserve. The preferred option was a bridge at the northern boundary of the Basin.

In 2008 and 2009, the Basin Reserve Inquiry by Design was conducted. The aim of these design workshops was to assess and recommend transport interchange scenarios for the Basin Reserve. As a result, preferred scenarios were shortlisted and recommended for technical assessment (Urbanismplus Ltd, 2009).

The Feasible Options Report in 2011 listed five possible options which would aim to solve the traffic issue. An option evaluation workshop was held with relevant technical specialists in order to compare these five options. This report outlines the key drivers of each option, as well as descriptions, cost estimates and BCR figures, transportation benefits, artists’ sketches and walking and cycling routes (NZTA, 2011). The five options were compared against several evaluation criteria and effects. This report concluded by recommending options A and B as preferred options. However, option A was preferred by the majority of the technical specialists and the public.

Figure 1 Map of GW and compact CBD (photograph by Muhammad Imran)

The main purpose of the Basin Reserve Bridge (BRB) was to partially separate SH1 westbound traffic from the local road network to improve congestion (see Figure 2 & 3). The proposal aspires to overcome the existing congestion, which is currently affecting SH1 traffic as well as local traffic, freight, buses, cyclists and pedestrians. The proposal also aims to (i) resolve the conflict between the two key transport arterial corridors of Wellington City, (ii) reduce traffic flows around the Basin Reserve, (iii) improve journey times and reliability, (iv) improve safety for all travel modes and (v) provide more reliable emergency service access to and from Wellington Hospital (NZTA, 2015).

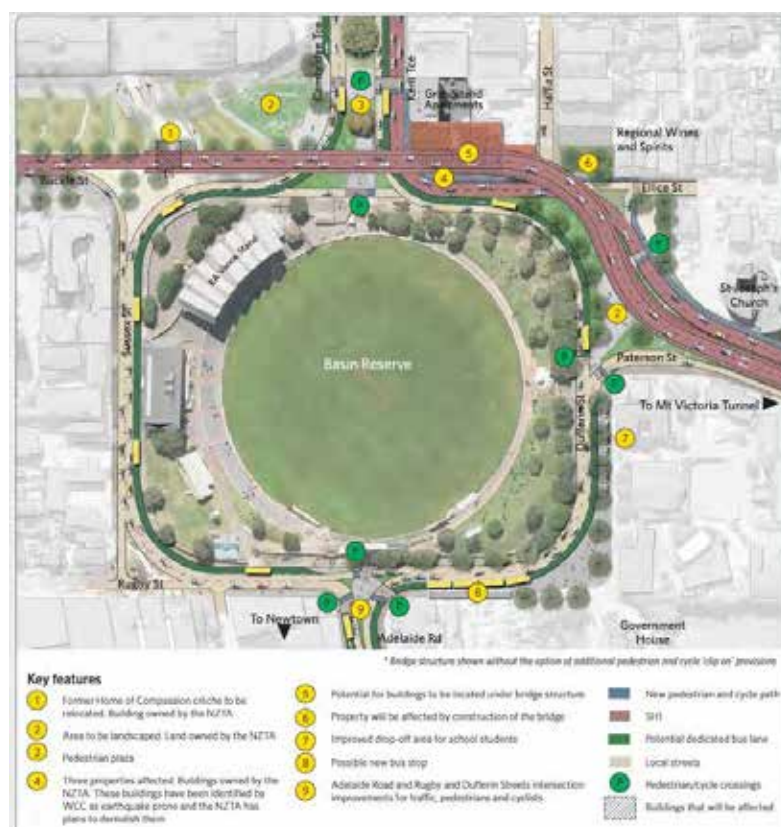

Figure 2 Project area showing the proposed road layout

NZTA lodged one notice of requirement and five resource consents for the consenting and designation of the proposal on 17 June 2013. The notice of requirement was lodged under section 145(3) of the RMA. The five resource consent applications were lodged under section 145(1)(a) of the RMA and sought to enable the construction, operation and maintenance of the project.

On 10 August 2013, the proposal was publically notified under section 95A of the RMA (1991), and public submission was open until 6 September. The EPA also identified 700 owners and occupiers of properties around the proposal area who each received a direct notification of the proposal. The total number of submissions received was 215 (three of which were late submissions that the Board decided to accept), and the NZTA filed further evidence in support of the consent applications. The submitters were largely made up of individuals (81.4%) and an overwhelming number of them either opposed the proposal in full or part. Key actors opposing the proposal in full or part include Save the Basin Campaign Inc., Action for Environment Inc., Mt Victoria Residents Association and Grandstand Apartments Body Corporate. On the other hand, main actors supporting the proposal in full or part were the GWRC, WCC, Cricket Wellington Inc., New Zealand Automobile Association, Basin Reserve Trust and Wellington International Airport.

On 22 July 2014 the EPA board of inquiry released its draft decision regarding resource consent applications; they were declined. They then released their final decision on 5 September 2014, which also declined consent. Consent was declined on many grounds, including: the adverse effects the project would have on heritage, landscape, visual amenity, overall amenity, that the transport benefits were less than originally thought and the proposed mitigation measures would do little to reduce the adverse effects on the local area (Board of Inquiry, 2014).

On 25 September 2014 NZTA decided to appeal the Board of inquiry's decision to decline the resource consents and the notice of requirement on the grounds of points of law. On 21 August 2015, the High Court delivered its judgement, which upheld the Board of Inquiry's decision to decline the consents and notice of requirement. Justice Brown determined that the NZTA was unable to establish that the Board of inquiry made an error of law in making the decision they came to. It was then announced on 4 September 2015 that NZTA had decided not to appeal the High Court's decision.

Figure 3 Before and after views of what the Basin Reserve project would look like.

NZTA lodged one notice of requirement and five resource consents for the consenting and designation of the proposal on 17 June 2013. The notice of requirement was lodged under section 145(3) of the RMA. The five resource consent applications were lodged under section 145(1)(a) of the RMA and sought to enable the construction, operation and maintenance of the project.

The media played an eventful and influential role in the Basin Bridge proposal process. Printed articles in the *Dominion Post* (a Wellington-based newspaper), online articles on stuff.co.nz and presentations on *One News* and *3 News* were among the most popular media outlets. There were also several social media sites, such as a Facebook page, Twitter and website created by the group Save the Basin (savethebasin.org.nz). The media, as in all stories of significance, were very vocal in sharing political and the public's views on the proposal. The following section identifies conventional and alternative discourses presented during this project.

3. Traditional and alternative discourses for the Basin Reserve Bridge (BRB)

This section critically reviews planning and policy documents, media reports and submissions to uncover distinctive arguments and narratives within five main headings: economic effects, safety effects, traffic effects, environmental effects and effects on people and their amenities.

a) Economic storylines

Several economic benefits were argued in favour of the proposal. However, these arguments were continually challenged by opponents. They include:

Improved road efficiency through decreasing travel times. The Copeland Report (2013) states that the Basin Reserve Bridge (BRB) reduces travel times by approximately 90 seconds would improve vehicle operating costs¹ by \$696 per annum, reducing accidents and improving trip time and reliability. Another report by Dunlop (2013) provides evidence on the significantly improved journey times the Bridge would allow for motorists. Wellington International Airport Limited (submission 103557) believes the BRB will improve their route capacity, reduce congestion on routes to the airport and improve travel times. They believe all these effects will have a direct positive benefit to the airport. However, these arguments are challenged on the ground that the BRB would reduce property values and lead to loss of income in rental properties. For example, Grandstand Apartments and Graham Wigley (submissions 103450 and 103505 respectively) noted such concerns with loss of income due to the potential decrease in amenity values of the apartments as a result of visual impacts and noise and the adverse effects these would cause. Copeland (2013) agrees that there will be some negative property effects from the proposal as a consequence of visual effects and noise (an increase of approximately 1dB and severance effects). The article by Sirmans, Sirmans and Benjamin (1989) supports the idea of rental property value and income declining when such a project affects amenity values such as views, noise and general disturbances. Julie Anne Genter (2013) from Bennion Law also believes that the 'negative economic, social and environmental impacts have not been fully assessed ... and these negative effects are likely to be significant' (p. 2).

Improve industry and freight movement and overall economic productivity. Figliozzi (2011) argued that the BRB improves freight transport movement due to less congestion and quicker travel time, which would eventually improve economic productivity in the region. Mitchell Partnerships (2013), Copeland (2013) and submission (103557) argue that improved freight movement would increase the reliability of this key route, contributing to making the Wellington economy more efficient and competitive. Throughout the construction phase, there would be an increase in jobs in the Wellington region and some increase in jobs due to ongoing maintenance of the bridge. Once the construction of the bridge is completed, there would be a generation of better economic opportunities for businesses, which would allow them to grow. However, St Marks Church School Board raised concerns that construction works would reduce their enrolment abilities, which would generate risk to the financial viability of the school (submission 103516).

¹ Based on 90 second saving, twice a day, 5 times a week, for 52 weeks of the year and petrol at \$2 a litre.

Positive Benefit-Cost-Ratio (BCR). The evidence presented by Copeland (2013) states that the benefit-cost ratio of the Basin Reserve Bridge has been estimated at 1.3 benefit-cost ratio², which shows that the project's economic benefits exceed the economic costs. They also estimated the whole Wellington Northern Corridor Road of National Significance investment package to have a benefit-cost ratio of 1.1, which would contribute to the long-term productivity and competitiveness of the Wellington region. However, 49 submitters to the proposal questioned the benefits. It is argued that the BRB would generate few benefits at all and that the adverse effects outweigh any claimed benefits. Many of the benefits are unknown and are reliant on the completion of unconsented future projects which may not eventuate (i.e. the other proposals in the Wellington Northern Corridor project). The majority of opposition submitters were also concerned that there had not been sufficient consideration of alternatives, such as options B and X. Politicians such as Julie Anne Genter (Green Party) also believed the proposal had a 'poor cost-benefit analysis and is more costly than other options' (3 News, 2014). Genter also states that the majority of popular and expert opinion also opposed the project due to its questionable benefits.

b) Safety storylines

There are several safety effects argued in favour of and against the proposal. These include:

Improved safety for all users. The Basin Reserve Bridge is strongly justified on safety grounds for all users in formal documents produced by Wendy Turvey (2013) on behalf of the NZTA. Turvey states that a reduction in traffic congestion will improve safety, especially for students who are being dropped off at nearby schools. Moreover, 1.4-metre barrier along the cycle and pedestrian lane of the bridge was proposed to improve safety. In spite of safety claims, there were 67 submitters (including the Basin Reserve Trust, Cycle Aware Wellington and Save the Basin Campaign Incorporated) out of the total 215, who opposed the proposal due to safety concerns for pedestrians and cyclists. As Ron Beernink (submitter number 103510) states, the current 3-metre-wide path proposed 'is not sufficient to allow for the likely traffic volumes and the likely scenario where pedestrians will walk side by side with cyclists'. Safety concerns were also raised for pedestrians and cyclists during strong winds, due to high exposure and little protection (for example, see Save the Basin Campaign Incorporated's submission 103493). These arguments are valid, as the NZTA report itself stated that winds on the Basin Bridge could be strong enough to 'knock over a high-sided vehicle or deter cyclists from using the road' (Johnstone, 2013). Moreover, a number of submitters raised safety concerns for pedestrians and cyclists during the construction phase of the project.

Improve security in the area. NZTA also produced a 'Crime Prevention through Environmental Design' (CPED) report, which lists methods such as well-designed lighting and surveillance to mitigate crimes and chances of vandalism area under the bridge (Stoks, 2013). To further improve safety and security, NZTA proposed placing a new commercial building under the bridge, which would activate the road edge (NZTA, n.d.; Turvey, 2013).

c) Environmental storylines

The Basin Reserve Bridge was strongly opposed on the grounds of air, noise and visual pollution and vibration, regardless of mitigation proposals. The details are:

Air pollution. A report prepared on behalf of NZTA (by Gavin Fisher, 2013), models the worst-case scenario effects of the project on carbon monoxide (CO), nitrogen dioxide (NO₂), particulate matter (PM₁₀) and benzene increases by 2021 and 2031. The evidence shows that the appropriate standards

² The benefit-cost ratio (BCR) was calculated using a national perspective. If a narrower Wellington City or Wellington region perspective were applied, the BCR would likely be much higher due to residents and businesses receiving the majority of the benefits, but paying a smaller proportion of the costs.

and regulations for CO, NO₂, PM₁₀ and benzene would not be exceeded in the selected years. Therefore, it was assumed that the project would not result in unacceptable adverse effects on air quality. However, the report does believe local dust levels would increase during the construction phase but could be mitigated through measures outlined in the Construction Environmental Management Plan and the Construction Air Quality Management Plan. The proposal is argued to contribute to combatting climate change via lower emissions from vehicles using the flyover.

However, 52 submitters raise their concern about negative air quality effects, especially dust and particulates, during the construction phase and potentially increasing carbon emissions during the operational phase. These negative effects on air quality were linked with the possibility of adverse health effects on the community, potentially affecting food hygiene and ventilation systems. For example, 24 submitters raised health issues such as asthma and lung cancer they expected from dust and other forms of air pollution in the surrounding environment. A submitter suggested NZTA establish and maintain a long-term air quality monitoring station at the proposed site to address these issues (Mitchell Partnerships, 2013).

Noise pollution. The project proposal addressed noise reduction measures in advance that include building roads with quieter surfaces and introducing noise reduction barriers (Dravitzki, 2013). Evidence produced by Vincent Dravitzki on behalf of NZTA states the operation of the Basin Bridge would increase noise levels by an average of the only 1dB, which is considered to be less than minor. It was argued that the project area had historically high noise levels, and after noise mitigation measures, noise effects would be very small. Moreover, it was promised all possible measures would be taken to ensure minimum noise during the construction phase.

There were 77 submitters, including the residents of the neighbouring Grandstand Apartments (103450), who were concerned with noise effects. Evidence from Constantin Wassilieff on behalf of the Roman Catholic Archbishop of the Archdiocese of Wellington states the noise level is expected to increase between 1-2.8dB; this is a small yet noticeable increase for near-by buildings. These adverse noise effects have the potential to affect the amenity value in the area, during both the construction and operational phases. Therefore, the submitters rejected NZTA's measures and called them 'inadequate'.

Visual pollution. The Basin Bridge proposed an integrated design approach and landscape design aiming to 'soften' the concrete structure and blending it into the surrounding environment. Deyana Popova, on behalf of NZTA, explains in her statement of evidence that the Basin Bridge would have significant adverse visual effects only within a 500-metre radius of the bridge. However, these effects could be mitigated with an integrated design approach. Popova does admit that there are some adverse visual effects that are not able to mitigated, especially when outside of the Basin Bridge site boundaries.

One hundred and fourteen submitters (out of 215) show their concern about the visual effects of the project (Mitchell Partnerships, 2013). A submitter referred to the Basin Bridge as being 'ugly', 'an eyesore' and an 'ugly wall of concrete' (Mitchell Partnerships, 2013). Grandstand Apartments Body Corporate (submission 103450) noted the 'significant interruption to the views from apartments in the building' and 'the south facing apartments will have cranes, drilling rigs etc., positioned and operating outside their windows'. Other submitters made reference to the loss of pleasant views across the Basin Reserve itself. Concerns were also expressed about the visual effects of the Basin Bridge from within the Basin Reserve. The Basin Reserve Trust (submission 103585) mentions how the proposed bridge will 'distract from events occurring on the field and detracts from the amenity value of the Basin as a peaceful and enclosed sporting venue'.

Vibration effects. NZTA proposed a Vibration Management Plan during the day and night time construction activities (Dravitzki & Cenek, 2013). According to Cenek (2013), vibration effects after the operation of the BRB are no different than those currently experienced. He also states that while

construction would increase vibration levels, this would be only temporary, of limited duration and could be mitigated through the Vibration Management Plan.

The majority of submitters were worried about construction-related vibrations (73%) (Mitchell Partnerships, 2013) and the potential effects this would have on amenity values around the Basin Reserve. One submitter, Tasman Garden Body Corporate (submission 103441), even suggested that NZTA should prepare a structural assessment of their property before and after construction and be responsible for any damage caused by the vibration effects of construction.

d) Traffic and access storylines

Access effects: The Basin Bridge proposal was strongly justified on the grounds of the traffic and access benefits. For example, the proposal would allow increased access around the Basin Reserve area, and in particular, would improve access from the eastern suburbs of Wellington. Due to the new bridge, a more reliable emergency service access to and from Wellington Hospital is expected (Mitchell Partnerships, 2013). It would also improve access to and from schools and their facilities (NZTA, 2015). It was stated that cycling and walking facilities in the project area would be improved, bus travel time would be reduced and the overall congestion level would be improved (Coulombel, and de Palma, 2014). Buses would get the main benefit by increasing their reliability (Dunlop, 2013). It is also proposed to encourage freight traffic to use the SH1 route after the building of the bridge, which would free up the local roads (Dunlop, 2013). There were 13 submitters who were generally supportive of the implications of the proposal on traffic (Mitchells Partnerships, 2013).

There were 63 submitters who were generally opposed to the project with respect to potential construction and operational effects on traffic. Most concerns related to the construction phase include access problems for emergency services, and an unsafe environment for cyclists and pedestrians. Even the Greater Wellington Regional Council (103546), who supports the proposal, has concerns with respect to the management of construction traffic effects. They advise that further information should be sought for the Construction Traffic Management Plan to ensure adverse effects are appropriately managed.

Congestion management and consideration of alternatives. 48 submitters consider that the Basin Bridge would not appropriately manage congestion and that there are other more suitable options that would better manage traffic congestion. Ninety-two submitters specifically argue that NZTA had not given sufficient consideration to alternatives required under sections 171 (1) (b) and section 32 (1) (a)-(c) of the Resource Management Act (1991) (Mitchell Partnerships, 2013). Mr Young, on behalf of Save the Basin and Mt Victoria Residents Association, says 'NZTA did not adequately assess cost-benefits of the flyover compared to other options' (Chapman, 2014). It was noted that the desired traffic improvements could be obtained from other solutions. For example, the construction of a second Mount Victoria Tunnel would be more appropriate, or a Sussex Street Tunnel, which Mark Ashby describes in his submission (103501).

In response to this criticism, NZTA argued that they produced multiple reports and documents assessing the possible options to solve the traffic issue. For example, the Scheme Assessment Report 2001, the Basin Reserve Inquiry by Design Workshop 2009 and the Feasible Options Report 2011, identified five possible options that aim to solve congestion. In 2010, NZTA organised an option evaluation workshop with relevant technical specialists and ran a series of public engagement meetings seeking further feedback on the preferred options A and B. After a process over many years, option A has been selected after more than enough consideration of alternatives for this proposal (Wayne Stewart, 2013). However, Justice Brown, the judge for the Basin Bridge case, agreed with the board of inquiry that 'other congestion-relief solutions could be applied to the Basin roundabout in order to pave the way for a second Mt Victoria Tunnel' (Forbes, 2015).

e) Heritage and amenity storylines

The Basin Bridge is strongly opposed on heritage and amenities grounds. The details are:

Heritage effects. In the Basin Bridge project area, there are three structures that have statutory recognition, one historic area, one residential character area and nine buildings with evident heritage values that are not protected by statutory recognition. There are also several listed and/or registered heritage buildings outside the project site but in very close proximity to it. Therefore, NZTA prepared a Heritage Management Plan and the Urban and Landscape Design Plan to support the BRB proposal. Salmond (2013) believes that the overall effect of the project on heritage effects is significant but that the effects will be minor after the proposed mitigation is implemented. Mitigation methods include relocating the former Home of Compassion Crèche, and reducing the visual impacts of the bridge and new structures being built.

The opponents of the proposal believe that the Bridge will generate adverse heritage effects that are irreplaceable for the historical suburb. For example, the project will damage the architectural heritage of the inner Wellington area, as well as affecting the historically significant Basin Reserve. Historic views and the surrounding historic environment will also be affected. Forty submitters opposed the project based on the potential heritage and archaeological effects. A notable submission in this area was from the New Zealand Historic Places Trust (103577) which agreed that the proposal would generate adverse heritage effects and disturb archaeological sites.

Amenity effects. There were 75 submitters who were concerned with the negative amenity effects the proposal would have on the surrounding environment. Many of these submitters believe the Basin Bridge would affect the uniqueness and character of the Basin Reserve as an iconic cricket venue and one submitter called it ‘official vandalism’ (Action for Environment Inc., 103573). There are also worries regarding the effects the project would have on the topography, character and landscape of the surrounding environment. The proposal does have some methods in place to mitigate the adverse amenity effects on the surrounding environment, but they are seen as being insufficient to screen the bulk and height of the flyover (Mitchell Partnerships, 2013). Nearby residents complain the amenity effects will affect their wellbeing and their house values. This argument is supported by Sirmans, Sirmans and Benjamin (1989), who agree that amenity effects, such as noise and congestion, surrounding apartments reduce their rental value.

4. Discussion and Conclusion

The paper aims to identify the main discourses of, and the arguments in favour and against, the Basin Bridge proposal. The main discourses are grouped into five themes: economic effects, safety effects, environmental effects, traffic and access effects and heritage and amenities effects. The analysis shows that the Basin Reserve Bridge proposal was very controversial, with high levels of resistance in the form of alternative discourses appearing from the public. However, most government organisations and businesses supported the NZTA on various grounds, especially for the project’s contribution to the local economy.

However, the Board of Inquiry concluded that the benefits did not outweigh the costs and the application for five resource consents and a notice of requirement was declined. NZTA decided to appeal this decision to the High Court on points of law, but the appeal was unsuccessful. The High Court believed the Board of Inquiry was correct in declining the resource consents and a notice of requirement on the grounds of the adverse effects the project would have on heritage, the landscape, visual amenity and overall amenity, as well as the fact that transport benefits were less than originally thought. The Board of Inquiry also believed the proposed mitigation measures would do little to reduce the adverse effects on the local area. NZTA has decided not to appeal the decision again, so the Basin Bridge seems very unlikely and its defeat is a major achievement of community resistance for a high-profile project.

Cities are increasingly recognized as an ideal place to contest transport infrastructure projects on environmental and social grounds. To what extent the community struggle has been successful depends on the specific social, institutional and political contexts and alternative discourses advanced during the process.

Social: The BRB provides an excellent example of community struggle and commitment to resist a highway project in the middle of a city. It shows that local social/community movements have the ability to stop a transport infrastructure project and shape and reshape public attitudes towards a future project. This happened because the current form of transport governance failed to recognise community actors who intervened in the purposive steering of society. These actors have been considered as time wasters and a hurdle to achieving efficiency in the implementation of the project. Although this paper analyses local actors' alternative discourses in resisting the BRB, resistance may vary from city to city and from project to project even within one city. Therefore, we should avoid generalisation that similar types of resistance and discourses can be found in Auckland or any other city.

Institutional: The resistance to the BRB shows that a deep level of change is required in transport planning in New Zealand. This may include a leadership role for local government in sharing and reshaping the debate rather than being a passive recipient of central government projects. At present, the alternative discourse that emerged during the BRB may not be powerful enough to reshape transport planning policies immediately, but it should be used as a seed for discussion.

Planning is regarded as a process of knowledge co-production between actors with different kinds of technical or contextual expertise. Therefore a collaborative planning approach can become more effective to broaden objectives and find alternative solutions to BRB. In collaborative planning, meaningful participation, on-going dialogue and an open-ended transparent process may deliver transformative outcomes by facilitating social learning, overcoming institutional challenges in a practical way and fostering innovation. This process may bring new discursive narratives that will be acceptable to all actors.

The BRB example in Wellington should be taken as a first step to redefining problems and generating creative solutions. The BRB debate can become a driver of transport innovation, where Wellington can be showcased to the rest of the world. At a minimum level, the BRB decision offers grounds for hope about possible transformations toward low-carbon transport policies as a priority agenda, at least for urban areas.

Political: The BRB example shows that grassroots initiatives help to generate valuable political and professional discussion and media coverage. It also shows that cities are very complex spaces, where diverse people and businesses, contested discourses and multiple infrastructures locate together in historical and futurist contexts. Cities are so different, even within New Zealand, that it does not make sense to use a similar objective of travel-time saving and economic growth for transport infrastructure investment. It is important to recognise the history of the place, the value of people, and the social, economic and political trajectories that shape people's lives. Therefore, cities provide opportunities to co-produce transport planning knowledge based on contextual realities empowered by visionary political and professional leadership.

Acknowledgement and note

I would like to acknowledge Gemma Brennan work as a research assistant on this project. Please note an earlier version of this paper was presented in the Rodney Davies Research Symposium in Wellington.

Session: Planning for accessibility and sustainable mobilities

Classifying governance initiatives for an effective integration of car sharing with urban planning and transport systems

Luisiana Paganelli¹

¹*RMIT University, carsharing@luisiana.com.br*

Abstract: Car sharing is a service in which members can access a car without having to own it. It is a relatively mature car-based component of the ‘mobility as a service’ (MaaS) system that has potential to work as sustainable transport when effectively integrated with urban systems and used as a complement to the transport network. Initiatives to integrate car sharing are relatively recent and not yet widely practiced, but they have been successfully implemented by some cities and there is an increasing interest in adopting them worldwide. However, this topic remains widely unexplored in transport studies and policy debates. This paper aims to address governance for car sharing integration by clarifying what this integration means, underlining its significances, and by classifying mechanisms and measures that can be adopted, mostly by local authorities, to achieve it. This work was based on literature reviews and on studies of practical examples focused on governance for car sharing developed by the author for her master and Ph.D. (ongoing) researches. The framework introduced here may provide insights on elements that should be considered while formulating strategies to incorporate car sharing into urban systems. It is also an opportunity to reflect on a significant, but relatively unexplored, topic in transport discourse.

Keywords: car sharing, governance, transport planning, integrated mobility.

Introduction

Overcoming car dependence still remains as a common global challenge faced by cities, especially the ones that are about to accommodate significant urban population growth in the next few years. At the same time, the disruptive emergence of the new mobilities, or ‘mobility as a service’ (MaaS) (Sochor et al., 2017), particularly car-based modes, is adding more pressure to an apparently defeated ‘anti-car’ urban planning system in most of the cities around the world. Meanwhile, “the real ‘disruption’ needed” (Stone and Kirk, 2017, p. 140), is to reshape cities with a new approach to transport planning and policy (Iacobucci et al., 2017; Marsden and Docherty, 2013) that “enables rather than frustrates” (Dodson and Mees, 2003, p. 33; Marsden and Docherty, 2013, p. 213) the achievement of more sustainable cities (Dodson and Mees, 2003; Legacy, 2017; Marsden and Reardon, 2017).

This change could begin by facing the disruption that is assailing the “current way of life” (Kent, 2013), and by confronting “orthodox tools, instruments, methods and framings” (Legacy, 2017, p. 180) of planning to reshape cities in the future accordingly. In this sense, Smolnicki and Sołtys (2016, p. 814) emphasize that, although the structural results of a “car-ownership-oriented-century” are widely recognized, the implications of a broad use of shared automobiles still need to be

understood. Hence, they suggest that a proper approach for that is to anticipate and prepare for the probable consequences of these disruptions, trying to avoid the potential negative ones (Smolnicki and Soltys, 2016). However, this can only be achieved with political will, awareness of the new mobility systems, and the development of critical, strategic and proper governance systems (regulation, promotion and adoption) aimed at incorporating these new modes in a way that ensures local communities will receive the benefits (Banister, 2011; Bouton et al., 2016; Clauss and Döppe, 2016; De Gruyter et al., 2014; Firnkorn and Müller, 2011; Iacobucci et al., 2017; Kloth, 2018; Stone and Kirk, 2017; UN, 2016).

Car sharing

Car sharing is a service that allows members to access a car without having to own it (Paganelli, 2013a; Santos et al., 2010; Shaheen et al., 1998), giving users the benefits of an automobile without the “burdens” of ownership (Alessandrini et al., 2015a, p. 147). This transport mode is considered a successful example of ‘access-based’ mobility systems (Botsman and Rogers, 2010; Gansky, 2010). Car sharing has emerged in Europe (Switzerland and Germany), where the pioneer and most relevant experiences with commercial developments were implemented in the 1980s, followed by more limited, but also successful, North American experiences in the 1990s (Shaheen *et al.*, 1998). This transport option is a relatively mature car-based component of the ‘mobility as a service’ (MaaS) system, seen as a sustainable transport mode and as an alternative to the private car due to its potential to generate social, economic, environmental, transportation and land use benefits, consequently reducing car dependence (Alessandrini et al., 2015b; Correa, 2016; Enoch and Taylor, 2006a; Kaspi et al., 2016; Kent et al., 2017; Kent and Dowling, 2013; Martin and Shaheen, 2011; Millard-Ball et al., 2005; Paganelli, 2013a; Shaheen et al., 1998, 2004, 2010; Solman and Enoch, 2005; UITP, 2002a, 2016, 2017).

Because car sharing has been evolving “along with technological innovation” (Shaheen et al., 2009, p. 42) for approximately 30 years (Bouton et al., 2016; Shaheen and Cohen, 2016, 2007), these evolution allowed a significant improvement in the services offered and a growth of car sharing operators (CSOs), resulting in the current implementation of different types and operation models of car sharing (Correa, 2016; Firnkorn, 2012; Paganelli, 2013a, 2013b; Shaheen and Cohen, 2016). The types of services can be classified into two main categories that consider physical aspects, operation models and the nature of the trips made with the vehicles. The first one is more related to the physical and operational characteristics and divides car sharing into two types of services: ‘round-trip’/‘station-based’, in which vehicles have to be returned to the same location (parking spot, area or charging station) where they were taken from - or to the vehicle owner’s parking space in peer-to-peer (P2P) car sharing (Ballús-Armet et al., 2014; Hampshire and Gaites, 2011); and ‘free-floating’/‘one-way’, in which vehicles can be picked up from and placed in any allowed parking space within a GPS delimited area, hence do not require a return trip. And the second category classifies trips as “scheduled”, when they can or need to be booked, and “spontaneous”, when trips can be made ‘on-demand’ (Brook, 2013). Worldwide CSOs offer different types of services under these concepts, which are also classified differently by distinct authors in the literature (Brook, 2013; Firnkorn and Müller, 2011, 2011; Nourinejad and Roorda, 2015; Paganelli, 2013a; Shaheen and Cohen, 2007). These types of car sharing, particularly the division between station-based and free-floating, have distinct implications in urban environments and produce contrasting, sometimes divergent, impacts in car use that depend on the characteristics of the cities where they operate (Britton, 2011; Glotz-

Richter, 2016; Iacobucci et al., 2017). Finally, this topic is vastly and constantly explored in the literature about car sharing, with studies that use a variety of analytical methods for the investigations (Firnkorn, 2012; Firnkorn and Müller, 2011; Kortum et al., 2016; Nourinejad and Roorda, 2015; Ruhrort et al., 2014; Schreier et al., 2017).

Researchers claim that car sharing has to be integrated with urban systems to achieve its potential as a sustainable transport mode, under governance arrangements that allow it to be used for combined mobility and as a complement to the wider transport system (Enoch and Taylor, 2006a; Firnkorn and Müller, 2011; Glotz-Richter, 2016; Huwer, 2004; Kaspi et al., 2016; Kent and Dowling, 2016; Millard-Ball et al., 2005; MOMO, 2011; Paganelli, 2013a; Shaheen et al., 2010; Solman and Enoch, 2005; UITP, 2016). Initiatives to integrate car sharing are relatively recent and not yet widely practiced, but some cities have successfully implemented them using various mechanisms (Baptista et al., 2015; Britton, 2011; Dia, 2017; Glotz-Richter, 2016; Iacobucci et al., 2017; UITP, 2002a). Furthermore, there is an increasing focus on their adoption and research has concluded that municipal administrations can incorporate car sharing as a tool to promote sustainable mobility (Glotz-Richter, 2012; Solman and Enoch, 2004). However, car sharing governance and integration remain widely unexplored in transport studies and policy debates (Akyelken et al., 2018; Caputo, 2012; Dowling and Kent, 2015; Kent and Dowling, 2016; Terrien et al., 2016). Additionally, it is not clear to planners and decision-makers how to integrate car sharing in a strategic, effective and comprehensive way (Enoch and Taylor, 2006b; Paganelli, 2013a).

This paper addresses governance for car sharing integration by clarifying what it means, underlining its significance, and by classifying mechanisms and measures that can be adopted, mostly by local authorities, to achieve it.

Governance for an effective integration of car sharing with urban and transport systems

Governance is a broad and rich topic that can be defined in a myriad of ways, depending on the context of the analysis, and it is unlikely that the literature will provide a definition that suits appropriately all situations. Thus, in the context of this study, governance is understood as a system of practices, “rules”, processes, legal tools, initiatives, actors (social and political, as well as public and private), interactions, partnerships, infrastructures and networks, that can be applied in different levels and scales (Gupta et al., 2015). Furthermore, integrating car sharing means recognizing it as an official transport mode, incorporating it in local urban planning schemes and allowing it to be used as a complement to the transport system. This conclusion was based on reviews of the literature (Enoch, 2002; Enoch and Taylor, 2006b; Millard-Ball et al., 2005; Paganelli, 2013b, 2013a; Solman and Enoch, 2004; UITP, 2002b) and on studies developed by the author until the moment.

For car sharing to work and generate the benefits mentioned previously, it is crucial that the system is effectively integrated with local urban planning and transport systems. In addition, to explore car sharing strategically and create appropriate governance arrangements for it, planners and decision makers need to understand how the system works and how to promote its integration. Previous works performed by the author (Paganelli, 2013a, 2013b) and a recent literature review pointed out that decision makers could benefit from guidelines that help to create initiatives aimed at recognizing car sharing and integrating it with urban systems. In this sense, it seems that an initial classification of possible mechanisms and arrangements of governance for car sharing could set a foundation for this “guide” and trigger an improvement of car sharing integration in practice. The

literature review also indicated that there is a profusion of information about car sharing governance distributed randomly in different documents or sources of related content, mostly in grey literature, with potential to be organized in distinct categories. However, to the author's knowledge, no organized document classifying these initiatives has emerged so far. Therefore, this study presents a preliminary classification scheme of governance for car sharing integration with urban planning and transport systems.

Methodology

The classification scheme proposed by this work was based on a review of scientific publications and grey literature, as well as on initiatives implemented in different cities that were identified by the author with a global study. The main goal of these tasks was to identify existing or possible arrangements and measures, which were then organized and categorized to develop the classification scheme.

According to Bailey (1994), three approaches can be applied to develop a classification scheme: conceptual, empirical, and operational. An operational approach means that the concepts represented in the categories are not arbitrary, but were found in empirical data and cases (Snowden, 2011). The process used to create this scheme was done in an operational level, from an empirical to a conceptual basis, because it followed a combination of empirical and conceptual approaches (Bailey, 1994).

Classification scheme - governance for car sharing

This classification scheme divides governance for car sharing in eight categories considering different features related to the system's development and implementation. These categories reflect characteristics of the places where car sharing operates, and indicate the natures of possible arrangements, initiatives, policies and regulations for its integration and management. The categories created are:

1. **Enablers of car sharing development:** basic conditions of cities required for car sharing's development and effective integration.
2. **Awareness and capacity building:** acknowledgement, understanding and recognition of car sharing, with the help from advocates and champions.
3. **Public support:** marketing, administrative and/or financial initiatives that support car sharing.
4. **Role of actors:** and their involvement in the implementation of car sharing - regulatory bodies, institutional arrangements, agreements, partnerships, civil society associations, coalitions, consortiums or taskforces, and fleets.
5. **Plans, policies and regulations:** implemented in national, regional and local levels, with strategies that formalize and incorporate car sharing as a transport mode into planning documents and procedures, encompassing all types of car sharing that operate locally.
6. **Public space and infrastructure:** parking spaces in public or private areas (on -street, off-street or on-site), the approach to allocate them, and car sharing vehicles' flow in the streets.
7. **Integration with the local transport system:** physical integration, combined mobility platforms, and possible gamification strategies.

8. **Performance and evaluation:** requirements for public support, data sharing, multimodal surveys and evaluation of effectiveness of the governance systems implemented.

This scheme is the first step toward a more detailed and comprehensive framework to depict the landscape of car sharing governance and integration. The content of the scheme is still under development and is not exhaustive, as more mechanisms may have been implemented but not publicized or may be outside of the author's current knowledge. Additionally, this framework will be updated and improved with results from a data collection that is under development for the author's Ph.D. research. Finally, besides the potential to be improved, this generalized scheme enables knowledge sharing (Smith, 2002) by providing a general terminology that can be used to further investigate, describe and discuss information about car sharing governance and integration measures.

Conclusion

Using a car instead of owning it can help reduce the number of vehicles and trips made with cars in cities, reduce costs and negative externalities of car use, encourage new forms of travel, free up parking spaces, as well as result in a more efficient use of resources, in particular urban space (Paganelli, 2013b).

Car sharing is not a "panacea" of urban mobility issues. However, it can be used by planners as a tool to create more sustainable urban areas (Glotz-Richter, 2012; Millard-Ball et al., 2005; Paganelli, 2013b, 2013a; Solman and Enoch, 2004). Moreover, most of the research done so far concluded that the positive effects of car sharing will only materialize if it is part of a larger system of adaptation in the cities, with integrated actions and a collective commitment to the pursuit of more sustainable life styles in terms of urban mobility (Paganelli, 2013b, 2013a).

The framework introduced by this work may inform and provide insights to policy makers, transport planners and operators on the elements that should be considered while formulating strategies or initiatives to integrate and manage car sharing in their cities. A more comprehensive and strategic approach to car sharing may lead to the creation of effective governance systems for it, maximizing its potential as sustainable transport and contributing to better outcomes in terms of sustainability in cities. Furthermore, this work brings an opportunity to reflect on a significant current topic that is relatively unexplored in transport discourse. Finally, the structure developed for this analysis can be adapted to other shared mobility services, perhaps impacting positively on how they are incorporated into urban systems.

Acknowledgements

The content of this paper is part of a theoretical framework that was elaborated by the author for her ongoing Ph.D. research and is part of a publication that is under assessment. It builds up on the work initially elaborated by the author for her master thesis, a descriptive approach to car sharing integration with urban planning in the USA (Paganelli, 2013a), developed at the Pontifical Catholic University of Parana, in Curitiba – Brazil and supervised by Dr. Fabio Duarte. The current work, developed for the Ph.D. research, encompasses an extended framework, with a global and more critical approach to the topic. This paper also contains information (translated and updated) from an

article that was presented and published in the proceedings of the Brazilian Congress for Transit and Transportation – ANTP, in 2013, a partial version of the author's master thesis.

This paper benefited from discussions with different people, to whom I thank for the contributions. Notable among them are the author's Ph.D. supervisors Prof. Jago Dodson and Dr. Chris De Gruyter from RMIT University, Dr. Elizabeth Taylor, from Monash University, and the former Ph.D. supervisor Dr. Ian Woodcock, from Swinburne University – all in Melbourne, Australia; Prof. Guido Perboli, from Politecnico di Torino – in Italy; and Dave Brook, a car sharing and new mobility consultant from Portland, in the USA.

Planning for accessibility and sustainable mobilities

The relocation of a circus school from the perspective of mobility of its participants

Inge Penninx¹ and Sophie De Mulder²

¹ Government of Flanders, Department of Environment & Spatial Development, Inge.Penninx@Vlaanderen.be

² Government of Flanders, Department of Environment & Spatial Development,
Sophie.Demulder@Vlaanderen.be

Abstract: In spatial planning theory and practice, travel behaviour is often linked to spatial structure (distance, safety...) and neighbourhood characteristics. A lot of mobility research considers also circumstances (age, luggage, weather...). Research in behavioural studies in economics, psychology, marketing... includes personality and choice of individuals in surplus. Empirical evidence of all these theories in real live cases is rather scarce. Using the real-life case of the relocation of a recreation service, we analyse its effects from several theoretical perspectives common in Flanders. We will confront the existing theories applied in materials on a Flemish scale with bottom up information from the case. Circolito is a circus school in Mechelen, a city in Flanders, Belgium, between Antwerp and Brussels. Its aim is to teach toddlers, children, youngsters and adults circus skills on a weekly basis. In the spring of 2018 the school moved from an inner-city location to a suburban location. A year before the move and short after it, all users were invited to fill out a survey concerning their mobility behaviour, trip chaining and perception of the location. The results of the survey will be discussed in relation to tools and practices in spatial planning in Flanders, applied in the city of Mechelen and the area of origin of the circus school participants. Although the case is specific, some of the results can help to formulate new research questions and discussion for policy.

Keywords: travel behaviour, spatial structure, real life case, human perspective, applied theories

Introduction

The reason to start a case research about the move of a circus school is quite simple. One of the authors has children that are active in that circus school. As a mother she was concerned about the new location that is located further away from the city centre, and she was wondering about the effect the relocation will have on the independence of her children and her own trip chaining. Being a spatial planner, she discerns quickly a difference between the two locations: the circus school moves from an inner city location to a suburban one. She was able to count on the support and cooperation of the director of the circus school, which is essential for the kind of research she wants to do.

In the paper we focus in the first paragraph on the spatial situation and context of the case and in the second on the theory that is commonly used in policy development in Flanders. The third paragraph explains the three methods that are used in this research, while the results are discussed in the fourth. In a short conclusion some ideas for further research are given, as well as some suggestions for further action.

Situation of the case of a growing circus school in the city of Mechelen

Mechelen is located between Antwerp and Brussels and is a medium sized to small city in Belgium (86.304 inhabitants 1.1.2018 (FOD statistiek)) with demographical growth on the agenda. Mechelen is also a regional centre with a lot of services for the surrounding area, especially secondary schools, but also a regional hospital, a regional fire brigade,... Demographic growth, together with the reorganisation and organisational upsizing of these kind of services require sooner or later choices regarding the location of these services. They can either expand on the original site or move to another more spacious location. In recent years, Mechelen directed a lot of services out of the city centre to a more suburban location, with more space availability and accessibility as main arguments. Leftover large plots in the city center are transformed into residential space, mixed with small scale services, such as day cares, shops and local services. These spatial strategies are quite mainstream in Flanders and Mechelen is exemplary for medium sized city policy in Flanders.

Figure 1. Circolito in Mechelen: location before (Klein Begijnhof) and after (Douaneplein) the move (Topographic map 1:10000)

- klein begijnhof
- douaneplein

industrial and recreational activities.

Mechelen is the home town of the circus school Circolito. That is a service provider, active in leisure time services. Its aim is to teach toddlers, children, youngsters and adults circus skills on a weekly basis. With the growing popularity of the school, it got short on place. The available space on site had reached its full capacity. Some short term solutions were found (e.g. certain lessons in the sports hall of Mechelen, some new branch offices in the broad area), but in 2018 a more definite proposal was put forward. The circus school was offered to move to a larger, more spacious location, with opportunities for further growth. The original location of the circus school, Klein Begijnhof is a part of a charming heritage site in the city centre of Mechelen. The environment is small-scaled, dense and with mixed use. The new place is located in an industrial shed, called Douaneplein. This is positioned on a former (and partly still used) freight site with customs facilities, and is now converted into a youth cluster under development. The location feels industrial and suburban and has

The main question of the research is to analyse the effect of the move on the use of space and on the behaviour of the users. Intuitively one would expect a change in modal split in favour of the car: Klein Begijnhof is a city centre location in a walker and cycle friendly environment, whereas Douaneplein is a suburban car environment.

Theory

According to Vleugels et al. (2007) modal choice in trip chaining is determined by demand and supply characteristics and is influenced by perception and trends. On the demand side, they place (1) spatial structure (scatter and distance), (2) travellers characteristics (personality characteristic: age, gender, household, address), (3) resources: physical condition, socio-economic position, car position and skills) and (4) motives (compulsory activities: travel to work, for business, education, services,...; leisure activities: recreation, social,...). On the supply side, they recognise time, comfort, ease and price. Aspects of comfort of the vehicle are among other things privacy, luggage, service and time spending. Comfort of the environment are accessibility, weather resistance, social security and services.

We note that it is difficult to find research that comprehends all these above mentioned aspects. Depending on the field of the research, certain aspects are highlighted. In spatial planning research and practice for example in Flanders, a lot of emphasis is laid on the relation between spatial structure, infrastructural factors and mobility behaviour (Van Meeteren et al., 2013, Verachttert et al., 2016, Van Den Bergh et al., 2018). Mobility, health and environmental research will recognize more the influence of psychological variables, personal motives, comfort of the vehicle, attitude and perception (Saelens et al., 2003, Hunecke Marcel et al., 2007, Zwerts et al., 2010, Reumers et al., 2017, GfK Belgium, 2018). At last, perception and mobility go together when we look at the mobility of children: the role of traffic and social unsafety, as perceived by the parents, is taken into account, especially regarding the decision of children's independent travel (Zwerts et al., 2010). But research that connects spatial structure or other spatial changes to behaviour is rather scarce: it is not easy to find a case where you can measure change or difference in behaviour as a part of a controlled (spatial) intervention (Saelens et al., 2003). In most research, mobility choices are studied in several case areas with different spatial characteristics (e.g. city, rural,...) and then compared with each other. These researches mainly deal with the mobility of inhabitants of a certain neighbourhood. Some Flemish researchers have also studied mobility in other kind of places or zones, such as shopping malls (Ronse Ward et al., 2013) and schools (Zwerts et al., 2010, D'Haese Sara et al., 2011, Boussauw et al., 2013). Often a survey is used to get insight into the mobility behaviour (Saelens et al., 2003), or observation is another possibility (Choi, 2014).

This research has a different study object. It is about a real-live intervention: the circus school Circolito moves to another location and the characteristics of the location change. For each pupil the route and probably the distance of the trip to get there change. How it affects behaviour and perception is researched with two surveys: one is held a year before and one shortly after the move. In order to focus on the change of the mobility behaviour, caused by the change in spatial characteristics, it is important that the other characteristics that could influence that behaviour remain constant. In our case research the aim of the journey, the activities at Circolito, is identical: the research population has not changed and the offer of lessons (hours, types) stayed the same.

We should note though, that this case is really specific. The circus school attracts a specific public that is not representative for Belgian, Flemish or Mechelen population. However, if the response on the surveys is large enough, our research can give an interesting insight into the effects of the move for the involved people.

Methodology

In this research we investigate the relation between spatial structure, distance, perception and mobility behaviour. The data for this aspects are collected with different techniques. We used a survey, distance-calculation in GIS and existing models of spatial structure in Flanders.

A survey about mobility behaviour and perception of the location

A year before the move and shortly after it, all members of Circolito were invited to fill out a survey concerning their mobility behaviour, trip chaining and perception of the location. With the collaboration of the circus school, the survey was sent to the contact email of each pupil. In most cases this is a parent. When several persons of the same household followed lessons, one email per pupil was sent to the contact email. Parents were asked to fill it out themselves or to send it to their older children.

The first part of the survey is meant to identify the respondent and the corresponding pupil by year of birth, activities in the circus school and address. In 2017 and 2018 more than 80% of respondents were parents. The only way to have some idea of the representativity of the research is to sort the respondents out by year of birth of the pupil. The age distribution of the research sample is comparable to the total population, with slightly more adults and less toddlers.

To study the mobility behaviour, the main research component is a specific trip chain of a specific pupil. The entire trip chain consists of several possible trips and stops and is structured as follows: possible trips before the stop at Circolito, the stop at Circolito (which is as well the aim of the trip), possible trips and stops during the lessons (which is meant for the possible accompanying parent) and at last, trips after the lesson. Questions about the activity and the location/address were asked for each stop in the chain. Questions about the means of transport between the stops and accompanying person were included as well.

The questions in the survey of 2018 were dealing in detail about the last trip to Douaneplein (new location) and the last trip to Circolito before the move, to Klein Begijnhof. In 2018 there was also a question about the weather and about the ‘normal’ or ‘usual’ transport choice.

In both surveys a part of the questions concerned the perception of both locations. The questions were meant to gain knowledge about the appreciation of the location, the layout, the pleasantness and the safety of the route used to reach the location. In 2017 respondents could make a forecast of the changes that the move would bring to their behaviour. In 2018 a question about the perception of the new and the old infrastructure was added, and some questions about the use of infrastructure in the building and the nearby area.

Distance objectivation

Distance is an important criterion in mobility behaviour. The surveys enquired about the time spent travelling and the change in distance. However, for analysis' purposes, more precise data were needed, and so we used the addresses of the stops. All addresses were converted into XY-coordinates by means of the CRAB system of Flanders Geographical Information Agency (FGIA), which allowed for spatial mapping. The points were used to generate routes with Arc GIS Network Analyst using a street network reference. This delivered distances for further analysis in relation with data from the survey.

Spatial structure objectivation

Policy research in Flanders has put a lot of effort into developing three models that relate mobility to spatial structures. The policy question is more or less the same in three researches: 'in which places or area's in Flanders is it interesting to develop more housing?' Three different scores are calculated to define places where 'to intensify in existing built environment, especially in terms of housing': (1) 'transit node value and service level' (Verachtert et al., 2016), (2) 'mobiscore' (Van Den Bergh et al., 2018) and (3) 'walkability-score' (VIGEZ, 2018, Vervoort et al., 2018, Vervoort et al., 2019).

First of all, one of the final products of the three researches is a map, showing several areas in Flanders with different scores. The map of the 'transit node value and service level' and 'walkability-score' are meant to be used by policymakers on a high scale, at the Flemish level. The 'mobiscore' is developed as an information-widget for immo-practice: people searching for a new home can get insight into the environmental cost of that location. Secondly, the three scores use the same dataset to define the service levels, namely the dataset collected by Verachtert et al. (2016), but a different selection or categorisation of services is made. Lastly, regarding the mobility-focus, the three researches use a different approach. 'Transit node value and service level' searches for points in Flanders where walking, biking and public transport are seen as a feasible means of transport. 'Walkability-score' only takes walking and biking into account. The 'mobiscore' uses the transport mode that is most likely to be used (based on probability), taking into account transport motive and distance.

The service level in 'transit node value and service level' is the most comprehensive, using 50 different kinds of services. They are classified in service category (education; culture and sports; residential support; health and social care) and service level (basic, regional and metropolitan)(Verachtert et al., 2016). The transit node value comprises different values to define several aspects, such as the ease to use the public transport, whether or not there are people living close enough to use it and the accessibility on foot or by bike. The score includes population density in combination with distance decay.

The walkability-score is developed from a health perspective. It draws attention on places where people are more likely to use an active means of transport. It combines street connectivity with population density and service mix. All aspects are calculated as z-scores, normalised to other locations in Flanders. Street connectivity is a way to measure how easy or difficult is it to walk from one point to another: a good street connectivity suggests that people are more likely to walk, than with

a bad street connectivity. Intersections per ha are used to calculate it. The service mix-function of the walkability-score uses almost all the services from the dataset, but it is categorized in another way than in the 'transit node value and service level', in order to stay as close as possible to the definition of the entropy score of Frank (2010) (Vervoort et al., 2018). The service categories are retail, entertainment, office and institutional. Not the total amount of functions, but the quality of the mix is taken into account. Although the score is developed from perspective of walking, Vervoort et al. (2018) presumes that a high walkability score is likely to encourage cycling.

'For Mobiscore the service categories are translated to travel motives from the 'Research Travel Behaviour Flanders'(Reumers et al., 2017). For each motive the probability of using a specific transport mode for a specific distance is taken into account. Used motives are those that are most relevant in terms of frequency share of all transport motives during one day for the entire Flemish population (ordered by share, descending: shopping, leisure, sports, culture; follow education; services (doctor, bank ...)). The motive 'work' is the second most important motive but only the mean distance for Flanders could be included. (Van Den Bergh et al., 2018). For each location in Flanders the distance to the nearest service and to the closest activities of each motive is considered. The focus on all transport modes is used to calculate the environmental cost. The environmental cost is a score from 1 (high cost) to 10 (low cost), with 5/10 a mean environmental cost for Flanders.

In this research we use the maps/scores to objectivate the differences in spatial structure of the different circus locations.

Results

In order to discuss the relation between spatial structure, distance and mobility behaviour, we first give the results of the different parts, starting with the survey, where we focus on behaviour and perception. We secondly confront these results with an objectified distance and lastly, with the spatial structure according to the three scores. In the final paragraphs, we combine the three aspects by giving some conclusions.

Mobility behaviour and perception of the location according to the survey

In this part we describe some facts and values, given by the respondents. We start with the difference between the expectation respondents had in 2017 before the move and reality in 2018 after the move. Then we take a look at changes concerning means of transport and the relation between perceived change in distance and change in mobility behaviour. Last paragraph deals with the perception of the different locations.

Expected change

The question 'do you expect that your/your child's mobility behaviour will change' in the 2017 survey was answered by 118 respondents. More than half of them (62) expected no change. The respondents who expected a change in their mobility behaviour, could answer in a comment field what they thought would change. All pedestrians thought they would change their means of transport, most of them would go by car. A quarter of the cyclists reported they would go by car and some of the motorists by bike. 11 respondents expected problems regarding the combination of the circus lessons with other activities.

In the 2018 survey a parallel question ‘did anything change due to the move?’ was answered by 115 respondents and strikingly 81 (or 70%) reported no change. Of the respondents who reported a change, 22 said that something changed ‘for the pupil’ (means of transport, travel company and / or activities before and after) and 12 for ‘the accompanist’.

The effect of the move is a lot smaller than respondents expected.

Change in means of transport

The ‘change for the pupil’ can be the means of transportation used to go to the circus school.

Figure 2. Means of transportation used to come to the lesson at both locations of the circus school (Survey 2018)
Klein Begijnhof (n=103) Douaneplein (n=105)

The graphic in figure 2 shows the reported means of transport at the arrival at the circus school (old and new location) for all the Circolito members from the survey 2018. It was intuitively expected that after the move less pupils would come on foot (from 6% to 3%), but it is striking that there is no increase in car use. It even

slightly decreases (from 44% to 43%). After the move, the bike is still far more used than the car.

However, the differences are small. The Sankey diagram in figure 3 uses the two surveys and shows more details.

Figure 3. Evolution in means of transport use per respondent (Survey 2017 and 2018).

Means of transport use before and after the move (n=118)

Means of transport use for location Klein Begijnhof in 2017 and 2018 (n=41)

Colors used: green “by bike”, black “by car”, orange “on foot”, red “public transport”.

There are just 10 respondents out of 115 reporting change in means of transport choice, resulting in the small change in modal split we noticed before (see figure 3). There is more variation in the answers of the respondents, when we compare both surveys (Sankey diagram on the right) than when we compare the parallel questions in the same survey (Sankey diagram on the left).

Perceived change in distance

In the 2018 survey a question tried to assess the change in distance for the pupil, by comparing the new to the old location: ‘Has the distance to reach the circus school changed for the pupil/you?’

Figure 4 Perceived change in distance in relation to reported change in mobility behaviour (Survey 2018)

As there was no mention of a locational point of reference (e.g. home, stop before), the answer is merely an appreciation or a perceived change in distance. Around 45% of the respondents (circa 50) thinks the new location is “further away” than the old one, around 1/3 of the respondents (circa 40) estimates it is “equally far” and for 1/5 (circa 23) it seems closer by.

We combined these results with the perceived change in mobility behaviour (figure 4). The biggest change is reported by people who think circus school is “further away” (37%), but also around 25 % of the other respondents report change. So we can conclude that the (perceived) distance is not the only argument to change behaviour.

Perception of the locations and routes to reach the location

From a scale of one to five stars, respondents could evaluate how the circus school location performs in terms of: (1) accessibility, (2) situation to combine activities, (3) pleasantness of the road and (4) road safety. In 2017 there were also questions about the quality of infrastructure for walkers, bikers and car users. Those questions were not repeated in 2018 because the site was not yet fully furnished when the survey took place. But there was in 2018 an extra question about the interior space.

About the interior space, Douaneplein seems to score better than Klein Begijnhof: the low scores 1 or 2 are given to the Klein Begijnhof, but not to the Douaneplein. For that aspect of the move is a success. However, we are more interested in the location from spatial perspective.

Figure 5. Percentage of the respondents per given stars on safety of the route to the location. (survey 2018). Klein Begijnhof (n=89) Douaneplein (n=96)

According to the respondents, the accessibility of Doauneplein is better than the accessibility of Klein Begijnhof: the results between 2017 and 2018 do not differ much. Research of the 2017 data (Pennincx, 2018) revealed a big difference in perception of accessibility, according to the respondents’ usual means of transport. Bike users give high scores to the location Klein Begijnhof while car drivers give more low scores to Klein Begijnhof. The perception of Douaneplein differs barely.

In 2018, the safety of the route to Klein Begijnhof is given less frequently 1 and 2 stars, than Douaneplein. A few more respondents give five stars to Douaneplein, but 4 and 5 stars combined, give a better result for Klein Begijnhof. So according to the survey, the routes to Klein Begijnhof have

a slightly safer name than those to Douaneplein. Pleasantness of the road gives almost the same results. Most comments in the free field next to the question about safety concern the traffic safety of cross points and the bicycle route from the city centre to Douaneplein. Some respondents comment social safety.

Figure 6. Percentage of the respondents per given stars on the question how well the location is situated to combine activities.

(survey 2017).

Klein Begijnhof (n=135)

Douaneplein (n=109)

(survey 2018).

Klein Begijnhof (n=102)

Douaneplein (n=103)

Concerning the possibility to combine activities, the results for both locations differ quite a lot according to the 2017 survey. Begijnhof scores high, with a peak of 45% of the respondents giving it 5 stars. The stars for Douaneplein are more evenly distributed, with 30 % selecting 3 stars, and few people giving it 4 or 5 stars. It seems clear that the perception of Klein Begijnhof is far more positive than that of Douaneplein. However, this perception changes, according to the 2018 survey. Begijnhof is has still a positive score, but the graph is flatter. Douaneplein has somewhat grown in popularity: more respondents give now 3, 4 or 5 stars. The fact that in the survey 2017 the location Douaneplein was not yet known, had probably had an effect on the given stars in the perception research.

In conclusion of the perception part, we notice that from spatial perspective the location of Klein Begijnhof is more appreciated than the location Douaneplein. But Douaneplein is not too bad. The differences are less pronounced in the survey 2018 than in 2017, when Douaneplein was still unknown.

Conclusion of the respondents perspective

A year before the move respondents overestimated their own behavioural change. A lot of respondent thought they would use the car, but stayed with the bike. The effective change can only partly be associated with the perceived change in distance, but it is very likely that the diminished amount of walkers is due to that change in distance. The lower perception on safety of Douaneplein than of Klein Begijnhof, especially for bikers, does not seem to have an effect. The fact that the new place was not yet developed and less known can be a part of the explanation of the wrong estimate the respondents made.

Distance

One of the hypotheses is that the move resulted in a change of distance for the pupils, mostly an increase. Literature teaches us that modal split is related to distance and that increase in distance will reveal more motorised transport. In this part we focus on the difference in distance.

We described above the relation between perceived distance and change in mobility behaviour. In this part we use the calculated distance and the change.

Change in distance from home to circus location for the respondents

We produced a graphic with reference values that refer to realistic distances for Flemish children of 10-12 years old to walk or bike (D'Haese Sara et al., 2011). Children of that age can walk as far as 1,5 km and bike as far as 3 km. We put in an extra reference for shorter distances (0-0,05km), because the circus school population includes also younger children.

Figure 7. Calculated distance between home and both locations of the circus school (Survey 2018, Arc GIS Network Analyst)

Klein Begijnhof (n=103)

Douaneplein (n=105)

The change in distribution of the respondents according to the distance to both locations is considerable. As expected, there is nobody living closer than 500m to Douaneplein, whereas that was 7% to Klein Begijnhof. The respondents living on walkable distance (0-1,5 km) for 10-12 years old drops down from 25 to 5%. There is an increase of 12% of respondents, who

live more than 3 km away from the circus school. According to literature, this distance is more likely to be travelled by car. But as we have seen above, the car is not used more often.

Relation between distance and means of transport choice

A more detailed categorisation of the distance, combined with the means of transport to get to the old and new location shows some interesting trends for the different means of transport.

Figure 8. Calculated distance of the trip from the location where the Circolito member was before the lesson (stop 1 / 2) and both locations of the circus school (stop 3) related to means of transport used at arrival (Survey 2018, Arc GIS Network Analyst)

Klein Begijnhof (n=103)

Douaneplein (n=105)

When we used the distance from home, we noticed that some members walked a distance that is beyond 5 km. Therefore, we used for this analysis the location where the member was before the lesson. This is more accurate, since 25% of the members do not depart from home, but from another location (hobby, school,...).

Clearly, to get to the new location, more respondents travel longer distances by bike.

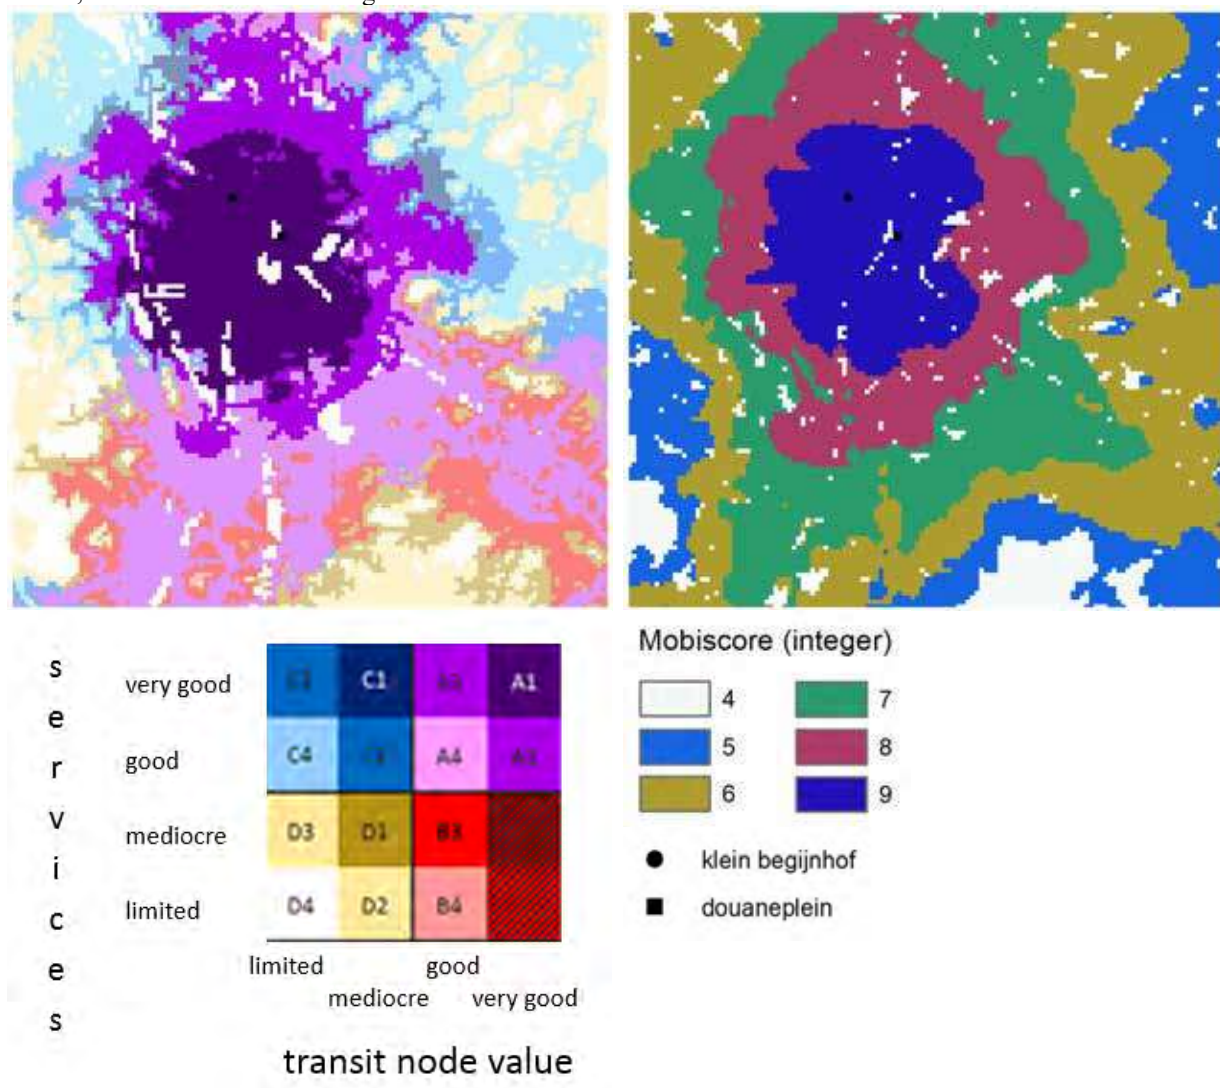

Spatial structure according to the three scores

Spatial structure of the locations

Both locations belong to the same category of ‘transit node value and services’ and have a value that stands for a very good transit node and a very good service level (A1 in the legend). For ‘mobiscore’, the site Klein Begijnhof (9,8) scores slightly higher (meaning lower environmental cost), than Douaneplein (9,7): this is because that Douaneplein is less accessible with public transport, than Klein Begijnhof. According to the walkability score, there is a wide gap between both locations: with 13,94 Klein Begijnhof belongs to the third highest category, with -0,57 Douaneplein to the lowest category but one (out of 10, figure 13).

Figure 9 Extract of the ‘spatial development potential map of Flanders and Brussels Capital Region, combining transit node value and total service level’ for the main recruitment area of Circolito circus school, Mechelen and surroundings.

Figure 10 Mobiscore mapped integer for the main recruitment area of Circolito circus school, Mechelen and surroundings.

We conclude that the locations are totally different from the perspective of walkability, but they do not differ much on ‘transit node value and service’ and ‘mobiscore’. This means that one should

expect less walkers and possibly cyclers at the Douaneplein, but the chance of public transport or car use should be more or less the same for both locations.

However, it is important to note that none of the three scores was developed with the location of a service as starting or reference point: they were developed from the perspective of a home location, and this was then seen in reference to possible services or other activities.

Spatial structure of the recruitment area

Figures 9, 10 and 13 show the spatial structure, by using maps of the three scores presented above. Both locations of the circus school are indicated.

The ‘transit node value and service level’ (figure 9) is given in a raster legend, combining different levels of services, with different levels of transit node value. On the map we notice that a central zone of Mechelen has the highest level of services and transit value possible. This zone comprises the centre, the subcentres of the agglomeration and includes some sparsely built up zones, especially in the south-east of the railway station. The further away from the centre of Mechelen, the higher the differentiation in score. In northern, southern and south-eastern direction, we notice how the railway structures space. Along the railway we also find places with a high transit node value and mediocre services. The west and the north-east have both a mediocre level of services and a mediocre level of transit node value.

The mobiscore shows a concentric pattern on the map (figure 10). The mobiscore is 9 or higher (low cost) for the centre of Mechelen, the subcentres of the agglomeration and the city centre circle include some sparsely built up zones. The next belt of score 8 or higher comprises villages and less structured settlements and the agricultural land and nature reserves in between. Settlements further away show a lower score.

The walkability-score gives us a more diverse pattern on the map (figure 13), where almost all the categories can be seen. The highest values are situated in the centre of Mechelen and the nearby built up zones. The circular structure is less visible. The less built up spaces have very low scores. Some small sized settlements further away from Mechelen have a medium score in their centre.

Spatial structure of the home environment and mobility behaviour

Figure 11 Percentage of the home location of Cicolito’s pro value of the score (Survey 2018)

Transit node value and total service level

Mobiscore

The results of the move of the circus school show a change, though modest, in modal split in favour of the bike. So far, there is no real explanation for this, and the three scores do not seem to provide more answers. However, the scores were developed from the perspective

of the locations of people’s homes. This implies that there should be a relation between the score of the home’s locations of the respondents and the means of transport used. Therefore, we combine the

above mentioned scores of the homes of the respondents with their chosen transport mode (figures 11 and 12).

Most of the Circolito members live in places with a high 'transit node value and service level' (A1) and a high mobiscore (9+). The biggest share of bike users, almost two out of three, lives at a location that belongs to the A1 category of 'transit node value and service level'. However, looking at the other categories of that score, the difference is modest. More than three out of four members that lives in locations with mobiscore 9+, use a bike. With lowering mobiscore, the share of car users increases.

The walkability score is more independent from the distance to Mechelen, the regional centre, in comparison with the other scores. There are not many addresses in the classes with very high and very low walkability score, but all classes in between count 13 to 18 addresses.

Figure 12. Walkability-score of home-locations combined with means of transport at arrival at Klein Begijnhof (KB) and Douaneplein (DP) (Survey 2018, Arc GIS)

Figure 13. Map of walkability-score and of home-locations (Survey 2018, Arc GIS)

Each point stands for a home address of a member

The classification on the map and the graphic uses natural breaks (Jenks) in 10 classes (using Arc GIS).

When we combine the scores with the means of transport in figure 12 we notice that a higher walkability score gives a higher chance of bike use. The turning point is a score of 5,5 to 8,13. Lower scores reduce the chances of bike use. However, we did not research the relation between distance and the score in detail. The location of Douaneplein still convinces four people living in places with low walkability of 1,3 to 3,27 to come by bike instead of coming by car. For at least two of them the new location is closer than the old one, because they come from the south-east.

Conclusion on use of the scores to explain mobility behaviour

The three scores are developed to encourage spatial development in places that are the least dependent on car use. For the case of the circus school they are relevant.

The people living in places with high values for ‘transit node value and service level’ and ‘mobiscore’ are more likely to use another means of transport than a car. Most of them use a bike. The walkability score gives us insight in places where people are stimulated to walk and seems useful to objectivate characteristics of the location. The new location is far less walkable than the old one, so there are less pupils coming on foot. We also see indications that higher walkability scores at the living environment of the pupils relates with more bike use.

Conclusion

The spatial planning theories we used, such as the ‘walkability score’ and ‘transit node value and services’, emphasise the relation between spatial structure, infrastructural factors and mobility behaviour on the one hand and mobility behaviour on the other hand. It made us expect that the move would reveal a change in modal split in favour of the car. A lot of changes associated with less bike use are found in the data: higher distance, lower safety perception, lower functional mix and lower street connectivity. But bike use does not decrease. We notice an increase in biking distance (figure 8), that the collected data and used theories cannot explain. Although it might be interesting for Flemish spatial policy to develop and test a bikeability score and to do research on other cases, we do not think this will give us an explanation for the minor change in our circus school case.

Schwanen (2012) recognises in this mainstream research the belief in the ‘homo economicus’: individuals that actively make rational choices. However he and others researchers (Bambust, 2015) also recognise the role of less conscious aspects in the process of choices. So is habit one of them.

In our circus school case, we may find a small indication of the role of habit. Habit is typically understood as more or less automatic behaviour that is acquired through repetition and positive reinforcement (Schwanen et al., 2012). The move was not meant to change the mobility behaviour, but the expectation was it would. In reality, the move has not proven to be a habit-breaking intervention. We believe that extra case research to learn more about habits and spatial characteristics is useful, but some changes in the survey and other kinds of research, such as observation, panel discussions,... will be needed.

Currently, the Flemish administration is discussing a possible broader policy approach, especially in the discussion of habit change. A group of social marketers has been appointed to bring knowledge and know-how about this topic within the Flemish administration. A popular social marketing model in Flanders is presented by Bambust (2015). And some tests in the field of nutrition are done in order to make use of habit-breaking interventions or nudging.

Concerning this, one part of the story is not yet told. In the week before the move, the director of the circus school presented the data of the first survey in a newsletter. He praised the public for the high bicycle use and expressed hope and expectation the bike use would not decrease after the move. We cannot prove the effect of this call, but it may be another aspect in the explanation. Using a positive message and exemplifying one’s behaviour can have a positive effect on people. This kind of

interventions is exactly what social marketing tries to achieve. It is important to do such interventions and to learn more about the effects. However, there is no need to wait to use these until they have proven to be effective: we have to use all the possible and ethical means to try to lower the car use.

Acknowledgements

We want to thank the director of the circus school for the kind cooperation to distribute the survey two times. Laura Hoebeke and Elsie Fauconnier provided much support in data analysis.

Using SNAMUTS to Plan for Change: The Place for Accessibility Modelling in Strategic Planning for Urban Transitions

Jana Perković¹, John Stone²

¹*Faculty of Architecture, Building and Planning, University of Melbourne, perkovic@unimelb.edu.au*

²*Faculty of Architecture, Building and Planning, University of Melbourne, stoneja@unimelb.edu.au*

Abstract: Accessibility Instruments based on big data, such as SNAMUTS (Spatial Network Analysis for Multi-Modal Urban Transport Systems), show great potential in facilitating strategic planning for mobility transitions, by providing useful and usable information on accessibility outcomes of public transport infrastructure scenarios. However, how should accessibility instruments best be used in existing strategic planning processes? This study used an experiential case study methodology to insert SNAMUTS into a real-life process of strategic planning for the Monash 'national employment and innovation cluster' in Greater Melbourne. It asked how, when and where accessibility modelling should best be introduced to improve accessibility outcomes in a long-term strategic planning process for urban transitions. The results demonstrate the significant problems with introducing accessibility data into the planning process in the context of politicised planning, weak sustainability vision and insufficient role definition between various stakeholders. In this context, the use of data and analysis in planning was limited to 'evidence-based lobbying'.

Keywords: urban governance, mobility transitions, the politics of transformation

Introduction

Unlike land use and even economic planning, transport planning is uniquely centred around infrastructure provision, requiring decision-makers to act for the greater good while making complex engineering decisions. As such, major decisions in this field typically occur at the intersection of complex technical and political processes (Stone *et al.* 2014:2). Not infrequently, transport planning is shaped by political conflict over goals towards which resources should be directed. In this process of managing technical processes against political outcomes, crucial role is played by measuring and modelling instruments, which can quantify infrastructure outcomes and translate them into non-expert language.

With advances in data collection and computing, the past decade has seen a new generation of accessibility instruments (AIs) emerge in transport planning research (Curtis *et al.* 2016). Unlike the simpler and more conventionally used 'agent-based models', accessibility indicators arise out of quantifying the interplay between land use, transport infrastructure, public transport service levels, demographics and the distribution of jobs and services. Accessibility measures not the gross supply of transport infrastructure, but its usability: it quantifies the outcomes that infrastructure has for the end-user, the citizen of the urban region. Accessibility Instruments have the potential to translate complex

correlations between land use and transport infrastructure into a single metric; at best, a simple accessibility map can be used as a basis for dialogue between transport and land-use planning authorities, as well as non-professional stakeholders (Moniruzzaman *et al.* 2017).

Historically, accessibility metrics were plagued by complexity, combining the measurements of distance, time, transport transfers, cost, and various opportunities at origins and destinations: the more complex (therefore accurate) calculations have been harder to communicate to policy-makers and stakeholders (Moniruzzaman *et al.* 2017). However, the new generation of AIs has been characterised by greater precision and technical capability, the ability to integrate 'big data' sets, with an ease of use and simplicity of output (colour-coded maps etc), as well as a holistic understanding of transport options (te Brommelstroet *et al.* 2016:1176). The visually expressed outputs (such as colour-coded maps) can communicate accessibility calculations to non-experts. For the first time, it is a viable proposition to implement accessibility modelling within the normal planning process.

The Instruments developed in recent years include TRACE (Retail Cluster Accessibility) developed at the University of Antwerp, ABICA (Activity-based indicators of connections and access needs) at Aalborg University and Technical University of Denmark, HIMMELI (Heuristic three-level Instrument combining urban Morphology, Mobility, service Environments and Locational Information) from Tampere University of Technology, and the German Guidelines for Integrated Network Design (RIN). Among the more interesting of these accessibility instruments or AIs (COST 2012) is the Australian SNAMUTS, or Spatial Network Analysis for Multimodal Transport Systems.

Broader in scope than most AIs, SNAMUTS allows not only for detailed, multi-modal public transport network analysis, but was developed specifically to fill the gap between transport and strategic use planning by incorporating measurements of activity clustering, identifying activity centres at district, regional and neighbourhood level (COST 2012; Curtis *et al.* 2016). Developed at Curtin University in Western Australia by Carey Curtis and Jan Scheurer, SNAMUTS uses publicly available public transport service data, combined with data for population, employment and road speeds, sourced from public agencies and census data (COST 2012). Starting from the perspective of the individual, it defines usable public transport nodes and segments and ranks them according to seven indicators of accessibility. The seven indicators of SNAMUTS were broadly inspired (Curtis *et al.* 2016) by the Space Syntax theory (see Hillier and Hanson 1984), and consist of:

- service intensity, or the amount of rolling stock (vehicles in simultaneous operation) required to operate the network at a SNAMUTS standard
- closeness centrality, or ease of movement to and from a transport node, in terms of speed and service frequency (an index rather than a real number)
- degree centrality, or the average minimum number of transfers from a node to get anywhere else in the network (a real number)
- nodal betweenness centrality, or the number of transport segments passing through a node weighted by catchment size and travel impediment (closeness), and shows concentrations of 'movement energy' in the network (also not a real number)
- 30-minute contour catchments, or the percentage of people and jobs accessible within 30-minute travel from the node in all directions (a real number)

- nodal connectivity, or number of services departing from the nodes and lines intersecting – i.e. whether the node is a good transfer point in the network (its TOD potential)
- network resilience, or the relationship between a node's significance in the system (betweenness) and its actual service levels (connectivity), indicating latent demand and overcrowding.

The composite map brings these indicators together into a 'semaphor' map of red, yellow and green regions, and provides a visual shortcut to understanding accessibility within the metropolitan region, which can also be used to compare cities. The simple visual representations of the seven individual indicators and the composite enable transport practitioners, but also other planners and non-experts, to easily focus on trouble spots and areas of opportunity, in group discussions (COST 2012).

In practice, various kinds of accessibility analysis form part of pre-feasibility modelling that is part of transport corridor studies, alongside other types of modelling. However, few AIs are used with any consistency or regularity in urban planning practices and even fewer have been assessed for performance. The most important study to date has been COST 2012, a dedicated study of 22 AIs through workshops with practitioners, which confirmed that AIs are overall useful and user-friendly (see Papa *et al.* 2017, Silva *et al.* 2017). However, the uptake remains poor (te Brommelstroet *et al.* 2016, Silva *et al.* 2017, Papa *et al.* 2017). Both instrument developers (predominantly academic and professional actors) and planning practitioners (predominantly public servants) identify conflicts in department policies, lack of incentives for cooperation between agencies, and separation of land use and transport institutions, as the most salient barriers to the wider uptake of AIs (Silva *et al.* 2017). Te Brommelstroet *et al.* (2016) note that the disconnect appears to be of a practical sort: the developers develop instruments based on an abstract idea of the needs and demands of specific planning contexts, while planners hold unrealistic expectations of what technology can offer.

Analysing the workshops conducted as part of the COST 2012 study, Silva *et al.* (2017:142) note that the workshops themselves help bridge the implementation gap: post-workshop surveys indicated that 70% of the participants stated they would use the insights created by the session in their daily practice, and additional 50% would select the AI for other planning decisions. Building on such insights, te Brommelstroet *et al.* (2016) advocate greater use of practical research methods, in which AIs are inserted into realistic professional situations, noting that, while honing the technological attributes of AIs is important, refining their usability by offering them to planning practice may be more effective (2016:1178).

2 Research Approach

2.1 Methodology

The experiential case study has been proposed by a number of urban planning policy researchers in recent years – particularly in transport planning (see Straatemeier, *et al.* 2010) as particularly apt for testing approaches in a 'real world' policy setting. In an experiential case study design, the researcher does not only observe, but actively intervenes in planning practice. Backed by a theoretical understanding on how practice can be improved, the researcher develops an intervention, applies it in a real-life situation, reflects on its effectiveness and (if needed) improves both the theoretical understanding and the intervention itself.

1. The experiential learning cycle. Source: Straatemeier et al. (2010), adapted from Kolb and Fry (1975).

Departing from the existing body of knowledge on accessibility modelling, our study sought to progress the research on AIs towards greater understanding of their practical application in the context of strategic planning, by identifying the uses of SNAMUTS within an existing, ongoing strategic planning process. The research design of choice was experiential case study (see Figure 1). Previous SNAMUTS workshops had focused on generating transport infrastructure recommendations for planners. In this study, rather than focusing on the outputs that AIs provide, the aim was to observe how the planning system responds to and integrates those outputs. The scope of the research would be in identifying how the abilities of this AI to provide a metric of the reciprocal influence of land use and transport infrastructure could help push forward the process of strategic planning. The focus would be on the on-the-ground processes, rather than planning theory; and the study would seek to understand and elucidate the needs of planners within the strategic planning processes – and match them to the capabilities of the AI.

After identifying a study area that is currently undergoing a strategic land-use/transport planning process, and reviewing the planning process through a desktop review of literature and preliminary interviews with planners and stakeholders, the researchers developed accessibility models for the area using the SNAMUTS AI. The models were introduced to the study participants in the context of a structured workshop. The workshop protocol had a structure that mirrors a typical planning procedure in Victoria, designed with close reference to recent literature on experiential learning in Accessibility Instruments, particularly Straatemeier *et al.* (2010), Curtis (2011), and Silva *et al.* (2017). In order to remain as grounded in the existing planning process as possible, the workshop asked of the participants to work on real questions arising in the planning process. The first part of the workshop involved observation of this process without any input from SNAMUTS. The second part of the workshop focused on the same question, but the process was complemented by the introduction of SNAMUTS models and visualisation, to allow for comparison of two work processes. Specific activities mirrored the typical SNAMUTS workshop, as described in Curtis (2011). Carey Curtis, the leader of SNAMUTS development team, was present at the workshop: this decision was guided by the observation by Silva *et al.* (2017) that the role of the workshop leader is to ‘narrate’ the process of using the AI tool. The workshop was fully recorded and analysed using thematic analysis.

A second set of interviews after the workshop completed the data collection, with the purpose of offering planners and stakeholders the opportunity to reflect on the workshop. A critical and reflective recounting of the experience was solicited, looking for answer as to how SNAMUTS maps filled the gaps in the knowledge around the outcomes of the strategic plans, how the AI met the needs of the planners, and how the long-term planning process was affected by the introduction of the visualisations.

2.2 Case Study: Monash NEIC

Monash National Employment and Innovation Cluster (NEIC) was chosen at the case study. Located some 30km southeast of the Central Business District (CBD) of the Australian city of Melbourne, Monash NEIC is Melbourne's largest established employment cluster outside the CBD, with 58,500 jobs. It is one of the six NEICs identified in Plan Melbourne as areas with the potential to provide high job concentration in suburban areas (VPA 2017). It has a critical mass of education, health, research and commercialisation facilities, including: Monash University, the Australian Synchrotron, Monash Medical Centre, CSIRO's largest site in Victoria, Monash Business Incubator, Melbourne Centre for Nanofabrication, Monash Enterprise Centre, and the soon-to-be-completed Monash Children's Hospital. The Eastern and South-Eastern sub-regions (of which Monash NEIC is part) are expected to grow by 550,000 to 700,000 residents between 2011 and 2031. The Monash NEIC study area satisfied some key prerequisites for selection as case study for this research, these being:

- the area has been identified as a growth area of strategic interest, and is currently the subject of a strategic planning process
- SNAMUTS data for the area had been collected and analysed previously
- there was an ongoing or workable relationship between the research team and planners involved.

The area has the distinction of being something of a case study in automobile dependency, and in how transport planning involves the interfacing of technical and political decision-making. The Monash University Clayton Campus was built in 1961, in what was then city fringe (see Figure 2). A site within metropolitan Melbourne was chosen over one in regional Victoria, in order to be closer to where its 'customers' lived, in the rapidly expanding south-eastern suburbs, as well as close to the industrial belt between Oakleigh and Dandenong. The first preferred site, recommended by Melbourne Metropolitan Board of Works' chief planner, was the Caulfield Racecourse, a large expanse of underutilised Crown land located at the junction of two rail lines, close to two trams, and only 18 minutes from the city. However, protests from small, but politically influential, racing club members pushed the campus further afield, "a decision that was ultimately political rather than economic" (Davison and Murphy 2012:15). In the end, the campus was built in Clayton, in the newly industrialising farmland, where residents both made cars and owned them in higher percentage than people in other suburbs – and out of the reach of Melbourne's public transport. The worries about access to the remote location were immediate: the campus was built on the promise of a 'spur line from Huntingdale', a soon-to-be-constructed railway line that would connect Melbourne's second university to the city (Mees 2010). The railway line, however, was never built: the vague promise was "occasionally repeated and long remembered but never kept" (Davison and Murphy 2012:21). Meanwhile, Monash Clayton became an 'automobile campus': as early as 1963, less than a quarter of

the students came to Monash University Clayton Campus by public transport (Davison and Murphy 2012).

2. Monash University stood on the very eastern edge of Melbourne in 1960. Source: Davison and Murphy (2012).

The 'Rowville line', as it came to be known (Knox City Council 2018), became a mythical project of sorts. It was included among the proposals for new rail connections in the 1969 Melbourne Transportation Plan, but not pursued (Davison and Murphy 2012). It was studied again as part of the Scoresby Transport Corridor Environmental Effects Study (EES) in 1998, which led to the EastLink freeway project, but was ultimately not proceeded with. The local council, Knox City, prepared its own feasibility study in 2004 (which came out positive), and then engaged in high-level advocacy, including the formation of the Eastern Transport Coalition (Knox City Council 2018), which led to a state government-led feasibility study in 2012. That study also came out positive, but ultimately concluded that the line would be required in 2027, 15 years in the future (Carey 2018). In the interim, a boost in bus services was recommended (Carey 2018). The services have improved in recent years, with a 'smart bus' (a high-frequency bus service) added in 2006 (Mees 2010) and a dedicated university shuttle that brings the bus frequencies to Huntingdale to 4 minutes (Planner 1, research interview), but Monash University is still dependent on buses for connecting to the nearby train line.

And with 32,000 students and staff (Resident 3, research interview), the University is by far the biggest employer in the area.

However, in recent years the area has been designated of strategic importance to the state. The 2013 Plan Melbourne, the current strategic plan for Victoria, designated Monash one of six National Employment and Innovation Clusters. Once released, Plan Melbourne triggered the process of creating strategic plans for the NEICs, led by the state planning body, Victorian Planning Authority (known as the Metropolitan Planning Authority at the time). An Advisory Group was formed between state planners and representatives of the businesses in the area, and two preliminary consultant studies were produced during the four-year preparation process, both assessing the commercial activity in the area and the business needs of the commercial residents of the NEIC. Though their importance to the process of planning Monash NEIC is limited, the consultant studies were significant in identifying and articulating transport needs of the area as central to its economic development. Both confirmed that poor public transport links were a major limitation in attracting businesses to the cluster, in bringing clients and retaining qualified staff, a limitation on market reach, and a constraint on the development of the cluster as a whole (Urbis 2014:3). Additionally, lack of public transport was cited as a significant problem for overseas visitors, attracted to the area's unique science enterprises of international distinction (Urban Enterprise 2015). Public transport was consistently placed as the top priority, with all other suggestions qualified as dependent on public transport improvements (Urbis 2014). Significantly, no transport or land-use (let alone integrated) strategy scenarios were considered in the preliminary studies.

In May 2017, VPA released the Draft Framework Plan for the area; our study commenced soon after. According to the initial timeline (Figure 3), the Framework Plan was to be adopted in early 2018. Our study was designed to test transport infrastructure scenarios under consideration by the planners during the time when the Draft Framework Plan was being discussed by the stakeholders. The workshop took place in November 2017, and the final round of interviews in early 2018. As the following section will detail, the planning process ended up significantly deviating from this timeline.

3. The official planning timeline for Monash NEIC. Source: MPA (2016).

3 Findings

3.1 Transport plans to date

The Draft Framework Plan released in March 2017 did not include a transport plan – perhaps not surprising, considering that no transport infrastructure scenarios were developed or tested in the four-

year preparation process, but somewhat unexpected considering the document's own mission (VPA 2017:1) to “boost local employment by... improving transport links and public transport” and the demonstrated high business importance of improving public transport in the area. The transport component of the Plan was limited to a two-page section, with its strategic ‘outcome 3’ being to “prepare” an “integrated transport plan” to “support economic growth” (VPA 2017:7). The actions supporting this outcome were an imminent freight road extension, a walking and cycling network to be developed by local councils in short-to-medium term, and a plan to plan for “a range of high-frequency and high-capacity public transport solutions to be developed in the short to long term” (VPA 2017:12) by the newly established transport authority Transport for Victoria (TfV), with no detail, timeline, or scenarios under investigation (see Figure 4).

Figure 5 Transport Plan

4. Monash NEIC transport plan. Source: Monash National Employment and Innovation Cluster Draft Framework Plan. Source: VPA (2017:13).

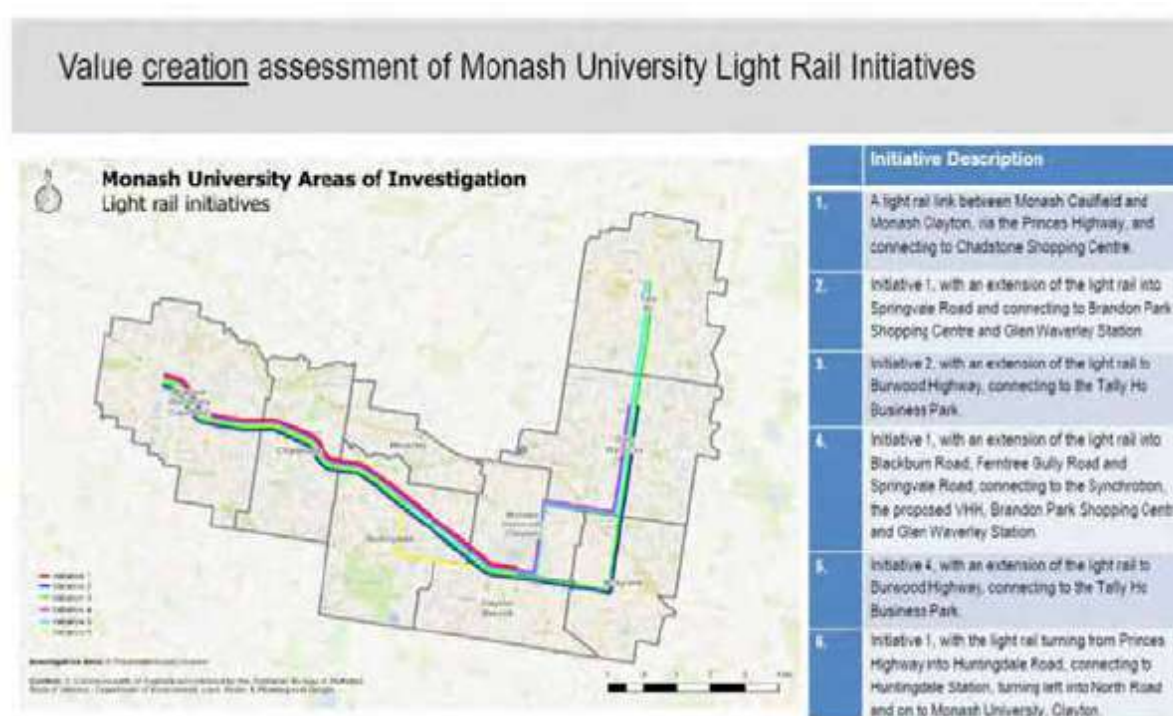

Indeed, the state government planners admitted that “the Draft Framework Plan was more of an attempt to jot on one page what all government agencies were already going” (Planner 2, research interview). In other words, the Plan collected previously approved projects in the area and showed them in relation to one another – no new strategy was generated in the preparation of the document. The interviews with state planners corroborated that there had been no confidential transport strategies either, that had been considered or assessed by state government planners. State planners from VPA and TfV both cited high staff turnover and departmental structure changes creating an uncertainty over whose responsibility it was to create a transport strategy. Local planners for Monash and Kingston City Councils were clear on what they wanted – a train line, or at the very least as much public transport as they could get – but that they could not make it happen without state government strategic support. One transport planner suggested that “a scenario suggests commitment (...) which could be interpreted as a political commitment. (...) [I]n the current political climate, public transport is very politicised and nobody wants to make claims they won't be able to deliver on” (Planner 1, research interview). This was echoed by a notable urban design consultant on Monash NEIC, who said that even the University transport submissions were kept confidential because “the State has been super nervous here about promising to do something before it's gone through a whole business case. [I]t will only say that once a business [case] is prepared, we'll commit to it – but before that, show nothing. Or show it so ambiguously that it's not clear” (Rob McGauran, research interview). The informants from the government planning agencies were reluctant to even informally suggest transport options. Additionally, multiple state planners emphasised that they perceived the current political situation (on both state and federal level) as not suitable for making long-term plans – or even suggesting scenarios. Whereas state planners perceived that they had the ability to enact land-use zoning changes, and were confident that those changes would result in a different mix of uses on the ground – this certainty was lacking in the political processes needed for commitment to infrastructure delivery.

When questioned about using accessibility modelling in public consultation, state planners showed interest in gathering community feedback on different scenarios as a form of data: it was suggested that strong support within the cluster for a detailed transportation scenario might help push it forward by building and demonstrating consensus on future direction. However, the same problem persisted, of planners not wanting to suggest what those scenarios might be. There was a strong suggestion that it would be more convenient for the professional planners if the infrastructure scenario proposal came from elsewhere.

3.2 Informal transport scenarios

Where state planners were very reluctant to suggest any transport infrastructure scenarios for Monash NEIC, the opposite was the case for the residents of the area. Transport facility managers and business strategists for Monash University and CSIRO, as well as planners from Monash, Kingston and Greater Dandenong City Councils, were eager to meet, propose and discuss possible infrastructure investments. The 'phantom' of the Rowville Line kept returning to conversations – but this time mostly as a light rail following a similar alignment, and no longer as a railway line. Representatives of CSIRO and Monash University expressed tremendous frustration at not being able to work with the

planning professionals to influence changes they saw necessary for their business expansion – such as improving walkable paths between the businesses in the area, building their own accommodation facilities, and connecting the region to the airport with fast rail.

5. Fotios Spiridonos' unofficially developed scenarios for Monash University Light Rail Initiatives. Source: Fotios Spiridonos, pers.comm.

Where state planning documents provided no transport scenarios for consideration, let alone accessibility studies, such scenarios appeared in privately commissioned studies. The most notable example was a study commissioned by Monash University's Fotios Spiridonos, the university's Manager for Campus Access and Transport, which examined value creation effects of six different public transport options linking Monash University to Huntingdale and/or Caulfield Stations with tram. The study (see Figure 5) was the closest to a fully-fledged transport scenario for Monash NEIC, in the sense that it defined both the mode and the alignment of potential new links – even though it did not detail service frequency or stop locations.

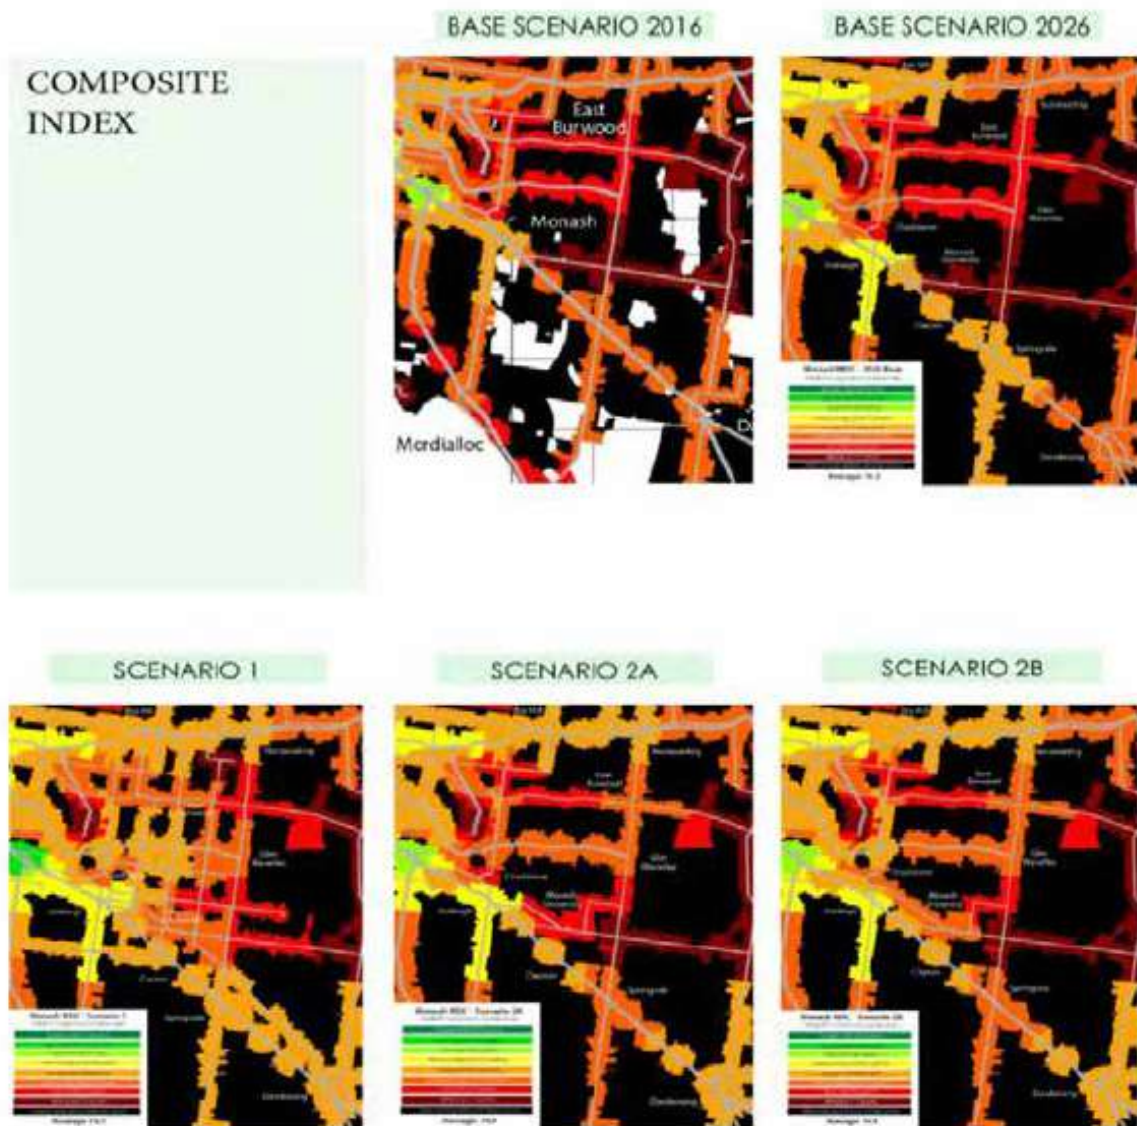

3.3 SNAMUTS modelling and workshop

The absence of transport scenarios under consideration by the state – formally and informally – the SNAMUTS models were produced for two transport proposals (known to us at the time) with the greatest level of detail: Fotios Spiridonos' Value Creation Assessment of Monash University Light Rail Initiatives, commissioned by PriceWaterhouseCoopers (unpublished and not publicly available at the time of writing, though Mr Spiridonos shared the basic details), and the transport 'composite' plan present in the Draft Framework Plan (VPA 2017) which involved “intensification and high-capacity public transport” on all major roads in the cluster.

Both plans had to be fleshed out in detail by the SNAMUTS team to model their effects. Mr Spiridonos' initiative was assessed on two scenarios with the best outcomes: Scenario 2A involved a

light-rail link between Monash Caulfield and Monash Clayton campuses, via the Princes Highway, connecting to the major Chadstone Shopping Centre, continuing via Burwood Highway and connecting to the Tally Ho Business Park (initiative 5), but extending at the northeastern end to Nunawading Station; and an alternative scenario (2B) following the same alignment east of Monash campus, also as far as Nunawading, but on terminating on the western side at Huntingdale station. Both scenarios included some modifications to the existing bus services, to avoid duplication of services. The 'transport intensification' plan in Draft Framework Plan for Monash NEIC was fleshed out in detail to include boosting the bus routes in the district to 10-minute frequencies during the weekday interpeak (and at least 30 minutes seven days a week), creating a multidirectional grid between (and to some extent beyond) the Dandenong and Glen Waverley train lines that frame the area north and south. The new bus grid included the existing SMART buses (routes 900, 902 and 903), as well as parts or all of existing routes 623, 693, 703, 733, 767 and 800.

Taking into account the realistic timeframes for infrastructure planning and constructions, both scenarios were modelled as a hypothetical situation in 2026, including demographic and job growth predictions for 2026 used by VPA, and all 'committed transport projects' likely to be completed or implemented by that date. To allow comparison, the existing state of transport at Monash NEIC was also modelled, as was the 'do-nothing scenario' for 2026, which only took into account the already committed infrastructure plans and demographic and job changes. The accessibility outcomes of those four scenarios formed the basis of the workshop.

6. SNAMUTS maps: Composite Index blends together the results of all SNAMUTS metrics to show an easily legible map of how public transport performs across the metropolitan area. It is intended to be absolute (i.e. allow international comparisons), but it remains an imprecise index due to the complexity of the underlying calculations.

The results (Figure 6) paint a stark picture of just how poorly connected Monash Clayton is – particularly stark when compared to the University's secondary campus in Caulfield, also shown on the maps. In every metric, Monash Clayton scores below the Melbourne metropolitan average:

Closeness centrality = 64 (Caulfield = 46), average 67

Transfers = 1.5 (Caulfield = 0.8), average 0.99

Betweenness centrality = 19 (Caulfield = 172), average 36.5

Nodal connectivity = 5 (Caulfield = 346), average 90

30-minute catchments = 3% (Caulfield = 18%), average 8.9%.

It is of note that accessibility results improve very little in alternative transport infrastructure scenarios (scenarios 1, 2A, 2B). Though all indices marginally improve with the additional bus or light rail services, the changes are microscopic, even compared to the accessibility index maintained by Caulfield: average transfer time to reach the rest of the network improves from 1.5 to 1.3 (scenario 1) or 1.4 (scenarios 2A and 2B), or betweenness ('movement energy', the sheer amount of PT) increases from 19 to 31-34 – compare this to Monash Caulfield existing betweenness centrality index of 172, 186-196 under future scenarios! Crucially, the 30-minute catchment of Monash Clayton, i.e. the percentage of the city's population and employment accessible within 30 minutes of travel of public transport, an index of huge importance for a university trying to attract top students, increases from a woeful 3% to just 4-7% (compare to 23-4% for Monash Caulfield in 2026, or 28-29% for RMIT University (currently 25%) and 24% for Melbourne University (currently 13%)). Only on nodal connectivity, or the potential for transit-oriented development, is there a significant improvement: the improved bus network (scenario 1) raises Clayton's TOD potential from 5 (extremely low) to a respectable 96. By contrast, improved light rail brings an improvement to 31 (scenario 2A) and 42 (scenario 2B) respectively.

In conclusion, the SNAMUTS modelling of the Monash NEIC area showed very poor accessibility metrics for Monash University Clayton Campus and the surrounding 'employment and innovation cluster'. This was not a surprise: after all, the government's own consultation documents showed that, and there had been a long history of advocacy for better public transport in the area. What did surprise, however, was how little the proposed transport infrastructure improvements – developed over many years and supposing lengthy and expensive interventions into the network – improved the status quo. While local accessibility marginally improved in all scenarios (as evidenced by the local network health in Figures 26-28 REF), absolute accessibility indicators remained on the low end of the scale in all cases.

3.4 Workshop observations and post-workshop interviews

Analysing the SNAMUTS results went beyond the scope of the study: the models were produced for the planners and stakeholders for Monash NEIC, and the role of the researchers was to elucidate the results and observe how they affect the planning process.

Three distinct themes emerged while analysing the conversations during and after the workshop:

1. *the maps allowed the participants to see metrics and understand the outcomes of infrastructure investment on accessibility outcomes, replacing some of the rhetorical arguments with more pragmatic questions;*

The Monash NEIC residents' most common observation about the planning process thus far was that the residents did not feel heard, nor that their needs were considered. There was a perception of a professional 'language barrier' in which the professionals in the cluster could articulate what they needed for their businesses to grow, but they did not know how to make a case for it – be it financial, political or administrative.

Resident 1: "It's all based on hard data, and that's important. Everybody talks about bad connection, but what does it mean?"

Planner 2: “It’s really important to carry people through these decisions as well, especially the community. A lot of people, when they’re confronted with a bunch of numbers on the page, tend to shut down, whereas this is a really clear way to see what the interventions would do.”

Resident 1: “The colours and the mapping made clear how badly connected certain parts are. It was quite shocking, actually. It gave a lot more information than I previously had. It made it very detailed.”

2. *A disinterest in discussing the details of public transport scenarios under consideration, which revealed a mismatch in roles between the planners and the residents.*

What became apparent during the workshop was that there was no-one in the role of strategic transport planner in the area. Instead of modelling the big-picture vision, planners from local councils were raising issues of individual behaviour change, and urban design at place level:

Planner 4: “Is anyone looking at urban design potential for improving the linkages and connections?”

Planner 4: “I’ll just throw this in. Employers need to think about how their people work. Employees could work from home. They could be staggered to work different hours.”

In contrast, it was the local stakeholders, representing businesses operating in the cluster, that talked about the strategic importance of the cluster, and need for infrastructure of metropolitan-wide impact. Here is a representative dialogue between the business manager at CSIRO and a transport planner at TfV:

Planner 1: “Monash University is doing a lot of master-planning. This recognised that, to achieve those outcomes, you have to do something to the road network. I guess the question is which comes first, and it has to happen simultaneously.”

Resident 4: “More of a comment: all of this looks like band-aids, because it’s still so reliant on the roads. Everything still goes in and out of the city. In European cities, you don’t need vehicles. Is any thought being given to the public transport network?”

Planner 1: “I guess it would be a long-term option. It’s often hard to justify the investment before the service has been proved. We’re thinking about prioritising buses - a 5-minute network, or a 10-minute network. High-level accessibility. And exploring that potential before we commit.”

Resident 4: “It just puts more buses on the road.”

3. *the main perceived usefulness of the data was as a tool for political lobbying with evidence-based input; there was a strong sense that the decision-makers were not present in the room – that the real strategic decisions about public transport in Monash NEIC would be made elsewhere*

In particular, when asked about the perceived benefits of accessibility modelling, representatives of businesses in the cluster expressed an interest in accessing numbers and calculations that they could use in what they perceived as a political, public opinion-dependent process of lobbying for infrastructure. The interest in comparing scenarios in detail was scarce: the respondents were not interested in gaining a nuanced understanding of how different transport and land-use scenarios

compare. What they wanted, instead, was “anything... anything you can provide us would be great” (Resident 1, research interview).

Resident 1: “It was a very insightful and a good way of presenting... that you could see what it meant in terms of bad connections, how long it would take. [...] It was a good way of presenting information that would speak to higher-level decision-makers.”

Planner 4: “It’s grounded. The methodology sounds very, very sound. It highlights the problems we have all been aware of... but puts the science behind. We may need to bring you to a new audience in order to move this forward.”

Planner 4: “If we were to put together a very influential group of people, could you do this presentation again?”

4 Post Scriptum

In April 2018, Victorian state government made a surprise announcement to build a light rail to Monash University (as well as a train link to Melbourne airport on the other side of the city), surprising commentators and transport experts alike (Currie, 2018). A financial commitment of \$3 million was made in the coming Victorian budget (June 2018 – June 2019) for designing and planning the light-rail route, which would connect two main Monash University campuses via Chadstone, as well as the Australian Synchrotron, the Monash Medical Centre and the future Victorian Heart Centre. The as-of-yet untimelined stage two would continue onto Rowville via Waverley Park. Planning work for stage one was to start immediately, and to include examining alignments, park-and-ride options, stop locations, cost and travel time benefits, and would include engagement with residents, resident businesses, and other local stakeholders (Carey 2018, Monash University 2018). (See Figure 7 for the proposed alignment). The plan showed a similarity with Fotis Spiridonos’ Value Creation plan, but had no obvious reference in Draft Framework Plan.

7. The proposed route of the new light rail link from Caulfield Station to Rowville. Source: Carey (2018).

Mere weeks later, the federal government announced it would invest \$475 million to build a (heavy) rail line to Monash, as part of the announcements in the federal budget for 2019 (Fletcher 2018). Media commentators noted that this represented a clash with the state government light rail commitment. It is important to note that neither of these announcements came with accessibility models or data on passengers – the maps supplied were mere illustrations of the proposed network.

In August 2018, some three months before the state election and five months after the surprise announcement of the light and heavy rail options for Monash Clayton, Victorian state government released a video announcement on social media announcing plans for a massive underground rail loop, that would link up all of Melbourne's radial commuter rail lines with an orbital line from Werribee Station in the outer west to Cheltenham Station in the south, stopping at both ends of Port Philip Bay at the distance of 20-30km from the CBD (Henriques-Gomes, 2018). Described as “the biggest public transport project in history” of Victoria, it would include 10 existing stations and five new ones including, crucially, one at Monash University in Clayton (see Figure 18). At 90km of new rail, \$50 billion projected costs, and the completion date of 2050, the plan sat closer to a vision than to a detailed plan. Still, speaking at a press conference a few hours later, Victorian state premier Daniel Andrews also added that the state government had already committed \$300 million to the project, that “all the geotechnical work, engineering, design and planning will be done beginning first thing next year,” that construction would commence in 2022 “if not sooner,” and that the project would be staged, with stage one involving the 25-km line between Cheltenham in the south and Box Hill in the east, the span of the rail that would pass through Monash University (Smith 2018:unpaginated). At the

time of the completion of this paper, no accessibility data of any significance has been released to accompany this announcement.

This is the context in which the post-workshop discussions took place: one of unexpected policy announcements that had taken everyone by surprise, and that were in no way envisaged in the 'ordinary' planning process for Monash NEIC in the previous years. The follow-up conversation took the opportunity to explore how those decisions were made. Three complex themes emerged in the interviews:

4.1 'Every little bit helps'

Rich descriptions of the decision-making process revealed that transport planning was a political, and not expert-led process, and that behind-the-scenes lobbying played an outsized role.

Planner 2: "From what I can gather, it wasn't so much TfV. It may have been successful lobbying of Monash Uni to the Premier, who then decided that this is the project that we're going to do. [...] My colleague Jess was speaking to [TfV] and it wasn't really on their work program either. So it was something that... it hasn't come out of the blue, but it has jumped forward a lot faster than people thought it might."

Fotios Spiridonos: "The only comment I have is that I like to be proactive, and that's why I had that value created work started in mid-2016, the report coming out in mid-2017, then trying to get it socialised, and that's good. To develop an evidence base for advocacy and I like to think that that's what it did. ... And as I said also it's an election year. what I'm trying to say, Jana, is every little bit helps."

4.2 'Happy with the outcome, don't mind the lack of process'

The second theme that emerged was, surprisingly, satisfaction: all stakeholders appeared happy with the outcome, rather than disappointed with the opaque process that led to it.

Resident 3: "It's all relatively good news."

Resident 1: "At Monash University, we don't have a position on [which proposal is better, light or heavy rail]. We welcome both proposals, as long as we get better connected. It's really important that it's not a slow tram or something, but that it's fast connectivity, that we can transport a lot of students. People come to Clayton every day. That's our point. ... So how does it fit in with what we're trying to create? Which is positive."

4.3 'Without process, we don't know where SNAMUTS would fit in'

Finally, in an echo of workshop observations, the vast majority of the interviewees struggled to identify when SNAMUTS could be used in the future, as the process going forward was both outside of their control, and fundamentally unknown.

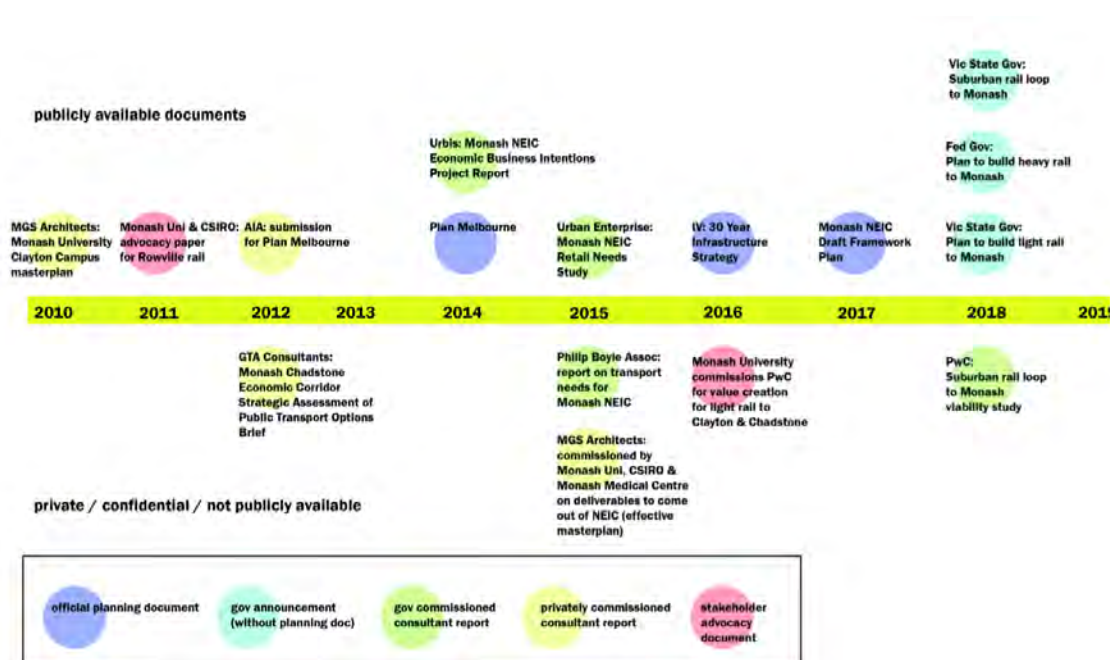

Resident 1: "I know they are doing a... feasibility study and analysis to come up with the best solution. I guess, in that context, they might benefit from SNAMUTS more. So... yeah. I don't really know how is the process going forward, how they will use the feasibility study, whether they will consider a model like that. I think it would definitely be interesting for them to see."

5 Conclusions

Accessibility is a useful indicator in any process of strategic planning. But once inserted into the planning process, accessibility – itself a complex concept – finds itself within a larger 'wicked' problem, a multi-stakeholder and multi-layered process of long-term change affected by many factors. The data is pointing to the conclusion that it would be challenging to place an Accessibility Instrument, a tool for providing an evidence base to policy, in a planning context characterised by politicisation. This in itself is not surprising; however, having put detail into an abstract situation, the study sheds some light on why this has not been able to happen – by demonstrating the limitations of the stakeholders' roles in a poorly defined process.

Rob McGauran summarised some of the problems with the integrated planning for Monash NEIC when he singled out transport planning in Victoria as a 'vexed political thing':

We have a history in this state of priorities for transport being based around swinging seats, not about transformation of a city. (Rob McGauran, research interview)

8. What actually happened: the full timeline of planning documents for Monash NEIC.

In contrast to best practice encountered in planning literature, the planning of Monash NEIC has been characterised by a highly inconsistent long-term process, with changing vision, strategic priorities, and financing. The assignment of roles has been (and remains) unclear, as even short engagement with the process has demonstrated that key decisions are made by political rather than planning players, lacking sufficient consultation even with responsible government bodies. It is notable that a number of key documents informing the planning process are confidential and not publicly available. Why confidential? The planning and financing of public transport infrastructure is certainly a matter of clear public interest. For the stakeholders from the private sector, those whose business interests, assets and professional roles are inextricably tied to the fortunes of the Monash NEIC area, the need to operate in an environment of great uncertainty and secrecy has led to frustration in some cases,

advocacy in others; as well as a tactical, ad hoc engagement with state politics, in the form of self-commissioned economic and planning reports, which are then used for lobbying – sometimes very successfully. The number of unofficial, confidential and purely secret documents in Monash NEIC almost rivals the official documents created within the process, and the extent of the problem becomes apparent (see Figure 8). Another salient characteristic of the transition process in Monash NEIC is its sheer unpredictability: the often expressed 'anything goes as long as we have a good outcome' attitude reflects a fundamental uncertainty around the likelihood of a good outcome. In other words, that government documents have marked Monash NEIC for a transition towards better connectivity does not give certainty to private actors: instead, small victories are celebrated each step of the way.

The introduction of SNAMUTS models into the planning process of Monash NEIC was welcomed by stakeholders and planners because it 'introduced clear metrics' to what appears to have, until then, been a largely impresionistic discussion of transportation outcomes. It is notable, and not entirely positive, that these metrics were immediately seen as a lobbying tool, not information to underpin nuanced decision-making. Decisions around public transport network structure, individual routes and stops, should be made in order to maximise accessibility outcomes. Only a public transport system that optimises accessibility will bring optimal economic, social and environmental benefits to the city.

Neighborhood walks as transport, outdoor recreation and public health

³Norwegian University of Life Sciences, kine.thoren@nmbu.no

Abstract: Facilitating walks close to residential areas is an important challenge in sustainable planning. The paper illuminates how efforts to improve conditions for and stimulate neighborhood walks are organized and integrated into Norwegian municipal planning. We mainly build on case studies in 3 municipalities of different sizes. Norwegian Travel Surveys shows that about 20 per cent of all daily trips are done on foot. Nevertheless, walking regarded as either transport, outdoor recreation or public health, have little attention in Norwegian municipal planning and management. Walking as transport is nearly absent. Transport planning is still primarily concerning motorized cars and busses and railroads, and to some extent bicycles. Walking is nearly invisible in the municipalities' organization and crumbles away in the planning system. To strengthen neighborhood walks, public health should be made as an overarching perspective for the interdisciplinary organization for walks. A main network for walking should be established through land-use planning, and substantially more emphasis should be given to achieve coherence between the 'grey' pavements and walking trails in the residential areas and the 'green' trails and roads for walking in the forests outside.

Keywords: walking; public health; outdoor recreation; transport

Background and purpose

Walking is the simplest and most effective form of movement with indisputable positive impact on public health, almost any speed and length of the walk. It is well documented that short walks are the outdoor activity that is carried out to the greatest extent (Statistisk sentralbyrå, 2017). Walks are something 'everyone' deals with independently of social class. Thus, to facilitate walking in the neighborhood with the residence as a starting point is an important challenge for sustainable planning in municipalities. Such neighborhood walks may have exercise, training and public health as the main reason, but might as well be outdoor recreation and experience, or as transport for specific task. Nevertheless, neighborhood walks concern the use of different types of land, planned and adapted through the municipalities' land-use planning according to the Planning and Building Act. The purpose of the paper is to shed light on how the municipalities work to improve conditions for and stimulate neighborhood walks. We examine how the work with neighborhood walks are organized and integrated in municipal planning and discusses how the municipalities' efforts for neighborhood walks might be improved?

What are neighborhood walks?

‘Neighborhood walks’ is a complex term with many dimensions. We are looking at neighborhood walks as a kind of walking and thus of importance to public health. The immediate understanding of neighborhood walking is for most Norwegians that neighborhood walks are a kind of outdoor recreation, like walk on footpaths and hiking trails in the ‘green’ near the residence. The public definition of outdoor recreation as “stay and physical activity in the open air in leisure time with the aim of environmental change and nature experience” has been fixed since the first parliamentary report on outdoor recreation in 1987 (Meld. St. 18 (2015-2016), p. 10). Nevertheless, in recent years there have been substantial changes in the perceptions. In the parliamentary report of 1987, it is stated that “The public work on outdoor recreation has traditionally not included outdoor activities in urban areas and other areas that are dominated by buildings.” (St. meld. nr. 40 (1986-87), p. 28). This understanding is substantially expanded in the last parliamentary report about outdoor recreation, leading outdoor recreation into towns and villages: “The understanding of outdoor recreation that is the basis also includes traffic and stay in green spaces inside cities and towns, such as parks and other green structures.” (Meld. St. 18 (2015-2016), p. 10). Then, the ‘grey’ areas are included, even though this term is not being used. In practice, neighborhood walks for many must start in the grey, on the car road, pavement or walk road. The same point of departure has walks from residence to work places, schools, kindergartens, shops, etc. These walks are in principle transport, primarily as “necessary activities” (Gehl, 1971). Travel surveys shows that the percentage of trips that take place on foot has been remarkably stable since the early 1990s and until today. In Norway, this proportion of walking tours is 21-22 per cent throughout the period (Hjorthol *et al.*, 2014, Statens vegvesen, 2019). In summary, we understand neighborhood walks as walking, which includes both public health, outdoor recreation and transport. Neighborhood walks take place both on walking trails, pavements, walk roads or car roads. It is just this link between ‘grey’ and ‘green’ walking routes that characterizes neighborhood walks. Neighborhood walks concern different forms of land-use and are thus an important element in municipal land-use planning.

Management cultures and multi-level governance

Neighborhood walks are included in tasks to multiple municipal units, but no units have neighborhood walking as their main task. It is challenging to give neighborhood walking a clear and strong position in municipal planning and management, i.e. because of different management cultures in a multi-level governance system.

Tasks within clearly defined areas of responsibility and competence, sectors, usually with their own laws and regulations, and incorporating bureaucratic and professional practices, will be more successful than tasks, which are cross-sectoral and give complex co-operation and co-ordination challenges. When performing various tasks in organizations, there is a need for argumentation and documentation of positions with reference to knowledge. Different ‘management cultures’ legitimizing which tasks are more important than others and how the tasks are to be solved, are developed. It provides routines for how problems are defined and solved and for handling tasks that are imposed by others (Kleven, Thorén and Skogheim, 2005). The institutional exercise of power through norms and existing schemes that legitimize positions and power is often not visible. The exercise of power is obscured and appears to be marvelous. Through historical processes and struggles, frames are created that govern what is taken for granted and not, and gives symbolic power in specific decisions, such as prioritization of various activities and types of facilities (Bergsgard, 2017). Just as important as the formal structures that provide the framework for actions, is how these structures are perceived by the peoples who are to perform

actions within the formal structures. Actions do not necessarily follow strictly the formal structures (Bukve, 2012).

Many of the tasks that are important for neighborhood walks are to a large extent governed by decisions in the management hierarchy over the municipality, at the county and national level. Here, there can be large variations in both horizontal and vertical links between management levels and sectors (Eckerberg and Joas, 2004; Bukve, 2012; Reitan, Saglie and Smith, 2012). The gaming fund for sport facilities is an example of such multi-level management. This is state funds covering up to 1/3 of the cost of facilities for sports and physical activity, including outdoor recreation facilities like walking trails, distributed by the county municipalities after applications from the municipalities. The remainder of the costs must be borne by the local authorities and sports clubs etc.

Methods and data bases

Cases

We build on case studies in 3 Norwegian municipalities. The cases are selected from an information-oriented approach with great variation between the cases, “maximum variation” (Flybjerg, 2006). The cases are not compared, but they represent examples of various Norwegian municipality types, primarily elected by population and geographic distribution. Trondheim in Trøndelag county is an example of a large Norwegian municipality (193 500 inhabitants). Moss in Østfold county represents a medium-sized city municipality (32 500 inhabitants), while Ringebru in Oppland county is an example of a small and rural municipality (4 500 inhabitants).

Data sources

The data basis is primarily municipal planning documents and interviews in the municipalities, as well as information about the municipalities accessible on the municipalities' websites. We have gone through the relevant planning documents which varies between the municipalities. This data collection goes until today, but the interviews were primarily conducted in spring 2014 (with some additions in spring 2016 and fall 2018). The interviews were conducted as single interviews in the municipalities following a semi-structured interview guide, carried out by all three researchers jointly. In each municipality we interviewed politicians (mayor/deputy mayor), administratively responsible for important neighborhood walks tasks and representatives of NGOs. A total of 20 interviews were conducted. In four of the interviews, two people participated, so that a total of 24 people are interviewed. Each interview lasted about an hour and a half.

Neighborhood walks in the case municipalities

Content

Here follows a description of how the work on neighborhood walks is organized in the municipalities and how it is integrated into planning in the case municipalities. Within each theme, we also include how neighborhood walks are handled at national and regional level. This provides important guidelines for the municipal level in our hierarchically organized management system. We do not go into detail and look primarily at the administrative organization and how the practical work on planning for neighborhood walks goes on.

Neighborhood walks as outdoor recreation

Responsibility for neighborhood walks as outdoor recreation is at national level divided between The Ministry of Climate and Environment and the Norwegian Environment Agency, the Ministry of Culture, and the Ministry of Health and Care Services and the Norwegian Directorate of Health. At the regional level, it is first and foremost the county municipality that has important tasks related to neighborhood walks. The county municipalities manage a range of grant programs for outdoor recreation and has regional responsibility for on behalf of the Ministry of Culture to distribute the gaming fund for sport facilities. Thus, the gaming fund closely links neighborhood walks to sports in the management context.

In Trondheim municipality, neighborhood walks are most visible as outdoor recreation and walking roads and trails. The responsibility is divided between departments for Culture and industry, unit for Sport and outdoor recreation, and Urban development, units for Municipal engineering, Urban operation and Urban planning. The last edition of the mandatory municipal plan for sports and physical activity (MSP) in Trondheim is divided into two parts, one for sport and physical activity and one for outdoor activities and green areas. Attention is still mainly directed towards the green areas and environmentally friendly transport possibilities to the green areas (p. 19). The plan has become a kind of continuation of the work on green infrastructure plans, but now rooted in the unit for Sport and outdoor recreation and not in the unit for Urban planning.

In Moss, unit for sports and outdoor recreation administratively sorts under Culture. Outdoor recreation is also included in the responsibility of department for Plan, environment and technical issues when it comes to parks, hiking trails, coastal paths etc. A survey in Moss shows that people in leisure time walk about as much on streets and roads as in the green areas, even though almost 90 per cent say they would prefer to walk in green areas (Thorén *et al.*, 2015). Neighborhood walks is no central theme, e.g. in the municipally approved plan for sports and physical activity. The plan comments the outdoor recreations' challenge to be heard in the debate about prioritizing sports facilities and facilities for physical activity. Most outdoor recreation users are disorganized and are 'quiet' users of what remains of public areas. Therefore, it is important that the municipality secures areas through good land-use planning (p. 32). The organized sport has plans and funds and thus sets the agenda. Moreover, the gaming fund for sports facilities is perceived as an expensive arrangement for the municipality (interview MSP responsible, March 25, 2014).

Ringebu had shared MSP plans with two neighbor municipalities to consider regional cooperation for major sports facilities. The Cultural unit has been responsible for this planning work in Ringebu. Neighborhood walks is not a priority in MSP work, because much might be achieved by cooperation with the sports, hiking and fitness clubs and other volunteers to arrange walks and clean and maintain paths (interview MSP responsible, April 2, 2014). The MSP plan states that: "It is important to motivate more to become physically active in everyday life and leisure time. Walking or cycling to work, school and leisure activities ... » (p. 74). Neighborhood walks are priority as activity, but not as a facility. In the rural municipality Ringebu, walking routes and destination is something that mostly exists in the mountains. But there have been some changes in recent years. The municipality has marked three (existing) walking trails close to Ringebu center. The ambition is to get more people out in their own local environment (see Figure 1).

Figure 1. Ringebru center with three marked routes. Map completed in the summer of 2018. Source: Ringebru municipality, 2018.

Neighborhood walks as transport

Neighborhood walks are one important part of transport, both the necessary transport for specific issues and the recreational based. Nevertheless, neighborhood walks are rarely mentioned in connection with transport, for which the Ministry of Transport and the Norwegian Public Roads Administration (NPRA) have the national responsibility. In 2012, the NPRA presented a *National Walking Strategy. Strategy to promote walking as a form of transport and everyday activity* (Statens vegvesen, 2012). The strategy was a part of the work on the National Transport Plan 2014-2023 (St. meld. nr. 26 (2012-2013)) but was nevertheless not mentioned in the subsequent National Transport Plan 2018-2029 (Meld. St. 33 (2016- 17)).

In the municipalities, the responsibility for transport is mainly related to the responsibility for land use, in Trondheim divided between the Urban planning and the Environmental unit. Much of the work is done by the Environmental Package for Transport in Trondheim and an urban environment agreement between the State, the county municipality and Trondheim municipality. The most important sources of funding are tolls and state funds, but also the county municipality and the municipality contribute. The proportion of funding for walking roads is negligible, just about 1 per cent for the 2010-2020 period (Environmental package for transport in Trondheim. Action program 2017-20, p. 7). The Transport plan 2006-2015 summarizes goals, status and measures for different focus areas. None of the new measures relates to pedestrians and walking. The Walking strategy for Trondheim 2016 has “Easy to walk all

year round” as its main object. The city council has adopted the walking strategy, but nevertheless walking and neighborhood walks are not considered as an important part of the transport system, at least not in the fight for funds for new facilities.

In Moss, transport sorts under department for Plan, environment and technical issues. The municipal Master plan contains a number of sub-objectives and strategies where particularly bicycling and also walking are important themes. Action plan for transport 2014 –2020 shows that Moss municipality has ambitions when it comes to walking as transport, including a walking strategy. Since Moss is a small municipality in terms of area, the plan emphasizes that it should be possible for many to walk to and from work or leisure activities. A large part of the inhabitants of Moss live within 2 km of the city center, and most of them live within 3 km from the center, see figure 2.

Figure 2. Map of Moss showing the distance from the city center in a radius of 2 km and 4 km. Source: Moss municipality. Action plan for transport 2014 - 2020, p. 6.

The land-use part of the municipal plan (2018-2030) has recently been approved. The chapter about transportation and infrastructure says that it must “... be facilitated and ensured easy access to good and safe alternatives in terms of walking and cycle paths, pavements, walking crossings and paths in the forests, so that more people can change from car to walk or bike transport” (p. 74).

Neighborhood walks as public health

Neighborhood walks as public health is linked to outdoor recreation and physical activity (Nordh *et al.*, 2017). The Public Health Act (PHA) (2012) attributes both local and regional authorities a notable responsibility for health promotion in the municipalities. The municipality shall have an overview of the state of health in the municipalities and overriding goals and strategies for public health work shall be determined through the work on municipal plans (PHA, sections 5, 6). Public health is one of the specified tasks and considerations for planning according to the Planning and Building Act. Plans should "promote the health of the population" (PBA, section 3-1). Possibilities for walks is of great importance to physical activity (Breivik and Rafoss, 2017) and is an important arena for the general public health work (Bergem *et al.*, 2010; 2018).

In the municipal planning strategy for Trondheim municipality 2016-2019 public health, "health in everything we do" (p. 8) and social security are referred to as two main tasks that are to be assessed in all plans, without drawing up separate plans for these tasks. The responsibility for public health is divided between several departments and units. There is an interdisciplinary group for public health, but no separate position as a public health coordinator. Public health concerns all agencies, but how should public health gain in the battle for attention and resources, if no one has a special responsibility? Many in Trondheim municipality point out that the public health group does not have any real tasks. The ambition of public health in "everything we do" is not being taken properly into account (interviews Trondheim municipality, April, 2014).

Neighborhood walks as public health is in Moss assigned to department of Health and care and social services. One of four priority goals in Moss Municipal Plan 2011-2022 is "Living Conditions and Public Health". The report on Public Health and Living Conditions in Moss. Overview document 2018 includes outdoor recreation and it is emphasized that preserving and creating green neighborhoods is an important public health measure. Local walking routes are particularly important according to the report because this is cheap 'sports facilities' and have "the greatest potential for activating an inactive population" (p. 58). The report states that if the neighborhood walks should be attractive "paths and walking routes must be cleared, marked and maintained" (p.71).

In Ringebu, the public health responsibility most of all belongs to the department of Health and care, but what we call 'neighborhood walks responsibility' is to a large extent included also in departments of Culture and industry and Planning and technical issues. Collaboration with the voluntary sector is strong, especially with the hiking and trim club. This close and far informal collaboration is emphasized in the interviews (April, 2014). In the social part of municipal master plan (2014-2026), Ringebu refers itself as a 'public health municipality', and that one will "facilitate for varied opportunities for neighborhood walks out of the urban areas" (p. 6). The importance of "good physical environmental conditions", which "actively contribute to forward-looking road network, walking paths/bicycle trail." In the plan Health and care on the way to 2028 there is nevertheless little concrete about measures in the outdoor environment and the focus on neighborhood walks, even if 'health and prevention' is one of the central focus areas.

Neighborhood walks as land-use

Neighborhood walks as land use is under the responsibility of the Ministry of Local Government and Modernization, the Planning Department, on national level, and the county municipalities have the main

regional responsibility. Planning according to the Planning and Building Act (PBA) is the most important tool in land use planning. There is only one land-use objective in the PBA which relates especially to neighborhood walks. We find this under the main objective green structure which can be divided into four sub-objectives, i.e. green corridors. Under the main objective of transport and communications installations and technical infrastructure, we find as expected main bicycle networks, but surprisingly, no main walking networks (sections 11-7 and 12-5).

In Trondheim municipality, responsibility for land use is divided between several units. The Urban planning office is responsible for planning according to the PBA, the Municipal technique unit is responsible for parks and green structure, the Environmental unit has general environmental responsibility and Trondheim urban operations is responsible for operation and maintenance. The social element of the municipal masterplan 2009-2020 for Trondheim defines four main goals, one of them is: “ By 2020, Trondheim is a sustainable city, where it is easy to live environmentally friendly ”, with a sub-goal that Trondheim must: “have a physical urban design which promote quality of life and health” and strategies including i.e. to ensure “easy access to parks and recreation areas” and to develop “good walking, bicycle and hiking trails”. In the context of environmentally friendly transport, neighborhood walks are mentioned, but primarily as walking trails, green structure, outdoor recreation and public health, and to a little extent as transport.

In the land-use element of the municipal master plan 2012-2024 for Trondheim, public health and increased everyday activity and coherent green structure and road network are addressed under Status and challenges. One of the principles for urban development is high density in the local centers and along public transport routes and facilitating walking and cycling on daily travels. Continuous bicycle mains are included in the chapter on transport, but walking is not mentioned. Many employees at the Urban planning office find it strange that sports and outdoor recreation is not under their responsibility, but belongs to Culture and industry. Therefore, the plans for sports and outdoor recreation to certain extent “live their own lives” so that the land-use needs and impacts are not properly included into the work of the land-use part of the municipal master plan (interview, urban planning office, 30. April 2014).

Green structures have been an important issue in municipal land-use planning in Trondheim ever since the 1960s. Nevertheless, detailed research shows that there are great challenges to plan, design and maintain continuous walking trails through built-up areas. An example is the hiking track/walking trail between Nidelva in the city center and the entrance to Estenstadmarka, see figure 3.

Figure 3. Walking route from Nidelva to Estenstadmarka, Trondheim. Source: Amland 2015, p. 74.

The route has been plotted in municipal land-use plans ever since 1965. A review in 2015 shows that this walking route is now composed of 29 different zoning plans, adopted at different times between 1955 and 2011 (Amland, 2015). In many of these zoning plans, priority have not been given to the walking route in land-use allocation. The walking route is in many places considerably reduced in width and usually adapted to the car roads at crossings. There is a lack of following-up and coordination of implementation and operation.

In Moss, the theme land-use planning belongs to department for Plan, environment and technical issues. The starting point for the approach to land planning in the Moss region is the county plan (from 2008) where public health is a prioritized theme. Sub-goals and strategies of importance to neighborhood walking are included in all four priority areas of focus in the plan. Briefly summarized, physical activity and low threshold services, universal design, establishment of walking and bicycle trails with accessibility throughout the year are included, facilitating the use of environmentally friendly transport through the strengthening of public transport and the establishment of walking/bicycle trails

The new land-use element of the municipal master plan for Ringebru, 2018-2030, states in the chapter about green structure that these “shall address the need to define the main structures of natural areas in and beside urban areas and green areas along watercourses” (p. 76). One of the newly marked routes (tour 2 in Ringebru center) is connected to waterways through the center areas. The tours are not newly established, but made visible through marking and a new hiking map (figure 1). The municipality wants

a densified center in Ringebu where service functions and living areas must be coordinated closely and avoid retail trade outside the center (interview municipal planner, April 2, 2014).

Organization and planning for neighborhood walks

Neighborhood walks is not visible in the municipal organization

Neighborhood walks as an interdisciplinary subject is of course dispersed in the municipal organization. Neighborhood walks as outdoor recreation follow in all three municipalities national guidelines that link outdoor recreation partly to nature experience and partly to physical activity both in sports and culture and in health. The outdoor recreations' management culture is still heavily oriented towards the green areas and primarily forests outside the built-up areas and to walking paths and hiking trails. The close link to the sports through the municipal plans for sports and physical activity and the sports great need for facilities, both for recreational sports and for top-level sports, gives little opportunity for neighborhood walks in the struggle for funds for the preparation of new walking trails that require construction work and costs (Thorén *et al.*, 2016). This is also connected to understandings about the simple outdoor recreation based on footpaths without major interventions or adjustments and hence without substantial establishment costs. The large facilities are not needed for neighborhood walks. National resorts, however, such as Granåsen in Trondheim, which will also be used for international championships, "have their standard requirements that must be followed, even though they may seem unreasonable, cannot pay attention to pettiness" (interview politician, 30. April 2014). The sports are linked to strong market participants who contribute both financially and with argumentation and legitimization of large construction investments that also affect the management culture and what is significant and necessary.

Almost all sports require large construction investments, and many sports, such as football and skiing, have so much support that it is almost taken for granted that temporal sports facilities are needed and that the costs must be covered, both by public and private funds and by considerable voluntary efforts. Outdoor recreation with its tradition of simple preparation, small government support and a high degree of voluntary work, has basically little to set up in competition with the sports. In the struggle for the funds that go to facilities for sports and physical activity, the outdoor recreation is part of the sports concept and thus virtually doomed to lose in the fight for facilities that are to receive gaming funds. On the other hand, it is a tradition in carrying out minor improvements and simple measures on walking routes and trails, both as separate municipal actions, coordinated with the activity of technical departments, often in association with voluntary organizations.

Neighborhood walks as transport is strongly characterized by professional traditions and management cultures, from national to local level. It is roads and railways that dominate, both economically, politically and academically. The road engineers and the economists have the professional hegemony. At the national level, the national walking strategy from 2012 is completely forgotten, at least not mentioned, in the latest national transport plan (Meld. St. 33 (2016-2017)). Still, it is the walking and bicycling trails that have to adapt to the car road network and not the other way around. This makes it often difficult to construct the shortest paths for walking and bicycling. There are changes going on, but it is particular in planning and development of bicycle trails that have had a greater impact, while the focus on walking is more absent. Within transport, major changes must be made to ensure that walking and neighborhood walks are recognized as an important mode of transport.

Neighborhood walking as public health is closely linked to walking as physical activity and has high priority in the municipalities. All municipalities have more or less organized arrangements for this. Public health is naturally linked to health and the municipalities' activity for preventive and treating work, which traditionally has no strong organizational links either to culture and sports or technical agencies. The management culture, both nationally and locally, is characterized by health and physical activity, and less connections to land-use planning and physical facilities. It presents challenges in finding well-functioning ways to organize the large and varied subject matter of public health. A public health coordinator is needed, but not enough, to be able to handle this comprehensive field of action. The municipalities lack arenas that combine the physical activity of walking and public health with walking as outdoor activities and especially with walking as transport.

Neighborhood walks as land use and land use planning are in all three municipalities relating to technical sector and responsibility for land planning and follow mostly established management cultures across the public administration levels. A main walking network is not even a land-use objective in the PBA. On the other hand, we see that practically oriented and committed employees in the municipalities' technical sector get a lot out of small funds for walking trail etc. by seeing measures in context and utilizing the opportunities for coordination of construction activities. Such measures can be decided and implemented quickly, without extensive search processes (interview, municipal employee Moss, March 25, 2014), and often in close cooperation with the voluntary sector (interviews with representatives of both the Culture department and the Trim club, Ringeby, April, 2014). Walking paths and hiking trails are important elements of the green infrastructure, but when the responsibility for the green structure, which in Trondheim, is added to the Unit for sports and outdoor recreation, it may mean weaker links to planning and municipal land-use plans.

Neighborhood walks crumbles away in the planning system

Neighborhood walks in planning context we find first and foremost in the municipal master plan, both in the social element and the land-use element, and in the plan for sport and physical activity. Moreover, we also find neighborhood walks in green structure plans, public health plans, transport plans and walking strategies. In all the three case municipalities, the social element of the municipal master plan have considerable attention around neighborhood walks. A nationwide survey that shows that almost 80 per cent of the planning managers in the municipalities think that the municipal master plan's social element, and just over 70 per cent that the municipal master plan's land-use element, contains guidelines for neighborhood walks measures (Thorén *et al.*, 2018, p.36-37).

In the land-use element, neighborhood walks are mainly dealt with in the context of outdoor recreation and continues green structure, walking trails and to a little extent as transport and road network. The transport plan for Trondheim, 2006- 2015, and the national transport plans, mentions barely walking. Although the Norwegian Public Roads Administration for several years has had an effort for walking strategies, this appears to be a work on the side of the ordinary and traditional work for the development and maintenance of the car road network. The municipal walking strategies have not yet led to major changes. Preliminary results from a recent national travel survey in 2018 shows a reduction in car trips and a transition to public transport and bicycle, while the proportion of walks is stable at 20 per cent. The outdoor recreation interests are concerned with the green and work for the shortest possible distance between the residences and green areas and continuous walking trails, preferably no more than 500 meters. The pavements/walk roads which in most cases are used to travel these 500 meters, are given

less attention. There is a little attention to the important connection between the grey traffic routes for walking in built-up areas and the green walking trails and the forested areas outside.

The municipal plans for sports and physical activity are the type of plans that, according to the planning managers in Norwegian municipalities, is mostly concerned with neighborhood walks measures, as much as 80 per cent consider this (Thorén, *et al.*, 2018, p.36). Yet we see from the case municipalities that when the funds are to be distributed, it is only a few percentages that go to neighborhood walks. It is the sport and sports facilities and associated physical activity that dominates. The gaming funds are perceived as complicated to obtain, with time-consuming application processes that may seem unnecessarily extensive and complicated for many walking roads and trails that are often simple and small facilities. Besides, the gaming funds requires considerable deductibles. Plans and studies for public health contain a lot about physical activity, outdoor recreation and neighborhood walks, but there are often missing connections to the physical facilities which is an important prerequisite for activity. The general impression is that we find considerable attention around neighborhood walks in plans and reports at the overall level, such as the social element of the municipal masterplans, but this attention gradually disappears on the way towards concretization and implementation.

Improvements for neighborhood walks?

Neighborhood walks are included in many themes, but nevertheless seldom is winning the battle for resources. Neighborhood walks is a typical interdisciplinary area and is therefore particularly tied to the two most interdisciplinary topics we have addressed in connection with neighborhood walks, public health and land-use planning. The main rationale for neighborhood walks we believe is in the public health, and the most important instrument we find in land-use planning. It gives the perspective of our discussion of possible improvements.

The outdoor recreation has a management culture that is still strongly linked to the green areas. The green areas are of course important to neighborhood walks, both as nature experience and physical activity. Nevertheless, the design of the grey areas closest to the residential areas are often the most important precondition, or barrier, for neighborhood walks (Thorén, *et al.*, 2015). Outdoor recreation will need to give more attention to this important relationship and work more for outdoor recreation on grey areas and the relationship between the grey and the green transport routes.

Transport is mostly concentrated on car roads and footpaths and bicycle trails in connection to the car network, with a management culture dominated by car road engineers. So far, the walking strategies have changed this picture. Public health is an interdisciplinary focus and responsibility area in the municipalities, also related to neighborhood walks, but first and foremost as physical activity. The connection to neighborhood walks as physical constructions is weak organizational (Tilset, Gjørund and Heggem, 2015). Neighborhood walks and public health have attention in the planning departments, but crumble when it comes to concrete plans and implementation. It is areas for development purposes and large transport facilities that receive the greatest attention and neighborhood walks only come as supplementary supplements. Neighborhood walks are primarily seen as walking trails in the green structure. There are great opportunities for improvement by increasing the effort for physical activity and the physical facilities that are a prerequisite for activity. Public health is an excellent argument for neighborhood walks.

Neighborhood walks are spread in the municipality organization. As important as the organizational chart and the units, is the cooperation between different parts of the organization. If the cooperation works, the formal organization has less importance. Nevertheless, there are some overriding principles for organizing neighborhood walks that in our project point out. Firstly, the interdisciplinary organization of public health must be strengthened. Public health must to a greater extent be able to combine efforts for physical activity and physical facilities in planning and implementation. This means both establishing a common organizational arena for all relevant areas of responsibility and that this arena must be centrally located in the organization. The second is to strengthen neighborhood walks as a purpose for planning, especially land-use planning. This means, to a greater extent than in most municipalities today, gathering organizational responsibility for neighborhood walks and land-use to the planning responsible in administration and politics. The hierarchical structure of planning under the Planning and Building Act is so strong that the responsibility for all major land-use objectives, also linked to neighborhood walks, should be here.

All land-use planning concerning neighborhood walks should be collected in the unit in charge of planning and directly attached to the work with the municipal master plan follow-up be zoning plans. This means making walking roads and trails and green structure to a very clear planning responsibility. It also includes ensuring much clearer coupling is between walking trails walking roads and pavements, so that we get a continuous main network for walking comprising both grey and green walking routes. A concrete proposal is to change the Planning and Building Act so that the land-use objectives in both the land-use element of the municipal master plan and in the zoning plans so that main walking networks is included in the same way as main bicycle networks.

Abstract: The diffusion of autonomous vehicles (AVs) is expected to increase rapidly in the next decades and its impacts can be potentially disruptive. To date, scientific literature on AVs mostly focused on technological innovation, safety issues, ethical dilemmas and normative aspects. A growing number of studies also addressed social aspects and potential demand for AVs. While at first less attention has been given to spatial and territorial impacts that AVs will determine, and on the need to govern their diffusion, concerns and literature on these issues are rapidly growing. Assuming the governance of AVs diffusion as a key aspect to limit their possible negative impacts on urban public space, this paper draws on the preliminary results of a research project led by Politecnico di Torino. The project adopts a backcasting approach that considers how circulation and parking of AVs should be differently regulated in various parts of the city. The paper highlights how defining future visions of AV regulation for these backcasting exercises raises issues and questions, that are relevant for implementing policies to control AV impacts on urban public spaces.

Keywords: autonomous vehicles; visioning; backcasting

Introduction

Despite the enthusiasm of media and manufacturers, there is great incertitude about the temporal horizon of the socio-technical transition to fully automated driving. Also the impacts that autonomous vehicles (AVs) will generate on our cities and lives are to a large extent uncertain. After a first phase of enthusiastic optimism, a growing number of scholars are pointing out the possible criticalities and negative impacts of AVs, in terms of car-dependence, decline of public transport, inactivity, sprawl, etc. (Cohen and Cavoli, 2019; Fraedrich *et al.*, 2019; Soteropoulos *et al.*, 2019).

To this respect, an unconditional introduction of AVs, left in the hands of technology enthusiasts and car manufacturers, could lead to severe consequences, raised by conflicts with the sustainability and liveability objectives of urban policies. But while the awareness of the importance to steer the introduction of AVs is raising, how to deal with such an uncertain future remains unclear.

Backcasting is acknowledged as a suitable method to face such uncertainty (Banister and Hickman, 2013; Tuominen *et al.*, 2014; Vergragt and Quist, 2011). Unlike forecasting, which outlines future development visions based on current trends, backcasting moves in the opposite way; it formulates future visions and proceeds backwards, to define the actions needed to achieve them.

Several visions for AV circulation in the future have been proposed in the literature, with various focuses and methodologies (Fagnant and Kockelman, 2014; Fraedrich *et al.*, 2015; Gruel and Stanford, 2016; Marletto, 2018; Milakis *et al.*, 2017; Papa and Ferreira, 2018; Smolnicki and Sołtys, 2016; Thakur *et al.*, 2016). Still, nearly all these visions are a-spatial, in that they hardly refer to the space in which AVs will be circulating and parking.

A research project led by Politecnico di Torino is studying if and how the introduction of AVs should be differently regulated in urban context, and how the rest of the mobility and land use system could be re-organized, so to maximize positive effects of AVs and limit their negative impacts. According to the backcasting participative methodology, the project has been divided into three phases: visioning, policy packaging, and appraisal (Soria-Lara and Banister, 2017). The aim of this paper is to explore a possible spatialization of visions through a diversification of circulation and parking regulations in different parts of the city, and to highlight which potentialities and critical issues it will raise on the use and consumption of urban public spaces.

Section 1 reviews the spatial impacts of AVs as they emerge from the literature; then the importance to steer the introduction of AVs with proactive policies (section 2) is discussed. Section 3 presents three visions that have been defined for Turin (Italy); these visions have been discussed in a focus group with local experts, which insights are discussed in section 4.

1. The impacts of AVs on urban public spaces

A wide range of potential impacts of a future widespread use of AVs has been analysed in the scientific literature (Cavoli *et al.*, 2017). Some of these impacts – which are obviously dependent on the adopted level of technology and the penetration rate of AVs in the mobility system – relate to the spatial urban dimension, in terms of use and consumption of public space.

First of all, automation of driving could reduce radically the road space necessary for car circulation and parking (Metz, 2018; Zhang *et al.*, 2015), as AVs will be able to reduce safe distance among them and to pick up/drop off the riders in front of the door and then park by themselves. On-road car parks could be removed (just leaving some spaces where cars will stop to pick up/drop off) and transferred to dedicated multilevel parking structures (Fraedrich *et al.*, 2018); these structures could be located out of the city where land is cheaper, leaving space in the dense city for new developments (Zakharenko, 2016).

At the same time, there is a risk that these benefits may be limited to the short term, and turn into negative impacts in the longer term (Childress *et al.*, 2015; Legacy *et al.*, 2018). Actually, AVs could increase vehicle miles travelled (Metz, 2018), for several reasons. First, they could reduce the value of travel time, as riders will not have to drive and could use this time to carry out other activities; this could foster sprawling processes, increasing average travel distances (Meyer *et al.*, 2017). Second, AVs will allow car-less citizens (such as elderly, disabled, young people) to ride a car, improving their accessibility but also resulting in an extreme car dependence (Papa and Ferreira, 2018). Finally, automation of driving could increase the effectiveness of cars to the detriment of public transport and non-motorised mobility; in particular, active mobility could be adversely affected (with negative consequences for health) also because conflicts could arise between AVs and pedestrians and cyclists (Millard-Ball, 2018).

Not only the magnitude, but also the (positive or negative) direction of most of these impacts will probably depend on the diffusion of sharing in AV use. Some researches consider the possibility that a relevant part of the current fleet of privately-owned cars could be replaced in the long term by shared vehicles, increasing the positive effects of AVs or at least reducing their negative outcomes (Alessandrini *et al.*, 2015; Fagnant and Kockelman, 2015; Fraedrich *et al.*, 2018).

2. Visioning and backcasting for policies

Urban and transport planning can play a relevant role in the transition to automated driving, in order to influence the direction of the above-mentioned potential impacts (Li *et al.*, 2018). At the same time, given the uncertainty about the timing and scale of these impacts, policymaking for AVs at the local and metropolitan level is quite complex, and successful advance planning may seem excessively difficult (Marchau *et al.*, 2018).

Some authors have provided policy recommendations for local governments, in terms of transport and land use policies that cities and regions could implement in the short and medium term to guide the transition to AVs in their local environments in the long term (see, for example, González-González *et al.*, 2018; Guerra and Morris, 2018; Papa and Ferreira, 2018). Most of these policies can be considered as “no regret” policies; indeed, they contribute to increase the sustainability of present mobility systems and, at the same time, their short and medium term effects could be useful to prevent negative AV impacts on the longer term. In some respects, these recommendations are quite general. Backcasting and visioning can offer useful insights for implementing them in a specific local context.

Backcasting is acknowledged as a suitable method to deal with the future by setting normative visions (Banister and Hickman, 2013; Tuominen *et al.*, 2014; Vergragt and Quist, 2011). While forecasting investigates probable and possible futures, backcasting goes the other way, from future to present. It identifies desirable futures and goals, and then defines policy pathways to achieve them.
