Backcasting is normally structured in three phases (Soria-Lara and Banister, 2017): visioning, in which the baselines of business as usual and alternative visions of desirable transport futures are set; policy packaging, which elaborates a set of policy measures and the pathways to steer development towards the desired result; and appraisal, through which the impacts of the policy pathways are assessed against a set of criteria (environmental, social and economic impacts, as well as feasibility and acceptability, etc.). Moreover, the backcasting methodology can be combined with participative tools, i.e. focus groups, workshops and interviews, in order to provide external stakeholder inputs (Carlsson-Kanyama *et al.*, 2008; Svenfelt *et al.*, 2011)

Defining the visions that will be subject to policy packaging and appraisal is therefore a crucial step. Several authors developed visions for AV development, with various focuses and methodologies, and the literature on visioning for AVs is rapidly growing. However, nearly all these visions are a-spatial, meaning they do not refer their envisaged AVs development to the space in which they will be circulating and parking. Parkin *et al.* (2017) propose four visions that are somehow spatialized, as they are referred to the space in which they will be allowed to circulate: segregated network for AVs, AVs only on main network mixed with human-driven cars, urban network, shared space. Nevertheless, also in this case, space is considered mainly as a container, and the focus is on the interaction of AVs with other users.

3. A visioning exercise

3.1 Aims and methods

This paper presents a visioning exercise that introduces a spatial dimension in the prefiguration of future AV visions to be used in backcasting, namely with reference to the Italian city of Turin. The proposed visions are

“spatial” as they consider how circulation and parking of AVs could be differently regulated in various parts of the city.

At first a brainstorming exercise was carried out by the research team to define possible future visions, all referred to a long term horizon when all circulating vehicles will be fully connected, autonomous (SEA level 5) and electric. Based on the authors’ own analytical thinking, this first phase led to the elaboration of three visions, characterised by different regulations in terms of AV circulation and parking.

In a second phase, seven local experts and practitioners in the transport field, ranging from politicians to managers and technicians, were invited to discuss and assess these three visions in a focus group. More in detail, these experts represented the main institutions and companies which are in charge of transport planning, managing and operating in the area of Turin:

- the Transport Department of the City of Turin;
- the Land use and transport Department of the Metropolitan Area of Turin;
- AMP – Agenzia della Mobilità Piemontese, the public transport Authority of Piedmont (the Italian region where Turin is located);
- 5T – Tecnologie Telematiche Trasporti Traffico Torino, a public company providing info-mobility and Intelligent Transport Systems for the whole Piedmont region;
- GTT – Gruppo Torinese Trasporti, the main public transport company operating in Piedmont region;
- Blue Torino, a full electric car-sharing provider operating in Turin since October 2016;
- Bike Pride, a local association focused on sustainable (in particular non-motorised) mobility.

The focus group was articulated in two steps. First of all, the three visions were presented to the participants, who were asked to fill in a questionnaire to assess (on a 1-10 scale) their “plausibility” and “sustainability” with specific reference to fourteen issues. An open discussion followed, aimed on the one hand at exploring possible further aspects not included in the visions, and on the other hand at investigating participants’ concerns about how AVs will integrate (or replace) other modes of transport.

3.2 Case study

Turin – the fourth most populated Italian city (about 886,000 inhabitants in the city, 2.3 millions in the NUTS-3 province), located in the North-Western part of the country– was chosen as a case study, for several reasons.

Turin is heavily car-dependent. It has one of the highest car ownership rates in Europe (639 cars / 1.000 inhabitants), and the modal share of private motorised mobility is quite significant (39%) (source: EMTA Barometer 2015, Istat). Car circulation is poorly moderated; only one restricted traffic zone, covering 2% of the municipal surface, and few small 30 km/h zones are active. Public transport (one metro, 8 tramway and about 100 bus lines) and the cycle network (nearly 200 km of cycle lanes and paths) are underused; their respective modal share are 24.3% and 3%. In the case of a mere transition from human- to self-driving cars, prospective negative impacts of AVs can then be particular significant in this city.

In 2018 the Public administration of the city launched a pilot project for testing AVs, initially in a closed, “simulated” urban area, and at a later stage on a 35-km route along the real road network. This street test is mainly aimed at placing Turin at the forefront of the transition to AVs, thanks to its economic specialization in the automotive and ICT sectors.

The Sustainable Urban Mobility Plan (hereinafter, SUMP) adopted by the city in 2010, is now at the end of its 10-year period of validity, and the elaboration of the next plan is starting. So, this is a right moment for the city to assess if and which short and medium term measures can be integrated in the new SUMP to try to steer the transition to AVs.

3.3 The three spatial visions

The three spatial visions were identified and articulated by the authors with reference to fourteen themes and sub-themes, namely:

1. road hierarchy, based on articulation into main roads (1.1) and local roads (1.2);
2. limitation to vehicle circulation;
3. parking areas, with specific focuses on street parking and areas to pick up/drop off the passengers (3.1), multilevel parking (3.2) and intermodal parking (3.3);
4. local public transport, with specific focuses on main lines (4.1), feeder capillary network (4.2) and reserved lanes (4.3);
5. sharing mobility, differentiated between motorised services (5.1) and non-motorised ones (bike-sharing, 5.2);
6. pedestrian areas;
7. bicycle facilities;
8. modal split.

Vision 1, called “Business As Usual” (BAU), is typified as the result of a sort of inertial interpolation of the transport policies set by the current SUMP of the city, which pursues a sustainable mobility, encouraging the use of public transport and soft modes and moderately deterring the use of private cars. In this vision, no tailored policy to assist and regulate the transition from human to autonomous driving has been implemented, so the conversion occurred in a rather inertial way. Road hierarchy is the result of the current revision process of speed limits: 50 km/h for main roads, 30 km/h for local roads. Vehicle circulation is banned in few restricted traffic zones. As regards car parks, they are partially transferred from roads to new intermodal and multilevel parking areas; the freed road space is devoted to AV circulation and ad hoc platforms to facilitate AVs’ passengers getting on and off the vehicles. The public transport supply is articulated in main lines and a feeder capillary network; reserved lanes are provided for main lines. Sharing (both motorised and non-motorised) mobility is provided by multiple companies. Some new pedestrian areas are added to the existing ones. As regards bicycle facilities, the vision complies with that of the current Bike Plan (adopted in Turin in 2013), which pursues the completion of ten radial and four circular cycle paths. The deployment of the BAU vision is assumed to lead to a modal split in which the use of private and shared motorised transport and of the bike will increase, the use of public transport will slightly decrease, while pedestrian mobility will consistently decrease as a consequence of the use of AVs for door-to-door trips.

Whereas Vision 1 continues the regulation approach currently adopted by the city of Turin, Visions 2 and 3 take this approach to two opposites.

Vision 2, called “Strong deregulation”, is based on a widespread liberalisation in the name of a complete confidence in the great outcomes of technological development; it assumes that AVs will enhance road safety, solve congestion problems, decrease the levels of air and noise pollution. In this vision, any speed limit is removed; AVs are able to circulate everywhere in the road network, with the exception of few pedestrian areas. Parking is possible only in ad hoc multilevel buildings, homogeneously distributed in some areas along the road network and in intermodal parking areas located at the termini of the public transport lines; on-road parking is completely removed and the freed space is devoted to AV circulation and ad hoc platforms to facilitate AVs’ passengers getting on and off. The public transport network is reduced to the metropolitan railway service and the metro line 1; all surface public transport is dismantled (as considered not competitive with respect to AVs)

freeing up additional space for AV circulation. Sharing mobility services are enhanced. Pedestrian areas are only kept in the historical city centre and overruled in the rest of the city. Also cycle paths are removed, reserving the saved space to AV circulation. As a result, in Vision 2 the modal split will entail a great increase of private motorised transport and a slight increase of car-sharing; the use of both public transport and soft modes will decrease.

Opposite to the “Strong deregulation” is Vision 3, called “Strong regulation”, which is characterised by a robust regulatory approach; strict policies concerning AV circulation and parking are planned to take advantage of AV benefits and limit their negative impacts. The road network is more distinctly hierarchized in main roads (having a speed limit of 50 km/h) and local roads, whose speed limit does not exceed 20 km/h. The meshes of the main road network are sort of “home zones”; inside each of these zones, every road is classified as local and only shared AVs or AVs belonging to the residents in the zone are allowed to circulate. Street parking are completely removed and the saved space is devoted to non-motorised transport; multilevel parking are built around each home zone, both for residents and visitors, and intermodal parking areas are realised at the termini of public transport lines. As regards public transport, streetcars run on reserved lanes on all the main roads; transport systems with exclusive right of way (metro and metropolitan railway service) are reinforced, whereas current bus services are banned within the home zones and replaced in the largest zones by autonomous shuttles. Sharing mobility is strongly encouraged, to the detriment of privately owned AVs. Bike-sharing services are enhanced as well. Furthermore, pedestrian facilities are improved and shared spaces having walking priority are systematically extended within all home zones. Cycle lanes are present on all main roads and bikers are allowed to freely ride on the local roads inside the home zones. As a likely outcome of the strict regulation lying behind the transport policies in Vision 3, the modal split will entail a consistent increase of all modes alternative to privately owned AVs, the latter being strongly hindered, whereas use of car sharing services will be boosted. The use of public transport and bike will slightly increase, and walking will record a more consistent growth thanks to the shared spaces in the home zones.

4. Discussion

4.1 Sustainability vs. plausibility of the three visions

Participants to the focus group were asked to evaluate and validate through the questionnaire the three proposed visions, with respect to their plausibility and sustainability, and to express possible concerns or changes to be made to each of them.

Overall, the three visions were validated, as no significant changes were proposed by the participants to any of them.

As regards plausibility, the overall average of the scores assigned in the questionnaire by all participants to each of the 14 themes and sub-themes shows that Vision 1 is - not surprisingly – the most plausible. It gets an average score of 7 out of 10, and it records the highest values for all the 14 sub-themes, except for traffic restrictions. Visions 2 and 3 were assessed almost equally plausible in terms of average score (respectively 5.5 and 5.3), but they perform very differently in relation to the sub-themes; Vision 2 is generally considered more plausible than the third concerning regulation of AV circulation and parking, and vice versa as regards the relation with public transport and non-motorised mobility.

The results are quite different for sustainability. Vision 3, which was judged the least plausible, is considered as the most sustainable; it scores 7.6 out of 10 on average, and records the highest values for 11 out of 14 subthemes. Vision 1 ranks second, with an average score of 6.2. Finally, Vision 2 is deemed as the least sustainable, with a low score both in overall average terms (4.4) and specifically for subthemes related to public transport and non-motorised mobility.

4.2 Key issues for policies

The elaboration of the three spatial visions and their discussion in the focus group let emerge some key issues for AV regulation that are not yet deeply investigated in the scientific literature, but are crucial to short and medium term policy making.

Circulation

A first issue concerns how private AVs are allowed to circulate in the road network, in particular in light of their feared impact on modal split (less use of public transport, less active mobility). Should they be let free to move on the entire road network, as in Vision 2? Or should their circulation be free only in a portion of the network (e.g., the main roads), and discouraged in the rest of the network, such as the secondary roads inside home zones? In this second case, different levers could be used to deter private AVs from entering these zones. The first one is differentiating speed limits, e.g. 50 km/h in the main roads and 30 or 20 km/h in secondary roads. Another possibility is to completely forbid privately owned AVs to access the secondary roads inside home zones (except the zone in which the owner of the AV resides), as in Vision 3. In this case, AVs could reach the border of the area in which the destination of the trip is located, but the final link in the travel chain should be made by foot, bike sharing etc.

The above-mentioned regulations could be used also to promote a transition from ownership to sharing, which is often identified in the scientific literature as a key factor to reduce potential negative impacts of AVs. Vision 3 for example applies restrictions to circulation only to private AVs and not to shared AVs, which are let free to enter secondary roads. As highlighted in the focus group, Vision 3 could also favour community car sharing services, organised just at the home zone level.

Parking

One of the potential impacts of AVs on the city, that is often cited in the literature, is the reduction of parking need. This reduction will concern the absolute number of car parks (if AVs will be most shared) and, in particular, the number of parks on roads, as AVs will be able to drop off the passengers at their destination and then travel empty to reach the nearest vacant parking space. The possibility of freeing up space on roads by gathering parking in dedicated structures (multilevel parking) raises questions on the location of these structures and the maximum distance that AVs should be allowed to travel empty to reach a parking. This question can be relevant in the short and medium term, as vacant lots in dense central urban areas are generally rare: should they be used for new residential or tertiary buildings, or for multilevel parking so to begin to reduce parking on road?

Finally, if parking on street will be removed, areas for picking up/dropping off passengers will probably be necessary: how many areas for each block and where to locate them will be issues for urban planning and design.

Multimodality

One key issue about AVs is how to avoid they increase their modal share to the detriment of non-motorised mobility (and its health benefits), also because they will make unnecessary even the short trips on foot from origin to parking, and from parking to destination. At the same time, as highlighted in the previous sections, AVs will probably allow to reduce car parks on road; this freed up space could be dedicated to pedestrians and cyclists. Vision 3 tries to combine these two issues: it forbids privately owned AVs from entering home zones, where all local roads are re-designed as shared space (without parking) having priority for pedestrians and cyclists; in this way, drivers should be fostered to walk or bike to their final destination.

As regard public transport, diffusion of AVs questions its spatial organisation. Will a hierarchical structure, based on main underground and tram lines and secondary feeder bus lines, still work? Or could feeder buses be replaced by shared AVs, robot-cabs and so on? This perspective is particularly relevant for a city like Turin, which – due to financial constraints – is now restructuring its public transport supply, and is deciding whether to linearly cut frequencies of all lines or to boost main lines to the detriment of secondary feeder buses.

Concluding remarks

The elaboration and discussion of the three visions for the city of Turin has shown that the spatial approaches in regulating AV circulation and parking are likely to play an important role to govern the impacts of AVs on the city. As just one case study has been considered, any claim to exhaustiveness and systematicity must be excluded. However, most of the emerged issues are not specific to Turin, but concern transport and urban factors that are relevant in every urban context, such as road hierarchy, speed limits, restrictions to circulation, parking location, multimodal integration, home zones and shared spaces.

The visions are currently being evaluated by 50 interviewees through in-depth interviews, and the one that will result the most preferable (as a combination of its sustainability and its plausibility) will be the objective for the backcasting exercise. At the same time, using such spatial visions, that expressly address the use of urban roads and public space, in participative exercises, can help to identify which measures could be adopted in the short and medium term. The involvement of different stakeholder can be useful to emphasize the possible strategies that the Public Administration should undertake in order to address the AV transition. This can be particularly important for cities (such as Turin) that are elaborating their SUMPs; indeed, these plans generally cover a time horizon of at least ten years, which is a plausible time-horizon to expect an initial appearance of AVs.

Beyond the plan: methods of triggering long-term change in urban and regional mobility

Agnes Förster¹, Eva Strobel²

Abstract: Mobility is a complex and dynamic phenomenon that operates on multiple scales and is highly interwoven with technological, economic, social, cultural trends. Currently, multiple urban and regional projects and initiatives address the issue. For a prolonged sustainable result, ‘communication’ and ‘participation’ accompany the process – but a set of actions disconnected from a larger strategy will fail to bring about change within a complex system. Mobility is produced in the constant interplay of transport offer, user demand and behavior in relation to spatial configuration and urban qualities. Transforming mobility is a long-term process to the extent that impact exceeds plan-action. This paper understands mobility change as multiple transformation processes. It demonstrates how the scope of planning has broadened and proposes communicative planning methods as triggers of long-term change in urban and regional mobility. Four interrelated fields of tension serve as a framework: (1) Start here today. (2) Networked thinking and design. (3) Involving players beyond ideologies. (4) Make a difference in space. This framework is used to discuss the change of mobility in the context of a dialogue format for practitioners and researchers. The transformative capacity of communicating planning methods in several cases from practice and research approaches are discussed.

Keywords: communicative planning methods, urban and regional mobility, transformation, systems thinking and action

I Introduction

For many cities and regions, coping with the increase in traffic is a pressing issue. The rising demand affects the quality of life, threatens the city’s or region’s economic success and, in many cases puts a strain on the political climate. When it comes to creating more housing, new jobs, the development of educational facilities or commercial areas, transport is an ongoing, contentious issue. Cities and regional associations seek help and look out for concepts that tackle these observed demands of mobility on a city or regional scale. At the same time, whilst locally perceived urgency is evident, there exists a very global view on the subject of traffic. Normatively expressed in the Sustainable Development Goals developed by the United Nations, mobility plays a key role in the development of a sustainable world. The SDG’s 9th goal sees the need, amongst others, to ‘develop quality, reliable, sustainable and resilient infrastructure [...] to support economic development and human well-being [through] equitable access for all’. Furthermore, in order to make ‘cities and human settlements inclusive, safe, resilient and sustainable’, the 11th goal sees the provision of ‘access to safe, affordable, accessible and sustainable transport system for all’ as a prerequisite (UN, 2015). Consequently, and with the intention to push-start this topic, public incentives provide funding programs, for example the national Mobility Workshop and Laboratory of FONA in Germany, as well as numerous projects EU-wide like the European large-scale project EIT-KIC for Urban Mobility (EIT, 2019).

Mobility is subject to strong dynamics. Various factors influence movement patterns and behaviors: Changing technological conditions, the digital transformation in general, new offers and services, new forms of mobility

styles, alternative drives e.g. electric mobility, and not least the steadily growing demand to maximize people's capacity for being mobile. Simultaneously, we observe changes in lifestyles, growing awareness of health and sport, demographic change, the need for an ageing society to be mobile and more (BBSR, 2011). These trends and dynamics are forces, difficult to control, that affect the various forms of mobility. It is therefore understood in current research and practice that we cannot approach or influence the change of mobility by looking solely at traffic and infrastructure but by grasping mobility as a system. If we then want to understand deeper the concept of mobility, we can define it as the possibilities to movement available to an individual that are dependent on various framework conditions (Sterzer, 2019). Based on this definition, we suggest to generate a system view and describe the movement dependent on transport infrastructure, the offers for moving as well as the spatial structure of a city or region and the users including their individual behavior.

Having understood mobility as a system and that it is constantly undergoing change, we are confronted with a particular challenge: simply increasing efficiency of the existing system neglects the dynamics of a changing system. Nor does it improve the situation sustainably, since boundaries become noticeable more than ever: urban space is limited, and environmental damage is considerable. Rather than accepting the current trend development affecting the mobility system and plan within it, the dynamics themselves need to be redirected. So, by changing our assumptions and objectives, we acknowledge that a fundamental change of the system is unavoidable. Second, the challenges that arise from the prospected demographic change, our changing behavior through digitalization and the new possibilities created by technical advances need to be closely faced and integrated into our assumptions and objectives.

In changing this mobility system, many players are involved – be they intended partners or not: state, market, civil society and intermediaries. In Germany, transport planning is a traditional public task separated from private organizations, even though economic stakes are high. The mobility system as a whole is still subject to strong economic interests and consequently to strong lobbying. At present, we observe changing markets and market shares as influencers on mobility. It is uncertain as to who will contribute to which extent to the system in the future. What will municipalities, public and private companies do and how may they and others organize themselves? And: what instruments and methods can the planner use when it comes to a profound system change? So far, the traffic development plan, as a classical cross-sectional task of urban development, has served as a framework for individual measures and investment strategies over a certain period of time. Due to increasingly varying interests and the complexity of the task, many cities no longer manage to set up a traffic plan that solves the problems sustainably. The lack of political will in general, or the challenge to gain a majority for a bold plan may determine a plan's fate. Sometimes fierce local resistance may stop a development with good intentions because the citizen remembers previous planning decisions that failed in succeeding their aim. At the same time, research findings do not propose better instruments but only help to deepen the knowledge about the problems by modeling and showing better data. Here, the assumptions underlying the modeling need to be changed, and it cannot be produced by the scientific realm alone. Distrust, divided political banks and missing concrete knowledge over-challenge the planning authorities that are left to changing the direction without clear guidance.

This paper asks about the possibilities of the planner to shape the change in mobility. It provides an overview on transformation research and characterizes transformation from a planning perspective. From this it derives that the understanding of practice in traditional planning models evolving into the practitioner actively taking part in transformation processes. Challenges for the planners and their methods are highlighted and discussed and developed that communication plays a key role. It proposes to focus on the communicative aspects of planning methods when the task is to shape transformation and puts the method itself at the center of discussion.

II From planning to transformation – a brief outline of three basic planning models

The question of how the transformation of mobility can be shaped focuses on the deliberate contribution of planners, i.e. the contribution of the public administration to a long-term extensive transformation process. Which concept of transformation is suitable and which planning mode may be effective? What is the resulting toolbox of methods and instruments that planners should apply? What future roles can be drawn for public administration?

II.1 Basic conception of transformation

The term ‘transformation’ is to be understood first of all as fundamental social change, whereas the term is also used to describe the change of e.g. political system or organization (Heyen *et al.*, 2018). From a sovereign perspective, the term transformation is used to designate the areas of society, economy or even the physical space, which are to be fundamentally rebuilt for sustainable development. Instead of repairing deficits in the existing structures it is important to comprehensively change these structures over the long term and to raise a system that today is insufficiently stable to a new level of persistent operability. Profound change can be triggered by disruptions, e.g. war, famine or a sudden regime change and caught in a brief period of time, but it can also happen over several decades and often only be identified in the historical context. Particular to the present situation is that we as planners observe and are part of a transformation, e.g. the transformation of the urban space, but the future date of completion and the associated spatial development perspective are still unknown to us.

Within the wide range of contributions to the discourse and research on transformation three main starting points can be identified:

(1) Type and extent of necessary change

The European Commission has committed to implement the 17 global goals for future development. Even though these goals are normative and show no paths to fulfillment, they partly represent the global dependencies at a most urgent level and provide reference points for the development of more specific goals on the regional and urban level.

The German Advisory Council on Global Change, in short WBGU, calls the sustainable global transformation of the economy and society a "Great Transformation". The aim is to reduce global greenhouse gas emissions to an absolute minimum and to create climate-friendly societies. To this end, production, consumption patterns and lifestyles in the three central transformation fields of energy, urbanization and land use must be fundamentally changed. The WBGU takes a comprehensive global view of the economy and society, and identifies the urban level as a key field for transformation. Though, conclusions for the spatial organization at the level of cities or neighborhoods are not part of the WBGU's main report (WBGU, 2016).

The research organization DRIFT for transition positions itself in the field of system innovation and sustainability transitions according to the Sustainable Transition Research Network and other research literature, and derives from it the urgent need to deepen the understanding of the ongoing changes in planning related sectors, cities and regions (drift, 2019). Both terms, ‘transition’ and ‘transformation’ are used to describe fundamental changes in society but for this paper we understand the term ‘transition’ to describe a field of research i.e. to observe it, whereas ‘transformation’ aims to describe both organizable and non-organizable change i.e. a designable process.

(2) Aim of future viability

The various contributions to the issue of transformation converge at the point where they address the viability of an economic, social or spatial system. Therefore, there are strong overlaps with the discourse on sustainability, especially when sustainability is understood as a process rather than a goal or condition (Thierstein and Walser,

2007). In order to reach future viability, transformation is then described as a targeted change towards sustainability (Heyen *et al.*, 2018).

Dealing sustainably with a complex system also means to reduce its complexity. Instead of developing evermore capacities for collecting facts and framework conditions, i.e. data collection, it is necessary to reduce the 'information overload' by recognizing essential patterns that shape the interaction of crucial aspects of networks (Vester, 2007). Vester calls this 'interconnected thinking' and understands it as a quest for practicability, because it reduces the need to find data and at the same time expands the scope of inquiry (Ulrich, 2005). Mastering complexity is a crucial task in gaining future viability.

The Wuppertal Institute conceives cities as real-time laboratories for research on and for transitions to sustainable development. In order to be able to measure transitions and gain knowledge about their path of development, urban landscapes or cities offer good opportunities for research and experimentation. What is measured and tested in the city itself is already contributing to change and, if appropriate communication structures, e.g., through intercultural research networks, are trained and in place, can initiate and accelerate development in a particular direction.

(3) Steering a complex system

Transformation refers to a mostly multi-layered process of change in which different variables closely interact. Given the basic understanding of a complex system, transformation is based on interventions within the system that are supposed to bring about desired changes. These go beyond simple cause-and-effect relationships. It is essential to understand the system's previous development path in order to identify possible starting points for effective interventions. In the transformation process, time simultaneously becomes a variable that can be formed, since for the most part different time horizons of the interventions and their effects are intertwined.

DRIFT's transitions perspective puts cities in focus and understands their complexity as a system in transition. Cities are the ground on which multiple system transitions emerge, arrive and react with each other. Putting this into a spatial perspective, DRIFT expresses that 'a city is [not only] related to other cities, its direct surroundings and to rural and natural areas worldwide' but also connected to other cities in its economic and ecological development, political actions and climate as well as its social and cultural status and trends (drift, 2019).

It is widely accepted that concepts of transformation understand transformation as a systemic change. This means that change comes about co-evolutionary and that its relevant interacting variables – relating to technological, economic, socio-cultural and institutional aspects – need to change concurrently and thereby influence each other again (Heyen *et al.*, 2018).

II.2 Characteristic features of transformation

For planners, the task to actively influence transformation processes comes with certain challenges. However, certain features and findings from the research and practice on transition and transformation provide starting points to proactively shape transformation. We know that the fundamental changes bring notions of complexity, uncertainty and unpredictability to all levels of society. We find that transformation as a process is dynamic and, to begin with, non-linear. How do we steer into a future that is unclear? How do we maintain openness in defining our goals? How do we interact with the multiple processes, not knowing how change will come about?

The multi-level perspective poses a widely accepted transition framework. Initially developed as a conceptual model in innovation research (Geels, 2011), it identifies three analytical levels that form transitions: niches, socio-technical regimes and socio-technical landscapes. We understand e.g. the change of mobility as a transition in the above sense. From a planner's perspective we may describe it by multiple transformation processes, which we can observe and partly shape on the city level. A simplified description of the transformation process we find in research on the diffusion of innovations and distinguishes four phases: a pre-development phase with high

experimental content (1), a take-off phase with first changes out of the niche (2), a breakthrough phase with structural change through accumulation of changes (3) and a stabilization phase in which a new regime equilibrium emerges (4) (Heyen *et al.*, 2018). At this point it remains a challenge to directly translate these phases into planning practice: to which extent can planners trigger these phases? Or from which level can a next phase be initiated? And is the stabilization phase –waiting for the next phases to come– in line with the overall goal of a sustainable world?

Furthermore, we know that drivers and catalysts for transformation processes are not singular, nor are the provoked processes running independently. Drivers and catalysts may be economic or technological factors and exert pressure on regimes. Ecological or technical crises may pose so-called ‘windows of opportunity’ in which change is accelerated which could be, for example, observed after the reactor incident in Fukushima when an energy transition became possible through a political majority (Heyen *et al.*, 2018). As a matter of course, obstacles arise in attempts of changing the system: one is, that existing paths for development already have a direction and limit decision-making (Heyen *et al.*, 2018).

DRIFT claims that the building of what they call ‘transformative knowledge’ forms a basis for planning in transition. Transformative knowledge is translated into ‘taking an integrated approach and treating the system as a whole’ and holds planners to question the status quo, to reflect their own actions and create deeper learning processes (drift, 2019). This approach then should form a knowledge base that is needed for fundamental and irreversible change.

II.3 Shaping transformation – three basic planning models

It is widely assumed that social transformation processes are neither easy to foresee nor are they malleable as a whole (Heyen, 2017). This is due to the fact that transformation processes follow their own dynamic and path, they are complex and are influenced by a variety of inhibiting and acceleration factors. The WBGU believes that ‘great transformation’ is difficult to control, but can be deliberately shaped to some degree – even though this is estimated to be optimistic (Brand, 2017, Rink, 2018, Shove, 2007). Taking into account the characteristic features of transformation and translating them into planning approaches and methods should be a first step in the right direction (Kristof, 2010).

But how to apply the basic understanding of transformation to contemporary planning models? Planning models support the understanding of the tasks and procedures planners and designers face. According to Archibugi, planning theory is an action-oriented analysis, that creates knowledge for the purposeful design of planning processes in order to enhance target achievement (Archibugi, 2004). By this, planning theory shall provide for a real added value in practice.

In the following section we will describe three planning models in order to translate the discourse on transformation to urban and regional planning processes. The models do not need to be mutually exclusive. Rather they focus different levels of complexity that are inherent in transformation processes. They reflect on the role of professional planners as part of a public planning authority and his capabilities of adopting effective planning methods and instruments. The sketch-like models help to understand the possibilities and limits planners, in order to steer or rather shape transformation processes.

Model 1: Planning as problem-oriented communication process to explore, agree upon, carry out interventions and assess their effects

Figure 1: Model 1

This first model refers to a generic planning cycle. A time axis is integrated in order to relate and compare to the following models 1 and 2. In this model, planning is understood as a problem-solving process, that consists of various relevant work steps that stimulate interaction between the professional planning world and the day-to-day world. The handling and managing of those work steps happen in cycles and repeats itself over time (Schönwandt, 2008).

A detected problem or deficit, often in an urban context, serves as the foundation for developing alternative solutions, that are proposed by the planning authority. Problem-finding and problem-solving are described as an iterative process of generating knowledge and refining and clarifying norms and objectives (v. Eisinger, 2012, Schönwandt *et al.*, 2011, Getzels, 1975). In the next step the choice of one solution occurs in a communication process that involves planning professionals as well as political, market and civil society actors. At the end of that planning phase a single future plan is adopted. Its implementation often relies on a set of responsibilities that are distributed among different players such as approving authorities, property owners, investors, organizations or committed users and citizens. When the implementation is finished, an evaluation process is introduced to compare original intentions with the results, and to share experiences or obstacles obtained during the process.

This model is both universal in its application to different issues and spatial scales of planning and fundamental in its systemic understanding of planning as an interplay of system structures and processes. The cycle may be passed through rapidly or slowly and relate to the close or farther future. However, the model remains unclear in describing a path into the future, as it does not show to which extent planning contributes to fundamentally changing a system. Many existing planning tasks draw upon this model in order to provide for reliable solutions: developing a new city-quarter, a bypass road or a waste management system, only to name a few. To achieve this, important preconditions have to be met: Planners need professional knowledge and skills, personnel and financial resources and the capacity to steer the implementation of the plan. The political, corporate and civil spheres have to equally bring in knowledge, skills and resources based on their willingness to cooperate and to provide for legitimacy of the specific planning process. The failure and crisis of planning has to be largely attributed to gaps and weak points within these preconditions which has led to widespread criticism of the prevailing planning approach and system.

Model 2: Planning as collaborative process to analyze and negotiate long-term alternative futures, define the path for transformation and implement subsequent steps of intervention

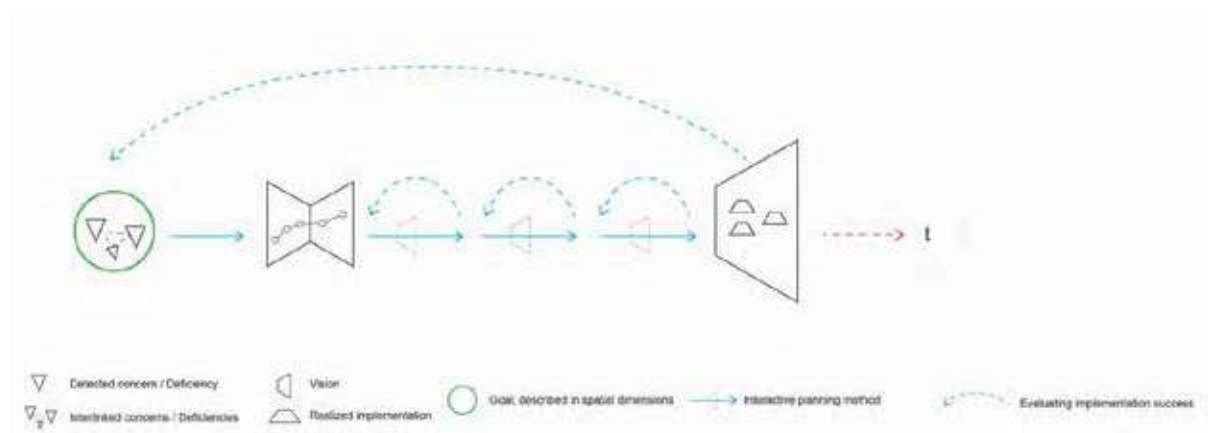

Figure 2: Model 2

The second model focuses on a long-term transformation of a complex system as in the case of structural change of an urban or regional area or the reconfiguration of an urban mobility system. Rather than looking for an immediate spatial solution, the planning group recognizes a pattern of networked problems and expresses goals in a positive vision of the future. As a result, there is a stronger focus on a systems analysis at the beginning of the process. In the next phase, visionary transformative scenarios are developed and translated into a transformation path that will consist of multiple implementation steps. What in the first model is done in one compact step, is here separated into more phases: a longer period of gaining orientation at the beginning and a road map of step-by-step implementation that happens over a longer period of time and allows for monitoring and readjustment throughout the process. As a result, the time horizon of this transformative path exceeds the one in day-to-day business that is often closely linked to election cycles.

According to current literature on transformation research, the development of an integrative and systemic knowledge base for creating transformative solutions is necessary (Jacob, 2018, Roorda, 2014). But how to push actors to deal with a long-term perspective? When starting a process, appealing narratives, that relate to people's perceived problems may serve as a positive trigger. Therefore, communicating future visions, mission statements or narratives is key when transforming a complex system (Heyen *et al.*, 2018). Hence, opening up the scope into a more complex starting position that is related to a long-term transformation process demands for a shared view of the future instead of a fixed goal or plan.

Cities can be seen as real-world laboratories for transformation processes. In their existing urban context they have to address and involve a broad variety of participants, stakeholders and citizens. In view of the range of their interests as well as the complexity of the system to be transformed, the creation of alternative scenarios and the definition of robust transformation steps that allow multiple futures might be a promising approach (Wiese, 2014, Alaily-Mattar *et al.*, 2014).

Model 2 defines a collaborative process that bridges system analysis, future scenarios and long-term implementation. Therefore, a common will amongst capable actors and financial and personnel resources for starting such a broad orientation and planning process are necessary preconditions. Another important prerequisite refers to the need to continuously steer and readjust the ongoing transformation process – as there is no blueprint to be implemented. When heading for a transformative path, the starting position needs to be redefined periodically. We might also be forced to readapt our previously developed positive vision of the future, our narratives and even our transformation path itself.

Model 3: Planning as multi-step communication and learning process to open-up and explore paths for transformation oriented towards the greater good and their successive assessment and readjustment

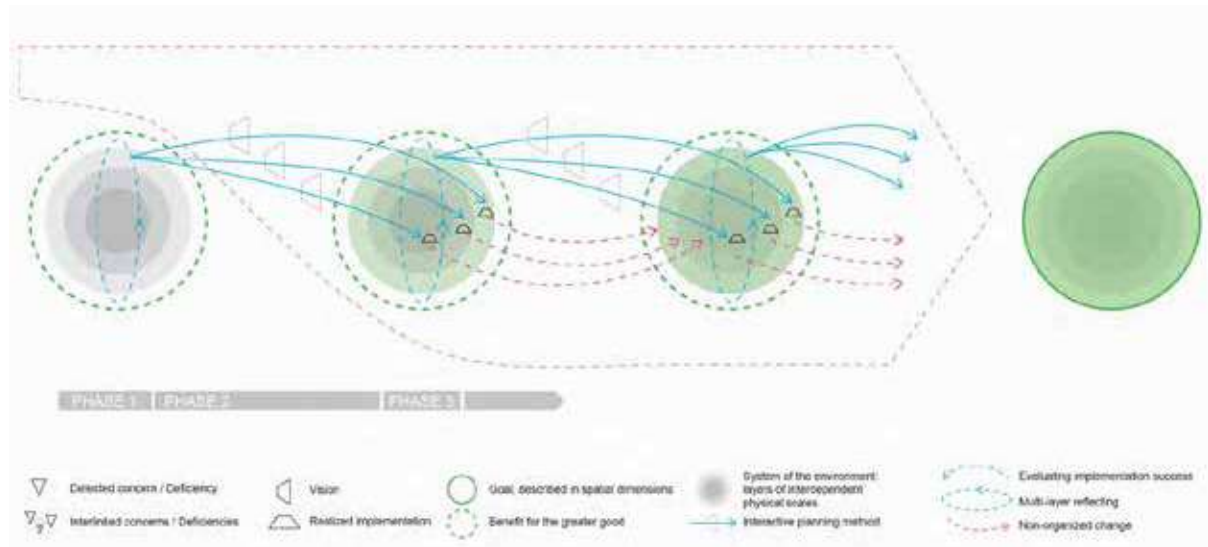

Figure 3: Model 3

The third model highlights planning steps that aim at triggering transformation processes oriented towards a greater good. We understand these planning actions as parts of a continuously changing system that comprise organized as well as non-organized change. The purposefully set planning steps are associated with the on-going non-organized change – be it two processes running independently or by correlation because of the intended and non-intended effects of the planning steps. So, rather than trying to masterplan a process architecture directed towards a greater vision, this model emphasizes the potential of organized smaller steps that aim at opening up paths for transformation.

We do not consider this model to be better than the two other models. Model 3 comes into play as important preconditions of model 1 and 2 do not apply as, for example, a common will and political mandate for coordinated and strategic planning towards a shared vision of the future.

In this model, the goal is defined in a much broader sense. Planning is directed towards the greater good, e.g. reducing CO₂-emissions state-wide or globally or creating better mobility for a better way of life. There is, however, no common view of how this goal would materialize spatially nor of the ways how to achieve it. Given this very open normative focus, three layers of analytical thinking and social and political awareness and learning are especially important: 1) The city is part of an interrelated multi-scalar regional or metropolitan system. 2) Cities have the capacity to create and initiate new solutions and act as trendsetters for others. We should therefore gather knowledge of what is happening in other cities. 3) We have to take into consideration global boundaries and thus recognize what consequences current city planning has on natural and rural areas worldwide (Wuppertal Institut, 2019).

According to model 3, the transformation process starts with a growing awareness of the status quo and the desire of collective reflection. This means to initiate communication among committed players that are open to mutual learning (Phase 1). In the next phase, a process is initiated that organizes multiple and often small-scale interventions that are networked on multiple scales. Careful preparation and implementation go hand in hand – as if the work steps of planning model 1 were passed through rapidly (Phase 2). Based on the understanding that the chosen interventions trigger transformation processes that may not be organizable a recurring evaluation is started. Taking into account the context of all three layers including the non-organized processes a new baseline is defined

that has developed a step towards the greater goal (Phase 3). This is a starting point for another set of networked interventions. Re-evaluating methods and interventions, taking steps ahead and back are part of the process. It rather describes an approximation or a development into a certain direction, which may gradually change the system.

III Rethinking communicative planning methods

What can be derived from these models for the activities of planners? And then how can transformation be shaped by which planning methods? We understand planning methods as intentional planning practices preparing interventions with a focus on tangible planning action. It is widely recognized to distinguish between methods and instruments to the degree that methods prepare instruments as spatial interventions. Methods generate knowledge, prepare objectives and solutions and support between the parties involved (Förster, 2014). Planning instruments may then be classified along their different types of interventions (Schönwandt *et al.*, 2007, Jung, 2008). Methods shall constitute effective building blocks within a purposeful planning procedure directed towards the achievement of the objectives set. They can be regarded as a not accidental sequence of activities that demands for careful preparation (Schönwandt and Voigt, 2005). In the planning cycle, methods are planned, resources provided, commissioned and carried out and then a success control is undertaken.

The spectrum of available planning methods is closely related to a broad variety of understandings of planning (Fürst, 2004). Despite the large differentiation of planning methods, one basic conception points to the understanding of planning as a social interaction – if not generally stated, then at least related to certain planning phases or work steps. Therefore communication is a prerequisite for the effectiveness of planning activities (Förster, 2014).

In order to overcome important shortcomings of planning, a renewal of planning is conceived from improved methods and instruments. This is significant as complex systems may be changed through improved processes that gradually reshape system structures. The latest version of the St. Gallen management model, which explains its complex organizational model through interwoven processes and structures, highlights the possibility to bring about change in action and points to the intrinsic motivation as a key to long-term and fundamental change (Rüegg-Stürm, 2017).

When we envisage how planners may shape transformation processes, we should go beyond the optimization of individual methods. Instead, our basic conception of methods should be questioned and reconsidered. According to our understanding of planning, which is supposed to influence transformation processes, we put the communicative aspects in the foreground and have generated three perspectives that are not contradictory but focus on complementary aspects:

- (1) In the first planning model, a broad variety of methods is linked to the different steps in the planning cycle. A main focus lies on the dialogue between different planners and their multifaceted setting. The different work steps in the planning cycle refer to a range of different, complementary skills and abilities that are necessary for planning processes as a whole – and how these different skills can be linked and integrated. They range from analytical to visual and communicative as well as design-oriented techniques. Instead of mobilizing a wide spectrum of individual skills, it seems to be particularly relevant to focus on productive interfaces and synergies in order to let them work together (Harris, 1999).
- (2) The second model focuses on a sequence of methods with which long-term visions of the future can be developed and then translated into a sequence of interventions, e.g. a roadmap. A specific mix of approaches forms a coherent planning process over a longer period of several months up to some years that involves key players up to a wider public. In many cases, an interdisciplinary approach is necessary

in order to systematically design this larger process, i.e. a mandate must also be available for this assignment, which can be difficult for some clients (Wiese, 2014, Wirth, 2019).

- (3) This open process as conceived in the third planning model demands for approaches that stimulate learning in the system without necessarily involving or pre-arranging a larger or more comprehensive planning process. Here, the interaction between processes and structures is at the center of consideration. "One cannot jump into the same flow twice". The mutual interplay of processes and structures is at the heart of the St. Gall Management Model, with the processes being everyday events and the current system structure being the result of past processes. This means that further development takes place in direct connection with the collected experiences up to the present time (Rüegg-Stürm, 2002). So, if we want to achieve 'system learning' with regard to our abstract goal – to improve the common good – we have to change our system structures in a relatively short time. Suitable planning methods and instruments should initiate a process, that produce a next round – in accordance with the French saying: "L'appétit vient en mangeant". Methods and interventions become tightly linked. These triggers for change should be applicable even if there is no significant budget, no clear political mandate and no clear objective. It is important to anticipate and take critical stages and reach thresholds in order to take new steps from there.

IV Urban Mobility: 4 key dimensions of communicative planning methods as agents of change

According to model 3, planning methods are conceived as incremental steps that trigger system transformation. Thereby, communication is a key to involve stakeholders, transport knowledge, start acting and perceive and evaluate the results. When translating this to the transformation of urban mobility, we hypothesize that four interrelated dimensions are particularly important.

Figure. 4: Four key dimensions of communicative planning methods as agents of change.

1) Start here today with tangible steps: Which processes and steps are particularly relevant at the beginning of a transformative process? There is a need to set up a strong basis for the starting position. Communication plays a particular role in forming transformative knowledge and since knowledge goes both directions informing and collecting, we may actively influence the so-called non-organized change. The sooner we interact and intervene, the sooner our intentions and actions can become part of the transformative process as e.g. experiences, which then may be passed on and trigger more – ‘Like a stone thrown into a pond’.

2) Networked thinking and design: Our actions, ideas, strategies and transformation concepts are doomed to fail when they have to tackle such big changes all by themselves. A coordinated set of smaller actions on multiple layers – those may include spatial design proposals, a town hall meeting or the invention of a new ticketing system – may legitimize a process more effectively. Also, it is important to understand and know what other plans and strategies are currently employed. Collecting experiences on how mobility is developing in other cities or regions is crucial, given that it is such a pressing and complex task.

3) Involving players beyond ideologies and gridlocked positions: The dissemination of change is significantly dependent upon the spectrum of participants, stakeholders and users we address and have on board. However, how to communicate and what has to be communicated is particularly relevant. When we argue for a mobility change for the better, those involved need to agree on a path towards a greater good. Mobility change is very much influenced by multiple factors and powerful parties. Therefore, it is particularly important to gather a most complete group around the table.

4) Use spatial interventions to make a difference in space: Spatial interventions may trigger experiences and change motivation and behavior through a most effective learning. The scale of a spatial intervention may also determine how well it is perceived, how intense the experience is and how far it may reach. There is a threshold to the scale of a spatial intervention for them to work as messengers.

We call methods following these dimensions agents of change as they may kick-off transformation processes. While planners apply these methods in the field of organized change, communicative interventions also transfer knowledge and experience to the non-organizable part. This framework is used to discuss the change of mobility in the context of a seminar for continuing education of professionals in all planning disciplines, as described in the next chapter. The transformative capacity of communicating planning methods are discussed along several cases from practice and research.

V Pt.Seminar on methods of triggering long-term change in urban and regional mobility

Pt.Seminar is a dialogue format on current planning methods run by the Chair of Planning Theory & Urban Development at RWTH Aachen University. The seminar encourages the exchange of knowledge between academia and practice. Practitioners from public planning authorities as well as private planning offices are currently looking for new ways to handle the ever growing complexity in their everyday work. Transforming urban and regional mobility is a particularly demanding task. In many cases, planners find themselves in hybrid situations with vague political mandates and outdated development plans that lack implementation in many respects. During the half-day session we focused on innovative planning methods that have been employed to actively take part in mobility change. Experts presented current approaches which then were discussed along those four previously illustrated dimensions: 1) start here today with tangible steps, 2) networked thinking and design, 3) involving players beyond ideologies and gridlocked positions, 4) use spatial interventions to make a difference in space.

Figure 5: Impressions from the Pt.Seminar

This event took place only recently in May 2019 and helped us to gain preliminary feedback to the relevance of our conception of transformative planning methods as triggers of long-term change in urban and regional mobility. The presented cases ranged from a research approach to mobility design, a GPS-supported method for the investigation of use and perception of space, a progressive mobility concept with an elaborated set of measures for a large city initiated by a public-private coalition, the conception of a cycle fast track and regional cycle path network, mobility in rural areas to a real-laboratory for sustainable mobility culture. The joint discussion of these cases in relation to the four dimensions revealed capabilities and limitations and important fields of tensions when applying communicative planning methods as triggers of change.

The presented examples of ‘starting here today with tangible steps’, released an intense discussion on the culture of the experiment. Experimental pilot projects should not be regarded as precursors of permanent solution only. Instead, the experiment could be installed as a principle, as a stand-alone planning approach. Selective experiments could be disseminated throughout the whole quarter, city or region. In that sense, experiments are not to be held as a demonstration of the right solution, but they push forward an open learning process. Therefore the evaluation of experiments is crucial. This rather playful approach can be supported by a set of rules that give room for maneuver.

Following up this idea, the representatives from public administration stated a lack of knowledge of how to adjust their rules to the experiments they are ready to support. Furthermore, the case of the Stuttgart Laboratory of Sustainable Mobility Cultures demonstrated, that experiments as planning approach need to be managed and

supported with resources (Mobilitätskultur, 2018). This would be a new field of activity for public authorities. At the same time, a loose coupling of step-by-step activities on the ground to mid- and long-term planning strategies and frameworks at the level of the city or region would be important. Starting here and today can operate as pre-testing for overall strategies, they may pave the way to successfully transform the system.

The dimension ‘networked thinking and design’ was discussed at two levels: First, planners and designers have to intervene in the system with effective packages of measures. That means combining multiple steps on multiple layers of the system. Second, a network of partners shall be established that supports the transformation process with different knowledge, perspectives and resources. The case of Munich Model City of Mobility 2030, as presented in the seminar, uses the interplay of Transport-Space-User as leitmotif for networked thinking within a dialogue process (Inzell, 2018). This is particularly relevant, as the process brings together partners from industry –including automotive industry– the Chamber of Industry and Commerce, municipal and regional transport services and public administration. Networked thinking serves as an approach to overcome individual interests and individual solutions.

Shifting the perspective from the individual to the common good was also a key issue when discussing the third dimension ‘involving players beyond ideologies and gridlocked positions’. Therefore it is important to acquire a broad variety of partners and to encourage them to talk about needs instead of measures first. The user perspective may open-up the discussion beyond clear positions. The reflection of one’s own mobility behavior as well as the recognition of the dynamics of mobility patterns in time and space sensitizes for diverse perspectives.

When looking for partners and followers, it is important to address those who are satisfied and encourage their ambition to want more. At the same time, we shall build up relationships to those who think different, to bolster the sceptics, to invite people to jump on the process and to allow others to correct their position without loss of face. Additionally, the discussion highlighted the relation between planning and politics which is in many cases unclear. Who pushes and pulls whom? The dialogue process on the Munich Model City of Mobility 2030 was not mandated by politics but was meant to stimulate an agenda setting process in times of political blockade.

During the seminar it was hypothesized that one can intrinsically motivate citizens, politicians and other planning participants on the basis of spatially experienced experiments which in the case of success at best trigger a next round of planning activities and actions.

The issue of ‘use spatial interventions to make a difference in space’ stimulated the debate on the question how we actually experience mobility in space. This also refers to our concept of culture and everyday practices. So far, the car not only occupies a large amount of the surface in our cities, but thus also receives high visual attention. Its presence in urban space is a prerequisite for its role as status symbol. Within the seminar, the positive experience of mobility was addressed as a pressing issue for the transformation process towards more sustainable forms of being mobile. This also includes the net quality of mobility.

Based on that, the capacity of space as a transformer was subject to intensive discussion. Visualizing change may be associated with a user benefit or may also be of symbolic value. The project To the Next Place in the village of Heimenkirch in the rural area of Allgaeu in South Germany designed prominent bus shelters produced by local carpenters (Seeholzer, 2017). These shelters are intended as meeting points for lifts, and are at the same time adopted as public gathering place. Shared lifts in cars – once being communicated as credible alternative – will predominantly be arranged via internet or phone calls. So, the shelters can be seen as spatial interventions that create awareness for alternative solutions and stimulate changes in behavior. This illustrates the close link between infrastructure, design and society that is important for the shaping of transformation processes.

VI Reflection

We hypothesize that communicative planning methods as triggers of change have to comply with one or more of the four dimensions as discussed above. When regarded together, some preliminary conclusions might be drawn.

Flexibility and adaptability

The involvement of planners and planning authorities in multi-step processes with recurring phases of reflection, multi-level planning activities, following interventions as tangible steps forward demand for a high level of flexibility. The proposed approach moves the different planning steps closer together and thus may speed up everyday business of planners. Therefore, they need the mandate to make decisions beyond lengthy administrative and political procedures. Otherwise, transformation will proceed without proactive public involvement. Moreover, planners need to be prepared to readjust their methods and instruments according the lessons learnt from the organized and non-organized change they provoke.

Courage and willingness to act

Triggering change goes beyond the elaboration of a plan – it demands for action. Planners have long been paralyzed by the development of too complex, too comprehensive, too long-term planning frameworks. As a result, they tend to have a rather passive role – waiting for comprehensive feedbacks of public agencies, for political decisions, for implementation through other authorities. When shifting to an understanding of communicative planning methods as triggers of change, planners need the mandate, courage and willingness to act.

Role of planners as part of the game

If planners follow these ideas, they will find themselves as players within the transformation process. This is related to a new form of responsibility. Planners as well as public planning authorities cannot refer to the fact that they have to wait for others nor shall they act on their own. They need to actively create networks and win new partners in order to drive the process. They have to learn that the formation of opinion, the declared commitment of key stakeholders and the strong political mandate are no precondition of their activities but a result of a positive learning process.

Multiplicity of communication

Finally, proactively triggering change in a step-by-step process multiplies the communication challenge. Planners need to address and involve more participants, stakeholders and users. Networked thinking and design demands for actively linking different levels and related responsibilities within the system. Interventions demand for a dialogue with target groups, parties concerned, licensing authorities, property owners, operating companies etc. These multiple addressees and related ways of communication may lead to a productive interplay such as communicating–reflecting–negotiating–intervening–experiencing and as such triggering change.

**Analysing the relation between territorial fragilities and accessibility:
a focus on individual dimension and needs.**

Bruna Vendemmia¹

¹DAStU, Politecnico di Milano, Dipartimento di eccellenza, bruna.vendemmia@polimi.it

Abstract: This paper aims at examining the relation between territorial fragilities, mobility and accessibility: mobility as social practice interlocked in time and space, and accessibility as the possibility of an individual to access at different out-of-home activities. The main purpose of this paper is to answer to the following questions: is it possible to establish a relation between the level of accessibility of a given territory and its territorial fragilities? As matter of fact, many research in last twenty years demonstrated the causality between low level of accessibility and mobility related social exclusion. In this paper I will show how an interpretation of accessibility, based on individual's needs and opportunities, may help to establish a relation between low level of accessibility and territorial fragilities. Indeed, traditional accessibility approaches brought to a misrepresented narrative, that describes a high infra-structured territory also as a more accessible and stronger one. Thanks to a bibliographical review oriented toward redefining the concept of accessibility, this work will challenge this narrative. It will be proved that a more accurate definition of mobility and accessibility may demonstrate that remoteness can be, at the most, one among the many drivers that lead to territorial fragilities.

Keywords: mobility; accessibility; basic needs; territorial fragilities.

Introduction: putting in relation mobility and accessibility with territorial fragilities.

The main aim of this research is to understand if there is a relationship between the level of accessibility of a given territory and its fragility, and which kind of territorial fragilities may be generated by low accessibility levels. In order to propose, at a later stage of this work, operative solutions that, working on mobility and accessibility, may help to deal with territorial fragilities.

The word “fragility” calls to our mind the image of something that can break easily, this is because, in physic, fragility is the particular characteristic of certain materials to break-up when exposed to given forces. Nevertheless, when talking of territorial fragilities, it seems more appropriate to refer at the “low capacity of a system to deal with circumstances which are opposite to the system itself and create the condition for conflict¹”. To apply the concept of fragilities to a territorial system moves the attention toward a systemic dimension, given by the territory itself, and oblige us to consider processes and time. For instance, if we are considering a complex system such as a territory it is more difficult to identify a direct cause/effect relationship between the conditions that started the fragilization process and the elements that broke up, as one cause may have implications on multiple territorial elements.

Also accessibility has been given multiple meanings, according to different academic fields. To the extent of this research I will define accessibility as “ the capability of individuals to participate in out-of-home activities” (Martens, 2017). Nevertheless, there is a dominant narrative, particularly diffuse in the field of transport studies, that identify accessibility with high level of infrastructure and fast connections and establishes a linear relation between high level of accessibility and urban growth and development (Hansen, 1959; Donati, 2009; Alampi and Messina, 2011), a narrative that suggests the idea that mobility is an essential requisite of the contemporary world (Kaufmann, 2011; Cresswell, 2010) and consider mobility “as education, as freedom, as modern” (Cresswell, 2010). According to

¹ From an unpublished text of F. Infussi about territorial fragilities (2019)

Luca Bertolini, for example, “since the industrial revolution, transportation and urban development have been tightly interconnected” (Bertolini, 2008), thus linking the concept of modernity with transportation and urban development and suggesting that a well infra-structured territory is also a more developed one. According to Bissel “the construction of transport infrastructure has often been viewed as the silver bullet that will solve commuting [and more generally mobility] problems once and for all” (Bissel, 2018), considering people mobility in the same manner of a liquid flowing through a pipe, larger is the pipe faster is the liquid, and assuming time and speed as the most important parameters to be considered when evaluating accessibility level. According to this narrative, that counters central fast places with marginal slow ones, a less infra-structured territory is less accessible and thus more remote and more fragile. Nevertheless, this narrative embodies some problems linked to the definition of mobility and accessibility: first of all, it matches mobility with transport; then, and related to the first one, it considers accessibility only as a spatial requisite not taking into account individual specificity and needs; last, and consequent to the first two points, it gives back a picture of territorial fragilities only as a consequence of spatial marginality and low level of infrastructures. As a consequence this approach does not allow to read territorial fragilities in its complexity and value fragilities only in the opposition to fast infra-structured and high accessible strong territory. Instead interpreting accessibility as the capabilities to reach opportunities and participate to out-of-home activities, links accessibility with other problematics that may generate fragility such as social exclusion and spatial injustice, as seen in figure 1. While the link between low level of accessibility and social exclusion has been extensively studied, particularly in U.K. after the constitution of the Social Exclusion Unit (2003) the relation within territorial fragilities is still poorly analysed and will be the subject of this research. Definitely accessibility, as a measurable dimension that connect individual and spaces, may help to understand territorial fragilities in its multidimensionality.

Figure 1

In the following paragraphs I will work on defining mobility and accessibility, building on bibliographical reviews, furnishing a more detailed and realistic image of the relations with territorial fragilities, and trying to invalidating the dominant narrative that a more infra-structured territory is also more accessible, developed, stronger and consequently less fragile one.

Reframing mobility and accessibility

It is nowadays well-established in different disciplinary fields, from transport studies to geography and urban studies, that mobility is passing through an important turn all over in Europe (Secchi and Pellegrini, 2010; 17), this process is expanding at the point that many scholars agree on the appearance of a paradigmatic transition in mobility (Bertolini, 2008; Sheller and Urry, 2006). The new paradigm asks for a redefinition of goals, processes and tools needed to plan and design urban mobility, and considers a broader range of modes, objectives, impacts, and improvement options of mobility (Litman, 2013; Faulconbridge and Hui, 2016). From a theoretical point of view, in its seminal book *sociologies beyond societies* John Urry (2000) suggested to replace the word mobility with mobilities. The use of the plural highlights the multiple types of mobility: corporal travels, physical movement of objects, imaginative, virtual and communicative travels (Urry, 2007), definitely we can consider mobility “as a single phenomenon that has the ability to take on different forms” (Flamm and Kaufmann, 2006). Furthermore we should also consider the different scales of mobility “from the small-scale of bodily movements, through infrastructural and transport aided movements to global flows of finance and labour” (Cresswell, 2011).

The idea of a mobility turn, although has been accepted in many different scientific fields it has not been appraised yet in urban design (Rosenberg and Shannon, 2018), where a dominant perception associates mobility only to physical movement and transport. Nevertheless “the way in which mobility is conceptualized and operationally defined [will] affects its application and research findings” (Kaufmann *et al.* 2004), thus interpreting and understanding mobility as a social practice interlocked in time and space will enable, also in the field of urban design, the elaboration of more convenient solutions to mobility related questions.

As matter of fact, the mobility turn underlines some important elements that can lead our reflection: 1) first of all, mobility cannot be understood only as the physical movement between point A and point B (Cresswell, 2010) but as a fundamental human activity that is revealed in different forms and at different scales; 2) second, mobility need to be studied with an interdisciplinary approach (Secchi and Pellegrini, 2010; Bertolini, 2008; Pucci and Colleoni, 2016; Rosenberg and Shannon, 2018) and touching different scales; 3) last, many scholars agree, nowadays, to consider mobility as a citizenship right (Secchi and Pellegrini, 2010; Carrosio and Faccini, 2018). To this regard François Ascher² defines the right to mobility both as the right to freedom and to be mobile in order to meet individual’s needs and expectations and the right to ensure a minimum level of mobility to all member of society (Ascher, 2005).

The reference to mobility as right together with the need to match this right with general costs³ of mobility draw attention toward the concept of accessibility (Colleoni, 2019; Sheller, 2018, Martens, 2017; Lucas, 2012; Pereira *et al.*, 2016, Pucci and Vecchio, 2019) . The notion of accessibility has been studied profusely in the field of transport studies. Following on this paragraph, I introduce some relevant interpretations of accessibility; the review presented in this paper is not pretending to be exhaustive, instead it focuses on those definitions that emphasize the complex nature of accessibility and interpret it as the capacity that allows individuals to reach opportunities and resources in order to be part of a territory and a community and, consequently, considers accessibility as a suitable principle to design more efficient, inclusive and equitable mobility system people-focused and needs-based (Pucci *et al.* 2019; Lucas, 2012). Many research projects have already demonstrated the causality between low level of accessibility and mobility related social exclusion (SEU 2003; Lucas, 2012; Kenyon *et al.* 2002), operationalizing an interpretation of accessibility based on individual’s needs, and highlighting that “the transport and land use system can reinforce social exclusion by increasing generalized cost of travel for person at risk” (Schonfelder and Axhausen, 2003). Nevertheless, I believe that these interpretation of accessibility, based on individual’s needs and

2. François Ascher identifies the “droit-liberté” et “droit-créance” (Ascher. F, 2005)

3. Mobility costs are not only economical but also social and environmental (Ascher; 2004; Sheller, 2018, Litman, 2013). The development of transport system involves negative impact at different territorial level: soil consumption due to the spaces occupied by car and mobility infrastructures (Sheller, 2018), congestion, emissions, noise nuisance, use of nonrenewable energy, and production of solid waste (Bertolini, 2008). Some authors also argue that an increase in physical mobility to tackle mobility-related exclusion is contrary to environmental aims; is financially costly; will take long time to be effective and is unlikely to meet all mobility needs of the all population (Kenyon, Lyons and Rafferty, 2002). To this reagrd, Bruno Latour also reasons about the relation between climate change scarcity of resources and the rise of social inequalities (Latour, 2018).

opportunities, may help also to study the relation between accessibility and territorial fragilities, which has not yet been deeply analysed.

In table 1, I synthetically introduce some definitions of accessibility highlighting for each of them the key factors. I started with a classical definition that clearly distinguishes between the different components of accessibility (individual and place) till to bring the attention toward definitions of accessibility more people-centred and based on capability approach. I consider those last very important as they allow a more multidimensional regard toward accessibility and call for new methods to measure and evaluate it. I finally consider also the concept of motility (Kaufmann *et al.* 2004), as it relates to accessibility but focuses “on the logic of the actor’s actions” in particular looking at the reasons behind modal choice and localisation (Flamm and Kaufmann, 2006), and thus may help to question traditional methods to evaluate accessibility.

Author	Definition	Key factors
Colleoni, 2019; Cascetta, Carteni, Montanino, 2012.	Characteristic of a place to be accessible or of an individual to get access at different places/opportunities	Traditional definition of accessibility according to place or people
Hansen, 1959.	The potential of opportunities for interactions with locations dispersed over space. Accessibility is a measurement of the spatial distribution of activity about a point adjusted for the ability and the desire of people or firms to overcome spatial separations	Accessibility referred both to person and context, the use of “potential” highlights the possibility to access as well as the measurability.
Pereira, Schwanen, Banister, 2016.	The ease with which persons can reach places and opportunities from a given location and be understood as the outcome of the interplay of characteristics of the individuals, the transport system, and land use”	Connection between individual, transport system and land use
Geurs and van Wee, 2004.	Focusing on passenger transport, we define accessibility as the extent to which land-use and transport systems enable groups of individuals to reach activities or destinations by means of a combination of transport modes	Accessibility as measure. Connection between individuals, activities and transport system. Measure of accessibility need to consider different components and perspectives
Handy and Niemeier, 1997	Accessibility is determined by: spatial distribution of potential destinations, the ease of reaching each destination and the magnitude quality and character of the activities found there. Accessibility is thus determined both by patterns	Land use + transport system + activities patterns and typology. Intuition in understanding the importance of people in measuring accessibility: the question of “wants and tastes”.
Martens, 2017.	The capability of individuals to participate in out-of-home activities.	Accessibility as choice, giving center stage to people. Accessibility contain the possibility of engaging in out of home activities more than to the number of activities. Capability Approach
Jones and Lucas, 2012.	Accessibility provides measures of the degree to which people can reach the goods and services that society considers are necessary for them to live their daily lives, but with an emphasis on potential/capability rather than actual behaviours.	Emphasis on potential rather than actual, connection between people and land use, and attention to individual needs
Flamm, Kaufmann, 2006	“Motility” can be defined on how an individual or a group take possession of the realm of possibilities for mobility and builds on it to develop personal projects. Motility focus on the logic of an actor’s action, in particular the reason behind the choice.	Potentiality of mobility and focus on the actor’s action

!

Table 1. Accessibility definitions

Traditionally, accessibility has been defined as a characteristic both of the place - passive - or of the individual - active - (Colleoni, 2019; Cascetta *et al.* 2012; Martens, 2017). Person accessibility, or active, refers to the ease of an individual to reach different activities; while place accessibility, or passive, is the attribute of an activity location to be reached by its users. This dualism between place and person, with an emphasis on the system performances instead of a focus on individual’s needs,

limited the efficacy of traditional mobility and transport approaches in the design of mobility systems (Pucci *et al.* 2019); as matter of fact, traditional approaches assumed as main goal, the exploitation of mobility system by maximizing the distance travelled within travel and money budgets and therefore seek to enhance travel speed (Litman, 2013), furthermore, decision making in transport investments have been traditionally based on “aggregate demand” (Lucas and Markovich, 2011) and rarely considers individuals activities needs and capabilities of diverse populations groups, making it hard to design a system of mobility more inclusive and responsive to individual needs.

Since the seminal text of W.J. Hansen, who defined accessibility as “the potential of opportunities for interactions” (Hansen, 1959), combining person and place and moving the attention toward “the ability and the desire of people or firms to overcome spatial separation” (ibi), many accessibility definitions have given more attention to connect the different component of accessibility: individuals through people needs, what has been defined “wants and tastes” (Handy and Neimeier, 1997); land use, through the attention paid at the distribution of the different activities, density and quality of services; and transport system as the availability of different transport modes at different time and with different travel costs (Geurs and van Wee, 2004; Handy and Neimeier, 1997; Pereira et alii, 2016). According to these definitions accessibility involves as much people as place, because places need to be “accessible to people in all their different circumstances” (Farrington, 2007).

Accessibility as capability

All those reflections help to develop a new narrative of accessibility that considers access not merely as a transport issue but as a problematic that involves also land-use planning and the needs of individuals through the design of mobility and connectivity places (Farrington, 2007). Definitions such as the one elaborated by Martens (2017) or Jones and Lucas (2012) emphasize the potential dimension of accessibility stating that what is relevant to be measured is not the actual number of activities, services or transport but the possibility of engaging in out-of-home activities. In this sense, accessibility is a capability, which is “the ability of human beings to lead lives they have reason to value and to enhance the substantive choices they have” (Sen, 1997), thus including in the definition of accessibility also the question of choices and personal development. Working on accessibility as a capability moves attention toward individuals and their choices of mobility. The idea of mobility as potentiality, is also at the base of the formulation of the concept of motility (Flamm and Kaufmann, 2006; Kaufmann *et al.* 2004). Motility has been defined as “the capacity of entities to be mobile in social and geographic space” or as the way in which entities “appropriate the capacity of socio-spatial mobility” (Kaufmann *et al.* 2004). Motility include: access, which refers to the range of possible mobilities according to place and time; competence, which includes skills and abilities of the individual; appropriation, that refers to how agents consider themselves appropriate and select specific options for mobility.

While considering accessibility based on actual number of activities reached and existing transport system - the functioning - allows a deep knowledge of the actual condition of accessibility and mobility: what an individual has succeeded in being or doing (Martens, 2017), working on accessibility as capabilities allows to consider also activities that are not possible to be reached as well as users that cannot be mobile at the moment - the capability - which is the range of beings and doings a person could achieve (Martens, ibi.). In particular, accessibility should be considered as a combined capability (Pereira *et al.* 2016) because of its importance to the development of other human capabilities and to reach basic needs.

Accessibility: measures and scales.

Notwithstanding the great quantity and quality of studies on transport-related social exclusion, overall in UK after 2001⁴, that interpret accessibility as a capability and pose the accent on individual’s needs, it is worth noting that those works explore the lack of activity participation among fragile groups of population but still use rough proxies to measure accessibility, such as, for example, the proximity to public transport stop (Martens, 2017).

Nevertheless, many different and sophisticated indicators of accessibility are already available in literature. Geurs and van Wee have made a very deep review of the different methods that can be used

⁴ In 2001 Social Exclusion Unit have been asked to work on the problems experienced by people in reaching work and key services (SEU, 2003)

to measure accessibility (Geurs, van Wee, 2004). They identify 4 different components of accessibility: 1) land use component which analyses the land use system including distribution and demand of opportunities, 2) transportation system which describes the transport system, 3) temporal component which studies the availability of opportunity at different time of the day, 4) individual components which describes needs, abilities and opportunities of individuals. They also list 4 different perspectives to measure accessibility: infrastructure-based; location-based; person-based; utility – based. According to Geurs and van Wee, ideally an accessibility measure should take into account all those different components. Even though in practice “applied accessibility measure focus on one or more components, depending on the perspective taken” (Geurs, and van Wee, 2004). This is due to different factors such as the availability of data the ease to be operationalised, interpreted and communicated. Grieco (2006), instead, suggests to work in three main dimensions of accessibility : 1) place-based measures including opportunities and services within the immediate surrounding of a person, 2) social-category stratification of the community to identify social need, 3) person based measures, such as individual public transport user’s profile of journey needs (Ohnmacht et al. 2016), adding, to the four dimensions considered by Geurs and Van Wee, the social one. Preston and Rajé (2007) suggested to use a matrix that combine area accessibility, area mobility and individual mobility to investigate accessibility in relation to social exclusion, and propose to use this matrix also to identify differences in accessibility between urban, peri-urban and rural areas. Last, research such as the one elaborated by Schonfelder and Axhausen (2003) tries to find a measure for dimensioning activity space, which is that part of the environment used by individuals for their daily activities that includes also the locations not necessarily visited yet, and thus investigates accessibility as a potentiality. In a recent work, van Wee (2016) added some further considerations to the review of accessibility measures, highlighting that accessibility measures should focus also, among others, on: short distances and slow modes, multimodality, ICT and perception of accessibility. Those works highlight the need to explore more the individual dimension of accessibility in order to identify individuals basic needs.

As matter of fact, defining accessibility as the capabilities of the individual to participate to out-of-home activities oblige to considers individuals activities, needs and capabilities of diverse populations groups, when measuring accessibility. Preston and Rajé (2007) suggested two possible approaches: the first one, a more disaggregated, requires extensive survey in order to collect information about individual users, its interest is in revealing a dense and detailed description of the phenomenon but is time and money consuming. A second approach, easier to operationalise, consists on the simulation of population interest based on census and available data and measure, a similar approach has been used by Pucci (Pucci *et al.*, 2019) to evaluate accessibility to work by public transport in the city of Buenos Aires. In my opinion, interesting results may be achieved by the combination of the two methods in different moments of the study and applied at different territorial scales.

As matter of fact, Jones and Lucas (2012) identify, in the existing literature, three different scales of accessibility: micro, meso and strategic. At the micro scale the measure of accessibility relates to the design of object and space and the ease with which people can perform various tasks. Meso level focuses on the neighbourhood level. Strategic accessibility, instead, is associated to town and regional dimension and put in relation land use pattern, transport network and activities desired by specific populations groups. Strategic accessibility is the most studied and documented both in policy perspective as well as in academic community (Jones and Lucas, 2012). Additionally a fourth level could be added, that considers long distance accessibility and deal with national scale, highlighting that measure of accessibility may differ also in consideration of the typologies of trips, long distances or everyday mobility, for example.

A possible way to look forward in the direction of establish a method to measure accessibility, paying attention to the fulfilment of individual basic needs, may be a category based approach that matches people and targets, ensuring that basic needs are delivered or may be delivered when and where they are needed. This approach may help to avoid social exclusion and the raise of conflict, offering solutions to deal with territorial fragilities. Although working on categories and groups still involves “a form of aggregation and tend to lose the richness of individuals’ lived experiences” (Preston and Rajé, 2007).

Conclusion

There is still a dominant narrative that associate mobility with freedom and accessibility with infrastructure, a narrative that, since industrial revolution, describes transportation and urban development as interconnected and considers the construction of new infrastructure as a solution to

mobility problem and social exclusion. According to this narrative low infrastructured territories are remote and marginal, this marginality and remoteness are considered an indicator of fragilities. As matter of fact spatial marginality can be one of the many drivers that can lead a territory to be fragile, although empirical evidences may show that can exist very strong remote areas as well as fragile but central territories.

In this paper I have argued that this narrative is linked to a definition of mobility only as physical movement and focus only on transport and land-use components of accessibility. Instead defining accessibility as the capability of individuals to participate in out-of-home activities: 1) emphasizes potentiality rather than functioning, 2) allows to consider accessibility as a measures of the degree of connection between individual needs, transport and land use.

Clearly this definition of accessibility calls for more sophisticated indicators that could take into account simultaneously the different components and adapt to different scales of observation. I suggest that, even if still simplified and based on aggregated data, a possible way to look forward in this direction may be a category based approach that matches people and targets according to different scales and trips. Clearly a complete measure of accessibility have to be based on the combination of multiple accessibility indicators, each of them calculated on different scales and components. Next research step will focus on testing this approach to some areas in Italy.

Abstract: Accessibility to services and opportunities is vital to achieve the EU goals of smart, sustainable and inclusive growth. Some territories are worse equipped than others in this concern, due to their intrinsic peripheral character. Their weak and scattered mobility demand has progressively made traditional public transport subject to efficiency savings and cut to the bone. Such measures contributed to worsen social inequality, as they affect especially those already vulnerable groups who do not have access to a car. In this light, to improve urban-rural connectivity is essential for granting equal access to services and opportunities and, in turn, greater social justice. Demand Responsive Transport (DRT) has been often seen as a panacea for all the circumstances where traditional services are not viable, but a range of barriers (institutional, cultural, technological and economic) suggests that its adoption is more challenging than it may seem. Drawing on the results of the ESPON URRUC project, the paper sheds light on this issue, exploring the variables according to which various DRT solutions may or may not prove viable in a given area. On this basis, the authors propose a transport policy toolkit that may support decision-maker aiming at enhancing urban-rural connectivity across Europe.

Keywords: rural areas; accessibility; policies; on-demand services

Introduction

Accessibility to services and opportunities is vital to achieve the EU goals of smart, sustainable and inclusive growth. Some territories are worse equipped than others in this concern, due to their intrinsic peripheral character. At the same time, the weak and scattered mobility demand that typically characterizes these areas makes traditional public transport inadequate and inefficient. As a consequence, in most of them public transport has been progressively subjected to efficiency savings and cut to the bone. Such measures contributed to worsen social inequality, as they affect especially those already vulnerable groups who do not have access to a car, due to physical, age or economic reasons.

In this light, to improve urban-rural connectivity is essential for granting equal access to services and opportunities and, in turn, greater social justice. Whereas the dematerialization of services and relationships may

help reducing the isolation of peripheral regions, physical accessibility to main centres is still crucial for territorial development, as it contributes to foster local economies and to increase the quality of life for those with inadequate or restricted access to services and opportunities.

Demand Responsive Transport (DRT) has been often seen as a panacea for all the circumstances where traditional services are not viable, but a range of barriers (institutional, cultural, technological and economic) suggests that its adoption is more challenging than it may seem, and that no one-size-fits-all solution exists. Taking stock of the literature on the matter and drawing on the results of the ESPON URRUC project – which addresses issues of urban-rural connectivity in non-metropolitan regions in Europe –, the paper sheds light on this issue, exploring the variables according to which various DRT solutions may or may not prove viable in a given area. On this basis, the authors bring forward a first draft of a transport policy toolkit that may support decision-makers aiming at enhancing urban-rural connectivity across Europe.

Next paragraph briefly presents general accessibility issues of remote areas; the URRUC project is then presented, describing its aims, case studies and related challenges; afterwards, the methodology used to develop the policy toolkit within the URRUC project is presented, and the summary of the results of its application to the case studies is shown. Concluding remarks highlight the preliminary results of the URRUC project, discuss opportunities and limits of the proposed toolkit and propose directions for further research.

Accessibility issues of remote areas

The first approaches to operationalizing the concept of accessibility were elaborated with reference to metropolitan areas in North America at the end of the 1960s (Hansen, 1959). However, in a couple of decades researches and studies acknowledged that accessibility problems were far more challenging in rural and mountain areas, where population density is generally low. This awareness is well summarized in the title of a famous book by Malcom Moseley published in 1979: “Accessibility: The rural challenge”.

When accessibility is dealt with in rural and mountain areas, which are significantly far from services and opportunities aggregated in urban centres, a change of perspective is required. Since the second half of the last century, most of these areas underwent intense processes of de-anthropization, that caused a reduction in the resident population and its progressive ageing. As a result, the number of potential users of basic services (such as education, health, etc.) in these areas fell below the critical minimum threshold of indivisibility; many local facilities had to be closed, and dependence on services concentrated in major cities increased.

At the same time, the low density and the scattered structure of the settlements (which are fragmented into small towns and semi-abandoned villages) make it difficult to activate public transport services. In fact, due to the low number of users and the dispersion of the origins and destinations of their trips, it is hard for these collective transport services to reach a sufficient level of financial and economic sustainability (Farrington and Farrington, 2005). Ownership of a private motorized mean becomes indispensable to access the services in the nearest main city, to the detriment of those who cannot afford or use a car, such as older residents, minors, low income families, etc.

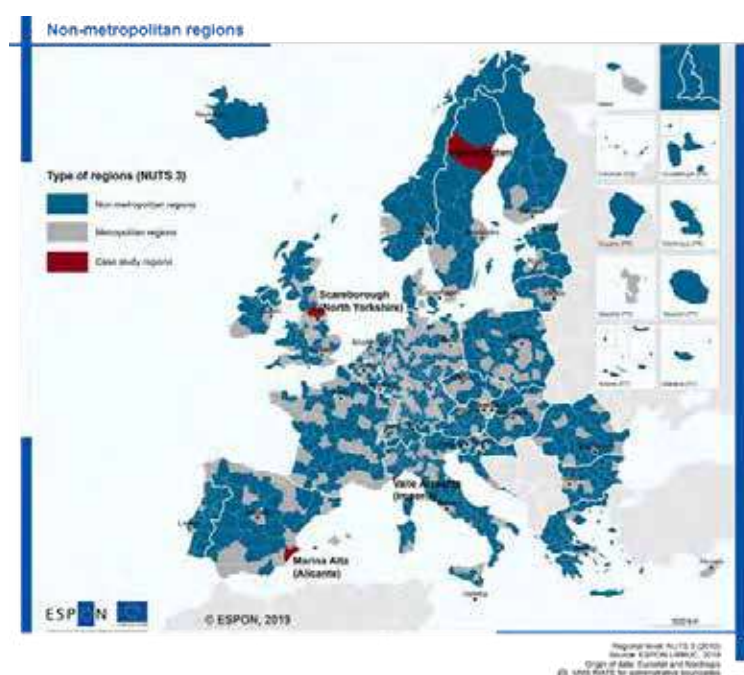

Moreover, physical inaccessibility of rural and mountain areas is often exacerbated by virtual inaccessibility. On the one hand, these territories are generally less covered by broadband infrastructure, which is essential for innovative solutions in providing those services (e.g. telemedicine and distance education) which are not locally available. On the other hand, a reduced digital literacy makes it even more difficult to activate such solutions (Malecki, 2003).

In the end, the issue of accessibility in rural and mountain areas is a vicious circle: reduction in the resident population implies the closure of most local services, which means less opportunities for studying, working, social interacting and so on; this underdeveloped condition increases the risk of further de-anthropization.

Therefore, even more than in urban centres, improving the accessibility of rural and mountain areas means acting on several fronts. It is not sufficient to strengthen transport infrastructures and promote more flexible transport services. It is also necessary to enhance the local territorial capital, bringing (or bringing back) in these areas, services, knowledge, social interactions, etc. (Gray, Shaw and Farrington, 2006; Schwanen et al., 2015).

The URRUC project and the territories at stake

Launched in June 2018 and lasting for one year time, the research project URRUC (Urban-Rural Connectivity in Non-Metropolitan Areas) is funded in the framework of the European Territorial Observatory Network (ESPON). The main objective of the project is to contribute to improving connectivity and accessibility related to urban-rural linkages in four non-metropolitan areas: (i) Scarborough Borough, (United Kingdom); (ii) Marina Alta (Spain); (iii) Regione Liguria, Valle Arroscia and the Province of Imperia (Italy) and (iv) Region Västerbotten (Sweden) (Figure 1).

1. Territories under scrutiny in the URRUC project. Source: ESPON and University of Coventry, forthcoming-a

All four share similar characteristics. They are coastal areas with poor connectivity and access to inner, rural areas. The size and dispersion of their populous makes infrastructural development difficult. Major urban centres are located by the coast and suffer from congestion due to commuting flows at peak hours, also coming from inner areas. This is driven by the needs of rural households to access core services, employment opportunities, education and recreational locations, which are primarily found in the largest urban areas. Investment in transport infrastructures and services is inadequate to meet these demands, as the nature of these territories, with small, dispersed populations, makes transport provision economically difficult and hardly justifies expenditure. Optimising transport solutions is further aggravated by seasonal flows associated with tourism.

More in particular, most of the rural and mountain areas of Marina Alta (some of them being accessible, other more remote) lack of adequate access to services and opportunities, especially as far as those who don't have access to the car are concerned. Although the potential market for public transport is wide, public transport is almost not taken into account when planning a trip. Those who have access to the car use almost only this mean of transport, both because of lack of adequate alternatives and of a poor sustainable mobility culture. Weak

horizontal and vertical coordination, fragmentation of competences and different knowledge and priorities challenge the improvement of accessibility of rural areas, and flexible solutions face a rigid legislative frame and some resistance to change.

Rural areas and suburbs of Scarborough Borough Council currently lack alternatives to private car for connections and accessibility to Services of General Interests. Social objectives prevail in such areas, whereas also economic ones are relevant for Scarborough, so connectivity is crucial and road expansion is seen as a priority by the local stakeholders. Commuters mainly use the car (or the bike where possible) and are satisfied with their mobility; public transport is unreliable and used mainly for leisure, so those who don't have access to the car are very disadvantaged. The specific and general contexts which surrounds operational conditions pose some challenges, especially in terms of fragmentation of competences, competing priorities and limited influence of the local level on upper-tier ones. Economic and commercial criteria strongly prevail on social and place shaping ones, worsening territorial and social inequalities.

The towns and hamlets of Valle Arroscia are dispersed over a wide mountain territory, some of them being far from the main road axis of the valley. Most of trips are made by car, and the current public transport system fails to meet the need of the few who rely on it. Hence, while car users are not in search of alternatives, some user groups suffer from territorial assignment. Public transport is seen as a last resort and at the same time poses serious challenges to those who rely on it to get to main urban nodes. Fragmentation of competences, different priorities, lack of vertical coordination between stakeholders involved in transport planning and operation raise challenges. Furthermore, local stakeholder has scarce influence on upper-tier decisions and the legislation, licensing and operation of public transport pose some limit to the introduction of flexible transport solutions.

Västerbotten territory features rural settlements, most of them being accessible and some very remote. Territorial density is very low and long distances and unfavourable weather strongly affect some user groups (i.e. those who don't have access to the car or inhabitants of remote hamlets in winter). To date, public transport is almost not considered as an option, and there is lack of information of the existing services. Still, public transport is generally seen with some interest, as well as digitalization of services. Vertical and horizontal cooperation is hampered by lack of time and resources, and there seems to be no intention to increase investment in public transport nor to finance potential solutions to improve connectivity in a cost-efficient way.

With the support and direction from stakeholder representatives in all four territories, the project aimed at improving understanding of urban-rural mobility and accessibility challenge in these regions and to provide appropriate tools for improving connectivity and accessibility through knowledge transfer processes. Furthermore, the project it also focused at exploring the actual potentials for transferability of findings by engaging in theory and literature-based activities, in order to provide learnings applicable to other Non-Metropolitan Regions across Europe with similar urban-rural connectivity issues, supplying valuable knowledge and outputs. These outcomes specifically address the six knowledge needs detailed below.

1. How can efficient public and private transport networks and sustainable solutions be advanced to enable access to key services, activities, employment opportunities and commercial possibilities for the population in remote NMRs?
2. What are the potentials, opportunities, and challenges for developing flexible and sustainable urban-rural transport connections and systems in comparable NMRs suffering similar connectivity and accessibility challenges?
3. What innovative solutions can be utilised, such as demand-responsive transport systems? What potential impacts can emerging technologies associated with climate change, such as low emission and electric vehicles, have on modes of travel?
4. What institutional/administrative barriers associated with cross-agency services impede the efficient implementation of transport policy in remote/inaccessible areas?

5. What can be learned from existing practices in Member States in developing and maintaining flexible and sustainable urban-rural transport connectivity in NMRs?
6. How can existing and future transport policy and other relevant policies be further strengthened to support the development of flexible and sustainable transport solutions in non-metropolitan regions, including transport initiatives at EU-level?

In order to provide answers to these questions, the research team developed a specific policy toolkit that could support decision and policy-makers in conceptualizing and implementing solutions for their respective territories. The main characteristics of this toolkit are provided in the section that follows.

A policy toolkit to support decision-making

One of the main tasks of the URRUC project was to develop “policy recommendations to further strengthening transport policy and systems related to urban-rural connectivity and interaction in non-metropolitan regions”. This task has been pursued through two separate but strongly interrelated research activities:

- Firstly, building on the case studies’ analysis and on a thorough review of the scientific literature and recent research projects, the research team developed four sets of policy recommendations, fitting the operational conditions and meeting the specific and general challenges of the stakeholders’ territories.
- The recommendations were then reflected upon in relation to their potential to fit other non-metropolitan territories in Europe, also on the basis of the NMR typologies identified in the literature and appropriately adjusted as a result of our analysis.

Bearing in mind the challenges and barriers to policy transfer and taking stock of literature on transferability (Dolowitz and Marsh, 1996, 2000; Cotella et al., 2015; Macario and Marques, 2008), a policy toolkit aimed at supporting decision-makers to enhance urban-rural connectivity across Europe is proposed.

More specifically, the methodology adopted to develop guidelines and recommendations for URRUC stakeholder territories and, in general, for European non-metropolitan regions affected by similar accessibility challenges, is composed of a number of complementary inductive and deductive steps, shown in Figure 2.

2. Methodological steps for the identification of policy recommendations (ESPON and Coventry University, forthcoming-b).

Firstly, a thorough literature review, focusing on both academic conceptualizations of the issues at stake and international research projects identifying good practices, led to the identification of a number of possible solutions aiming at improving accessibility and urban-rural connectivity in non-metropolitan regions.

Eleven possible alternatives to the private car were selected (most of them being Demand Responsive Transport solutions). Namely: bus on demand, car clubs, car sharing, feeder, ride-sharing, service delivery, shuttle van, social transport, taxis, shared taxicabs, village minibus. These possible alternatives were assessed against a set of analytical categories identified in the literature analysis (Ambrosino, Nelson, and Romanazzo 2004; Davison et al. 2012, 2014; Hunkin and Krell 2018; Loveless 2000; Mounce et al. 2018; Velaga et al. 2012; D. S. Wright 2013; S. Wright et al. 2014) and complemented by the case studies. These are:

- geographical coverage: what type of area is the service covering? Categories: rural accessible, rural remote, hill/mountain accessible, internal mountain, suburb;
- eligible users: who are the main users? Categories: territorial assigned person, commuter, student, tourist;
- type of use: which kind of use is the service meant for? Categories: single user/small group, collective users;
- booking: how does the users book their journey? Categories: phone (call/SMS), Internet (app/website), other (i.e. infopoint, on vehicle, etc..);
- booking: when is booking required? Categories: On day/real-time, in advance (> one day), repeating (on regular basis);
- timetable: how flexible is the timetable? Categories: on demand, fixed, mixed (i.e. on demand at fixed times);
- route flexibility: how flexible is the route? Categories: Fixed route, fixed route with possible deviations (i.e. within a corridor), fully flexible;
- routing pattern: where are users picked-up/dropped-off? Categories: one to one, one to many/many to one, many to many;
- vehicle size: what size of vehicle should be used? Categories: car, minibus/van, bus;
- price: what is the price for the user? Categories: free/discounted, paid/standard, paid/premium;
- financing: how is the service financed? Categories: subsidized, partly subsidized, commercial;
- performance objectives: what kind of goal is the service meant to achieve? Categories: economic, social, environmental;
- level of demand: what is the expected or measured level of demand (total passenger trips / total vehicle hours x trip length)? Categories: very low/less than 10, low/between 10 and 20, medium/between 20 and 50, high/greater than 50.

Subsequently, the relevance of each of the above-mentioned criteria and category was assessed for each of the four stakeholders' territories. In so doing, conditions were set for a pre-assessment, to check the fit of each solution in relation to the specific operational conditions of each of the stakeholder territories. As far as the operational level is concerned, also the relevance of some non-material and cross-cutting actions (digital platforms, territorial mobility management and dematerialization of services) was assessed for each case study, taking into consideration also the territorial level at which they would best be implemented, and possible criticalities and barriers in terms of resources, digital coverage and know how).

Beside the operational conditions, the analysis had shown that each of the four case study territory presents a set of challenges hampering accessibility and urban-rural connectivity. Building on the framework proposed by Davison et al. (2012, 2014), these challenges were divided in two macro groups (specific and general), each further characterised by sub-themes (market, consumers perceptions, stakeholders, policy and government, economic, sociocultural and technological features). Building on this conceptualization, the identification of the specific and general challenges that characterise the four territories at stake has allowed for the identification, for each of them, of two additional sets recommendations. Specific and general recommendations are meant to reduce the barriers that currently hamper the implementation of measures to improve accessibility and urban-rural connectivity.

Such recommendations were then further discussed with the stakeholders, in order to assess their actual priority and complexity in the respective territories. Combining the priority and the complexity of each recommendation, their deliverability was assessed on a scale of four (high, medium-high, medium-low, low).

Finally, each case study was provided with both detailed descriptions and summary tables showing the operational conditions, specific and general challenges which feature its territory, as well as operational, specific and general recommendations.

To fulfil the project's goal of providing recommendations for EU non-metropolitan regions, a comparative synoptic evaluation of the recommendations for the case studies was made, and the operational features of each of the identified transport actions, as well as the actual transferability of the suggestions aimed at solving the identified specific and general challenges were presented.

This policy toolkit supported the process of co-definition of recommendations for the case studies, and will serve not only to guide the action of local stakeholders, but also to set the ground for a proactive dialogue with the upper-tier administrations who are responsible for planning and providing the transport offer.

Application to the URRUC case-studies

Recommendations for each of the case studies were structured according to the structure described in the previous paragraph. The following subparagraphs summarize the selected operational specific and general recommendations for each case study, showing for each recommendation the priority, complexity and rate of deliverability.

CREAMA - Consortium for the Economic Recovery of Marina Alta

Table 1. Marina Alta. Synthesis of operational, specific and general recommendations

	Recommendation	Priority	Complexity	Deliverability
OPERATIONAL	Village minibus (mixed use)			
	Social transport			
	Bus on demand			
	Ride sharing			
	Service delivery			
	Railway			
SPECIFIC	Careful analysis of the real users' needs			
	Win the trust of commuters			
	On time, regular and accessible PT			
	Strengthen a PT friendly culture			

	Flexibility in transport and service provision			
GENERAL	More compact urban development model			
	More incisive and concertized planning			
	More flexible legislation			
	Horizontal and vertical cooperation			
	More funding			
	Better access to public transport

Comparative analysis and recommendations for EU non-metropolitan regions

As mentioned in the previous paragraphs, one of the goals of the URRUC project was to provide recommendations non only for the case studies, but also for those EU non-metropolitan regions with similar characteristics and challenges to the four stakeholders' territories.

To this aim, the challenges and recommendations for the four case studies were compared and clustered into a smaller set of recommendations, based on the affinity among recommendations made by different case studies. Table 5 is a synoptic representation of the recommendations made for the case studies, highlighting their priority for each case. It sets the ground for the definition of recommendations for EU non-metropolitan regions, as a result of the inductive-deductive approach described above.

As far as alternatives to the private car are concerned, recommended alternatives were picked among the 11 possible solutions that were previously defined¹. Similarly, the non-material and digital solutions that were recommended refer to three common clusters that are the same for all the case studies (digital platforms, mobility management and dematerialization of services). For such recommendations the synoptic representation shows the recurrence and priority in each of the case studies. A more varied frame emerged from the structural interventions (which are very context-dependent and differ in each case study) and specific and general recommendations. Hence, such recommendations were clustered: the 16 specific recommendations that emerged from the case studies were reduced to 7 clusters, and the 14 general recommendations were reduced to 5 (Table 5).

Table 5. Synoptic representation of the recommendations for the case studies

	Recommendation	Marina Alta	Scarborough	V. Arroscia	Västerbotten
OPERATIONAL	Bus on demand / call cars				
	Village minibus				
	Feeder				
	Shuttle van				
	Car and ride sharing				
	Social transport				
	Service delivery				
	Digital platforms				
	Mobility management				
	Dematerialisation of services				
	Structural interventions				
SPECIFIC	Careful analysis of users' needs				
	Targeted policies (various users)				
	Strengthen PT-friendly culture				
	Mixed use of transport services				
	Strengthen local skills and roles				
	More funds for transport				

¹ Namely: bus on demand, car clubs, car sharing, feeder, ride-sharing, service delivery, shuttle van, social transport, taxis and shared taxicabs, village minibus.

GENERAL	projects				
	More importance to tourism				
	Governance (horizontal, vertical)

	Compact urban development				
	Reverse marginalisation				
	Bridge the digital divide				
LEGEND					
Priority		High	Medium-high	Medium-low	Low

Recommendations listed in Table 5, which are fully described in Annex VIII of the final report of the URRUC project (ESPON and Coventry University, forthcoming-c), provide an insight on similarities and peculiarities of the four case studies, as well as a list of suggestions for EU non-metropolitan regions facing issues of urban-rural connectivity.

Conclusion

The proposed contribution presented the results of the project ESPON URRUC, aiming at developing recommendations towards better accessibility and connectivity in four non-metropolitan regions in Europe and, more in general, in all territories, sharing similar characteristics to those under scrutiny in the project.

It did so by explaining the methodology adopted by the project to develop these guidelines and recommendations, i.e. a preliminary policy toolkit that should help local public authorities in formulating decisions on the matter. Rather than resembling quantitative decision support systems and models, the proposed toolkit focuses on the interaction between stakeholders and on the joint identification of operational conditions and specific and general challenges and frame, and often constrain, urban-rural connectivity issues. On this basis, it guides stakeholders in the process of “weighting” the various potential solutions vis-à-vis the identified conditions and challenges, in so doing allowing them to assess their priority and complexity, and eventually their deliverability.

Whereas the proposed list of suggestions deriving from the application of the toolkit to a territory is far from being exhaustive, its objective is to stimulate policy and decision makers in EU non-metropolitan regions to think in innovative terms about transport and connectivity challenges and potentials that characterise their territories.

The toolkit helped stakeholders to realize that before designing operational solutions, it is necessary to act on the underlying preconditions for improving accessibility of rural areas. Issues of governance, legislation and sociocultural aspects revealed to be strong barriers, that would thwart any attempt to provide alternative services. Hence, before trying to provide alternative services it is necessary to reflect on such preconditions.

As mentioned above, the policy toolkit presented in this paper is to be considered as a preliminary work, which has been tested only in the four case-study areas. Dialogue with the stakeholders helped to identify possible improvements, and more research is needed, i.e. to consolidate the weight assignment system, to test the toolbox in other territorial contexts and to refine the methodology accordingly.

Acknowledgements

The authors would like to express their gratitude to all the members of the ESPON URRUC research Consortium, and in particular to the colleagues from the University of Coventry, Nordregio and the University of Valencia.

‘Sticky Flows’ and ‘Productive Frictions’: Untangling the Mechanisms of Street Urbanism

Huê-Tâm Jamme¹

¹University of Southern California. jamme@usc.edu

Abstract: Streets are the ultimate ‘places of movement.’ Adopting a mobility perspective on street urbanism, this paper analyzes how the interaction of movement, places, and people explains the range of activities and socioeconomic opportunities supported by the streets of Ho Chi Minh City (Vietnam). The context is one of a tangible transition from motorbike to car mobility. This paper aims at identifying mobility-specific mechanisms through which a mobility transition brings about socio-spatial change. Mixed methods served to analyze data collected through participant observations, video recordings of street life, and interviews with street users. The results show a consubstantial relationship between today’s dominant motorbike mobility and vibrant street activity. In contrast, car mobility is negatively correlated with street life. Motorbike mobility is characterized as a ‘sticky flow’ – low speed, thickness, and propensity to seep in and out of the curb. It is argued that such flow is conducive to ‘productive frictions’ between movement and the built environment. By connecting people on the move and people in places, these frictions play a significant role in the production of streets as integrative spaces of opportunities. The mobility transition in HCMC is one towards fewer and fewer points of productive frictions in the urban space.

Keywords: Mobility, Street Urbanism, Ho Chi Minh City

Introduction

Ho Chi Minh City (HCMC), the economic engine of Vietnam, has a rather unique ‘*transportation signature*,’ or ‘*mobility image*:’ there are about as many motorbikes sharing the road (8.5 million) as there are people living in the city (H.K. Kim, 2017). On average, every household owns two of these light, small, and quite affordable vehicles¹ that provide the flexibility of a bicycle coupled with the comfort of motorized transportation (Truitt, 2008). The fact that the vast majority of the population (83% in 2014) relies on this transportation mode for all mobility needs (JICA, 2016) gives the city’s streets and other public spaces a rather fast pulse, an active feel, that some may describe as loud and relentless. The mobility image of the city was radically different less than three decades ago, when the picture of any busy street or intersection would include many more bicycles than motorbikes. Like other Asian cities, most trips were non-motorized at the time (Replogle, 1992; Tiwari, 2002), the main reason

¹ The typical vehicle is either a semi-automatic motorbike or an automatic scooter. The engine capacity usually is either 110 or 125 cc.

being that years of war and restrictions under communist rule had left the population unable to afford anything else.

As for the city of tomorrow, there are signs indicating a possible transition towards either cars, transit, or both, as the dominant forms of mobility. After three decades of market economy, the emergent middle class has been increasingly tempted with the comfort, safety, and symbolic status they can now afford through automobile ownership (A. Hansen, 2017; Thu, 2016; Tuan, 2015). The number of private cars remains low compared to motorbikes. In 2017, there were one million cars registered in the city (H. K. Kim, 2017). Automobile ownership is growing at an alarming rate (15% per year since 2014 according to Hansen, 2017), which significantly contributes to traffic fatalities, pollution, and congestion. Cars now fill up entire lanes in certain places at peak hour, they generally occupy a disproportionate share of road space, forcing motorbikes to squeeze in the leftover road space. Meanwhile, public policies have been paving the way for more cars on the roads; the local government is considering a complete ban on motorbikes in the city center by 2030. The rationale is that motorbikes should soon become a thing of the past. By then, public transit should have become a viable alternative for the carless. This is assuming that the rail transit network continues to expand at a faster pace than the first metro line, supposedly about to open in 2020, but nearly one decade behind schedule. Nevertheless, whether it is towards the car, transit, or both, what societal changes will the shift away from motorbike mobility entail?

Minute observations of street urbanism dynamics, of the micro social and spatial arrangements unfolding on the streets, can help anticipate the larger societal transformations led by a mobility transition. The street is where mobility problematics meet public sphere challenges. The objective is to first gain an understanding of the ways in which present mobility practices explain everyday social interactions, and long-term social integration, or lack thereof. I do so in HCMC drawing on five months of fieldwork, including participant observations, systematic video recordings of street life, in-depth interviews with urban dwellers about their mobility practices, with informal street vendors and conventional store owners about their business activities. I develop a theoretical framework that elaborates on Henri Lefebvre's theory of the social production of space. I adopt an ecological approach to the street environment in order to grapple with the complex interactions between its two major functions, as traffic corridor and public space.

I argue that the nature of movement through urban space influences both short-term social interactions on the streets and long-term socioeconomic integration in the city. In HCMC today, I first highlight some significant correlations between mobility practices and street activity. Then I shed light on the ways in which the dominant motorbike flow, an offspring of bicycle mobility, explains the vibrant street life typical of HCMC's public spaces. I qualify motorbike traffic as a '*sticky flow*' because of its propensity to irrigate the banks of the roadbed. Furthermore, I demonstrate that a mechanism of '*productive friction*' between such sticky flow and the built environment produces both social interactions on the streets and economic opportunities to live off the connection to the street. At the core of the lived space of urban mobility, productive frictions bring together people 'on the move' and people 'in places'. The mobility transition from motorbikes to cars in the case of HCMC for example can then be interpreted as a shift towards a less sticky flow traversing the urban space, therefore leading to fewer opportunities for productive frictions, in other words to a growing disconnect between people's trajectories, both literally as they move in the city, and figuratively as they proceed in life.

Literature Review

1) 'Mobility Transition' Research Agenda and 'New Mobilities' Paradigm

In a recent effort to theorize 'mobility transitions', Temenos, Nikolaeva, Schwanen et al. (2017) define the concept as a process, a shift from one 'particular moment of assembled technologies, infrastructures, societies, and economies' to another. They ask: 'What kind of societal changes will this entail?' Geels' (2002) multi-level perspective on socio-technical transformations has driven the mobility transition research agenda. The multi-level perspective is concerned with the interactions between technology, industrial innovation, market mechanisms, policy, culture, and civil society. The normative imperative of environmental sustainability has been the primary motivation for the multi-level framework. As a result, existing studies applied in the transportation sector focus on transitions away from automobile dependence, towards low- to no-carbon societies, in places like the Netherlands or the United Kingdom (Geels, 2012). The 'Mobility Transition' research agenda has yet to embrace the question of the societal changes entailed by transitions that occur in reverse, away from sustainability, towards automobile dependence. Most countries of the developing world are experiencing such transitions (e.g. Kenworthy, 2011). Globally, the total vehicle stock has been projected to grow from 800 million in 2002 to over 2 billion units in 2030, with the bulk of the increase taking place in emerging economies; China's increase will have been nearly twentyfold for example (Dargay, Gately and Sommer, 2007). To complicate the matter, several transitions may be occurring concomitantly in such contexts, towards both sustainable and carbon-based mobilities (Jones, 2016), like it is the case in Vietnam, against a backdrop of rapid urban and economic development. Yet, little is known about non-Western mobilities in general, Asian mobilities in particular (Cresswell, 2016), and none of the existing studies adopt a new mobilities perspective (e.g. Cervero, 2013; Cervero & Golub, 2007; Mateo-Babiano & Ieda, 2007; 2009).

The 'new mobilities' paradigm, on which the 'mobility transition' research agenda draws substantively, has marked a mobile turn in the social sciences (Sheller & Urry, 2006). It followed on earlier work concerned with the structuring effect of the automobile on societies (Sheller & Urry, 2000; Urry, 2000). Mobility is considered meaningful, as opposed to being thought of as an abstract line between two points on a map, a derived demand from the need to reach destinations, as it is usually the case in transportation research. It is conceived as an 'entanglement of movement, representation, and practice' (Cresswell, 2010). Mobility is a sensual and social experience, and therefore should be considered from the perspective of the people on the move, not that of the locations in which movement lands. The 'new mobilities' paradigm therefore advances a mobile ontology to explore social phenomena, arguing that after the spatial turn of the 1980s, as initiated by Soja (1980) in particular, the social sciences have remained static and location-based in their way of addressing dynamics of exclusion. In her latest book *Mobility Justice*, Sheller (2018) makes the case that by focusing on the spatial distribution of transportation resources, costs, and opportunities, studies on destination accessibility and environmental justice have failed to consider the injustices rooted in uneven mobilities. Mobilities are uneven at all levels, and all levels are interconnected, from everyday bodily moves constrained by individual capabilities, gender, sexual and racial circumstances, to cross-country migrations bound by international relations and climate change. Sheller demonstrates how a mobile ontology helps explain power dynamics in the contemporary world. Nevertheless, the sustained effort to supersede a spatial perspective in mobility research has led to a situation where *places* now tend to be overlooked. It seems important to bring the focus back on the social production of 'places of movement' (Sheller & Urry,

2006) as originally conceived in mobility research, as part of a dynamic relationship between movement, space, and people (Cresswell 2006; 2016).

2) *Street Urbanism from a Mobility Perspective*

Urban streets are the ultimate ‘places of movement.’ Yet, scholars interested in street urbanism have been most concerned about its function as public space than its other defining feature as the stage of mobility. Public space is civic by nature, it is the physical space of the abstract notions of civility and public realm. It is ‘the common ground [...] that binds a community’ through a common sense of belonging, not only to a place, but also to a group (Carr, Francis, Rivlin, & Stone, 1992). Streets have been posited as the ‘quintessential public space’ (Mehta, 2013)—Kostof went as far as to claim ‘[t]he only legitimacy of the street is as public space. Without it, there is no city’ (Kostof & Castillo, 1992, p. 194). Sidewalks, a contested space, are the ‘most important and the most overlooked public space’ (Kim, 2015). Regulating sidewalk uses is an exclusive practice, it is a way of controlling who has access to public space (Blomley, 2007). In their study of the homeless of New York whose livelihood depends on sidewalk access, Duneier and Carter’s (1999) depicted the sidewalk as a space that ‘reveals today’s urban life in all its complexity: its vitality, its conflicts between class and race, and its surprising opportunities for empathy among strangers.’ Both in the global North and in the global South, the act of vending on sidewalks is instrumental to migrants’ social and economic integration in the city (Bell & Loukaitou-Sideris, 2014; Donovan, 2008; Eidse, Turner, & Oswin, 2016; A. M. Kim, 2015). The major difference is regulation. Western streets are known for being more regulated than Asian streets for example, where the culture of the street has often been depicted as one of great social and economic diversity, where the space is used for private, public, and domestic uses alike: vending, meeting, squatting, gossiping, eating, exercising, and so forth (Edensor, 1998; Drummond, 2000; Kim, 2015; Mateo-Babiano, 2009; Mateo-Babiano & Ieda, 2010).

However, the modernization of transportation infrastructure might be signing the “death of the street” (Holston, 1989), by systematically giving priority to traffic flows over public life. Focusing on their function as infrastructure (Ehrenfeucht & Loukaitou-Sideris, 2010), modern planning practices aim at regulating and controlling the streets in ways that bring order (Scott, 1998) to a complex, seemingly ‘messy’ environment (Hou & Chalana, 2016), in ways that clarify the blurry boundaries between public and private space, between movement and non-movement. Such efforts are occurring in HCMC, as attested by repeated sidewalk clearing campaigns justified by a need to give sidewalks back to pedestrians, street widening projects and parking investments motivated by a need to tackle congestion (Gibert, 2018; Nguyen et al., 2015). The death of HCMC’s street may be around the corner. Harms (2009) has already documented the retreat of street life into airconditioned private spaces in what used to be an active public space filled with people sitting outside coffee shops. The paradox is that if civic life as it unfolds in public space were to slowly disintegrate, it would be in the name of a ‘civilizing process’ (Harms, 2009).

HCMC has long been known for its vibrant street life. Streets and sidewalks have been described as an extension of people’s living space—their house or their store—and characterized by a blurry boundary between public and private uses (Drummond, 2000; Mateo-Babiano and Ieda, 2007). Like other Asian cities such as Bandung, Bangkok or Manila, non-movement has precedence over movement on HCMC’s sidewalks (Mateo-Babiano, 2010). At any time of the day people will be eating, exercising, praying, selling or buying goods on the sidewalks. On the streets she surveyed in HCMC, Kim (2015,

p. 103) found that most of the sidewalk space that is not reserved for pedestrian movement is used for motorbike parking (42%), followed by merchandise spillover from conventional stores (26%), leisure (13%), outdoor sitting from restaurants and informal food vendors (12%), and other uses such as motorbike taxis and services. The extensive network of narrow streets and alleys is another indigenous feature of HCMC. The city shares many built environment characteristics with other places of the developing world, including a high density, and a mostly non-gridded and poorly hierarchized street network (Cervero, 2013). Alleyways serve the densest neighborhoods in the city (more than 80% of the urban population lives in the maze of alleyways) and are used alternatively for access to private residences, as people's back kitchen, outdoor business, or other private activities, or for socializing. Totalling to the city's largest public space (85% of the street network), narrow alleyways are being progressively upgraded and modernized to give priority to traffic over other uses (Gibert, 2018). In sum, urban scholars have thoroughly documented the richness of HCMC's street life, but have internalized a dichotomy between the two functions of the streets, as spaces of mobility on the one hand and spaces of activity on the other.

More generally, the normative idea that streets should be 'for the people,' and not 'for cars,' is at the core of western-based discourses on street design and urbanism, sustainable mobility, and accessibility (Cervero, Guerra, and Al, 2017; Jacobs, 1958; Tiwari, 2017; Wallström, 2007). Such premise has crystallized an antagonism between motorized traffic and street life, between private mobility and inclusive public spaces. On the contrary, non-motorized transportation and public transit are commonly associated with more vibrant urbanisms (e.g. Calthorpe, 1993; Ewing et al., 2013; Mehta, 2008). Pedestrian counts are typically used as a proxy for measuring street life and the vibrancy of public spaces (Gehl & Svarre, 2013; Whyte, 1980). Over the last decade a growing number of studies has explored the relationships between streetscape characteristics and pedestrian activity (e.g. Boarnet et al., 2011; Ewing & Handy, 2009; Ewing, 2016; McDonald et al., 2018), and have typically found a positive and significant relationship between street activity and walkability. In many regards, HCMC appears as a counterexample. A city that is not particularly walkable, in part due to the weather (hot and humid year round), in part because the sidewalks are so busy, where only 1% of the population typically travels on foot as a result, where transit is on the way but not developed yet, and where 83% of all trips use a private motorized transportation mode (JICA, 2016), still supports a particularly rich, vibrant, and active street life. This apparently idiosyncratic case, and yet similar to many other cities of the developing world, suggests that urban design scholars may want to pay more attention to the ways in which different forms of mobility contribute to shaping and preserving the street as 'quintessential public space.'

Conceptual Framework and Research Questions

I propose to look at HCMC's streets as 'places of movement,' from an ecological perspective. By focusing on Asian street spaces known for a blurry boundary between movement and non-movement, I bring to the fore a core idea of the 'new mobilities' paradigm, according to which there is no substantial difference between travel and activities. 'Activities occur while on the move' thus producing and reproducing places (Sheller & Urry, 2006). A similar idea was previously developed by French transportation planner Georges Amar (1993) in his article promoting an ecological approach to transportation systems. He argued that there is a consubstantial relationship between movement and the built environment, that the type of movement traversing space informs the diversity of land uses and social encounters, and reciprocally. He proposed a typology of 'urban transportation ecologies' based

on the extent to which movement ‘adheres’ (sticks) to the built environment. Typically, walking is the type of movement with the highest level of *adhérence*, whereas airplane travel only ‘lands’ in ‘places’ but is otherwise disconnected from the built environment. It is the level of ‘adherence’ that makes the difference between a street and a highway. In practice, Amar made land use and transportation planners responsible for organizing human movement and encounters as one system, as opposed to a system of connections between locations. Borrowing from natural ecology, he defined the planning goal as a ‘climax’ of optimal diversity of movements associated with an optimal diversity of human encounters.

Henri Lefebvre’s (1974) spatial production theory inspires a framework to analyze urban transportation ecologies as the ‘lived space of urban mobility’, in relation with broader process of socio-spatial change. Lefebvre defined space in general, and the urban space in particular, as both socially produced and means of social reproduction, through dialectical relationships between the *conceived space* of planners and technocrats, the order they impose through abstract signs and codes (p. 43); the *perceived space* or dominated space that people experience through the senses without contesting it, the stage of all moves and activities, such as the movements between work, private life, and leisure (p. 48); and the *lived space* that users, artists, and philosophers appropriate through resistance to or contestations of dominant representations of space (conceived space). In this paper, I draw on Lefebvre’s socio-spatial theory to analyze the dialectical relationships between the lived space and the conceived space of urban mobility. I focus in particular on the everyday tactics through which people appropriate and at times contest an imposed order through urban design and planning regulation of the street space. I relate this dialectic as it unfolds in everyday life to its equivalent at the level of broader processes of socio-technical transformations. The mobility transition is conceived as dialectical relationship between planners’ conceptions of movement in the city of tomorrow, and people’s lived experience of the transition.

Therefore, adopting an ecological perspective on HCMC’s streets, I propose to explore how the interaction of movement, people, and places, influence not only street life and public interactions, but also socio-spatial transformations. More specifically, this paper addresses the three following research questions:

- In HCMC, to what extent does street activity depend on the nature of transportation flows traversing the street space?
- What are the mechanisms explaining the relationship between transportation flows and street activity?
- How do these mechanisms inform the socio-spatial transformations that the mobility transition brings about?

Methods

1) Data collection

I answer these questions using a range of quantitative and qualitative methods, drawing on data collected during five months of fieldwork (August-December 2018). In addition to participant observations of street life, I conducted 32 structured interviews in Vietnamese with people of different socioeconomic backgrounds about their mobility practices and life trajectories; 36 non-structured interviews with street vendors and conventional retailers; and 200 systematic recordings of traffic flows

(traffic videos) and street activity (side videos) on 19 different street segments. More information about the data collection protocol is provided in Appendix 1.

2) Measurements

The map in Figure 1 shows the 19 streets on which observations were made. On the map, the streets are classified as per OpenStreetMap typology, but another classification was used for the analysis. Type ‘1+1’ corresponds to two-way streets with one lane in each direction; ‘Type 2+2’ to streets with two lanes in each direction; ‘One-way’ streets, ‘Market’ and ‘Alleyways’ are self-explanatory; ‘Segregated’ streets have hard medians separating different traffic flows (typically, cars and trucks do not have access to outside lanes). The unit of observation is a ‘street segment,’ each observation including the ground-floor of the buildings, the sidewalk in front, and the traffic lanes between curb and median. In other words, when a two-way street was observed on both sides, each side counted as one observation. Segregated streets led to two observations per side (one for the inside lane[s], and one for the outside lane[s] with adjacent sidewalk and property line). An exception was made for alleyways, where properties on both sides and traffic in both directions were counted as part of the same observation. Pedestrian street Nguyễn Huệ was excluded from the analysis conducted in this paper, as well as Hẻm 440 Nguyễn Kiệm as it did not fall in any of the categories described above.² All street segments in District 3 were missing the 12:00PM observations. A total of 163 observations were included in the analysis (see Table 1).

With the support of a Vietnamese research assistant, a methodology was developed to count and classify all the street uses present on the video recordings. The same research assistant was responsible for all the counting, first under the supervision of the lead researcher, then alone, in order to avoid inter-rater reliability issues. The 5-step counting methodology is described in detail in Appendix 2.

Table 1 – Frequency of street observations by district and by type

Street type	District 1		District 3		District 7		Phu Nhuan		Total	
	Streets	Obs	Streets	Obs	Streets	Obs	Streets	Obs	Streets	Obs
1+1	2	24	1	10	2	18	1	12	<u>6</u>	64
2+2	0	0	0	0	0	0	1	12	<u>1</u>	12
Alleyways	0	0	1	5	0	0	3	18	<u>4</u>	23
Market	0	0	0	0	0	0	1	6	<u>1</u>	6
One-way	0	0	1	10	0	0	1	12	<u>2</u>	22
Segregated (inside)	1	12	0	0	1	6	0	0	<u>2</u>	18
Segregated (outside)	-	12	0	0	-	6	0	0	-	18
Total	<u>3</u>	48	<u>3</u>	25	<u>3</u>	30	<u>7</u>	60	<u>16</u>	163

² It is an alleyway in the city’s nomenclature but it is too large and too busy to fall in the same category as other alleyways, but too residential to be considered with other ‘1+1’ streets.

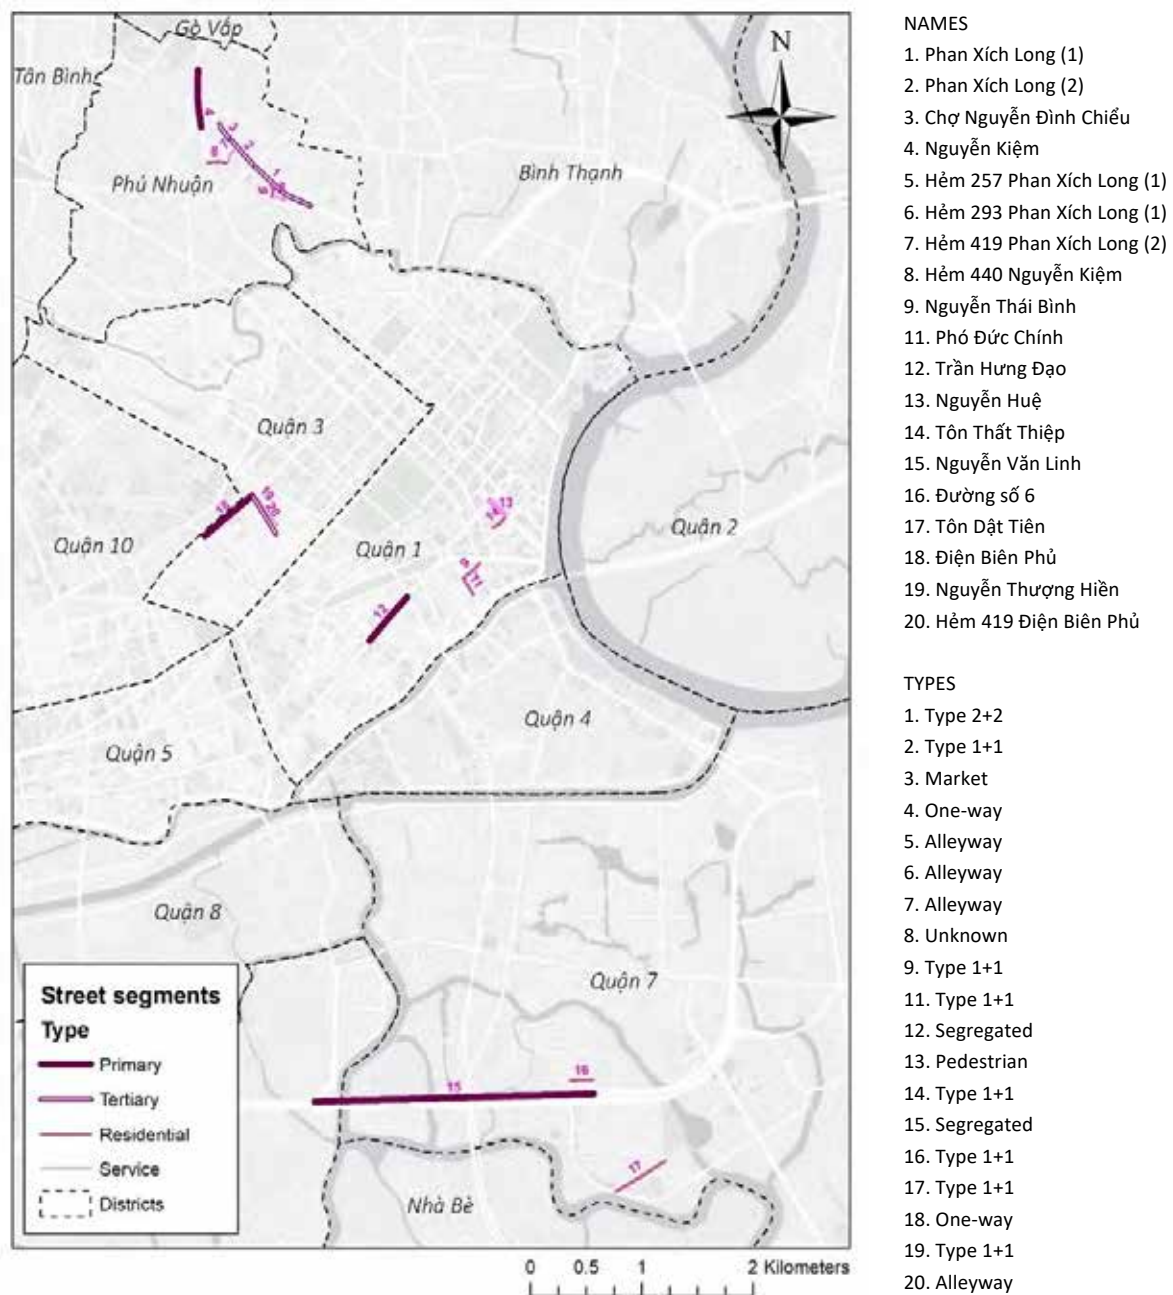

Figure 1 – Surveyed Street Segments

3) Analysis

The development of the measurement strategy led to a typology of street uses along the spectrum from movement to activity, and the definition of corresponding variables. The video data was used to calculate some descriptive statistics by type of street and by district. Several *t*-tests were ran to compare the statistical significance of the difference in means of key variables between a type of streets and the whole sample for example (one-way *t*-tests) or between two measurements of one construct (paired *t*-tests). Similar statistical analyses were conducted while focusing on one type of streets only (Type ‘1+1’) as a way to control for the type of street and tease out the neighborhood effect. Using this sub-sample

of observations, correlation coefficients were calculated between a selection of built environment-, mobility-, and activity- variables. The interview data on mobility practices served to further explain the relationships identified quantitatively between mobility and activity variables. Photographs of street activity and the interview data from street vendors and retailers mostly served triangulation purposes to ensure the validity of the results.

4) *Limitations*

The measurement strategy has some limitations. Due to resource constraints, both side and traffic videos were recorded by the same person in most cases, not simultaneously but consecutively (traffic video immediately after the side video). This means a risk of double counting, as a person sitting on the sidewalk at the time of the side video recording could have been counted as stationary, but then also on the move on the traffic video if she happened to leave in the meantime and pass in front of the camera. Another limitation is that the gender of street users was not recorded in the people's counts, which prevents any gender interpretation of the results. Finally, when building the database, the traffic counts were converted into motorbike-equivalent units using Cao and Sano's (2012) conversion rates, which were estimated based on traffic observations in Hanoi (Vietnam),³ but the article did not include a conversion rate for trucks. The bus rate was applied, which is an approximation.

The proposed analytical methods have some limitations as well. First of all, the statistical methods proposed for analyzing the data are quite rudimentary at this stage, focusing mostly on the means of all variables. Further analyses will consider more elaborate modeling techniques (e.g. Poisson regression models), but additional control variables will be needed, relative to the built environment in particular (e.g. population density, sidewalk width). Second, most variables included in the analysis are count variables, which means that correlation coefficients are probably biased due to skewed distributions of the data. Third, there is no elaboration on observed variations between different times of the day. Finally, the video data includes a significant amount of qualitative data that is not analyzed in this paper.

Results

1) *Typology of Street Uses*

Street uses were classified along a spectrum from movement to activity. Strictly about movement are all the traffic variables, as they correspond to counts of people and vehicles on the move. A sub-set of mobility practices was classified as 'non-compliant tactics.' These include practices such as driving the wrong way, riding on the sidewalk, and walking on the traffic lanes. At the other end of the spectrum are street activity variables that are strictly about static uses. These include variables such as the number of open commercial locations, people hanging out in public space, street vendors. The total count of street vendors was broken down into three categories, including vendors on the sidewalks, vendors on lanes, and motorbike taxis (*xe om*) or cyclos waiting for customers (those on the move were counted as 'motorbike' traffic for motorbike taxis, and 'other' for cyclos). Finally, there is a subset of variables that are neither strictly about movement nor strictly about activity, or both at the same time. Such '*mobility-activity*' variables involve mobility means that are temporarily static. In the case of HCMC,

³ Car = 3.4 MEU; Bus = 10.5 MEU; Minibus = 8.3 MEU; Bicycle = 1.4 MEU (Cao & Sano; 2012)

typical mobility-activity variables include motorbikes parked on the sidewalks, motorbikes or cars parked in traffic lanes, and ‘*motobuyers*.’ The act of ‘*motobuying*’ designates a common practice in Vietnamese cities where a motorbike rider pauses movement for a short amount of time (less than five minutes in general), puts one foot down on the ground, and without stepping down of the vehicle, makes a purchase to take away from a street vendor, which can be either formal or informal (see Figure 2). In what follows, ‘mobility-activity’ variables fall under the broader category of street activity.

Figure 2 – ‘Motobuyers’ purchasing drinks from a street vendor (left) and from a store (right)

2) General Description of Streets, Flows, and Activity

a. Built environment

Most recordings were made on commercial streets and boulevards. On average, the sampled street segments were lined with 15.33 locations per 100 meters. A large majority were commercial locations (68%), followed by housing (21%). The share of commercial locations approached or even exceeded 80% along two-way streets of type ‘1+1’ and ‘2+2’, and along the outside lanes of segregated streets. The share of ground-level housing locations was small on these commercial streets (less than 10%). However, the ratios were inversed in alleyways, where the majority of ground-floor locations were used for housing (76%), followed by commercial (18%). On all types of streets, very few locations were classified as institutional, mixed-use buildings, or parking lots (less than 2% in each category). Finally, the selected street segments were mostly continuous blocks. A negligible share of all locations consisted of intersecting streets (0.3%). A relatively larger share (5%) were entrances of alleyways, but such block discontinuities were nearly inevitable given the density of the network of alleyways in HCMC. See Appendix 3 for a summary of built environment characteristics by type of street.

b. Street flows by type of street segment

Against this backdrop, the transportation flow of all surveyed street segments was largely dominated by motorbikes (see Table 2). A major share of all traffic counts (71%) were motorbikes driving on the lanes. The share approached 90% of all counts on ‘2+2’ streets and on the inside lanes of segregated streets. Only in the market was it lower than average in the market (64%).

% Truck MEU	5,0%	3,5%	5,9%	0,0%	8,6%	1,7%	18,1%	0,0%

In terms of modal share, cars represented the second largest share of all traffic counts (11%). Unsurprisingly, the car share was almost negligible in narrow alleyways (less than 1%). The share was equally low in the market, which was not accessible to cars either, not because of width but due to the market activity itself. When converted into MEU, the average car share on all surveyed street segments (22%) turned out to be twice as large as that measured in terms of traffic counts (11%). The results of a paired *t*-test indicated that, at the .05 critical level of statistical significance, the mean MEU car share was significantly higher than that measured as counts, $t(155) = 12.51$, $p = .00$. The difference between the two measurements was of particular importance for '1+1' streets. Compared to all streets, the mean share of cars as proportion of all counts was not significantly different, as shown by the result of a one-way *t*-test, $t(62) = 0.95$, $p = 0.17$. However, the difference in means was significant when car shares were calculated as MEU, $t(62) = 2.55$, $p = .01$. In other words, although the share of cars out of all

moving objects was not particularly higher on this type of streets, the share of road space cars occupied was significantly higher, relative to other transportation modes.

In third and fourth positions in the modal split came the shares of pedestrians walking on the sidewalks (5% of all traffic counts), and that of bicycles riding in lanes (2%). After segregated streets, which had an exceptional share of pedestrians (26%, see below), ‘1+1’ streets appeared to support relatively more pedestrian traffic (4%) than any other type of streets. Naturally, the share of pedestrians walking on sidewalks was null on street segments that did not have a sidewalk, i.e. on alleyways and on the inside lanes of segregated streets. As for bicycle traffic, alleyways and the market were supporting a relatively larger bicycle share than average (4%).

The outside lane(s) of segregated streets appeared to be an exception when looking at the average modal shares. The recorded motorbike share was much smaller than average (25%). The car share was quite high numerically (27%), but the difference in means was not significant at the specified alpha level. Finally, a rather large share of all traffic counts were pedestrians walking on the sidewalk (25%). This most likely due to the fact that one of the street segments of this type—Tran Hung Dao—was located in the heart of the backpacker district of HCMC. On that street, pedestrian counts mostly included tourists, who are generally more likely to walk on the streets than their local users.

People and vehicles engaged in non-compliant mobility tactics represented a total of 9% of all traffic counts. The most common of these tactics consisted in walking in the lanes (7% of all traffic counts). A particularly large share of moving users were counted as such in the market (30%), where sidewalks were too busy to be discernable, and in alleyways (17%) where, if any, sidewalks were not continuous and extremely narrow. The second most common tactic was to ride a motorbike the wrong way (3%). This practice was significantly more prevalent on the outside lanes of segregated streets, where motorbikes driving the wrong way represented 15% of all traffic counts, $t(17) = 3.66, p = .00$. The share was numerically higher than average on one-way streets as well (5%), but the difference was not statistically significant. Non-compliant uses were almost inexistent on streets of type ‘2+2’ and on the inside lanes of segregated streets (less than 1%).

c. Street activity by type of street segment

Of all locations recorded along the surveyed street segments, an average of 8.19 per 100 meters of property line were formal commercial locations that were open to customers at 3:00 PM (Table 3). Streets of type ‘1+1’ were the most active type of commercial streets along this variable ($M = 10.81$) and segregated streets the least ($M = 6.02$). Alleyways had even fewer stores open at 3:00 PM ($M = 3.62$), given the large majority of housing locations (see above).

A ‘mobility-activity’ variable, ‘motorbikes parked on sidewalks’ outnumbered all other measurements of street activity. All street observations considered, there were nearly 20 parked motorbikes per 100 meters of street segment. The mean number of parked motorbikes was the highest on the sidewalks of segregated streets ($M = 26.57$), followed by ‘1+1’ streets ($M = 25.61$), and ‘2+2’ streets ($M = 23.67$). Of all commercial streets, one-way streets had the fewest motorbikes parked on their sidewalks ($M = 10.64$). In addition, some motorbikes were counted as parked in the traffic lanes. For reasons mentioned above, this practice was most common in alleyways ($M = 5.63$) and in the market ($M = 6.14$), but

motorbike parking in traffic lanes also occurred on ‘1+1’ streets ($M = 3.42$). In comparison to motorbikes, the average number of parked cars was very small on all streets ($M = 1.22$).

Table 3 – Means of activity variables by type of street

	All	1+1	2+2	Alley	One-way	Seg. Outside	Seg. Inside	Market
Commercial open at 3:00PM	8,19	10,81	8,25	3,62	9,19	6,02	-	-
Motorbikes parked on sidewalks	19,83	25,61	23,67	1,55	10,64	26,57	-	0,00
Cars parked (street parking)	1,22	2,15	1,12	0,29	0,26	0,43	-	0,00
Total street vendors	2,29	2,41	1,13	0,99	0,98	0,73	-	17,54
- Street vendors on sidewalks	2,07	2,32	0,78	0,25	0,89	0,63	-	17,54
- Street vendors on lane	0,19	0,09	0,19	0,74	0,00	0,10	-	0,00
- Xe om (and cyclo)	0,03	0,01	0,16	0,00	0,09	0,00	-	0,00
People on sidewalks (not walking)	9,27	13,43	9,07	3,97	3,78	7,62	-	0,11
People on lane (not walking)	2,30	0,86	0,80	2,51	0,35	0,86	-	30,81
Motobuyers	0,53	0,35	0,35	0,57	0,22	0,00	-	5,48
Motorbikes parked on lane	3,04	3,42	0,91	5,63	0,91	1,19	-	6,14

The average number ($M = 9.27$) of people sitting or standing on the sidewalks (not walking) was about half that of parked motorbikes. Moreover, some people were doing the same in the traffic lanes ($M = 2.30$). Streets of type ‘1+1’ were the most active of all streets along the former variable as well ($M = 13.43$). Segregated and ‘2+2’ streets were closer to average, whereas the mean was much lower along one-way streets ($M = 3.78$).

The mean number of street vendors was higher on ‘1+1’ streets ($M = 2.41$) than almost any other type of street. All streets considered, the mean number of vendors ($M = 2.29$) included a majority installed on the sidewalks ($M = 2.07$), few vendors in the traffic lanes ($M = 0.19$), and very few motorbike taxi drivers or cyclos ($M = 0.03$). There were no street vendors in the lanes of one-way streets. The market constituted an exception with a much higher number of street vendors ($M = 17.54$), and also a greater mean number of ‘motobuyers’ ($M = 5.48$) than average ($M = 0.53$). Nevertheless, ‘motobuyers’ were recorded every 200 meters on average in alleyways ($M = 0.57$), and every 300 meters approximately on ‘1+1’ and ‘2+2’ streets.

3) *Street Flow and Street Activity in a ‘Modern’ Environment*

The results presented in this section aim to tease out the Phu My Hung (District 7) effect, where the selected streets were planned according to an ideal of modern city life. The analysis builds on a subset of data ($N = 64$) that includes only observations made on Type ‘1+1’ streets. This is a way to ‘control’ for the variations due to street type, while focusing on streets that have appeared so far to be the most active, and where the car effect can be expected to be most tangible. Moreover, ‘1+1’ streets are the only ones for which the distribution of observations enabled a comparison between neighborhood environments. A striking figure when comparing the street flow variables (see Appendix 4) was the very low mean number of all traffic counts on the ‘1+1’ streets surveyed in District 7 ($M = 13.94$) compared to the average for all such streets ($M = 76.73$). The motorbike share as proportion of traffic counts ($M = 56\%$) was also much lower than average ($M = 73\%$), and the difference in means was

statistically significant, $t(17) = -3.13, p = .00$. In contrast, the car share ($M = 24\%$) was twice as large as average and the difference in means was also statistically significant, $t(17) = 2.64, p = .01$. The contrast was even larger with the car share measured in MEU ($M = 49\%$). Streets of District 7 were the only one where the mean car share ($M = 49\%$) was larger than the mean motorbike share ($M = 45\%$). However, neither the mean share of pedestrians on the sidewalks nor that of bicycles riding in lanes were significantly different from those measured on similar streets in more typical districts.

Most street activity variables involving people on the streets had lower means than average on '1+1' streets of District 7. It was the case for the number of commercial locations open at 3:00PM ($M = 7.23$ as opposed to $M = 10.81$); the number of street vendors ($M = .15$ as opposed to $M = 2.40$); the number of people sitting or standing on the sidewalks ($M = 7.50$ as opposed to $M = 13.43$) or in the traffic lanes ($M = .43$ as opposed to $M = .86$); and the number of 'motobuyers' ($M = .06$ as opposed to $M = .34$). The mean numbers of motorbikes parked either on sidewalks or in the lanes were smaller than average. In contrast, the mean number of cars parked next to the curb ($M = 4.51$) was higher than in any other districts.

4) *Correlations between Street Flows and Street Activity*

Continuing the analysis using the small dataset ('1+1' streets only), this section highlights some correlations between street activity, built environment, and street flow variables (Table 4). The number of sidewalk vendors was more strongly correlated with the number of ground-floor housing locations ($r = 0.50, p < .05$) than with that of open commercial locations ($r = 0.31, p < .05$). As for the number of street vendors located in the lanes, there was a positive, yet not significant, relationship with the number of housing locations, but no correlation with the number of open stores. The number of motorbikes parked on the sidewalks, however, was strongly and positively correlated with the number of open stores ($r = 0.60, p < .05$).

The number of people hanging out (sitting or standing) on the sidewalks was strongly, positively, and significantly correlated with the number of sidewalk vendors ($r = 0.66, p < .05$). Similarly, it was strongly correlated with the number of motorbikes parked on the sidewalks ($r = 0.60, p < .05$). However, the relationship with the number of open stores was weak and non-significant. The number of 'motobuyers' was positively correlated with the number of vendors in the lanes ($r = 0.45, p < .05$), and that of people in the lanes ($r = 0.38, p < .05$). However, the relationship with the number of sidewalk vendors was weak and not significant. It was weak as well, but significant, with the number of open stores ($r = 0.30, p < .05$).

Pedestrian traffic appeared strongly and positively correlated with the number of sidewalk vendors ($r = 0.63, p < .05$) and with the number of people hanging out on sidewalks ($r = 0.75, p < .05$). Although quite weak and not statistically significant, the relationship between the *motorbike share* and the number of street vendors was positive, both with those on sidewalks and those in the lanes ($r = 0.19$ and $r = 0.20$, respectively, $p > .05$). On the contrary, the *car share* (in MEU) was negatively correlated with the number of street vendors. The relationship was statistically significant with the number of sidewalk vendors ($r = -0.31, p < .05$). The signs were negative for all correlations between car share and street activity variables. The relationships between other modal shares and street activity were not statistically significant. Similarly, there were no significant correlations between non-compliant mobility tactics and street activity variables.

Table 4 – Correlation matrix of built environment, street activity, and mobility variables

	<i>Built environment</i>		<i>Street activity</i>					<i>Mobility tactics</i>			<i>Parking</i>

5) *On the Relationships between Everyday Uses of the Streets*

The next series of results draws on qualitative data in order to explain the differences in means and correlations highlighted so far. The overall maneuverability of the motorbike seems to provide a crucial explanation for the observed associations between motorbike mobility and street activity. Parking on the sidewalks (or in the traffic lane next to the curb) is the typical preliminary step before entering a store, sitting down at the terrace of a café, or having a noodle soup from a street vendor, hence the strong correlations with commercial activity and street vending. Such parking habit is made possible by the small size, light weight, and little encumbrance of the motorbike (Truitt, 2008), coupled with the fact that the curb is purposely designed as a 45-degree ramp for motorbikes (and bicycles) to step up and down between the roadbed and the sidewalk. Furthermore, the maneuverability of the motorbike is also what makes the act of ‘motobuying’ possible. When reflecting on their travel diary the day prior of the interview, most motorbike users seemed to conceive such practices neither as full stops nor as complete activities. For example, one respondent started the section of the interview about his activities the day before as follows:

Interviewer: *‘Let’s now talk about the places you went to yesterday’*

Respondent (a motorbike user): *‘Oh, I didn’t go anywhere. I only went to work in the morning, and then back home.’*

Interviewer: *‘On your way to work, did you stop anywhere?’*

Respondent: *‘No, I didn’t stop anywhere’*

Interviewer: *‘Did you buy anything?’*

Respondent: *‘Yes, I bought breakfast.’*

Interviewer: *‘How did this happen?’*

While in most places around the world window-shopping on a commercial street gives pedestrians the possibility to make spontaneous stops and purchase decisions; ‘sidewalk-shopping’ and ‘motobuying’ are the equivalent for motorbike users in Vietnamese cities. Most respondents who typically commute by motorbike reported such practices being part of their everyday routine. They would ‘motobuy’ to buy breakfast in particular.⁴ A respondent explained: *‘[As I drive,] I look. I see what options there are. If I see something I want [to eat], I buy it.’* The transportation mode people use, and whether they make a full stop or not, are decisions they also make on the go. Another respondent described how she has different mobility means associated to different breakfast options (and breakfast places):

‘There is pho near the apartment building where I live. [If I feel like eating pho], I just walk out of the building and go. Banh gio [a steam rice cake wrapped in banana leave], I buy on the way. Banh cuon [rice paper steamed raviolis], it’s also on the way. For vegetarian food [she is vegetarian 10 days a month for religious reasons], it has to be inside a restaurant. So I park.’

⁴ Vietnamese people tend to have quite elaborate breakfasts that they typically do not cook at home. *Pho*, the famous Vietnamese beef noodle soup, is a breakfast favorite for example. It takes eight hours to simmer a flavorful broth and it cannot be cooked in small quantities.

There is in fact a strong co-dependence between street vending, and motorbike mobility. The correlation coefficient was not significant in earlier analysis for reasons most likely related to the fact that all streets had a very large share of motorbike traffic, with very little variation from one observation to another (no effect to pick up). The co-dependence between motorbike mobility and street vending is as real as the one between pedestrian traffic and street vending. Both relationships are most apparent when observing street vendors' tactics as they seek to 'catch' customers. All street vendors interviewed for this study reported that the vast majority of customers reached either by motorbike, or on foot. Street vendors appeared to use different location tactics depending on the type of traffic flow they want to catch. Those who primarily target pedestrians sit low near the ground, facing the sidewalk, and possibly turning their back to traffic, as in vignettes 1 and 2 below (Figure 3). Vignette 3 shows a typical stall targeting 'motorbuyers.' The vendor (not-visible on the picture) is standing behind a stall facing traffic, and the merchandise is at eye level for people on motorbikes. In this case, the stall is in the traffic lane of a narrow alleyway. Finally, vignette 4 shows a specific case where a watch vendor has positioned his stall at ground-level, on the sidewalk, not to catch pedestrians but motorbike users in a particular situation, when they wait at the traffic light (light not visible on the picture). Many formal businesses use similar tactics as informal street vendors to catch the motorbike flow in particular. Some conventionnel cafés for example position a cart similar to the one shown in Vignette 3 right next to the curb in order to catch sell to 'motorbuyers' in additional to seated customers.

Figure 3 – Four street vending location tactics by type of flow

In contrast, car mobility goes against street activity because of its lack of flexibility. Current motorbike users who said they were considering shifting to the car in the near future were asked to reflect on all

the stops they had made the day before (including the quick ones they would not have considered stops outside the interview), and whether these would have been possible had they been going by car. Typically, the first answer would be ‘Yes, why not?’ but, admitting they had never thought about this question, they would then correct themselves: ‘No, I guess not.’

‘There is nowhere to park near the market [where the interviewee had purchased ingredients from four different sellers the day before, in ‘motobuying mode’]. I will have to buy everything from Coop.Mart [a supermarket]. There is underground parking.’

Current automobilists confirmed that their range of options was constrained by their mobility. They almost never buy anything anymore from a street vendor, rarely stop for a coffee on the sidewalk. While it seemed to be a matter of choice for one of the interviewed car users, all others said it was by constraint, because of limited parking options, coupled with the impossibility to stop spontaneously like motorbikes do without seriously disrupting traffic. Nevertheless, they accept the tradeoffs as compared to driving a motorbike, they enjoy being sheltered from the surrounding environment, being protected from the dust, the heat, the rain, and the exhaust fumes, and knowing their children are safer in case of an accident.

Knowing that they cannot catch it, street vendors avoid contact with the automobile flow. This is most evident when observing one-way streets, where traffic regulation requires that motorbikes drive on the right lane(s), cars and other larger vehicles on the left lane(s). Typically, street vendors will be concentrated on the right side of the street. As a robustness check, this hypothesis was tested comparing the counts of street vendors on both sides of the one-way streets included in the sample (Nguyen Kiem and Dien Bien Phu). The result of a *t*-test showed a significant statistical difference for Nguyen Kiem. The result was not significant for Dien Bien Phu, but the surveyed street segment had large hospitals on the left side, which attract street vendors. A left-side street vendor selling *chào* [rice porridge] confirmed that she very never has cars stopping by, and rarely has customers reaching by motorbikes. The vast majority of her customers are relatives of hospital patients who walk out of the hospital to buy lunch for themselves and the patient.

Findings

Two complementary concepts have been identified to further explain the consubstantial relationship between transportation flows and social interactions in HCMC’s streets: the ‘stickiness’ of the motorbike flow and resulting ‘productive frictions.’

1) ‘Sticky Flows’

Borrowing from Amar’s (1993) ecological perspective on transportation flows and the built environment, first of all HCMC’s motorbike traffic can qualified as particularly ‘sticky.’ As per Amar’s definition of *adhérence*, the flow is integrated in the built environment. It has its own content and space, it enables spontaneous stops and a number of activities while on the move, it opens up possibilities of improvisations and detours. A high-level *adhérence*, or stickiness, is high, is longitudinal: there is an uninterrupted relationship between movement and the built environment, a consubstantial relationship between movement and what it leads to. On the contrary, when the adherence is punctual, the movement ‘sticks’ to the built environment only at origins and destinations but it disconnected otherwise. The observations made in this paper invite to qualify motorbike mobility as a ‘sticky flow.’ Furthermore,

the case of motorbike mobility enabled to identify some mobility-related technicalities to further conceptualized **‘sticky flows:’ a rather low speed, a certain thickness (or density of users on the move), a propensity to seep through the banks of the road bed, to overflow the built environment, typically the sidewalks, and the direct contact between its participants and the environment through the senses.** Based on this definition—low speed, thickness, propensity to infiltrate, and direct environmental perceptions—pedestrian mobility definitely ranks highest on the stickiness ladder, whereas car mobility falls to the bottom rung.

2) *‘Productive Frictions’*

Moreover, this study proposes a complementary concept, that of ‘productive frictions,’ to explain how ‘sticky flows’ relate to a density and diversity of human interactions in the built environment. The mechanical notion of ‘friction’ is one of the components in Cresswell’s mobility definition. The friction is conceived here as socially produced, and as critical to the production and reproduction of the ‘lived space of urban mobility.’ Permitted by the resistance of a sticky flow as it traverses the built environment, **‘productive frictions’ are the interactions between street users ‘on the move’ and street users ‘in place,’ thus producing opportunities for social interactions. They necessitate a temporary inversion of movement and non-movement—only when movement pauses do places become activated.** In the case of HCMC, the sticky flow relentlessly rubbing against the banks of the roadbed creates opportunities for strangers and semi-strangers with different socioeconomic backgrounds to remain in constant interaction with each other. They would hardly every meet otherwise. The ‘productive frictions’ highlighted here are at the core of the symbiotic relationship that exists between motorbike mobility and street activity (Piazzoni and Jamme. Forthcoming 2020). They play a critical role in shaping HCMC’s streets as the vibrant public spaces they are. Moreover, they participate in the production of a fertile ground of socio-economic opportunities on the banks of the streets, as sidewalks present possibilities to live off the connection to the street.

3) *Mobility Transition and the Social Production of Space*

In a rapidly changing context like HCMC, the concept of ‘productive frictions’ enables to anticipate the socio-spatial transformations that the on-going mobility transition brings about. On the one hand, evidence from Phu My Hung (District 7) and from current car users suggest that HCMC’s street spaces will undergo a radical transformation if car mobility is to supersede motorbike mobility. The explanation being the consecutive loss of frictions points in the system of movement. On the other hand, HCMC’s streets and sidewalks may remain a vibrant public space if the mobility transition were to turn predominantly towards sustainable mobilities: walking and biking coupled with mass transit. Non-motorized mobilities are even ‘stickier’ than motorbike mobility in fact, so at least as conducive to the ‘productive frictions’ and the production of places in the urban space.

These foreseeable consequences associated with different modalities of the mobility transition are not groundbreaking: cars have caused the ‘death of the street’ in other modernizing cities of the developing world, while car-oriented cities in the Global North know that promoting non-motorized mobilities is key to activating the streets. Nevertheless, the contribution here is an explanation for these assumed processes, a theoretical underpinning to substantiate urban discourses that have internalized a dichotomy between motorized traffic and public sphere. The mechanism that almost inexorably links car mobility and the ‘death of the street’ can be described as follows: a non-sticky flow becomes the

dominant form of mobility, therefore contact between people on the move and people in places becomes more and more punctual, movement through space loses its spatial production function, the density and diversity of human interactions dwindle, social disintegration ensues. On the contrary, promoting non-motorized mobilities is re-injecting some stickiness in the system, creating friction points.

Conclusion and Discussion

This paper built on a case study of HCMC's street urbanism, where the street network can be thought of as an endless drive-through that people on the move traverse with unlimited options and opportunities to take part in street life. Formal or informal, most street vending places are 'third places' as defined by Oldenburg (1999): places that enable people to stay in touch, to support each other, to develop a sense of belonging to a place and to a group.

I highlighted two mechanisms that help understand how spatial transformations of street urbanisms relate to broader processes of social change led by a mobility transition. The level of 'stickiness' of movement that traverses the urban space informs the possibilities for 'productive frictions' between people, movement, and places, thus shaping opportunities for everyday interactions and long-term opportunities for integration.

Based on this premise, the issue in practice becomes a matter of arranging human movement in the city in ways that care for a diversity of levels of friction in the transportation system, knowing that all forms of mobilities have their own level of friction. The two concepts advanced here invite to planners and urban designers to work with the complexities of multi-modal environments. In places like HCMC that are highly-multi-modal, the goal should not be to simplify the mobility landscape, by banning one form of mobility to force another one through for example; simplifying, one way or another, only leads to creating discontinuities in an existing system of movement. The loss of friction points is a social cost associated with a mobility transition, one that impact societies even more directly than social costs commonly considered: congestion, pollution, and traffic fatalities. Ultimately, as Manuel Castells put it (Castells, 1989, p. 353): *'What we must prevent at all costs is the development of the one-sided logic of the space of flows while we keep up a pretense that the social balance of our cities has been maintained.'*

Acknowledgements

The author would like to thank the Ecole Française d'Extrême-Orient for the financial and logistical support received to conduct fieldwork in Ho Chi Minh City. Many thanks to Tấn Quỳnh for his patience and dedication in assisting this research.

Appendices

Appendix 1 – Data Collection Protocol

Interviews: The interviews about individual mobility practices lasted about one hour and included five sections. First, interviewees answered question about their past and present personal circumstances (age, family size, job, income, education, housing situation, and so forth), and their projects, expectations and preferences in these regards. Second, they described their past, present, and anticipated mobility means. The third section aimed at revealing the relationship between everyday mobility practices and urban activities. Following the template of a typical travel survey, interviewees first described their trips and activities the previous day. Then they were asked whether these activities would have been possible with the mobility means they had in the past and those they anticipate (or hope) to have in the future. They also spoke more generally about things they commonly do, especially leisure activities, and associated mobility means. The fourth section aimed at revealing perceptions and meanings attached to different streets. Finally, open-ended opinion questions addressed three major policies likely to transform the urban space in HCMC: the metro project, the ban on motorbikes by 2030, and the sidewalk clearing campaigns. The interview guide was approved by the Institutional Review Board of the University of Southern California. Eligible participants were 18 years or older and had lived in HCMC for at least one year. The final sample 32 of participants included a diversity of profiles in terms of common transportation mode (moto, electric bicycle, bicycle, walking, car, motorbike taxi, and bus), age, gender, and income, but was not representative of HCMC's population.

Video recordings: The video recordings were conducted on 19 streets located in different urban environments, including typical districts characterized by a dense network of alleyways (Phu Nhuan and District 3), the historical and institutional center (District 1) planned according to a grid pattern during the colonization era, and the Phu My Hung neighborhood (District 7) was planned and developed in the last two decades in ways supposed to offer the comfort of modern life to those who can afford it (Harms, 2012; 2016; Kim, 2008). Several types of streets were included, ranging from narrow alleyways to large boulevards. With the exception of alleyways, which by definition cut through residential neighborhoods, all selected streets were lined with 3- to 6-story mixed-use buildings typical of HCMC's urbanism, with stores on the ground floor and additional commercial or residential space in the upper floors. Using an action camera, each street was filmed six times over the course of one day (at about 6:30 AM, 9:30 AM, 12:30 PM, 3:30 PM, 6:30 PM, and 10:30 PM). First, a tracking shot was used to record 'side videos' of the sidewalk and background properties, by following the curb either on foot or on the back of a motorbike; second, a static shot was used to record 5-minute 'traffic videos' (motorized and pedestrian). All videos were recorded in November, during the dry season, so the weather was quite similar from one day to another (approximately 30°C in the afternoon, no rain). Finally, the waiting times between recordings were used for participant observations of street life, photographs, and short interviews with vendors and retailers. Thirty-six interviews were conducted, including 25 with informal street vendors.

Appendix 2: Counting Methodology (Measurements using Video Data)

For each street segment, the methodology included the following steps:

- Step 1: Using the 6:30 AM video, list all activities in anchor ‘locations’ along the property line. Each location was attributed a location number, a name (e.g. the store’s name), a type (e.g. store, house, alleyway, parking lot, institutional use) and a short description.
- Step 2: Using the same video, add to the list all activities happening in front of anchor locations. For example, the screenshot in the Figure below shows a street vendor in front of location #3. This vendor was recorded under the same location number (#3), the type was ‘sidewalk vendor,’ and the description said, ‘lottery ticket seller.’
- Step 3: Using the same video, indicate whether the listed activities are ‘active’ (open) or not at the time of observation.
- Step 4: Count the number of stationary people and parked vehicles (by type) in front of each location. People (or vehicles) on the sidewalk were counted in another category than people (or vehicles) in the traffic lanes, provided that the distinction could be made. Pedestrians on the move were excluded.
- Step 5: Using the 6:30 AM traffic video, count the traffic exited the shot by transportation mode. Each pedestrian was counted as one in the pedestrian traffic category. For vehicular traffic (motorbikes, cars, trucks, buses, bicycles, e-bikes), each vehicle was counted as one in respective categories.
- Step 5: Repeat steps 2-5 for all other videos recorded on the same segment (other times of the day).

Abstract: The last-mile problem has been the hot focus question in the field of urban planning for a long time. In recent years, booming dockless public bicycle system in China provides new solution of this problem. However, large number of dockless public bicycles have occupied large amount of public space and disturbed people's daily life. To support dockless bicycle system efficiently, it's urgent to understand the parking modes of dockless public bicycle and their impacts on public space use. Using big data from the OFO BSS in Shenzhen, demographic data, building environments and the location of points of interest. This study defines the "parking density" and "parking duration" of sharing bicycles to analyze the parking characteristics. We take Nanshan district in Shenzhen city as a representative case, and divides Nanshan area into a 500m*500m grid, counts the number of bicycles parked in each grid. The factors affect dockless public bicycles are grouped into four main categories: transportation, land-use/build environment, population-job and meteorological data. We summarized four parking modes and a logit regress model was applied to explore the relation between parking pattern and open space. Based on the results of the model, we discussed the management of public bicycles in Shenzhen and made some suggestions.

Keywords: Dockless bicycle sharing system; Parking mode; public space

1. Introduction

Public bike system (PBS) also called a bicycle sharing system (BSS), which was born in 1965 in Europe has been developed for three generations. The third-generation system included electronically-locking racks or bike locks, telecommunication systems, smart cards and fobs, mobile phone access, and onboard computers (Demaio, 2009). The concept of PBS/BSS is simple: A user arrives at a station, takes a bike, uses it for a while and then returns it to another station. It is economical, eco-friendly, healthy, ultra-low carbon emissions and more equitable, has increasingly received attention in the last decade and have rapidly emerged in many cities all over the world. A characteristic differentiating bike sharing systems from other non-motorized systems is that they do not necessitate ownership of bikes and therefore facilitate increased complementarity between biking and transit. Bicycle-sharing systems free the user from the need to secure their bicycles avoiding bicycle theft issues. At the same time, the decision to make a trip can be made in a short time frame providing an instantaneously accessible alternative for a one-way or a round trip. Generally, many studies referred to the docked system, which need several fixed stations with docks in each station used to store bicycles and finish rent and return operations. The dockless system, also considered as the fourth-

generation system, based on the mobile app and GPS, which eliminates stations and docks. Passengers can easily pick up and drop off bikes anywhere using their cell phone.

This system is quite spread nowadays in China through enterprises as OFO and Mobike since early 2016. Majority of bike-sharing schemes contains fewer bicycles compared with a dockless sharing bicycle. Many available bicycles and no restrictions on parked locations may result in different characteristics of public bicycles using and their influencing factors from dock system. Dockless public bike system brings new experiences and conveniences as well as some problems: (1) the emergence of huge number of dockless public bicycles means that more parking space needs to be set up in the public space of the city. This is bringing challenges to urban planning and urban management. (2) meanwhile, the feature of “drop off bikes anywhere” will result in a lack of certain constraints on the user's parking behavior. The user's parking location may disturb or affect the daily activities of city residents such as parking bicycles on the pavement. (3) For areas where many bicycles are parked, if the demand and supply do not match, it will result in a waste of bicycle resources and urban space resources.

However, few studies focused on the dockless parking system which needed to be deeply discussed. This paper selected Shenzhen, one of Chinese fastest urbanizing city, as a representative Metropolis case, and explored dockless bicycles by OFO bike sharing system. OFO bicycle-sharing system was launched in Shenzhen in December 2016 with more than 2200,00 bicycles. This paper mainly studies the inactivity of the dockless public bike system. Four issues are discussed: (1) How to measure the parking of dockless public bicycles? (2) what are parking modes of dockless public bicycles? (3) What's the relationship between parking modes and built environment? (4) how to manage public space to support efficient dockless parking?

2. Literature review

2.1 The systems perspective of sharing bike research

Sharing bike involved in many areas of research and it is broadly based on two perspectives: user perspective and systems perspective (Faghih-Imani and Eluru, 2015). In this study, we only focus on systems perspective.

2.1.2 The systems perspective

System perspective research can be divided into three categories.

(1) Based on the practical usage, a number of studies focus to deal with bike sharing rebalancing problem, using intelligent algorithms. In bike sharing system, the lack of resources is one of the major issues: a user can arrive at a station that has no bike available or wants to return her bike at a station with no empty spot. Fricker and Gast (2016) propose a stochastic model of a homogeneous bike-sharing system to study the effect of users' random choices on the number of problematic stations and compute the rate at which bikes must be redistributed by trucks to ensure a given quality of service. You, Lee and Hsieh (2017) provide an integrated model for the problems of fleet sizing, empty-resource repositioning and vehicle routing for bike transfer in multiple-station systems. O'Mahony (2015) tackle rebalancing the system during rush-hour, developing novel methods for optimizing rebalancing resources and formulate an optimization problem whose goal is to produce a

series of truck routes to get the system as balanced as possible during the overnight shift. Chen, et al. (2015) address the layout planning of public bicycle system within the attracted scope of a metro station. and locations of service stations and the optimal route options for the implement of redistributing strategy. Lozano, et al. (2018) proposes a multi-agent model that provides visualization and prediction tools for bike sharing systems.

(2) Explore the spatial and temporal patterns of bike use over the time of day, using data mining and visualization techniques. Whereas the aim of clustering is to identify mobility patterns in BSS usage by partitioning the stations into different clusters having a similar usage. Wong and Cheng (2015) presents the insights of imbalanced public bicycle distributions through the analysis of spatiotemporal activity patterns of bike stations. the clustering algorithm is used to analyze how station activity patterns are geographically distributed in the city based on their usage patterns and explore how these activity patterns relate to underlying cultural and spatial characteristics of Taipei City. Temporal and spatiotemporal patterns among bike stations of Barcelona bike sharing system were explored by Froehlich et al.(2008). Numerous researches also used a hierarchical clustering method to generate clusters and investigate usage patterns geographically distributed in the city to understand the impact of the inhomogeneity of the city on the long-run activity of stations (Vogel and Mattfeld, 2011, Lathia, et al., 2012). Brien et al.(2014) proposed a classification of bike-shares, based on the geographical footprint and diurnal, day-of-week and spatial variations in occupancy rates. Etienne and Latifa (2014) present one such automatic algorithm based on a new statistical model which will automatically cluster BSS stations according to their usage profile. Zhou (2015) investigated the spatiotemporal biking pattern in Chicago by analyzing massive BSS data from July to December in 2013 and 2014, constructed bike flow similarity graph and used a fast greedy algorithm to detect spatial communities of biking flows.

(3)Thirdly, study on demand estimation and corresponding methodology. These studies examine the influence of BSS infrastructure, transportation network infrastructure, land use and urban form, meteorological data, and temporal characteristics on BSS usage. This is the most relevant reference for this research. Faghih-Imani et al.(2014) collect station-level occupancy data from two cities and transform station occupancy snapshot data into station level customer arrivals and departures to perform our analysis. develop a mixed linear model to estimate the influence of bicycle infrastructure, socio-demographic characteristics and land-use characteristics on customer arrivals and departures. In the work of Krykewycz, et al.(2010) various demographic, land use, and infrastructure factors understood to be favorable for bike share usage were spatially analyzed to define a primary market area. El-Assiet al.(2017) investigate the effects of weather, socio-economic and demographic factors, as well as land use and the built environment on bicycle share ridership, a regression analysis was performed on three different levels. Hampshire and Marla(2012) explaining the factors affecting the bike sharing trip generation and attraction. Using usage data from bike sharing systems in Barcelona and Seville, 9 census level demographic data, and the location of points of interest, employ a panel regression model to produce consistent estimates of trip generation and attraction factors in the presence of unobserved spatial and temporal variables. Zhang et al.(2017) employed a multiple linear regression model to examine the influence of built environment variables on trip demand as well as on the ratio of demand to supply at bike stations in China. Faghih-Imani et al.(2014) investigated factors affecting bicycle share demand at the station level using real-time ridership data. The results showed that stations close to major roads had lower trip activities compared to stations that were situated

around minor roads and bicycle lanes. A number of land use and built environment variables, temporal characteristics and weather variables such as temperature were investigated. Maurer(2011) used a pair-wise suitability analysis to understand the effects of variables such as job density, household income, and alternative commuters on public bicycle share ridership to propose the locations of bicycle stations in Sacramento, California. Gebhart and Noland(2014) used real-time ridership data for Capital Bikeshare in Washington D.C. to investigate the impact of weather variables and proximity of bike share stations to metro stations on ridership levels. Buck and Buehler (2012) investigated the influence of bicycle infrastructure, population density, land use mix around stations, and the number of households without a car using bicycle share systems using ridership data from Capital Bikeshare. Wang et al.(2012) evaluated the effect of socio-demographic, land use, built environment and transportation infrastructure variables on bicycle share ridership. Rixey (2013) explored the influence of socio-demographic characteristics such as education, income, and employment and population density on monthly ridership data from three United States.

Most studies focused on the factors affecting the use of public bicycles and the scheduling methods between stations. Since the shared bicycle does not have a centralized station, the starting and ending position of the vehicle is only related to the user's personal travel destination, so the impact of the built-up area on the shared bicycle usage will change. In addition, because the shared bicycle does not have a fixed site, but is dispersed in the city, the network formed by it is extremely complicated; and its more fluid characteristics also makes it difficult to monitor the number of vehicles in real time. In addition, there are significant differences in the number of vehicles used between different regions. Based on the above characteristics of shared bicycles, the original site-based data analysis method and the small network-based global optimization scheduling strategy are difficult to apply to the current shared bicycle.

Therefore, combined with the current use of public bicycles without dock, this paper will focus on the relationship between the parking characteristics of the dockless public bicycles and the built environment. Explore the parking mode of dockless public bicycles under the influence of different built environment factors, and then coordinate the relationship between urban public space and dockless public bicycles, rationally plan bicycle parking facilities, and promote green travel to provide relevant suggestions.

3. Data sources and method

3.1 Data source

3.1.1 The data of bike status

OFO is one of the biggest companies operating dockless bike-sharing systems in China, with a market share of about 50%. OFO bike is equipped with GPS to provide useful, accurate trip data. OFO began operating in Shenzhen in December 2016 with more than 20,000 bicycles in September 2017. This study takes Nanshan district which is one of the city centers of Shenzhen as case study. Nanshan has a high accessible road traffic network with subway and bus system cover the whole area. The climate in Nanshan is also pleasant, so it is very suitable for short-distance travel by bicycle. In order to describe spatial distribution of the dockless public bicycle and compare the parking characteristics between different areas, this study divided Nanshan district into 500m*500m grids with a total of 823 grids.

Grids with an average 24-hour bike less than 10 were removed. Finally, 500 grids were taken into our analysis (Figure 1).

Figure1 the grids of Nanshan District

The raw data were obtained from the OFO website, which contained about 46.5 million pieces of messages including information of trip start time and date, trip end time and date, start location and end location. This study scanned the working status of these bicycles every 5 minutes and got records the working day of the fourth week of September 2017. The data content includes the bicycle ID, the time and date when the bicycle starts to be used, and the bicycle position coordinates. There are about 57.6 million bicycle status records in a day. We determined bicycle parking by identifying unmoved positions and corresponding duration during the day by bike's location and time stamp to explore parking mode.

Table 1 The raw data of OFO using

Time stamp	Bike ID	GPS signal	X	Y
2017-0321T00:13:21	7556118647	1(1-work,2-non-work)	113.884828	22.857536
2017-0321T00:13:21	7556073013	1(1-work,2-non-work)	113.884834	22.857274
...
2017-0321T00:27:44	7556146932	1	113.896694	22.458407

3.1.2 The factors of impacting bike parking

These factors are grouped into four main categories: transportation, land-use/build environment, population-job and meteorological data. Detailed indicators are shown in Table 2.

Table 2 The parking variables and influencing factors

Variable	Calculation	unit
Parking variables		
Parking density	Number of public bicycles parked in a grid at a time	num/ per grid
Parking duration	Average of the parking duration of all parked vehicles in a grid	minutes
Independent variables		
Density of fast way	Length of Expressway in a grid	km/km ²
Density of major& secondary road	Length of Major road and secondary road in a grid	km/km ²
Density of minor road	Length of Minor road in a grid	km/km ²
Bus stops	Number of bus stops in a grid	num/ per grid
Subway	Distance to the nearest subway	m
Population	Number of residents in a grid	1000/ per grid
Job	Number of Enterprise POI in a grid.	num/ 1 grid
Mix used	Information entropy	/
Residential land	Percentage of Residential land in a grid	/
Commercial land	Proportion of Commercial land in a grid	/
Educational Land	Proportion of Educational Land in a grid	/
Green Land	Percentage of Green Land in a grid	/
Building density	Number of building in a grid	num/ per grid
Service facility density	Number of shop and restaurant in a grid	num/ per grid
Altitude	Average altitude of a grid area	m

The parking density of a grid is the parking number of dockless public bicycle in a certain period. We first calculated parking number of each hour, then the average number of 24 hours is the parking density of a grid. The parking duration refers to the time interval value of a single dockless public bicycle from the time of stopping to the next use. The parking duration of a grid is the average of the parking duration of all parked vehicles in a certain period.

The land use mixing degree is to first calculate the area proportion of each type of land use in the grid, and then calculate by the following formula (1):

$$MixUsed = -\frac{\left(\sum_{i=1}^N p_i \ln p_i\right)}{\ln N} \quad (1)$$

p_i ——the percentage of i land type ;

N ——the number of all land types.

The data of subway comes from the website (<http://www.szmc.net>) of Shenzhen Metro Group Co., Ltd. The road net and bus data are provided by Shenzhen Urban Transport Planning Center. The information of population, job and land use is supplied by the Shenzhen Urban Planning Bureau and the Urban Planning and Design Institute of Shenzhen. We use points of interest (POI) data from BAIDU (see www.baidu.com). The terrain data of Shenzhen comes from google map.

3.2 Statistical analysis

First, we calculate the parking density and parking duration of each grid. According to these two attributes, we use the cross-classification method to divide the grid parking type. In this way, each grid corresponds to a parking mode, and then the built environment indicators of each grid are calculated. The multinomial Logit regression model is used to analyze the influencing factors of parking mode and the parking mode preferences in different built environments.

4. Results

4.1 Statistical characteristics

4.1.1 Parking density

62 thousands dockless public bicycles had been parked in Nanshan district for more than 10 minutes, and on average, 49 thousand bicycles parked per hour, which occupied 7.3 ha public space. By grid analysis, the parking density was around 100 bicycles per grid per day, and the maximum number of bicycles in one grid was 575.

Figure 2 shows an uneven spatial distribution of parking density of dockless public bicycles in Nanshan. Obviously, the bicycles were unevenly distributed. The central area had a significant higher density than others because these are the main functional areas of people's daily life, such as living, employment, leisure, transportation, etc. The low-density areas were mainly close to less-developed area, mountain and other bicycle ban zones such as parks and waterfront.

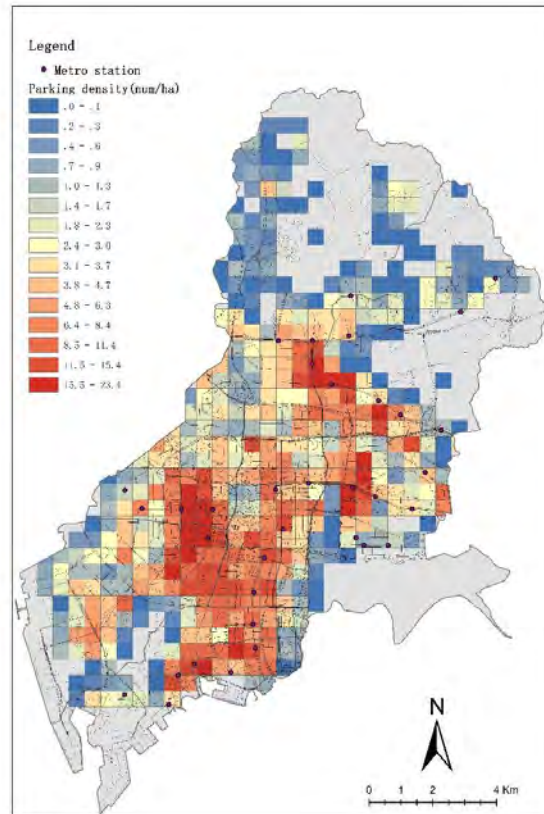

Figure 2 The spatial distribution of parking density of dockless public bicycles in Nanshan

3.1.2 Parking duration

The average parking duration of bicycles was 341 min per time, which meant bicycles were used around every 6 hours. The parking durations of around 10 thousand bicycles were more than 1420 min, which continuously occupied public space whole day. Figure 3 shows the spatial distribution of parking duration of dockless public bicycles in Nanshan. Grids in the center area of Nanshan had a significant shorter parking duration and peripheral grids had a longer parking duration. The short-term parking of grids was mainly in high-tech employment center, universities and commercial centers. These areas are mostly with good location, a large number of enterprises, well-constructed urban roads and mixed land use. In addition, the grid with subway station in has a high probability to be a short-term parking place. The grids with long-term parking were mostly in the suburb areas. The destinations of one-way riding such as Shenzhen-Hong Kong port area also caused long-term parking. By comparing the spatial distribution characteristics of parking density, it can be found that the area with a long parking period generally belongs to the area with a lower parking density.

Figure 3 The spatial distribution of parking duration of dockless public bicycles in Nanshan

3.1.3 Parking patterns by Cross-classification

Figure 4 is a scatter plot of parking density and parking duration, in which X-axis is the parking density, and the origin is the average value of parking density and parking duration. Obviously, parking duration is negatively correlated with parking density. Four quadrants represented different parking characteristics of dockless public bicycles: (1) The grid in the first quadrant had high parking density and long-term parking and we called it **High-High(HH)** parking mode, which meant bicycles were static and dense stacked. (2) The grid in the second quadrant had low parking density and long-term parking. We named it **Low-High (LH)** parking mode, in which the bicycles were not many and inactive. (3) The grid in the third quadrant was the **Low-Low (LL)** parking mode which meant there were a few bicycles but efficiently used. (4) At last, the grid in the fourth quadrant with high parking density and short parking was **High-Low (HL)** parking mode, which was the most active mode.

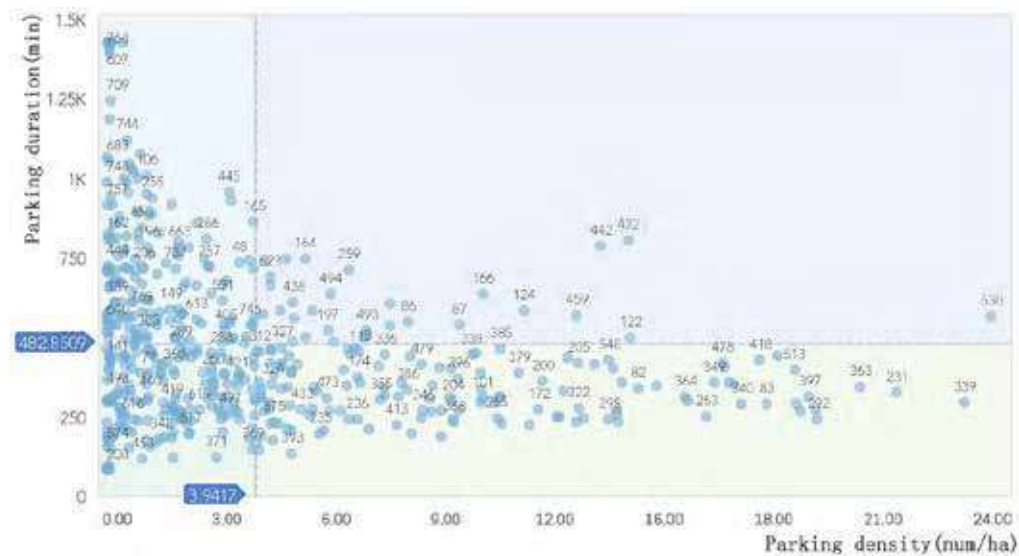

Figure 4 The scatter plot of parking density and parking duration

3.1.4 The spatial distributions of four parking modes

By categorizing the grids by 4 parking modes, the distribution of each parking mode were shown in Figure 5. Among all grids, HH mode accounted for 6%, LH mode had 34%, LL mode accounted for 32% and the left 28% was HL mode.

Table 3 shows the average value of built environment variables for each parking modes. Grids of HH mode had the highest density of fast way and grids of HL had the highest density of all other road types. LH mode grids had the poorest public transportation service (less bus stops and far away from metro station). HL mode was with the highest population and job density, and the LH mode was with the lowest ones. In terms of land use, HL mode had the highest mix use degree, residential land and proportion of commercial land. LL mode had the highest educational facilities and green land. The HL mode also had the highest service facility density followed by LL mode.

Figure 5 The spatial distribution of four dockless public bicycles parking mode in Nanshan

Table3 Statistical characteristics of built environment of four parking modes

Built environment variables	HH	LH	LL	HL
Density of fast way	32.91	14.25	20.06	22.97
Density of major & secondary road	46.10	15.49	27.22	51.01
Density of minor road	62.48	43.65	58.01	79.30

Bus stops	2.52	0.77	1.95	3.90
Subway	1222.15	2019.12	1226.13	672.47

Mix use	0.50	0.39	0.45	0.54
Residential land	0.02	0.02	0.02	0.07
Commercial land	0.03	0.02	0.05	0.06
Educational Land	0.02	0.01	0.09	0.05
Green Land	0.03	0.03	0.05	0.03
Building density	0.10	0.06	0.12	0.21
Service facility density	0.28	0.05	0.35	1.75
Altitude	12.95	35.64	28.02	16.23
Number of grids	31	167	162	140

4.2 The influencing factor of parking mode

A logistic regression model was applied to explore the built environment impacts on parking mode. The LH mode area had low artificial built environment and high altitude which was obviously far away from people's daily life. The number of dockless public bicycle in this area was small. Although the parking duration was long, this would not be a problem to occupy public place. We took LH as the compared group. The results are listed in table 4. The model's likelihood ratio is statistically significant at 0.01 level and the pseudo R square is 0.418.

Table4 Multinomial Logit Estimates Results of Built Environment Factors

(1) Results show that compared with LH parking mode, HH parking mode is with denser high-class roads (fast road, primary and secondary roads), probably because of spatial segregation of bike lanes by high-class roads. Grids with denser bus stops have positive impact on being a HH mode, since bike plus subway is not competitive than bus in these areas. Meanwhile, area with more shops and restaurants are the easier to be HH mode than LH mode. In addition, with the lower the altitude, public bicycles are easily stacked to increase the parking density and parking duration. Therefore, we can infer that it is easy to form a HH parking mode when those areas are separated, bus-oriented, lower and with lots of shops, where the attraction demands are **one-way demands**, to restrain bicycle flows out of the areas. As a result, bicycles in this area stack and cause long-term parking, strongly occupied public space and disturbed people's outdoor activities.

(2) Close to subway station, dense job opportunities, lots of educational land and shops, less mixed land use indicate those special zones such as universities and independent high-tech parks, and form LL parking mode. These regions are normally independent managed, with big scale and closely interrelated, where the demands of dockless public bicycles are limited, clear, stable and continuous, therefore the use of dockless public bicycles is very efficient and the parking duration is short. The public bicycles in this area have less exchange with other areas. LL parking mode is self-sufficient, with the least occupation of public space comparing with other 3 modes.

(3) High-grade urban roads, closer to the subway station, high population density, high density of jobs, high density of shopping and restaurants, and relatively lower the altitude have a significant impact on the HL parking mode. Areas with the combination of the above characteristics will tend to be the core area of people's daily activities and have strong and aggregate demands to use bicycles. To meet the demands, bicycle operators often set up excessive bicycles to serve people at any time. Due to the large travel demand, the dockless public bicycles are used at high frequencies, resulting in a high density, low duration parking feature. At the same time, the bicycles in the area exchange frequently with the bicycles in the surrounding area. In HL mode areas, bicycles are most active, and besides parking space, the turnover space, bike lane and other facilities are urgently needed.

4.3 Suggestions for public space governance to adapt dockless public bicycles

Comparing the parking demand of public space, first, the two parking modes of LH and LL have little impacts on the occupation of public space. For the LH parking mode, a small number of public bicycles are parked in the area for a long time, which is not conducive to the maintenance of public bicycles. Bicycle maintenance and parking spots can be combined to design as part of a public space service facility. For area with LL parking mode, it is necessary to pay attention to changes in land use or transportation facilities in the area, which will cause changes in the demand for public bicycles. Some public space can be reserved as a potential bicycle parking slot. Secondly, HH parking mode and HL parking mode have high pressure on public open space. On the one hand, a multi-level parking facility system can be constructed, combining a centralized and decentralized layout. In areas where public open space is limited, multistory parking can be used. On the other hand, bicycles with less use is a waste of public open space and it is reasonable to control the scale of the dockless public bicycles. In addition, for the HH parking mode area, the considerable bike lane design is necessary to encourage bicycle flow and to overcoming those obstructions from slope and one-way destination.

Besides, the dispatch management of dockless public bicycle is an also important optional strategy for reducing public open space pressure. Dispatch management strategies can be divided into active dispatching and passive dispatching. Active dispatching encourages cyclists to ride public bicycles in the HH area to other areas in need by setting incentives for operators; and passive dispatching is to transport dockless public bicycles from HH area to the demand area by full-time dispatchers and vehicles. This involves vehicle route and bicycles redistribution problem.

In terms of urban spatial management strategy, some public open place should adopt a limited open management strategy for dockless public bicycles, allowing a certain number of dockless public bicycles to enter, which not only does not create pressure on the spatial environment in the region, but also meets people's cycling needs. In some important areas, such as the area within 10m around the entrance and exit of subway station, a no-parking area for public bicycles is set up to prevent public bicycles from occupying safe evacuation space.

5. Conclusions

This paper took Nanshan District in Shenzhen city as a representative case, to analyze the parking characteristics of dockless public bicycles by "parking density" and "parking duration".

For the "parking density" and "parking duration" of sharing bicycles in Nanshan, the short-term parking of grids are mainly high-tech employment centers, universities and commercial entertainment areas. The areas with long-term parking are mostly in the suburb areas close to mountain or construction site. the central area has a significant higher density than others. Based on cross classification, we presented four parking modes, and applied a logistic regression model to explore built environment impacts on parking modes.

The results show that spatial isolation, public transportation, urban centralization, functional zone and attitude all significantly influence the parking modes and cause uneven spatial distribution and uneven uses of dockless bicycles, and cause serious occupation of public space. To improve the efficiency of bicycle parking and reduce the useless occupation, considerable bike lane system to encourage bicycle's flow, compact parking facilities to save space, dispatch management to improve efficiency, diverse policies to ease the burden of public space are all necessary strategies.

“Imagining the future of my neighbourhood”:

Residents’ perceptions of sustainable mobility and regeneration around metro stations in the city of Thessaloniki

³Aristotle University of Thessaloniki, zachariadou@outlook.com

Abstract: New development around public transport stations has long been seen as the main alternative to low-density urban sprawl and car dependent land use patterns. Less attention has been given, however, to involving local residents in the public discussion about the potential of public transport infrastructure for sustainable regeneration of their neighbourhoods. The present paper presents an experiment undertaken to seek out how local residents would actually conceive the future of their neighbourhood and its potential for sustainable regeneration based on the metro which is under construction in the city of Thessaloniki. The experiment focused on two metro stations under construction in two different neighbourhoods in terms of their socio-spatial characteristics. After a questionnaire survey to residents and businesses, two interactive workshops were held on the day of the nearby open market, one in each station. The survey and workshops operated as knowledge production for both sides: the local residents that were helped to envisage the metro as a future challenge and the research team that had to incorporate their expectations into an ongoing pilot urban project. The paper highlights the potential of the use of qualitative methods in the research and planning of sustainable mobility and neighbourhood regeneration.

Keywords: Transit-oriented neighbourhood regeneration; sustainable urban mobility; residents’ perceptions; Thessaloniki metro

1. Introduction

Public transport has long been seen as the backbone of the transition to urban sustainability whereas new development around public transport stations has been proposed as the main alternative to low-density urban sprawl and car dependent land use patterns (Cervero, 2015, Curtis *et al.* 2009, Papagiannakis *et al.*, 2017). Coupling public transport investments and urban development mainly through mixed use development around public transport stations, what is mostly known in the literature as a Transit-Oriented Development (TOD), is one of the more widely accepted policies seen as the undisputed path to achieving efficient and sustainable urban development forms.

As urban areas are continuously experiencing transformations of slow or more rapid paces, urban development characteristics and dynamics, mobility and accessibility patterns and in general a city’s spatial geography are all components which are interconnected in a complex way (Naaes, 2006). In places where new public transport services are provided in existing, compact, mixed-use areas which have been classified by some writers as high-density TODs (Thomas *et al.*, 2018), such transport investments not only transform neighbourhood identity but also reshape the lives of residents, in some cases by forcing the most vulnerable to leave (Chapple and

Loukaitou Sideris, 2019). Therefore, it is crucial to study patterns and changes that occur at a local scale and identify potential strategies that enhance local identity and the sense of space from a resident's perspective.

Among the main objectives of a TOD is to increase the quality of life of the local community inhabitants given that a TOD contributes to increased transport alternatives in congested urban areas, to the reduction of energy consumption and air pollution, to increased safety for pedestrians and cyclists and to the reduction of road accidents (Parker *et al.*, 2002) and consequently to more vibrant communities. Yet, policies that advocate a TOD pattern have given less attention to involving residents in the discussion about the potential of public transport infrastructure for a sustainable regeneration of their own neighbourhoods. It is worth noting here that recent research has shown the impact of compactness within a wider range of urban form typologies and found that the higher the density, the higher the neighbourhood satisfaction due to the main important components of the compact city that is public transport, accessibility to city centre and land use mix (Mouratidis, 2017).

Neighbourhood regeneration strategies are strongly associated to sustainable community development and to the overall sustainability of the cities as it combines multiple social, economic, environmental and institutional objectives (Kafkalas *et al.*, 2015). Additionally, these strategies promote compact forms of development in existing urban areas, while reducing the need for suburban development. The demand for prosperity along with the request for open-endedness and constant re-interpretation of urban places, more important when it concerns small urban spaces, have led to changes in the approaches of local scale planning, aiming to reconsider the quality of public space (Aravot, 2002, Whyte 1980). A subsequent practice of urban regeneration, especially at the neighbourhood level, is the placemaking approach, as this approach is based on working with the local community through participatory forms of planning involving residents and employees in the intervention areas (Laven *et al.*, 2016). In this way, social and economic productivity, and physical improvements are considered more successfully implemented in an area. Promoting local involvement through placemaking policies contributes to the redesign of dominant uses of specific public spaces, such as streets, changing them from simple transport corridors to significant spaces for human activity. Thus, their regeneration as a public space of shared nature, in other words as "shared spaces" (Clarke, 2006, Grey and Siddal, 2012), addresses basic objectives of neighbourhood regeneration such as good connectivity, safety and preservation of social cohesion. Such approaches and tools improve the integration of urban and transport planning by focusing on the implementation of measures that enhance accessibility and quality of the public realm giving priority to local community and vulnerable users.

Thessaloniki is a typical Mediterranean city with high densities and a characteristic mixed-use pattern throughout its main compact area (Yiannakou, 2013). Since 2008, a metro transport system is under construction passing through the most densely and mixed-use parts of the inner city. Thessaloniki Metro has been for years a politically controversial mega-project as financial and other critical obstacles, especially major archaeological findings, led to a very slow pace of its construction. Degradation images and closures of many businesses in the surrounding areas have dominated the perception of local residents for this mega-project, almost exclusively conceived as a problem within the city's heart and less as a potential of upgrading the local quality of life.

Taking into consideration this dominant image of the residents regarding the metro under construction, the paper presents an experiment undertaken to seek out how local residents would actually conceive the future of their neighbourhood and its potential for sustainable regeneration based on the metro which is under construction in the city of Thessaloniki. The experiment focused on two new metro stations (currently under construction) in two different neighbourhoods of the city. For the needs of the study, a questionnaire survey to residents and businesses was initially undertaken followed by two interactive workshops that were held on the day of the nearby open market, one in each station. A profile of the study areas and the methodology followed is presented in the second section while the third section analyses the findings and discusses the main results of both the survey and the workshops.

2. A profile of the study areas and the methodology of the case study

For the purpose of the case study, two different neighbourhoods were selected within the dense compact area of Thessaloniki with different, however, socio-spatial characteristics: the first one (Patrikiou Station study area) is located within the older, typically residential, inner part of Thessaloniki, a former middle class area which has been gradually deprived over the last decades; the second one (Kalamaria Station study area) is located in one of the main municipal centres of Thessaloniki, a typical middle class area in the compact city.

a. Study area of Patrikiou Station

The study area of Patrikiou Station (Figure 1), located in the east part of the Municipality of Thessaloniki, the central and largest municipality of the city, is a typical compact and high density residential inner-city area. Densities in the area range between 600 and 700 inhabitants per Ha, with buildings up to 5 floors and mainly of an age of 40-50 years old. At a ground floor level, most uses consist of multiple retail outlets, freelancers, services and utilities which serve daily needs of local residents. A considerable number of the ground floor outlets are closed, without any use, which is partly due to the economic crisis of the country since 2010. Within walking distance of less than 10-minute walk of the metro station under construction, there are facilities of leisure, sports and green areas with the most significant one the Mina Patrikiou park, a neighbourhood park and one of its most characteristic public spaces. The study area is located within the wider zone of influence of nearby coastal zone of the city, known as Nea Paralia, which offers recreation facilities and activities for the residents of the entire east and south east part of the compact city. The study area is crossed by two main roads of the city (Vasilissis Olgas and Delphon), one of which functions as a major arterial and entrance to the city and the second as one of its minor arterials. In terms of the mobility characteristics, the proximity of the area to public transport services (bus lines) is quite satisfactory. However, it lacks an integrated pedestrian and biking network.

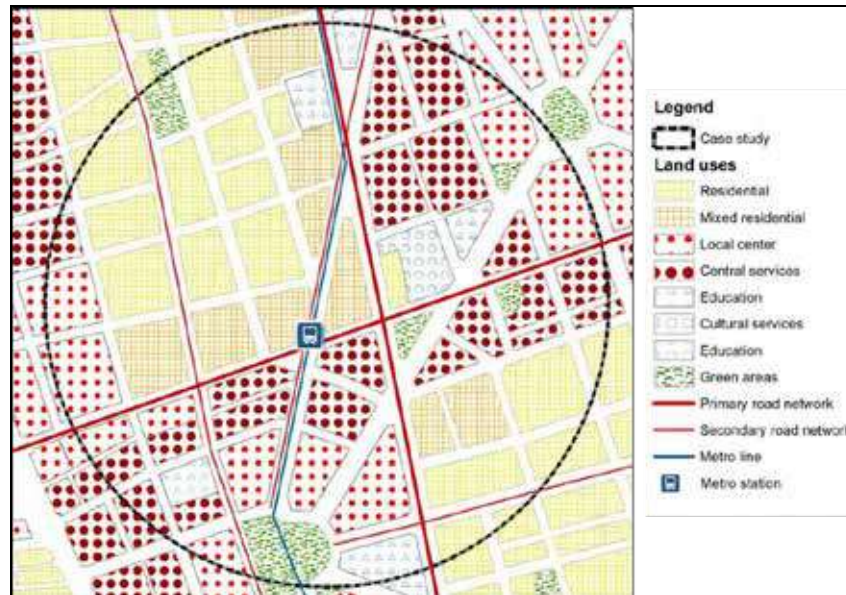

Figure 1: Land uses in Patrikiou Station study area

b. Study area of Kalamaria Station

The study area of Kalamaria Station (Figure 2) is located in the centre of the Municipality of Kalamaria, situated in the south east compact area of Thessaloniki. This study area is also distinguished by mixed uses of a local centre nature that are developed along a pedestrian zone as well as other main streets of the area. The area is compact with rather lower densities ranging between 120 to 270 inhabitants per Ha, with buildings of 4-5 floors and mainly of an age of 20-40 years old. The immediate zone of influence of the metro station bears common urban characteristics with those of Patrikiou Station area. At a ground floor level, there are multiple commercial and recreational uses as well as education, care and cultural services all developing along the main road axis (Metamorphoseos, Aigaίου and Pontou). In the case of Kalamaria Station study area, there is a much smaller number of closed stores without use comparing with that of Patrikiou Station, along with a greater number of residential ground floor uses and parking lots. Regarding the mobility characteristics, the area is also characterized by satisfying accessibility and proximity to public transport (bus lines). Despite the long length pedestrianized streets of Metamorphoseos and Kominon, the wider area lacks an integrated pedestrian and biking network.

Figure 2: Land uses in Kalamaria Station study area

c. Methodology

The methodology of the present case study included the following three steps: 1) An analysis of the two study areas based on field recording and mapping of their critical urban and mobility characteristics. 2) A questionnaire survey in order to understand the main characteristics of the users of the study areas, to evaluate these areas based on the respondents' perceptions about the local problems and to record their views and expectations regarding the potential of upgrading the neighbourhood around the future metro stations. The questionnaire survey was held in the first week of December 2017 and was addressed to a sample of 180 people (90 questionnaires in each study area) who work, live and visit the two study areas. The questionnaires were conducted in public places, retail and leisure stores of the study areas. 3) The organization of two participatory workshops, in order to involve people living, working and visiting the study areas in a future neighbourhood regeneration project based on the metro stations.

Regarding the third step, in order to make sure that people would participate in some way or another, both workshops were held as open interactive events organizing the whole event as part of people's regular activity in

their neighbourhoods. Thus, the two workshops were conducted on a day when the weekly open market is held in the study areas. The workshops were promoted with the slogans “Imagining the future of my neighbourhood” and “The Metro in our neighbourhood: I participate, I propose, I make the place where I live” and were carried out in cooperation with the Municipalities of Thessaloniki and Kalamaria and with the support of the company responsible for the construction of the metro project, Attiko Metro SA. The events took place in 6 and 14 June 2018. A total of 150 people took part in the events, 76 and 74 people at Patrikiou and Kalamaria Station areas respectively. During the events, the participants were invited to express their everyday difficulties encountered in their neighbourhood and their perception on how these problems affect the quality of the urban environment, the local economic activities, the identity of the area, the mobility patterns and the housing prices. They were also asked to state their suggestions and expectations for future regeneration interventions envisioning their neighbourhood after the accomplishment of the metro construction.

The study group provided the participants with guidelines for the evaluation of the areas as well as example ideas in order to encourage them to take part in the event. The participatory process included the use of post-it notes, where participants could write down specific problems as well as their personal ideas for a future regeneration plan. On satellite maps of the study areas the participants could assess specific places that they consider problematic, attractive or prosperous as well as their own proposals for the regeneration of the study areas. In the proposal maps, participants were able to mark up the zones which they prefer to be developed with commercial uses, leisure uses, green areas, as well as the creation of traffic calming or pedestrian streets.

3. Main findings

Table 1 presents the main characteristics of the respondents in the questionnaire survey in both study areas. The findings from the field research as well as the results from the questionnaire survey were mapped (Figures 3 and 4) in order to understand critical issues and correlate them with the results of the participatory workshops.

Table 1: Sample characteristics

Gender	Female	Male					
Patrikiou	52%	48%					
Kalamaria	41%	59%					
Age range	16-24	25-34	35-49	50-64	65+		
Patrikiou	11%	27%	31%	26%	5%		
Kalamaria	36%	18%	23%	14%			
Profession	Free lancer	Retired	Unemployed	Public servant	Private servant	Student	Household
Patrikiou	38.7%	5.6%	5%	37.1%	2%	8.2%	3.4%
Kalamaria	21.4%	10%	2%	11.3%	24.3%	22.9%	8.1%
Annual income (€)	0-5,000	5,000-10,000	10.000-20,000	20.000-40,000			
Patrikiou	53%	36%	8%	3%			
Kalamaria	51%	29%	4%	6%			
Status of Respondents	Residents	People working in the area	People visiting the area				
Patrikiou	56%	35%	9%				
Kalamaria	70%	22%	9%				

Looking into the main findings from Patrikiou Station study area (Table 2, Figure 3), it can be observed that, according to the users, the area is well accessible due to its easy connection to the city centre by public

transport. However, they indicate the lack of an integrated pedestrian and bicycle network. The users think the operation of the metro in the area will allow public transport multimodality, as the area will be served by metro and bus connections. A notable problem for the users is the lack of parking spaces and of an integrated parking management plan for residents and visitors. Real estate prices, which are considered to be ranging at low levels due to the economic crisis, are expected to increase up to 20% with the launch of the metro. Finally, the area was evaluated as having considerable open and free spaces and greenery areas, with the presence of Mina Patrikiou park, in about 5 minutes' walk from the station.

Table 2: A summary of the results of the questionnaire survey

	Evaluation of Patrikiou				Evaluation of Kalamaria			
	Dissatisfied	Partly Satisfied	Satisfied	Very Satisfied	Dissatisfied	Partly Satisfied	Satisfied	Very Satisfied
Degree of satisfaction by public transport	14%	29%	52%	5%	14%	29%	52%	5%
	High		Low		High		Low	
Housing price rates	78%		22%		80%		20%	
Distance from the city center	73%		27%		56%		44%	
	Sufficiency		Absence		Sufficiency		Absence	
Green areas	12%		88%		15%		85%	
Public spaces	20%		80%		46%		64%	
Parking spaces	24%		76%		41%		59%	
Pavement quality	40%		60%		35%		65%	

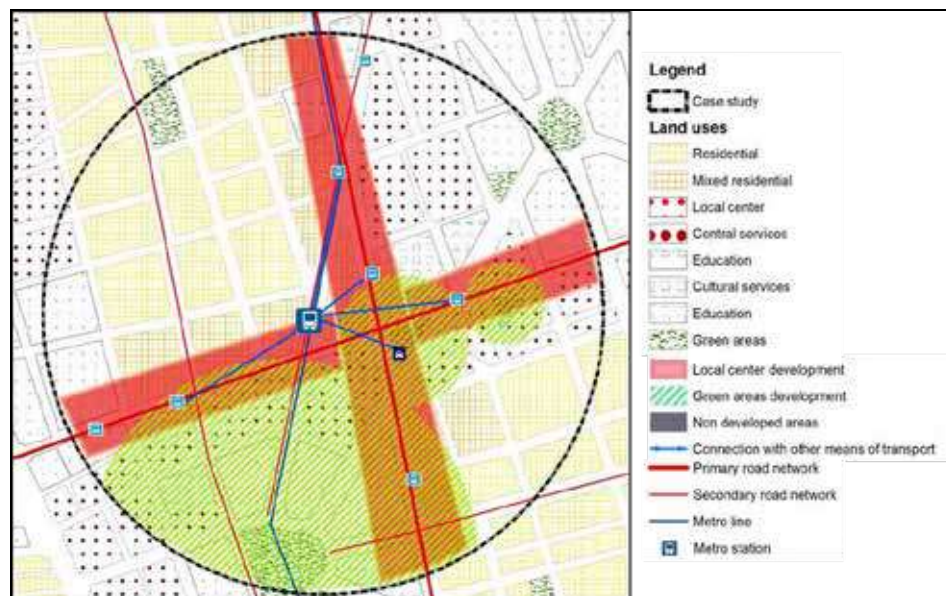

Figure 3: Evaluation map of the Patrikiou Station study area

Regarding the main findings from Kalamaria Station study area, the users find as the most forceful characteristic of the area the main pedestrian street which is the most central and vibrant street of the municipality with

immediate proximity to the station. The connectivity of the area to the centre of Thessaloniki is also considered satisfactory, although the area is in larger distance from the city centre than the Patrikiou Station one. It was also stated that the proximity of the bus stops from the station will enhance public transport intermodality. The users agree that the lack of parking space in the area makes necessary the implementation of a parking management plan. Regarding open space and green areas in the zone of influence of the station, residents and visitors seem to enjoy the operation of the central pedestrian street which functions as the urban centre of the municipality. Housing prices in the area are higher than the ones in Patrikiou Station, however, a decline in the prices during the last years as a result of the financial crisis was also recorded. These prices are expected to change due to the metro operation in the area, with an increase of 20% -25%.

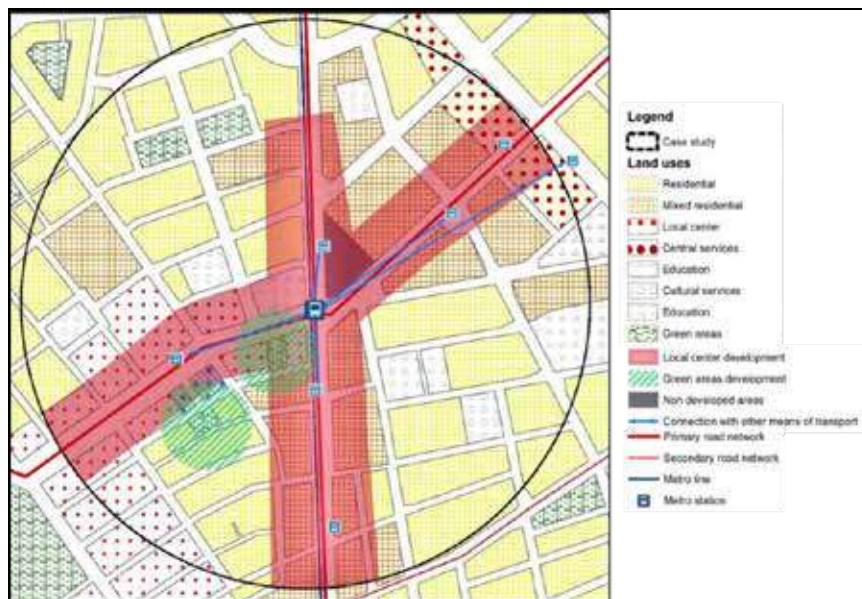

Figure 4: Evaluation map of Kalamaria Station study area

Based on the results underlined from the workshop "The Metro in our neighbourhood", in Patrikiou Station study area the participants noted more or less all the above mentioned problems that were identified in the evaluation based on the questionnaire survey and made the following specific suggestions regarding the regeneration of their neighbourhood and the public realm enhancement:

- Maintenance of the pavements and construction of necessary facilities for people with disabilities
- Establishment of a bicycle network and creation of parking facilities next to the station area
- Implementation of a parking management plan and development of parking spaces also suitable for disabled people
- Redesign of the Mina Patrikiou park with standards oriented to children and disabled people
- Informative signs, either with information about the area and the available public infrastructure and how people could make the best of it
- Protection and enhancement of all open and green areas and more specifically of the Mina Patrikiou park.

As mentioned above, during the event the participants were asked to mark on a map the preferable type of development in the area (commercial, recreational, green uses, traffic calming streets or shared spaces) (Figure

5). The majority of the participants proposed to pedestrianize or implement traffic-calming measures on Solonos street, as well traffic-calming or shared space measures around the Mina Patrikiou park in order to protect children playing in the park during the day. A smaller percentage of participants suggested to pedestrianize or implement traffic-calming measures on Kritis street in order to restore economic vitality in the area. Both these streets function today as collector roads and are congested with parking. Similar suggestions were made for specific local streets aiming to protect children crossing these streets to access their school.

Figure 5: Invitation poster and map with the participants' proposals (Patrikiou Station study area)

Regarding commercial development, the majority of participants stated that greater development of commercial functions after the metro operation should be promoted in the streets Solonos, 25 Martiou and Delphon, as they represent the main arterial or collector roads of the area and they are directly connected with the station. In addition, it was highlighted that Kritis street, the street that trespasses the study area, which has also been stated as downgraded zone with a decrease of commercial stores due to economic crisis in the last years, is expected to be upgraded after the operation of the metro. Considering green areas that should be developed, the participants stressed the lack of greenery mainly on 25 Martiou street as well as on the local streets Chalkidikis, Alexandrias and Christovasili. In addition, they mentioned that the metro will affect positively the aesthetic and environmental enhancement of nearby Mina Patrikiou park, which is and the most popular area during the day.

In the case of Kalamaria Station study area, the results of the workshop "The Metro in our neighbourhood", underlined the following suggestions regarding the regeneration of this neighbourhood and the public realm enhancement:

- Restructuring the mobility patterns of the area oriented to pedestrians, to children and to people with disabilities
- Development of an integrated bicycle network
- Implementation of a parking management plan and parking facilities near the station as well as construction of underground parking infrastructure in connection with the station
- Redesign of an open parking space into a green space with an underground parking
- Playgrounds installation on the parks

The majority of the participants suggested the implementation of traffic-calming measures in Aigaiou and Pontou streets in order to reduce the speed of the vehicle and protect pedestrians. Furthermore, it was suggested to pedestrianize most of the local streets (Soumelas, Vazelonos, Iasonidou, Kyriakidou) which are connected to the main pedestrian street Metamorphoseos, because they have very narrow sidewalks. In the new car free streets, only residents would be allowed to park their vehicles and as a result, the walkability will be improved.

Figure 6: Invitation poster and map with the participants' proposals (Kalamaria Station)

Most participants stated that the greatest development of commercial functions after the operation of the metro will take place on the main arterials Pontou and Aigaiou as well as in the part of Metamorphoseos which is today closed due to metro construction. As they acknowledged, this will arise as result of their proximity with the station. A significant observation for the case study is that most of the participants claimed that the area is full of commercial and leisure stores in the main pedestrianized zone of Metamorphoseos and Komninon streets and therefore there is no need for further development of such land uses in the area. Regarding the development of green areas, the participants stressed the importance of the sustainable upgrade of the outdoor parking area between the streets Chaldias, Karolidou, Kiouptsidou, with the creation of a park and underground parking. Finally, a smaller percentage of participants suggested the redesign of an existing park between the streets of Metamorphoseos, Amisou and Soumela.

4. Discussion and conclusions

Public participation represents a tool whereby the community can express its needs and desires. Incorporating a public participation process regarding new policies or policy changes for sustainable mobility and neighbourhood regeneration, is one step, and perhaps the 'easy' one as the real challenge is 'implementation' (Public Participation and Citizen Engagement, 2015). So, the main purpose of the present paper was in fact to bring experimentally into the broad public the question of the future of their neighborhood in connection to a large transit infrastructure under construction, which for years was creating negative attitudes on behalf of the local residents due to its impacts during the construction stage. This experiment attempted to study whether we can build a broad local support to such big projects through a neighborhood regeneration plan around public transport, in other words through a transit-oriented regeneration, and through that to urge for the implementation of more sustainable forms of development and mobility at the local scale.

Figure 7: Pictures from the two citizen workshops

The overall results of both the questionnaire survey and the workshops indicated that in both study areas a TOD regeneration plan based on the metro station were very welcome by the citizens involved. As a matter of fact, it was notable that the citizens didn't comment at all on the problems and impacts of the construction of the metro.

The most important benefit of applying such a methodology was the interactive education between planners and participants. Planners can educate and inspire participants by explaining the planning guidelines and presenting already successful examples, and therefore participants can express ideas, problems and needs that the planner missed or haven't taken into consideration. In an effective public participation, citizens' involvement can result in better and more informed decisions and thereby, generate durable and sustainable solutions. It goes without question that an authentic public participation requires rethinking the underlying roles of, and relations between the involved parties (King *et al.*, 1998) such as the citizens, experts and public authorities. The survey and workshops of the present research operated as knowledge production for both sides: the local residents that were helped to envisage the metro as a future challenge and the research team that had to incorporate their expectations into an ongoing pilot urban project. Public involvement in the present research, through questionnaire surveys and interactive workshops, showed the potential of the use of qualitative methods in the research and planning of sustainable mobility and neighbourhood regeneration. Furthermore, these methods helped to identify different types of citizens and the way they may affect or be affected by decisions taken in the process. Overall, such an approach can enable to integrate local knowledge into urban planning and regeneration policies (Berman, 2017).

Public involvement includes the promise to the public that its contribution will influence decisions in a planning process and thereby represents a way of building trust between local government and citizens. For such an experiment to be useful and effective further elaboration is necessary to draw the attention of the local authorities and encourage the drawing of a neighbourhood plan and the implementation of specific interventions based on placemaking practices and advocating for social, human-scale places. It is also important to ascertain that the citizens' individual ideas will be implemented in some way or another and that closer attention will be paid to their needs and desires. Planning a sustainable neighbourhood based on the citizens' perspective

represents a tool for upgrading public space with an emphasis on human scale. It is a policy of revitalizing public space in cooperation with its users and residents, aiming at the creation of attractive places that will satisfy their needs. A collaboration between residents, planners and decision-makers along with a continuous contact and communication among them can increase the added value and may bring significant positive effects at the local scale as well of large scale public transport investments which usually are evaluated only by their contribution to city and metropolitan scale development.

Abstract: This dissertation seeks to analyse how the integrated land-use and transport planning could contribute achieving sustainable urban form. It has been evidenced that there is a close interrelationship existing between land use and transport. Moreover, it is essential to evaluate the effectiveness of planning practice for achieving a more sustainable future from an integrated perspective of land use and transport. London Kings' Cross and Olympic Legacy have been selected as two studying cases, as London can be regarded as an excellent research platform with the well-developed planning system. In general, this study will analyse and explain the contribution of integrated land-use and transport planning for sustainable urban form in three levels. Firstly, the theoretical relationship between sustainable urban form and its influencing factors will be summarised. Then, the primary planning principles will be summed up through the analysis of integrated planning strategies. Finally, the effectiveness of planning practice will be assessed through the case-specific planning policies. The conclusion in various levels will improve the connection between theoretical research and planning practice for achieving sustainable urban form through integrated land-use and transport planning.

Keywords: Sustainable urban form, Integrated land-use transport planning, London King's Cross, London Olympic Legacy

1. Introduction

1.1 Theoretical background and purpose of study

In the 21st century, urban sustainability is regarded as a crucial issue for the development of human society. It is evidenced that the integrated efforts of land-use and transport planning usually have significantly positive impacts on sustainability in an urban context, which is also regarded as the achievement of the sustainable urban form (Mason, 1994). The definition of sustainable development and its relationship to the urban context is a priority to understand the concept of sustainable urban form (SUF). Since the conference of World Commission on Environment and Development (Brundtland, 1987), the universally accepted definition of sustainable development is described as an event which is capable of meeting today's needs without compromising the ability of future generations to meet their own needs. Previous research has revealed that shifts in behaviour and attitudes could significantly affect the acceptance of urban sustainability. Implicitly, manipulating land uses which support potential reductions in transport emissions should be one of the most effective methods of achieving sustainable urban development.

1.2 Research question

The principal aim of this paper seeks to answer the question of how could urban planners and policy-makers promote sustainable development in planning practice from the viewpoint of integrated land-use and transport planning (ILUTP). The interrelationship between sustainable urban form (SUF) and integrated land-use transport planning (ILUTP) will be established to explain how land-use and transport planning could collaboratively contribute to SUF in planning practice.

1.3 Overview of study process and significance of the study

Firstly, main influencing factors in achieving SUF will be critically analysed to explain why the relationship between land use and transport planning is vital in achieving SUF. Secondly, a literature review about the theories of the land-use transport interaction will be discussed to explain the interrelationship between land-use and transport planning system. Strategic planning policies will then be reviewed to classify main planning principles for achieving SUF. According to the analysis of strategic planning policies, case-specific policies of two study cases will be comparatively analysed. Finally, the contribution of ILUTP to achieve SUF will be assessed.

The primary contribution of this research may be to further explore the correlation between land-use planning system and transport planning system for make SUF successful. On the other side, the comparative analysis of case-specific planning policies in two study cases will help to define similar and different focuses on integrated principles in achieving SUF.

2. Literature review and criticism

2.1 Theories about sustainable urban form

It is hard to identify which urban form is most sustainable for development in cities. Williams et al. (2000) argued that certain types of urban forms could be more sustainable in some respects, involving

reduced travel demand and green energy usage, but detrimental in others, perhaps in causing social inequalities. In fact, the concept of sustainability covers a variety of aspects. It is necessary to analyse the connections between urban form and various sustainable features at different geographical scales.

Figure 2.1(a) Egan wheel: Key components of sustainable communities. Source: Mazni et al, (2010)

From the perspective of planning sustainable community, Egan (2004) reviewed a series of key components in sustainable place making, which involves transport, ecosystem, economy, social equity, housing, governance, public services, and the built environment (Figure 2.1a). However, addressing key sustainable components appropriately in urban development can be challenging due to the complexity of the large cities.

Clearly, sustainability is not just dependent on physical form alone. However, expectations about the magnitude of an urban form's influence on sustainability are significant. Manipulating land uses could be regarded as an effective method of achieving sustainability especially for the sustainable transport systems in urban areas (Williams et al. 2000). Presently, there are two basic types of urban development patterns:

- **Compact city pattern**

The compact city pattern implies intensive land use patterns and a predominantly monocentric urban structure. The high density, the high spatial accessibility, and the high share of non-car travel modes could be expected in the compact city. From the perspective of energy efficiency, the compact city form is recognised as having the most efficient land use and transport systems by the Green Paper on the Urban Environment, which claims European policies on SUF (Brundtland, 1987).

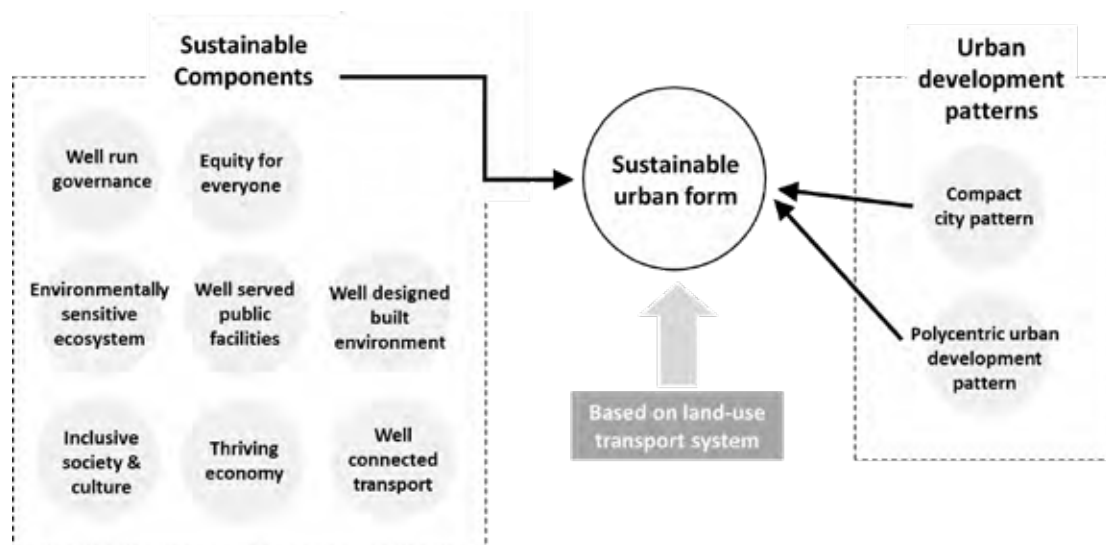

- **Polycentric urban development pattern**

The polycentric urban development pattern pursues a relatively high density around a central core that is surrounded by local employment and business centres. Development is restricted to the central zones adjacent to the sub-centres while a vital role for the central inner city is retained. As a result, high accessibility of primary facilities by non-car mode can be ensured, and more open spaces within the metropolitan area can be preserved (Wegener and Fürst, 2004).

Though a variety of urban development patterns have been proposed as theoretically sustainable urban forms based on sustainable land-use patterns and transport systems, there is not a clear consensus about which type of urban development pattern is preferable for achieving SUF. The different development histories of metropolitan areas, such as London or New York, make the urban development pattern significantly diverse. SUF cannot be designed as a specific type of form affected by the pre-existing historical urban development patterns. For different cities, urban planner and policy-makers will determine different pathways of sustainable development. But there is still a common agreement for urban planners and policy-makers.

From the perspective of transport, SUF could be regarded as a type of urban development pattern which significantly promotes a sustainable travel system regarding the considerable reduction in energy consumption and an increase of the journey efficiency and road safety. In any case, a highly sustainable land-use pattern and transport system can be regarded as the cornerstone for SUF (Figure 2.1b), which is why research on SUF should focus on the interactive relationship between land use and transport.

Figure 2.1(b) The composition aspects of SUF, from the perspective of sustainable components and urban development patterns. Source: Made by author

Meanwhile, there is some practical analysis of SUF including the compact city pattern, urban villages pattern, mixed-use neighbourhood pattern, and the adaptable city pattern. Burton (2000) and Williams (1999) concluded that urban compactness achieved through higher residential density and mix of land use could promote greater public transport usage and social communications in town centres. Newton (1997) discussed some different urban forms beyond the distinction between compact and dispersed city form. He recommended the concept of the urban village located near public transport infrastructure as an ideal form for small-scale towns focusing on reduced travel distance and low-carbon emission.

Masnavi (1998) emphasised the variables of density and mix of uses as key influencing factors in achieving sustainable neighbourhoods, which significantly affect travel behaviour and attitudes of residents regarding travel mode choices, social interaction, and their perceptions of environmental quality. Besides, urban adaptability, which means the ability of different urban forms to adapt over time to the increase of travel need and land-use density is also discussed in the SUF debate. It is evidenced that particular shapes and sizes of urban grid, such as regular grid, adapt well to the urban change in density and travel patterns. (Scoffham and Vale, 1996).

In combination, considerable amounts of research have been conducted revealing the most effective development patterns for a more SUF. The research elements based on land use characteristic have positive impacts on sustainable travel patterns and travel behaviour (Table 2.1a).

Table 2.1(a) Aspects of sustainable development and their impacts

Elements of sustainable development pattern	Possible impacts
<i>High density;</i> <i>Mix of land uses</i>	Improve public transport usage with good accessibility to transport facilities; Improve social communications through design of active street space
<i>Small neighbourhood size;</i> <i>Neighbourhood location around town centres</i>	Decrease travel distance with commensurate lowering of carbon emission
<i>High density;</i> <i>Mix of land uses</i>	Improve travel mode choice, but only if the transport options are provided; Increase social interaction
<i>Regular urban grid which promotes the increase of density;</i> <i>Small-size block which is easily redeveloped into walking block</i>	Increase density, easily adapt to changing travel patterns

Besides, Newman and Kenworthy (1999) argued that the compact city development pattern could only have limited impact on sustainable travel behaviour if the travel strategies restricted car usage and improved travel mode choices. It is asserted that proximity to travel destinations did not have a significant influence on travel mode choices without considering travel purpose. Van and Senior (2000) argued that mixed-use and high-quality neighbourhood design with more accessible walking and cycling routes could encourage sustainable mode choices and reduce car dependency for daily shopping needs.

Based on the analysis of planning policy on transport, the relationship between urban form and travel patterns is criticised at the regional scale. Headicar (2003) concluded that the travel patterns are not just related to the size of neighbourhoods. It is suggested that residential density should be strategically considered, for example, in connecting to town centres or employment centres. Stead et al. (2000) speculated that if the location strategies for settlements catered to increased travel demand for work and shopping by offering more sustainable mode choices, then a greater reduction in car use and energy consumption will be achieved at the urban scale.

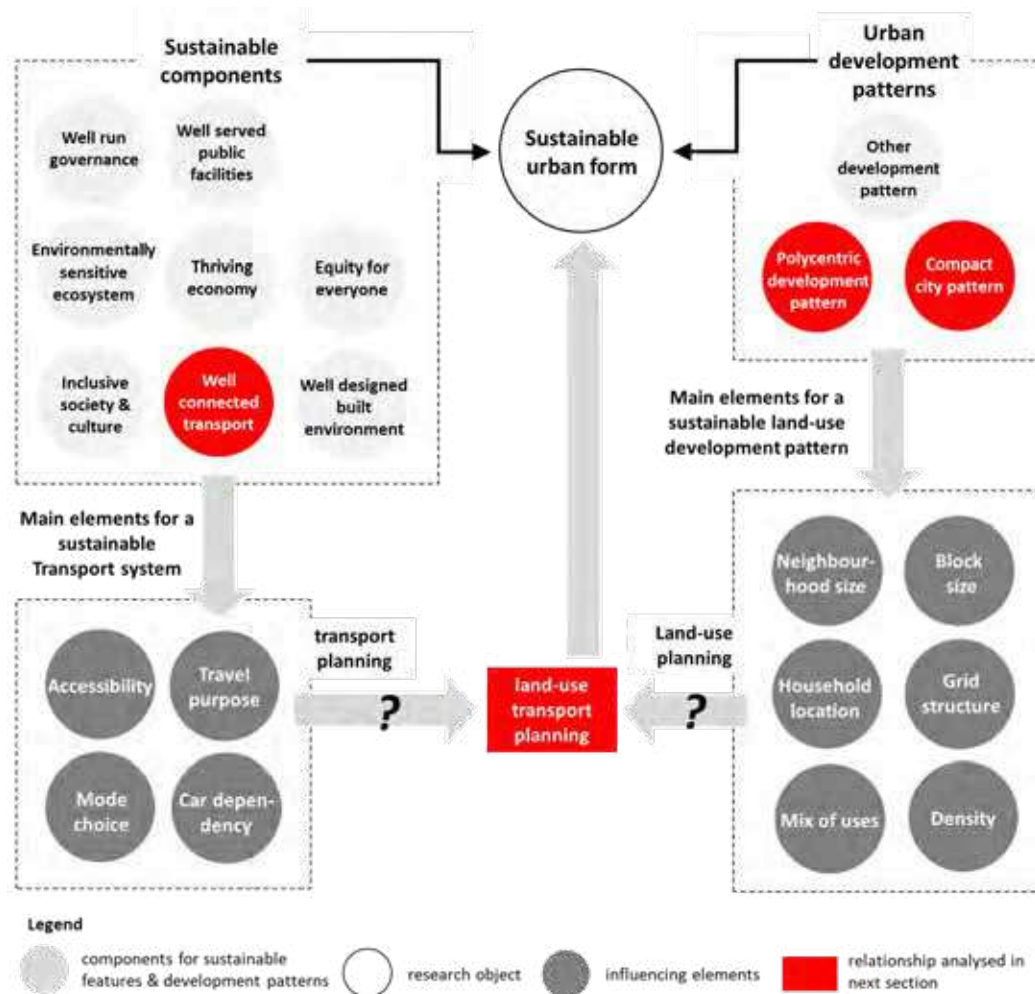

Overall, the main elements of a sustainable transport system have been illustrated (Table 2.1b), among which higher density development, good spatial accessibility to public transport, mixed land use, more travel mode choices, and proactive household location are key, and these elements could have evident influences on sustainable travel patterns and behaviour in achieving more SUF.

Table 2.1(b) Aspects of sustainable transport system and their impacts

Elements of a sustainable transport system	Possible impacts
<i>Reduce car usage;</i> <i>Create more travel mode choices;</i> <i>Focus on travel purpose and distance of work and shopping</i>	More sustainable mode choices may result, such as walking, cycling and public transport
<i>Increase the mix of land use;</i> <i>Improve neighbourhood design for cycling and walking</i>	More sustainable mode choices for travel generated by shopping; Reduce car uses for daily shopping
<i>Large neighbourhood size with good connection with transport infrastructures;</i> <i>High residential density</i>	Promote the transport accessibility and attractiveness of public transport
<i>Household locations;</i> <i>Accessibility of public transport;</i> <i>Create more travel mode choices</i>	Reduce car uses which then reduces energy consumption

In fact, all research discussed previously co-determine the sustainability of urban development patterns and transport patterns (Williams et al. 2000). The interrelationship between transport planning system and land-use planning system need be explored further through the integrated planning view of land use and transport system (Figure 2.1c).

Figure 2.1(c) The potential interrelationship between SUF, land-use planning system and transport planning system. Source: Made by author

2.2 Theories about the land-use and transport interaction

Theories concerning the interaction between land-use and transport planning system involve technical, behavioural, and strategic dimensions. For example, land use has impacts on travel behaviour. Meanwhile, transport could influence the location behaviour of firms and households. But issues of coordination between land-use and transport planning in different urban contexts are still less well known (Wegener and Fürst, 2004).

According to the EU research project, 'Transland' which evaluates strategic policies and their impacts on future urban developments in the field of integrated transport and land-use planning, theoretical and conceptual work on the integration of land use and transport has been reviewed. Theories on the two-way interaction are put forward to address the locational and mobility responses, involving households, travellers and firms, to changes in the land use and transport system. It is proposed that land-use and transport planning should be seen as an integrated mechanism, producing the land-use transport feedback cycle (Figure 2.2a). The mechanism in this 'cycle' is based on a set of relationships including the distribution of land uses, human activities, transport infrastructure, and spatial accessibility.

Figure 2.2(a) The land-use/ transport feedback cycle to illustrate the land use/ transport mechanism. Source: Made by author, Wegener and Fürst, (2004).

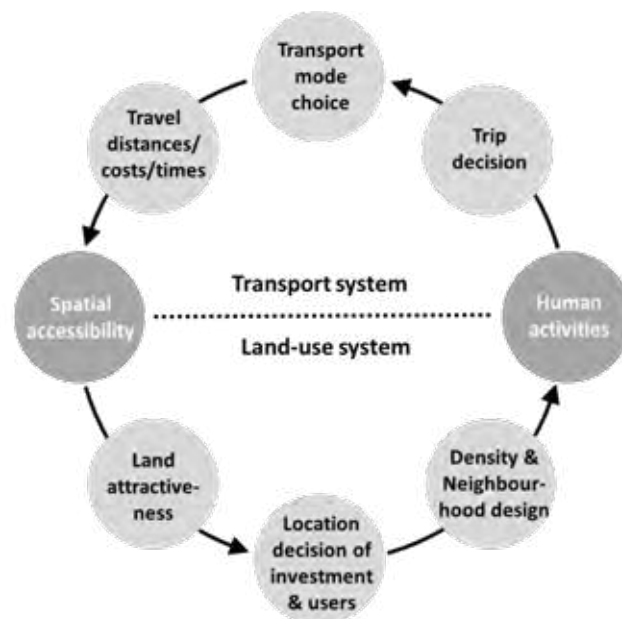

The results of the land-use and transport interaction are expressed concerning expected impacts on urban density, employment density, neighbourhood and open space design, development locations, accessibility, and travel cost/ time (Figure 2.2b). There are two influencing directions in this interactive mechanism, which is the impact of land use policies on transport behaviour and the impacts of transport policies on land use outcomes. It is summarised that the impacts of land use policy on transport behaviour could be reflected through the traffic variables such as trip length, mode choice, and travel cost. Besides, the impacts of transport policy on land use characteristics could be mainly measured by the location decisions reflected in different land-use categories.

Figure 2.2(b) Expected influencing factors within land use/ transport mechanism. Source: Made by author, Wegener and Fürst, (2004).

In general, the current research has explored a two-way interactive paradigm of urban development, which consists of four main elements including the land use system, human activities, the transport system and spatial accessibility. Land-use planning policy is regarded as an important factor to generate travel demands, while transport planning policy has an inevitable influence on the changes in land use because of diverse location decisions of investments in future development. Moreover, changes in land use characteristics will further generate more travel demands and inevitably have impacts on current transport behaviour. Thus, the dynamic relationship between the land use system and the transport system have been established (Figure 2.2c). Based on this interactive relationship, the interrelationship between SUF and the specific influencing factors can be established.

Figure 2.2(c) Dynamic relationship between the land use system and the transport system. Source: Made by author, based on an article by Wegener and Fürst, (2004).

2.3 Strategic policy Review

To guide the sustainable planning practice, a variety of strategic policies have been stated, which adopt the integration of land-use and transport planning, such as Planning Policy Guidance 13¹ (PPG 13), National Planning Policy Framework (NPPF), Sustainability of Land Use & Transport in Outer Neighbourhoods² (SOLUTIONS), and Smart Codes³.

¹ 'PPG 13' aims to deliver the UK government's objectives for transport development and encourages the integration of planning and transport. (National planning policy framework, 2012).

² 'SOLUTIONS' is a research conducted by Engineering and Physical Research Council, which aims to develop a guidance to support the implementation of sustainable land use and transport. (Suburbansolutions.ac.uk, 2017).

³ 'Smart Codes' is a guidance for smart growth, including multimodal transport, infill development, affordable housing, and other practices in planning regulations (American Planning Association., 2017).

This paper has summarised the major planning objectives from these policies, basically involving the formation of urban form, the promotion of transit-oriented development, the classification of walking and cycling transport system, the improvement of spatial accessibility and safety, the application of traffic and parking management to reduce the usage of private cars (Table 2.3). In addition, the key planning factor has been categorised, which could be regarded as a set of the main influencing factors for making the sustainable development possible.

Table 2.3 Strategic policies for the integrated approach to land-use and transport planning

Framework	Planning objectives	Key factor
<i>PPG 13 & NPPF</i>	Manage the major generators of travel demand in district centres and make them near to the transport interchanges	Developments site locations
	Promote more sustainable mode choices for people and moving freight	Public transport, Walk and cycle
	Promote accessibility to work, shopping, leisure and other services by public transport, walking and cycling	Accessibility of facilities, Work-housing balance
	Reduce the need to travel in urban areas, especially for the reducing of car uses	Travel demand management
	Create safe and secure layouts which minimise conflicts between traffic and cyclists or pedestrians	Walk and cycle, Neighbourhood design
<i>SOLUTIONS</i>	Regulate land use and transport, particularly for the conservation area and the allocation of dwellings and employment	Work-housing balance
	Invest the development of land and transport, for example improving the capacity of existing transport networks and establishing more travel links	Strategic transport network
	Price the use of land and transport, such as the extra travel taxation in central region like the congestion charging zone.	Travel demand management

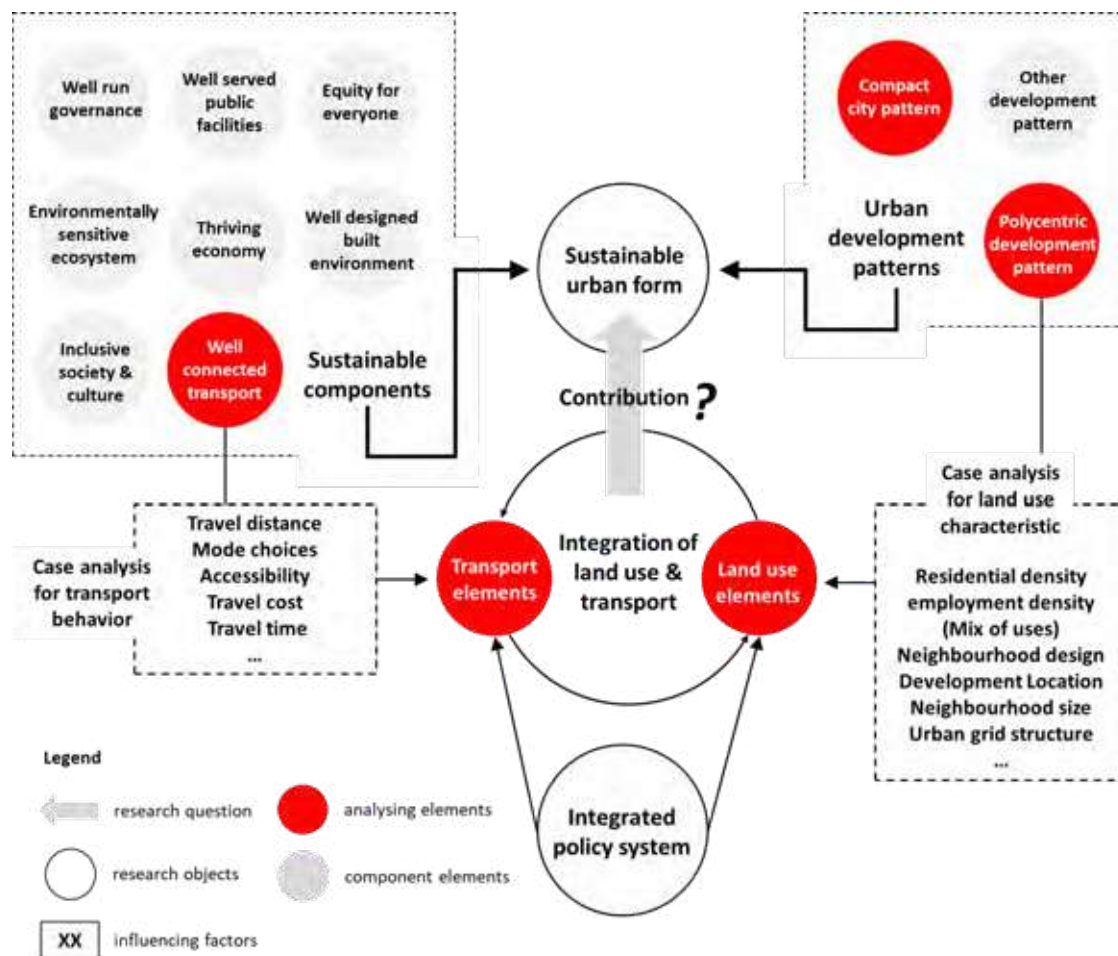

Smart Codes	Accommodate the mixed-use blocks and buildings to stimulate community development and promote the wellbeing of residents	Mix of use, Neighbourhood design
	Provide the appropriate flexibility of live/work units used for commercial and residential development	Work-housing balance
	Develop a high-density, high-intensity and mixed-use employment district centre	Development density Mix of use
	Encourage the development of affordable housing in more accessible areas and increase the community density	Development density, Development site locations
	Protect the transfer right of development for different purposes, such as green spaces preservation, historical district preservation.	Mix of use
	Cluster the residential development and creating the physical active community	Neighbourhood design

2.4 Theoretical framework - interrelationship between sustainable urban form and integrated land-use transport planning

A theoretical framework is established, which shows the expected interrelationship between SUF and its influencing factors (Figure 2.4). More importantly, the interactive mechanism between these factors has been revealed by the land use and transport system relationship. Banister and Givoni (2010) argued that an integrated view of land-use and transport planning could guide them in the direction of more effective measures to achieve SUF. Based on the perspective of an integrated land-use and transport planning system, a sustainable development pattern could be possibility assessed.

Land-use system considered in spatial planning will define particular types of urban forms (i.e. compact, polycentric) which can promote more social interaction, activities and sustainable transport behaviour. Transport system considered in spatial planning could contribute to reducing unnecessary long-distance travel, car use and to guiding more sustainable travel behaviour. More importantly, once more sustainable travel behaviour has been achieved, this will have positive impacts on later land-use investment and development to strengthen its pre-existing sustainable land-use characteristics. Finally, SUF will be accomplished through this dynamic-interactive relationship, especially regarding the aspect of sustainable transport.

Figure 2.4 Interrelationship between sustainable urban form and integrated land-use transport planning. Source: Made by author

3. Methodology for the research process

3.1 Research approach

The approach of this research will mainly focus on the exploratory, qualitative research on the integration of land-use and transport planning to promote the evolution of more SUF through primary principles of planning policy and planning practice instructed by them. The research can be regarded as a collaborative effort to criticise planning guidance on how local planning authorities can contribute in making urban development more sustainable through the integration of land-use and transport planning.

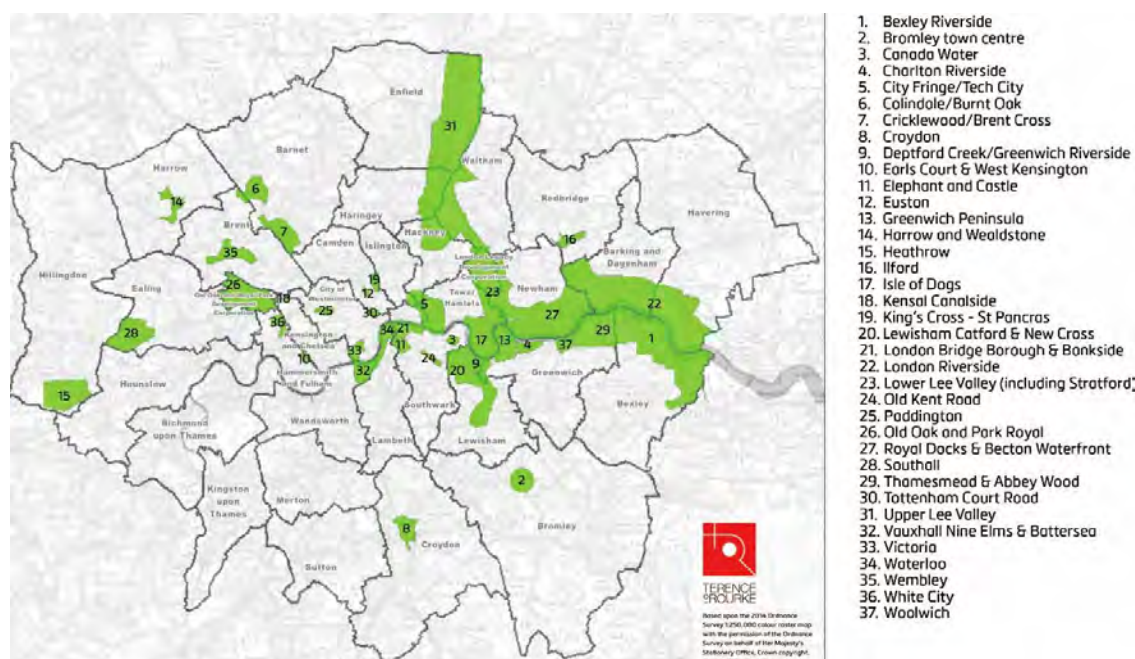

3.1 Research scope

According to the model of urban development pattern, the compact city model and polycentric urban development pattern is commonly recognised as more sustainable growth pattern, which is also mainstream urban development model in most western countries. Cities under the effects of high development density and high-efficiency public transport system such as London, Paris, Barcelona have great potential to be more sustainable through the integrated land-use transport planning. More

importantly, the research should concentrate on a highly-developed city currently experiencing pressures of urban growth.

London is an excellent platform for the analysing the practice of integrated land-use and transport planning because of the large-scale urban intensification and numerous regeneration events. Thousands of new homes and jobs are proposed to create in London's 38 opportunity areas. The delivery of SUF through urban development practices in these opportunity areas will significantly affect the urban sustainability in London (Figure 3.1).

Figure 3.1 The location map of London's 38 Opportunity Areas. Source: Londonfirst.co.uk, (2017)

4. Case study analysis

4.1 Background for Kings' Cross and Olympic Legacy area

The regeneration of King's Cross can be recognised as a transport-led development project, while the urban regeneration in London Legacy district was significantly promoted by the 2012 Olympics and its redevelopment. Though the two cases have different development histories and historical backgrounds (Table 4.1), they have strong similarities in their development objectives.

Table 4.1 Overview of the case study areas

Area	Kings' Cross Opportunity Area (KCOA)	London Legacy Development Corporation area (LLDC)
<i>Developing vision</i>	a vibrant, inclusive, and sustainable redevelopment project with the	a mixed-use development driven by the 2012 Olympics, London's eastern

	significant potential to utilise its excellent transport accessibility	gateway and intersected by the Channel Tunnel Rail Link
Total area	24 hectares (excluding the area of railway stations)	73 hectares (Phase 1, known as ‘Stratford City’)
Principle Development objective	High spatial accessibility, mixed use (including commercial, retail, education, residential, green spaces), high density (especially compared to traditional residential areas), improvement of transport interchanges, local community involvement.	

In brief, regeneration of Kings’ Cross and Olympic Legacy is mainly driven by the massive investment in transport infrastructure and land use development, which contributes to integrated land-use and transport planning more significant (Figure 4.1a, Figure 4.1b). These cases both reflect the strong character of the compact city pattern or polycentric urban development patterns, such as high density of housing and employment, a mix of uses, and high spatial accessibility for public transport. Land use characteristics and transport behaviour in local areas will be substantially changed by these regeneration projects. The two cases have relatively high value for assessing the contribution of integrated land-use and transport planning to develop a more SUF.

Figure 4.1(a) Location and the boundary of Kings’ Cross Opportunity Area. Source: Made by author

Figure 4.1(b) Location and the boundary of London Legacy Development Corporation Area. Source: Made by author

4.2 Case-specific policy analysis in Kings' Cross Opportunity Area

Currently, Kings' Cross presents one of the most significant regeneration opportunities in Europe. It is also the largest plot of brownfield land in central London. As a gateway from Europe to London and the UK, St Pancras International and Kings' Cross railway station play vital roles in the urban-regional transportation system.

4.2.1 Spatial accessibility and connectivity in urban-regional scale

Delivering efficient urban-regional transport connection is an integral part of the regeneration objectives (Kings Cross Opportunity Area planning & development brief, 2003). The location of Kings' Cross and two transport interchanges offer significant advantages for the improvement of spatial accessibility and mobility (Figure 4.2.1). The physical boundaries of the regeneration site should be broken down to provide a full connection with the rest of London. It is argued that the area's transport accessibility underpins the potential for high-density development, which is also fully integrated with public transport network (Kings Cross Opportunity Area planning & development brief, 2003).

Figure 4.2.1 The spatial connection of KCOA with central London. Source: *Kings' Cross Central: Urban Design Statement* document

In a word, the planning policy related to spatial accessibility usually focuses on the improvement of transport connectivity within the urban-regional area. For KCOA, two transport interchanges, Kings'

Cross Station and St Pancras International Station including CTRL terminus, are key catalysts to guide the direction of redevelopment. This transportation hub comprised of two railway stations, CTRL terminus and Kings' Cross St Pancras underground station become one of the most crucial transport gateways for central London. Under this developing condition, the form of high-density development will also be considerably promoted by the integrated rail transport system. On the other side, locating at the fringe of Central activities zone (CAZ) and smaller size of regeneration site (around 24 hectares) enhance the demand for developing density and intensity, because of the significant increase in land values.

4.2.2 Social and economic activities in regeneration area

Financial links can be promoted by allocating newly available jobs widely. For social interactions, the focus is on community involvement, which primarily includes making better access to employment and training, improving local people's qualification through education and creating attractive communication environments. High-density mixed use is an effective way to enhance the competitiveness of business, maximise affordable housing provision to meet changing needs and contribute to the vitality of the whole project. Depending on this mixed pattern of land uses with optimised density (Figure 4.2.2), the land-use capability of offices, retail, leisure, education can be increased. The hugely demand of housing and diverse services in central London will be met.

Figure 4.2.2 Strategic land use framework in KCOA. Source: *Kings' Cross Central: Urban Design Statement document*

To conclude, the planning policy related to the social-economic activities generally emphasis on the enhancement of local vitality by high density and mixed-use development. The policy requires the commercial development should achieve plot ratios of at least 3:1 wherever there are good transport accessibility and capacity. Moreover, that ratios nearer to 5:1 is recommended to be achieved in highly accessible areas (Queenelizabetholympicpark.co.uk., 2017). To make optimum mixed use of the site, a flexible framework of land use plan is proposed that allows the mix of uses in the north part to be chosen to respond to a changing social-economic climate.

4.2.3 Transport availability for sustainable travel modes

Encouraging more sustainable travel modes by improving the attractiveness of public transport, walking and cycling will have significant impacts on reducing car dependency. To increase the attractiveness of sustainable travel modes in KCOA, new reliable bus routes linking the site with surrounding

communities and Camden town centre should be considered (Figure 4.2.3). The provision of bus priority measures wherever needed to maximise the reliability of existing and new services for jobs, shopping, leisure and other activities. Besides, high-quality pedestrian and cycle links to public transport nodes should be well-designed. For car parking and storages, the provision for car parking is expected at deficient levels. For example, the developer should demonstrate on minimising the traffic generation in the site. The proportion of car-free housing is required to reach at least 75%.

Figure 4.2.3 Public transport system plan in KCOA. Source: *Kings' Cross Central: Urban Design Statement document*

In summary, the planning policy related to promoting the availability of sustainable travel modes builds on the well transit-connection of public transport, walking and cycling. A network of tertiary vehicular routes can minimise most of the car traffic in the centre of the site except for the essential vehicle services such as fire access and deliveries, which will make public realm more quiet and safer for pedestrians. In Kings' Cross, private and public car parking is combined to make the best use of shared facilities, which can also provide for different demands at different times of the day and week (Queenelizabetholympicpark.co.uk., 2017). Also, more cycle parking can improve the attractiveness of cycling travel instead of travel by private car.

4.3 Case-specific policy analysis in London Legacy Development Corporation Area

Different from the regeneration of Kings' Cross, the redevelopment of London Legacy emphasises on a larger-scale site, which covers the area in four London boroughs. After the 2012 London Olympic, the London Legacy Development Corporation was established to promote and deliver physical, social, economic and environmental regeneration of the Olympic Park and its surrounding areas by securing sustainable development and ensuring the smooth transformation of these Olympic venues in the long term (Queenelizabetholympicpark.co.uk., 2017).

4.3.1 Spatial accessibility and mobility in urban-regional scale

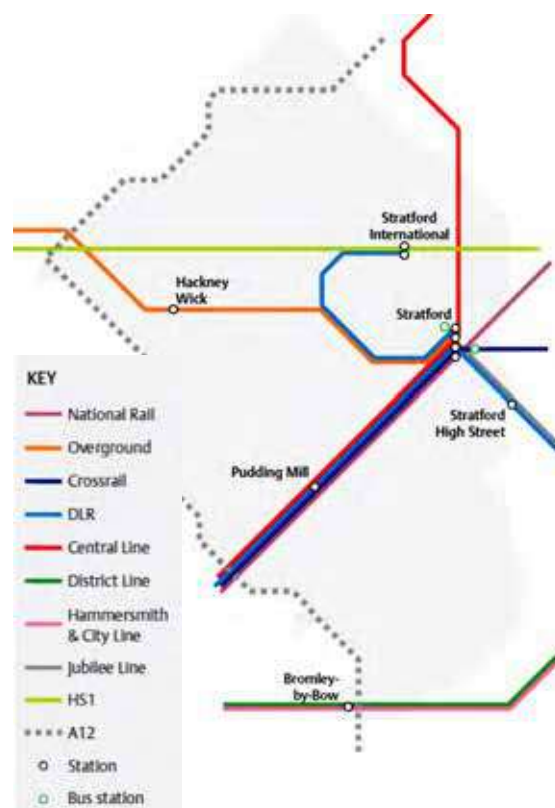

Improving the strategic transport connection and transport infrastructure is considered as the priority to develop business growth, jobs and lifelong learning in Stratford area. The Legacy Corporation area occupies a key strategic location at the meeting point of the London-Stansted-Cambridge-Peterborough Growth Corridor and the Thames Gateway Growth Corridor (Anon, 2017). Strategically, this area is connected to the major business and growth hub of central London, including Canary Wharf and the

Royal Docks (Figure 4.3.1a). The potential of being another London Metropolitan centre improves spatial accessibility more important for the redevelopment after the 2012 Olympics.

Figure 4.3.1(a) Location of LLDC area in London. Source: *A walk around Queen Elizabeth Olympic Park*

Figure 4.3.1(b) Public transport and connectivity in LLDC area. Source: *LLDC Local Plan 2015 to 2031*

In general, the improvement of public transport infrastructures and services at all levels is the cornerstone for delivering the social-economic growth in Stratford area, including the development of international, national, regional and local transport connectivity. The efficient and well-designed stations, including the development of Stratford Station for Stratford City and the 2012 Games, the new stop of Channel Tunnel Rail Link at Stratford International Station, the capacity enhancements of Jubilee Line, Overground and DLR, strengthen the spatial accessibility and mobility of LLDC area (Figure 4.3.1b). Based on that, Stratford becomes one of the best-connected places in London, which attracts substantial investment for the further land redevelopment.

4.3.2 Social and economic activities in regeneration area

Developing a strong local economy and driving the transformation of east London as a new city centre is the vital objective for the regeneration in LLDC area. To reach this target, the economic profile of the area should be strengthened, which depends on providing additional floor spaces in a wide range of sizes, types and forms.

More particular, the local plan about employment clusters will foster a range of job opportunities, and it is also the key to the character and vibrancy of the regeneration site. With the spatial distribution of employment areas and social infrastructures in several hierarchies, the daily social activities can be centralised around the central development area. More social communications can be promoted within the new-designed public spaces. On the other side, a mix of housing types should be provided to create the sustainable neighbourhood and avoid problems that may result from over-concentration of certain size and types of accommodation. It is required that all community planning proposals should reflect identified housing size, building form and tenure requirements.

4.3.3 Transport availability for different travel modes

Managing development and its transport impacts to promote sustainable transport choices and prioritise pedestrians and cyclists is an essential policy to minimise reliance on the private car to ensure that the regeneration of the Legacy area is optimised and more sustainable. The plan aims to lead to dramatic changes in Londoners' behaviour and attitudes to their cars and contribute to decreasing car ownership per household in local communities. In doing so, several specific policies should be considered, such as implementing a locally connected street network that prioritises pedestrians and cyclists as the most important travel modes, followed by public transport and the private car (Figure 4.3.3) (Queenelizabetholympicpark.co.uk., 2017). The amount of new development across its areas, in particular as the town centres and employment clusters, should be related to the transport capacity of existing or planning improvements to transport infrastructures and services.

Figure 4.3.3 Transport prioritises. Source: *LLDC Local Plan 2015 to 2031*

Besides, facilitating local connectivity with the redevelopment of high-quality built environment can significantly strengthen the attractiveness of walking and cycling within the area. It is believed that the improvement of local connectivity is a critical issue for the liveability of this area. Currently, physical barriers such as motorways, railway lines and canals, increase the difficulty for people to move around the area. It is crucial to forming a network of linked walks connecting with adjacent neighbourhoods and town centres throughout the Olympic Park, which will adequately respond to the potential of social activities.

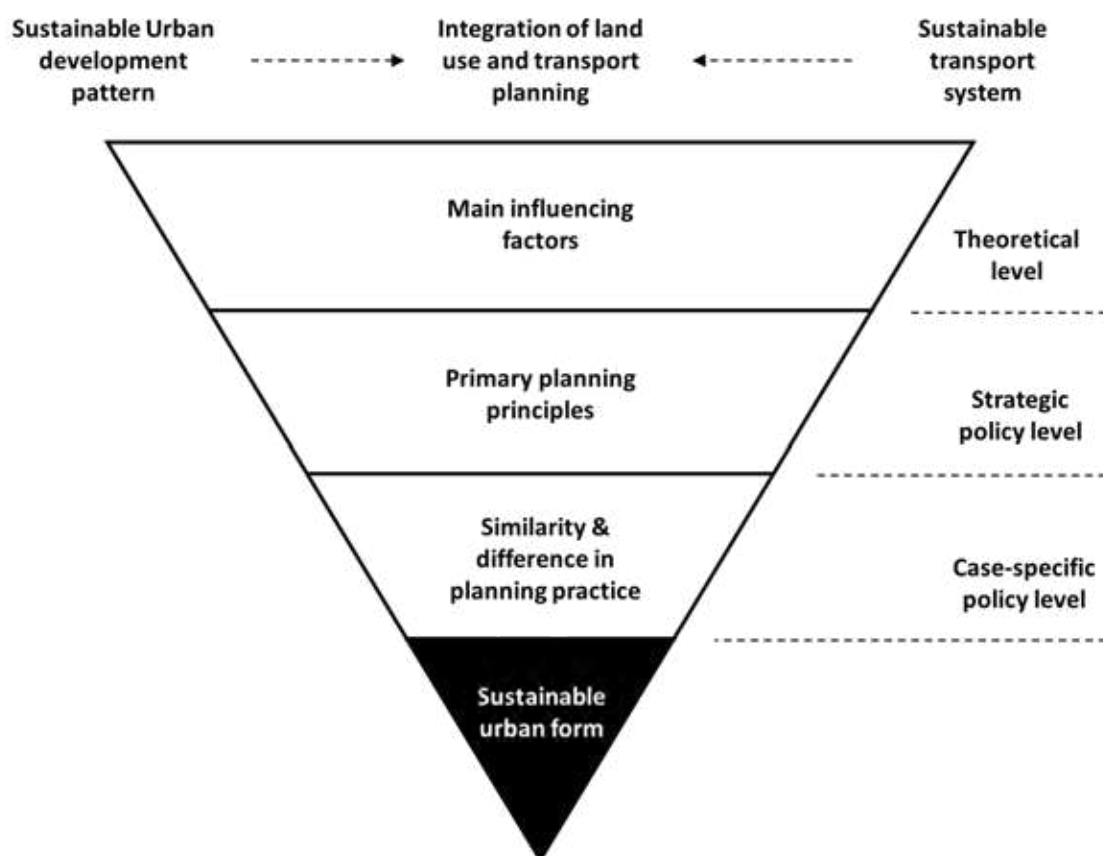

5. Conclusion and recommendation

5.1 Contribution of integrated land-use and transport planning for SUF

It has been evidenced that land use and transport planning are two principal systems in co-determining the sustainable effectiveness of spatial planning in practice. In general, the transport planning policy can be regarded as a kind of ‘push’ measures to limit the unsustainable travel behaviour, such as long-distance car travel and car dependency. While, the land use planning policy can be considered as a kind of ‘pull’ measures to indirectly guide more sustainable land-use characteristics, which greatly promote the social-economic vitality in town centres and communities.

This research concludes that the integrated land-use and transport planning consisting of sustainable urban development pattern (i.e. compact city model and polycentric urban development pattern) and sustainable transport system (the most crucial components for sustainable objectives) can significantly contribute to achieving SUF (Figure 5.1).

Figure 5.1 The framework about contribution of ILUTP for achieving SUF at three levels. Source: Made by author

Besides, the complexity of SUF and ILUTP has been revealed. The reason is probably that a various range of influencing factors are involved in the land-use planning and transport planning systems, and they have impacts on co-determining the sustainability of urban development. More complicated, it is difficult to assess the efficiency of each influencing factor on promoting SUF because of the significant

difference in urban areas. However, the contribution of ILUTP for achieving SUF can still be assessed in the western countries with the well-developed planning system, through the analysis of planning strategies and empirical studies. Based on this research, contributions of ILUTP for achieving SUF have been concluded in three respects, involving influencing factors summarised from the literature review, planning principles classified from planning strategies and different planning practice assessed through case-specific policies.

a) Main influencing factors for affecting SUF

Main influencing factors are summarised from land-use and transport planning policy which promote SUF through positively affecting transport behaviour and land-use characteristic in development areas.

The influencing factors related to changing transport behaviour have a ‘push’ impacts on achieving SUF in the short term, which mainly include the improvement of public transport infrastructures to change people’s travel modes, traffic management and minimised parking provision to reduce the use of the car.

The influencing factors related to affecting land-use characteristic usually have a ‘pull’ impacts on achieving SUF in the longer term, which include strategic development location, accessibility of key facilities, size of development settlement, work-housing balance in local area, a mix of uses in town centre, high development density especially for residents and employments, design for walkable neighbourhood and open streets.

b) Primary planning principles for instructing SUF

To guide planning practice, three primary planning principles have been summarised, include the promotion of spatial accessibility, diverse activity and sustainable transport availability.

Principle-A: Spatial accessibility supported by the improvements of transport infrastructures and transport network connectivity to attract investments and connect the travel origins and destinations much easier;

Principle-B: Diverse activities in town centres and new communities supported by high-density development and mixed land use to create social and economic vitality;

Principle-C: Transport availability for mode choices supported by high-quality design and amenity of public spaces to promote more sustainable travel behaviour.

c) Case-specific planning policies for achieving SUF

The similarity of case-specific policies in planning practice has been assessed and summarised from the case-specific policies as well as the difference (Table 5.1). It is also explored from the case-specific planning policies that the location of regeneration projects may result in somewhat different outcomes in planning practice for achieving SUF.

Table 5.1 Similarity of case-specific planning policies in KCOA and LLDC area

Principles	Similarity of case-specific policies
<i>Principle-A</i>	<ul style="list-style-type: none"> Deciding the form of regeneration as high-density and mixed-use development by establishment of integrated transport system at the beginning; Easily getting more capital investments from related stakeholders to speed up the regeneration process; Potentially generating vast numbers of inbound and outbound daily trips through the improved transport infrastructure and system;
<i>Principle-B</i>	<ul style="list-style-type: none"> Greatly cutting down the travel distance between homes and workplaces by offering relative numbers of new homes and workplaces and keeping work-housing balance locally; Compulsively providing sufficient proportion of affordable housing in development communities to promote the mix of accommodation, the mix of residents and the mixed use of public spaces;
<i>Principle-C</i>	<ul style="list-style-type: none"> Directly reducing car uses through discouraging unnecessary car travels, such as daily light food shopping, leisure activities by working out more strict parking measures; Indirectly reducing car uses through encouraging more sustainable mode choices by designing more walkable public spaces and street layouts, particularly in new communities;

The development location may affect the development pattern of the project and change the spatial character of the city. Kings' Cross is planned as a viral connection node, and new employment centre in central London as the transportation interchanges have already been here. The project can be treated as an expansion of central London, which significantly strengthens the spatial character of the compact city in central London. While London Legacy is planned as a new urban centre for the great London, which relies on the consistent improvement of transport accessibility since 2012 Olympics. The project can be recognised as a development for a new urban centre, which shapes the spatial character of Great London as a polycentric urban form. In general, the regeneration project in KCOA and LLDC area will both contribute to promoting London as a more sustainable city at regional-district scale.

5.2 Limitation of the research and recommendation for further analysis

The conclusions reflect primary concerns for urban planners and policy-makers toward more SUF from the perspective of ILUTP. The outcomes may not be specific enough to explain the achievement of SUF through influencing factors, primary principles, and case-specific policies, because of the limited time and lack of data. The measures of quantitative analysis focusing on the changes of travel modes, density, and the mix of uses will be greatly helpful to evaluate the correlation between SUF and ILUTP.

d) Shortcoming and failing within this research

One significant limitation is those previous conclusions about achieving SUF aim at assessing the effectiveness of integrated policies in urban regeneration projects. The outcomes of ILUTP have limited influence on the improvement of sustainability in surrounding areas. But the SUF should not just be accomplished through urban renewal projects under the instructions of integrated land-use transport planning, which may lead to creating a 'sustainable island' surrounded by the 'unsustainable sea'. A more ambitious target should be considered, emphasising on how to promote more SUF for the whole city through the integration of land use and transport planning.

e) Further questions arising from the research

It is also claimed that the influencing factors in social respect can also affect the sustainability of urban development, especially having considerable impacts on the sustainable transport system. Stead et al. (2000) once argued that socioeconomic conditions could explain more variation in travel patterns than do land use characteristics. It is believed that the influence of land use could not be as significant as it previously assumed. The socioeconomic component, such as household car ownership, household socioeconomic group and working residents proportion, need to be paid more attention instead of issues of land use or transport.

Bicycle-Metro Integration for The 'Last Mile' in Shanghai*

Ze Zhang¹, Tong Cai²

¹*College of Architecture and Urban Planning, Tongji University, zhangze47@qq.com*

²*College of Architecture and Urban Planning, Tongji University, tong.cai@qq.com*

Abstract: Cycling is always considered to be one of the most popular daily traffic tools in cities due to its flexibility, convenience and low cost. Moreover, Bicycle-metro integration is theoretically considered to be an effective solution for improving public transportation efficiency of "last mile" between home and metro station in big cities. However, this proposition has not been fully proved in practice. In recent years, the emerging dockless bike-sharing system makes it possible to examine the spatial integration between flexible bicycle traffic and rail transit. Compared with traditional public bicycle systems with fixed docks, such as New York Citibike, this new bike-sharing system demonstrates the mobility and flexibility of cycling. We randomly sampled the GPS coordinates of 80,000 dockless bikes in Shanghai, which represent the origin and destination points of cycling. We mapped the bicycle traffic on an equal population cartogram of Shanghai to distinguish overall patterns within the center of Shanghai. Results show that most of the high-frequency cycling streets still centre around metro stations. The streets basically present a gradual decline from the metro stations to outlying areas in terms of cycling frequency, which indicates that bicycle-metro integration has already become the basic model for daily transport in Shanghai.

Keywords: Bicycle-metro integration, the 'last mile', dockless bike-sharing system, Shanghai

Introduction

Traffic-oriented development (TOD) is a way to ensure the sustainable development of transportation and urbanization. As a fast, efficient and large-capacity transportation mode, the subway system is the focus of the TOD strategy. However, in the suburbs of the city, the subway stations are sparsely distributed, and their service radius often needs to be extended to more than one mile or even three miles, which seriously reduces the public accessibility of the subway system. In such cases, passengers in the subway system usually enter the station by other means, such as walking, cycling, and taking a bus. This transfer process is described as the last mile issue. Improving accessibility and strengthening the integration of other modes of transportation with subway stations will definitely increase the passenger capacity of the subway system.(Zhao and Li, 2017).

Meanwhile, cycling is always considered to be one of the most popular daily traffic tools in cities due to its flexibility, convenience and low cost (Akar and Clifton, 2009; Parkes et al., 2013). The traditional bicycle sharing system began in the late 1990s and has been extensively researched to date. For bicycle sharing systems in different cities, Pfrommer et al.(2014) determined that the peak usage of working days is between 7 am and 9 am, 4 pm to 6 pm, and the weekend peak is at noon. Ahmed et al.(2010) argue that the shared bicycle system is busier in warmer months, which usually confirms the relationship between weather and private cycling tendencies. A study of bicycle-sharing travel time based on data from Melbourne, Brisbane, and Washington,

**Supported by the International Exchange Program for Graduate student, Tongji university (No. 201901025)

DC Researchers at the University of Minnesota and the University of London determined that this duration was within a narrow band between 16 and 22 minutes (Fishman, Elliot, Simon Washington, and Narelle Haworth., 2014). Another study shows that average users of a particular bicycle sharing service typically travel longer than annual membership (Buck, Darren, et al., 2013). Tao et al.(2013) analyzed the global and space-time modes of traditional public bicycle sharing systems in Nanning, China, and studied the impact of urban patterns on these models. Froehlich et al.(2009) conducted a spatio-temporal analysis of the use of bicycle stations in the shared bicycle system in Barcelona for 13 weeks, applied clustering techniques to identify sharing behaviors between stations, and compared experiments with four prediction models used in nearby stations. result. Some studies have focused on the sustainability of bicycle sharing systems.

Bicycle–metro integration is an effective solution for improving the accessibility of metro systems and facilitating green transportation (Zhao and Li, 2017). In recent years, dockless bike-sharing programmes have been launched in China at an impressive speed. These new common-usage bikes cover almost every street in Chinese big cities, and can be accessed via smartphone (Chinta and Sussan, 2018). Compared with traditional public bicycle systems with fixed docks, such as New York Citibike (Faghih-Imani and Eluru, 2016), this new bike-sharing system demonstrates the mobility and flexibility of cycling. People do not have to depart from or arrive at fixed docking stations; they may enjoy cycling from/to anywhere in the city. This design is effective in solving the ‘last mile’ problem, which is spreading across hundreds of cities around the world, including San Francisco, Seattle and London, by providing people with the transportation tools between public transport hubs and home.

Data and methods

With a surging number of active users, bicycle sharing is growing rapidly. Shared bicycles are used by more than 32 million users every month on average, reaching a coverage of 8.04% in first-tier cities in China. Currently, GPRS-based smart locks are widely used in the bicycle sharing industry. OFO, as the first and one of the biggest dockless bike-sharing firms in China, provides the bicycle-sharing system with more than 700,000 bikes in Shanghai. This study randomly sampled the GPS coordinates of 80,000 OFO bikes in Shanghai, which represent the origin and destination points of cycling.

Figure 1. Working mechanism of dockless bike-sharing system

Source: <https://www.zdnet.com/article/chinese-bike-sharing-company-fofo-arrives-in-seattle/>

Navigation in the Google Maps App provide a feasible approach to generate the cycling route from the origin and destination points. Furthermore, in order to eliminate the interference caused by the passing behavior of the research, The 80,000 cycling origin–destination (OD) lines were intercepted into 141,317 cycling directional lines, each with a length of no longer than 500 metres, which is generally considered as the basic service radius of metro stations.

Results and discussion

In order to explore the spatial relationship between rail transit stations and shared bicycle riding behavior, as shown in Figure 2, the shared bicycle riding behavior is divided into five categories: starting, riding, inner, outer and transit. Cycling data. This study mainly focuses on the starting and riding, arrival and riding behaviors around the various rail transit stations, and records the starting, reaching, and internal riding of the 500-meter radius around the rail transit station i as Di , Ai and Ci .

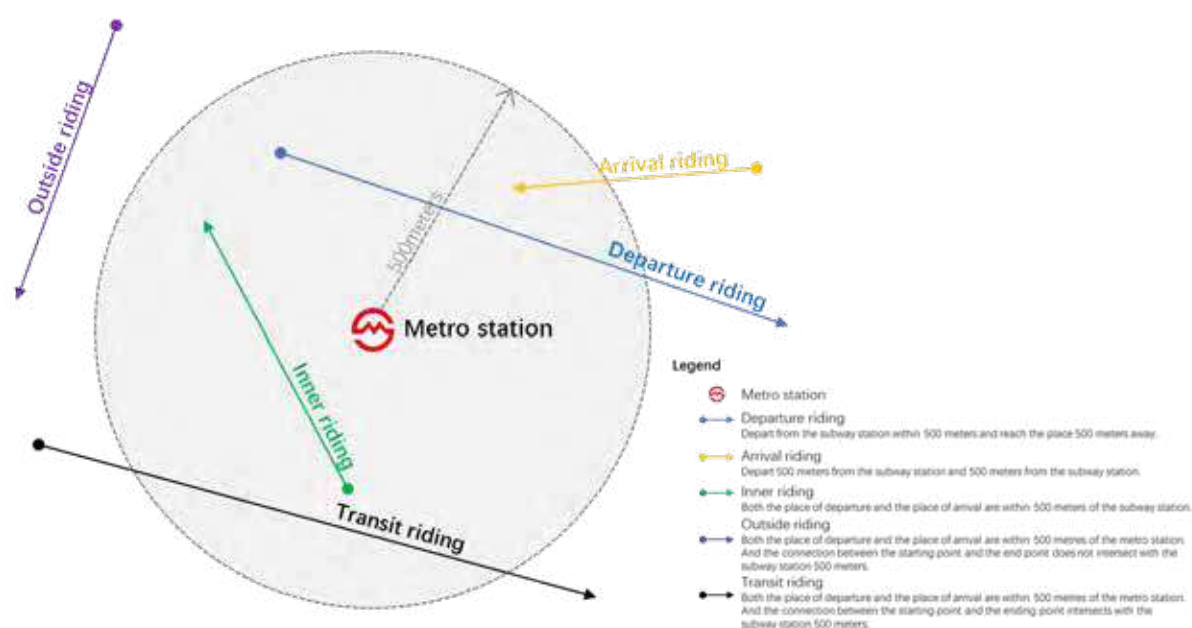

Figure 2. Division of riding behavior based on metro stations

According to the test, the number of riding, arrival, and internal riding around the Shanghai Rail Transit Station were 35,492, 31,646 and 1,245 respectively, and the number of rides related to the 500-meter range of the rail transit station reached 68,383. The ratio is as high as 85.48%, which indicates that there is a great spatial matching relationship between the shared bicycle riding data and the rail transit as a whole.

Shanghai Rail Transit Line 1 was selected as the research object, and Shanghai Rail Transit Line 1 was the first subway in Shanghai. There are 28 stations on Line 1, including 8 interchange stations, running through the Shanghai city from north to south, connecting the city center (People's Square), the city's sub-center (Xujiahui area), the suburban area, and the transportation hub (Shanghai South Railway Station, Shanghai Railway Station) can reflect the spatial connection characteristics of subway and bicycle travel in different locations. After testing, there were a total of 9455 cycling data around the rail transit line 1 site, accounting for 11.82% of the city's data.

Comparing the number of rides within 500 meters of each orbital station, it is found that: 1) the urban center system is clearly reflected: the city center, the sub-center and the commercial center of the district have high riding capacity; 2) the starting distance and the number of arrivals There is a clear positive correlation (the correlation coefficient between the two reaches 0.960), but the starting distance of each station is generally higher than the arrival of the ride (the ratio of the two is 1.26:1); 3) the number of terminal rides is obvious

“Zoom in” phenomenon: the number of rides around Xinzhuang Station and Fujin Road Station is significantly higher than that of Outer Ring Road Station and Youyi West Road Station; 4) There are some gradients in the process of attenuation of the center-suburb ride: such as Hengshan Road - Xujiahui, Tonghe New Village - Hulan Road.

Compared with the starting and the riding, the distribution characteristics of the two are relatively the same, except that the total number of starting and the line density is obviously stronger than that of the riding. Compared with the bicycle to the railing station, people are more It tends to ride from the perimeter of the rail transit site.

Compared with working days and rest days (Table 1), the average daily riding time on working days is 895 times, which is slightly higher than the rest day (858 times), but the riding distance is 1896 meters, which is obviously less than the riding distance of the rest day (2601 meter). At the same time, comparing the total travel time of each time period, it is found that there is a clear “early peak + late peak” double travel peak feature on the working day, while the rest day more reflects the single travel peak feature of “noon peak”.

Table 1. Working days and rest days in 500 meters of each station on the rail transit line 1

	Weekdays		weekends	
	Cycling frequency(per day)	Average cycling length(meters)	Cycling frequency(per day)	Average cycling length(meters)
Departure cycling	524	1874	495	2785
Arrival cycling	371	1928	363	2352

We mapped the cycling directional lines of Shanghai (Figure 3) to distinguish overall patterns within the centre of Shanghai. The cycling directional lines are represented clearly as groups of radial lines from/to metro stations. Furthermore, with the help of the bicycle route navigation of Google Maps (www.maps.googleapis.com), each cycling trip was simulated by inputting coordinates of its start point and end point. Each street is assigned the number of starting and ending trips (no longer than 500 metres), which represents the cycling frequency. As is shown in Figure 3, most of the high-frequency cycling streets still centre around metro stations. The streets basically present a gradual decline from the metro stations to outlying areas in terms of cycling frequency, which indicates that bicycle–metro integration has already become the basic model for daily transport in Shanghai.

Figure 2. The cycling directional lines and cycling frequency of Shanghai's metro station voronoi diagram

Planning, Law and
Property Right:
in the face of transitions

Right to the city, human rights, and Canadian cities

By Sandeep Agrawal

Right to the city

The idea of the *right to the city*, as conceived by Henri Lefebvre¹, raises questions of how or whether human rights intersect with cities. Can rights be used to implement Lefebvre's notion? In Canada, federal and municipal governments are deploying human rights policies in combination with city planning to realize this right to the city.

A fundamental question here is whether a difference exists between the right to the city and human rights in the city? Much academic debate on Lefebvre's concept encompasses two inter-related principal ideas:

- The city is an *oeuvre*—in which all its citizens participate and make decisions that contribute to the production of urban space
- Spaces are produced by their inhabitants by physically appropriating them—accessing, occupying, and using them in everyday life.

Right to the city resists the power of capital and the state by calling city inhabitants to engage in direct struggle and urban politics to achieve access and occupancy in urban spaces.

Human rights

Human rights are the rights we each possess by virtue of being human, based on our inherent dignity and equal worth as human beings. These are the “highest moral rights, [as] they regulate the fundamental structures and practices of political life, and in ordinary circumstances, they take priority over other moral, legal and political claims.” This Universal Declaration of Human Rights (UDHR) of 1948 is the foundation of human rights law, inspiring an extensive body of legally-binding human rights laws.

I interpret the *right to the city* as several human rights—rights to expression, religion, life, liberty, equality, housing and property² — as they relate to city inhabitants in the form of political engagement, equitable services and the accommodation of diversity. An aspect of city life is the notion of a right to property,³ but Lefebvre rejects this idea, arguing that it undermines the right to appropriate and inhabit the city. However, he does acknowledge that the right to housing as the right to adequate housing and shelter is a necessary but insufficient condition for the right to the city.

Many planning scholars who resist the prevailing neo-liberal tendencies in planning have embraced Lefebvre's concept, while others point to gaps and disconnects within his ideas and between his concept and human rights. For instance, it critically overlooks practical guidance on what this right to the city entails or how it informs relations between urban dwellers and the state. Even while it significantly resists the privatization and homogeneity of public space, it is more useful as a rhetorical device than a policy-making or legal instrument. The concept remains vague, with undefined terminology: What is a “right”? What is meant by “the city”?

For Lefebvre, the right to the city was a “cry” to initiate a radical struggle against the state and capitalism, but it was not supported by law in any conventional sense. Thus, this concept diverges from codified, legally binding human rights. However, we can still adopt it by relying on current institutional frameworks and invoking moral and legislative policy that affects people, along with their spaces and

places. The judiciary can further facilitate this orientation by interpreting and applying human rights in the state's policies and practices. More recent scholarship⁴ interprets Lefebvre's later writing as a potential encouragement to finding a more transformative potential within existing legal rights framework.

Several countries, including Canada and some European nations, as well as the UN, champion the right to the city as part of a broader agenda for human rights.⁵ In Canada, both the *Charter* and provincial and territorial human rights legislation provide the basic mechanism and legal framework for this idea. The humane development of inclusive cities depends on these constitutional and quasi-constitutional guarantees and their inherent values⁶. The Canadian *Charter* and human rights legislation provide rights to individuals, but they are increasingly being viewed as "collective rights," such as the rights of Indigenous peoples or persons with disability—the convergence point in the contemporary interpretation of the *Charter* and the right to the city.

Rights are enduring legal protections that are granted to individual citizens by the liberal-democratic state. The state, however, conceives of rights as ends—that is, the struggle is over when a legal right is secured—which is antithetical to Lefebvre's conception of ongoing resistance to capitalism and the state. Fainstein's *Just City*⁷ supports political institutions and public policies despite their imperfections. She endorses, instead, reforms through existing political-economic processes and argues against the need for social unrest to achieve justice. The construction of cities makes justice possible for everyone, through "continued pressure on the existing democratic practice." Nonetheless, in neoliberal cities, social equity is largely disregarded in favour of growth.

The Charter and Canadian cities

The *Canadian Charter* delineates the rights and freedoms of people only in relation to government activities, versus human rights legislation, which encompasses both private and public acts. Specifically, *Charter* Section 15 guarantees equality before the law and the right to equal protection and benefit of the law without discrimination based on race, disability, and analogous grounds. Laws (including municipal government bylaws) inconsistent with the *Charter* may be declared invalid and may lead to the payment of damages or other remedies. Notably, these constitutional guarantees are not absolute. *Charter* Section 1 places "reasonable limits [on rights] prescribed by law as can be demonstrably justified in a free and democratic society."

Interactions between individuals and organizations (for example, between employers or landlords) are governed instead by human rights legislation, like the Alberta Human Rights Act or the Ontario Human Rights Code. Therefore, provincial and territorial human rights agencies deal with discrimination issues based on race, religion, age, or sexual orientation, and thus may vary by region. However, overlaps do occur when an act of government occurs in an employment context or when the federal, provincial, or municipal government provides services, facilities, or accommodations.

Canadian municipalities have made significant progress on the human rights front, enabled by either federal and provincial legislative changes, or due to government responses to court rulings. As well, the federal government now maintains a human rights-based approach to a national housing strategy. Human rights issues in municipalities have also evolved over the last decade, increasing in the last few years.

Two key factors affect planning at the municipal level:

1. Increasing challenges to municipal bylaws based on *Charter* Sections 2 (right to expression, religion, and peaceful assembly), 7 (right to life, liberty, and security) and/or 15 (right to equality) and to court decisions that favour protecting these rights—such as the right of the homeless to erect tents on public properties and improving working conditions of city sex workers.
2. New federal legislation or amendments to existing federal regulations, some emerging from court rulings that protect human and *Charter* rights—such as safe injection site locations, methadone clinics, and cannabis dispensaries.

These two factors have prompted municipalities to review, revise, or even rescind existing bylaws, create new land-use classes, or revise existing zoning bylaws to accommodate new resulting land uses.

Implications

Now more than ever before, human rights are a critical issue at the municipal level. Certainly, new federal legislation now shapes municipal planning in unprecedented ways, such as with the locations of safe injection sites and cannabis dispensaries within the municipal fold. However, these new issues follow perennial ones, like secondary suites, user characteristics, minimum separation distances, and keeping livestock within the city limits. Still, provincial and municipal governments continue to make significant human rights progress, as in these examples⁸:

- Alberta revised its human rights legislation to include age (in relation to the provision of goods, services, accommodation, or facilities), sexual orientation, and gender identity and expression as grounds of discrimination.
- Alberta municipalities amended their bylaws to align them with human rights legislation and the *Charter*: Calgary removed its prohibition on secondary suites in residential areas; Edmonton changed its group homes use-class, and a complete review of a zoning bylaw is currently in progress.
- In 2014, Ontario included human rights in its provincial policy statement, mandating that municipalities ensure their planning and policies adhere to the *Charter* and the province's human rights code.
- Many Ontario municipalities changed the definition of group homes and other supportive housing facilities, as well as the use of minimum separation distances.
- City of Toronto established equity, diversity, and human rights offices.

In closing, I wish to highlight that the Canadian state has taken the lead in guaranteeing its citizens the *right to the city* and all the related rights that attend this. Lefebvre challenged whether this was possible for a state to do. Concomitantly, the Canadian judiciary has further clarified, applied, and even expanded the scope of human rights as they relate to various aspects of city life. According to Qadeer⁹, even if rights exist in law, their actual realization depends on the institutionalization of equality in economic, social and cultural matters; entrenched institutional biases and power politics may still prevent any progress made in law. Hence, Lefebvre's perspective remains valid in its emphasis that the *right to the city* is the *ongoing pursuit* for better conditions for city dwellers. This continual struggle appears to yield better results when worked within the existing political and institutional structures.

Sandeep K. Agrawal is a professor and director of the School of Urban and Regional Planning at the University of Alberta. His current research works span a broad range of issues from human rights, multiculturalism, and annexation to housing and homelessness in First Nations communities. He is a co-

author of the book *Understanding India's New Approach to Spatial Planning and Development: A Salient Shift?*, published by Oxford University Press.

¹ Henri Lefebvre was a French intellectual who was inspired by critical theorists such as Marx, Hegel, Nietzsche, and Heidegger. Spanning over three decades, his writings offered a critique of existing society and presented an idea of new society, a possible world beyond capitalism, the state, and consumer society. For instance, Lefebvre, H. *Writings on cities* (E. Kofman & E. Lebas, Trans.). Cambridge, MA: Blackwell (1996).

² The right to property is constitutionally guaranteed in the USA, is included in the UDHR, and is also part of Alberta's *Bill of Rights* although not included in the Canadian *Charter of rights and freedoms*.

³ Multiple interpretations of right to property exist. According to UDHR, "right to property" means that everyone has the right to own a property and no one shall be arbitrarily deprived of their property.

⁴ Such as Huchzermeyer, M. The legal meaning of Lefebvre's the right to the city: addressing the gap between global campaign and scholarly debate. *GeoJournal*. 83 (2018). 631-644.

⁵ The right to the city exists in many forms within states' constitutions—a direct right, an embedded right as a component of other rights, and as an implied right (Oren, Alterman, and Zilbershatz, 2014). There also exist "quasi-rights," which are neither fully realized rights nor legally binding.

⁶ They find support in two other important documents: the 2006 European *Charter for the Safeguarding of Human Rights in the City* and the UNESCO–UN Habitat project of 2006, which focuses on city dwellers and their "collective rights" to welfare, governance, and efficient public services.

Transposition of Advocacy Experience as Triple-Loop Social Learning in Albania: Fighting HPPs in Protected Areas from the Vjosa River Basin to the Canyons of Osumi

Abstract: This paper traces the learning experiences of communities, living near protected areas, taking to the Administrative Court, in view of a lack of environmental crime law that would render these cases penal procedures, government decisions awarding the right to build hydropower plants to several national and international companies. We focus on the first four such administrative lawsuits in Albania, arguing against the construction of HPPs in the protected areas of the Vjosa river basin, the Valbona Valley National Park, the Seta river, and the Canyons of Osumi, from 2016 to 2018. Based on Brown et al.'s definition of triple-learning loops as a process transformative of decision-making paradigms and of the learning process itself (2015, pg. 1685), we demonstrate how the fight to protect national parks, biomonuments and dependent livelihoods, accompanied by social media campaigns and protests, have informed practices of participatory social learning (Brown 2015, 1686). We break down the dynamics of the multi-level and multi-agency approaches of these claims, to denote and explain the role of multiple social actors opposing the lack of compliance with environmental legislation on protected areas. We, ultimately, argue that the switch in feedback loops has acted as a catalyst for sustained behavioural change, and rendered possible the transposition of advocacy practices across different communities.

Keywords: triple learning loops; protected areas; environmental law; adaptability; Albania

Introduction

Since 2008, one of the main priorities of the Albanian government has been the exploitation of water resources in the country. First and foremost, the idea for the exploitation of water resources in Albania is based on the wrong conviction that given how the per capita water use in the country is among the highest in Europe this resource is endurable and associated benefits are permanent. Thus, the Albanian government focused on the massive development of hydropower plants (HPPs) of different sizes and types. These efforts however, have been accompanied by an indiscriminate action to exploit all water resources, independently of their ecological and biological values and approved permits for HPP constructions have been awarded independently of their social and environmental impacts. This way “[t]o date there are around 500 hydropower plants in Albania that are either operative, under construction, or planned. Of these, 105 are located in protected areas. Such power plants have had a significant impact on local biodiversity (Gjoka, 2018).” The lack of transparency that surrounded the processes of concessions the government made to private, foreign and in-country companies contributed to a widely chaotic misinformation process that made for a powerless citizen. At present, 95% of

Albania's electrical consumption needs are covered by production from hydro sources (Ministry of Infrastructure).

However, the implementation of such policies is not backed up by any significant, or meaningful study, on water resources in Albania and any proof that the production capacities of existing and proposed HPPs would eventually outweigh the permanent destruction of the natural ecosystems where they were built or are planned (Revista Monitor, 2013). The case is even more so when it comes to HPPs built in protected areas (PA). More to this point, several environmental NGOs and activists in Albania and elsewhere argued against these measures. The various privately-owned HPPs have brought about significant alterations to the Albanian landscape. The most prominent biologists in Albania saw themselves improvising as activists and arguing in favor of protecting the flora and fauna (Miho 2015a; Miho 2015b; Miho 2015c).

More specifically, just to briefly reference the average drop in annual rainfalls, the Albanian Institute of Statistics (INSTAT) reports, net domestic production of electricity decreased by 36.6% in 2017, with “public hydro plants decreas[ing production] by 42.7% and independent and concessionaire power producers decreased [production] by 21.3%” (INSTAT). The contrary was true a year later, to be fair. According to the same data gathering and interpretation process, in 2018, a good year given the rise in 89% gross domestic production of electricity, “public hydro plants contributed 68.4%, while independent hydropower plants realized 31.6% of the net domestic electricity production” (INSTAT).

As studies on the impact of HPPs, small and medium, that have sprung everywhere are beginning to be carried out either by Albanian biologists and scientists, or international bodies concerned with the environment it is obvious that the abovementioned premise does not hold true. While Albania might have a high water resource per capita in general, the relatively low and fluctuating productivity of HPPs when compared to their environmental impact does not always justify their presence.

Furthermore, the indiscriminate construction of HPPs has forever altered the landscape of the livelihoods of the communities that reside near them. While often advertised as one of the last unexploited European gems, local eco-tourism has suffered, especially in the case of touristic initiatives relying on the Valbona river PA, as we will show later on in this paper.

The current government came into power in 2013 with the promise they would halt the ferocious HPP development, but this did not prove to be the case and personal and corruptive interests have since often prevailed. Then again, the Albanian government is paying lip service to European integration strategies aiming at supporting and developing sustainable tourism, increasing environmental quality and contributing to ‘blue growth’, such as the EU Strategy for the Adriatic and Ionian Region (EUSAIR).

The situation escalated to the point that an assessment study, titled ‘Identification of water related conflicts linked to hydropower project in Albania’ (Qendro, 2017) carried out as a joint effort of several main environmentally focused think tanks and NGOs operating in Albania in 2017 showed the dire consequences of the clashes between communities threatened by the construction of HPPs and state authorities. More specifically, between 2012 and 2016, 34 people were arrested, among whom protesting the Cernaleva HPP three women and one minor, while six casualties were recorded overall.

Meanwhile, the negative impact of HPPs on ecosystems and the communities left without water became the subject of several journalist denouncements both at home and abroad. Among the most outrageous examples, the Rapuni 1 and 2 projects built in the Shebenik-Jablenica national park registered the desertification of much of the protected area and failed local mini businesses relying on water mills (Qendro, 2017).

Community Organization and Knowledge Transfer

This section of the paper traces the learning experiences of communities, living near protected areas, taking to Administrative Court, in view of a lack of environmental crime law that would render these cases penal procedures, government decisions awarding the right to build hydropower plants to several national and international companies. We focus on the first four such administrative lawsuits in Albania, arguing against the construction of HPPs in protected areas and more precisely those of Poçëm in the Vjosa river basin, the Valbona Valley National Park, the Seta river in the Dibër Municipality, and in the Canyons of Osumi, from 2016 to 2018. We demonstrate how the fight to protect national parks, biomonuments and dependent livelihoods, accompanied by social media campaigns and protests, have informed practices of participatory social learning (Brown et al. 2015, 1686).

The most sensational case of an HPP being built on a river while highly disrupting its ecosystem was that of the HPP planned in Poçëm, in the Vjosa river, one of the few existing wild rivers in Europe. The plans for Poçëm made the round of the news and of the European community of environmentalists, whom organized and staged several protests in Tirana, in front of governmental buildings. What gave protesters a leg up in this fight was the successful association of Vjosa with the ‘Blue Heart of Europe’ area of which the river is part, tracing the beginning of the river as the Aoos in Greece and making casual references to the mythologies the latter is tied to. Biologists, nature conservationists and both traditional and social media jumped on the branding. Although within national parks from Slovenia to Greece a total of 1,003 HPPs were estimated to exist in 2018, while 188 were being built and 2,798 were planned (Morris, 2018), the argument that the dam in Poçëm would forever alter the landscape of Vjosa caught up. Poçëm’s case altered the landscape of protests organized by small and poor communities, which often were paid fleeting attention by traditional media, but never received any support from outside civil society organizations (CSOs) and/or environmental actors. The community protest in Poçëm benefitted from visual materials and strategic protest tools, such as people chaining themselves to block nearby national roads (Koha Jonë, 2016). Another peculiarity of the protests in favour of the preservation of the Vjosa River was the public stance against the governmental decision on the part of five Mayors, belonging to the Përmet, Tepelenë, Memaliaj, Mallakastër and Selenicë Municipalities, who argued against the Environmental Impact Assessment that informed such decision, in February 2017 (BIRN, 2017).

Thus, Poçëm marked the first instance of a community, 37 individuals supported by three national NGOs, taking the state to court, and more precisely sued the now former Ministry of Energy and Industry, the now former Ministry of Environment and the National Environmental Agency, over the approval of an HPP permit. The sensationalism had turned into excitement and hope and the materialization of the protest into a court case, the first of its kind. CSOs felt more compelled and secure enough to speak up and insisted on the government’s obligations to several international agreements, such as the Bern Convention (ecoalbania, 2018). On 2 may 2017, via Decision no. 1813 (ecoalbania, 2017), the Administrative Court of First Instance of Tirana found the approval of the HPP permit on Poçëm to be invalid and stated that the expenses incurred by the plaintiff were to be covered by the indicted parties. More precisely, the decision of the Court stated that the developer did not fulfill his duty, and did not inform the general public on the public hearing, according to conditions specified in point 6 of DCM no. 247, date 30.04.2014, ‘On the definition of rules, requirements for informing procedures and the involvement of the general public in environmental decision-making processes’. The latter states that the developer must notify and inform the public via audiovisual media channels, printed local and national media, given the national character of the HPP project, the placement of informative tables at the place where the project is to be developed, and making available material concerning the public hearing at the offices of the Local Government Unit (ecoalbania, 2017).

Although the victory of the community impeding the construction of an HPP in Poçëm was historical and ground-breaking, the practice of building HPPs in protected areas did not stop there. Another, more sensationalist, case was that of the HPP permits approved on the Valbona river.

“In January 2016, local people in Valbona Valley National Park learned of the plans to build as many as 14 hydropower plants along 30km of Valbona River, 8 of them wholly within the National Park. The procedure and content of the projects’ environmental impact assessments demonstrate non-transparent decision making, disregard for local communities’ well-being and indifference towards high conservation value ecosystems, including a complete disregard of the fact that the development is occurring in a protected area” (Toka, 2018).

Here the Valbona community benefitted from a relatively long, taking into account the history of the nation, and stable operations of eco-tourism. The Valbona community had been attracting tourists from all over the world as one of two most popular mountain destination, together with Theth, and had been advertised internationally by big international actors acting in the country, such as The Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ) Albania, which supported the development of the Peaks of the Balkans trail. Needless to say, the Valbona community protests made use of the momentum built by the protests still occurring with regard to the Poçëm HPP and representatives of the cultural community in Albania, who had supported the electoral campaign of the ruling party or the Prime Minister himself given his role in the cultural promotion of the country abroad, voiced their stance against the HPPs. A series of events and actions were organized by different stakeholders, among which the most popular proved to be two concerts: one organized in Valbona, which attracted Albanians from all over the country and from Kosovo as well, and another one in Tirana in the city center. Protest supporting the conservation of the Valbona River were also held in New York. The concerts were played by internationally renowned figures. The events were accompanied by some ongoing fund-raising that goes toward the legal battle.

The court case regarding Valbona proved to be a harsher battle, accompanied by some outrageous court standings. First and foremost, the suing community, the Valbona community, at a certain time was not even recognized as a lawful representative of the region by the Administrative Court of First Instance of Tirana. The first lawsuit “was thrown out by the court after 14 hearings and 5 months,” as the Court stating that the government makes decision with the best interest of the citizen in mind. The plaintiff argued that their rights to free speech and “right to information, involvement in decision making and judicial recourse in development decisions with environmental impacts,” (Toka, 2018) deriving from the Aarhus Convention of which Albania is a signatory, were not respected. The case is still being processed, while the construction company, or the HPP company, is sporadically working on the project, excavating and permanently altering the environment. Conversely, the developer Gener-2 and their subsidiary company Dragobia Energy have taken to court one of the main organizers of the protest over damages on their image. The Toka NGO, as the leader of the lawsuits and any other organization against the HPPs in Valbona, nevertheless states that the experience so far has been overall a positive one. “The battle so far has been notable in helping to change the national perception of protected areas and National Parks, from distrusted, ‘mysterious’ zones created by the government to limit the rights of inhabitants to national treasures belonging to the people” (Toka, 2018).

In 2015, the National Territorial Council, part of the National Territorial Planning Agency, released a permit for the construction of four HPPs onto the Seta River, to the HydroSeta Power company. Given how the area is protected by Albanian law, and more precisely via Decision of the Council of Ministers no. 676, date 20.12.2002, “On the provision of protected natural areas” and Law no. 112/2012 “On the integrated management of water resources”, inhabitants of the area brought their claim to court asking for the partial annulment of the concession contract concerning the construction of the last HPP, SETA 4. The inhabitants claimed that this particular HPP would impact two, out of four, canyons which are within the protected area. While the inhabitants of the area argued that the deviation of the water resources would impact PAs and decimate the trout population, the representative of the former Ministry of Infrastructure and Energy argued that given how the HPP would not be built on PAs or biomonuments the plaintiff’s claim had no grounds. The inhabitants of Çidhën faced the state in court since 27 July 2017 and during 17 months they participated in a total of 20 judicial sessions. In August 2017 the police prosecuted 20 inhabitants that tried to block construction

in the area. In December 2018, the Administrative Court of First Instance definitely dismissed the plaintiff's claims and although the case was presided by a judge, "the decision was taken by a majority of votes" (Curri, 2018).

Nevertheless, a last case arguing for the protection of PAs, was still won by a community taking on the role of the plaintiff. A concession to the HEC Bigas and Veleshnje company, to build two HPPs in the Bigas watershed, in the Canyons of the Osumi River was kept secret for years, from 2013 to 2018 to be precise, until the case was uncovered by one of the top media channels in the country. Following the highly unpopular news, and how the Canyons of Osumi have become one of the main touristic attractions in the country, highly advertised via celebrities and high-level politicians, and hence a meaningful generator of revenues for the areas, adjacent communities, touristic operators and the general public started protesting the decision both in the streets and online. In a very successful first, the construction permit given to the developer was found to be irregular by the Ministry of Tourism and Environment and the Ministry of Infrastructure and Energy (MIE). More precisely, the MIE announced on 15.02.2018 that the administrative act concerning this case's Environmental Impact Assessment was null. Ultimately, the developer would sue the government on the rescission of the permit to no avail.

Figure 1. Map of hydropower plants in protected areas throughout Albania (source: exit.al)

A successful series of community protests was that of the inhabitants of Zagoria. The Albanian branch of the Dutch giant, Shell, had signed another silent contract with the National Agency of Natural Resources, representing the former Ministry of Energy and Industry, to drill in four different blocks in Albania via DCM 350, date 12.6.2018, "On the approval of the contract dividing production on the research, development and production of hydrocarbons in the soil, in Albania, Block 4, between the Ministry of Infrastructure and Energy, represented by the National Agency for Natural Resources and Shell Upstream Albania B.V.". When the Dutch

company announced community hearings, as per Law no. 10281, date 20.05.2010, “On concessions”, protests ensured. The popularity of the region, deriving not just from its touristic destination status but from the fact that one of the most popular bottled waters comes from Zagoria and is named after the region, social media followed up with online petitions and denouncing the nature of the arrangement. Ultimately, unable to conduct public hearings with the communities and overwhelmed by the pressure coming from public opinion, Shell Upstream Albania declared it was giving up its search for oil in Zagoria.

Indeed, the transformation of the overall situation regarding translated into such pressure for the next Minister of Infrastructure and Energy, after the restructuring of the Ministry and the government even more widely, that in February 2019 she declared that she would freeze works on the two HPPs that were to be built in Gramsh, near the Holta Canyon, another very popular tourist spot (Spasić, 2019). The declaration did come after protests were organized by inhabitants of Gramsh and villages near the Holta Canyon. In a first, the Minister also stated that she would investigate 182 licenses issued to build a total of 440 HPPs (Spasić, 2019), and backed her statement with the fact that the damages these SHPPs would cause outweigh the economic gain they generate (Spasić, 2019).

What had occurred at a national level, thanks to social media, traditional media and journalists that were willing to challenge the status quo of silent deals, agreed upon away from the public eye, was participatory social learning which had translated these actions into “knowledge exchange, adaptive management and local leadership, together with recognition of informal or tacit knowledge systems that extend beyond conventional scientific knowledge (Nazarea 2006 in Brown 2015, 1686).” Participatory social learning allows for “[p]luralistic approaches to knowledge development can provide an important enabler for engagement of civil society in sustainability planning if they can incorporate longer time horizons, adaptability and feedbacks, integrated approaches, and systems thinking (Burch et al. 2014 in Brown 2015, 1686).”

As Löf explains in his paper, *Exploring Adaptability Through Learning Layers and Learning Loops*, the need of small communities, that depend on water resources and rely on protected areas statuses in various locales throughout Albania to sustain their livelihoods, to adapt and react against a situation always in their disfavor led to various learning loops (2010). Social learning with relation to environmental protection and conservation has also been the subject of relatively recent studies (e.g. Keen and Mahanty 2006; Maarleveld and Dabgbégnon 1999; Pahl-Wostl et al. 2008; Stagl 2007; Wals 2007 in Löf 2010, pg. 534).

“Social learning has for instance been applied to denote individual learning in a social context; learning by social aggregates (Stagl 2007); or synonymously with participatory processes, co-management and collaborative governance (Mostert et al. 2007). The latter conceptualization emphasises that multiple-loop (group-layer) learning does not come automatically but requires deliberate and strategic efforts. (Löf 2010, pg. 534).”

Transformation of Feedback and New Learning Loops

Based on Brown et al.’s definition of triple-learning loops as a process transformative of decision-making paradigms and of the learning process itself (2015, pg. 1685), we demonstrate how the fight to protect national parks, biomonuments and dependent livelihoods, accompanied by social media campaigns and protests, have informed practices of participatory social learning (Brown 2015, 1686). We, further, argue that these communities have been able to turn a self-reinforcing feedback loop, one where economic laws undermine national and international environmental legislation contributing to the mismanagement of national natural resources for over a decade, to a balancing one, where implementation of environmental legislation is equated to higher community awareness and organization. Employing Löf’s distinction of governance versus government and governing (2010, pg. 534), we break down the dynamics of the multi-level and multi-agency

approaches of these claims, to denote and explain the role of multiple social actors opposing the lack of compliance with environmental legislation on protected areas.

For years, and more precisely since the communist regime in Albania, HPPs were built in PAs altering the livelihoods of the communities living near them and making use of protected resources. Caught in a negative feedback loop where corruption weakened democracy and left no space for governance, Albanian citizens kept quiet. Switching to a double-learning loop would have meant that the citizens in the communities of Osum, Vjosa, Seta and Valbona would have had to put up with the at least one of the elements represented in the loop diagram in Figure 2, - ultimately, an impossible task if they wanted to achieve social and environmental justice.

In the previous section of the paper, we have shown how communities, together with other key actors, were able to switch to a balancing loop (Drutman, 2015), in which corruptive practices of economic legislation were countered by pro-active communities arguing in favour of the rightful application of national environmental legislation, thus, bringing the democratic system in Albania to a new stable system.

To better support the claim of this paper, that is to say that the learning loops in Albania represent a case of triple-loop learning rather than a double-loop one, it is worth shortly focusing on the distinction between the two.

As Petersen points out, landscape conservation has usually made use of single-loop learning processes, where problem solving was directed by the desired achievement, with new strategies being continually envisioned and

implemented after initial failures (2014, pg. 784). Nevertheless, this kind of learning loop only led extremely low successful percentages, and it led to even less operational changes (Petersen 2014, pg. 784). In other respects, double-loop learning requires the identification, development and integration of new behavioral changes, “as informed by the new values and frames, into group norms and relationships so that it becomes the new normal (Putnam 2014).” While Brown et al. provide the best definition of a triple-loop learning process:

“Triple-loop learning takes actors beyond pre-existing structures by challenging existing decision paradigms and the contexts which frame the decision-making process, including underlying principles and norms (Maarleveld and Dabgbegnon 1999; Pahl-Wostl 2009). Full triple-loop learning may therefore be conceptualised as learning about the learning process itself and how this process can be further enhanced to tackle new challenges and opportunities (Brown et al. 2015, 1686).”

In short, the differences between the different learning loops that have wanted to specify in this paper, with regards to the events that have taken place in Albania following the approval of HPPs in nationally protected parks, is also presented by Löf, in his publication with the *Environmental Education Research* journal:

“*Single-loop* learning refers to ad hoc or routine learning, simply responding to errors by making smaller adjustments. *Double-loop* learning refers to actively trying to change protocols and organisational norms in response to detected errors (Argyris and Schön 1978). *Triple-loop* learning entails fundamental change of the entire mental model the governance or management process is based on (Keen and Mahanty 2006 in Löf 2010, pg. 533, authors’ emphases).”

In this paper, we, ultimately, argue that the switch in feedback loops has acted as a catalyst for sustained behavioural change, and made possible the transposition of advocacy practices across different communities in Albania. We have focused on these learning loops as they challenge the status quo and disrupt the correlation between poverty, inequality and environmental degradation. Most importantly, we hope this paper serves as a reminder that environmental and social justice are deeply interwoven and that changes with regards to adaptability and governance call for:

“[b]alancing short term needs with longer-term requirements for sustainability while managing multiple uses, accounting for legacy issues, and integrating the dynamic and complex relationships between human and nature through space and time requires a more complex and integrative approach than is normally used in biodiversity conservation and natural resource management (Thiault et al. 2017, pg. 448).”

We also aimed to show in this paper, that the approach toward the protection of national parks and connected livelihoods employed “[m]ulti-modal (direct, deliberative), multi-level (local, urban, national) and multi-user (policy, [activist], research) learning loops (JPI Urban Europe)”, not only as the Looper project distinguishes in general, but also as has become general knowledge when dealing with conservation efforts and/or water management (Petersen 2014, pg. 782; Balazs 2014, pg. 99).

Conclusions

HPPs, be them small or medium, in a time of technological acceleration most often cannot catch up with their own temporalities, - the multiple timelines that include needs for approvals, public hearings feasibility studies, and the upkeep - and the social and political worlds, - often small and already having achieved self-sustainability, just like the ones we have presented in this paper, - where they would be of relevance are already obsolete. The role of the technical/engineering expert becomes irrelevant and the role of the nature conservationist takes crucial importance. The false image these failed megaprojects projected as a necessary

modernity were not only met by a knowledgeable public, but one that was willing to learn and do more. At a time of a new climatic regime, the vision of relying for energy production on the exploitation and alteration of small and medium HPPs proves unsustainable. Drawing from UNFCCC data, rainfall in Albania is expected to decrease by approximately 14.37% by 2080 and by more than 18% by 2100, while becoming more unpredictable throughout the year (Gjoka, Hoxha and Bashmili, 2018, 107-8). The overview of the exploitation of water resources in Albania, as a top-down process regulated by central government deepening financial strains for local communities, presents us with what Bruno Latour hypothesizes, “the explosion of inequalities and the denial of climate change are one and the same phenomenon (2018, p. 1-2).”

This paper is instrumental in the way it gives out an accurate account of the learning loops through which communities around Albania, living near protected areas and living off of them, passed in an organic manner with on-the-spot organization, guided by the principle of law. The social learning lesson we draw from the above cases is that it is precisely the triple-loop learning that which makes for long-term structural change (Balazs 2014, pg. 100). Furthermore, it is imperative to demonstrate, as this paper does, that these communities shook things up and completely transformed the feedback loop that the news and top-down development approaches dictated daily via the news. These communities were successful in gaining national and international visibility and went from marginalized groups to efficient governing bodies. They transformed a negative feedback loop, one where corruptive practices weakened democracy and public institutions, into a positive feedback loop, one in which governance and adaptability determine the fate of communities and the environment, and the kind of development they seek. The first four cases of citizens taking the state to court over nature conservation marked the forming of a new public, proactive, international, collaborative, engaged and engaging, and a shift from passive to active citizenry. A culture about water, biodiversity, the protection and conservation of ecosystems as values to be upheld not as commodities to be fought upon, and about the support and promotion that remote populations, which perform this kind of work, deserve was set. “[S]ocial learning provides a link between procedural and distributive justice; to the extent that it changes water management institutions (Balazs 2014, pg. 99).”

What this paper ultimately demonstrates is that communities are willing and able to contribute to effective governance even in a developing and problematic context such as that of Albania. However, what is lacking in the latter is the use of online platforms and other traditional methods, such as traditional community planning and design workshops, to effectuate policies. These tools were, however, only employed to resist top-down, environmentally exploitative policies. To conclude, we would very briefly state that the current state of development and planning policies should shift focus from ‘sustainability’ to inclusive development, which “focus[es] on social wellbeing and protecting the ecosystem services of nature through redefining political priorities, especially in the context of the Anthropocene (Pouw and Gupta, 2016, 104).”

Monitoring and enforcement of short-term rentals rules. Mission impossible?

Inês Calor¹, Mateus Magarotto^{1,2}

Abstract: Short-term rental platforms, especially Airbnb, represent a deep change in the housing sector. In Portugal, the first attempts at designing regulatory measures to balance short-term rental are far from achieving high levels of compliance. As in other European cities, the monitoring and enforcement of rules drawn up so far entail difficulties for most of the management entities. This paper aims to discuss the relationship between the type of rules designed for short-term rentals, and the enforcement effort required from public entities. The methodology relies on a brief analysis of the rules implemented in different European cities through available literature, and a detailed assessment on the evolution on the Portuguese case, evaluating the expectations on the level of compliance with short-term planning rules. To access enforcement effort, we propose a systematization of the type of rules in place in the main European cities. In countries with traditionally low levels of compliance and reduced enforcement results (such as Portugal), reducing the enforcement effort seems the 'smart' thing to do. We conclude that monitoring and enforcement of short-term rental rules is not a 'mission impossible' but it is certainly a demanding one.

Keywords: Airbnb; Short-term rental; Housing; Tourism; Illegal development

Introduction

Online platforms have a growing impact on society and urban life, allowing easy connection between people and offering the most varied types of services. The so-called "sharing economy" (for un- or underutilised assets), of which Uber and Airbnb platforms became icons, definitively changed the traditional forms of transport, accommodation, tourism and, consequently, the way to inhabit cities. This growth of the sharing economy or "economy of trust" is faced by many economists as a new economic paradigm and is expected to change substantially the service sector (Dudás, Vida, Kovalcsik, & Boros, 2017). The short-term rental sector has grown exponentially in recent years leveraged by Web applications that offer accommodation all over the world at a one-click distance. The last count of Airbnb indicates its use by nearly 500 million guests distributed across 191 countries¹. The emergence of other similar platforms, such as Flipkey and VRBO, reveal a general acceptance of this type of service and interaction. The ease of access to users and the offer of a wide variety of accommodation is now an important factor in the decision to travel or stay in any part of the world. The new technologies associated with tourism are a way of evaluating tourism business models and also to create competitive and alternative forms of accommodation (Munkøe, 2017). This business model, and competitive accommodation, are increasingly segmented and influenced by changes at consumer level, especially in

¹ <https://press.airbnb.com/pt/fast-facts/> (accessed 26 May 2019).

the last decade (Turismo de Portugal, 2007). A few years since its emergence, these new forms of rentals have caused a profound economic, social and urban impact in many cities. On the other hand, they created the opportunity for individual owners to obtain a steady income (either complementary to the family economy or by job creation), to increase cities' tourist capacity, and to encourage urban rehabilitation in city centres (R. Lopes, 2018). In Portugal, the tourism sector contributed favourable to economic growth, helping to overcome a period of crisis. On the other hand, negative externalities are strongly contested in major cities: "unfair" competition for the hotel industry, disturbance of the tranquillity and security of multi-family dwellings, and housing price-increases. Airbnb's "sharing" principle faces increasing criticism, given the fact that its offer contains a large share of entire apartments where the host is not present, and the professionalization of services is similar to hotels.

The rise of housing sales prices in Portugal between 2015 and 2017 is one of the highest in Europe, estimated at 20% (INE, 2017). The emergence of short-term rentals is aggravated by the relative ease in obtaining credit and to the incentives to foreign investments. The average value of the new loans is approaching 100,000 euros, the highest amount since January 2009 as in the period before the beginning of the last crisis (INE, 2017). Therefore, long-term rentals (historically not popular in Portugal) suffer a chronic shortage of supply and disproportionate rise in prices. After decades of rent freezing, there was an owner-favourable amendment to the Rental Law. The cease of old long-term rental contracts is now succeeding, and apartments are being made available for much higher prices or turned into short-term rental accommodation.

High prices of real estate in cities centres is not a new issue. The problem of the gradual voiding of housing in favour of commercial activities and services was recognized decades ago (Mendes, 2014). Nevertheless, the phenomenon of the short-term rental now exerts influence more widely, and, above all, the speed of change in city real-estate dynamics has no precedent.

All over the world, government and public administration bodies face a dilemma: how to regulate short-term rentals so that they can minimize negative externalities without losing their positive effect on the economy. State intervention and new restrictions on renting entire apartments is part of the current social and political agenda in most European countries (Dudás et al., 2017; Gurran, 2017). However, these first attempts to impose restrictions demonstrate that drawing-up regulations is not enough. Given the magnitude of interests and profits in perspective, owners often choose to ignore rules. In this matter we recall Bowles' estimate that *"20 per centre of the regulated population will automatically comply with any regulation, 5% will attempt not to fulfil it, and the remaining 75 percent will fulfil it as long as they think the 5% will be caught and punished"* (Bowles, 1971 in Zaelke, Kaniaru, & Kružiková, 2005, p. 24). Therefore, monitoring and enforcement are key issues in the process of ruling.

Depending on the type of rule, monitoring of short-term rental activity may require economic and (specialized) human resources. The existing traditional planning enforcement teams from local authorities are likely to need adjustment, to be able to respond to the high number of lodgings to inspect, assure in-time response to neighbours' complaints, to do digital monitoring of ads and/or eventually to serve numbers of enforcement notices. In countries with traditionally low levels of compliance and reduced enforcement results (such as Portugal), reducing the *enforcement effort* from public entities seems the 'smart' thing to do. In this paper, we argue that the enforcement effort depends greatly on the design of short-term rental rules. Implications are relevant: How often are on-sight visits required, and how many enforcement officers are needed to cover them? Does enforcement proof depend on easy-to-reach information or on circumstances (i.e. the presence of the owner during while guests are staying)?

Enforcement has always been the orphan in planning, being considered the weakest link of the planning system (Dobry, 1975 in McKay & Ellis, 2005), however short-term rentals impact and the urge to put in place effective regulation brings a new relevance to the topic. This paper discusses the relationship between the type of rules designed for short-term rentals, and the enforcement effort required from

public entities. The methodology relies on a brief analysis of the rules implemented in different European cities through available literature, and a detailed assessment on the evolution on the Portuguese case, evaluating the expectations on the level of compliance with short-term planning rules. To access enforcement effort, we propose a systematization of the type of rules designed in the main European.

1. Planning compliance in Mediterranean countries

In southern European countries illegal development is a still a wide-spread phenomenon. Previous studies estimate that more than 282,000 entire new buildings were illegally constructed in Portugal between 1991 and 2011 (Calor, 2017), 300.000 in Andalusia (Ruiz Olmo, 2015) and 1 million in Greece (Potsiou, 2015). Italy, Turkey and other Balkan countries have approximate levels of compliance (Falco, 2017; Ozer, Vardar, & Naz, 2007; Unsal, 2009; Zanfi, 2013). Building extensions, balcony enclosures, swimming pools, changes of use and other minor works are also frequently undertaken without permits.

Changes of use and subdivision of apartments are likely to be the kind of development promoted by short-term rentals. These are the most difficult to monitor and enforce. Detecting an entire illegal building is fairly simple and evidence easy to collect (i.e. aerial imagery or on-site pictures). Extensions, swimming pools and other physical elements may be more difficult, but once detected, evidence is on the ground. However, changes of use and apartments subdivisions are hidden from external sight and monitoring may require more sophisticated methods. Regarding the difficulties in enforcing changes of use, we recall of a story of a dubious Greek hotel whose owner claimed that the persons in the building were his cousins and friends whom he often entertained in his big house... He may well be successful in claiming 'absence of evidence' in a Mediterranean country court.

For several reasons Portuguese municipalities tend to be condescending on illegal development (Calor & Alterman, 2017). Studies show that municipal officers and politicians avoid detecting, serving notices and taking action in court in most circumstances. Enforcement may be initiated but, for political, social and economic reasons, is rarely taken to the limit (Leite, 2010; D. Lopes, 2004).

The same (or greater) difficulties apply to identifying primary housing, holiday housing and tourist accommodation. Today it is not rare that a single building fits all-in-one types of housing. Enforcement actions to distinguish primary housing (for relocation of residents) from holiday housing (for demolition) in squatter settlements in Ria Formosa (Algarve, Portugal) involved several officers for months, and required regular visits to hundreds of houses (Calor & Magarotto, 2018).

Additionally, the high profitability of this sector encourages imaginative solutions. The plurality of hosts and the possibility of money increases a tendency to circumvent established rules. Some amusing "informal" rental accommodation examples can be found online. Among our favourites are a garage-bar with the bathroom in the "closest bush" in Prague, Czech Republic in 2015², or a caravan parked in the centre of New York with WC at the nearby gymnasium, at additional cost at 2018³. Notwithstanding these obvious cases, mostly one cannot identify the legality of advertised accommodation.

Summing up, the level of compliance with planning rules in southern European countries is probably mid-way between developing countries (often referred as the Global South) and northern European countries (Calor & Alterman, 2017). In southern European countries illegal works are common, owners are audacious, and the administration is incapable (and unmotivated) in dealing with the high number of breaches of planning control. On the other hand, neighbours' complaints are not frequent, or socially

² <https://www.airbnb.pt/rooms/10457093> (accessed June 26, 2015).

³ <https://www.airbnb.pt/rooms/25374851> (accessed October 6, 2018).

accepted. In this context, how reasonable is it to expect that owners and promoters comply with short-term accommodation rules? Will authorities be more willing and capable of enforcing them than planning laws?

2. An overview of short-term rules and enforcement strategies

Restrictions have been enforced in several countries and cities with a high number of short-term accommodation. Strategies vary and the speed of the change of rules change is high. Rules are increasingly complex and de updated is difficult. However, this is probably the most interesting contemporary case of boundary shifting between formal and informal.

In London, a limit of 90 days' rental is applied to individual owners, except if they obtain a specific planning permit for a vacation home (Ferreri & Sanyal, 2018). In San Francisco (USA) the limit is 30 days (Gregory & Halff, 2017; Martin, 2016). In Berlin, entire houses must be registered and taxed as vacation homes. Renting rooms is accepted, with the condition that the host be present. In Barcelona, the number of entire apartments is restricted by areas, through specific zoning (Segú, 2018). In a more extreme attitude, New York has recently updated its laws to ban the advertising of short-term rentals (Dudás et al., 2017; Gurran, 2017).

The difference between entire apartment- and room-rentals (in the presence of the host) requires intensive monitoring. Even when officers are successful in entering the apartment, what evidences can prove the host presence? Personal objects or pictures? In northern European countries, telling-on-the-neighbours might help but these circumstantial evidences are not easy to be considered valid in southern European courts.

The strategies of cities to monitor and ensure rules compliance depend on the type of rules. London (and other cities) established an agreement with Airbnb to ensure automatic blocking beyond 90 days but doubt arises if the owners will comply or simply use other platforms (Ferreri & Sanyal, 2018). Several French cities also have a 120 day time-limit for renting an entire primary housing but no limit applies to room rentals (Heo, Blal, & Choi, 2019). To overcome the problem of differentiating the type of housing, since June 2018 French hosts need to categorize their listings within those three categories: primary residence, secondary residence and non-residential space⁴. Another national law comes into effect in January 2020 forces online platforms to automatic report host income and to transmit user data to the French tax authorities on a yearly basis, including gross income and number of transactions.

In 2016, the city of Barcelona fined the platform at 600,000 euros for advertising unlicensed accommodation. But the practice resumed. The number of enforcement officers needed to find illegal lodgings rental spaces in Barcelona has been greatly increased, as well as the amount of the fines (Segú, 2018). In New York, despite the ban, thousands of entire-apartment advertisements continue to be publicized (Dudás et al., 2017).

Airbnb policy on not revealing consumers or transaction data has led to the emergence of companies dedicated to the extraction of data from the platforms, such as the non-commercial "Inside Airbnb"⁵ and the commercial "Airdna"⁶. The latter provides statistical and geo-referenced information about the properties advertised on Airbnb in major cities, using sophisticated artificial intelligence methods to distinguish the occupancy dates of those blocked by the hosts. There are also new "start-ups" dedicated to gathering information about unlicensed accommodation, for sale to neighbours or to the public administration (Gurran & Phibbs, 2017). These new start-ups create an important balance in this era of

⁴ <https://www.airbnb.pt/help/article/1383/responsible-hosting-in-france#regulations> (accessed May, 30, 2019)

⁵ <http://insideairbnb.com/> (accessed October 1 May 30, 2018).

⁶ <https://www.airdna.co/> (accessed October 1, 2018).

a shared economy, where enforcement relies in digital tools as much as in physical sight visits (Harris, 2015).

3. Portuguese national strategies and tax regulation

Until recently, short-term rental was an activity free of obligations and restrictions. Despite tourist rentals were common in coastal areas during summer, authorities had always turned a blind-eye to this economic segment. In 2008⁷, the first law short-term rentals was included in a general tourism legal framework where the minimum conditions for lodgings were established. It defined short-term rental or “local accommodation” (“alojamento local”) as an establishment *“that provides temporary accommodation to tourists, in exchange for a remuneration”* and that do not *“meet the requirements to be considered tourist ventures”*. In 2014⁸ specific law entitled Legal Framework for the Exploration of Short-term Rentals was enacted and the activity was further regulated, introducing the obligation for apartments, rooms and hostels to register. The online registration application requires (i) personal information about the person responsible, (ii) a national tax office declaration (“activity initiation” to ensure that owners would be able to issue invoices), and (iii) the housing occupancy permit number (issued by municipalities after building completion). Different to other countries, “tourist apartments” permits are not granted for individual apartments or houses (may only have that designation when integrated in a tourism complex, i.e. hotel or apart-hotel). As such, any conventional house or apartment is eligible for short-term rental. After online registration has been submitted, the owner can start advertising and renting immediately. A municipal inspection would be scheduled within a month and, if it is positive, an administrative fee is due and the process concluded.

Therefore, we can note that the registration process aims on the one hand to prevent tax evasion, and, on the other, to ensure that tourist accommodation complies with minimum housing standards. At the municipal level, the first measures were pecuniary. Since January 2016 the municipality of Lisbon charges a tourist fee (two euros per day per guest). Mafra and Porto followed. Similar to other European cities, an agreement between Airbnb and the municipalities of Lisbon and Porto guarantees the direct collection of the tourist tax. Owners are responsible for paying the fees directly to municipalities when rentals are directly booked or advertised on other platforms.

Despite being competing economic activities, recent academic studies show that the impact of short-term rental in the hotel sector has been moderate, keeping the profit levels of most hotels but bringing difficulties to establishments in the low-range economical segment (AHRESP, 2016). In the main Portuguese cities, Lisbon, Porto, Braga and Coimbra, the rise in prices is significant. Gentrification is an evident phenomenon, displacing not only poor populations but also medium income ones to beyond the city centre. In academic literature the impact of short-term rentals in house-price increases is undervalued. The causes of price increases are thought to be a combination of additional factors such as low interest rates and incentives to foreign investment (R. Lopes, 2018). The proposals of the parliamentary groups have succeeded, and discussion on how to deal with high house-prices is on the political agenda. A new set of laws aiming to deliver affordable rental housing is close to being approved, and it is expected that relief from taxes on long-term rentals and other programs for increasing the housing rental stock will be debated.

An intense political debate on the policy to adopt towards short-term rental culminated with an amendment the Legal Framework for the Exploration of Short-term Rentals⁹. In force since October 2018, the changes focus on providing larger guarantees to condominiums members (they can now

⁷ Decree-Law 39/2008 from March 7.

⁸ Decree-Law 128/2014 from August 29 approved the Legal Framework for the Exploration of Short-term Rentals.

⁹ Decree-Law 62/2018 from August 22.

oppose to registers) and grant municipalities wider powers to establish zoning, restrictions on the number of local lodgings and cancellation of registrations. This law thus enables municipalities to design an urban strategy.

Today, obligations for owners can be summarized in the following list:

- **National tourism office:** register the lodgings (obliges to comply with housing standards and fire regulation and to have a complaints book).
- **National tax service:** issue an invoice within five days of the guests' payment reception, pay annual income tax and tax on capital gains (upon selling).
- **Foreigners and Border Service:** submit international guests' data within three days of arrival.
- **Social security:** monthly contribution or a trimestral declaration with total income.
- **Municipalities:** pay inspection fee (upon registration). In Lisbon, Porto and Mafra a trimestral declaration is required, with number of stays and correspondent payment of the tourist fee.

All these obligations may be fulfilled on separated internet platforms.

With a reduced tradition of monitoring and enforcement, expectations of compliance in Portuguese owners is low. A simple search on Airbnb reveals the existence of several advertisements without a registration number, or in places where it cannot be obtained such as informal settlements in public maritime areas (Calor & Magarotto, 2018). Additionally, a study by AHRESP (2016) found that the number of accommodation units officially registered in September 2016 was much lower than those advertised on Airbnb. In the capital, the difference is almost 3,500 properties, corresponding to 37.4% of those advertised on Airbnb. The parishes of Santa Maria Maior and Misericórdia (in Lisbon) and the centre in Oporto City show the greatest incongruence in the numbers - in the central parishes in Oporto it is estimated at more than 50%.

Recently, the municipality of Oporto reported that revenues from the tourist fee surpassed expectations by 50% (Lusa, 2018). As the fee is directly charged by the Airbnb platform, this difference may well relate to the difference between the number of registered accommodation units and those actually made available for rental.

Under these conditions, what are the expectations of the Portuguese Administration that it can effectively implement restrictive zoning rules for short-term rentals? Is it prepared to monitor, enforce and deal with social and political deviations from the rules? More importantly, what lessons can it learn from the experience of other cities?

4. Municipal strategies

After the 2018 law amendment, a few municipalities immediately took the opportunity to “freeze” new registrations in specific areas. In November 2018, the Lisbon municipal assembly decided to prevent further registrations in certain central areas, and the Mafra municipality did the same for the “Urban Rehabilitation area of Ericeira”¹⁰.

Very recently, in May 2019, a new municipal regulation was passed from the Lisbon municipality which “*establishes rules to apply to the new registries of short-term rentals in areas delimited as containment areas*”. The zoning defines two categories: “**absolute containment**” in areas that the ratio between registered lodgings and primary housing is calculated above 20% and “**relative containment**” for a 10-20% ratio. New registers will not be granted for areas of “absolute containment”, with one exception

¹⁰ <http://www.cm-mafra.pt/pt/municipio/alojamento-local> (accessed May, 30, 2019)

for entire buildings renovation if the building was previously in ruins and unoccupied for longer than three years. In “relative containment areas” the exceptions are broader: when an entire building or an independent unit is unoccupied for three years and has suffered profound rehabilitation works or when there was a change of use approved from industries, logistic or services to housing units in the last two years. Nevertheless, no registrations are allowed if there was an official rental contract in the last five years (even if the previous conditions are met)¹¹. It is worth noting that the enforcement section of Lisbon municipal regulation mentions that it “*can be asked to collaborate with administrative and police forces and protocols can be hold with associative and public interest entities, or contracts with private entities to undertake specific actions, namely inquire into existing establishments and their conditions*”.

No other zoning-based policy is yet known for other municipalities. Porto has announced a draft of municipal regulation for June 2019 (Lusa, 2019) but so far no restrictions to the number of short-term rental registrations have been put in place.

5. How ‘smart’ can short-term rules be?

The assertion that “*enforcement is the weakest link in the planning system*” (Dobry, 1975 in McKay & Ellis, 2005) remains actual and is pertinent. As stated above, planning enforcement in southern European countries faces strong opposition and lack of efficiency. Those countries where enforcement is particularly challenging should think “smart”, meaning, to have especial attention on the design of rules for short-term rentals by anticipating their implications on the resources for monitoring and enforcement. In a simple exercise, we suggest a systematization of the type of rules implemented in a few European cities and comment on the enforcement effort they require.

- **Time-limited rules.** May be monitored in several ways, but agreements with web platform companies, as in London, make it simple. However, owners may use different platforms to manipulate the restrictions, so digital monitoring is still necessary. Site visits seem necessary only after owners have exceeded the time-limit.
- **Accommodation-type rules.** Rules that differentiate rooms from entire apartments, as in Berlin and Paris. To verify the presence or absence of the owner, regular visits to the lodgings are necessary and, because it relies on circumstances, enforcement may be delicate. Monitoring may rely on neighbours’ claims, so incentives and open-lines for citizens to communicate with administration seems a key-tool.
- **Zoning rules.** Rules may be more restrictive in specific areas of the city. Barcelona, Lisbon and many other cities are applying different rules according to different zones. As locations at Airbnb may not be accurate, digital monitoring and sight-visits might be necessary to make a match between building pictures and platform information.
- **Registration rules.** Requiring a register makes monitoring and enforcement much easier, as responsible-person contacts are available. Implemented in Portugal and Berlin, it allows data crossing with other public bodies and practicable to serve enforcement notices if subsidiary rules are not followed. If a registration number is mandatory on the advertisement, digital monitoring becomes easier - despite still being necessary to check the correspondence between the added details and the registration data (fake numbers may be used). It also makes it easier to establish maximum quotas for the number of lodgings allowed.
- **Banning rules.** Some cities do not allow short-term rentals at all, such as New York. Banning entire apartment rentals in specific areas is implemented in Berlin. These kind of rules are easy to monitor but not easy to enforce due to the general trend of acceptance of this type of rental.

¹¹ <http://www.cm-lisboa.pt/viver/urbanismo/alojamento-local> (accessed May, 30, 2019)

National policies and local governments have opted for a combinations of rules (for some European cities see Table 1). In Paris, where the number of existing accommodation units in Airbnb is the highest, all types of rules except banning are in place. Despite its necessity, this wide strategy demands a considerable number of specialized human resources for the different tasks involved, such as digital monitoring, sight-visits and enforcement-notice serving.

Table 1: Short-term rental type of rules in European cities.

Short-term rentals type of rules					
	time-limited rules	accommodation-type rules	zoning rules	registration rules	banning rules
Lisbon (PT)			X	X	
Berlin (DE)		X	X		X
Barcelona (ES)			X	X	
Paris (FR)	X	X	X	X	
London (UK)	X	X	X		

The difference between entire apartment and room rentals (in the presence of the host) requires intensive on-sight monitoring. Even when officers are successful in entering the apartment, the owner might not be there. What evidence is accepted for the owner's presence? Having personal objects or pictures would be enough? This sort of rule seem difficult to enforce, at least in southern European countries' social context.

In general, the type of rules that depends more on digital tools than site-visits demand less resources. Even if specialized human resources are needed for this task, it allows them to cover a wide number of situations in a shorter time. Plus, evidence is easy to collect. We also consider especially positive the implementation of registration rules, as it guarantees an access to owners (which is very important in countries where cadastre and property rights are not always accessible to local administration).

5. Conclusion

The rapid evolution of the short-term rentals business has caused a paradigm shift in major European cities. The growth of the economic sector has been accompanied by attempts to regulate the activity, and different types of rules have been adopted. The number of obligations for owners are summed up and their complexity is increasing. Consequently, the probability for voluntary or involuntary incompliance is high.

In countries where enforcement is particularly challenging, regulation should anticipate the implications of enforcement effort on public administration. If rules require non-existent resources or actions that are difficult to put in practice, they are likely to fail. To better access the enforcement effort we suggest a systematization of the type of rules implemented in a few European cities: (i) time-limited rules; (ii) accommodation-type rules; (iii) zoning rules; (iv) registration rules; and (v) banning rules.

From this exercise it is perceivable that monitoring and enforcement of short term rental rules is not a 'mission impossible' but it is certainly a demanding one. Digital monitoring is relatively new for authorities and may require skills that are more sophisticated. Airbnb have accepted collaborating with administrations on time-limited type of rule, but it has been resistant to help monitoring other types of rules (despite the costs of court cases). The yet-to-be-implemented French law on automatic reporting of host income and transmitting user data to the tax authorities seems a step forward in the relations

between public administration and online platforms. If successful, most probably other countries will follow.

In comparison to most European countries, Portuguese regulation is still “soft”. From the above mentioned, only registration rules are in place for the entire country and zoning rules apply for Lisbon and Mafra only. Nevertheless, based on the experience on planning enforcement, there are good reasons to believe that municipalities will not be motivated to deal with monitoring and enforcement tasks. Besides the lack of enforcement resources, there is also an economic interest behind low levels of monitoring in cities where a tourist tax is charged directly by online platforms. As Porto municipality remark shows, municipalities will probably have little interest in “chasing” unregistered lodgings as they profit from them. On the other hand, the national administration has an objective interest in reducing tax evasion, so it is more likely that they probably more active in enforcement.

Finally we underline that improving compliance with short-term rules should not be regarded as a formal issue or exclusively an administrative responsibility. It is a matter of order, justice and collective responsibility. For consumers there is also a "social" responsibility behind the verification of the legality of the lodgings to rent, as a conscious and respectful attitude towards the local inhabitants.

COMMON VALUE: TRANSFERRING DEVELOPMENT RIGHTS IN THE FACE OF CLIMATE CHANGE CHALLENGES

Besmira Dyca

Phd candidate, Northumbria University, email: besmira.dyca@northumbria.ac.uk

Abstract: Flooding accounted for more than 37% of natural disasters in 2017, affecting 55 million people and amounting to 20.3 billion \$ of economic losses worldwide. These figures are the highest in the last decade and with higher urbanization rates, the number of people living in precarious and flooding prone areas is increasing. Under the light of these challenges, Flood Risk Management narrative is evolving towards integration of nature-based solutions and Green Infrastructure. This paper investigates the role of Land Value Capture instruments in financing Green Infrastructure. More specifically, this research focuses on the Transfer of Development Rights (TDR) instrument, which has enabled some planning authorities in the global north and south to successfully adopt preventive measures in flooding prone areas. Through TDR, property devaluation in flood prone areas or areas where Green Infrastructure is to be implemented is cross-subsidized through capturing part of the “windfalls” in properties benefiting from GI, by transferring development rights from the former to the latter.

Keywords: Flood Risk Management, Green Infrastructure, Land Value Capture, Transfer of Development Rights

Introduction

Floodplains can be described as areas between levees or within the river valley, which can be inundated or overflowed when the river becomes “too full” (Hartmann, T., 2016; Cambridge University Press, 2019). Yet floodplains are also the locations where the first civilizations emerged. The ever going symbiotic yet conflictual relationship between water and human activity is not a contemporary phenomenon; indeed Hartmann (2016) refers to floodplains as contested land. However, with the latest trends of urbanization and increased occurrence of extreme weather events and flooding possibility, the amount of human resources and capital exposed to flood risk is increasing.

There is now a common accordance that higher levies and grey protective infrastructure alone will not resolve the future flood protection needs; perversely it might contribute to higher vulnerability towards disasters from unpredicted and extreme weather events. For instance, traditional solutions to flood, like levees take up space from the river beds, reducing their retention capacity and therefore contributing to higher exposure to flood risk over time. Hartman (2016) illustrates this phenomenon with a specific example, referring to River Elbe that lost 2,300,000,000 m³ of its retention volume since the 12th century, which for a specific locality, such as Wittenberge can translate into an increase in water levels by 50cm. Therefore, flood risk management narrative is shifting more towards finding nature-based solutions and investing in green infrastructure (GI). However, there are various barriers that hinder the

implementation of green infrastructure, the most relevant of which have to do with development pressures in flood prone areas, scarcity of land for accommodation of GI and lack of financial resources for their implementation (O'Donnell *et al.*, 2017).

On the other hand, various studies have revealed the impact that GI has on land markets (Lamond and Proverbs, 2006; Bin and Polasky, 2013; D'Acci, 2018; Jung and Yoon, 2018; Zhang *et al.*, 2018). Recouping some of the incremented value of land by the public authority, with the purpose of covering all or some of the costs of providing infrastructure and services is what is usually referred to as Land Value Capture. Smolka and Amborksi (2000) define LVC as “the process by which a portion of or all land value increments attributed to the 'community effort' are recouped by the public sector either through their conversion into public revenues through taxes, fees, exactions and other fiscal means, or more directly in on-site land improvements for the benefit of the community”. LVC has been widely investigated as a means to finance infrastructure and promote sustainable urban development, however not much literature is available about its role in Flood Risk Management programs – most research is related to transport infrastructure and traditional methods of tax capture and/or betterment. The purpose of this paper is to explore the potential how LVC can facilitate the implementation of GI, by focusing on one particular LVC instrument: Transfer of Development Rights.

Flood Risk Management and Green Infrastructure

A recognition for more sustainable and natural solutions has increasingly become a cross cutting topic in various international, national and local FRM policy documents. The 2007 Flood Directive of the European Union for instance, points towards the need of providing more space for rivers as a sustainable flood prevention measure. The European Commission Strategy “Green Infrastructure (GI) - Enhancing Europe's Natural Capital” further highlights the need for mainstreaming green solutions to urban problems, including disaster risk management. Green Infrastructure¹ is defined as “strategically planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services” (European Commission, 2013). Dutch authorities have recognized since 2000 that the current water management systems relying on technological solutions and grey infrastructure will be insufficient to face future coastal and river flooding risks; hence more space should be made for water. Similarly, the aftermath of Hurricane Katrina in 2005 has pressured policy makers in the state of Louisiana and the city of New Orleans to think of alternative ways to increase the urban resilience towards extreme weather events. Consequently, the New Orleans Masterplan emphasises the need for a shift from traditional flood protection infrastructure to more natural solutions, including solutions such as wetland conservation (Kazmierczak and Carter, 2010).

The integration of GI in urban areas provides many advantages in comparison to grey infrastructure, from integrating urban green with other urban infrastructures, to multifunctionality, serving not only its

¹ Here the term “Green infrastructure” is used interchangeably with “Blue Green Infrastructure”

infrastructural purpose but also an ecological, social and economic role. Due to its multifunctional properties, GI is considered to be more efficient in handling complexity in an urban setting in comparison to more traditional infrastructure (Hansen and Pauleit, 2014). The multifunctional nature of GI and other benefits associated with it such as increased public spaces, improved image of the city and overall contribution to a better quality of urban life are sometimes bigger drivers for implementation than their effect in climate change adaptation (Kazmierczak and Carter, 2010). Despite GI planning being more suited for urban areas in terms of aligning ecologic, economic and social interests, its implementation remains very limited and calls for a careful identification and evaluation of the barriers that restrict its mainstreaming.

Challenges for the implementation of Green Infrastructure in Flood Risk Management

While GI has attracted a lot of attention amongst academics as well as policy makers, publications and guidelines about it have by far outnumbered the actual practices of its implementation. Regardless of its many benefits when compared to more traditional alternatives, the implementation of GI seems to be perceived as more complex and remains stubbornly slow. Clean Water America Alliance (2011) has categorized the main barriers to GI implementation into four groups: Technical and Physical Barriers, Legal and Regulatory Barriers, Financial Barriers and Community and Institutional Barriers. Technical and Physical Barriers include lack of technical knowledge on GI and its benefits, lack of experience in its implementation, limited empirical information regarding its costs and benefits, as well as physical challenges such as availability of land. In terms of Legal and Regulatory Barriers, the most important challenges derive from lacking or conflicting local rules and from land use policy and property rights which might complicate matters. Lack of funding and perceived high costs for upfront implementation and maintenance are also amongst the most common barriers towards mainstreaming of GI. The multifunctional nature of GI calls for effective cooperation and partnerships between various stakeholders. Hence, education and capacity building of political leaders, administrators, professionals and of public in general is essential.

Similar findings were attained by a study in the city of Newcastle. The most prevalent barriers were of socio-political nature, from reluctance to support novel approaches, lack of knowledge and education on the subject, to lack of finance (O'Donnell *et al.*, 2017). Indeed, when it comes to implementing GI for flood prevention purposes, seeking to mimic pre-development hydrology, financial constraints are often linked to the spatial requirements of such projects, which generally demand more land available for their implementation than grey infrastructure. For example, traditional systems address storm water management through underground pipe networks, whereas a green solution might entail systems that allow storm water to infiltrate into the ground, which sometimes requires additional land reserved and designed for this purpose. Similarly, “making room for rivers” approach to flood prevention also calls for planning of submergible land, which can serve other alternative purposes as well, in terms of green and open spaces, but which cannot be developed and is ultimately reserved to its ecological, social and climate mitigation function. However, empirical studies that evaluate the economic benefits of GI, which would serve to inform decision making and explore alternative ways of financing GI, have been limited.

Nevertheless, Kazmierczak and Carter (2010) argue that while environmental protection and economic development are traditionally considered conflicting issues, recent local initiatives have provided examples of how the latter can support the implementation of green infrastructures. The municipality of Faenza is implementing an incentive program which allows developers to take advantage of higher FARs in exchange of providing green roofs, green walls, contributing to public green spaces and water retention systems. Similarly, South East Dorset local authorities are also deploying developer contributions to mitigate adverse effects that developments might exert on Dorset Heathlands. Berlin's Biotope Area Factor is another example listed by Kazmierczak and Carter (2010) in the realm of developer contributions for the implementation of climate change mitigation measures.

Notwithstanding various local initiatives in exploring the financial benefits of GI and ways of taking advantage of such benefits to support their implementation, financing of GI through capturing part of the value it creates in the land markets is still a rather unexplored path.

Flood risk management, Green infrastructure and Land markets

Understanding how the land and property market reacts to flood risk, flood events and mitigation measures, especially Green Infrastructure is an imperative step towards exploring innovative financing mechanisms through land value capture. While there is not a one size fits all formula in measuring such impacts, there are several attempts made in this direction, some of which have been summarized in the following sections.

Flood risk, flood events and Property market

Measuring the impact of flood risk and flood events in the real estate market is not a straightforward process, as real estate values tend to fluctuate due to many factors which can be location-specific and therefore difficult to isolate. However, there are some generalizations which can be drawn from the existing body of literature that shed some light into the relation between FRM and land markets. Although attempts to establish a link between disaster risk and real estate market has been considerable, most studies have focused on the ex-post side of the event, therefore analysing the impact of a disaster after it has happened (Jung and Yoon, 2018). Nonetheless, it can be safely assumed that the potential risk of a disaster, when recognized, should be reflected in the market prices of real estate goods – buildings and land.

Bin and Polasky (2003) concluded that a common finding of various studies during 1985-2001 was that properties in floodplains² are on average 4% to 12% cheaper than comparable properties outside of the floodplain. Indeed, a study they conducted about Pit County, North Carolina, that was hit by Hurricane Floyd in 1999, causing torrential rains and flooding, concluded that the market value of similar housing units inside the floodplain was 5.8% lower than outside of it. Also, they point out that the sale value

² Floodplains are defined as areas that would flood in a 100-year flood event

reduction is higher than the capitalized insurance premiums, suggesting that some potential flood damages might not be insurable. One reason for this could be that floods cause non-monetary losses, including items with sentimental value or the psychological and physical hassle experienced during and after the event by those affected, which is difficult to monetise. However, this was not the case before the Hurricane event, when the sale value difference between housing units inside and outside of the floodplain were lower than insurance premiums. This might indicate that homeowners and buyers are not completely aware of the flooding potential and the cost of potential damage, therefore underestimate the risk of living in the floodplain (Bin and Polasky, 2003). Hence risk awareness can play a crucial role in terms of how much this risk affects the real estate market.

Considering the dynamics of the real estate market, the time elapsed after the disaster is as crucial as location and distance from the flood risk areas. Jung and Yoon (2018) have analysed the impact in real estate market of both the proximity to flood prone areas and the time passed after the inundations in Gyeonggi Province, South Korea, from 2008 to 2013. Their study finds that within 6 months after the flood events, its impact on the properties under investigation extends up to 300m from the inundated area, with the following rate: 0-100m from the inundated area suffered an average of 11% depreciation in price, 100m-200m suffered an average of 7.4% depreciation in price and 200m-300m suffered an average of 6.3% depreciation in price. In terms of the magnitude of such effects in time, within the 300m distance from inundated area, the properties were studied for the intervals of 1 month, 1-3 months, 6-12 months and more than 12 months after the flooding and the effect on market prices was depreciation by 57.6%, 49.2%, 45.9% and 33.4% respectively. After 12 months the effect of the event on the single-family housing values was negligible (Jung and Yoon, 2018).

While the negative effect of flood risk and flood events in land markets can be considered a common sense, the magnitude of this impact, in terms of value depreciation, geographical impact and time duration of the impact varies widely from one case to the other. In broad terms, Lamond and Proverbs (2006) describe four different scenarios of how flood risk affects property values. First scenario refers to a low risk area, where a weather event might negatively affect property values for a while, but they bounce back soon after because the probability of reoccurrence is low. Second, intense weather events in disaster prone areas tend to not affect the property market substantially, since the market already reflects the risk, or because of established public compensation programs or insurance schemes. Third scenario refers to extreme weather events in areas previously considered safe have a considerable and long-lasting effect in the property market since the area is no longer considered safe. However, the effect of natural disasters in property market values is closely linked also to the government interventions measures. Hence, the fourth case presented shows that market prices decrease temporarily after a disaster and increase even higher than before if public funds are allocated to restore the area and protect it from future natural risks.

Green infrastructure and Property market

Different from the impact of floods on the property market, the impact of green infrastructure in the latter is still in the early stages of research. This is mainly due to the limited experience with the implementation of Blue Green Infrastructure and therefore limited cases for empirical investigation. Nevertheless, inquiries on which factors affect more the decision from the demand's side and impact

more property values have concluded in results that might be relevant to consider when discussing about GI.

Classic economic theories of land rent are mainly based on simplified models of cities with a monocentric structure, where *ceteris paribus*, the value of land and improvements decrease with increased distance from the city centre. On the other hand, contemporary urban location theory recognizes that with advancements in transport options and technologies, as well as with the decentralization of functions within the city, land markets reflect a more complex pattern and might not necessarily decrease with increased distance from CBD (Balchin *et al.*, 2000). Quality of life and quality of urban environments are becoming increasingly determining factors of property valuation or depreciation, but their translation in economic terms has been challenging (D'Acci, 2018). Quality of life has been defined and redefined with every study focusing on it, however a common denominator of such definitions remains safety. Nevertheless, when it comes to disaster risk management, the multifunctional character of green infrastructure brings to the table, besides its role in providing safer environments, also recreational and landscape advantages, contributing to higher quality of urban environments and to its consequent reflection in the real estate market.

Facing increased disaster vulnerability in fast growing urban areas, the Chinese government launched in 2014 its “policy of allowance” promoting the construction of sponge cities, seeking to support more sustainable urban development models that will increase cities’ resilience and overall improve the urban environments and quality of life by mimicking natural processes. Shortly after, Wuhan city, one of the ten largest cities that suffer frequently from river and pluvial flooding, was selected as a pilot and scheduled to implement the sponge city working plan in 2 years’ time. Covering only CNY 1 billion out of the total cost of CNY 15 billion through a central government grant, the city of Wuhan is lagging behind in the implementation of the project and is searching for alternative ways of financing (Zhang *et al.*, 2018).

A study by Zhang *et al.* (2018) evaluates citizens’ awareness and perceptions on urban flooding and sponge city, and most importantly their willingness to pay. Eventhough this study cannot measure the actual impact of such a project in the real estate market, it has a substantial contribution in understanding what the public’s perception on the economic value of such interventions is and which elements of green infrastructure are the most significant ones in the public’s perception. Flood risk perception is a combination of the perceived exposure to the flood risk and the perceived consequences this risk might cause (Zhang *et al.*, 2018). While 16% and 23% of the 423 survey respondents claimed that they were impacted by floods respectively in their homes and workplaces, 73% of them responded they were affected due to the disruption of public transport, indicating that the impact of a flood event is usually much larger than the area physically affected by it. The majority of the respondents whose properties were exposed to flooding claimed that they suffered property blight, however half of them expected the property values to recover to their pre-flood levels if adequate flood protection measures were to be undertaken. Hence, most of the respondents were aware of the economic benefits of protective infrastructure in terms of safeguarding property values. Nevertheless, when asked about their appreciation towards the “sponge city” project, its multi-functional benefits, in terms of providing more green space coverage and higher quality of public spaces were ranked of similar importance to its flood mitigation role. This indicates that the impact of GI in property values is more likely to be higher than grey

infrastructure, given its multi-functional benefits, which complement its risk mitigation role, of which the general public might not be completely aware and informed. Indeed, 83% of the respondents assume that the values of their properties would increase with the implementation of sponge city, and half of them believe that this increase would be in the range of 2%-11%.

Indeed, proximity to green areas and pleasant landscapes can increase property values substantially, in some cases up to 117% in the case of Centennial Olympic Park, in Atlanta (American Planning Association, 2002). A study for the city of Turin reveals that the real estate prices can differ as much as +143% in areas very close to one another and with similar accessibility and distance from the city centre (D'Acci, 2018). Additionally, it was estimated that the real estate values decrease with 0.23% for each 1% increase in distance from city centre whereas they increase by 0.58% for each 1% increase in the quality of life³; attesting for a higher impact on property values of the quality of life than distance from city centre.

Ultimately, there is a growing body of literature that confirms the positive impact of the multi-functional benefits of green infrastructure, in terms of increased flood resilience as well as quality of life, in the property market. Yet, not enough has been achieved in exploring mechanisms through which this potential economic value created by GI implementation can be captured by public authorities to provide alternative ways of financing GI.

Land value capture and Flood Risk Management

Land Value Capture (LVC) has been widely investigated as a means to finance infrastructure and promote sustainable urban development. Conventional ways of providing infrastructure and services neglect the uneven distribution of costs, mostly covered by general public contributions, and benefits, largely obtained by landowners through windfalls (Smolka, 2013). In this regard, the goal of land value capture is to mobilize some or all of the increment in land value, which results from any effort other than that of the landowner's, for public use. Such increments might be the result of improvements in infrastructure and services in the proximity of the benefiting properties, or changes in land use and regulations which provide more development rights for certain properties.

Land value capture instruments are very diverse and some of them have been implemented for a long time, although not specified as LVC per se, but rather in the realm of taxes, fees or land management instruments. The table below is an attempt to summarize and classify the various LVC instruments and map their implementation internationally. Given the variety of instruments and practices, and their historic implementation, this summary is by no means comprehensive, but rather a general overview of LVC and the documentation of their implementation in literature.

³ In the cited study, the quality of life is calculated as the arithmetic average of factors such as: green, shops, quality of streets, buildings, squares, agreeable pedestrian areas and social context

TYPE	INSTRUMENT	BRIEF DEFINITION OF THE INSTRUMENT	EARLY PRACTICES	TYPES OF PROJECTS FINANCED	LOCATIONS	MAIN CHALLENGES
Financial/ Fiscal Instruments	Betterment levies/ Special assessment	A fee charged on the incremented value of a property attributable to a public investment Betterment levies are charges on real estate property owners who benefit from infrastructure improvements	1691 - New York	Infrastructure (mostly transport/road network)	Colombia Most countries in L.America have it in the law	* Definition of benefit area * Value increment attributable to public effort * Impact it has on real estate prices
	Developer exactions and Impact Fees	Developer Exactions: Developers required to install at their own expense internal infrastructure Impact Fees: For projects forecasted to have significant impacts on infrastructure beyond the project development areas	1970 North America 1990 UK Town&Planning act	Infrastructure	North America Chile UK (section 106) Guatemala Argentina Colombia Brazil	*impact fee formula
	Property tax	The Property Tax is a tax imposed by local government on the ownership or occupation of property.	Antiquity - Egypt, Persia, Babyllon, China 1st Cent BC - Roman Empire	It is usually not earmarked (can be used for different expenditures)	Almost in every country worldwide.	*Land vs. Improvements tax *Property value assessment
	Tax increment Financing/ Business Retention Strategy BID, TID	Consists in using the future flow of property tax increases generated by a public intervention to finance its costs	1952 - North America	Urban Upgrading/ Transformation	North America United Kingdom	*allows recovery of only a small portion of the value created *contributes to asymmetric service distribution

Urban Transformation	Land Readjustment/ Land pooling	Allows the merging and reconfiguration of lots in a given area in accord with a plan that increases their value and provides the land necessary for public uses	1791 - Washington DC 1934 - South Korea	New developments in periphery Slum upgrading Urban transformation Post-disaster recovery	Germany South Korea Japan	*Takes a long time *Citizen participation is crucial
	Cooperative Land Banking	CLB separates the private ownership of buildings from land ownership, with all the land becoming owned by a cooperative controlled by its residents. The double tenure created allows CLBs to capture the uplift in land values from urban development, which can then be used to make the cost of sites and services self-financing.	19th Century UK	Internal infrastructure and services within the CLB	UK	*Redefining the nature of property rights on economic basis
	Community Land Trusts	A community land trust is a non-profit organization formed to hold title to land to preserve its long-term availability for affordable housing and other community uses	1984 - Burlington	Social Housing	North America	*Depends on initial donation of land & operating grants
	Land Sharing	An innovative model of urban redevelopment and slum upgrading through sharing of land between profitable (commercial) developments and social housing for informal dwellers.	1970s - Thailand	Social Housing Internal infrastructure inside the land sharing area	Thailand Cambodia	*Requires a booming property market *Well established communities *Community organization and consensus *Intermediation from third parties *Appropriate physical/technical and financial feasibility studies

Asset Management	Public Land Management/Sales	Land sales represent a special form of capital revenue, which can be used to help finance general capital expenditures (usually related to new infrastructure)	1970 - World Trade Development Center (financed from land sold from Port Authority)	Major Infrastructure projects New developments Social Housing	US Denmark Netherlands Egypt	*Transparency and accountability *Short term instrument- limited impact
	Public land leasing	Revenues generated from leasing of public land with market prices can be used to cover infrastructure investment needs	China	Transport/Road infrastructure	China	*Applicability depends on the amount of public land available *Transparency and accountability
	Land Acquisition and Resale/ Compulsory purchase of land	Capturing the value created from acquiring private land, investing in infrastructure and selling of the remaining land at higher prices to cover infrastructure costs	1853 - Paris	Infrastructure	UK France	* Limitations on the powers of public authorities to purchase land not needed for public works
Other	Transfer of Development Rights	TDR severs the development value from the property and allows the owner to realize that value through more extensive development of other property.	1961 - New York 1995 - Sao Paulo	Historic and Environmental Preservation Flood Risk Mitigation	North America Brazil	* the value of the transferable development rights uncertain *Is TDR a just compensation

Table 1 Summary of LVC instruments applied internationally (Source: Table compiled by author based on Harrow, 1929; Peterson, 2009; Dye and England, 2010; Vetter and Vetter, 2011; Smolka, 2013; Blanco *et al.*, 2017; Salm, 2017)

Although experience with engaging LVC to finance GI is lacking, the scope of some LVC instruments have expanded with time to accommodate environmental objectives. The section below scrutinizes Transfer of Development Rights, an instrument initially used for historic preservation purposes, and later on adopted for the implementation of environmental protection agendas. Recent practices of TDR can be a starting point for further research on how this instrument can contribute to alternative financing for GI.

Transfer of development rights as a Land Value Capture instrument

Transfer of development rights (TDR) (or air rights/density transfer/purchase of development rights) is an instrument that falls under the Land Value Capture instruments utilized for providing more sustainable and environmentally resilient urban areas. TDR builds on the idea that property rights exist as a separable bundle of rights, such as the right to use, to farm, to build, to mine and the like, which can be transferred and/or can be made available for market transactions (Kaplowitz, *et al.*, 2008; Nelson *et al.*, 2012). TDR focuses especially in the right to develop and considers this right transferable from designated “sending areas” to designated “receiving areas”.

TDR operates under specific legislation that allows additional development potential in areas deemed appropriate for densification or other types of development benefits, defined as “receiving areas”, which developers can take advantage of when they provide in cash or in-kind benefits for off-site public benefits or compensation for off-site land conservation, in areas defined as “giving areas” (Pruetz, 2016). The specific legislation addressing the implementation of TDR is combined with zoning and/or land use regulations. Such legislation should regularize additional development rights in receiving areas, considering the maximum carrying capacity of receiving areas, as well as mechanisms of transferring such development rights from giving areas; be it through the creation of Banks or other mechanisms.

Traditionally used as an instrument to preserve farmland and environmentally sensitive areas, currently TDR practices have expanded their scope to serve various local government planning goals, such as creation of parks, green infrastructure, scenic views and landscape preservation, trails and other community benefits (Nelson *et al.*, 2012; Pruetz, 2016). Areas where such services are to be provided are defined as “giving areas”, where landowners, either voluntarily or compulsorily, participate in the program by selling their development rights to developers in “receiving areas”, either through direct negotiation, through the mediation of the local government or through a bank. Once this is carried out, a legal instrument is registered with the property deed in the giving area which permanently limits or freezes the development of land, in fulfilment to the predefined planning goals. This legal instrument is generally referred to as a conservation easement (Pruetz, 2016).

Receiving areas are areas where densification can occur beyond a predefined baseline. The bonus development can refer to residential density, additional land coverage, height, or other modifications that developers might deem as desirable. Evidently, the motivation to participate in the program should derive from extra benefit created for developers, having covered the costs of participating in the TDR program and of providing bonus development (Pruetz, 2016). TDR legislation includes methods and formulas to calculate the maximum TDRs that can be accommodated in receiving areas

and to establish a TDR value that is attractive to both developers in receiving areas and landowners in sending areas. It is important to bear in mind that TDR programs do not intensify development but rather redistribute according to more sustainable development models (Chiodelli and Moroni, 2016).

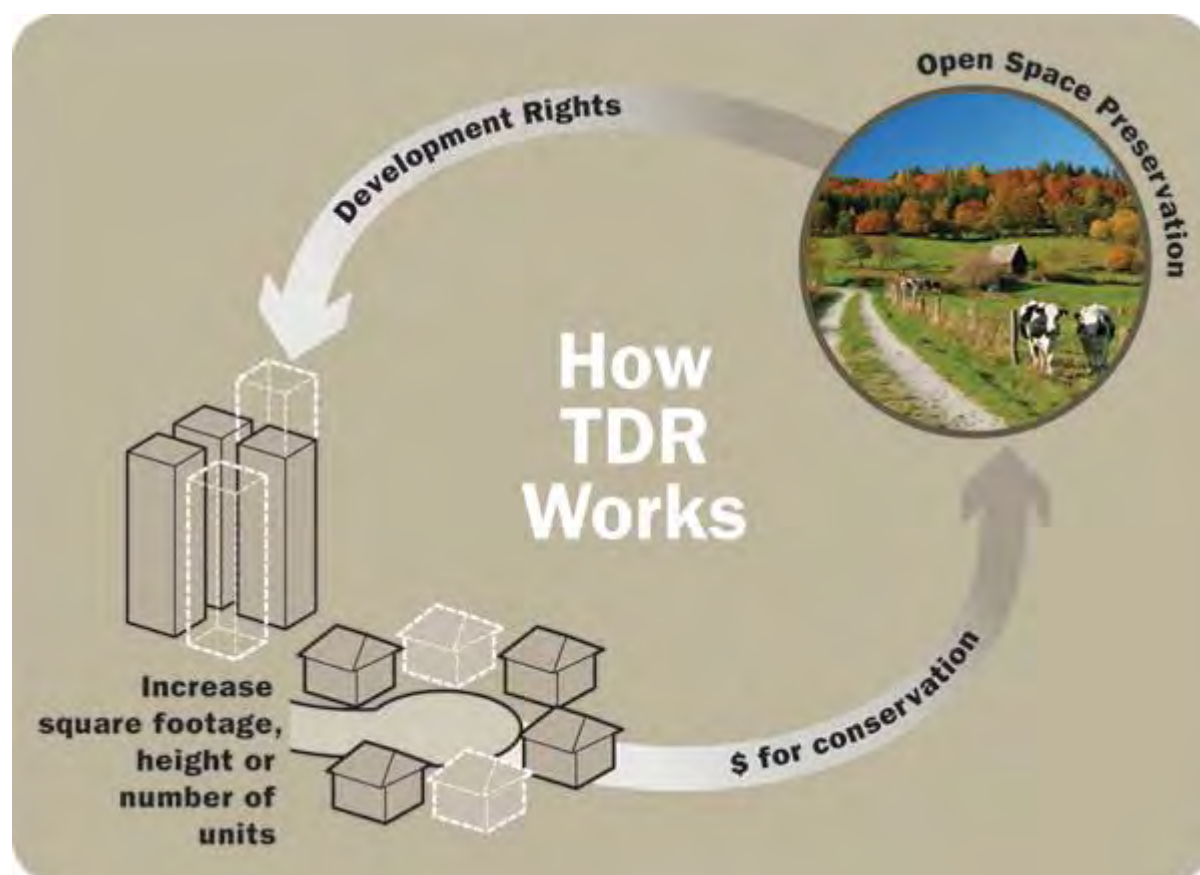

Figure 1 Infographic on how TDR works (Source: King County, retrieved from <https://www.kingcounty.gov/services/environment/stewardship/sustainable-building/transfer-development-rights/overview.aspx>)

One challenge of managing TDR programs is that the timing of issuance of TDRs in sending areas might not coincide with the timing of TDR purchase from developers in receiving areas. Hence, separation of TDR extermination from acquisition has called for intermediary institutions such as development rights banks (Stinson, 1996; Puertz, 2016). Indeed, TDR banks buy, hold and sell development rights to facilitate the process and create a mechanism of perpetually investing in TDR purchase in giving areas and support land conservation. For instance, TDR bank in King County, Washington, initially purchased TDRs using property tax revenues, and invested the proceeds from the sale of these TDRs to further purchase TDRs in other areas "...converting what would otherwise be a one-time use of public money into a perpetual revolving fund for preservation" (Puertz, 2016, p.5).

Facilitating Green Infrastructure provision through TDR

Stinson (1996) suggests that there are three main concerns that brought about TDR programs: pressure to develop historic landmarks, higher demands for open spaces in congested metropolitan areas and economic incentives to develop environmentally sensitive areas. TDR addresses such

pressures by reconstructing the economic incentives in land use. Indeed, the first TDR program sought to address the challenges of preserving historic landmarks in the high-pressure building market of New York in the early '60s (Stinson, 1996). Over time, many TDR programs were adopted to fulfil several development goals of local governments, many of which lean towards mitigation of climate change induced risks. Up to date, more than 320 cities around the world have implemented TDR programs, 283 of which in US, while the rest in 11 other countries such as Australia, Brazil, Canada, China, France, India, Italy, Japan, Mexico, Spain, and the Netherlands (Pruetz, 2016). More than half of these programs were designed to address environmental challenges and protect natural resources (Nelson *et al.*, 2012). Although the experience with TDR programs for flood risk mitigation is limited, such cases attest for the untapped potential of this instrument. Some coastal TDR programs, initially designed to protect the ecosystems of environmentally sensitive areas, have expanded their objectives to target adaptation to sea level rise. For instance, 13 out of 20 counties in Florida that have implemented TDR programs are coastal counties (Linkous and Chapin, 2014).

The High Line project in New York is a very accurate example of how a major GI can be implemented through the facilitation of TDR. The High Line consists of a public park built on top of an abandoned elevated train line, the implementation of which was rendered possible through a TDR program as part of the Special West Chelsea District in 2005. This TDR program unlocked the development rights of the giving area, namely properties underneath and immediately to its west of the high line, by encouraging their transfer to the receiving area, mostly focused on nearby Avenues 10 and 11 (City of New York, 2015). Receiving areas could increase their FAR up to 1 in some subareas and 2.5 in others. Through this program the city was able to provide an open corridor with numerous positive externalities in terms of environmental benefits and improved quality of life.

Figure 3 High Line TDR program (Source: City of New York, retrieved from: <https://www1.nyc.gov/assets/planning/download/pdf/plans-studies/transferable-development-rights/research.pdf>)

While the standard measure of the success of TDR programs is the overall surface area of land conserved in giving areas, the Florida experience of TDRs evolved during 90's and 2000's towards further sophistication of the market of transferable rights and receiving area development. Ultimately, the success of TDR programs relies largely on the additional profits that developers take advantage of by participating in the program in the receiving area. Henceforth, refining the calculation of the developers' demand to exceed baseline development in receiving areas becomes central to the success of a TDR program (Puertz, 1997). However, whilst a couple of decades ago profits were linked with more square meters developed, today other modifications in the development, which might improve the quality of life and attractiveness of the area can be equally important. In this sense, the impact of GI in the market values of the nearby properties can be translated in increased potential to absorb more development right, but also in higher market values of the same development rights. Balancing

windfalls on properties benefiting from the implementation of GI with property blight of the properties whose development is limited or frozen because of the implementation of GI should be the next step of research towards new models of TDR programs.

Conclusion

Traditional grey protective infrastructure against flood risks are no longer enough to address the challenges that climate change is posing in many urban areas. Green Infrastructure is promoted as solution to more environmentally resilient cities based on a more holistic approach to understand and address the complex dynamics of social-ecological systems (Hansen and Pauleit, 2014). Within the last few years, GI has become popular with policy makers and public authorities as a way to integrate land uses in a more sustainable way. Its multifunctionality, including provision and connection of open spaces and green areas, makes GI even more attractive for the public, which might not always be aware of how GI contributes to ecosystem services and towards mitigating flood risk. Indeed, the study conducted in Wuhan revealed that when it comes to infrastructure for flood protection, citizens are more willing to pay for GI provision because of its effects on the quality of life and landscaping benefits, rather than because of its contribution to flood risk mitigation; a risk which many citizens are often not aware of or underestimate (Zhang *et al.*, 2018).

Empirical research on the impact of GI in land markets is still in initial stage, however studies on the factors that affect the demand side show that the quality of life and the quality of urban environments are becoming increasingly important factors, especially in the recent years when the effect of distance as a factor is decreasing due to technological advances and changes in lifestyle. Studies in cities in different contexts around the world, such as the experience in US, China and Italy, all show that the willingness to pay from the demand side, especially in residential areas, increases substantially when the quality of life, an important part of which are open and green spaces, improves in a given area (American Planning Association, 2002, D'Acci, 2018, Zhang *et al.*, 2018). The advantage of GI is that it provides open and green spaces, combined with other functions in terms of ecosystem benefits and increased environmental resilience towards extreme weather conditions. How can public authorities capitalized on this added value of GI, in terms of land market appreciation, to finance such infrastructures? This is a question that deserves more attention in public policy and academic research. The existing experience with Land Value Capture in financing mostly road infrastructure and public transport projects, can be transferred when it comes to GI provision for flood risk mitigation purposes. Transfer of Development Rights, an LVC instrument with an emphasis on land conservation, can be an attractive instrument in terms of cross-subsidizing property windfalls of the properties benefiting from GI and property blights of the landowners in properties where development shall be frozen to provide GI. TDR requires attractive land markets to subsidize land conservation and perpetually freeze development for GI provision. The positive impact that GI has on land markets of the beneficial areas presents an incentive for such areas to be designated as receiving areas, where additional development rights can be transferred to. Further research should explore such new models of TDRs and the legal, institutional and financial implications of implementing them for GI provision.

Urban-legal Paradigms Supporting Post-Millennium Evictions: the Role of the Courts in Displacement Practices

Fernanda Jahn-Verri¹

¹*University of California, Los Angeles, fjverri@ucla.edu*

Abstract: Why is Brazil, a country with one of the most progressive and inclusive land legislations in the world, being accused of violating its citizens' constitutional right to housing? Why is the Brazilian Judiciary, despite all the legal mechanisms created by recent laws to reverse exclusionary patterns of land use, executing forced evictions of thousands of marginalized families? I argue that these violations and removals must be understood as legalized displacement. Namely, land dispossession practices are not only a direct result of the commodification of housing, but of a much broader discrimination process, in which the courts are playing a major role. Judicial dispossession can be read as a direct outcome of eviction mandates ordered by the courts. However, what makes it legitimate is not only the fact that it is ruled by judges, but that these practices are embedded within governmental, legal, and policy apparatuses. Drawing from Porto Alegre, a city with a tradition of participatory planning programs, this article will analyze how urban-legal paradigms support post-millennium evictions in Brazil by addressing how legal frameworks on land use and property rights are used to justify displacement. By employing archival research and discourse analysis, I show that courts are ignoring recent legal mechanisms created to ensure the constitutional right to housing in the country. I find that judges are mobilizing discourses that idealize private property regimes at the expense of alternative forms of tenure already established by paradigmatic land legislation. At stake here is the fact that these removals are expelling the vulnerable populations from the city. Lastly, I am calling into question the false distinction frequently made between evictions in the context of the Global South - perceived as violent conflicts involving mostly informal tenants - and similar processes in the Global North, often understood as part of more "legalistic" processes.

Keywords: displacement, right to the city, Brazil, eviction

Introduction

Why is Brazil, a country with one of the most progressive and inclusive land policies in the world, being accused of violating its citizens' constitutional right to housing? Why is the Brazilian judiciary, despite all the legal mechanisms created by recent legislation to reverse exclusionary patterns of land use, ordering the eviction of thousands of marginalized families? There is a substantial body of literature that argues that displacement is being caused by the financialization of housing. However, I hypothesize that these violations and removals must be understood as what I call *legalized displacement*, namely displacement practices that are not only a direct result of the financialization of housing and land, but of a much broader process of discrimination in which the courts are playing a major role. In this paper, I will analyze the apparent gap between the legal framework on land use and

its application in Brazil. My main goal is, thus, to investigate how these removals are validated through urban-legal paradigms or, as Gherner (2011, p. 131) puts it, how eviction can be perceived as an “act of governance rather than violation”. Thus, at stake here is a re-framing of rights and the infringement of the constitutional right to housing through judicial mandates that are challenging recent reformist laws on land and property rights.

Despite having one of the most progressive land regulations in the world, approximately six million households do not have access to adequate housing in Brazil (Fundação João Pinheiro, 2017). The Federal Constitution, established in 1988, declared housing a constitutional right. The City Statute, promulgated in 2001, reinforced that property rights should be subjected to the “social function” of landed property by creating mechanisms to prevent sub-utilization of urban parcels through instruments like progressive estate taxation and adverse possession law. Officially, these new laws enabled municipalities to demand that owners of vacant properties and idle land promote their immediate use. These decrees also produced the legal framework to ensure the right of individual and collective actors to claim formal tenure of urban parcels that they have occupied for more than five consecutive years. In practice, however, despite these legal apparatuses, judges are determining to evict thousands of families from abandoned private and public properties in central urban areas of Brazilian cities.

A growing body of literature argues that the banishment of the poor from the city is more than a simple outcome of housing commodification or a direct consequence of urban development projects led by the State (see Caldeira, 2000; Roy, 2017). Some authors suggest that displacement is increasingly being endorsed and carried out by judiciary systems on behalf of aesthetic norms or the “public interest”, at the expense of the urban poor who are criminalized in the process (Gherner, 2011; Bhan, 2016). With my work, I will elaborate on these displacement processes and reveal the discourses performed by the courts when ruling eviction cases. In this paper, I will answer the question: *How are legal frameworks on land use and property rights being used to justify displacement?* Although tenant security is also threatened by real estate speculation and other financial maneuvers, I claim that the state, particularly the judiciary, plays a major role in practices of dispossession. I argue that legal instruments created by recent legislation have provided the courts with legitimate reasons to issue eviction notices. Lastly, I show that judges are mobilizing political ideologies that condemn certain property regimes in favor of other models, thereby challenging land use legislation passed recently.

To reflect upon the legal discourse that it is being used to support displacement in Brazil, I ground my analysis in the case of Porto Alegre, the fifth most populous metropolitan areas (IBGE, 2012). I have chosen Porto Alegre because of its participatory planning tradition. The city has a past of progressive housing policies, community participation programs, and social justice movements that overlap with the tenure (for over a decade) of the *Partido dos Trabalhadores*, or “Workers Party” (PT), in its municipal government. To answer my research question, I conducted a discourse analysis of court records filled in Porto Alegre from 2001 to 2018 involving squatter settlements of private and public properties.

Historical background: land and property rights in Brazil

An assessment of Brazil's trajectories of land legislation and housing policies reveals that the State always had a fundamental part in both protecting and impairing the access to shelter of the urban poor. Like in many Latin American countries, the government in Brazil has played a central role in the housing sector (Bonduki, 1994; Villaça, 2000; Holston, 2008). In this sense, the 1988 Federal Constitution and the 2001 City Statute were paradigmatic as they opened a new chapter in Brazil's history of property rights, creating an innovative urban-legal framework to democratize the access to adequate housing and correct centuries of non-egalitarian and discriminatory land practices (Maricato, 2010). Nonetheless, recent legislation might also have had perverse consequences. Initiatives targeting land regulation, associated with social housing programs, might have increased social-spatial segregation and the risk of displacement. On one hand, these instruments gave more power to local authorities, including the judiciary, to displace and relocate people based on their settlement and tenure conditions. On the other hand, these laws, by enforcing the right to urban property and making more people eligible to hold land titles, also inflated the urban land market in Brazil and made millions of people more vulnerable to financial manipulations within the formal housing market (Fernandes, 2011).

After years of negotiations and mobilizations at all levels, the Brazilian Legislature passed the new Federal Constitution in 1988, giving municipalities more power in terms of urban land management and regulation. The document also created the concept of the *social function of property* “along with the recognition and integration of informal settlements into the city, and the democratization of urban governance” (Rolnik, 2011, p. 242). In the early 2000s, the federal government passed another important piece of legislation focusing on land and property rights, the paradigmatic 2001 City Statute. Macedo argues that, in terms of private property, the Statute “innovates by establishing preemption rights for local governments, whereby areas of interest can be demarcated in local Master Plans and potentially acquired by local governments for projects of social interest, such as low-income housing” (2008, p. 262). In addition, Fernandes argues that this Legislation offered local authorities a whole new set of instruments “to reverse to some extent, the pattern and dynamics of formal and informal urban land markets, especially those of a speculative nature” (2007, p. 213). One of these instruments was the *usucapião coletivo* (collective adverse possession law), allowing not only single actors, but also communities living in a vacant private property uncontestedly and continuously for at least five years to jointly claim its ownership. The Statute also created “grants for special use”, which is similar to *usucapião* law but applied to public land. Nevertheless, these legal tools might also have had the opposite effect, actually boosting spatial-segregation in Brazil. The 2001 City Statute's emphasis on property rights and land regularization might have made it more difficult for the urban poor to resist displacement. Land titling programs, for example, have incited the interest of major construction firms and investors in informal settlements, creating a bigger land market in Brazil (Alfonsin et. al., 2003).

The case of Porto Alegre

Most research on housing justice and inequality in Brazil until now has focused on cities like São Paulo and Rio de Janeiro. Even though Porto Alegre's metropolitan area is the fifth largest in the country (IBGE, 2012) and despite the city's history of progressive housing policies and participatory planning programs, limited attention has been paid to the state capital of Rio Grande do Sul. In

addition to hosting the first edition of the World Social Forum in 2001, Porto Alegre was also the first city in the world to apply the Participatory Budgeting program (PB), allowing residents to decide on the allocation of a share of public investments. The PB, implemented in 1989 by the Workers Party (PT), also encouraged popular articulation around themes like urban infrastructure and housing. In fact, Porto Alegre is the state capital in Brazil in which PT had its longest municipal term (1989 – 2003) (Fedozzi, 2001), in which the socialist administration helped establish several housing movements in the city.

Under the military regime (1964 – 1985), irregular tenants living in “inappropriate” zones (e.g. the riverside) would only be allowed to stay in the area depending on their “political behavior” (Baierle, 2007). When PT won the municipal elections in the late 1980s, however, the scenario changed. Under PT’s administration, the 1990 Organic Municipal Law was passed (instituting “concessions of right to use” and, thus, giving people the right to occupy vacant public land) and the Housing Cooperative Program was created in 1993 (giving technical support and legal assistance to housing groups, including land acquisition and regularization) (Alfonsin, 2005). PT’s strategy concerning land disputes in Porto Alegre was very clear: not to expropriate, but to mediate agreements between squatters and property owners (Fruet, 2005). When PT left the municipality, though, the new mayor revoked the Organic Municipal Law and instead of a land regularization plan, developed a mortgage program. In fact, during my preliminary fieldwork, evidence extracted from eviction court records indicates that in 2003, the municipal approach towards squatter settlements changed to the extent that local authorities would no longer expropriate private property, particularly “to avoid illegitimate land appropriations” (TJRS, 2017, p. 43). In fact, Soares and Sanches (2018) argue that today in Porto Alegre, the more organized and combative the housing organization is, the more the judicial and police forces are employed to dismantle what could serve as an example for others. As a leader of *Lanceiros Negros Vivem* squatter group told me informally during preliminary fieldwork in August of 2017, “the position of the current administration has changed towards us. Local authorities tend not to engage with the movements as they used to and many families are getting evicted just months after they squat” (female occupant).

Discussing Landscapes of Property and the Theories of Racialized Displacement

My paper addresses the economic, political, and judicial dimensions of land, housing, and property rights. I am approaching these themes starting from the premise that the legal space both produces and is produced by the social space. In other words, I assume that law is not objective, but, as Blomley (1994) argues, constantly echoing power structures and incorporating social and cultural systems. Thus, drawing from the literature on racialized displacement and property regimes through a legal geography perspective, I frame my research problem around the idea of *legalized displacement*. I am conceptualizing legalized displacement as an outcome of *judicial dispossession*, by which I mean eviction mandates ordered by the courts. What is significant about such mandates, however, is not only that they are ruled by judges, but that these practices are embedded within the governmental, legal, and policy systems. Evictions, in this case, are understood as legitimate actions and inserted in broader processes of racialized capitalism.

Racialized Displacement Processes

The market alone cannot explain the level of displacement taking place globally today. More than a direct and inevitable outcome of the commodification of housing, practices of dispossession must be addressed as discriminatory politics or, as Roy (2017) suggests, racialized displacement. Although concepts like the financialization of housing help us understand much of the urban transformations currently taking place across the world, this framework does not fully clarify the continuous entanglements between capitalism and racial discrimination. As Fraser summarizes, “exploitation-centered conceptions of capitalism cannot explain its persistent entanglement with racial oppression” (2016, 201, p. 163). According to her, “the subjection of those whom capital expropriates is a hidden condition of possibility for the freedom of those whom it exploits” (2016, p. 166). Roy also claims that foreclosure can be understood as mechanisms of social and racial banishment. While investigating the Chicago Anti-Eviction Campaign, the author found that banks confiscate houses located “at city’s end” (2017, p. A3). She argues that these processes hide discourses on models of ownership and embody not only a loss of property, but more critically, a loss of personhood. Similarly, Desmond (2016) concludes that eviction is a commonplace practice in inner-city black neighborhoods in Milwaukee. He argues that women are more than twice as likely to be displaced than men. Particularly black women tend to have less-flexible schedules, receive lower wages, and often are the sole providers for their family, preventing them from working extra hours to “work off” the rent. In sum, Desmond emphasizes that, while black men in the United States are locked up, “black women are locked *out* (emphasis added)” (2016, p. 121).

Racialized logics also shape state policies and justify courts’ decisions. Perry argues that, in the case of Salvador, Brazil, black women are disproportionally subjected to forced removals by local authorities. The evictions she investigated were allegedly being led in order to “make way for new structures that were meant to attract tourists to the city center” (2013, p. 49). However, the author argues that judges ordered the eviction of poor black women even when they presented the required documentation proving land ownership. She summarizes, “black women, especially those living in the poorest urban neighborhoods, traditionally have been consigned to a ‘de facto status of non-citizens,’ occupying not only the spatial margins of cities but also the socioeconomic margins as the poorest of Brazil’s poor” (2013, p. 115). Bhan and Ghertner also look at state-sponsored displacement in India, examining the fundamental role played by the courts in evicting the poor in Delhi. The former explains “the involvement of the courts rather than the state” (2009, p. 128) differentiates contemporary evictions in India. Similarly, Ghertner claims that judges confronted with the lack of proper documentation, abandoned previous bureaucratic prerequisite and statutory requirements for ordering evictions and “made the appearance of filth or unruliness in and of itself a legitimate basis for demolishing a slum” (2011, p. 287). While suggesting that some bodies, due to their limited mobility, are becoming more displaceable than others, Yiftachel argues that displacement is switching “from an act to a systemic condition through which marginalizing power is exerted through policy and legal systems” (2017, p. 3). He claims that urban planning has become a very powerful governing tool and that “planning (or lack of) provides the authorities with a set of technologies with which they can legalize, criminalize, incorporate or evict” (2009, p. 96).

Social and racial discrimination in the (re)making of the city is not new. Spatial segregation has always been present in urban planning, from Haussmann’s efforts to revitalize Paris to Moses’ attempt to redevelop New York. What has changed, on one hand, is the sophistication level of financial, policy, and legal instruments being used to exclude. On the other hand, discriminatory politics are

now increasingly hidden behind populist discourses, rhetoric that I intend to analyze in my dissertation.

On Property Regimes

The processes described in the previous sections are entangled with legal and social foundations of property rights. Discourses performed by the state, especially by the courts, validate certain tenure models while condemning others, ultimately producing dispossession (Ghertner, 2008; Bhan, 2013). Property regimes built around the idea of private and individual right, for example, might limit the access of the disfranchised to the urban space, untimely boosting socio-spatial segregation (Singer, 2010; Griffin, 2010). Therefore, frameworks on property entail not only claims to territory, but it also mobilizes concepts such as power and identity. There is a growing body of literature studying regimes of property focusing on the rhetoric associated with principles of ownership. Many authors discuss the challenges implicated in understanding private property ownership as the “proper” and acceptable mandate. In the next paragraphs, I will build on these scholars and elaborate on what Roy (2003) identifies as “paradigms of propertied citizenship”, in which certain prerogatives are being given exclusively to those who can afford to become homeowners.

Blomley (1994) uses the term “landscapes of property” to urge scholars studying property regimes to take into account not only the social scope of property but its historical and geographic dimensions as well. He criticizes the geographical alienation of legal studies and calls for spatialization of law, defending a closer look at the connection between the law and legal systems, including not only the effects of law upon space but also “the ways social spaces affect law” (2004, p. 99). Porter (2014) and Graham (2010) agree and claim that the notion of property needs to consider the relationalities embedded in it. The latter suggests that “property is not a thing but a relation of claims” (p. 403) while the former encourages us to reflect upon the significances of property within different legal and cultural discourses and practices.

In addition, it is important to think about the problems of ignoring or condemning alternative property models. Postcolonial scholars have already highlighted the danger of associating modernity to specific “modes” of space production. As Robinson puts it, the concept of urban modernity “has assumed a privileged link between modernity and certain kinds of cities” (2004, p. 709). Hence, besides challenging the dichotomies of informal-formal, illegal-legal as two disconnected systems (Sousa Santos, 2002; Roy, 2005; Benjamin, 2008), it is fundamental to acknowledge alternative mandates of property that are not necessarily related to the Anglo-American liberal model based on individual rights and ownership (Esteva, 2014; Leitner & Sheppard, 2018). In fact, Gillespie (2016) questions the universal applicability of Western standards of propertied mandates and proposes a new framework of thinking about property relations in different contexts by debating concepts such as tenure security, exclusion, and rights. He claims that “legal concepts of property need to be more place sensitive so as not to potentially undermine or destabilize existing and evolving social norms and conditions” (2016, p. 264).

By framing property around the idea of exclusion, Blomley argues that “property provides both a rationale for dispossession and a ground for its opposition” (2016, p. 594). In this sense, the American paradigm of propertied ownership was responsible for shaping socio-spatial boundaries in the North-American cities and excluding individuals that did not meet quintessential norms of residence (Roy,

2003; Wyly et. al., 2012). Roy, for example, asserts that “property citizenship for the select was made possible through the impossibility of shelter and social citizenship for all” (2003, p. 484). Furthermore, property territorialization embodies a specific form of spatial and social classification (Blomley, 2016, p. 597). As Gibson-Graham (1997) suggests, property is not a fact but an aspiration, and a very powerful one though.

Mobilization of judicial discourses in eviction cases

To understand the role of the judiciary in the displacement of squatter settlements, also called “occupations” by housing rights movements, I examined court records involving informal tenants in Porto Alegre. By conducting a discourse analysis of these documents, I clarified the arguments used by the courts to justify (and counter) forced removals. I accessed these eviction court records through the online database for the Rio Grande do Sul Court of Justice (TJRS), the tribunal responsible for analyzing lawsuits filed in Porto Alegre. Because I am primarily investigating how the courts apply legal frameworks established in the last two decades in Brazil, I analyzed only the decisions published since 2001. I used keywords like “property”, “repossession”, “occupation” or “land invasion”, and “collective” to narrow my search on the TJRS database to only include decisions involving squatter occupations. I discarded results with keywords such as “commercial”, “commerce” and “rural”. The results generated are summarized by Table 1 below:

Table 1: Squatter settlements-related eviction cases in Porto Alegre ruled by TJRS (2001 – 2018)

Year	Number of qualifying cases	Number of cases ruled against squatters
2002	0	n/a
2004	2	1
2005	3	3
2009	1	1
2014	0	n/a
2015	1	1
2016	2	1
2017	2	2
2018	1	1
Total	12	10

Data collected from TJRS *jurisdição* online database

TJRS is an appellate court that takes on appeals cases once the municipal court has issued a decision. Therefore, the number of actual eviction cases involving *ocupações* (“occupations”) in Porto Alegre since 2001 could be much higher. I chose not to investigate the decisions published by the municipal court because documents from this database cannot be accessed using specific keywords, but must instead include the name of at least one of the parties involved in the litigations or their lawyers.

Of the twelve cases I analyzed, only two of them had decisions that favored the squatters.

Decisions in favor of squatter settlements

In the two cases in which the judges¹ ruled in favor of the squatters, the decision was based on the premise that evictions would aggravate the “social problem” of lack of housing. First, in the lawsuit arbitrated in 2002, the court accepted the appeal of seventy families. The squatters were occupying a property owned by the Rio Grande do Sul Housing Company (*Companhia de Habitação do Estado do Rio Grande do Sul* – COHAB). They sustained that the property had been abandoned for over thirty years and, thus, was not fulfilling its *social function*. They also claimed that they had the *constitutional right to housing*, and it was the state's duty to grant it. The defendants’ lawyers also highlighted that carrying out with the removal would result in the eviction of dozens of families that would “be subject to complete abandonment, having nowhere to go”. (TJRS, 2002, p. 2).

The court responds to these arguments by stating that:

Although it is necessary to seek in the discipline of the civil law the legal subsidies required to solve controversies, one cannot forget the particularity of this new social fact [my emphasis], that of collective invasions, in which people organize themselves in movements that represent neither the solution of an individual problem, nor the interest in individual advantage or benefit, but the fulfillment of a basic need of a community [...]. On the other hand, the right to housing is constitutionally guaranteed and, unless proven otherwise, those who do not have a shelter to live in are in a state of need. (TJRS, 2002, p. 5).

One of the judges assigned to the case claims that he grounds his decision, accepted by the other judges of the case, on two legal principles: the court’s responsibility to the community and the theory of proportionality. The former refers to the fact that Judiciary needs to take a position on issues of strong popular appeal – “will the Judiciary only represent another instance of power against the citizen, or will it embody the last instance of power, in his favor?” (Idem). Finally, he also sustains that a judge must seek the “least harmful solution” and asks what are the least damaging answer in this case:

[...] to turn away from the needy families who find themselves in the property shooing them away with their junk and pain, or delaying the permanent resolution a little more showing understanding of the seriousness of this Brazilian drama, which does not generate irreversible burdens to the other party? (TJRS, 2002, p. 6).

In the second case determining the permanence of squatters in occupied property, ruled in 2016, the court had similar remarks. Although the judges do not make direct reference to the social function of property or the constitutional right to housing, they agree that evicting four hundred families from the private property they occupied would represent a “social problem of housing” (*problema social de moradia*). Thus, the judges allowed the families the right to stay put while waiting for a federal appeal.

¹ In TJRS second instance, usually three State Court judges, called *desembargadores*, deliberate. However, the ruling may be made by a collegiate of five judges or, in certain cases, even result from a monocratic decision.

Decisions against squatter settlements

The arguments used by the judges when ruling against squatter groups in the other ten cases are basically built around two main principles: the *indisputability* of private property and the fact that occupations constitute an *illegal act*. The application of these two different discourses, nonetheless, depends who owns the occupied property, a private or public actor. The latter justification is mostly used when the complaint is a public entity and, in these cases, judges usually emphasize the lawlessness of the “infraction” being committed by the “invaders”. They often claim that these squatter settlements are *unfair* in the extent that if the state were to guarantee the right to housing to all those who illegally occupy third party’s property, other marginalized citizens not adopting the same *occupation tactic* would not be entitled to similar privileges. (i.e. access to shelter).

However, when a private actor is involved, the argument is frequently centered around the premise that collective claims cannot surpass *individual rights* when it comes to property. When analyzing the ten verdicts evicting squatters, private land was the object of seven of them. One quote, in particular, stands out because it is repeated by one judge in two different decisions. Despite acknowledging the mechanisms created by the 1988 Federal Constitution and the 2001 City Statute, in these lawsuits registered in 2004 and 2005, he highlights:

Even when we understand that properties must fulfill a social function, it is not within the scope of a possessory lawsuit that the State should decide whether the owner was or not subtracting the property from its social purpose. If we accept the defendants' [squatters] argument, all landlords would be liable to lose possession - albeit only in the course of the proceeding - of their property to the homeless when the latter consider the land a socially unproductive property. The fact that a parcel is not occupied by buildings or plantations, even for a long period of time, clearly does not mean that the property in question lacks a social function; at least while the owner has not been yet questioned by the competent authorities about how he will give a proper social allocation to his property. What cannot be admitted, with the danger of implementing a new form of social and legal insecurity, is that those with no access to housing through planned invasions, executed in the dead of night, settle themselves permanently in duly registered and regularized urban parcels, on the basis - possible to be invoked in relation to any non-built plot of land - that the property is not meeting its social purpose. To admit this type of conduct would mean to ensure housing only to those who will have the organizational capacity to promote invasions, establishing a real parallel power to that of the State, which, evidently, is not fair, much less acceptable. (TJRS, 2004, p. 3; TJRS, 2005b, p. 5).

Moreover, in the 2005 lawsuit, after including in his monocratic decision that the squatters accuse the owner of not paying property taxes for several years, the judge claims that this *alleged fiscal debt* is irrelevant in litigations related to possessory claims.

In another case, while ordering the removal of seventy families, another judge maintains that “the principle of the social function of property, guaranteed by the Federal Constitution should not be analyzed in isolation, and should coexist harmoniously with the rules disciplined in the Civil and Civil Procedure Codes that regulate the matter” (TJRS, 2009, p. 5). The codes the magistrate is referring to are those that protect property rights.

Additionally, in a paradigmatic ruling due to the social relevance of the work developed by the defendant, a housing rights group protecting women's rights, the judges responsible for the case also emphasize private property rights. The squatter group, known as *Ocupação Mirabal*, a movement that shelters only poor women who have suffered domestic abuse and their children, was occupying a vacant private property owned by a religious institution. One of the magistrates, in the decision, praises the "socially relevant" work being performed by the group, but highlights that the occupied building is private *not public*. His remarks suggest that his decision could have been different if the contested property was owned by the state. Another judge who was part of the body ruling on the case claims:

However expressive the purpose of the movement is, the protection of private property and its social function is also a fundamental constitutional right. [...] The movement counts with my support as a citizen; as a Judge, my duty is to protect society, a context in which it is necessary to restricting infractions to principles such as social function and private property, values that constitute the foundations of personal and contractual freedom safeguarding the common good of society. Freedom does not exist, nor does it resist without property and its social function. (TJRS, 2017a, p. 9).

It is interesting to notice that one judge acknowledges the "efforts of local authorities", highlighting that the *political option* adopted by the municipality starting in 2003 has changed towards squatter settlements. This posture was to no longer expropriate "invaded" private land, "in particular for the purpose of avoiding unlawful appropriations" (TJRS, 2018, p. 43). This passage suggests that political ideologies, in fact, might influence judicial outcomes.

Finally, in one of the decisions involving private property, published in 2015, the court recognizes the *constitutional right to housing* as a fundamental right. However, judges claim that when ordering the eviction of the squatters:

We are not denying the validity of constitutional principles and norms regarding the right to housing or the dignity of the human person [but] it is necessary to consider the impossibility of rewarding the illegal conduct of the aggravating actor - who confessed to having invaded the property of a third party - to the detriment of the other part that obtained the property and exercised its ownership lawfully and regularly. (TJRS, 2015, p. 12).

In regard to the lawsuits involving the occupation of public property, two main arguments emerge. First, as previously indicated, the fact that these practices performed by squatter groups are *outlawed*. This type of discourse can be found in two passages in particular: "Although *legitimate* subjects of debate, it is not possible to admit invasion of public areas for the purpose of claim or protest" (my emphasis) (TJRS, 2017b, p. 11). In another ruling, the judge argues that "it is impossible to let them [squatters] stay in the property under the argument that it would be fulfilling with the *social function of the property*, since the article on the social function of property in the 1988 Federal Constitution does not protect those who enter, *irregularly*, in public property" (my emphasis) (TJRS, 2005a, p. 10).

The second premise used by the courts is that the judiciary is not the place to solve *housing policy* related issues:

Any solution for the relocation of the people who invaded the property, be they children, elderly, and pregnant, should be sought in the political arena, in conjunction with competent administrative agencies. The Judiciary cannot, in violation of the law that deals with possessory litigation, enter into an area of exclusive competence of the Executive Power. [...] The condition of social vulnerability is not exclusive to the group that invaded the public property, as social needs are not an exclusive problem of the Municipality of Porto Alegre, since they are present in absolutely all other states. (TJRS, 2016, p. 10).

The ruling presented above, published in 2016, is contradictory. The object of the lawsuit is a parcel owned by the Municipal Housing Department (DEHMAB) that was being occupied by three hundred families. The DEHMAB was trying to evict the families from the contested property claiming that the area would serve to accommodate other 1,300 families removed by the municipality from another area that was being required for the expansion of the local airport. Paradoxically, the judge ordering the forced removal of these three hundred families to shelter other families now displaced due to state-sponsored infrastructure works. In other words, while the court suggests that a solution for the relocation of squatters should be resolved within the scope of the Executive power determines the removal of these families to solve another “housing issue”. In this sense, the judiciary, as Bhan (2009) highlights, is becoming indeed the primary site of urban planning.

Conclusion

The question that guided this analysis was *how are legal frameworks on land use and property rights used to justify displacement?*. At stake here is not only the fact that evictions might be using to displace and exclude certain marginalized groups from the city, but, particularly in the case of Brazil, the *violation* of the constitutional right to housing. By addressing the judicial dimension of land, housing, and property rights, I showed that law is not neutral and detached, but, in fact, constantly reverberating power arrangements, including regimes of property. Drawing from the literature on property and displacement through a legal geography lenses, I reflected upon the notion of eviction as a legitimate act ultimately being used to control, plan, and rule. By grounding my analysis in Porto Alegre, I also showed how a city with a tradition of participatory planning is now witnessing the marginalization of the housing justice movement.

Therefore, when courts order the eviction of squatter movements, for example, they are not only ignoring the legal mechanisms created to ensure that Brazilian citizens have adequate access to housing. They are, in fact, violating these people’s constitutional right to housing, as tenure security is a key factor in one’s entitlement to adequate shelter. When the City Statute was established almost twenty years ago, people fighting for urban reform in Brazil became hopeful that private property regimes and land speculation would now be challenged. Nonetheless, I claim that some of the instruments supposedly created to fight dispossession, instead are being used to displace. In other words, as Bhan argues, displacement is occurring “through democratic processes rather than in their absence” (2016, p. 9).

With this preliminary investigation, I demonstrated how legal frameworks on land use and property rights have been mobilized for and against dispossession. Courts in Brazil are mobilizing political ideologies that condemn certain tenure models in favor of other property regimes, defying thus established land use legislation in their rulings. Data found on TJRS online database illustrates this.

Despite some limitations of this study (especially in regard to subset of lawsuits),² further investigation needs to be done with the other parties involved in these cases, particularly the squatter movements themselves and their lawyers. We need to understand how these poor people's movements are contesting displacement, including the legal remedies that their lawyers are mobilizing to contest evictions.

Research on the Implementation Mechanism of Privately Owned Public Space——Planning Implementation of the Publicly Transferred Land in Fuzhou City 2008-2017

Hong Jiang¹

¹Tongji University, 1610111@tongji.edu.cn

Abstract: Public space is the core content of urban planning. Privately Owned Public Space refers to the contractual control of urban planning management through the land development process, by stipulating the land development rights (preconditions) to open the part of the space to the public. Privately owned public space separate the property rights from use rights of the land and provide public space through space sharing, taking the advantage of the cost control by the enterprises and property owners. The provision of the privately owned public space includes incentive zoning and prescriptive regulation. Incentive zoning is a kind of transaction behavior between the public interest represented by the government and private interests represented by private developers. Prescriptive regulation is the establishment of rules and regulations by the land transfer mechanism and property rights system, which is realized through cost transfer and space sharing. The empirical study on the implementation of the public space for private property rights for public land transfer in Fuzhou City shows that through appropriate institutional design, peace and harmony between public and private can be achieved, and the quantity, quality and service effect of public space can be improved. In the transition period of urban development, it provides a new possibility for the construction of public space in other cities.

Key words: public space; implementation mechanism; planning; property right

Introduction

Public space is the core content of urban planning implementation and management, and the quantity and quality of the public space always need to be improved to meet the needs of the city. As the main investor in the construction of public facilities and the main provider of public services, the city government is the main body of investment, construction and management of urban public space. In contrast to this, Privately Owned Public Space refers to the contractual control of urban planning management through the land development process, by stipulating the land development rights (preconditions) to open the part of the space to the public. Privately owned public space separate the space property rights from usage rights, and produce public space through space sharing, with the advantage of the cost control by the developers and property owners.

The privately owned public space first appeared in the United States in 1961 through incentive zoning (Kayden JS, 2000, Schmidt S. et al, 2011, Yang Z. and Xu M., 2013, Yoon H. and Srinivasan S. 2014, Yu Y., 2016), followed in Hong Kong, Taipei, Seoul, Tokyo and other cities (Qi Y., Yan Y. and Yang W., 2015, Dimmer C. et al., 2013, Yeung M., 2014). Cities in China

that carry out public space provided by incentive policy include Shanghai, Nanjing, Wuxi, Hangzhou, Guangzhou, Beijing, and Shenzhen (Tang S., 2016).

Till the end of 2014, the City of New York had built a total of approximately 3.5 million square feet (325,000 square meters) of privately owned public space in 332 projects through the incentive zoning policy, 98% of which were concentrated in Manhattan Island. Those projects were distributed in the densely populated downtown and middle town accounted for 14% and 30% respectively, effectively alleviating the lack of open space in densely populated areas (Yu Yang, 2016).

Concept of the privately owned public space

Urban public spaces such as streets, squares, and parks are not pure public goods, but rather a quasi-public goods with crowding. Space usage rights can be “exclusive” through space access control. That means the urban public spaces have the attributes of the club item—non-competitive but exclusive, non-exclusive for all members of the club but exclusive for non-club members, such as green space in the urban access control community, the theme park needing tickets to enter, etc. (Zhang K. and Du N., 2012).

If a city has a range of open spaces at different levels and can be supplied to the public in the form of well-designed and managed “club spaces,” it will be more efficient, livable and sustainable (Webster, C., Zhang, Bo., and Li J., 2008).

“Privately Owned Public Space” first appeared in New York in the 1960s. Kayden (2000) proposed that its meaning consists of two parts: “private property rights” refers to the land where the public space is located and /or the legal status of the building, the owners will continue to control the overall access and use rights of their private properties, and without the express permission of the owner, the citizens generally cannot obtain access and use rights. “Public space” means a tangible location on private property, and the owner has provided the public with legally binding access and use rights, ownership is maintained privately.

Privately Owned Public Space refers to the contractual control of urban planning management through the land development process, with the agreement on land development rights (preset conditions) and the public rights (some part of the land open to the outside world). Privately owned public space separates the property rights of the public space from the right to use, realize the production of public space by space sharing. In contrast, in other land transfer projects, the government handed over the construction and management of public spaces such as mountains or public green spaces around the project to the real estate developers, which were built and managed by the developers and remaining the public property rights. The maintenance of public property rights has not changed. Such situations also belong to the introduction of social investment to build public space, contrary to the privatization of public space, privately owned public space realizes the publicization of private space and is conducive to the realization of public interest.

Implementation mechanism of the privately owned public space

There are two types of the privately owned public space. The first one is that the government turns the responsibility for the construction of public space into a private burden, and transforms

the property rights of the public space into private ownership, thus shifting the responsibility for building public space, such as the public green belt along the urban roads and the rivers. The second type is the public space not within the government's construction plan, which is set up by land transfer and private development and construction projects to provide, a part of the private property but open to the public, such as street green space, squares, and public parking lot, etc. In the first case, the number of public spaces did not increase, the government shifted the cost, and the society participated in the joint construction of public space. In the second case, the number of public spaces has increased, and it is possible to improve the quality of public spaces and to make the distribution of public spaces balanced.

Regarding the supply of public space, Hughes (2001) divides the types of policy instruments provided by public space into supply, subsidy, production and regulation. The Chinese city government mainly produces tools in the process of expanding urban public space (Zhang Q., 2009), characterized by the government directly responsible for the production of public goods and services (Liu Z., 2010). Therefore, the emergence of public space in private property rights is a useful supplement to the current government-led public goods offering.

There are two main types of privately owned public space provision, one is incentive zoning and the other is prescriptive regulation. The premise of the implementation of the incentive zoning method is to ensure that the profits generated by private developers through the development of private public space is greater than the cost of their input. The incentive zoning method mainly meets this premise in two ways: one is to increase the profit of the developer; the other is to reduce the cost of the development. The increase in profits is mainly based on the floor area rate incentive policy; the reduction of development costs is mainly achieved by relaxing the planning conditions (mainly including the distance of the building red line, the proportion of the building base to the construction land and the relevant provisions on the building volume etc.) (Zhang, T. and Yu, Y., 2010). Some cities in China have also proposed similar incentives for zoning, such as Shanghai, Shijiazhuang, Harbin, Qingdao, Taiyuan, Lanzhou and other 16 cities (Li, J., 2016).

The implementation of incentive zoning is based on the private ownership of land property, separating the ownership and use rights of the public space, and trading the public space use rights with the public interest represented by the government and the private interests represented by private developers. Through negotiation, private developers give up part of the space – “right to use” and the government compensates by incentives. The risks of this kind of implementation are that case-based negotiations may bring market unfairness and political rent-seeking. The quality of public space is difficult to quantitatively evaluate. The increase of the volume-rate ratio, that is, the increase in development, brings negative externalities to the surrounding areas.

In contrast to incentive zoning, by the control detailed planning mechanism in China, the construction of public space can also be implemented through prescriptive regulation. The prescriptive management and control implementation mechanism is to include the construction requirements of the function, location and area of the public space in the land transfer contract. The specific form may be the textual expression or the statutory plan.

The technical content of the control detailed planning is transformed into the contract clause, which is essentially the additional responsibility of changing the control method of space from technical requirements to property rights. The implementation mechanism of this approach is

to transfer the responsibility and cost of the construction, management and maintenance of public space from the government to private property owners. The risk is that if the government abuses this method, it is actually evading its responsibility as the main provider of public goods, increasing the cost of land development and construction, and pushing up the land price. The construction cost and long-term maintenance cost are borne by the property owner.

Incentive zoning and prescriptive regulation have their own advantages. The method adopted by local planning management departments is based on actual conditions and should be clarified at the local regulations. In terms of the current control detailed planning and implementation management in China, incentive zoning and prescriptive regulation are applicable to different situations.

Under the system of planning adjustment, if the original floor area ratio is reasonable, there is still technical feasibility to increase the development volume, and incentive measures can be adopted, especially in the need to provide facilities and space involving major public interests such as subway stations. It is used to compensate for the loss of private property rights.

However, if the plot volume ratio is the maximum, then increasing the development volume will cause overload of public facilities and various social problems. If the system of planning adjustment is vague, it is necessary to adopt prescriptive regulation and to establish the requirements for public space construction before land transfer.

However, no matter which method is adopted, the policies and procedures are required to be clear, and stakeholders have the right to participate in the negotiation process and influence the results. If their interests are damaged, they should be compensated.

Fuzhou Private Property Public Space Practice

Taking the urban area of Fuzhou as an example, there are two types of implementation methods for privately owned public space, and in the “Technical Regulations for Urban Planning Management of Fuzhou City” (2000 edition), the floor area ratio reward for providing public space for construction projects has been stipulated, but in the planning and management practice since 2000, the Fuzhou Urban and Rural Planning Bureau has not approved a volume-rate awards project arising from the provision of public space. In the new edition of "Fuzhou City Planning Management Technical Regulations" (2016 edition), the contents of the relevant award regulations were deleted.

According to the statistical analysis of the planning conditions and related information of 261 plots of land sold in Fuzhou City from 2008 to 2017, 90 plots of land parcels with public space were clearly defined by means of prescriptive regulation, and the area of the privately public space was 737,235 square meters, accounting for 6.1% of the total land area (12,075,857 square meters). The total price of the privately owned public space through the land transaction is 9.6 billion yuan (CNY).

As far as the implementation effect is concerned, the public green spaces and the squares along the main road of the city have a good effect after being built, which has effectively supplemented and improved the urban public space system. Privately owned public parking spaces are not open to the public because they do not have uniform identification and management requirements, but only serve as public parking spaces in the community. After the unified transformation along the river landscape, the river green space is integrated and

connected to enhance the transformation to form a strip park. It is worth noting that there have not been any disputes or negative events in Fuzhou that have been brought due to the opening of the privately owned public space.

The prescriptive regulation mechanism for the privately owned public space in Fuzhou includes the following four basic elements:

(1) Information disclosure

The land transfer announcement is publicly released before the land is transferred, and the planning conditions such as the location, area, and function of the privately owned public space are clearly defined. All land bidding participants can obtain relevant planning condition information from the land administration department, including the relevant planning requirements of the privately owned public space, and calculate the land bidding cost based on this.

(2) Property rights

Different from the incentive zone, the method adopted by the prescriptive regulation is to add additional conditions of property rights of the project, open the specific space to the public through space sharing, and realize the production of public space through the additional responsibility of property rights.

(3) Technically feasible

The opening up of private property public space has two basic technical requirements: First, the open public space is located at the edge of the land, and the non-open part is relatively complete, such as at urban road intersections, along urban trunk roads, along urban riverside sections, at community entrance, etc. Excluding the open public space, the remaining plots remain intact and the rest of the plots can still be managed separately if necessary. Second, the open space is still an integral part of the overall land use. The economic indicators such as floor area ratio, building density and green space rate are calculated together with the rest of the land, and the overall indicators of the land are balanced through the design of the plan.

(4) Cost control

In the process of construction and management of public space, because of clear property rights and responsibilities, the construction cost is controlled by the real estate developer during the development and construction process, and the daily management is managed and maintained by the property company, which is beneficial to the advantage of the cost control of the market entity and improve the space quality and management efficiency.

The current implementation process also has the following problems:

(1) The construction of private property public space requires review as an important content in the planning management approval and acceptance, but the land and property registration management department does not indicate in the land certificate and title certificate when registering property rights. This is the most important institutional paralysis.

(2) The privately owned public spaces built in Fuzhou has not been clearly marked on the spot. There are no use regulations, notices, and corresponding inquiry system, which make the public lack information and guidance in the process of use.

(3) After the establishment of the privately owned public space, there is no public supervision and no law enforcement supervision. The management and opening of the privately owned public space, depends solely on the self-discipline of the property owners.

In response to the above problems, in order to ensure the implementation, the relevant

provisions of the public space should be clearly reflected in the property rights registration, the supervisory duties of the competent authorities should be clearly defined, and clear identification signs should be set up on the spot, and an inquiry and use information service system should be established, which is to facilitate public use and supervision.

Conclusion

Privately owned public space is actually realized through the mechanism of land development. Property owners bear the cost of construction and maintenance, and the public enjoys the public space. The privately owned public space of prescriptive control reflects the institutional characteristics of China's socialist market economy. As the representative of the land owner and the public interest, the government assumes the responsibilities of the organizers, negotiators, managers, and supervisors, and realizes the production of public space through policy formulation and system design.

The emergence of the privately owned public space, whether it is incentive or regulatory, is the construction of laws and institutions by public administration department. In the land transfer mechanism and property rights system, planning technology is transformed into policies and systems, through cost transfer and space sharing. The advantages of the privately owned public space are the clear property rights responsibility, the controllable maintenance and management costs. The essence of incentive zoning implementation is planning adjustment, and the implementation process of which is to negotiate from the bottom up. Prescriptive regulation is government-led, technically feasible, and cost-controllable, the implementation process of which is carried out from the top down.

Privately owned public space is only a supplement to public space, which is an increase method rather than an alternative one, and the government should not shirk the main responsibility for public goods.

China's land transfer system is separate from ownership and use rights. The ownership is owned by the state and the land use right is transferred. Due to the shortage of local government public construction funds, local governments hope to use social funds to build public space. The emergence of the privately owned public space has the legal basis and economic motivation. The case of Fuzhou can be used as an empirical demonstration of the effectiveness of the privately owned public space construction in densely populated areas of China.

LEGITIMACY CRISIS OF THE VILLAGE PLANNING IN CHINA AND ITS RESOLUTION

Yanqun LI¹, Hong GENG²

Abstract: Based on the three-phase legality theory of regulation, standard and morality of the new institutionalism school, the legal basis of village planning is embodied in three attributes: state legal empowerment, industry standard management and public interest expression. The introduction of the Urban and Rural Planning Law in 2008 has endowed the village planning with legal status from the national legislation level, and promoted the legitimacy structure of village planning towards integrity, which has made the village planning officially enter the era of "legalization". However, a comprehensive review of the development results of village planning over the past decade reveals that the current village planning legitimacy structure is now facing some major legitimacy crisis, such as the absence of subject under the contradiction of jurisprudence, the failure of planning caused by the deviation of technical rationality, and the dilemma of seeking a maximization of public interests. The legitimacy of village planning presents a crisis state of complete structure and incomplete function. To resolve the legitimacy crisis of village planning has become an important part of village planning towards public policy in the new era. Based on a comprehensive analysis of the original mechanism of crisis generation, this paper proposes the corresponding resolution paths as follows. Firstly, repairing relevant legal gaps in village planning. Secondly, establishing rational technical guidelines for planning. Thirdly, turning to "contractual village planning" with multi-subject affirmative, in order to promote the village planning legal structure to an ideal condition of form and function integrity.

Keywords: Legitimacy Crisis; Technical Rationality; Public Interest; Multi-subject Affirmative

Introduction

Legitimacy, originated from the western political science philosophical debates about "authority and obedience"(WU, 2011), is regarded as the legal foundation for the establishment of political order for the ruling class(Otfried, 2005). Later, Max Weber(1997) introduced the field of sociology to describe the institutional scenario in which social members identify with the value of political order and generally obey it. Weber believes that the source of legitimacy comes from the political order established by the ruling class. However, this empirical theory of legitimacy polarizes the political color of legitimacy and lacks the value judgment on the justice of political order(LIU, 2018). Based on the discussion on the value basis of legitimacy, Jurgen Habermas(2009) revised Weber's theory of legitimacy from the perspective of rational constructivism, believing that legitimacy should be first based on the values of justice, and then on the recognition and obedience of social members. The new institutionalism school represented by Scott(1998) introduced the theory of legitimacy into a more

secular behavior system and life scene, such as social organization, enterprise management and urban construction. He proposed *the three-phase theoretical framework based on legitimacy*(Table 1), which has become the basic paradigm for the legitimacy research of modern administrative management and social governance(Ying, 2016).

Table 1: Scott's theoretical framework of three-phase legality

Dimension of Legitimacy	Interpretation of Legitimacy Dimension
regulation	Recognition and empowerment of national laws and regulations
standard	Public affairs operation complies with the professional and industry related standard procedure requirements
morality	Operation of public affairs conforms to the moral cognition of social members

In terms of village planning, legitimacy is manifested as the empowerment of national laws, industry standard management and villagers' public interest expression. The empowerment of national laws not only gives the legal basis for government organizations to compile village planning, but also gives village planning legitimacy as a tool of public policy. Industry standard management ensures the value basis of scientific, fair and just contents of planning. The expression of villagers' public interest determines the obedience and recognition of village members to village planning. All three together constitute the village planning complete three-phase legitimacy structure. In the early stage, due to the lack of legal empowerment in national legislation, village planning in China was always in the administrative management stage of government departments, and its relevant rules and regulations were not binding enough to form a complete legal structure in a strict sense. Until 2008, a new version of the Urban and Rural Planning Law of the People's Republic of China(hereinafter referred to as the URPL) has incorporated village planning into the urban and rural planning system in China, giving village planning legitimacy at the national legislative level and providing legal support and institutional guarantee for the comprehensive formulation and implementation of village planning. At this point, the village planning really moves towards the structure integrity stage of legitimacy.

With a decade Implementation of the URPL, the popularization and implementation of village planning in China has been carried out nationwide. However, throughout the whole process of village planning from establishment to implementation to supervision, it is found that village planning is still faced with relevant conflicts and loopholes of laws and regulations, technical failure of planning establishment, implementation and management, relative deprivation of villagers' public interests and many other problems. Village planning is still in a state of complete legitimacy structure but incomplete function. In fact, as a policy tool for the grassroots people's government to macro-control the allocation of village resources, the three-phase legitimacy attribute of village planning has been regulated in the UPRL. To discuss the village planning legality lies in a rational speculation on the empowerment related legislation. *Therefore, based on the three-phase legitimacy theory framework of the new institutionalism school, this paper comprehensively reviews the evolution process of village*

planning empowerment, demonstrates the legitimacy crisis currently faced by village planning from the perspective of legitimacy, and explores the resolution mechanism of legitimacy crisis in combination with the new environment of village planning development in the new era, in order to promote the legitimacy of village planning towards the ideal state of formal integrity and functional integrity.

1. Empowerment process of village planning in China: "Compliance" towards "Legality"

Through a comprehensive analysis of the empowerment process of village planning in China, it is found that according to the difference in the rank of its empowerment law, it can be divided into two stages: "compliance" under the empowerment of administrative regulations and "legality" under the empowerment of national legislation.

1.1 "Compliance" era: village planning under administrative regulations

Long-term since, rural housing construction in China lacks reasonable planning guidance and rigid government control. The demand-oriented village construction is characterized by chaos, disorder and liberalization, which continued until the 1970s. Along with the reform of rural land system and economic development, the phenomenon of a large number of rural houses occupying farmland has gradually attracted the attention of the senior decision-making level of the state(Fang and Liu, 2006). Since 1979, the state council and the ministry of construction have successively issued a series of meeting communiques, technical specifications, management regulations, compilation methods and other guidance documents to guide the responsible subjects, behaviors and technical standards in the whole process of village planning, from establishment to implementation and supervision(Cao, 2012). The documents include two national work conference on rural housing construction, the Town Planning Principles (hereinafter referred to as "Principles"), the Rural Land for Building Management Ordinance(hereinafter referred to as "Ordinance"), the Village or Town Planning and Construction Management Regulations (hereinafter referred to as "Regulations"), the Village Planning Standard (GB50188-93) (hereinafter referred to as "Standard") and Town Planning Method (hereinafter referred to as "Method")(Table 2).

Table 2: Core contents and significance of relevant guidance documents on village planning from 1979-2000

Time	Document name	Core content	Significance of village planning
1979	1st national work conference	Earnestly plan, carefully design. Strengthening policy guidance to village planning and construction	First raise of village planning in the national document, marking that village planning was officially incorporated into the national public management system.
1981	2nd national work conference	Governments at all levels are required to "promptly formulate regulations to guide village planning and	The exploration of village planning goes deep into the level of system construction and explores the legalization of village

		construction".	planning under the legal construction.
1982.1	"Principles"	Construction must conform to the planning, which shall be compiled by the competent departments at various levels.	The legal foundation of village planning has been laid advocating establishment to system restriction.
1982.2	"Ordinance"	Make clear the system construction of village planning of establishment and approval.	Established the "compliance" status of village planning in the level of national administrative regulations.
1993	"Regulations"	Clearly delineate the responsible behaviors and subjects in the establishment, implementation, examination, construction and supervision of village planning.	Clearly delineate the responsibility subject and authority of relevant matters of village planning, which ensures the accurate operation of village planning.
1994	"Standard"	Clearly delineate the professional normative content and operational requirements of village planning.	Standardized the regional differences caused by the disunity of village planning in the past from the professional and technical level.
2000	"Method"	Same as the previous column	Same as the previous column

These documents officially incorporated village planning into the national public management system, promoted village planning from advocacy to institutional constraint, laid the legal foundation for village planning, and made village planning conform to the "compliance" situation of administrative rules and regulations(Kuai, 2010). At the same time, the implementation management of village planning has effectively stopped the chaos in the construction management of the vast rural areas and promoted the standardization and legal development of village construction activities.

1.2 "Legality" era: legal-rational empowerment from the URPL

The aforesaid "Regulations" are administrative regulations issued by the state council, while the "Principles", "Standards" and "Methods" are derived from administrative regulations issued by the state construction department, which are not strictly national laws. In this case, the three-phase legitimacy structure of village planning is in an incomplete state. Due to the weak effectiveness of the above documents, the village planning had to obey the other national laws in the process of comprehensive establishment and implementation, which leads to problems such as lack of motivation, obstacles in implementation and negative law enforcement. Therefore, in order to strengthen the legal status of village planning, solve the problem of rural construction and coordinate the economic and social development of urban and rural areas, the tenth NPC standing committee voted and passed the

URPL in 2007, which was fully implemented on January 1, 2008, marking that village planning officially entered the "legality" era of national legal empowerment.

As village planning is incorporated into the urban and rural planning system by the URPL, the "legality" status of village planning as a guiding document for village development and construction is strengthened, and the establishment, implementation and management of village planning move towards the rigid control stage. Under the legal effect of the URPL, various provinces and cities have issued corresponding regulations, guidelines and measures for village planning, accelerating the process of village planning in China. By the end of 2016, the number of administrative villages with village planning has reached 323,373, accounting for 61.5% of the total number of administrative villages counted. The number of natural villages with village planning has reached 830,335, accounting for 31.73% of the total number of natural villages counted (Figure 1). Village planning has entered the "legalized" development era.

Figure 1: Statistics of administrative and natural villages which compiled village planning during 2007 to 2016.

2. Legitimacy crisis of village planning: legal contradiction, technical deviation and interest dilemma

However, although village planning has obtained the legitimacy empowerment of national legislation, forming a complete three-phase legitimacy structure, there are still some legal principles, technical and moral gaps in its legitimacy structure, resulting in its legitimacy in a state of complete structural form and incomplete function. Village planning is facing a major legitimacy crisis.

2.1 Crisis of regulatory legitimacy: Dislocation, absence and offside of subjects under legal contradiction

As mentioned above, the administrative legitimacy of village planning is derived from the empowerment of relevant national laws and regulations, especially the legal empowerment of the URPL, which lays the legal administrative status of village planning. However, due to the conflict and ambiguity of relevant laws and regulations, village planning faces a legal crisis in the process of compiling and supervising.

2.1.1 Dislocation of establishment subject of village planning under the conflict of laws

First of all, it is the multi-conflict of various laws which leads to the dislocation of the subject of village planning. Article 22 of the URPL proposes that "The people's government of a township or town shall take charge of establishing the township or village planning", which clearly defines that the compilation and administration of village plans shall be vested in the people's governments at the township level. Village planning has become a policy tool for the local government to intervene in rural governance "from top to bottom". However, in accordance with article 111 of the Constitution of the People's Republic of China, "The residents and villagers committees establish sub-committees for people's mediation, public security, public health and other matters in order to manage public affairs and social services in their areas", means that the villagers' committee is responsible for its own public affairs and public welfare undertakings. The Organic Law of the Villagers Committees of the People's Republic of China (hereinafter referred to as the "OL") further clarifies the relationship between the people's government of townships and the villagers committee. Article 5 of the "OL" stipulates that "the people's governments of townships, nationality townships and towns shall give guidance, support and assistance to the work of the villagers' committees, but shall not interfere in matters falling within the scope of villagers' autonomy according to law. That is to say, the responsibility subject of public affairs and public welfare undertakings in the village should be the villagers' committee, and the people's government of townships can only guide and help without intervention. As a policy tool to coordinate the allocation of public resources in rural areas, village planning, like urban planning, expresses the value orientation of public interests(SHI, 2011), which should belong to village public affairs. Therefore, a certain legal conflict can be found between the "top-bottom" village planning system established by the URPL and the villagers' self-government system established by the "OL".

2.1.2 Absence of supervision subject of village planning under the broad laws

As a specific administrative act in urban and rural planning administration, planning supervision must obtain administrative license or legal remedy from relevant legal system when executing (He, 2011). However, the URPL only clarifies the supervision subject of village planning, while without the specific procedures of supervision and administration of the administrative action made specific provision. In this case, the supervision of village planning is often prone to the absence of grass-roots management bodies (Qi, 2011). *On the one hand, the matters involved in village planning and construction are complex and tedious, while the professional and technical personnel provided by the grassroots government are in serious shortage. On the other hand, the village planning and construction under a complex social relations network involves multiple interests, which easily leads to a negative law enforcement.* A survey in Lanxi city, Zhejiang province, proved that village planning professionals are mostly related to villagers, leading to their negative law enforcement behaviors of not dealing with and not punishing when exercising their regulatory powers.

2.1.3 Offside of construction subject of village planning under the fuzzy laws

Article 37, 40 and 41 of the URPL respectively make relevant provisions on the issuance of the planning license for construction land, the planning license for construction projects and the planning license for rural construction. The planning license for rural construction only requires enterprises, public facilities and public welfare undertakings within the planned area of the village to apply to the

people's government of the township or town according to the related laws. *But the relevant construction projects are not required to conform to the relevant content of village planning.* Such fuzzy terms directly reduce the legal effect of village planning, which leads to the possibility that the projects approved with the planning license for village construction in the village may still be inconsistent with the village planning content and break through the control content of the village planning. The survey found that more than 70 percent of rural land violations discovered in Hubei province in 2016 were approved with village construction planning licenses, with 60 percent of those in conflict with village planning.

2.2 Crisis of standard legitimacy: Planning failure caused by technical rationality deviation

The standard legitimacy is expressed as correct technical rationality in village planning. However, due to the deviation and dislocation of technical rationality, the planning is faced with great uncertainty in the establishment and implementation, which is likely to lead to the planning failure (Yu, 2004).

2.2.1 The uncertainty of standards for the establishment of village planning

One is the absence of national technical standards. With the introduction of the new town planning standard (GB50188-2007), the old version of the town planning standard (GB50188-93) was abolished at the same time. But the new standard is only applicable to the town planning and township planning outside the residence of the county-level people's government, resulting in the vacancy of the national mandatory technical standard guiding the village planning (Zhang and Ji, 2008). As the code of conduct and relevant content of village planning are not specified in the URPL, it can neither serve as the unified technical standard of village planning nor provide clear legal support for the content of village planning.

Another is the ambiguity of the content of local technical standards. Due to the lack of unified national standards, within the permission of the urban and rural planning law, provinces and municipalities in China successively issued corresponding guidelines (or regulations, methods, etc.) for village planning establishment as the standards for the compilation of local village planning. Although the establishment subject of village planning and its related contents are clearly defined in the local standards, the implementation, supervision, inspection and other management problems of village planning as well as the reward and punishment mechanism are not clearly assigned with responsibility (Table 3). As a result, uncertain elements appear in village planning and management, and village planning is faced with technical failure.

Table 3: Contents related to standards of village planning issued by some provinces and municipalities in China

Provinces/ Municipalities	Standard	Year	Contents of Implementation	Contents of Inspection & Supervision	Contents of Reward & Punishment
Beijing	Guidelines for village planning (trial)	2017	The implementation plan, responsibility	The supervision and inspection subjects and related	Defined the reward, without the punishment

			subject and technical requirements are not clearly specified	procedures are clarified	mechanism
Shanghai	Guidelines for the establishment of village planning (trial)	2010	The implementation plan, responsibility subject and technical requirements are not clearly specified	The supervision and inspection subjects are not clarified	Not mentioned
Chongqing	Technical guidelines for the establishment of village and town planning	2013	The implementation plan is clarified in guidelines 2.12 and 2.13	Not mentioned	Not mentioned
Jiangsu	Guidelines for village planning	2008	The implementation plan is clarified in the 4th chapter of the guidelines	Not mentioned	Not mentioned
Guangdong	Guidelines for the establishment of village remediation planning	2013	The implementation plan is clarified in the 6th chapter of the guidelines	The supervision and inspection subjects of village planning are not clarified	Not mentioned
Shanxi	Guidelines for the establishment of village planning	2014	The implementation plan is not clarified in the guidelines	Not mentioned	Not mentioned

2.2.2 Inapplicability of the methods and tools of village planning

The second kind of technical rationality deviation is the inapplicability of the methods and tools of village planning. That is to say, planning technology path dependence biased towards city orientation. Under the influence of modern urban planning thoughts, planners tend to directly apply the technical methods of urban planning in the process of village planning, while ignoring the differences between the working base map and the main body of village planning and urban planning (Table 4). As a result, village planning not only violates the "law of natural growth" in rural areas, but also does not conform to the values of "theory that man is an integral part of nature" in rural areas. Problems such as "urban community" and "villagers gathering and going upstairs" are prominent (Mei et al. 2016, Gu and Jiang, 2015).

Table 4: Differences of working base map and subjects between urban planning and village planning in China

Base map or subjects	Contents of planning	Urban planning	Village planning
working base map	Land ownership	State-owned land	Village collective owned land
	Land usage	Urban construction land	Village construction land and agricultural land
	Planning pattern	Mechanical form under guidance policy	Organic form in free growth
	Social environment	Profit-driven values	The values of harmony between man and nature
Working subjects	Participant	Government, developers, citizens	Village autonomous organizations and villagers
	Service principal	Citizens, developers	Village autonomous organizations and villagers
	Interest subject	Government, developers, citizens	Village autonomous organizations and villagers
	Construction subject	Government and market	Self-built

2.3 Crisis of moral legitimacy: Dilemma of maximizing the public interest

Habermas believes that the political order must be established on the basis of the value of justice, in order to obtain the universal recognition and obedience of social members. The basis of the value of such justice is the value orientation of public interest (Wang et al, 2007). As a public policy of the government to coordinate the allocation of various resources in the village, village planning is a public product involving the vital interests of all villagers. It should and must take the orientation of villagers' public interests as the initial motivation and the maximization of public interests as the final goal. However, in the actual implementation process, the village planning is often easy to enter the dilemma of maximization of public interests due to restrictions such as elite deprivation, operation of black box and symbolic public participation.

2.3.1 Village planning weakens the choice of maximization of public interests

On the one hand, the top-down village planning is motivated by the rural society, economy and land urbanization, and carries out administrative intervention in the allocation of spatial resources and the supply of public products, ignoring the expression of villagers' will and public interests, which results in the weak public interest attribute of village planning. Especially now, with the establishment of the village free economic market, the village has gradually evolved into a compound field of interwoven monetary interest relationship network and emotional interest relationship network. The maximization of private interests based on the principle of individual freedom has become the universal pursuit of social members. *In the establishment process of village planning, there is no balance of interests between the grassroots government, developers, villagers' self-governing organizations, villagers and other multiple subjects, and the "Pareto Optimality" of public interests cannot be achieved. Instead, it enters into the "Sen's paradox Paratian liberal"* (Wang and Li, 2010).

When the value orientation represented by the public policy cannot meet the interest demands of the whole society, the government can only choose to take the maximization of administrative collective interests or part of individual interests as the value orientation, and selectively ignore the multiple demands of the society members. *The village elites such as the village able person and the strong village collective become the biggest beneficiaries, whom also dominate the discourse power of village planning, project fighting and implementation. "Elite deprivation" and "operation black box" appear in the village planning and construction projects, which leads to the village interests from the maximization of public interests to the maximization of private interests.*

2.3.2 Village planning weakens the choice of maximization of public interests

On the other hand, the current laws and regulations have no clear statutory constraints on the public participation mechanism of village planning in terms of procedures and systems, and *there is no unified quantitative standard for the number and degree of participants, resulting in a large flexible operation space for public participation in the establishment process of village planning.* A village survey shows that village planning is often prepared without public discussion by villagers, and the publicity process of village planning only lasts for 15 minutes without any consultation from villagers.

According to "the Theory of the Ladder of Citizen Participation " raised by Sherry Arnstein(1969), China's village planning is still in the stage of "Tokenism" such as "Placation", "Consultation" and "Informing" (Figure 2), which is not true and effective public participation (Zhang and Zhou, 2015).

Such public participation lacks substantial public interest expression channels and planning feedback, resulting in a serious squeeze on the channels for villagers to express public interest. In this case, the villagers lose the main behavior ability and show low trust and resistance to the grassroots government, thus refusing to obey the village planning.

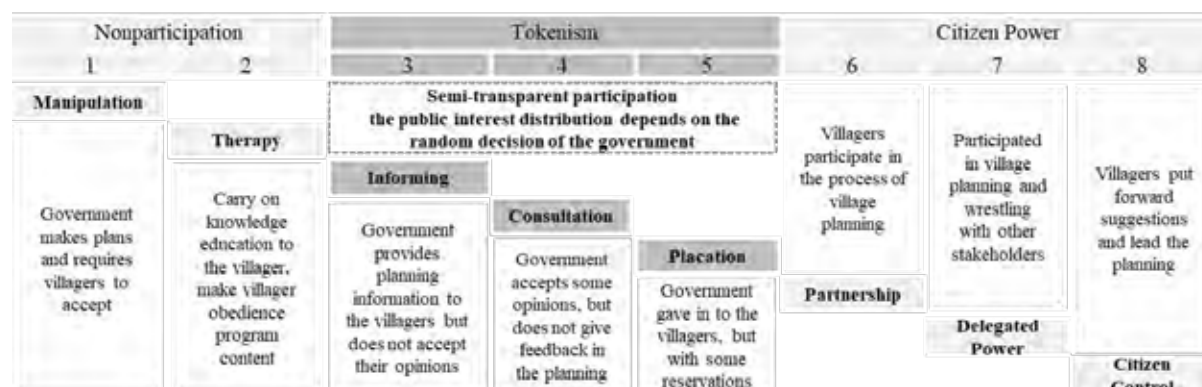

Figure 2: The Ladder of Villager Participation in current village planning in China

3. Resolution of the legitimacy crisis of village planning

To sum up, the legitimacy crisis of village planning comes from three directions. Firstly, the relevant conflicts and loopholes of laws and regulations. Secondly, the technical problems of planning establishment, management and implementation. And the last is the relative deprivation of villagers' public interests.

3.1. Legal remedy of the URPL

He Qiangwei (2001), a Chinese law professor, believes that the rationality of modern urban and rural planning comes from the empowering act of legislation, which directly affects the value basis of the legitimacy and rationality of the administrative act of urban and rural planning. That is to say, the legitimacy basis of the administrative act of village planning is directly related to the full range of empowerment laws and regulations. And the systematic loopholes of laws and regulations directly determine the legitimacy crisis faced by the later implementation of village planning. In accordance with the URPL, Administrative Procedure Law of the People's Republic of China, and Administrative Reconsideration Law of the People's Republic of China, villagers have the right to challenge the establishment and implementation of village planning and its legal status as a normative document, namely the legal right to carry out legal remedy(Chen and Liu, 2001). But in reality, the jurisdiction of this legal remedy cannot cover the national law. Therefore, *perfecting the URPL and establishing the legal remedy mechanism of village planning have become the top priority to eliminate the crisis of village planning legitimacy.*

Specifically, according to the Constitution, the articles of the URPL on the establishment, implementation, supervision and inspection of village planning should be reasonably amended, as shown in Table 5.

Table 5: List of amendments to relevant regulations of village planning in the URPL

Article No.	Original Content	Modify Principle	Modified Content
Article 22	The people's government of a township or town shall take charge of establishing the township or village planning, and shall file such planning with the people's government at the next higher level for examination and approval.	Add contents of villagers' participation in village planning	The people's government of a township shall take charge of establishing the township planning. The village autonomous organization shall apply to the people's governments of a township and town for the establishment of village planning. It shall take charge of establishing the village planning, or may entrust the people's government of a township or town with the establishment.
Article 41	To build facilities within a village planning area, the construction entity or individual shall file an application with the people's government of the township or town, which shall submit the application to the competent department of urban and rural planning of the people's government of the city or county for issuing a planning permit for rural construction.	Add contents of planning permit for rural construction must conform to the content of village planning.	To build facilities within a village planning area, the construction entity or individual shall file an application with the people's government of the township or town. The people's government of a township and town shall examine and verify whether it conforms to the village planning. If yes, the people's government of a township and town shall submit the application to the competent department of urban and rural planning of the people's government of the city or county for issuing a planning permit for rural construction.
Article 52	A local people's government shall report the implementation situation of urban and rural planning to the standing committee of the people's congress at the same level or the people's congress of the township or town, and shall be subject to the latter's supervision.	Add contents of supervision and inspection of village planning	A local people's government.....to the latter's supervision. The implementation of the village planning shall be reported by the villagers' autonomous organizations to the people's congresses of the townships and towns

3.2 Update the standard of village planning

With the revision of relevant provisions in the urban and rural planning law, the technical operation of village planning also requires the establishment of rational technical guidelines for planning, forming the legalization of the whole process from legal provisions to implementation. Therefore, the current establishment system, standard system and technical system of village planning need to be adjusted to meet the needs of the new era of village planning.

3.2.1 Reconstruction of the establishment system of village planning

The current four-level establishment system of village layout planning, village comprehensive planning, village construction planning and special village planning should be adjusted into a three-level system. *Specifically, the contents about village development goals, positioning and comprehensive layout of village layout planning and village comprehensive planning should be incorporated into the mandatory contents of the comprehensive planning at the next higher level as the legal basis for later village construction planning and special planning.* And integrate the remaining contents of the village comprehensive planning with the village construction planning into a new village planning. Ensure the consistency of village planning from planning to implementation, and serve as the guiding basis for special village planning.

3.2.2 Revising the standard system of village planning

Due to the absence of national standards and the chaotic characteristics of local standards, it is necessary to issue the unified national village planning standards as soon as possible and establish a rational village planning standard system to standardize the technical methods and achievements of village planning across the country. In view of the big differences in the social, economic, cultural and ecological environment of villages in various provinces and municipalities, the standard system of village planning need to be divided into mandatory and non-mandatory (Table 6).

Table 6: Revised standard system of village planning

<i>Standards in village</i>	<i>Mandatory or non-mandatory</i>	<i>Explanation</i>
Land use classification	Mandatory	The unified classification of land use shall be determined to ensure the consistency of the planning base map
Infrastructure allocation	Mandatory	Determine the minimum standard of infrastructure allocation according to the building climate zoning to ensure basic living needs
Ecological management	Mandatory	Determine the bottom line of village ecological control and unified demarcation standards for village ecological control areas to protect the ecological environment

Scale determination	Non-mandatory	The village scale should be reasonably determined according to the current population, economy and construction level of the village
Per capita construction land	Non-mandatory	The standard of construction land use should be determined according to the actual per capita land use in villages
Public facility allocation	Non-mandatory	The allocation standard of public facilities should be determined according to the scale and level of villages
Landscape control	Non-mandatory	The requirements for landscape control should be determined according to the actual situation of the village

3.2.3 Rectification the technique system of village planning

We should respect the "natural law" and "value rationality" of villages, get rid of the dependence of traditional urban planning technology path, establish a set of village planning results and technical requirements with strong applicability, and form a complete and specialized technical method for village planning, so as to provide technical basis for village planning in various regions.

3.3 Establishing a contractual village planning

How to give full play to the "public policy effectiveness" of village planning and realize the high overlapping of "policy effect" and "villagers' interests" has become an important basis for the moral legalization of village planning. Modern contract theory holds that village planning is an "inter-subjective consensus" reached by social members based on procedural justice, and also a "contract" result of free choice among multiple interest subjects. Achieving "contract equality" has become an important symbol of village planning towards public policy. From this perspective, village planning should adhere to the principle of contractual equality and achieve a relationship of equal rights among the multiple subjects, so as to achieve a fair result of village planning.

The way to realize the multi-subject equal rights in village planning lies in empowering the people. That is to say, it empowers villagers to participate in all processes of village planning, transforms villagers from marginal groups into behavioral subjects and decision-making subjects of village planning, and changes from "tokenism public participation" to "substantial public participation". The details are as follows:

First, a village planning team should be established, including village autonomous organizations, villagers and planners. Village autonomous organizations are responsible for entrusting planners to establish village planning and organizing villagers to participate in the process of the establishment. Villagers are responsible for coordinating their participation in village planning and making suggestions and interest appeals. Planners need to go deep into the rural site survey, widely collect the real needs of villagers. And they also need constantly feedback the needs and wishes of villagers into the planning scheme to maximize the expression of the public interests of villagers and village

autonomous organizations. Secondly, a fair "contract" should be sought among the grassroots government, developers and the village planning team, so as to balance the interest game among multiple subjects. Finally, on the basis of fair "contract", the village planning team, developers and the grassroots government jointly complete the implementation and management of "contractual village planning".

4. Conclusion

Although the URPL has promoted the legalization of village planning at the national legal level, and also given village planning the legitimacy as the legal basis and technical blueprint for village development from the perspective of national legislation. However, a series of problems still exist in the implementation of village planning, which are rooted in the imperfection of the three-phase legitimacy structure of village planning, the uncertainty of the implementation environment and the instability of the reality foundation. As a complex administrative act, village planning contains a complex process from abstract to concrete, from blueprint to implementation. In the future, further argumentation and analysis are needed to truly promote village planning towards public policies and ensure the legal status of village planning in the process of rural construction.

Track 15: Tourism, Public Spaces and Urban Cultures

Land use planning, tourism intensification and regulation of short term commercial visitor accommodation: the case of Edinburgh

John McCarthy

Heriot-Watt University, Edinburgh, Scotland, j.p.mccarthy@hw.ac.uk

Abstract: Many cities globally have seen an expansion of short-term rental accommodation (via online platforms) as a means of increasing capacity and encouraging additional tourism revenue. This has led in some cases to concern for more effective regulation, for instance via land use planning, because of problems such as loss of amenity. There are also concerns that this has led to displacement of the supply of traditional residential letting, as well as a rise in overall rents and capital values. This paper considers the case of Edinburgh and the associated potential of regulation via land-use planning. It explores how such regulation might seek to minimise problems while retaining benefits arising from expansion of the overall tourism sector and associated revenue. However this is not straightforward, as evidenced by the significant variation in practice between cities this regard. In addition, there are significant associated problems related to the difficulties of detection, monitoring and enforcement in relation to letting activity. The experience of Edinburgh in these respects is instructive for many other cities globally which experience similar pressures.

Keywords: urban, regeneration, tourism

Introduction

The use of Short Term Lets and Short Term Commercial Visitor Accommodation (STCVA) has grown globally to a significant extent in recent years. In Edinburgh, the use of such accommodation has been particularly prevalent during the peak tourism months, especially August and December/January. Essentially, STLs comprise home-sharing (with a property or part of this being rented for a small element of the year but with the property remaining the primary residence of the owner) and Short Term Commercial Visitor Accommodation (with a whole property rented for a significant part of the year and not the residence of the owner) (Crommelin et al, 2018).

The use of STLs has been a way of expanding accommodation to meet the increased demand from tourists during peak periods (Swanson, 2018a). The contributing factors in relation to such growth include the increasing demand from tourists for accommodation which is more like a home than a hotel, with access to residential amenities such as a kitchen (Guttentag, 2015), as well as the increasing use of cheap air travel. The rapid expansion of such uses in many cities has been facilitated by the expansion of the 'sharing economy' (Ferrerri and Sanyal, 2018), with the rapid growth of peer-to-peer services which have allowed easy and rapid proliferation and delivery of STL, including for instance Airbnb and Booking.com.

While the specific causes and effects of STLs are context-dependent to a large degree, the outcomes in many cities have been similar and transformative, and have raised a series of common questions and issues in relation to implication for existing communities. Consequent approaches to regulation, for instance in relation to loss of amenity, have so far been varied (Gurran, 2018).

This paper considers the case of Edinburgh, in terms of the implications of the growth of STLs (focusing on STCVA), including the potential for regulation to ameliorate the problems caused, whilst allowing benefits (particularly economic benefits arising from increased tourism spend) to be maximised.

A significant factor in Edinburgh is the city's distinctive history of home sharing, because of the high seasonal variation of tourism in the city (arising from its history of the festivals essentially taking place in August, as well as the large numbers of tourists coming to the city for the New Year 'Hogmanay' festival). As a consequence, there has been a long-standing practice of many residents providing temporary accommodation for visitors. This kind of use – what may be called 'home sharing' – does not have a significant impact on wider housing and does not have the same level of implications on cities as does STCVA (Gurran and Phibbs, 2017).

In overall terms there would seem to be around 9,000 STL/STCVAs in Edinburgh, with these being largely concentrated in the centre of the conurbation; over half of all Airbnb bookings in Edinburgh occur within the city centre (Mitchell, 2019). This pattern of uses seems to broadly replicate evidence elsewhere in Europe (Colliers International, 2018). In addition, in Edinburgh, whole-property lets are the fastest-growing sector of STL/STCVA, and in 2017 the sector amounted to 20% of all visits to the city; there was also a 70% increase year-on-year in such visits during 2017 (Mitchell, 2019).

Impacts and issues

A range of impacts may be seen to have arisen from the growth in the above types of accommodation, globally as well as in the case of Edinburgh. Perhaps the most evident in many cities has been the effect on residential amenity, for instance in terms of increased noise, anti-social behaviour, and related concerns over security and safety (for both visitors and residents). Such effects are of course part of a wider process whereby tourism uses gain prominence over traditional residential uses. This and related factors are considered below.

Loss of amenity

The introduction of STL/STCVA may affect residential amenity in many ways, for instance via noise and anti-social behaviour, as a consequence of the fact that visitors lack the relationship to the area that long term residents have. An extreme case in this context is that of so-called 'party flats' with clear implications for noise and nuisance. Of course, for home-sharing, such issues are ameliorated since neighbours can complain directly to the permanent resident, who also would seem to have an incentive to ensure that visitor behaviour is appropriate since they need to maintain appropriate coexistence with neighbours.

A further issue in this context is the nature of the accommodation itself. In Edinburgh for instance a large number of STCVA arises in tenemental properties, which coincide with areas where there is high demand for visitor accommodation. Particular problems may arise in such areas as a consequence of their high residential density, and the prevalence of common areas which may be neglected by landlords. Indeed, some observers have consequently suggested that tenemental properties are unsuitable in principle for use as STCVA. Certainly, the effects of visitors arriving at unusual hours, and using keyboxes to gain entry to flats and perhaps being unaware of which flat they need to access, might be magnified in such properties. While local authorities do have powers in relation to addressing noise and anti-social behaviour, there may be limited enforcement in practice.

Maintenance

There are also issues concerning the need for building maintenance; in Edinburgh, this relates particularly to the common spaces within traditional tenements, particularly the communal stair or 'close'). The assumption is that the operator of STL/STCVA is less likely than a traditional resident to carry out the repair of such areas, and so

in a tenement which comprising a number of residents and/or STL/STCVA operators there may be a greater reliance on a smaller number of residents for essential maintenance. Indeed, there have been anecdotal accounts in Edinburgh of tenemental properties with only one remaining resident remaining, leading to severe disturbance in such cases.

Of course, it may be argued that it is in operators' interests to ensure that their property is well maintained so as to ensure that there is sustained demand for it (ASSC, 2018). But in normal circumstances priority for maintenance is less likely where a permanent resident is absent. In addition, commercial operators may visit properties infrequently, and they may outsource cleaning and waste removal services, leading to a loss of accountability for maintenance issues.

There are also specific factors pertaining to Edinburgh in terms of maintenance issues, since the concentration of STL/STCVA in the Old and New Town areas means that they are also concentrated in areas with a very high density of historic buildings, which are more liable for need for maintenance.

Safety

Equally, there are many concerns on the issue of safety, because operators of STL/STCVA may be less likely than permanent residents to take account of the need for safety certification fire regulations for instance. This may be compared to the need for compliance for the operators of hotel and bed and breakfast accommodation. As with maintenance, it may nevertheless be argued that operators should be incentivised to ensure appropriate safety arrangements are in place in order to ensure a sustainable business operation (ASSC, 2018).

Specifically, there is a range of safety legislation in Scotland for the private rented sector as well as traditional guest accommodation such as hotels, for instance for gas, fire and electrical performance as well as more general public health and safety; however, this does not apply to private residential accommodation used for STL/STCVA. This is a significant issue for instance in view of the potential for STCVA to provide de facto 'hotels' (albeit potentially unregulated), which can put visitors (as well as neighbouring residents) at significant risk. In addition, in the case of safety, residents operating STL home-sharing may in fact be at greater risk than commercial operators, since they may have lesser knowledge of legal requirements. While the ASSC requires members to have certificates in relation to safety of their accommodation (ASSC, 2018), many operators may not be members, and this anyhow would not apply to home-sharing STL uses.

Loss of housing

Many observers also highlight the potential impacts of STL/STCVA via the loss of available housing. STCVA attracts a higher investment yield than traditional longer term letting, so many landlords choose to 'convert' traditionally let properties to STCVA, possibly involving the removal of existing tenants, as well as the loss of opportunity for traditional letting when properties are put up for sale. Indeed, it may be suggested that this process has contributed to a net loss of 10% in the PRS housing sector in Edinburgh in recent years (Mitchell, 2019). Such a loss of housing has also been noted in London for instance, particular in terms of the loss of affordable housing for short term rent (Simcock and Smith, 2016).

In Edinburgh, these issues are compounded by the geographical concentration of STL/STCVA, with clear 'neighbourhood' effects in terms of loss of traditionally let or occupied housing evident in areas such as within the Old and New Town World Heritage Site. Nevertheless, arguments over loss of housing have been contested however with contrasting views asserting that housing supply in Edinburgh is not significantly impacted by STL/STCVA growth (ASSC, 2018).

Gentrification

It is also asserted by many that the growth of STL/STCVA has led to gentrifying effects for instance via the increased costs of housing (linked in turn to reduced supply). There would certainly seem to be clear evidence of such impacts in Edinburgh, and the proliferation of STL/STCVA would seem to be acting as a contributing factor to driving up property prices. This is linked in turn to broader arguments in relation to gentrification as a process, and in Edinburgh this is reflected in the increase in development of uses such as hotels in the Old Town for instance. These arguments are of course reflected in many other cities including in particular Amsterdam, Berlin, San Francisco, New York and Barcelona, prompting a range of regulatory responses (Brauckmann, 2017; Wachsmuth and Wiesler, 2018).

World Heritage Site

The case of Edinburgh is also distinctive because of the presence of the World Heritage Site, which coincides with the main area of concentration of STL/STCVA. This may be seen to exacerbate the potential damage to historical heritage in the city, as shown for instance by the proliferation of key safes (allowing secure exchange of keys) which are located on many communal buildings of historic value. Moreover, more broadly, the contribution of the increase in STL/STCVA in the historic centre of Edinburgh may contribute to a loss of community character which in turn may exacerbate the threat to loss of World Heritage status, particularly with Edinburgh's World Heritage Site being distinctive as a residentially inhabited site.

Taxation

There are also concerns in Edinburgh (similar to many other cities) over the loss of taxation revenue associated with increasing STL/STCVA since it is argued that there is significant non-compliance with regulations in this sector with respect to council tax and non-domestic rates for instance, though it is asserted by the ASSC (2018) that there is little verifiable quantitative evidence in this context. Certainly, however, in many other cities (such as Barcelona for instance), the growth of this sector would seem to have led in many cases to provision of what are in effect unregulated and untaxed hotels.

Wider tourism context

The growth of STL/STCVA is clearly part of a wider growth of tourism, which is often encouraged as a means of economic diversification, via making use of opportunities arising from the global growth in the tourism sector (particularly in contexts such as China). There is a strategic aim in Edinburgh to increase tourism in the city, with the 2012 strategy aiming to increase tourism numbers by one-third by 2020 (ETAG, 2012), though, clearly, this would seem likely to lead to sustained tensions with city residents. There have also been associated calls for a tourism tax to address the externalities resulting from increases in tourism numbers..

Certainly, the growth of STL/STCVA in Edinburgh offers a way of increasing accommodation for tourists without the need for significantly increased numbers of hotels. There is also a global trend for tourists to seek greater 'authenticity' in their tourism experience, which might be seen to be assisted by growth in STL/STCVA. In addition, such growth might be more dispersed throughout the city than traditional hotel and related accommodation, which could assist with wider dispersal of economic benefits (ASSC, 2018; Scottish Government, 2018).

Legislative context in Scotland

The growth in the provision of STL/STCVA in Edinburgh, as well as related concerns over the issues set out above, have led to calls for more effective regulation and control of the sector. This is also paralleled globally

(Edelman and Geradin, 2015). In the context of land use planning in Scotland, a current difficulty arises since STL/STCVA do not constitute a ‘use class’ for the purpose of requiring planning permission; consequently, where such a use is brought to the attention of the local authority for instance via planning enforcement complaints, this means that an individual decision must be made concerning whether the operation constitutes a change of use (Mitchell, 2019). This would seem to lead to inconsistent decision-making and confusion for the stakeholders involved; it would also seem to lead potentially to wasted resources applied to appeal processes.

These issues are particularly relevant for STCVA, since this can clearly be seen as distinct from normal residential use. Nevertheless, there is significant debate on this issue: some assert that STCVA (as well as STL) is compatible with a residential use class (ASSC, 2018), while others argue that all cases of STCVA should constitute a change of use. In fact the City of Edinburgh Council has produced guidance on this issue via its *Guidance for Business* (CEC, 2018); this sets out factors for consideration which include impact on local amenity; size, scale, frequency and pattern of the use; and the character of the area in which the use is located.

Future ways forward

Self-regulation

Some argue that this would allow several potential ways forward in the case of Edinburgh, with respect to the growth of STL/STCVA. In overall terms this is based on the assumption that markets have the capacity to regulate themselves (Gurran and Phibbs, 2017). Certain, in Scotland, the ASSC suggests that a voluntary code could be helpful (ASSC, 2018); nevertheless, membership of this organisation is not universal for STL/STCVA operators, and, in any event, the only reasonable sanction against non-compliance would be revocation of membership (Mitchell, 2019).

The Scottish Government’s Expert Advisory Panel for the Collaborative Economy (Scottish Government, 2018) considered proposals from Airbnb for self-regulation in terms of STL/ATCVA. Specifically, Airbnb argued that self-regulation could allow operators to let properties for up to 90 days per year (though not including the summer and winter festival periods). This has been criticised since the time periods appear to be generous (since in practice they could allow in excess of 150 days per year); and the self-regulation would of course not apply to other platforms hosting STL/STCVA.

Licensing

There would also seem to be significant potential for some form of licensing to be applied to address the issues identified above. As of 2019, the City of Edinburgh Council had requested the Scottish Government to ensure that the necessary legislation was passed to allow this to progress. Specifically, the local authority hopes to introduce a licensing requirement for STL/STCVAs which operate for over 45 days per year; a test for operators; and the potential for limitation of number of STL/STCVA uses within a geographical area of the city. These proposals would seem to have support from many stakeholders in the city (Mitchell, 2019).

Planning permission requirement

As a result of the increasing concerns in Edinburgh, the Scottish Planning Bill currently (as of 2019) progressing through the Scottish Parliament has included consideration of an amendment proposing a change in the definition of ‘development’ in law which would require a planning application for a change of use from residential to operation of ‘a dwellinghouse for short-term holiday lets’ (namely where this is not the sole or main residence of the owner, though the definition could take into account the threshold of a certain number of days per annum for letting), but this has been contested.. Such a provision would allow the local authority to produce relevant policies for instance to determine the overall level of STCVA; the areas where it is to be focused,

and areas deemed to be at risk from growth in this sector (Mitchell, 2019). The implementation of such proposals would arguably allow many outstanding issues to be addressed as well as bringing more consistency in the treatment of STCVA.

This leads in turn of course to the potential for framing of appropriate policy for instance to either concentrate or disperse STCVA uses, in what way. However, this is not straightforward. Arguments for dispersal suggest that this might reduce problems of erosion of amenity in the city centre for instance, as well as bringing economic benefits to more marginal parts of the city, via the (albeit limited) spending of visitors in local shops and on local services. The notion of dispersal of such uses would also seem to chime with the common strategy to address problems of tourism congestion in cities by moving tourists away from ‘honeypots’. Such a policy has been applied successfully in many cities such as Amsterdam, and has been suggested as a way forward for managing tourism impacts in Edinburgh. However, there is no clear consensus on where in Edinburgh STCVA might best be located in the future, in relation either to area, or to type of property. In relation to area, some suggest the need for alternative tourism zones within designated parts of the city (such as Leith), but equally of course there is also the potential for extreme dispersal, or a mixture of both of these approaches. In relation to the type of property, many commentators have suggested that tenemental property, widespread in the city centre, is not ideally suited to such uses, and that additional STCVA would result in disproportionate loss of amenity in areas that have a significant concentration of tenemental or flatted accommodation. This would further underline the argument for dispersal from the city centre.

Conversely, however, there may be cases where concentration of STCVA uses in the central areas of cities might be deemed appropriate, for instance where there is clear linkage to local services and attractions, or where there is limited public transport availability. What would therefore seem to be needed is further research in this context to ensure that policy going forward can be evidence-based to enhance its effectiveness.

Availability of data

An added advantage of the use of measures such as licensing and planning permission requirements would be the consequent increased availability of data in relation to the actual use of STL/STCVA, since the use of such data seems essential for the development of appropriate policy. At present the diversity of platforms in relation to STL/STCVA means that the generation of accurate data is difficult (Cockburn Association, 2018), and peer-to-peer platforms have not always been willing to share relevant data (Frenken and Schor, 2017). Hence, if data could be obtained directly from operators (for instance from licensing/planning permission requirements), this would assist greatly with the formation of appropriate policy (Mitchell, 2019).

Conclusions: legislation and policy

There are clear implications from the above discussion for the need for appropriate legislation and policy to address STL/STCVA. In terms of legislation, measures to require planning approval for operation of STCVA would allow the local authority scope to manage the development of these uses. This might be accompanied by a system of licensing. Such measures would have the potential to address to an extent concerns surrounding issues such as safety, and would have clear benefits for the collection of appropriate information. While measures such as these have relevance more generally in other contexts, the potential for some form of ‘model’ solution for regulation of these uses is contested.

On the one hand, the issues brought about by the growth of STCVA and STL would seem to be similar in many contexts globally, particularly between contexts with similar characteristics, such as historic cities with high (and growing) levels of tourism. This would seem to imply the potential for cross-national learning to develop good practice for application in different contexts. In addition, platforms such as Airbnb have emphasised the advantages of a ‘model legislation’ approach (at least within one nation state) whereby the same regulatory

approach can apply in different contexts (Ferreri and Sanyal, 2018). On the other hand, however, there are also clear arguments in relation to the importance of geographical and other specificities, which suggest the need for different local approaches. Nevertheless, of course, legislation in relation to planning requirements might be applied in national legislation, but applied via locally derived policy.

This leads to the potential need to develop policy via local authorities such as Edinburgh to set out where STCVA might best be located. Certainly, the provision of clear data in relation to existing provision of STCVA (coming for instance via licencing and planning requirements) could be very helpful in this respect. But the issue of location policy for STCVA could usefully be the scope of further research, since this issue involves potentially conflicting concepts and assumptions.. Clearly, further research in relation to the potential of such policy could be of benefit to many cities globally as well as Edinburgh.

Evaluation of the Land Value Capture (LVC) experience in the City of São Paulo, Brazil

Eduardo Alberto Cuscé Nobre¹

¹Associate Professor, Faculty of Architecture and Urbanism,
University of São Paulo, eacnobre@usp.br

Abstract: The use of Land Value Capture (LVC) tools has been advocated by many authors as way of financing public investment and projects. The rationale behind these tools is to capture part of capital gains on land derived from public sector interventions on urban development, such as infrastructure implementation or land use regulation change. They can be of great importance in very limited budget environments such as rapid urbanising countries that need to provide a great amount of infrastructure and urban services to accommodate urban growth. The City of São Paulo, Brazil, has implemented LVC since the 1980s through a wide range of different tools. The objective of this paper is to evaluate the implementation of two of these tools, Additional Building Rights Certificate (CEPAC – *Certificado de Potencial Adicional Construtivo*) and Additional Building Rights Levy (OODC – *Outorga Onerosa do Direito de Construir*), from 2002 until 2014. Rather than evaluating these instruments just from a revenue point of view, the work intends to analyse also how effective they are in reducing social disparities, considering the location and kind of investments done. This work was financed and present partial results of a Research Project funded by FAPESP (São Paulo State Research Support Agency), process # 2017/15256-1.

Keywords: urban planning, public policy, land value capture, São Paulo.

1. Introduction

1.1 Background

The discussion about the use of new urban planning tools based on land value capture (LVC) for urban projects financing in the city of São Paulo dates back from the 1970s. The experience of Spain, Italy, France and the USA had much influence in the study and proposition of a new legal framework separating the right to build from the right of property, based on tools such as Additional Buildings Rights Levy, compulsory urbanization, pre-emption rights and the Transfer of Development Rights (TDR)(São Paulo, 1979).

In these discussions, the concept of “Created Land” was highlighted, corresponding to the “any built area that exceeds a certain proportion of the plot area” (Azevedo Netto, Moreira, et al., 1977, p. 9). This concept arose in 1975 reflections that were being developed by several technicians of the public administration, mainly linked to CEPAM (Centre for Studies and Research of Municipal Administration of the State Department of Home

Affairs)(Moreira, De Ambrosis, et al., 1975). It was widely disseminated in the following years by CEPAM and IAB (Institute of Brazilian Architects), in seminars on the subject, and in the general and specialized press (Memorando, 1977).

Based on this concept, it was proposed to use three new instruments: a single Floor Area Ratio (FAR) for the whole city, the Transfer of Development Rights (TDR) and the proportionality between public and private land. On fixing a single FAR for the whole city, any exceeding built area above this FAR would only be possible by transferring the building rights from another area, either by the acquisition of these right from private owners, or from the Municipality, and in this latter case, either in cash or in the offer of other land of interest to the community.

In the case of the transfer of building rights, this would occur through certain rules set by Local Authorities. Finally, all this discussion was based on the proportionality between public and private land, in other words, the proportionality of population density, which would come from building densification, and the provision of land for public facilities, such as kindergartens, schools, health unities and public spaces, or for redevelopment projects. In the case of the TDR, the idea was also linked to the preservation of buildings of historic interest, as was already done in cities like Chicago and New York in the USA.

The City of São Bernardo do Campo was the first in Brazil to adopt the “Created Land” in its Master Plan, charging for any construction above the single FAR and depositing the money arose from these charges on a “Green Area Fund”, to be used to acquire land for public spaces and parks (Contador, 1977).

The concepts defined on this period would later base the creation of the Additional Building Rights Levy (OODC – *Outorga Onerosa do Direito de Construir* in Portuguese) to obtain resources for urban development. Rezende et al. (2009), in an article analysing the theoretical construction of the OODC, corroborate this idea, showing the evolution of the line of thought of the “Created Land” throughout the 1970s, 1980s and 1990s until the regulation of the OODC by the Federal Law 10.257 / 2001 (Rezende, Furtado, et al., 2009).

Also in the late 1970s, the Municipality of São Paulo itself considered the adoption of “Created Land”, as evidenced by studies developed by COGEP (General Planning Coordination), predecessor of SMDU (São Paulo Urban Development Department) (City of São Paulo, 1979). In addition to the study of foreign experiences, these studies presented analyzes of the economic, physical, legal and institutional aspects of the application of “Created Land” and the use of TDR in historical areas (Espallargas et al., 1979a; and 1979b).

The São Paulo Mayor Olavo Setúbal (1975-1979) even sent a bylaw project regulating the “Created Land” to the Municipal Council, however, the project was withdrawn from the agenda, under pressure from the Brazilian Minister of Finance, Mário Henrique Simonsen, who considered the instrument as inflationary (Memorando, 1977).

Over the years the concept continued to be discussed by the technical staff of the City Hall and in 1991 was incorporated into the proposal for Master Plan revision. This law project proposed the adoption of a single FAR equal to one for all the Urban Zone, with the exception of special zones and cases provided by law.

Densification areas were defined where the FAR 1:1 could be exceeded up to the limit of an available building area stock. The funds collected would be deposited in the Urbanization Fund (FUNDURB) and should be used as a priority in the execution of the ZEIS (Social Interest Special Zones – a sort of inclusionary zoning) programs, in the fulfillment of affordable housing demand, in the public spaces implementation, drainage works and roads of the structural transport system programs.

Despite the new concepts brought by this plan, it suffered great resistance from the real estate sector. The point was not to be against the single FAR, but to be against the value equal to one. For the industry, the FAR should be at least 2:1. Finally, at the time of presentation to the City Hall, entrepreneurs made strong resistance to keep the “rules of the game” unchanged, that is, the existing zoning (Antonucci, 2002). At that time, many criticisms were made by several people related to the real estate market, including architects that said that the adoption of OODC would render construction unviable in the city of São Paulo.

1.2 The Interconnected Operations (IO)

However, the concept of created land was only used in the city of São Paulo through the Interconnected Operation urban planning tool (Montandon, 2009). Established under bylaw 10,209/1986, this instrument allowed owners of land occupied by favelas or precarious housing to request the City Hall a major FAR than the allowed, provided they were obliged to build or to donate social housing to the favela population. The name interconnected operation came from the necessity of a married operation between the modification of the FAR, removal of the favelas and relocation of the population in the built housing units.

Subsequently, this instrument was amended by bylaw 11.773/1995, which allowed for the revision of the FAR and other land use regulation of any land in the city, with a financial counterpart linked to the Municipal Housing Fund (FMH). By this law, the revised FAR could reach 4:1 and the building could occupy 80% of the plot area (OR – Occupation Rate of 0.8).

In 1998, the State Public Attorney charged an ADIN (Action of Unconstitutionality) against the use of the IO by São Paulo Municipality in the State Court as it gave to the Executive prerogatives of zoning change inherent to the Legislative. The Court accepted the action and the use of the tool was considered unconstitutional in 2000.

2. Recent implementation of Land Value Capture Tools

2.1 The Consortium Urban Operations

Another urban planning tool that used the concept of the created land was the Urban Operation. The idea of this instrument emerged from a series of studies carried out by SEMPLA (City Planning Department), between 1983 and 1985. The dossier resulting from these studies defined urban operations as “integrated sets of urban interventions developed in determined areas of the city under the coordination of the municipality, aiming to obtain results relevant to the objectives of the Master Plan”, with the objectives of making feasible the production of social housing, urban infrastructure, public facilities with the participation of private entrepreneurs (City of São Paulo, 1985 *apud* Montandon, 2009 , p.15).

The above concept of Urban Operation was inserted in the proposal of the 1985/2000 Master Plan, but in the real plan, established by the bylaw 10.676/1988, its concept was simplified and its importance reduced, since the Interconnected Operation was already working.

The instrument was only implemented in 1995 with the creation of the Faria Lima Urban Operation in the bylaw 11.732/1995. According to its registration prospectus at the Securities and Exchange Commission: “The Faria Lima Urban Operation was the first to produce effective financial results, that is, to generate a self-financing

environment for the execution of the public interventions provided by the additional building rights levy, thereby without compromising the municipality budget”. (City of São Paulo, 2008, page 47)

In 2001, the City Statute, Federal Law 10.257/2001, ruled the Urban Policy Chapter of the 1988 Federal Constitution, included this urban planning tool, redefining it as a Consortium Urban Operation (OUC), which is “a set of interventions coordinated by local authorities, with the participation of the private entrepreneurs, which aims to achieve structural urban transformations, social improvements and environmental remediation of a given area” (Brazil, 2001, article 32, paragraph 1). In 2002, the PDEMSP - São Paulo Municipality Strategic Master Plan established nine urban operations (City of São Paulo, 2002, article 225, § 2o).

The changes introduced in the City Statute and the 2002 Master Plan allowed a new form of financial funding beyond the OODC. The CEPAC (Additional Building Rights Certificate) is a bond issued by the Municipality of São Paulo, marketed on the stock exchange, corresponding to an additional building area for any plot within the perimeter of a Consortium Urban Operation. Each CEPAC is equivalent to a certain amount of square meters for use in an additional building area or in modification of uses and parameters of a land or project.

There are currently four regulated urban operations in the city of São Paulo: OUCAB - Água Branca Consortium Urban Operation (created in 1995 and revised in 2013); OUCAE – Água Espraiada Consortium Urban Operation (created in 2001); OUC – Centro Urban Operation (created in 1997); OUCFL – Faria Lima Consortium Urban Operation (created in 1995 and revised in 2004).

Currently, there is already a great theoretical reflection on the use of this instrument in São Paulo. The criticisms range from the exclusionary effects due to the “expelling” of lower income population, increasing socio-spatial segregation (Fix, 2001; Maricato; Ferreira, 2002); through the privilege of real estate issues of private interest to the detriment of the public interest (Castro, 2006); the lack of an urban design and an emphasis on the great road works (Vilariño, 2006; Nobre, 2009); and lack of efficiency in the recovery of land value capture in comparison with the public investments made (Montanton, 2007).

Urban operations proved to be an instrument with a high financial attractiveness, since in nineteen years of implementation they managed to raise R\$ 6.3 billion (around € 1.4 billion), corresponding to an additional building area of 5.97 million square meters, averaging R\$ 1,050 per additional square meter (€ 233), and in the OUCFL (Faria Lima Consortium Urban Operation) was the one that most appreciated, with the initial market value of CEPAC varying from R\$ 1,100 in December 2004 to R\$ 4,000 in May 2010 (SP Urbanismo, 2014a).

However, with regard to investments, there is a predominance of road works of the amount spent on all urban operations in the city of São Paulo. According to municipal data, 43% of the money spent on public works on urban operation was on road works. The second largest expense was in land expropriation for the works, corresponding to 19% of the amount. Public transportation and social housing expenses together accounted for only 31% of the total (14% for the former and 17% for the latter), partly explaining the criticism received from the way in which the instrument has been used.

Another issue that seems pertinent is that the OUC (Consortium Urban Operation) collects more, and consequently concentrates more investments, where there is already a great interest of the real estate market. In this regard, the two operations in the Southwest Region of the city accounted for 89% of the total amount collected by all four operations. This represents a very large spatial concentration of investments, since the areas of these two operations together amount to only 2% of the area of the city and by definition of the City Statute the resources collected inside an OUC can only be applied within its perimeter. This increased the socio-spatial differentiation on an already very segregated city.

In the review of this instrument in the current Master Plan, part of these problems may be remedied, since according to paragraph 1 of Article 142 “at least 25% (twenty-five percent) of the funds collected shall be invested in social housing within the perimeter of the Urban Consortium Operation, preferably in the acquisition of land for the housing units” (City of São Paulo, 2014). However, the implementation of collective transportation systems was not considered in this review.

Another issue that may improve the implementation of urban operations reviewed by the Master Plan is that they have now a greater social control, since their management council has to be parity between the Public Power and civil society.

2.2 The Additional Building Rights Levy (OODC)

Despite its use in interconnected operations and in the urban operations, the Additional Buildings Rights Levy (OODC – Outorga Onerosa do Direito de Construir) only came to be ruled for the whole city in the 2002 MASTER PLAN, after its definition in the Statute of the City, which consolidated the use of the concept of created land at the National level.

Pursuant to this Law, “city Master Plans may establish areas in which the building rights may exceed the Basic FAR up to the Maximum FAR, defined by the plan, upon the payment of the levy, taking into account the proportionality between the existing infrastructure and the expected density increase in each area” (BRASIL, 2001). It may also establish areas in which alteration of land use may be allowed. A bylaw shall establish the conditions to be observed for the ODDC and change of land use, determining: i) The formula for the levy; ii) The cases that may be exempted from payment; iii) The counterpart of the beneficiary.

The 2002 Master Plans first ruled the OODC for the whole city and defined the Areas of Possible Additional Building Rights Grant, whereas the building rights to could exceed the basic FAR (Cab) up to maximum FAR (Cam). The additional building stock was defined for the 96 Municipal Districts of the city. All the resources acquired by this levy should be deposited in the FUNDURB (Urban Development Fund).

One of the major difficulties to implement the OODC at this time was the possibility to use a formula whereas additional building rights were given for free as well as the plot coverage was diminished, tool based on the New York Incentive Zoning of that city 1969 Master Plan. Certainly this device was placed in São Paulo 2002 Master Plan as a transition for the real estate market to become accustomed to the new rules.

The OODC concept was revised in the 2014 Master Plan. The additional constructive potential was considered as a legal right, owned by the City Hall, with urban and socioenvironmental functions, corresponding to the difference between the constructive potential used and the basic constructive potential.

The basic FAR was defined 1:1 to the whole city in accordance with the created land idea of the 1970s. After 12 years of OODC implementation, the real estate market has already become familiarized to the instrument. The maximum FAR 4:1 was defined for the Structuring of Urban Transformation Axes Zones (ZEU), in the some economic development incentive zones (ZOE), and in the social interest special zone (ZEIS). The consortium urban operations will define their coefficients, respecting the basic FAR of 1:1. In the rest of the city, the maximum FAR is 2:1, except for areas where it was already smaller than this.

Interestingly, if on the one hand the amount of additional area is very close to the additional area built in all urban operations, on the other hand, the amount collected corresponds approximately to 1/4, while the average

value per square meter corresponds to 1/3, demonstrating the power of land value capture of the OUC. This was due in part to the outdated Municipality Land Value Map, and in part by CEPAC being a financial asset not tied to a specific venture, being bought by banks and investors, who then resell it for a larger amount of money, valuing the bond.

With a new calculation formula and update of the Municipal Land Value Map, it was expected a considerable increase in the collection of OODC. According to studies by SP Urbanismo (2014b), considering an average of residential and commercial gross area increase of 3.7 million square meters per year, the expectation of net collection with OODC's counterparts was R\$ 480 million a year (€ 106 million), representing an increase of three times the of average collected so far (2011).

Regarding the expectation of additional built vertical area, the values seem to be consistent with what has been happening in the city of São Paulo. According to data from the TPCL (Land and Building Taxes Register), between 2002 and 2012, there was an increase of residential and commercial built areas of 41.5 million square meters or 4.15 million square meters per year, (SMDU, 2014).

However, the economic crises Brazilian economy underwent following the 2008 USA Subprime Crises impacted São Paulo real estate market, reducing the amount of collect money to the half of it as the construction sector is very susceptible to economic changes, being the first to decrease production in times of crisis, returning rapidly in times of economic growth.

3. Final considerations

The implementation of LVC tools in São Paulo presents controversial results in the experience of interconnected operations, consortium urban operations and the additional building rights levy.

In spite of the fact that, historically, the use of collected resources for social purposes (social housing, community facilities and public transportation) has increased, the analysis of its implementation has shown a tendency towards aggravating socio-spatial disparities in a city already segregated in the two first cases (interconnected operations and consortium urban operations).

In the case of interconnected operations, the construction of social housing in the outskirts of the city as a counterpart to changes in urban legislation represented the removal of the population from the favelas and precarious housing from a privileged location in the city center to the outskirt regions, lacking in services and urban infrastructure. In any case, the use of the instrument was declared unconstitutional.

In the case of consortium urban operations, the predominance of the use of the resources collected in large road works, some of which are exclusively dedicated to the automobile, demonstrates an option that goes against the objectives of the universality of public policies and social justice of the Master Plan, since only a third of the daily metropolitan journeys are carried out by this modal and precisely by the population of higher income (METRÔ, 2007).

In addition, the two most successful urban operations in the resources collection are located in the most highly valued regions and most endowed with urban infrastructure in the city, which is why they are of interest to the real estate market. Due to restrictions imposed by the City Statute, resources collected in the intercropping operations can only be invested within the perimeter of the operation.

In this way, instead of a “virtuous cycle”, a “vicious cycle” of investment-valorization-reinvestment-valorization is created, increasing socio-spatial disparities. The fact that these two urban operations represent only 2% of the area of the municipality and have almost four times more resources to invest than FUNDURB is another factor that demonstrates the distortion of the use of this instrument.

The 2014 Master Plan seeks to reverse these negative aspects defining that at least 25% of the funds raised should be earmarked for the acquisition of land for social housing within its perimeter, but did not define anything about the implementation of public transport systems.

Regarding to social justice and public policies implementation, the additional building rights levy is the only instrument that can contribute to these. The recent regulation obliging the municipality to invest 30% of the resources for the acquisition of land for the social housing production and 30% for the implementation of public transport systems, bicycle and pedestrian ways, ensures that 60% resources are invested in objectives that are in line with the social objectives of the Plan.

Unintended outcomes of the marketized housing agenda in Sweden:

- the trolls that never were invited who we now have to deal with

Ylva Norén Bretzer

School of Public Administration, University of Gothenburg, Box 711, 405 30 Gothenburg

e-mail: Ylva.Noren-Bretzer@spa.gu.se

Abstract Max 150 words (now 164)

This paper discusses how the housing agenda in Sweden has been handed over to the municipalities, under the EU instructions. The marketized housing sector has resulted in unexpected local outcomes, or *trolls*, as for example private slum-lords, exploiting their properties to a maximum but with no local responsibility to the tenants. Also, a black market of temporary housing -or beds- is found, which often target vulnerable immigrants. Thirdly, private-public partnerships has emerged, often termed *business improvement districts* (BIDs), who collaborate locally in order to serve long time interests for the property owners, the tenants, the local business-owners and the wider community. In sum, the neo-liberal agenda is found to strengthen the local communities and partnerships, but the tools to deal with the anomalies still lies at the central state. The neo-liberal agenda needs to be anchored by place and local actors in institutional long-term relations in defined places. Results imply that the planning processes need to address this new landscape of actors, and processes.

Prepared for the AESOP Annual Congress in Venice, July 9 – 13, 2019

#14: Planning, Law and Property Rights

Introduction

“Housing mortgages are closed for a whole generation, they earn too little” the Swedish Daily News wrote 8th of June, 2018.¹ The conclusion comes from a report produced by the market leading national mortgage institute SPAB. The investigation was based on the top 20 municipalities and the prices for a 30 sqm flat, and the average incomes of 25-29 year olds, males and females. Even if the youngsters have saved up some capital, their salaries will most likely not meet the qualifications set out by the banking sector. The result is that young people will stay with their parents up to the age of 30, if they are not lucky to have parents that can deal with the lending issues. The ideal of social mobility which for long was a Swedish sign-mark is proved to be lost in history.²

How did we as a society end up here, and could we not foresee this situation? The situation in Sweden is only one example of many across the European continent. This paper aims to discuss how the marketized housing agenda in Sweden has resulted in a number of possibly unexpected local outcomes, which to some extent also spur illegal activities. Additional responses to these anomalies are local public-partnerships which in part form a counter-response, in the shadow of absent national urban policies. The paper will close with a discussion on how the absence of a thought through housing policy has invited some illegal *trolls*, where the civil society and the local governments now have to deal with the mess – primarily expressed in low-status neighborhoods. But as the citation above indicates, this paper elaborates on the conclusion that the consequence of the outsourced housing ‘issue’ or ‘package’ has diminished the welfare of a generation.

¹ *Svenska Dagbladet Näringsliv*, the Economy Section, 2018-05-05, p. 5.

² The same phenomena have been reported from Great Britain and many other countries across Europe. One of the latest examples is published in *The Guardian*, UK Surge for housing costs for poorest ‘worst in Western Europe’, March 21st, 2018.

The Swedish housing context in brief

The housing policy was for decades one of the core responsibilities for the Swedish state, and the country was “...successful in solving its housing shortage with a minimum of social dislocation.” (Goldfield 1982). Previous research has agreed that a typical retrenchment of the housing policy has taken place (Lindbom 2001), but I would take it even further to claim that a devolution to the municipal level took place in the 1990s, combined with increased reliance on the market forces.

The public responsibility and commitments to provide decent housing to segments with weak incomes constituted the prerequisites for the Million homes program in 1965 – 1975, a core mission for the Social democrats at the time. Generations after have disgusted these housing types and areas, regarding them as expressions of large-scale programmatic planning and disrespectful of peoples’ cultures, demands, living expectations and their own initiative capacities (Linton 2015; Eriksson 2001; Rådberg 1997; Le Corbusier 1987). Initially, they were often built for the labor population in areas close to industries in the mid-sized and larger cities. Since the larger refugee waves emerged from Latin Americas, Iran/Iraq, former Yugoslavia, Eritrea and Somalia, and lately also from Syria; these areas have had a large influx of various nationalities. Often, the Million program areas have been appreciated as the first step into the Swedish society, but during the past two decades the integration into the general labour market and society has slowed down. When these socio-economic vulnerable people have been destined into such geographically specific areas, problems have also followed in terms of degraded status of the Million program areas, higher levels of criminality, a common sense of unsafety, and poor management of the housing-stock.

When the Million program housings were built in the early 1970s, the government had destined large subsidies to the builders. These subsidies prevailed at a decreasing level, but when the financial crises set in during early 1980s and again in 1991 (when the *Riksbank*³ raised the rent to the banks to 500%), the state financial crisis was a cold fact. Following the trends around at the time, the state started a process of sorting the responsibilities; primary schools were decentralized to the municipalities;

³ Sweden’s central bank.

railways, post, telecom, electricity market and national airlines were privatised, as the state run drug-stores and the liquor monopoly (Norén Bretzer, Randrup & Persson, *forthcoming* 2019). As Sweden at this time was approaching the EU for membership, which got realised in 1995, the national political stand on the housing matters transformed from profound national engagement into a minimal. Even if it was not clearly spelled out, the intent of the policies were to adapt to the European common practices in the housing sector. The building subsidies were significantly reduced in 1994 and the former ministerial units *the Housing department* existed from 1974 until 1991. Between 1987 and 2006, a parliamentary committee existed as the *Housing committee*, but was later fused together with the *Civil committee*.

A more recent governmental committee report on housing policy from 2015 bear the significant name *EU and the municipalities' housing policy, SOU 2015:58, (EU och kommunernas bostadspolitik)*, which symbolises how the housing policy clearly is regarded by the Swedish state as a clearly municipal (and market) responsibility. This report primarily reads that the housing responsibility essentially is municipal, and that the EU regulations on assistance to market actors in the housing branch must be respected. Further, it states that the state itself possibly could assist (the municipalities) with legal and in rare circumstances financial help, primarily directed to weak markets. The state can also act as a partner for dialogue.

We should also bear in mind that the numbers of vacant dwellings were all-time high between 1994 up to 2000, which indicated a temporary over-capacity, and in those years houses were even torn down in some economically weaker municipalities with low employment opportunities (SCB 2012, p. 40 and SOU 2015:58, p. 20f). This situation contributed to the low willingness at the municipal level for quite a number of years to engage in any new housing developments.

A contrasting fact is that the National Board of Housing, Building and Planning has in numerous reports underlined the refurbishment needs in the existing housing-stock, and the urgent need for some additional 600 000 dwellings until 2025 (Boverket 2017:17). These volumes correspond to a new Million program investment, and the building activities have indeed increased, and the population

numbers have increased even more. The needs are especially large in the Stockholm and Malmö regions, where the prices have sky-rocketed on the private market, and the waiting lines for public housing is at least six, seven years in Gothenburg (Boplat Göteborg) and over 10 years in Stockholm (Bostadsförmedlingen, Stockholm). The Swedish housing-market has throughout the past 27 years changed in such a way that the number of detached homes have decreased with -3%, as has also the rented apartments. On the other hand, the coop apartments have increased by +6% throughout the period (Table 1).

Table 1. The Swedish housing market 1990 – 2017 (number and per cent)

Year	Detached Houses	Rented apartments	Coop apartments	Other	Dwellings Total
1990	1 874 233	1 554 457	616 078	0	4 044 768
2017	2 069 353	1 753 499	1 034 420	1 980	4 859 252
1990	46	39	15	0	100%
2017	43	36	21	0	100%

Source: SCB, Boende 2017, U166.

This has not occurred in an environment with fixed population parameters. Throughout the period 1990-2017, those aged 25-34 increased with 17%, 35-44 year olds increased by a modest 2 %, 45 to 54 year-olds increased by 24% and the last group on the labor market, 55-64 year olds increased by 37% (SCB, population data). [INCLUDE PARAGRAPH ON PRICE INCREASES, ABOUT 20 TIMES IN RUNNING PRICES, CONVERT TO FIXED PRICES] This is a core reason why the coop apartments have increased tremendously throughout the period. Newcomers to the housing-market have met a decreasing share of first-step rental apartments, and the other two alternatives, buying a home or a coop apartment would require a good bank-record and savings. Not all citizens who want to establish their lives, work-life and families would be advantaged in this new housing landscape, as the governmental commission wrote:

“There are significant entrance hinders for housing-seekers in the form of high housing prices. Long housing queues and the demands that the landlords are putting to coming tenants hinders some households to get acces to renal apartments. A growing group of housholds cannot get access to new built housing or to housing in the most attractive areas as their housholds are not eligble the bank morgages demanded to buy a home or any possibillity to get a rental home for

an affordable level of rent. Hence, there are groups in the society who risk to be secluded from parts of the housing-market. The housing needs may from a political perspective be seen as larger than what the citizens can demand, in particular when it comes to elderly, youth and newcomers.”(SOU 2015:58, p. 18).

The citation indicates an interesting awareness of the new privatised housing-political context, where access to housing to an increasing extent has been a matter of who has resources and access, and who has not. This exposé has also shown that there is a shortage of housing in Sweden under the present conditions, and that prices have increased throughout the past 27 years in such a way where we now are in a situation where the next generation stepping into the housing-market will see most of their welfare resources taken by the banks – if they ever will get a chance to enter. But the rest of this paper will not be about those who are making it, but about the unwanted consequences, the *trolls*, of this unbalanced housing situation. But before we enter this discussion more specifically, we will need a paragraph on methods and follow up with an ideological section on the neo-liberal thoughts in general and applied to the housing-market per se.

A methodological note

This paper is not a typical research paper, taking out a theory and some data in order to carry out disciplinary hypotheses testing. Nor is it a bunch of interviews collected in relation to an agreeable theoretical framework. This is a first draft that puts together the problem of housing shortages for socio-economic weak groups with the ideological theory-framework which at present seems to be more important for most political actors, than solving the housing problems for the mentioned groups. By collecting numerous of reports and news-paper articles as my initial data, I am starting to lay the ground for complementary interviews and other data collection. From having participated in the Urban investment program in early 2000s, to having done research in poor urban areas with the interest of energy efficiency, sustainable development, crime prevention and urban regeneration, an interest has slowly grown in what the back-sides of the de-regulated housing-market are, and the following harsh living conditions that follows, maybe not for evil but as a necessity. Documented fragments of these

activities therefore come from printed sources, but will in updated versions be complemented along the lines possibly suggested by the reader.

The neo-liberal agenda and how the Swedish housing policy disappeared

To be written later, but a tentative synopsis is:

- Sweden at a financial crisis, a Europe in retrenchment, combined with Thatcherism
- Neo-liberal ideology, according to theory, expectations and promises
- What was so attractive with neo-liberalism, as it was received in Sweden?
Risk-transfer over to the civil society, risk minimizing
- What did we miss? The ‘race to the bottom’ – and future generations?
Disconnecting the social control

Three trolls that came with neoliberalism, the Bad, the Ugly... and the Last Straw

The housing issue has up to now never been able to climb on the political agendas, as it is very complex and essentially fragmented at the municipal level, the regional level and increasingly so also at the state level. In 2014 a Housing crisis committee was appointed by the Chambers of Commerce in Stockholm and Gothenburg, chaired by Klas Eklund.⁴ In addition, the chair of the national Central Bank, Stefan Ingves, went to the media and asked for a parliamentary Housing Commission. The response came immediately from the Christian Democrat minister Stefan Attefall, who said that preparation work was under way.⁵ However, one governmental coalition later, to this date 2019 is an pressing issue slumbering underneath of the political ice. In the meantime, people and potential tenants need to go on with their lives. In the grey, and potentially black zones of the economy, we will

⁴ www.bokriskommitten.se

⁵ www.svd.se/bostadsminister-stefan-attefall-ingves-ar-inte-fullt-informerad

find the slumlords and the illegal trade with apartment contracts and even single bed spaces.

The Bad trolls – the Slumlords

Management has been the term a la mode since the early 1990s, used as a common recipe or treatment by engineers, business scholars, economics and the social engineers alike. But very little attention is brought to mal-management, neglected management or even illegal management. In the poorer urban neighborhoods in Sweden it has been practically known for decades that when housing estates become less attractive, maybe due to large investment needs or maybe because the jobs moved away and the labor-force took a different direction, unserious estate owners may come to the playground.

Example 1: Gamlestaden (The Old Town)

Gamlestaden was such a place, situated in Gothenburg at the west coast of Sweden, where the world-renown industries of SKF⁶ originates. This *Old Town* of Gothenburg had historically been abandoned for the New Town further down the river, and when SKF changed its HQ location, the housing estates of Gamlestaden decreased in attractiveness. To make a long story short – Gamlestaden became a place where poor people were located by the authorities, as for example refugees, drug-addicts or just ordinary poor. Many small private estate-owners were present in the area at the early 1990s, but the houses had not been maintained for a long time, and both the interior and the exterior were in desperate need of restoration. When the (Business Improvement District)⁷ BID Gamlestaden was initiated in 2001, it occurred at the background of degenerating social conditions, increasing criminality and drug use, and shootings at local restaurants.

⁶ www.skf.com/group/our-company/index.html

⁷ Partnerships between estate owners, business, civil society and the public sector has evolved in Northern America, the UK, Germany and is also emerging in Sweden. Various urban renewal initiatives have been around under labels of Business Improvement Districts (BIDs), Urban Improvement Districts (UIPs), Neighborhood Improvement districts (NIPs), Housing Improvement Districts (HIPs), Business Improvement Areas (BIAs) and Business improvement Zones (BIZs), among several commonly used terms (Meltzer 2012; Kreutz & Krüger 2011; Edlund & Westin 2009; Cook 2008; Hoyt 2005).

One initial type of problem identified was the frustration from the public estate managers that the often small private estate owners did not talk with one another, and they took the advantages of selling short-term or long-term housing to the Social Office, but they did not care about the actual living conditions in their houses. Some 18 years later, we know that the public estate owners and some of the private together under the collaborative umbrella BID, have invested in outdoor safety, indoor standards and neighborhood governance in dialogue with the residents. One of the main problems remaining, is that some estate-owners do not want to participate: for the sake of dramatization, let me call them slum-lords.⁸ This is also a way to differentiate the good landlords from the bad ones, those who collaborate with their tenants and the local community, and those who don't.

Example 2: Malmö

Let us move from Gothenburg to Malmö, also a harbor city at the very south of Sweden. In the area of South Sofielund, a centrally located area that have for long been known for its low living standards, but therefore not necessarily cheap rents. The local Estate Registry conducted a project where they were knocking the doors, house by house, to inspect the standards, the owners and the tenants (Figure 1).

⁸ This is not similar to the 'slum-lord' found in a shanty-town, or in shacks. They might be related, but the slum-lord in the Swedish context pays very little interest in the locality, as the person or the owner often is nationally or internationally based. See further <https://en.wikipedia.org/wiki/Slumlord>

Figure 1. Millionaires on slum management

Comment: The illustration is derived from Sydsvenskan 2011-04-17, page 4, part 3.

The illustration shows that it is possible to detect which owners neglect their responsibility to the tenants and to society at large. We have the regulations, and in combined efforts between state and local agencies, it is possible to act against these phenomena.

The South Sofielund example, and Gamlestaden, are only two among many examples. Similar problems are known from the citydistricts Bergsjön, Hammarkullen and Biskopsgården in Gothenburg, as in Landskrona. There are actors in this branch who just want to maximize profits for the least costs, their business idea is to buy up cheap housing, pay as little as possible for maintenance etc, and a few years later sell the stock when the general market has increased its prices.⁹ Even connections to criminal networks have been detected among the landlords, but it is important to recognize that there is a very broad scale between good and bad. Sometimes, when situations have gone too far, the municipality and its tax-payers have to buy-out these wrecks from the slum-lords, in

⁹ Skånska Dagbladet 2011-12-18.

order to start anew. This meaning that the tax-payers sometimes over-pay non-serious property-owners in order to get them out of the area.

The Ugly trolls – the housing traders

Another third type of activities which have been going on for decades is the trade with housing opportunities.¹⁰ It has escalated during the recent one or two decades of housing shortages. Such can be

- Trade with first and second hand apartment rental contracts
- Trade with official addresses of residence
- When contract-holders are renting out their apartments to second or third agents, taking an unmotivated surplus
- Bed-places per night on mattresses

The Stockholm police issued a report on the issue, identifying that in the distant city-districts of Älta and Fisksätra it is known that so-called *black rental contracts* are applied. The Stockholm Police (2015?) estimated that about half of all rental apartment changes relate to criminal activities (p. 7). They also mention that it seems as if the trade with *black contracts* is rather normalized among the population. Rental tenants are often aware of what they could get to give up their apartment, or change for a less attractive location – especially in relation to what they initially paid. The traded apartments bring a large share to the landlord, and the dealer and the register splits on a smaller share. It is not illegal to buy a black contract, but to sell, but only a handful has proceeded to courts. The business takes place with very low risks involved, and it is a way for criminal resources to find a way. The deficit in housing has turned into a neat business opportunity for those who want to clean their laundry well, without passing the tax-office.

¹⁰ This section is primarily based on Dagens Samhälle 2016-02-18.

The issue was noticed by the government in 2017, when a committee directive was formulated (dir 2017:9), and an SOU report was finalized 2017:86. There are many suggestions in a positive direction, but to the cost of increased control mechanisms, also for the obedient landlords. However, when contracts-holders have been proven to misuse their position, they may lose their contract, the commission suggests. At least this is a first step, it remains to be seen what effects it actually will get – both on the overall housing-market and on the rental queuing-time.

The Last Straw – can BIDs bring any order?

The historical exposé over the erased housing policy held together by the Swedish government depict a landscape which to a large extent have been handed over to the private actors in the roles as tenants, potential and actual coop owners, builders, housing estate enterprises (private and public). The initial promise was possibly to ‘minimize the state’, to bring order to the state in tight control of core responsibilities and to adapt to the European common practice – as it was understood by the Swedish government at the time.

What the national government did not consider was, whether there would be any free-riders out there, or actors that would not work for the common good in the housing estate branch. It has taken years to get a clear picture of what is going on in the slum-like districts, and what the driving forces and options are.

From a liberal theory perspective, citizens would become freer and also more care-taking about their properties if they were having the owning and managing responsibilities themselves. Hence, the state largely out-sourced this issue-area to the citizens. A different way to frame it would be that the state used a risk-minimizing strategy when the housing policy area was handed over to the public (ref.) This prediction may have been true for the majority of the population, or at least the share that have made great surpluses from buying and selling coop apartments throughout this market boom throughout the past 25 years.

But everyone did not become winners. This is clear now, when the next generation is trying to enter the market with empty hands. Not only refugees have difficulties under the present housing regime, but also youngsters 16-30, divorces single persons with or without children, and even widowed persons have problems. Further, if you are over 50 years of age, some banks will not allow you mortgages in order to buy a house or an apartment (if you have stayed in a rented apartment throughout this 'golden age'). The idea of 'freedom of movement' seems to apply to a rather limited group throughout this exercise, and what adds to the societal costs in this equation are that more or less illegal actors in this business to quite an extent end up on the winning side.

The New Urban Agenda signaled the importance world-wide to bring new alliances through public-private partnerships. Could such arrangements possibly contribute with anything new into this discussion? From the two examples mentioned, BID Gamlestaden and BID Sofielund, we learn that when the locally responsible actors, private and public, join together in a given district or location, downward spirals may deplete or change around. Yet, there is too early to draw any specific evaluations on these, as systematic such yet are absent. But these two have emerged in districts with many small estate-owners, who one by one is only there for the money. But when the municipality joins together with the more responsible actors, it becomes evident that there are a few free-riders around who do not apply to the rules of society. The situation constitutes a classical game-theoretical collective action dilemma (Ostrom 1990), as long as no one else collaborates, I will gain from taking part in any collaborative efforts. But when other actors around me become collaborators, I might loose from being the last person on-board. The possible expectations coming with the BIDs, at least as they operate in the Swedish context, these partnerships may take the control back over 'lost districts' and landscapes. We find such collaborations between estate owners in the country-side as well as in the urban contexts, but yet, much more need to be investigated and evaluated with regards to improved living conditions.

In Sweden, BIDs has emerged as collaborative forums evolving across actors related to a defined geographical area. We find BIDs in the three largest cities, Stockholm, Gothenburg and Malmö, but also BID-inspired collaborations in rural areas such as Vrångö, Floda and Örensköldsvik in the north.¹¹ These have often originated with place-related problems such as decaying neighborhoods, industrial areas in transition, aging population and an attractiveness lost. Not all places share the same expressions; but the problem boils down to the changing conditions, places, estates and local citizens remaining. With regards to planning, law and property rights – I did not mention that Sweden does not have a legal framework for its BID collaborations. Hence, there is still much room for experimentation and variation, but planning issues are definitively on the table among these private and public actors.

Neoliberal Governance and Accumulation by Dispossession in Karaburun Peninsula, Izmir, Turkey

Yağmur Özcan Cive¹, Adile Arslan Avar²

Abstract: The transition to neoliberal governance brought along the transfer of the property or the right to use of natural areas to the private sector. Having undertaken the role of deregulation and reregulation, the state has provided the legal framework of new capitalist activities leading to the commodification and marketization of natural areas, which were previously non-commodified or non-marketized. In this way, the biophysical world has been encompassed in the accumulation process. On the other hand, with privatization or the assignment of use rights, unowned, state-owned, communally-owned areas have become spatial fixes for capital. Hence, the people living adjacent to, or in these areas, have been deprived of the right to use of them. Karaburun Peninsula is encompassed into this process especially after the 2000s. The forests, pastures, natural conservation areas, coastal and the sea, which were belonging to State or open to the use of local people, have been enclosed for, and exposed to the sustainable energy investments, fish farming, quarries, industrial agriculture, and tourism by private sector initiatives. So, the local people have been dispossessed by legalized transfer of use or property rights, as they can no longer sustain their daily practices and relations to nature to make their living.

Keywords: privatization, dispossession, enclosure, governance

Introduction

This paper aims to examine the regulatory mechanisms which support neoliberalisation of nature and dispossession of local people in Karaburun Peninsula. The Peninsula presents a very specific modality of “actually existing neoliberalism” regarding how natural areas were absorbed in capital accumulation, and how accumulation by dispossession occurs with neoliberal policies and practices. Neoliberalisation of nature in the Peninsula has been occurring by deregulations and reregulations but in vigorously contested ways in the national and local contexts, as it was lastly witnessed in Yaylaköy, a village settlement that was announced as “disaster zone” by a decree of Presidency in order to block local people’s resistance but to open the way of wind power companies. Privatization and marketization occurred by the allocation of pastures, forests, coastal waters, agricultural lands and natural protection areas and partly private properties to private firms at the expense of livelihood of local people. Private investments in industrial olive production, wind farms, fish farms, quarries, secondary houses are localized mostly in common biophysical sources of the local people. As the natural and common lands are commodified, so local people are dispossessed intensely.

The Karaburun Peninsula has been exposed to all general strategies and characteristics of neoliberalism as Bakker (2010) defined: privatization, real subsumption (intervention to biophysical processes and capacities), market proxies and marketization (see Ryterri and Puhakka, 2012, p. 256). In Turkey, especially by the 2000s, reregulations and laws about expropriation of private lands and allocation of common natural areas (the Treasury lands, State lands, public lands) to private investments have increased. This means that the lands at the disposal of the State were commodified (Adaman, Arsel and Akbulut, 2017, p. 4, see Özcan Cive and Arslan Avar, 2019, p. 18).

The reregulations in the laws such as Forest and Pasture laws are carried out to support investments in natural areas. Thus, the investments started to occur on natural areas by the allocation of common natural lands such as mountains, pastures and forests. The first regulations leading to privatization and marketization of natural areas were the Tourism Incentive Law (no. 2634) in 1982 and the Assignment of Institutions except Turkey Electricity Administration for Electricity Production, Distribution and Trade Law (no. 3096) in 1984. The former laid the legal framework for the development in natural areas and forests, the latter for deregulation of energy market and opening the way to allocation and leasing the natural areas to private sector. Secondary house development began at coastal line of the Peninsula as an early neoliberal practice, after 1990. The changes in the Forestation regulation paves the way of private forestations in agricultural lands in 1994. The pastures in the Karaburun peninsula were converted to olive groves by the support of that regulation, after 2006. Aquacultural production was privatized by the regulation in related law in 2003, and fish farms have increased in the coastal waters of the Peninsula. Wind power production began to be applied by the constitution of the legal framework for the sustainable energy sector, after 2005.

The list of allocated and expropriated parcel data was collected from state institutions (Chieftaincy of National Property and Karaburun Cadastral Office). The data of investments and their local overlaps with natural areas and private properties were analyzed by using GIS and KML data in ArcGIS. The synthesis map in Figure 1 is created by the authors. As to be seen in the figure, the allocation and the transfer of use rights of pastures, agricultural lands, forests, coastal waters and natural protection areas to private companies resulted in profound dispossession of the local people.

The article concludes that the neoliberal investments constitute on natural areas as agricultural lands, pastures, forests and natural protection areas, and seas under conservations of the Peninsula. Through the privatization and marketization of natural areas, private companies gain the usage rights of natural areas. On the other side, the private properties and the usage right of local people on State or common land are taken away. In this way, accumulation by dispossession occurs in the Peninsula.

Transition to Neoliberal Governance and Changing Property Rights on Natural Areas

As Harvey argues, by the 1970s, capital extends its limits and finds new places to overcome crisis (see Baker and Cohen 2014, p. 131). The state is restructured in a way of undertaking the role of supporting capital accumulation. On the one hand, deregulations were implemented for creating more competitive and free market. The state has withdrawn from public services and strict controls on nature, and the reregulations were applied for more flexible and consumer-friendly market such as decreasing state intervention and taxes, on the other. Privatization and marketization were promoted by cutting public services and investments. Also, the public services such as water supply, energy production were transferred to the private sector (Harvey, 2003, Jessop, 1994 see McCarthy and Prudham, 2004, p. 276, Castree, 2010, p. 10-11, Bakker and Cohen, 2014, p. 129-130). The new governance model, deregulations and reregulation are constituted to fulfill the new type of state's obligation for creating opportunities for the market.

Countries tried to adapt the legal framework to the new governance model that is created at local, national and global scales. Rescaling of management and government were promoted to achieve expanding capital circulation. Over-

accumulation of capital started to be transferred to new places which have natural and rural characteristics (Arrighi, 2006, Fletcher and Neves, 2012, Harvey, 2001 see Devine 2016, p. 638). During the process of rescaling and transition to a market-based system, the biophysical world gets involved in capital accumulation and became a subject for the global market (Castree 2003, 2007 see Duffy, 2008, p. 328). This means that untouched or common natural areas and resources exposed to more intervention for making profit. The property rights of the previously non-owned or communal owned areas were transferred to private actors, and enclosed (Castree, 2010, p. 10-11,18).

The enclosure of the natural areas and divestments of property and use rights on them are the characteristics of a new type of capital accumulation as “accumulation by dispossession” (Harvey, 2003). In so far as rivers, forests, pastures, etc. became harnessed to capital accumulation, the access of the local people, villagers, indigenous people, goat breeders to natural areas and common lands is prevented (Çoban *et al.*, 2015, p. 19-20, Mercile and Murphy, 2017, p. 1042 – 1043).

In this process, also the legal framework was created for the conservation of natural areas. The latter are enclosed by approval of the reregulated or newly enacted laws, or deregulation practices. Laws and regulations defined the use of natural areas with restrictions and opportunities, that is, for whom they would be restricted and for whom it is allowed to use. “Allowable natural destruction” was consisted of making profit on the natural areas (Apostolopoulou, 2014, p. 18 - 19). New types of institutions at the international scale were established for the conservation of natural areas and management of the global capital. The role of governments decreased and a part of their authorities were transferred to local and non-state actors like NGOs or councils in accordance with global conventions and contracts. In this way, a free environment was created for the capital with the change in the authority of control.

Having been exposed to deep commodification at the global scale, nature is no longer an “anchor” of capital. Rather, natural areas and features became “spatial fixes” for the new type of capital accumulation. Bakker (2004) conceptualizes environmental features, outcomes and circumstances subjected to capital accumulation as “ecological fixes”. Castree (2008) presents “environmental fixes” which include new governance mechanisms such as marketization and privatization of nature, reregulation, deregulation, flanking mechanisms, and commodification of communal, non-owned or state-owned lands, environmental degrading in the areas. Bakker and Cohen (2014) developed these concepts with spatial and scale dimensions, and they presented “eco-scalar fixes” as strategies to overcome the crisis and environmental degrading with managements on naturalized boundaries. Bakker and Cohen (2010) also show that the “eco-scalar fixes” are closely associated with environmental degrading and uneven development.

Neoliberalizing Nature: Turkey Experience

In Turkey, the neoliberalisation began in 1980 with 24th January decisions that defined a shift in economy from inward-oriented industrialization model to the global liberal economy (Temizel 2007, p. 76, Bal, 2011, p. 44). Accordingly, new laws were enacted for the privatization programs and marketization. The state began to cut financial support for public services, to promote activities for the growth of private sector through tax tariffs and low interest rates. Following the regulations for leading up foreign investments and commercial activities by the 1990s, foreign investments began to increase. One of the path breaking event in neoliberalisation in Turkey was the decrease in the central regulation authority of the State Planning Organization (DPT). Its some authorities were transferred to the Undersecretariat of Treasury (Temizel, 2007, p. 112). By the 2000s, the deregulation and reregulation began to increase for easing flexibility of market and privatization implementations. It follows that some important state institutions, which were suppliers of public services such as POAŞ (Petrol Office incorporated company which is petrol supplier company of Turkey in the past), TEDAŞ (the Incorporated Company of Turkey Electricity Distribution)

and THY (Turkish Airlines), were privatized according to the IMF (International Monetary Fund) contracts and programs (Bal, 2011).

In Turkey, as well as it was elaborately shown by Theodore and Brenner (2002) and McCarthy and Prudham (2004) in the European and the USA contexts, the government has undertaken regulatory and promoting role to develop the private sector (İşlar and Harris, 2013, p. 2, Özgül, 2017, p. 36) rather than rolled-back, as well. New laws were enacted or the existing ones were reregulated in order to provide the land demands of neoliberal activities. So began the use of natural areas, State lands and Treasury lands for this aim. For example, although the 1983 dated Expropriation Law (no. 2942) had been stated to be operated under the war conditions, it has been used as a mechanism to supply land for energy investments since the 2000s (Erensü, 2017, p. 125-127).

On the other hand, Turkey got involved to global scale neoliberal conservation through some international contracts and conventions on conservation of natural areas such as the Paris Climate Convention, Bonn Convention and Bern Convention. It follows that a legal framework for protection areas was structured by new laws like the Protection of Cultural and Natural Properties law (No. 2863) in 1983 in a way of adapting national policies to global context (Dağıstan Özdemir, 2005, p. 23-24). However, it was not necessary to wait so long until the restrictions on the use of natural areas were bent by the amendments in related laws.

Privatization and marketization of natural areas were made possible by new laws or the regulations in existing ones. This means that the scale of the capital accumulation was expanded. Tourism Incentive Law (no. 2643) in 1983 and the Assignment of Institutions except Turkey Electricity Administration for Electricity Production, Distribution and Trade Law (no. 3096) in 1984 firstly paved the way for allocating Treasury lands, forests and natural areas to private sector for tourism investments and electric power production. The Electricity Market Law (no. 4628) in 2001, and the Water Rights Agreement on Electricity Production in 2003, the Use of Renewable Energy Resources to Generate Electric Power Law (no. 5346) in 2005, and ensued amendments and reregulations in these laws increased the use of the natural areas. Industrial agriculture, quarries, energy infrastructures, “sustainable” energy production, alternative tourism activities, fish farming, private construction and operation of physical and social infrastructures were allowed even in natural protection areas and national parks.

Especially after 2000, Turkey undergo multidimensional spatial and governmental restructuring and rescaling resulting in profound changes in natural areas and their management. With the establishment of Development Agencies (law no. 5449) in 2006, the administrative boundaries were rescaled at NUTS II levels and redefined according to “economic regions”. And, strategic development plans began to be made for economic regions. With the Metropolitan Municipalities Law (no. 5216) in 2004 and the Fourteen Municipality and Twenty-Seven Provinces Law (no. 6360) in 2012, on the one hand the authorities of district municipalities were transferred to metropolitan municipalities, and the rural areas and their natural features were included in Metropolitan boundaries, on the other. Having been turned into “neighbourhoods”, villages are no longer subjected to Village Law (no. 237, issued in 1924). Regulation and rescaling of authorities and boundaries also changed property rights of villages and properties of “common village areas”, which were used to belong to “villagers”, were transferred to different central authorities.

The role of the Ministry of Environment and Urbanization is crucial in this respect. It was firstly endowed with the authority related to management, control and approval the plans on natural areas in 2011. Subsequently, its authorities about making upper scale and binding plans on the naturalized boundaries and administrative regions extended to the management and planning on the natural protection areas and special natural protection areas by the reregulation of related laws. The institution undertook also the authority related to the approval of the investments such as geothermal energy, wind farms, hydroelectrical power plans, quarries, etc. in the natural areas. The approvals should base on the Environmental Assessment Reports, related plan decisions and “public interest”. However, the regulation on

Environmental Assessment was changed, and its restrictions were decreased. Furthermore, the decision about the use of natural areas became more centralized. “Public interest” related to the investments is decided by the Council of Ministers. Lastly, in 2018, the decision about the “public interest” together with some other authorities of the Council of Ministries were transferred to the “Presidency” following the transition from Parliamentary system to Presidency system in Turkey.

Accumulation by Dispossession in Karaburun Peninsula

Karaburun Peninsula is a specific place for unfolding the neoliberalisation processes and their consequences in biophysical and social world. Almost the whole Peninsula excluding urbanized parts is covered by natural conservation areas announced after 1990. It has a significant ecology with natural protection areas, natural areas and resources with its biodiversity and vegetation. Bird species, plants and mammals (such as Posidonia seagrasses, Audion gulls and Mediterranean monk seals) are under protection by international contracts such as Bern Convention and CITIES. The whole of the Peninsula and the Ildırı bay are defined as an important natural area by Doğa Derneği (which is the partner institution of Bird Life International). Also, they were proposed as biosphere reserve area. Lastly, the Peninsula and the Ildırı bay and islands there in were announced as special environment protection region by the decision of the Presidency. However, let alone being protected, natural areas of the Peninsula have been encompassed into capital accumulation through neoliberal policies. They were privatized and marketized through deregulations and reregulations especially after the 2000s.

On the other hand, there had been 13 settlements with village status. These villages were included in the metropolitan municipality boundaries and gained “neighborhood” status through rescaling by the Law on Fourteen Municipality and Twenty-Seven Provinces Law (no. 6360) in 2012. The local livelihood is still based mostly on agricultural productions (olive, mandarin, narcissus, artichoke, etc.), goat breeding and associated products (local cheeses, goat milk and hair). Rescaling and transferring most authorities to central institutions brought about profound changes at the expense of nature and livelihood of local people in the Peninsula. The transfer of use rights of common lands, forests, pastures and peasants’ private lands to private companies through leasing, allocations and expropriations resulted in dispossession of local people.

By the 1990s, the secondary housing development that had been delineated on the coastal line began as an early neoliberal activity in the natural areas. It was laid down with the strategies of Tourism Master Plan and Çeşme - Karaburun Coastal Environmental Plan (1989). The ensuing plans, strategies and regulated laws support the development of the tourism and the secondary houses on coastal line and natural protection areas. The amendment of the Tourism Incentive Law (no. 2634) in 2003, opened the way of allocation of natural areas for ecotourism, cruise tourism, health tourism and sport activities. The proposals of the current environmental plans support the development with suggested transportation links through yacht ports and highways. The current Izmir Regional plan (Izmir Development Agency, 2013), Izmir-Manisa Environmental Plan (Ministry of Environment and Urbanization, 2013) and the West Izmir Master Plan (Izmir Metropolitan Municipality, 2018) support excursion tourism and alternative tourism activities in the Peninsula. Their strategies suggest to spread development in forests and Treasury lands. In this way, policies and plans which are carried out on naturalized boundaries provide the transferring of use right of the natural areas.

By the 2000s, industrial olive production, and the “sustainable” energy production from wind farms and their concomitant infrastructures began to spread through on unregistered or registered pastures. The amendment related to Forestation Regulation was announced in 1994. The regulation granted the use right of fertile agriculture lands for the forestation with special species like olive trees. An amendment in the same regulation in 2003 allowed the allocation of Treasury lands for plantation of these species under the name of “private forestation”. The pastures, whether

registered or not registered but having been used from immemorial past, are subjects of the law because they are classified as “agricultural land”. So, in the north of the Peninsula the unregistered pasture areas, which are Treasury or State lands and used by goat breeders in the winter, were transferred to private companies for olive cultivation. These areas were fenced. Goat breeders stated that their access to pastures, the water sources or to other grazing lands was blocked. Even their paths, which are owned by their ancestors, were closed. According to the accessible data, 1330.78 ha Treasury lands, which almost cover all pasture lands in the north of the Peninsula, and %3.51 of its total surface area, were allocated by private companies or entities (Figure 1). The agricultural statistical data shows a remarkable increase in the number of olive trees after 2006.

The project proposals for wind power generation in the Peninsula began in 2005. The allocation of Treasury lands and forestlands for “sustainable” energy investments became possible by the law on the Use of Renewable Energy Resources to Generate Electrical Energy (no. 5346) in 2005. Energy investments and their infrastructures began to be allowed in pasture areas by an amendment in the law in 2008. Also, by an amendment in the Environmental Assessment Regulation in 2014, the obligation of environmental assessment report for such investments was removed (Çoban *et al.*, 2015, p. 7). Some wind farms and their infrastructures started to be constructed and operated without completing, and even by violating, legal procedures in 2013. Positive environmental assessment report decisions were cancelled by the lawsuits based on expert reports stating that wind turbines have negative impacts on ecology and biodiversity of the Peninsula. Objections, lawsuits and legal procedures about environmental assessment report decisions, the licenses and plans of wind farms still continue. However, as it was witnessed in Yaylaköy, where pastures, agricultural lands, roads and paths to pastures and fields are occupied and destroyed by wind turbines and their infrastructure works, local resistance and legal procedures were blocked by the decree of Presidency announcing Yaylaköy as “disaster zone”. Through this decree, as the Lodos Energy Company’s director declares to Yaylaköy people, “after 20 years there would remain even no village called Yaylaköy” (Akdemir, 19.05.2019). For the decree on “disaster zone” requires the village to be evacuated and relocated.

There are 6 wind farms operated by private energy companies (Yaylaköy, Ayen, Çalık, Egenda, Öres-Fina) in the Peninsula. Existing 100 wind turbines are licensed and 46 not-licensed but under operation, or in the project stage (EPDK YEK list 2018, EPDK digital data 2017; Google Earth Satellite photos, 2018). Despite court decisions to cancel the operation of some companies, they continue to construct new wind turbines and infrastructures. The project areas cover %40 of the Peninsula, and the wind turbines are denser in Yaylaköy village. As shown in Figure 1, the wind farms and their infrastructure, especially roads, are located in forests, agricultural lands, pastures and natural protection areas, some of which are Treasury lands or property of Ministry of Forest, or private properties of villagers. At least 80 parcels of villagers were expropriated and allocated for the wind farm project. Indeed, as an officer from Karaburun Cadastre Office stated, there are more parcels allocated to wind farms, but all data about these parcels is not accessible (especially, in the Mordoğan Wind Farms, the Egenda and Ayen Energy Wind farms, and the parcels in Tepeboz and Bozköy as the parts of the Karaburun Wind Farms by Lodos Energy).

The conflict is not only between local people and wind energy companies. Industrial olive producers and wind farm companies are controversial about property and use rights on unregistered pastures, which are the property of Treasury. Some wind turbines were constructed in the Treasury lands, which olive producers had leased for private forestation previously by the way of allocation. Indeed, the constitution of wind farms in the areas allocated to olive groves seriously violates the law of Reclamation of Olive Cultivation and Budding of Wild Olive Trees Law. The law prohibits construction and industries less close than three kilometers to olive groves. Thus, deregulation is observed in the Peninsula besides reregulation practices for transferring rights of properties for capitalist activities on already privatized nature.

The wind farm areas almost wholly overlap with registered or unregistered pastures, and other natural areas. Wind farms are enclosed and the access of local people to forests, pastures, even to their agriculture lands was prevented. Cultivated fertile lands and the roads to agricultural lands were destroyed during the construction and infrastructure works. According to the data of parcel lists taken from Chieftaincy of National Property, Karaburun Cadastral Office and data from www.parselsorgu.org, the expropriated private properties are mostly agricultural lands. The enclosed olive groves, which had been reclaimed on the pastures allocated to private companies, had already cut the access to winter grazing lands. Wind farms prevented the access to the grazing lands which are used in summer period by goat breeders in Bozdağ mount and Yayla. Also, the goat breeders declare that milk fertility and the number of goats decreased because pastures and grazing lands have been narrowed down. The agricultural statistical data confirm the decreasing milk production (from 1038 tons in 1996 to 917 tons in 2015) in spite of the increasing number of goats (from 21470 in 1996 to 35600 in 2015). It is also observed in the agricultural statistics that the croplands, vineyards and fruit production decreased as citrus and olive production increased (TMOBB, 2012, Karaburun City Council, 2019).

Besides the lands of the Peninsula, the sea is marketized by the way of transferring the use right of the sea and coastal waters. In the west of the Peninsula, Gerence gulf and the Northern coast of the Peninsula through Parlak, are enclosed by fish farms. There are 34 fish cage groups in the areas which are run by 10 private companies in 2018 (Google Earth, 2018, Directorate of Provincial Agriculture, 2018) The fish farms have 42.590 tones production capacity. The companies (such as Agromey and Akuvatur incorporated companies) generally export aquacultural productions to other countries such as the Netherlands, Greece, United States, etc., and they have offices in these countries. The development of the fish farms began previously, in the early neoliberal period. However, coastal waters began to be privatized, and the fish farms began to increase gradually after the revision of Aquaculture Production Law in 2003. Then, the Potential Areas for Aquaculture Work Facilities Protocol defined the Gerence gulf as an aquacultural production area, and prohibited the local fisheries in the area in 2008. As a response to the protest and lawsuits, the fish farms moved to offshore in 2012. However, the East of the Peninsula is still prohibited for local fishery. In 1998, 13 villages and 248 houses were depending on the fishery activities in the Peninsula (see IZTECH, 2005). There are currently 6 settlements where fishing activities are carried out. The settlements are located in the west of the Peninsula, and some of them have urban characteristics (Karaburun Centre and Mordoğan neighborhood).

Some activities like mining are supported by the laws before the neoliberal period. The Mining law had already allowed mineral search and extraction in natural areas. Following the deregulation in mining sector, such activities in natural areas were further supported by the laws, as mentioned before. Currently, there are 3 companies and entities (Kulesan, Polat Mining and Ali Tekin) operating a mixed concrete plant, clay quarry and quarry. They are localized in natural areas, and near to olive groves or coasts in Mordoğan and Yaylaköy. The companies have international connections. Two quarries in Eğlenhoca and Kösedere were previously closed, in 2017 and 2018. Despite that the quarries violate the Reclamation of Olive Cultivation and Budding of Wild Olive Trees Law, they were approved without fulfilling the requirement of environmental assessment in 2012. The agricultural lands of local people are damaged during the construction or the mining operations. Also, the use rights on State lands are transferred to private actors. Thus, mining facilities which are integral to the global economy are carried out while the livelihood of local people is under the threat.

The current plans suggest both conservation and use of the natural areas and resources of the Peninsula. There are various proposals about the conservation status of the Peninsula in Izmir West Master Plan, Izmir-Manisa Environmental plan and also Integrated Coastal Plan for Whole Izmir, while plan decisions support the investments especially in wind farms and fish farms. Plan notes suggest improving wind energy potential of Izmir, and also of Karaburun without any specific restriction. It is only necessary to obtain opinion from the local government. All development and implementation plans about wind farms are based on these plan decisions. Also, Izmir West Master

Plan suggests moving the fish farms to anywhere in the Peninsula, although all coastal waters of the Peninsula is under conservation by Izmir-Manisa Environmental Plan and international conventions. The Integrated Coastal Plan for Izmir suggests a solution for logistics of fish farms which must settle on natural protection areas. However, the suggestion is not for the conservation of the natural areas, but rather for easing the operation of logistics of aquacultural production. Furthermore, the plan suggests the reregulation of the Forest law, and reduction of the classification of the first degree natural protection areas for the approval of logistic services and construction on these areas. Thus, the plan aims to transfer the use rights of coastal and natural protection areas to aquacultural production companies through reregulation in the laws. As a result, the plans in naturalized boundaries or regional scale support the investments, and propose reregulation and deregulation practices. Hence, they are defined as “eco-scalar fixes” to promote accumulation by dispossession in the Peninsula.

On the other hand, the rescaling processes which extended through the natural areas occur in the Peninsula. The policy making authority and management of the Karaburun and their natural areas were transferred to firstly Metropolitan Municipality by the laws no. 5216 and no 6360, and the status of the villages change into neighborhoods in 2012. Also, the situation about boundaries that are included in the Metropolitan area brought along some problems in common village lands and their property and use rights. However, the Ministry of Environment and Urbanization has already undertaken the approval of the investments and management of the natural areas since 2011. As a result of the efforts in the last 5 years, the whole of the Karaburun Peninsula with Ildırı islands and bay were announced as Special Environment Protection Region with 823 numbered Presidency decision in 15th March 2019.

Although this decision seems to have increased natural protection, the legal background of the Special Environment Protection Regions is not so sufficient to prevent the investments and land allocations for neoliberal activities. The announcement brought along rescaling authorities and boundaries in these extended and naturalized boundaries. Authority of making plans, approval for investments, and the allocation of lands in these boundaries were transferred to the Ministry of Environment and Urbanization. Sustainable energy investments and their infrastructures in Special Environment Protection region, national parks, natural protection areas, etc. had already been approved by the revision in the law on the Use of Renewable Energy Resources to Generate Electrical Power in 2010. Besides, in Karaburun, deregulation process began to occur with starting newly purposed wind farms in Yaylaköy without doing management plan for the Special Environmental Regions. Although the law sets an obligation that “the whole scale plan must be done after the announcement of the Special Environment Protection Region”, the additional plans for newly proposed wind turbines and their infrastructure were not cancelled, and the construction of wind turbines has been continuing.

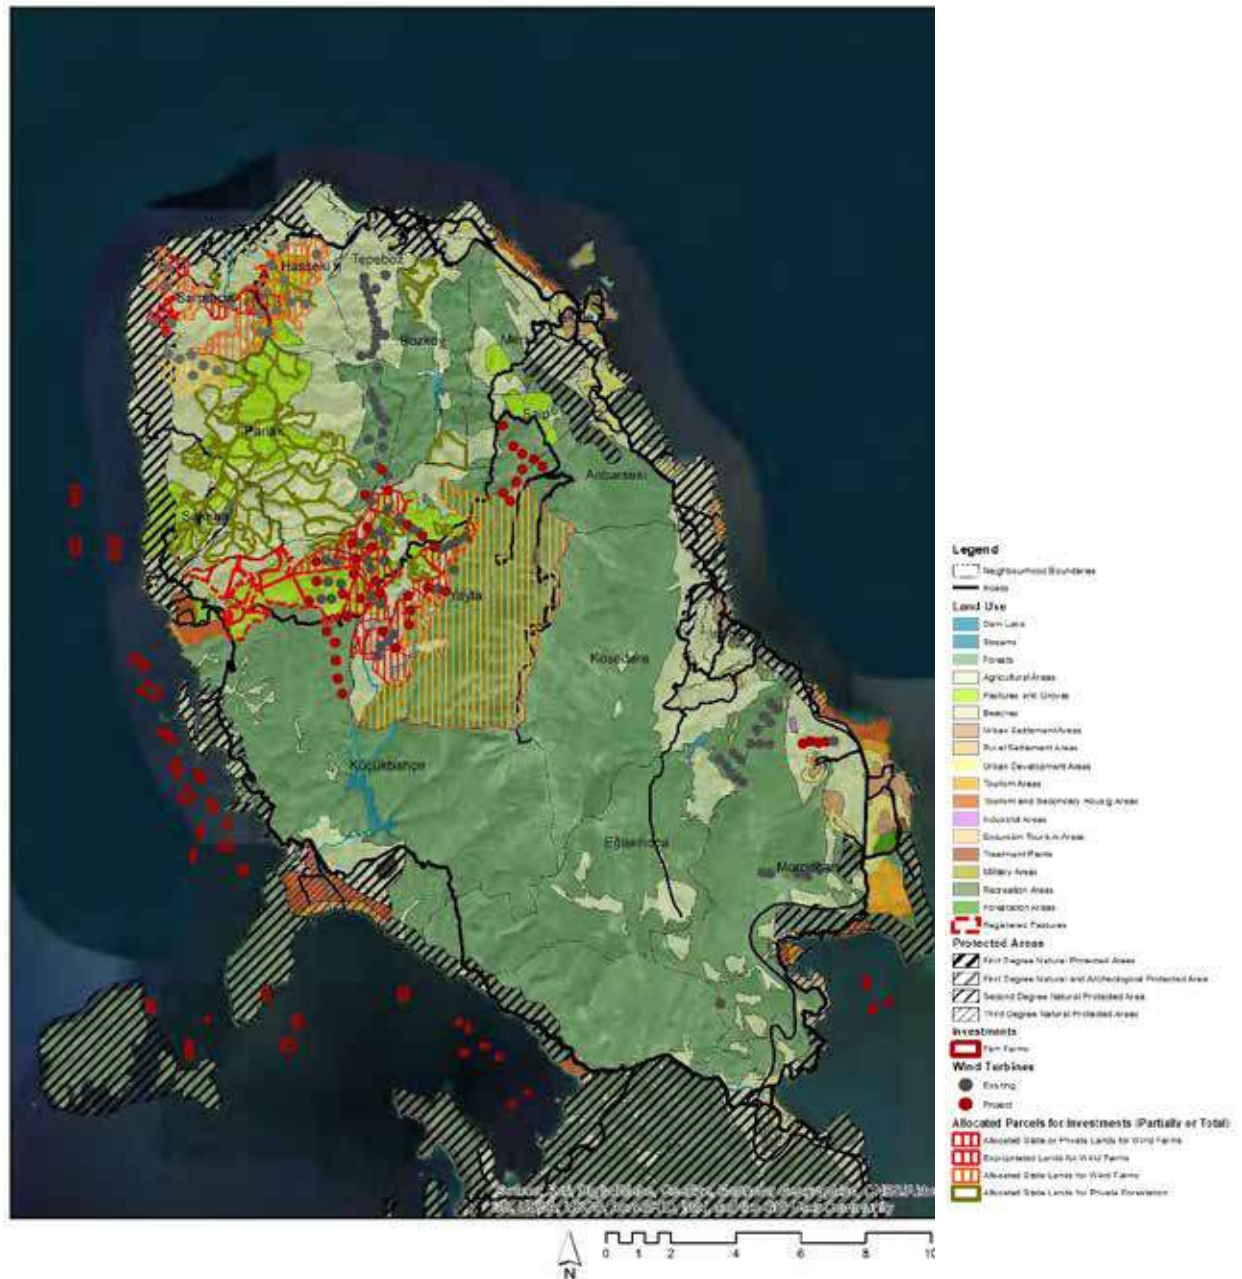

Figure 1. Investments, Natural Areas and The Parcels associated with Transferring Property Rights

Conclusion

The natural areas of the Karaburun Peninsula began to be marketized and privatized through the transfer of use rights to private companies under the auspices of neoliberal policies in Turkey. Conservation as well as use of the natural areas increased and intensified in parallel with deregulations and reregulations about natural areas. After 2005, the implementations of the neoliberal policies increased market proxies such as wind power generation companies. The coastal waters in the west of the Peninsula were privatized and marketized under the support of the reregulation in the Aquacultural Production Regulation and related regulations. Besides, olive groves reclamation narrowed down pastures used by the local goat breeders from immemorial past after 2006, and the local production in the Peninsula shifted to industrial production by private companies. Secondary housing has already developed on the coastal line, in the early neoliberal period; however, the support of alternative tourism investments increased by the proposals for new transportation links and strategies in current plans (after 2010) which are made in naturalized boundaries, or economic boundaries.

Reregulation of the laws corresponds to “environmental fixes” Castree proposed. They are tools and mechanisms operated to privatize the natural areas such as forests, natural protection areas, agricultural lands, sea and pastures. The natural areas of the Peninsula, which are non owned or communally owned lands such as unregistered pastures and forests, were allocated, and private properties of villagers were expropriated for capital accumulation, thus dispossessed the local people.

On the other hand, Cohen and Bakker (2014) redefine “environmental fixes” as “eco-scalar fixes” for the sake of emphasizing the scalar, spatial and naturalised characteristics of the “environmental fixes”. Karaburun Peninsula has been directly affected by the rescaling and restructuring of boundaries and authorities in Turkey. The nature of the Karaburun Peninsula is firstly delineated for tourism and alternative tourism development in the Izmir Regional Plan. Then, it was included in the Metropolitan area, and the boundaries were naturalized when it was announced as Special Environment Protection Region. Through this last decision, the authorities and management of use, and property of lands on natural areas and common lands (as unregistered pastures and common village properties) became more centralised. The Coastal Environmental Plan for Çeşme and Karaburun, the Integrated Coastal Plan for Izmir and future plans on Special Environmental Protection Region which are made on naturalized boundaries appear as “eco-scalar fixes” in the Peninsula. As the natural areas including the commonly used assets are harnessed to capital accumulation through “eco-scalar fixes”, so local people of the Karaburun Peninsula are dispossessed.

Masters of Transition?

Vít Rezac

¹*Affiliation name, email address rezac@fa.cvut.cz*

Abstract:

My grandmother lived in six different regimes. Influence of Austrians, then Germans and later on Russians on Czechs and Slovaks - with Jewish flavor until the 40th - framed Central European region and its spatial planning culture in the XX century. One may say people living there supposed to be masters in transition. The paper presents outcomes of a qualitative comparative research of planning law in the central European region and seeks possible lessons to be learned to tackle with upcoming challenges. The study demonstrates - based on data from residential development in the Czech Republic - the impact of social and economic changes to statutory (regulatory) planning system and its instruments. Transition from socialist to capitalist system combined with current and upcoming challenges (sustainability, hazards, social changes etc.) creates colorful puzzle to be disentangled. There were many attempts to address these issues in different ways but it does not seem the light at the tunnels' end might be seen. After almost 30 years of democracy in the central European region there is permanent legislative uncertainty in the construction business there. This depreciates private savings and diminishes competitiveness of the country. Nevertheless, there were and are examples of legislative interventions which try to tackle the never ending transition.

Keywords: planning, construction; public and private; planning legislation; central Europe

Introduction

My grandmother lived in six different regimes. Six regimes, three times under foreign authority. I did not pay attention to that fact when I was young. It was just the way it is in complicated location of central Europe. But the fall of iron curtain in 1989 changed the scale of thinking of people living there. The „eternal times with Soviet Union“ suddenly changed to „temporary times“ for my generation.

Regimes go away, people stay

Habsburg Monarchy (I)

But let's start chronologically. In 1904, when my grandmother was born, Habsburg „Kaiser“ reigned in Bohemia. The legal framework has been stable for dozens of years, last time improved by Metternich in middle of XIX century. The society lived almost 100 years without serious troubles except of stormy 1848 and a short conflict with Prussia in 1866. Exactly in the same year the very first planning rules were introduced in Bohemia (10. 4. 1886 No. 40 z.z., valid for Prague, Pilsen and Budweiss). The law commenced the longest and the steadiest period of planning regulation which

lasted in fact until 1949. Building code from 1866 and its modifications founded basic principles of public building legislation in the modern way, anchored its basic legal institution and set up rules for building permitting, change of buildings, rules for construction supervision as well as final construction inspection. The first rule had rather a police character to prevent damages or hazards impending from construction activities. In the same time the rules limited the ownership rights of citizens, which was new in building industry. The building code was the only document in this field to regulate construction business and fixed the competence of building authority and regulated sanctions for building offenses. The rules were simple, very much pointed to reach the goal in straight way. Therefore it was not complicated to become a builder or even a developer. An example: a secondary school professor Mr. Edvard Benes purchased a plot in a suburb of Prague in 1904 and with a help of his mother-in-law financed the construction of house of flats. The income from rents helped him to survive when he dedicated his career to work on dismantling of Habsburg monarchy during the World War I. And he succeeded to found a new state: Czechoslovakia.

Czechoslovakia (II)

The new state brought a second regime in which my grandmother spent her productive life. Czechs call this period 1918 – 1938 *The First Republic*. Czechoslovakia was a democratic country with very high level of parliamentary democracy and juridical power. Nevertheless the legislation was based on Austrian model, which was step by step improved. The new government tried to propose a new building code, but the works were never completed. Since 1919 the new state approved every year so called „construction traffic act“ to streamline market discrepancies, particularly in housing stock. The country dealt with housing shortage right after the WWI. The shortage became critical namely after the Big Crises in 1929. The legislation focused on programs of development of so called minimal apartments for people in need. Czech architectural scene took actively part in housing shortage solution, many architects entered into left or even communist oriented groupings. And the former professor – developer became the second president of Czechoslovakia in 1935.

Protectorate of Germany (III)

The interruption of democratic development came with occupation of Czechoslovakia in the eve of the World War II. When Hitler entered Prague on March 1939 – this was the third regime in my grandmother's life, he changed everything. The most visible change which occurred in the very first moment was change of driving cars left to driving right. This indicated further changes. Planning became also a focus of new rulers. In the times when many respected planners sit in SS-headquarter in Berlin and served the Nazis, there were made several practical changes in Czech building legislation. The land use planning principles adopted from Germany were implemented to structure the settlement system (this approach remained in socialist period too). The very first rules for financing of municipalities were introduced (decree No. 109/1942 Sb.). Planning committee for City of Prague was established.

Czechoslovakia rebirth and clinic death (IV)

My grandmother was 41 when World War II ended. A short period of three years (the fourth regime) combined with presence of Russian „advisors“ in the country between 1945 – 1948 determined the destiny of reborn Czechoslovakia. This period was too short for new building legislation activity. Nevertheless the Czech experts who had no real job during World War II were working on new legislation for a restored state.

The socialist state 1948 – 1989 (V)

In 1948 after communist putsch begun another period of planning legislation. This was the fifth and the longest lasting regime my grandmother lived in. The early communists building code came already in 1949 (No. 280/1949 Sb.). As mentioned earlier its base was created in left oriented groups during the war and later on. The next codes (No. 84 and 87 /1958 Sb.) outlined a qualitative new approach of land use planning where spatial issues are solved in their complexity in contrary to older types of plans focusing on specific land and its regulation. Since then the socialist law distinguished between private and state builders, whereas the private construction was limited to individual family housing only. Socialist building legislation evolved a system of decrees and restrictive norms (hygiene limits first of all) which tied up the construction business and converted towns into „block of flats“. The branch (transportation, heavy industry, agriculture, forestry etc..) way of thinking in planning and legislation settled in that time (and survived till today). The socialist bureaucracy changed the building code once more. The new law from 1976 (No. 50/1976 Sb.) was a modern type of planning and building legislation. There were long discussions in construction industry including evaluation of international experiences prior the final approval of the code.

Last transition – from socialism to capitalism (VI)

My grandmother died on April 1990, four months after election of Vaclav Havel as Czechoslovak president. He was very much involved in planning issues not only because he had many friends among architects. Havel believed that a suitable order in the society, an order in a broader sense, may re-establish stability of democratic system. The planning in the Czech Republic was faced with a question how to react on completely changed vision of the goals of the society [Maier, 1998].

Central European context

Czechs were in similar situation like their neighbours in central European region. In post socialist countries that now form the eastern member states of the European Union there was a general vision of the society from the early nineties to catch up to the developed West. The dream of reaching the level of western European economic development and living standards was the main driver for economic transition and EU integration [Salamín, 2015]. Post-communist states initially had to embrace the substantive concept of the rule of law drawing on liberal and democratic values, which became a valid ticket for ‘The Return to Europe’ journey [Priban, 2017]. In spite of modest convergence, however, the difference between the West and the East has remained dominant until today.

In the last three decades, post-communist states experienced a fascinating political journey, from using the rule of law concept in the most general way as an early signal of the coming constitutional

and political transformation, to specifically (as EU Member States) addressing the problem of the supremacy of EU law and its effect on emerging national democracy and constitutional sovereignty. In other words, they moved from asking the question ‘which rule of law?’ to the question ‘the rule of which law?’ [Priban, 2009].

Figure 1: Length of building approval process in central European region in days, *source: World Bank, 2011 and 2019*

In the field of planning legislation every country went through a complicated process.

Slovakia brings to mind former Czechoslovakia situation from the thirties of XX century. After almost 30 years after the change to capitalism there is no new planning legislation. The Slovak building code is still based on the Czechoslovakian 1976 Building Act. In the meantime, so many changes were adopted that the concept is hardly distinguishable. But the principle of two stage decision making process based on land use plan reminded. As a reaction of way out in complicated cases (highways, international private industry projects) the Slovak parliament passed the code No. 175/1999 Sb. about „key investments“ which can be declared - if meeting certain conditions - publicly beneficial. The point is that the state government may declare finally any project as publicly beneficial even though it does not meet any criteria.

Hungary made benefit of regulatory instruments which worked even in the socialist time [Albrecht, 2014]. Their approach is investor friendly oriented, housing policy is market led [Tosic, 2013]. The branch planning view is very strong, spatial planning sometimes might have a service function only.

The most courageous way had chosen Poland. After several years of negotiations the government decided to follow German way of planning system with conceptual land use plan (obligatory for authorities only) and regulatory plans (obligatory for individual builders). This reform from 2003 was painful, there is still a lot of criticism there [Ossowicz, 2014], but the code placed Poland to a level with readable planning approach which is attractive to international businesses.

Case study: new planning legislation vs. housing

The young democratic state adopted the take-over policy and relatively quickly updated the building code form 1976 to new political circumstances without meaningfully touching the procedures (No. 262/1992 Sb.). As soon as the country waked up form high inflation and collapse of heavy industry new

foreign investments occurred [Sykora, 1994]. The building code was not able to cope with that pressure and had to be modified even twice a year. Finally, a principally new code was adopted in 2006 (No. 183/2006 Sb.). Unfortunately, it did not help much and since then 23 modifications and 2 major amendments (No. 257/2013 and No. 225/2017) had to be approved. More and more tasks were and are put on the arms of building authorities. As soon as the load becomes critical a reaction from responsible bodies suggests another improvement of the law which supposed to shorten the process. But, as a rule, new fields of unexpected troubles are created. Example – one process which was manageable by building authority in hours (a half page of text) was replaced by a qualified legal statement of a new authority which requires several days of work (four pages dealing with the same content).

This spiral of interventions led to housing shortage in larger cities, first of all in Prague. The Figure 2 shows the relationship between housing development in Prague, mortgage index and GDP growth. There is an evident slowdown in construction business in the last 5 years in spite of fact that the economy is flourishing and mortgage rates are lowest ever. Many argues [ARTN, 2019, OECD, 2017], likely by right, that the reason is the complicated Czech legislation.

Figure 2: Housing development in Prague, hypo index and GDP in the Czech Republic, source: Czech National Bank, 2019

And it is likely true. The building code has an overlapping field of other 80 codes (environment, infrastructure, agriculture and forestry, transportation, preservation etc.). There supposed to be submitted about 40 to 60 statements of different bodies prior any decision making. The planning process and adjacent following permitting process works if there are no doubts or obstacles on the way to realization. In small towns where there is a lack of investment and any new project is welcomed to improve the quality of life (housing, creation of new working places) the legislation works well. But in large cities or in complicated locations the system is not able to generate outcomes (approval or refusal) in reasonable time.

The getaway of the current status is an attempt to change the building code fundamentally after 12 years of its validity. The key argument is that the system breaks away from itself and is not functioning anymore. The opponents argue that the building industry as well as the society got used to the legal framework of the valid code form 2006 and any principal changes open new fuzzy legislation fields.

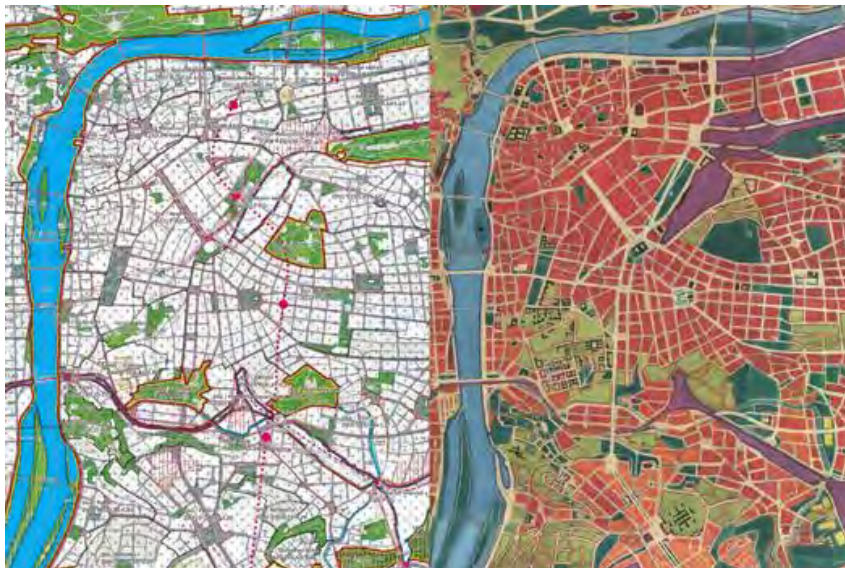

Figure 3: New Metropolitan Plan proposal (left) vs. current valid land use plan of Prague (right),
source: IPR Prague, 2019

Another attempt to escape from the paragraph labyrinth is simplification of current rules. One speaks about change of planning paradigm [IPR Prague, 2018]. An example is the new Metropolitan Plan of Prague, which is being designed and discussed. The old functional approach was refused and replaced by structural approach (compare in the Figure 3). The city, in this plan, consists of 3D structures and the agreement about the use of land is to be reached by meeting criterion of beauty and sustainability. The traditional colours on plans were replaced by zones of kindred structures.

Conclusions

The sketched case of planning in transition shows that planning is a complicated matter very deeply anchored in the legislation culture and tradition of individual countries. International models cannot be simply copied as the construction code is said to be as complex as civil code. Code is anchored in dozens of other acts, in administrative proceedings, in taxation, in sovereignty principles of municipality etc.

Planning legislation shall follow not only the best know-how but also reflect the behaviour patterns and habits of its users. If there is not enough time, measured in decades, transition flavour mutes the attempts to find an agreement in the society.

Somehow the history in our country repeats: major transition in the society followed by a good will to change is combined with using an old but known system anchored in refused regime from practical

reasons. Finally, the old system is refused however (an endless) search of a new one begins risking that no majority can be reached.

Being a member of European Council of Town Planners I noticed when informally discussing with my foreign colleagues that planning legislation is very fluent one and almost nobody is really satisfied with current status of respective building code. There is slow but permanent movement of planning legislation, coming either from construction industry, environmentalists, or motivated by economy of the country. But it seems to me that there is one country with a very stable system with almost no audible complain. It is Germany. I asked this question to prof. Schmidt-Eichstaedt, one of the key experts of German building legislation. He stated that any attempts to change or modify the German planning system failed as the expert community appreciate stability and predictability more than any other expected positive / practical outcomes. I guess it might be a lesson for us, transition masters. Transition makes you flexible, creative, aspiring for the better future, but it does not target predictability – one of the key issues of proper spatial planning.

²*Istanbul Technical University, senceturk@gmail.com*

Abstract: In urban settlements, social and technical infrastructure has a critical significance. There are three main problems related to social technical infrastructure in Turkish settlements: their site selection in local plans, the provision and implementation and sustainability of social and technical infrastructure areas. Problems about site selection in local plans and the provision emerged as a result of the adoption of neoliberal policies. Problems about implementation and sustainability of social and technical infrastructure areas can arise with plan changes and plan notes. The paper is focused on the third problem. That is, the paper aims to analyze how social and technical infrastructure areas were used for out of purpose on Istanbul case. For this, plan changes in the last ten years are examined. The findings are important for the holistic evaluation of social and technical infrastructure in urban areas.

Keywords: social and technical infrastructure; provision; implementation; Istanbul, Turkey

1. Introduction

Urban areas are places where individuals live and their accommodation, transportation, education, health, worship, socio-cultural needs are interacted and together in urban areas. Social and technical infrastructure areas are the areas where individuals meet all their needs except accommodation, and they play an important role for cities and citizens. All functions in the city are in constant interaction and have a dynamic structure. If the number and type and location of the social and technical infrastructure are shaped according to the housing population, physical and economic characteristics and social structure, it provides a regular and balanced development of the dynamic structure of the city (Cetiner, 1991). The need for social and technical infrastructure to be provided by public or private sector varies according to the planning approach. The financing of social and technical infrastructure areas by the public or private sector also changes on a national and local scale. The quality and quantity of social and technical infrastructure areas affect the welfare and economy of the city (Ennis, 2009).

In Turkish settlements have three basic problems relate to social technical infrastructure. First is related to the site selection of social and technical infrastructure areas in local plans. Second is related to the provision of social and technical infrastructure. Third is related to implementation and sustainability of social and technical infrastructure areas.

Firstly, site selection of social and technical infrastructure areas in local spatial plans is significant problem. They are determined in a way that it can respond effectively to urban needs according to

traditional planning approach. Neoliberal policies directly affect the site selection criteria that affect the city structure (Turk, 2017). While public institutions are aimed to maximize the social benefit in site selection, the private sector pursues a maximum profit-making policy. It is stated that the facilities belonging to private enterprises or non-profit organizations prioritize the principle of efficiency and efficiency and weaken the approach of equality and accessibility for all people (Pakoz, 2014). In parallel, site selection of social and technical infrastructure areas directly affects the land values and the city economy.

Secondly, there are also problems related to the provision of social and technical infrastructure. According to the traditional planning approach, public services and facilities are provided by the public under the welfare state approach. The social and technical infrastructure areas respond to the needs of the citizens in terms of quality and quantity, and they are established in public lands and operated by public institutions, and it results as positive (Cetiner, 1991). With the adoption of neoliberal policies in the 1980s, the situation has changed. Cities have become a part of capital and power for the state and have been used as an income tool. With the influence of neoliberal economic policies, special social and technical infrastructure areas have increased. Private land development tools are being used much more than public land development tools. For example, the study on health facilities demonstrates that the number of private health facilities has also increased (Pakoz, 2014).

Thirdly, there are problems in the stage of the implementation and the sustainability of social and technical infrastructure in Turkey. Social and technical infrastructure areas can be used out of purposes with plan changes and plan notes that are not properly implemented. After the implementation of local plans, that means the transition of the social and technical infrastructure areas to public ownership, these areas can be used out of purposes.

This paper focusses on the third problem. That is, the paper aims to analyze how social and technical infrastructure areas were used for out of purpose on Istanbul case. This paper contains six sections. Second section gives the definition and significance of social and technical infrastructure areas in general. Third section includes social and technical infrastructure areas in Turkey. This section is divided into three parts. While first part gives legal structure, second part explains the implementation tools. Third part gives using social and technical infrastructure areas out of purpose. Fourth section includes the analysis. Fifth section explains the findings of the analysis. Last section is devoted to conclusion.

2. Social and Technical Infrastructure Areas

The cities have a settlement hierarchy and is grouped as follows; housing, housing group, small neighborhood (10 housing groups), neighborhood (5 small neighborhoods), primary school (2-3 neighborhoods), district (2-3 elementary school settlement), urban unit (2-3-4 districts) (Cetiner, 1991). It is stated that the main infrastructure areas like administrative facilities, social facilities, cultural facilities, educational facilities, health facilities, technical reinforcement areas are required for the urban unit (Cetiner, 1991). Social and technical infrastructure areas are determined according to the standards, but it differs for each country and city and it is stated that generalization cannot be made (Eker and Ersoy, 1980). Social and technical infrastructure areas are grouped as education, health, green and sport fields, management areas, socio-cultural facilities and transportation, and the site selection is important (Ersoy, 2015). Social and technical infrastructure areas are beneficial services that ensure the continuation and development of living conditions in the urban areas. Social and technical needs need

to be addressed together and it is important to improve the conditions of the city (Alnsour, 2016). For example, the importance of green areas, is well known. It is stated that the parks need to be supported in terms of transportation and should be planned by considering their distance. At the same time, the needs of the population addressed in the design of these areas need to be taken into consideration. Management and protection is important after the application (Guo et al., 2018). As it is understood, all social and technical infrastructure areas, such as parks, are in constant interaction and have a dynamic structure. It needs to be planned as a whole. Access distances should be taken into consideration and emphasized that the city should be designed according to the needs of the city. Protection and management play an important role in ensuring sustainability.

Social and technical infrastructure areas and social benefit have an important role in increasing the quality of life of the city and the inhabitants and providing justice and equality. Plans are made for the purpose of public interest. Social benefit is taken into account in the planning and implementation of social and technical infrastructure areas. It should not be made according to the benefit of a particular group or individuals. Planning, implementation or changes in social and technical infrastructure areas should also take into account the interests of the whole community. In addition, the quality of life of the city and its inhabitants is directly proportional to the quality and quantity of infrastructure areas. The purpose of urban planning as improving the quality of life (Ciftci, 1999). The provision of social and technical infrastructure in an equipped manner ensures that individuals are happy in the city where they live (Tas et al., 2017). While the cultural sector, which is one of the social and technical infrastructure areas, affects the urban economy, it also emphasizes the role on the quality of life (Koramaz and Koramaz, 2017). For example, green areas, which are one of the social infrastructure areas, are directly influential on human health (Pouya, 2017). The open green areas have a balancing role with their economic, ecological, social, social and physical aspects and increase the quality of life of urban residents (Tepe, 2018). In addition, the importance of social and technical infrastructure in terms of ensuring justice and equality is emphasized. Infrastructure areas, easy, convenient and accessibility in the choice of places to be more qualified, efficient and cheap service will be provided to more users (Ciftci, 1999). Increasing accessibility and quality of educational facilities, which is one of the social infrastructure areas, provides equal opportunity (Turk and Dokmeci, 2017). Accessibility and effectiveness should be taken into account for all individuals of the society in order to ensure social and technical infrastructure and justice and equality. Infrastructure areas should be equal and accessible to all people as they aim to meet the needs of all individuals of the society (Pakoz, 2014). The presence, absence and quality of infrastructure services affect the city's welfare and the city economy and help the real estate market. For the realization of these objectives, infrastructure services should be widely and easily accessible (Ennis, 2009).

3. Social and Technical Infrastructure Areas in Turkey

3.1. Legal Structure

Given the legal process in Turkey; settlements and structuring in these settlements; plan, science, health and environmental conditions to be compatible with the Reconstruction Law No. 3194 land use is provided. Within the framework of this law, there are regulations in which plans and plans are changed according to which criteria are defined and standards are specified. These standards are valid for urban areas at whole of country. In this context, the first regulation, the Regulation on the Principles of Plan Making was published in 1985 and numbered 18916 and entered into force. The Regulation on Making

of Spatial Plans published in 2014 no: 29030 has been repealed. Finally, the Planned Areas Development Regulation was published in 2017. The Planned Areas Development Regulation covers the areas in the implementation of local spatial plans and there is no general definition in the form of social and technical infrastructure areas. In the Regulation on Making of Spatial Plans, social and technical infrastructure areas are defined under sub-headings, and minimum standards and minimum field sizes are determined according to different population groups. The first article of the Regulation on Making of Spatial Plans is that the minimum standards and field sizes of urban, social and technical infrastructure, specified in the ANNEX-2 Table of this Regulation shall apply. This material is compatible with the regulatory planning system determined in Turkey is noted that areas of general social and technical infrastructure and standards based preparation to be applied. The second clause of the Regulation on Making of Spatial Plans is that in accordance with the principles determined by the Ministry of minimum standards or if the top level land use plan at the province level is determined by the standards determined. These two items contradict each other and it is observed that the transition from the regulatory planning system to the planning approach based on discretion is observed (Erdem Okumus and Turk, 2017).

In Article 11 of the Regulation on Making of Spatial Plans is that: If the minimum size for the use of education, health and religion in the local spatial plan revisions and changes is not enough as minimum size as in this regulation, area size is determined by plan in accordance with the proposal or opinion of the relevant public institution. With this article, it is possible to implement the practices which are not in compliance with the standards by taking the opinion of the related institution and also the investors do not have to provide the required size in case they adhere to the general standards (Erdem Okumus and Turk, 2017). In addition, in the Regulation on Making of Spatial Plans, the phrase “*made by public or private sector*” is included in the definition of social and technical reinforcement areas. Thus, the privatization of services and areas is normalized and the public cannot give these services. Public and private enterprises need to be defined separately and the provision of these services by the private sector hinders the use of public spaces for public benefit (TMMOB Chamber of City Planners, 2014).

3.2. Implementation Tools of Social and Technical Infrastructure in Turkey

These services are provided by public institutions as well as in the welfare state understanding so that social and technical infrastructure areas can be accessed and used equally by all. Since urban areas are predominantly private, public access is ensured by the public institutions. Tools that used to implementation of local plans and the transferring to public ownership of these areas are in Turkey; ‘voluntary method’, ‘expropriation’, ‘land readjustment’ and ‘plan notes’. The acquisition of these areas can be made by public power or by the consent of the people.

Voluntary method is a means that is applied depending on the consent of the person and the others are carried out by public power. The method of voluntary abandonment is an instrument that is applied with the consent of the owner, and it is converted into a parcel of land parcel by dividing or joining. In practice, it is a method used to obtain the building permit of the property owners. The demand of the owners of the property is the function of provincial cadastral parcels as defined in the local spatial plan. Depending on the size of the parcel, assembly or division is applied (Turk, 2003b). However, 15th and 16th article of Reconstruction Law no 3194 describes how to perform the process of land assembly and division, which, in contrast to what is perceived in practice, is not a method used to create urban plots (Turk, 2003b). However, due to the existence of exceptions to the regulations, it is a method used by

the municipalities to produce the parcel as land readjustment (Turk, 2003a). Since the necessary areas for social and technical infrastructure are provided free of charge, the municipalities are attracted to the owners of the property from which they have been granted the permission of local spatial plan. But it enriches owners with little interruption (Ersoy, 2005). This situation may create inequalities among the owners (Turk, 2003a).

Land readjustment is also referred to as the dough method and all parcels in regulation area are assumed as a whole, and then plan is implemented like single parcel. Some public services are free of charge up to 40% as contribution percentage. According to Reconstruction Law No. 3194, public services and public use areas are divided into two sub-groups. Public service areas such as primary and secondary schools affiliated to the Ministry of National Education, road, square, park, car park, children's playground, green ground, place of worship and police station are obtained as free of charge as contribution percentage with up to 40% of the scope of land readjustment. The second group of areas are allocated to public facilities such as hospitals, kindergartens, recreation areas, municipal services or other facilities. The areas in the first group are the services of the local government and the services under the second heading are mostly the duties and responsibilities of the central government or provincial administration (Turk, 2003a). While the land readjustment method is using, social justice is provided for share the areas to all those who benefit from the service for the second group (not regulating contribution percentage (DOP in Turkish)) areas (Ersoy, 2000). The owner of the property cannot sell or use it for any other transaction because the public parcel is functionally publicized until the parcel is publicized (Kocak, 2014). In addition, this method provides the implementation of the plan as a whole (Meshur, 2008) and the city development planned (Turk, 2009).

The expropriation is the tool used for public services, regardless of the consent of the owners of the property, for the payment of the cost of public services. Expropriation is defined as the acquisition of property by public legal entities and institutions by paying the price in cash (excluding some privileges) in accordance with the decisions of the immovable and resources of the private persons for public benefit (Ersoy, 2005). It is used to obtain areas that are not covered by the contribution percentage when using the tools of land readjustment. In cases where the contribution percentage is more than 40%, this method is used for the areas in the first group. The expropriation of the property required for public investment in small projects accelerates the project (Boztoprak et al., 2015). However, in case of a budget shortage, the integrity of the plan deteriorates and the implementation of the plan may be prolonged. An application that limits or even eliminates the right to property causes the property owner to be expropriated because he does not provide the property owner with the opportunity to acquire immovable property. It is stated that expropriation is a method that causes long, expensive and unequal among individuals (Ersoy, 2005). In addition, all shareholders during the expropriation of the shares that are shared after the land readjustment can cause the process to be prolonged since they are negotiated and purchased (Turk, 2003a).

Plan notes, the implementation of local spatial plans are organized, the plan is considered as a whole. Plan Notes are not a detail of the plans, but an essential part (TMMOB Chamber of City Planners, 2016). It is defined as a binding section that provides spatial form and order for the application in order to explain and regulate the plan decisions. He states that the plan notes are a whole with the plan decisions, they are related to the local spatial plan and they aim to give detailed information about the local spatial plan (Turk, 2018). In the case of more than 40% of the social and technical infrastructure areas determined in the local spatial plan, municipalities should be expropriated, but these methods are

not implemented due to lack of budget (Turk, 2018). Alternative solutions are very attractive for municipalities since they do not offer bargaining opportunities for the real estate owners of the existing implementation methods (Turk, 2003a). This means that these methods are attractive for the municipalities, so that they solve the problem of expropriation cost of municipalities as well as obtain public space free of charge (Turk, 2003a).

According to the first paragraph of Article 1 of Protocol No. 1 of the ECHR (European Court of Human Rights), it is stated that a person may be deprived of his property or property only from the public interest. It is understood that the confiscation of the property of the persons can only be carried out with the reason of public interest. These areas, which are obtained both by public power and with the consent of the person, cannot be used except for the purposes specified in the Reconstruction Law no 3194.

3.3. Using Social and Technical Infrastructure Areas Out of Purpose

Plan changes can be made in order to change socio-economic conditions and to eliminate some problems encountered (Sesli and Karadavut, 2009). However, in practice, it is emphasized that the plan changes are not made in accordance with the main purpose (Hasol, 20008). Disregarding public interest, future concerns and the changes in plans made according to the interests of certain groups reveal negative results in the urban areas (Sesli and Karadavut, 2009). Plan notes are all together with the plan decisions and provide detailed information and explanations about the plan decisions during the implementation phase. However, with the plan notes, social and technical reinforcement areas can be used outside the scope of the plan. If the owners of the property are more than 40% of the areas corresponding to the public use, they do not leave the volunteers, so the plan notes and the owners of the property are compromised (Turk, 2018).

There are various reasons for the privatization policies of the states or public-private cooperation, especially for finance, but evaluating the social and technical infrastructure areas of the public in this context may lead to the use of these areas beyond the objective (Emoh et al., 2016). It is stated that social and technical infrastructure areas, which are in the hands of the public, can be used for non-objective changes that are not appropriate for their purposes (Kokturk, n.d.). It is emphasized that the social and technical infrastructure areas of the public have been transferred to the private sector in order to privatize and support the investor (Hasol, 2008). The areas where privatization practices are most effective under the neoliberal policies are the areas where the public is traditionally maintained. In these applications, the public interest is ignored and the urban area is used as a rent vehicle (Erdem Okumus and Turk, 2017). Social and technical infrastructure areas are transformed from public service to investment decisions that contribute to market economy. In this way, public spaces are transferred to private property or by the investor for public service. These practices are trying to provide convenience to entrepreneurs in the private sector, but planning legislation is prevented and ignored (Erdem Okumus and Turk, 2017).

Planning is a process which consists of planning and implementation stages and it is a successive process that triggers each other in both stages. In this section, the use of the social and technical infrastructure areas outside can be evaluated under two sections. First is interventions to social and technical infrastructure areas with plan decisions. These interventions can be categorized under three parts. First part includes changes related to social and technical infrastructure areas against to the standards defined in the regulation. Second part contains changes land use functions of social and technical areas. Third part includes interventions related to increase in development rights for provision

of social and technical infrastructure areas. Second interventions state using social and technical infrastructure out of purpose after plan implementation. These interventions can be categorized under two parts. First parts include transferring to private person or private sector. Second part contains changes of function related to social and technical infrastructure areas after plan implementation (See Figure 1).

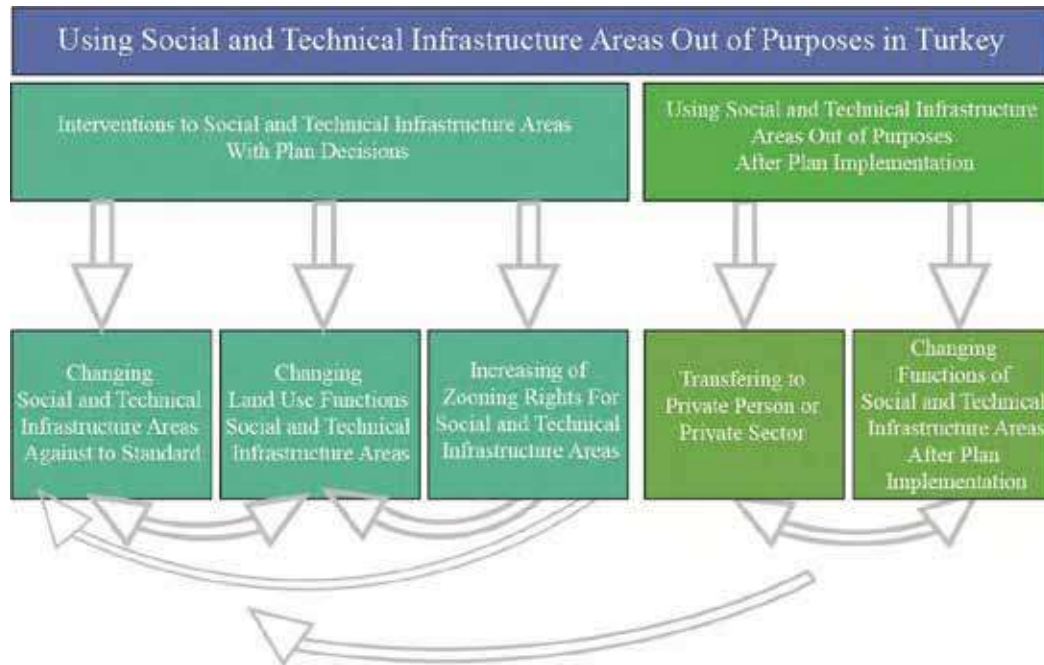

Figure 1: Using social and technical infrastructure areas out of purposes and their relations (Source: Illustrated by the author.)

4. Analysis

4.1. Research design

In order to select sample areas, the local spatial plan and plan changes, which were planned in the Istanbul Metropolitan Municipality Council between 2008-2018, were examined. The Planning Directorate has benefited from the data in the IMOS (İmar ve Şehircilik Otomasyonu (Zoning and Urbanization Automation)) system and has been detailed according to the Parliamentary Decisions within the scope of the analysis. After the examination, the selection was made among the areas according to the usage groups. Five type of problem is defined about using social and technical infrastructure areas out of purposes. A total of 25 sample areas were selected for each of the five problem mentioned above. In the sample areas, the results of using social and technical areas out of purpose were analyzed.

In the analysis of the results of the using social and technical infrastructure areas out of purposes; plan modifications and plan notes were examined. The files of the selected areas, council decisions, plan changes, plan objections and plan proposals were reviewed. After the examination, the social and technical infrastructure areas (social benefit, quality of life and justice and equality) were analyzed and their results were analyzed in the areas selected for each subheading ('changing social and technical infrastructure areas against to standard', 'changing land use functions social and technical infrastructure areas', 'increasing of development rights for social and technical infrastructure areas', 'transferring to

private person or private sector’ and ‘changing functions of social and technical infrastructure areas after plan implementation’). As seen Table 1, there are lots of result in urban areas.

Social Benefit		
Life Quality	Man-Made Environment	Plan Integrity
		Population and Structure Density
		Regional Transportation
		Local Transportation
	Social Environment	Land Value
		Income
		Need
		Service Quality
	Economic Environment	Land Value
		Service Price
		Supporting Investors
		Privatization
	Health	
	Ecology

	Income	
	Public Policy	Public Use
		Privatization
	Compliance with Reconstruction Law no.3194	

Table 1: Results of Using Social and Technical Infrastructure Areas Out of Purposes (Source: Illustrated by the author.)

4.2. Findings

According to the analysis of interventions with plan decisions to social and technical infrastructure, increasing the development right with the plan notes results negatively in terms of fairness and equality with aspect of compliance with Reconstruction Law no.3194. In addition to not complying with the Reconstruction Law no. 3194, increasing the development rights with plan notes can also result in a change in function and a change in the standard of social and technical infrastructure areas. Increasing the development rights with plan notes is a method that provide easiness in practice. This method is developed as a result of inadequate implementation due to lack of budget, the rights of the property owner are protected and even the right to additional development right can be granted. However, with this practice, social benefit is not taken into consideration and it causes the production of rent. It reduces the quality of life and may result in the deterioration of urban identity. At the same time, this decision, which disrupts the integrity of the plan, also results in the plan becoming dysfunctional.

The social benefits are not taken into account in the plan changes that are examined. It is seen that the changes have positive results in the economic environment (although some of them are individual) with the analyzed aspects. It can be stated that positive results are observed in terms of quality of life in terms of economic environment in the examined areas. However, in the built environment; plan integrity, population and structure density, transportation, in social environment; land values, income, needs aspects emerge negative results and it can be expressed that the quality of life is decreasing. In the examined areas, fairness and equality cannot be provided mostly through the examined aspects. In transferring to private person or private sector, there is more negative result than in changing functions of social and technical infrastructure areas after plan implementation. Changing land use functions

social and technical infrastructure areas (sub-group of interventions with plan decisions to social and technical infrastructure) is differentiated with changing functions of social and technical infrastructure areas after plan implementation as aspect of that areas are in public property. In case of transferring to private person or private sector, there can be privatization of the public areas. These areas are acquired in public ownership for public benefit reason. Privatization may result in both changing the ownership of these areas and using these areas out of purposes. In cases where there is no change of ownership, the private sector operates the public areas.

As a result of the field analyzes, the most negative result is in the increasing development rights with the plan notes (sub-group of interventions with plan decisions to social and technical infrastructure). These practices are unlawful by the judiciary. In the context of the using social and technical infrastructure areas out of purpose after plan implementation, it is seen that more negative results occur in the urban area when transferring to private sector or person.

In conclusion, social and technical infrastructure areas are using out of purposes with plan decisions. These situations lead to negative results in terms of life quality and social benefit. Increasing in development rights with plan notes are not in accordance with the Reconstruction Law no 3194. Besides, social and technical infrastructure areas are using out of purposes after plan implementation. This causes more negativity in terms of quality of life, social benefit and justice and equality. But in many aspects, it increases the quality of life economically with the analyzed aspect as individually.

5. Conclusion

Social and technical infrastructure has a critical significance. There are three main problems related to social technical infrastructure in Turkish settlements. The paper aims to analyze how social and technical infrastructure areas were used for out of purpose on Istanbul case by examining plan changes in the last ten years.

Plan changes can be made out of purposes both in planning stage and implementation stage. Moreover, plan notes are also used out of purposes in planning stage. Interventions with plan decisions to social and technical infrastructure areas can be with both plan changes and plan notes. ‘Increasing development rights for the areas’ occurs with plan notes. ‘Changing the areas against to standard’ and ‘changing land use functions of the areas’ occurs with both plan notes and plan changes. ‘Increasing development rights for the areas’ causes the another two. Using social and technical infrastructure areas out of purposes after implementation also cause ‘changing the areas against to standard’ and ‘changing land use functions of the areas’. There is more problem in this stage that these areas are in public ownership and are purposed public benefit.

All problems result negative effects on urban areas as aspect of social benefit, life quality and fairness and equality. Plan integrity, population and structure density, transportation, land value, income, need, service quality and price, supporting investors, privatization, health, ecology, accessibility, public use and compliance with Reconstruction Law no.3194 are the issues of using social and technical infrastructure areas out of purposes.

Within the scope of this paper, the suggestions developed for the identified problems are as follows:

- In order to control the density resulting from plan change, it is necessary to limit the density of the plan notes and plan changes. If a plan change is made, a plan note should be added as to maintain the current precedent.
- Within the scope of transferring the increasing value in the urban space to the public, the protocols with the private sector should be transparent. The balance between the private sector's income and the benefit it provides to the society needs to be established. In order to achieve this, the protocols (planning agreements) should be placed on the ground in Public Law. Plan notes should not include expressions that disrupt plan decisions and the plan notes prepared in this way should not be approved and applied.
- The development programme of municipalities should be mandatory. In case of failure to prepare the development programs, it is necessary to define clearly what kind of problems will arise.
- As the projects and plans that direct the development of space in the city also direct the preferences, lifestyles and needs of the inhabitants, it is necessary to ensure the participation of the citizens in the decision-making process that encompasses the whole of the city, as well as to increase the sanction power of the local government. In this context, raising awareness of the citizens is also of great importance.
- After implementation of local plans, with plan changes, it can be observed that the transfer to the private sector or the person. In parallel with the quality of service within the scope of public-private cooperation, the price of services also increases. Since planning is the first priority to ensure public interest, the price of the service should be taken under control as publicly available
- Intelligent management, which is a component of smart urbanism, will provide transparent and participatory decision-making policies. In addition, the use of virtual reality applications in the implementation of the plans will enable the understanding of the results of the plans in the third dimension. The effect of the plan changes on the main plan decisions can be determined in this way, the main plan decisions and the results that may emerge in the urban space can be determined before the implementation.

Interrelation between inclusivity of public spaces and social cohesion: Metamorphosis of a historical park in Ankara, Turkey

Müge Akkar Ercan¹, Nihan Oya Memlük²

¹Middle East Technical University, akkar@metu.edu.tr

²Gazi University, oyamemluk@gmail.com

Abstract: Public spaces with different degrees of inclusiveness and exclusiveness are critical in both attaining and sustaining social cohesion between diverse groups, thus achieving coherent community life from neighborhood to city scale. This paper aims to examine the notion of social cohesion through the lens of the inclusivity of public spaces. Providing a model for the qualitative assessment of the inclusivity/exclusivity of public spaces, this research assesses the largest historic park in Ankara, *Gençlik Park*. It studies the metamorphosis of this park from its heyday to 2018 regarding the four dimensions of access in relation with design, management, control and use processes, as well as the contextual aspect of the inclusivity-exclusivity continuum of public-private spaces. It argues that the inclusive nature of public spaces evolves over time along with the local and global contexts within which the public space is set and bounded. Revealing multiple, site-specific and interrelated driving forces behind the inclusivity of the public space, it shows how the original design of the park has been modified, and how this affected the inclusivity of the park, and the social cohesion in the city.

Keywords: public space; social cohesion; inclusivity; Ankara

Introduction

Public spaces are inevitable components of cities. Bringing together different groups of people regardless of their class, ethnic origin, gender and age, and performing as the arenas of social interaction, they help the formation of the richest quality of a multi-class, multi-cultural and heterogeneous society. They carry out educational, informative and communicative roles to strengthen public life. People coming from different segments of the society interact and learn about each other in public spaces. Therefore, public spaces with different degrees of inclusiveness play a critical role in both attaining and sustaining social cohesion between diverse groups to achieve a coherent community life at neighborhood, district and city levels. This paper aims to discuss the interplay between social cohesion and inclusivity of public spaces, first by providing a model of inclusivity for the qualitative assessment of public spaces, and second by using this model to assess the inclusivity of the largest historic urban park in Ankara, namely *Gençlik Park (GP)*. As a city-scale park, GP was built in the 1930s along with the nation-building ideology of newly-founded Turkish Republic to create a modern, secular and Westernized society and to build a social cohesion and unity among different segments of the population. This paper examines the metamorphosis of GP, its changing inclusivity over the last 90 years, and thereby its impacts on contributing the social cohesion in the city. It relies on qualitative and quantitative

evidence (archival documents, direct observations, a survey of 180 questionnaires and in-depth interviews with the sixteen old park users), involving a mixture of primary and secondary data.

The inclusivity model of public spaces

Public spaces, by nature, are inclusive and pluralist (Tiesdell and Oc, 1998; Williams and Green, 2001). The *inclusive public space* can be defined as possessing four mutually supportive qualities of *access*: Physical access, social access, access to activities, and access to information, discussions and intercommunications (Akkar, 2005). *Physical access* is the access to the physical environment (Tiesdell and Oc, 1998). Public spaces are inclusive, as long as they allow everybody to be physically present with the availability of entrances and universal design principles which its accessibility and connectivity to paths of circulation and a variety of public and private transport modes (Akkar Ercan and Memlük, 2015).

Social access involves the presence of hints and signals, in the form of people, design and management elements, suggesting who is and is not welcome in the space (Carr et al., 1992). *Visual access* or *visibility* of public spaces, symbols used or represented within these spaces and feeling of safety and comfort affect social accessibility of public environments (Carr et al., 1992; Rishbeth, 2001). Likewise, the emotional bonds between individuals or groups and environments generate symbolic meanings and cultural importance of the places, with which public spaces help form personal or collective histories and memories, leading to the creation of place attachment (Rishbeth, 2001), and a sense of continuity for a group or a society (Loukaitou-Sideris, 1988). Binding the individual members of the group or society together, these feelings enhance social unity and cohesion (Lynch, 1992; Moughtin, 1999). Similarly, the design, activity and management of public spaces need to reflect the needs, values and aspirations of all social groups from different ethnic, social and income levels to ensure the provision of inclusive public spaces (Rishbeth, 2001).

Public spaces are also inclusive, as long as they accommodate a variety of activities accessible by the publics. As the societies become highly multiplied, diversified and differentiated and the distance between social groups widens, the need for multi-functional public spaces arises. The more variety of facility the public spaces comprise, the more inclusive they are (Akkar, 2005).

Access to information, discussions and intercommunications means the availability and accessibility of the information about the design, development, management and use processes on public spaces. Inclusive public spaces are places where the information, discussions and intercommunications regarding these processes are truly open to all (Akkar, 2005). This requires the presence of inclusive and participatory public spheres, guaranteed by the public authorities (Akkar and Memlük, 2015). By facilitating renegotiations between the publics and public authorities, such arenas enable the meanings and functions of public spaces to change in conformity with citizens' needs and interests (Akkar, 2005), and reinvigorate society through collective action (Madanipour, 2010). Language should not be a barrier to access development and use processes of public spaces (Rishbeth, 2001).

This *inclusivity model* can be understood at the physical and procedural levels. The first three access dimensions of this model are *physical*, as they primarily denote the accessibility of physical space, whilst the fourth access dimension denotes a *procedural accessibility*; i.e. the access to the design, development, management, control and use processes of urban space (Akkar Ercan and Memlük, 2015). These two levels of access should overlap to achieve *inclusive public spaces* (Akkar Ercan and Memlük, 2015). Public spaces ideally should be inclusive to protect cultural diversity, create the spatial experience of democracy, reduce the potential social conflicts of the society, promote an urbanism of tolerance and social cohesion, reintegrate a socio-spatially fragmented city, expand citizenship, empower community, and get people involved in the governance and maintenance of their cities and public spaces (Madanipour 1999; Shonfield 1998). To achieve these higher values and objectives, the

inclusion of all segments of the public in the physical and procedural public spaces is crucial (Akkar Ercan and Memlük, 2015).

Four access dimensions of this model offer valuable empirical tools to define an *ideally inclusive public space* and to assess the inclusivity capacity of a public space. Since the relationship between inclusive public space and exclusive private space is a *continuum* rather than a dichotomy, it is possible to define public and private spaces with different degrees of inclusivity/exclusivity (Akkar, 2005). Therefore, regarding four aspects of access for a specific time-period, the extent of 'inclusivity' of a public space depends on the degree to which the public space physically and socially is open to all, and the activities occurring in, and information, discussions and intercommunications about the design, development, management and use processes are accessible to everybody (Akkar Ercan and Memlük, 2015; 2019).

As the change in public spaces is inevitable, their inclusivity levels or qualities evolve in time in relation with the local and global contexts (Akkar Ercan and Memlük, 2015). This premise underlines contextual aspect of the *inclusivity-exclusivity continuum* of public-private spaces. The characteristic contexts of places and how they vary from one city to the next determine the inclusivity qualities of public spaces. The *spatial or locational context*, including the location of the public spaces in a neighborhood, district or city, their distinguished features such as their morphology, natural invariants and the characteristics of their surroundings and urban fabric, identifies their inclusivity or exclusivity (Akkar Ercan and Memlük, 2015). The changes in these features in time also impact on the inclusive/exclusive nature of public spaces. The *political economic context* –i.e., the political institutions, the political environment and the economic system of a society- influences the physical form of a city, or urban space, in addition to the governance processes of its design, development, management, control and use (Akkar Ercan and Memlük, 2015). Likewise, the changes in society, the economy and the prevailing politics in a city/society can impact on the inclusivity or exclusivity levels of the public spaces. Last, the inclusivity/exclusivity level of public spaces is (trans)formed within a *historical context*; it can be shown and communicated through the history that has shaped them, requiring continuous interpretative mediation. Urban design process is a process which begins long before contemporary development proposals are dreamt up, and these in turn build upon a very long history that continues to inform processes of change through to today (Madanipour, 1997). Thus, we have to look at the inclusivity/exclusivity of public spaces as a *historical continuum*, which begins with a look to the past (Akkar Ercan and Memlük, 2015). How far a space is inclusive or exclusive is shaped by an accumulated history of experience and practice, although the change in the level of inclusivity or exclusivity depends on local and global contexts. Despite globalization, this change sometimes can be very place-dependent (Akkar Ercan and Memlük, 2015). For these reasons, looking at the inclusivity qualities of public spaces through a historical context is critical, as will be shown in the example of GP.

Evolving inclusivity of GP from its heydays to today

GP is a 27.5-hectare park located at the south-west of the historic city center of Ankara, namely Ulus. The Park is surrounded by important landmarks of the city, such as the Central Station to the southwest, large sports complexes and Ataturk Culture Centre to the northwest, Opera House and Symphony Hall to the south, public and government buildings and a bus station to the east, the Central Bank and the Radisson Hotel and the famous *Vakıf* apartment building with two historic theatre halls to the north. The history of GP goes back to the mid-1920s (Uludağ, 1998; Akansel, 2007). The transformation of this swamp into an urban park and its tale of inclusivity can be examined under four major historic periods: 1925-1950 representing the park's early years, 1950-1980 characterized by its heydays, 1980-2005 covering its declining period and the period after 2005 corresponding to its regeneration (Memlük, 2012).

This paper, suggesting an inclusivity model for the assessment of public spaces, has depicted how the inclusivity of GP has changed over the last 90 years within the spatial, political-economic and historical contexts of Ankara. Studying four subsequent periods regarding four *access* dimensions in relation with the design, management, control and use processes, it found that GP's inclusivity has changed in every historic period according to the spatial, political-economic and historic contexts (Akkar and Ercan, 2015). Between 1925 and 1950, along with the nation-building ideology of the newly-founded Republic, GP was designed and built as an inclusive and democratic park to build a social unity and cohesion among different segments of the population (Kasaba, 1997; Bozdoğan and Kasaba, 1997; Akansel, 2007; Demir, 2006; Özdemir, 2009; Cantek Şenol, 2012). From the 1950s to the 1980s when Ankara became a dual city with the rural migration and the emergence of squatter poverty neighborhoods along with the liberalization policies and the transition to multi-party democracy, GP became more inclusive and democratic for the upper and middle classes, but less inclusive for the new urbanites; i.e. rural migrants, squatters dwellers (Bozdoğan and Kasaba, 1997; Akkar Ercan and Memlük, 2015; 2019). Between the 1980s and 2005, along with the degeneration of Ulus, the rapid urban sprawl of Ankara, and the rising dominance of Islamic wing party in the local politics, which pursued the disinvestment policies on the Park to erode its historic and cultural values, thereby its early republican identity, GP became less inclusive for the upper and middle-income groups, but more inclusive for the low-income classes, squatter dwellers and the marginal groups (Akkar Ercan and Memlük, 2015; 2019). Since 2005, GP has become more inclusive and democratic for low and middle-income conservative groups, but less inclusive and democratic for its previous users –mostly coming from secular, middle and upper-income classes, and particularly *new middle* class (Akkar Ercan and Memlük, 2015; 2019).

Throughout these years, the lack of public involvement in any renewal or regeneration schemes/stages of the park have undermined the GP's *inclusive* and *pluralist* qualities. The absence of the GP's procedural accessibility in any historic period has always resulted in the dominance of some segments of the urban population with their hegemonic cultural symbols and values. Every time GP was renewed, its authentic, cultural and historic values and the collective memories about the Park have been compromised and eroded to an extent. This ultimately resulted in the (re)configuration of a public space which has served for the benefit and enjoyment of some groups, while deliberately disregarding and excluding the needs and values of others. Consequently, although the city should be a network of historic and new public spaces, it has turned into another sort of network, where public space ghettos or fortified public spaces of the rich and the poor, the conservative and secular sections of the society, with distinct patterns of consumption, have been built through the past and current municipal policies. This has continuously entailed the spatial segregation and polarization, impinging adversely the ideal inclusive qualities of the public spaces of Ankara. However, especially public spaces in cities should be used to spatially harmonize all the social, economic and cultural differences in a society, and to generate new social solidarities among inhabitants related to their common and individual future.

The lack of procedural accessibility of GP in any historic period has caused not only the neglect of the historic and cultural values and images of the park, but also the loss of both the sense of place attachment and the collective memory among the (older) citizens. This has ultimately resulted in the erosion of a sense of continuity, social unity and cohesion, and strengthened social exclusion and stratification. However, the symbolic meanings and cultural importance of public spaces generated by the emotional bonds between these places and their users contribute to the creation of the sense of continuity for a group or a society; and these feelings ultimately bind the individual members of the group or society together, and enhance social unity and cohesion (Loukaitou-Sideris, 1988; Lynch, 1992; Moughtin, 1999). Histories and elements constituting the identity of public spaces therefore should be well-preserved to foster social inclusion, social coherence and unity.

Conclusion

The analysis of the GP's changing inclusivity over the last 90 years leads to several conclusions. First, the inclusivity/exclusivity of public spaces is not only the problematic of contemporary public spaces. Instead, it has always been a conflicting issue if the inclusivity of public spaces is examined in a historical perspective. Although genuinely inclusive public spaces might be very rare in reality, it is possible to find various types of public spaces with different extent of inclusivity and exclusivity. As in the case of GP, the *inclusive* nature of a public space might change and evolve depending on the *time* dimension, depending on the local and global contexts within which the public space is set and bounded (Akkar Ercan and Memlük, 2019).

Second, the approach that conceives the inclusivity-exclusivity continuum of public-private spaces within a historical context reveals *evolutionary* aspect of this continuum (Akkar and Memlük, 2015; 2019). As in the case of GP, the inclusivity/exclusivity of public spaces acquires a continuously evolving process. This continuum is not static and unchangeable, but instead varies circumstances and attitudes change. Additionally, it is not uniform and undifferentiated, but rather has several components and forms. Hence, the inclusivity of public spaces is a *dynamic* concept, which is continuously (*re*)shaped in time within particular local and global contexts, including historical and cultural trends, diverse modes of governance, regulation, political priorities and the political and market forces. It evolves continually, but at the same time, established components of inclusivity –four dimensions of access- are confirmed again and again over time. For this reason, inclusivity of public spaces has a *plural* character that appears through a *time* perspective (Akkar and Memlük, 2015; 2019).

Third, the production of inclusive and democratic public spaces is the outcome of political process. As shown in the case of GP, the political group which gains power in local (or national) politics affects the inclusivity level of public spaces. Thus, the inclusivity/exclusivity levels of public spaces are arguably determined by the political forces and power relations. Public spaces are political arenas (Akkar Ercan, 2007), actively fought over by groups with seemingly irreconcilable ideological visions (Carmona, 2010). The inclusivity/exclusivity nature of public spaces is (*re*)shaped through on-going processes between the interests and values of opposing political, social and economic actors. Creating inclusive and democratic public spaces therefore requires the recognition of a democratic model where decision-making processes of public spaces would effectively enable the publics not only to project their own preferences, values and inspiration, but also to listen to and be appreciative of those of others. Such inclusive decision-making processes will engage a broad range of publics in the process of shaping the public space, and help them to understand and recognize a diversity of interests and perspective among the publics (Paddison and Sharp, 2007). An inclusive decision-making process requires to:

- find new mechanisms of communication and collaboration that will allow the inclusion of the multiple publics,
- have a political authority, which is willing to ensure the continuous presence of democratic and egalitarian procedural accessibility by giving all segments of the public the opportunity to raise their voices and opinions about the public spaces (Akkar and Memlük, 2015; 2019).

With an inclusive decision-making process in which deliberations are used as the mechanisms to endure a consensual rather than authoritarian style of interaction, it is more likely to generate and maintain inclusive public spaces that will ultimately help achieve social cohesion and reduce socio-spatial fragmentation and polarization in contemporary cities (Akkar and Memlük, 2015; 2019).

Where the streets have names

Lorenzo Barbieri¹

¹*Independent researcher, lorbarbieri@hotmail.com*

Abstract: The subject of street names can be interesting to understand a country's history. The choice of a street name testifies to a country's interest towards a topic: as, for instance, naming the high street after a renowned patriot, a war hero or a scientist. Over the years various countries renamed streets or squares to make a statement in favour or against a particular historical period. This paper seeks to study the toponymy of Italian streets. By analysing the toponymy database published by Istat, it aims to: rank street names from most to least frequent (by municipality); classify them according to broad categories (*e.g.* geographical names, politicians, scientists, saints, etc.); georeference them by municipality. This work allows the author to consider the ranking of streets and the reasons behind it. First, the ranking shows the relative importance of a street name. It highlights Italy's young history: an emphasis on the capital cities, on the *Risorgimento*, on the Italian language. Secondly, the classification shows the recurrence of some themes: the most important categories are cities, politicians, WWI references, and *litterati*. Lastly, showing the location of street names on a map also allows to make a geographical analysis of Italian toponymy: some names could be more frequent in specific regions than in others due to the influence of local traditions, to political reasons, etc.

Keywords: street names; location; categories; history

Introduction

Street names define a country's identity. As a subject, toponymy is interesting in that it helps to understand a country's history. This article seeks to describe the toponymy of Italian streets, both by reflecting on the frequency of names and categories, and by showing and analysing their location. After a short look at the state of the art, it exposes the methodology and goes on to discuss the result of the research. The discussion opens with the first 100 street names ordered by occurrence. This is followed by the description of the various overlapping categories according to which the first 100 street names can be classified. A look at the first 20 names in each region concludes the discussion. Some concluding remarks and suggestions for further development close the article.

State of the art

This work draws on an article published by the German newspaper *Zeit* (Biermann *et al.*, 2018), which studies the street names in Germany. The authors, together with a service provider, worked on data harvested from the OpenStreetMap open-source database. They programmed a searchable database of the over 450,000 street names in Germany, which anyone can research on their website or download for free. In doing so, they noticed some interesting patterns on the

distribution of street names. Some of them are located only in specific parts of the country, such as in former East Germany. The most common street names refer to abstract concepts, such as *school*, *garden* and *main* street.

This result is different from what happens in Italy, where the most common street names refer to a person, a place, a significant date, etc. Azaryahu (1996) states that commemorative street names have a role “in substantiating the ruling socio-political order and its particular ‘theory of the world’ in the cityscape” (p. 312). This is in contrast with places like the United States where street names are simply alphanumeric. In the past, street names were chosen with regard to local history and topography. The use of other non-local names started in France in the 18th century and diffused in the rest of Europe after the French Revolution and the reign of Napoleon, during which many streets were renamed.

In terms of renaming streets, Drozdowski (2014), looks at how the street of Kraków, Poland, changed their names across the 20th century, under three powers: Nazi, Soviet and Polish. In particular it looked at street name changes in the city centre in 1934 (Polish), 1943 (Nazi), 1964, 1985 (Soviet) and 1996 (Polish). It concludes that, through the years, “the street names in Kraków have provided visible, distinctive, and daily reminders of the historical and socio-political intentions of those governing that space” (p. 76).

An article by Oto-Peralías focuses on street names as socio-cultural data and shows the example of Spain with regard to religiosity. Instead of looking at single street names, the author elaborates an indicator of religiosity. It concludes that “street names actually reflect the local community’s social and cultural values” (p. 18).

Therefore, it can be safe to assume that toponymy is an interesting field. General studies are common but in-depth studies on a country, city or topic can shed new light on unexplored fields. Bearing this in mind, one can proceed with the analysis of the Italian case.

Methodology

This article, similarly to Biermann *et al.* (2018), aims to study the toponymy of Italian streets. In 2015, the Italian National Institute of Statistics (Istat) published toponymy data that derive from their data elaboration and control activities for the 15th Population Census (Istat, 2015) and which include, along with the names and codes for region, province, municipality, locality:

- the street type designation (*e.g.* via, viale, piazza, strada);
- the street name;
- the house number.

Unfortunately, this data is provisional, as it only includes 7456 municipalities (92%) out of 8092¹ and two-thirds of the house numbers. Moreover, not all street names are standardised: for

¹ This was the number of municipalities as of the 2011 census. Since 2012, a rising number of municipalities have been merging with one another. As a result, at the time of writing, the number of municipalities is 7914.

instance the street name *Giuseppe Garibaldi* may appear as the full name, as an abbreviation or as a surname only, either *G. Garibaldi* or *Garibaldi*.

Therefore, an extensive work of standardisation was carried out for the most common street names, that is, those occurring in at least 10% of the Italian municipalities (around 750). A further standardisation was necessary for the names occurring in at least 10% of each region's municipalities to take into account specific names in Italian regions.

In the case of some street names some generalisations were made, such as:

- *Santa Maria* contains all the denominations of Saint Mary, including *Addolorata*, *Annunziata*, *Beata Vergine*, *Immacolata*, etc.; by counting all the street names, Santa Maria would have reached first place, but when counting one occurrence per municipality it moved to the sixth;
- *Sant'Antonio* refers to the most popular saint Anthony in Italy, known as Sant'Antonio da Padova, and includes all the unspecified *Sant'Antonio*;
- *San Giovanni Battista*, being the most popular Saint John in Italian religious culture, includes all the unspecified *San Giovanni*;
- *Martiri della Libertà* includes all the denominations related to martyrs and fallen for the sake of freedom (including, for example, *Caduti della Libertà*);

The street name data was elaborated with the SAS (version 9.4) statistics software, which helped to extract, standardise and rank street names. The first 100 street names were extracted, together with their one-time occurrence in each municipality and ranking. This data was joined to the geographic municipality data (point-shaped data) with the open-source GIS software QGIS (version 3.4), to create maps showing the location of street names.

Discussion

The following table (Table 1) shows a list of the first 100 street names by occurrence in Italian municipalities (each street name appears only once in each municipality: e.g. *Via Roma* and *Piazza Roma* count as one occurrence).

Rank	Street Name	%	Rank	Street Name	%	Rank	Street Name	%
1	Roma	76,92	35	Ugo Foscolo	20,24	68	Raffaello Sanzio	12,53
2	Guglielmo Marconi	55,43	36	Alessandro Volta	20,17	69	Martiri Della Libertà	12,49
3	Giuseppe Garibaldi	53,66	37	Vittorio Emanuele II	20,04	70	Isonzo	12,39
4	Giuseppe Mazzini	44,38	38	Galileo Galilei	19,98	71	San Giuseppe	12,38
5	Dante Alighieri	43,54	39	Giacomo Puccini	19,97	72	Pietro Mascagni	12,20
6	Santa Maria	40,50	40	Cristoforo Colombo	19,90	73	Giuseppe Di Vittorio	12,16
7	Giuseppe Verdi	39,18	41	Gioachino Rossini	19,89	74	Vittorio Alfieri	11,99
8	Giacomo Matteotti	37,93	42	Monte Grappa	18,37	75	Pace	11,94
9	Camillo Cavour	37,41	43	Sant'Antonio	18,31	76	Gorizia	11,86
10	IV Novembre	35,53	44	Repubblica	17,92	77	Filippo Turati	11,84
11	Papa Giovanni XXIII	34,51	45	XX Settembre	17,74	78	Pietro Nenni	11,82
12	Alessandro Manzoni	32,31	46	San Martino	17,29	79	San Giovanni Bosco	11,71

Rank	Street Name	%	Rank	Street Name	%	Rank	Street Name	%
13	Aldo Moro	32,12	47	Sandro Pertini	17,01	80	Fratelli Cervi	11,61
14	Antonio Gramsci	30,74	48	Vincenzo Bellini	16,38	81	Giotto	11,25
15	Cesare Battisti	29,75	49	Michelangelo Buonarroti	16,28	82	Carlo Alberto Dalla Chiesa	11,17
16	Alcide De Gasperi	28,80	50	Francesco Petrarca	16,24	83	Fiume	11,16

33	I Maggio	20,40	67	Gaetano Donizetti	12,73	100	Guglielmo Oberdan	9,64
34	San Rocco	20,28						

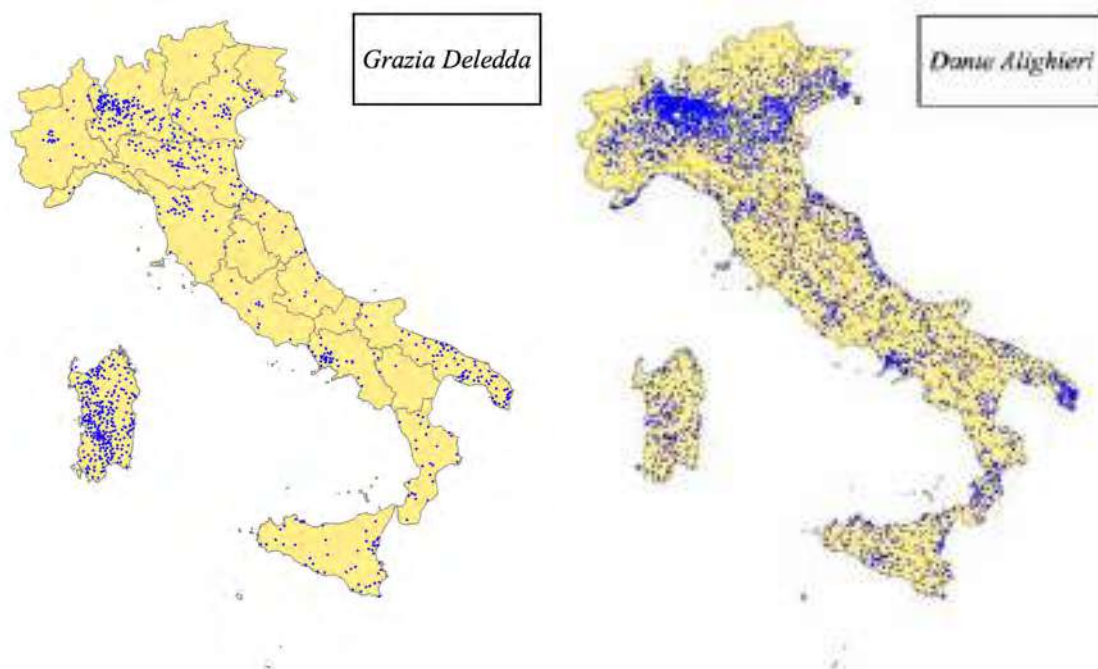

There is a variety of categories within the first 100 street names. For the purposes of this article the broad categories are, in no particular order: gender, places, scientists, patriots, politicians, artists, literati, seafarers, priests and religious people, significant dates, military people, heads of state (both kings and presidents), World War I and II, and victims of Mafia. It is worth noting that some street names fall into more than one category. For instance, *Monte Grappa* (#42) refers both to a place and to the setting of one of the final battles of World War I in the Italian front.

Roma, the capital city for almost 150 years, ranks first (77% of municipalities), as the comparison between figures 1 (municipalities) and 2 (*Roma* street name) shows. The name of the capital city is less frequent in *Valle d'Aosta* and in *Trentino-Alto Adige*, two autonomous regions where the main languages are French and German (mainly in the province of *Bolzano-Bozen*) respectively, and therefore have a different toponymy based on local names. The other two former capital cities of Italy are in lower positions. *Torino* (#55) was the capital of the Kingdom of Sardinia and then became the first capital of the new country in 1861. Five years later the capital was moved to *Firenze* (#86). *Roma* became part of Italy in 1870 and was made the capital the following year.

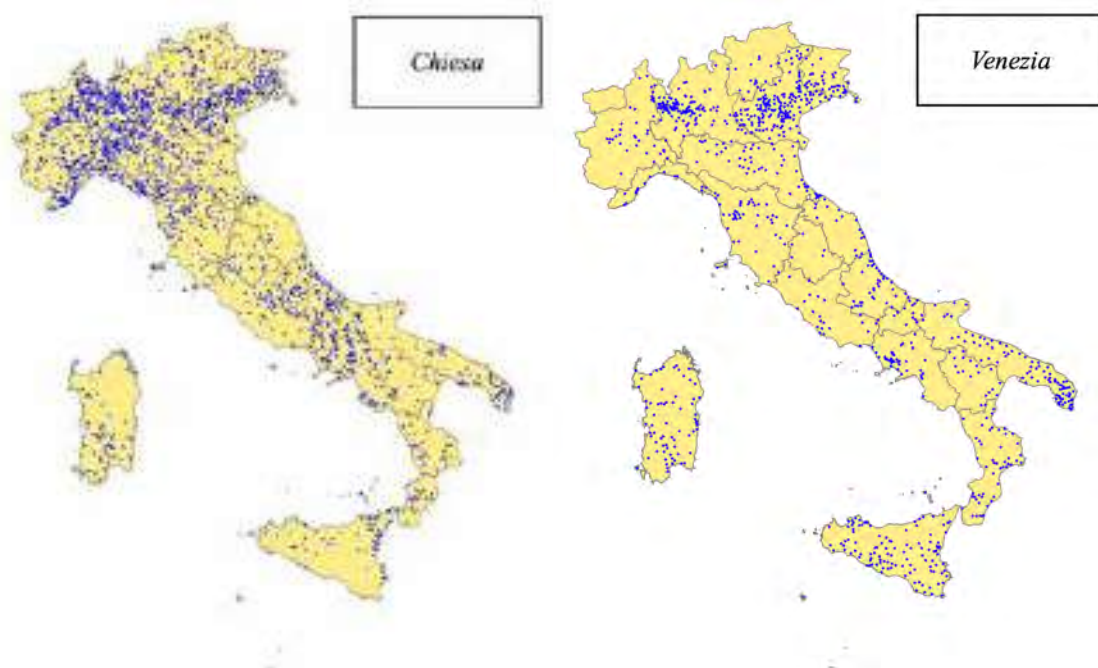

What is striking in terms of gender is the large majority of male figures – 68% – and subsequently the very small presence of women, which are only three among the first hundred: *Santa Maria*, a widely followed saint and religious figure, is in sixth position. The second woman, ranked 85, is *Grazia Deledda*. She was a Sardinian writer who lived between the 19th and the 20th century and was awarded the Nobel prize for literature in 1926, the second Italian writer and the only woman to do so. Lastly, a few positions down is *Santa Lucia* (93), a martyr known for protecting the blind, who lived in Siracusa in the 3rd century A.D. Another 29 street names are not related to people and therefore are gender neutral.

As expected, *Grazia Deledda* street names (figure 3) are mostly located in Sardinia, her home region. In comparison the most frequent literate, *Dante Alighieri* (figure 4), is present in most of the country and is ranked fifth. The category of the literati contains 14 names among which the most important are: *Alessandro Manzoni* (#11), *Giacomo Leopardi* (#21), *Giosuè Carducci* (#22) and *Giovanni Pascoli* (#26). The former is famous for his novel *I promessi sposi*, but also wrote poems, which is what the other three writers are mainly known for.

Place names represent another highly frequent category, with 19 occurrences. Other than the capital cities, frequent place names are *Chiesa* (#20, figure 5), which highlights the importance of Catholicism in this country, *Europa* (#28), which refers to the continent, and *Castello* (#32), which emphasises the presence of castles, fortresses and towers in many towns. Among the cities, it is worth noting *Venezia* (#66, figure 6), highly concentrated in the north-east of Italy.

Many place names overlap with another important category: street names relating to World War I. Other than *Monte Grappa*, cited above, these are *Piave* (#17) and *Isonzo* (#70), two rivers upon which many battles were fought, *Vittorio Veneto* (#18), a town named after the final victory of the war, *Trieste* (#24), *Trento* (#25), *Gorizia* (#76) and *Fiume* (#83), four major Italian cities that were part of Austria-Hungary until the end of the war. The World War I street name category has

13 occurrences, among which the most notable are: *IV Novembre* (#10) and *XXIV Maggio* (#64), the dates marking the end, in 1918, and the beginning, in 1915, of the conflict respectively; *Cesare Battisti* (#15) an Italian patriot born in Trento, at the time in Austria-Hungary, who fought with the Italian army and died during the war; *Nazario Sauro* (#59), born in Istria, followed a similar fate; *Armando Diaz* (#54), the general who led Italy to victory after the defeat in Caporetto. On the other hand, World War II plays a smaller role in Italian toponymy, with only three occurrences. The most notable is *XXV Aprile* (#19), the day of Italy's liberation from German occupation, marking the end of the war for the country.

The category of politicians plays an important role, with 16 occurrences. The ones which are among the first ten positions are related to the *Risorgimento* period, roughly 1848-1870: *Giuseppe Garibaldi* (#4), *Giuseppe Mazzini* (#5), *Camillo Cavour* (#9). They all contributed in different ways to the unification of Italy, which eventually took place in 1861. *Giacomo Matteotti* (#8) and *Antonio Gramsci* (#14) were both opponents and victims of Fascism. *Aldo Moro* (#13) and *Alcide De Gasperi* (#16) are influential figures of the Republican era, the former killed by the Brigade Rosse.

In a strongly catholic country, it is not surprising to find saints and religious people among the street names. Apart from those already cited above, some notable names are: *Papa Giovanni XXIII* (#11), one of the most popular popes of the 20th century, *San Francesco d'Assisi* (#29), the saint patron of Italy, *Don Giovanni Minzoni* (#60), an antifascist priest who was killed at the beginning of the regime.

The category of artists contains 12 street names, with the composer *Giuseppe Verdi* (#7) at the top of the list. Other important figures are the polymath *Leonardo da Vinci* (#27), the composer *Giacomo Puccini* (#39), the sculptor, painter, architect and poet *Michelangelo Buonarroti* (#49).

The “patriots” category partly overlaps with the politicians and the World War I ones. The first patriots that were neither politicians, nor war heroes, are the *Fratelli Rosselli* (#87), two antifascist brothers who were killed in the vicinities of Paris. They are followed by another set of brothers, *Fratelli Bandiera* (#89), heroes of the *Risorgimento*: Venetians, they attempted a revolution in Calabria, but were captured and executed.

The most significant dates have already been covered between the two world wars, apart from *I Maggio* (#33), May Day, and *XX Settembre* (#45), the date when Rome was seized from the Papal States and became part of Italy.

Although with only five occurrences, the category of scientists contains street names among the first half. *Guglielmo Marconi*, the pioneer of radio communications, is in second place, while *Leonardo da Vinci* is already covered among the artists. The other three scientists are the physicist *Enrico Fermi* (#31), the chemist and physicist *Alessandro Volta* (#36) and the astronomer *Galileo Galilei* (#38).

Some street names are devoted to what could be called abstract concepts: *Libertà* (#30), which is freedom, and those who died for it, *Martiri della Libertà* (#69); *Repubblica* (#45), the form of government that Italy chose after the end of WWII; *Risorgimento* (#51), the age of change that brought about the unification of Italy in the 19th century; *Pace* (#75), which likely conveys the desire for peace after two world wars.

Heads of state, be they kings or presidents, are the next category. At the top, we find *Umberto I* (#23) and *Vittorio Emanuele II* (#37). The latter was the first king of Italy but chose to keep the number he had as king of Sardinia. The former, his son, was assassinated by an anarchist in 1900. *Sandro Pertini* (#47) was the most popular president of the Republic of Italy. He is followed by another popular president, albeit a foreign one: *John Fitzgerald Kennedy* (#61), the US president who was assassinated in 1963.

People from the military form another category, containing, apart from World War I generals and patriots: *Salvo D'Acquisto* (#62), a *carabiniere* who traded his life for that of twenty civilians who were about to be killed by the German army during the occupation of Italy; *Carlo Alberto dalla Chiesa*, a general who was killed by the Sicilian Mafia for his work against organized crime. Another victim of Mafia is the judge *Giovanni Falcone* (#90), who presided over one of the largest trials against the Sicilian Mafia and was killed for it.

The last category in terms of occurrences is that of seafarers: *Cristoforo Colombo* (#40), is the Genoan explorer who first set off to discover America. The continent was named after *Amerigo Vespucci* (#96) who realised that the discovered land was a new continent, not part of Asia as previously assumed.

It is also interesting to look at regional differences in the frequency of street names. Table 2 below illustrates the tag clouds of the 20 most frequent names for Italy as a whole and the 20 regions.

1-Piemonte	2-Valle d'Aosta	3-Lombardia	4-Trentino-Alto Adige
5-Veneto	6-Friuli-Venezia Giulia	7-Liguria	8-Emilia-Romagna
9-Toscana	10-Umbria	11-Marche	12-Lazio
13-Abruzzo	14-Molise	15-Campania	16-Puglia
17-Basilicata	18-Calabria	19-Sicilia	20-Sardegna

Roma is still the most frequent street name in the majority of regions. A notable exception is Valle d'Aosta, where local names are more frequent. In some regions new names that did not make it to the national top 100 show up. It is the case in Trentino-Alto Adige for *Damiano Chiesa*, a patriot who, just like *Cesare Battisti* and *Nazario Sauro* was executed for treason by the Austrian military. Similarly, Veneto celebrates the *Alpini* military corps, who fought on the Austro-Italian front. Friuli-Venezia Giulia features among its first twenty street names *Ippolito Nievo*, a local writer who strongly believed in a united Italy and wrote a novel about it. The seven *Fratelli Cervi* were part of the *Partigiani* in Emilia and were executed by the Nazi. *Gabriele D'Annunzio*, a famous writer born in Pescara is featured in Abruzzo. *Giustino Fortunato*, included in the twenty most frequent names in Basilicata, was a politician who advocated for the development of the south of Italy. Moreover, the 17th century philosopher *Tommaso Campanella* hailed from south Calabria. Sardegna remembers many local notables, among which it is worth mentioning *Eleonora d'Arborea*, a local leader in the 14th century who updated the main group of laws of the region.

Analysis

By looking at street names in Italy, it is possible to interpret how Italy sees itself as a country. Since street names can only be given to people who died at least ten years before (PARLAMENTO, 1927), it is obvious that toponymy nods to the past. Another reason is that cities and towns do not expand as much as they did, for instance, after WWII, so there are fewer streets to be named. Italy places a lot of emphasis on its patriots and politicians, those people who helped shape the country through ages such as the *Risorgimento*, the world wars and the birth of the Republic. Places, cities, rivers and countries are also often honoured with a street name.

There is a lot of emphasis on the world wars period, mainly the first, likely because it was fought on Italian soil and led to the annexation of Trentino-Alto Adige and Venezia Giulia. The emphasis on WWII is caused by the importance of the *Resistenza* from 1943 to 1945, when the war was formally over but most of Italy was occupied by the Nazi forces and gradually liberated by the Allies, while the *Partigiani* resisted to the occupation.

In a strongly catholic country, saints, popes and religious people in general are also widely featured among street names. In opposition, scientists get a comparatively smaller recognition. The Italian language served as a uniting factor for a country that is only 150 years old: this is why literati are largely celebrated in roads and squares. Artists and musicians are also largely featured, highlighting the prominent role of Italians in art in the past centuries.

Concluding remarks and future developments

This article sought to analyse street names. It looked at the first 100 street names by occurrence in Italy and discussed their various and overlapping categories. It also observed the differences among regions for the first 20 street names. The analysis tried to summarise the themes emerging from the discussion.

The study of street names in Italy proved to be a very interesting topic. There is scope for further analysis, for instance at the municipal level in larger cities. It could be interesting to associate the street name to the actual position of the street instead of the municipality as a whole, similarly to what was done by Biermann *et al.* In this way one could observe whether street names are located near street names of the same category (*e.g.* a neighborhood in Rome features street names of European cities) or if the most significant street names are located in the town or city centre (*e.g.* street names such as Roma and Garibaldi are often given to the high street or the main square). Moreover, a further strand of research at the municipal level could be the analysis of name changes over time, for instance to substitute controversial street names after the end of Fascism or to allocate a street to a local notable who died recently.

The data provided by ISTAT proved really useful and easy to associate with the location data of each municipality. It would be even better if it was better standardised and associated with the actual position of the street. OpenStreetMap, being an open-source database, could be an useful starting point for an in-depth study of the street names of a city. In terms of standardisation, a future update of the existing data or a new release after the next census data is published should be expected.

Acknowledgements

The author would like to thank the working group behind this article: Alessandra Reale (Istat) for the great help in retrieving and analysing the data; Giovanni Alfredo Barbieri (Istat) for sparking the idea of this work; Federico Benassi, Marianna Mantuano and Maria Rosaria Prisco (Istat) for the fruitful discussions.

Abstract: The paper proposes a new perspective in the design process of tailored development policies via the innovation boost. Stemming from the current debates on regional diversification together with the emerging role of the city in pursuing local innovation ecosystem, the aim is to explore new development policy configuration in which the evolutionary framework prompts the response of different territories to continuous shocks. The relevance lies in bridging Resilience, as an ongoing process of change rather than a recovery to a (pre-existing or new) stable equilibrium state, with Diversification, as a leverage of regional resilience to absorb shocks, and Evolutionary Theory based on “continuing and progressive change”. In this perspective, the innovative aspect stems from conceiving Transition Management (TM) as a keen strategical approach to translate the combination (Resilience, Diversification, Evolutionary Theory) into policy design and implementation. The paper is a place to present the TRENd project expected to construct a platform on the basis of capturing resilience and evolutionary path as policy design factors to push forward the state-of-the-art of approaches to innovation policy. This paper introduces the background and rationale of the TRENd project, analysing the academia’s discussions on the S3 implementation in EU regions to find the existing gaps in the current EU Cohesion Policy. It then presents the TRENd approach, discussing its objectives, methodology, conceptual framework, and implication. Finally, it draws a brief conclusion and offers suggestions for the upcoming research activities.

Keywords: TRENd project; transition management; resilience; diversification

Introduction

A stark spatial development unevenness throughout the EU regions, which has been widening, has put the efficiency of the current EU Cohesion Policy under question. As the graph below shows (Figure 1), there is a considerable variation in the regional GDP per capita (in terms of purchasing power standard) both in the EU and within the Member States. Pushing the reforming process of Cohesion Policy forward, therefore, proves to be an urgency for the post-2020 regional policy programming for creating new reliable industrial paths that represents a crucial challenge for both first-tier and lagging regions, and shift from structural-change oriented programming methodology to one with an evolutionary perspective. This paper intends to introduce a new perspective in the design process of tailored development policies that are more adequate in responding to local needs via the innovation boost. With this new perspective, it is aimed to respond to the current debates concerning the post-2020 EU Cohesion Policy programming which have focalised around the following issues (Bachtler *et al.* 2017):

- “Innovation ecosystem” is increasingly aspired by cities and regions alike. This is due to the ongoing structural change across the EU that requires a different policy and institutional focus on “ecosystems” of open, interconnected, cooperative multi-stakeholder networks for developing strategic partnerships. Such an ecosystem is critical to respond rapidly and flexibly to continuous technological, market and social changes during the structural change;
- The environment conducive to the development of innovation ecosystem must be tailored to adapt to specific national, regional and local contexts. Meanwhile, in order to be adapted to the actual needs of different territories, policy packages need to be designed and delivered with an integrated and coordinated approach at national, regional and local levels;
- Development strategies that are differentiated or place-based are badly needed especially at local level to promote adaptation to the specific shocks on regional economies generated by globalisation and market integration require.

Figure 1: Variation of regional GDP per capita within EU Member States in 2017 (in PPS, EU28 = 100).
Source: Eurostat (2017).

To curtail these economic disparities, the EU regions are challenged to develop their growth trajectories in a way to avoid the “me-too effect”: the intention of underdeveloped regions to adopt smart specialisation strategies (S3) – derived from more developed regions – which are too ambitious for their potentials (Bevilacqua *et al.* 2015).

In a very short time, S3 has experienced an extraordinary success becoming a policy hit from academic concept. It represents a suitable example of “policy running ahead of theory” (Foray, David, & Hall, 2011). A posteriori, an analysis on the first wave of RIS3 implemented across the European Regions, Capello & Kroll (2016) identifies a manifold group of “fragilities” which impedes S3 to fully address its objectives across both wealthy and lagging regions.

1. Smart Specialization agenda fails to provide a suitable answer for regional contexts endowed with weak levels of connectedness, entrepreneurial spirit, size in terms of

- market potential, industrial diversity, quality of local governance and a critical mass of capabilities to develop collective learning processes;
2. From the first evaluations of RIS3 plans, emerges a widespread lack of capacity for the identification of new related activities which impedes to diversify the technological domains around local historical specialization patterns. The authors warn that in many backward regions there is an increasing tendency of “lock-in”. Regional Authorities face difficulties in upgrading the quality of existing specialization through a creative and appropriate diversification process.
 3. Taking into account the Italian lagging regions, the two authors raise doubts about the appropriateness of specialization patterns for the future development of these regions, traditionally characterized by few or no local research institutions and with no critical mass in high-tech activities.
 4. Despite it is desirable to relocate peripheral regions into the global value chains, sometimes this is out of the local policy makers’ sphere of control. The presence of Multi National Enterprises (MNE) in those regions is limited to a few subsidiaries which are not able to draft their own strategy which, conversely is set by international headquarters placed in different regions.
 5. Considering local Small and Medium Sized Enterprises (SME) with a weak absorptive capacities and creativity, the only actors able to take part at the regional strategy making process are the stakeholders in local science.
 6. The authors warn also front-runner regions can have difficulties to target effectively the EDP. The choice of priorities can be very limiting when the regions are endowed with a wide number of specialisations.

In sum, the authors conclude that “the smart specialization strategy has failed to explain concretely how the concept could provide a common political rationale for a socio-economically and territorially diverse set of regions and nations facing different place-based challenges and different innovation modes, hence, quite legitimately, different general policy agendas” (Capello & Kroll, 2016). Consequently, the endeavour of the EU Cohesion Policy to pursue a change-oriented methodology through a new regional innovation policy has been nuanced by continuous shocks and crises. These, in turn, increased regional and territorial disparities across the EU.

As debated, the urgency to adopt game-changer regional policies is an issue perceived by both wealth and lagging regions. Regarding the translation of the current EU Cohesion Policy, on the one hand, the first-tier regions used to be highly specialised in certain sectors, putting themselves at risk of becoming path-dependent and potentially victims of “lock-in” phenomena. In this respect, we recall the “cluster lifecycle” approach (Fornahl & Hassink, 2017, Pronesti & Bevilacqua, 2018). On the other hand, the lagging regions are exposed to risks of multiple nature (Annesi *et al.* 2018). Those regions would eventually cope with the need of transforming risks into opportunities in compliance with the window of locational opportunity (WLO) approach.

In this respect, the robust branch of literature concerning the Evolutionary Economic Geography (EEG) becomes useful to this narrative since it points out the need to discover a “novelty” intended as a new, promising set of economic development trajectories. In particular,

“evolutionary economics deals with the long-term processes of changing economic structures, more in particular with the increasing variety of technology and organisations, and with the strategies of economic actors to adapt to changing structures, that is strategies to survive” (Lambooy & Boschma, 2011. P.113).

This paper adheres to this EEG backdrop constructing an improved approach to the design of regional innovation policies in the post-2020 EU Cohesion Policy reforming process. This preliminary analysis explores how the structural change – largely advocated in the EEG view – can be addressed at a strategic regional policy level. Therefore, we recall the most recent milestones in this literature branch.

Capello and Lenzi (2018) propose three pathways towards the new path creation, including creation, diversification and upgrading (*ibid.*) as is shown in Table 1. Their interpretations are based on the conceptualization of three main archetypal innovation patterns: “science-based pattern”, “creative application pattern”, “imitative innovation pattern”. In their framework, they emphasize a pillar of the EEG, the path dependence as it “affects structural dynamics and therefore the possibility to move from one trajectory/paradigm to another, and how such moves can occur” (p.5).

Table 1: Creation, diversification, upgrading and regional learning trajectory dynamics: indicators. Source: Capello & Lenzi (2018).

Pathway	From Basic to applied science trajectory	From applied to basic science trajectory	From informal to formal application trajectory	From passive to active imitation trajectory
Creation	Making the best use of existing excellence niches in applied sciences <i>Indicator: no GPT patents for capita</i>	Making the best use of existing excellence niches in basic sciences <i>Indicator: GPT patents for capita</i>	Making the best use of technological niches <i>Indicator: Patents for capita</i>	Attracting new economic (MNC) activities <i>Indicator: FDI penetration rate</i>
Diversification	Emerging research activities toward basic science fields <i>Indicator: Continuity of the knowledge base</i>	Enlarging research activities toward basic science fields <i>Indicator: Originality of the knowledge base</i>	Enlarging local production towards technology-oriented modes of innovation/industries <i>Indicator: Technological diversification</i>	Enlarging local activities to related ones <i>Indicator: Related variety in local sector</i>
Upgrading	Enriching the knowledge base in basic science fields <i>Indicator: Specificity of the knowledge base</i>	Enriching the knowledge base in basic science fields <i>Indicator: Generality of the knowledge base</i>	Formalizing the knowledge base <i>Indicator: Citations received per capita</i>	Redirecting local production to more complex goods <i>Indicator: GVA in (medium) high-tech sectors</i>

Note: FDI, foreign direct investments; GPT, general-purpose technologies; GVA, gross value added; MNC multinational cooperation.

All in all, the authors emphasize the multidimensional nature of the evolutionary process the regions need to change their economic structures. Consistently, the following section proposes the research background to unfold a novel regional policy approach needed to support the diversification.

Research Background: Transition with Resilience for Evolutionary Development

As debated the academics from the EEG group seek to find out policies successful to accomplish what policy makers request: “regional diversification” as a strategy towards the path creation (Neffke et al. 2011). According to Boschma (2017), the diversification patterns in EU occur upon related and unrelated pathways. In this respect, we recall the “proximity” (Boschma, 2005) along with “the

related variety” (Frenken et al. 2007) as significant milestones in the economic geography studies. Up to date, the latter has been the centre of an extensive literature that emphasises the opportunity to develop economic linkages on industries related to the existing portfolio. On the one hand, the related diversification is found to be a more common phenomenon in regions (Boschma et al. 2017), indeed is one of the rationales underpinning cluster policy (Porter, 1990). On the other hand, the unrelated diversification seems still uncharted in terms of policy guidelines, monitoring/evaluation and spatial outcomes.

The strategic approach to regional diversification has been the object of several debates in both academic and policy arenas. A novel strand of literature recalls the transition management (TM) to explain the “reorientation of existing functions in terms of forms and nature, prompting a change in their main organizations, arrangements, aim and scope” (Capello and Lenzi, 2018). In this view, the innovation has to be considered as an outcome of “bricolage” (Boschma et al. 2017) where all actors (e.g. quadruple helix) contribute to share and recombine resources towards a new path creation.

The TREnD (Transition with Resilience for Evolutionary Development) research project drafts from the preceding MAPS-LED (Multidisciplinary Approach to Plan Smart Specialization Strategies for Local Economic Development) project, which pointed out the territorial dimension of innovation in Smart Specialization Strategy (S3) steering process and how S3 can be translated into spatially-oriented local development policies. Despite the novelty of the S3 concept, MAPS-LED highlighted how S3 implementation process needed an evolutionary approach to face continuous changes, crisis and shocks. Accordingly, the TREnD project reveals the need to diversify regional economic portfolio, which is deemed crucial by EU regions. The most advanced regions tend to minimize their own extent of being “path dependent” and so preventing the hazardous risk to fall into the “lock-in” phenomena. At the same time, the lagging regions seek to adopt the S3 towards filling the gap with their wealthier counterparts.

Plenty of evolutionary economics strive to explain the creation of novelty otherwise known as new (industrial) “path creation”, which is understood as:

“... an iterative construction process where networks of distributed actors jointly create new market segments and user profiles, adapt regulations, lobby for subsidies, or define new technical standards and thereby ultimately create the conducive environment that helps a new industry develop and prosper in a region (Garud and Karnøe, 2003, Garud et al. 2010)” (Boschma *et al.* 2017).

While Capello and Lenzi (2018) carried out a strategic analysis on the terms seeking to explain the interplay between knowledge base and territorial assets, Boschma and others (2017) elaborate on the difference between regime and niche creation, which does not have to be confused with unrelated diversification. Within this backdrop, they point out four types of regional diversification (Table 2). They describe each type of institutional work needed (maintenance/creation), the risk to be borne, the key actors to embed, and the interplay between local and global value chain.

In sum, there exist gaps in the existing knowledge on regional diversification, and bridging it with transition management looks promising and viable. In fact, Boschma and others (2017) discuss the distinction between Transition Studies (focusing on niches contending the regimes) and the Evolutionary approach (focusing on the novel sector in a defined territory). The bridge between those two narratives can disclose important but still uncharted research avenues. Second, the spatial

outcomes of regional diversification remain largely uncharted. Finally, the policy approach concerning lagging regions in view of path creation would add significant value to the policy agenda.

Table 2: Types of regional diversification. Source: Boschma and others (2017)

FUNCTION	DEFINITION
Replication	most conservative diversification logic in which a region develops related industries by adopting a technology that is institutionalized in a global socio-technical regime
Transplantation	a diversification trajectory in which a region develops an industry unrelated to its knowledge base and institutions, yet based on adopting a regime technology from the global system
Exaptation	diversification logic where new applications are discovered for existing knowledge or technology
Saltation	concept of saltation leading to a new niche would refer to an innovation that is not only new to the region but also new to the world.

The TREnD Approach

Conceptual Framework

The TREnD project's rationale is to provide critical mass to manage the continuing and progressive change by building a logical framework featuring metrics of Resilience and TM. In this view, the project is expected to move forward the current state of the art by building an “innovative bridge” among the nature of diversification, the extent of “resilience and TM” processes implemented.

The overall objective is twofold: 1) to adjust the exiting evolutionary perspective for a more integrated spatial planning able to coordinate the regional and the local level for making and delivering tailored development policies with a place-based approach; and 2) to introduce an evolutionary perspective to the post-2020 EU Cohesion Policy by constructing an improved approach to the design of regional innovation policies that incorporates transition management (planning) and resilience building (governance). Such an objective stems from the fact that, facing the ongoing social and economic transformations, a region or urban system's ability to respond to crises and shocks by changing its structure and function is critical to sustainable local development. To strengthen this ability, regional economic resilience needs to be leveraged through adopting and implementing Transition Management (TM) strategies and developing new growth paths, namely, economic diversification.

Regional economic resilience has been heralded as “the ability of a system to adapt, reorganize itself and change its path of growth” (Kakderi & Tasopoulou, 2017; Martin, 2012). This definition, among others, embeds the Schumpeterian belief which rejects equilibrium-based economic approaches. In fact, the concept has recently been interpreted in an evolutionary perspective “as a permanent process of adjustment and change, and the positive contribution of change to structural improvements” (Wink, 2014). Alike the cluster life-cycle, resilience-building processes can be interpreted as continuous trade-off between a shift in the short run towards unfolding a new growth path, namely the “adaptation”, and the capacity of the system to adapt in the long term, marked as “adaptability” (Pike, Dawley & Tomaney; 2010). These two concepts along with the knowledge base inherent of the

territory, seem critical to explain the nature of the regional economic variety, namely unrelated/related (Boschma, 2015). In fact, regional economic variety works as a “shock-absorber” and it is directly proportional to resilience at diminishing the local-input-output linkages (Martin, 2012) and, in turn, the exposure to the risk of “path dependency”. Despite a growing interest on the regional economic resilience, and its relevance in explaining “the capacity of a region to develop new growth path” (Boschma, 2015), the concept deserves to be better defined in respect with a time framework regarding the resilience processes, with their legacy from the past trajectories, their place-based metrics, their impact measurements.

Based on the above considerations, the aim is addressed to construct a ground-breaking approach to meet the need of EU regions to diversify regional economic portfolio. This is proposed to be achieved by deploying TM as a fundamental instrument to translate the combined Resilience-Diversification-Evolution logic into policy design and implementation. To achieve this objective, the research project seeks to:

- identify and examine the factors enabling or hindering the TM strategies at a governance standpoint;
- assess the territorial features critical to enable a resilient-building process;
- unveils the unexploited potentials for “re-shaping trajectories” disclosed through the windows of local opportunities due to the external shocks to which regions are continuously exposed.

In order to achieve these goals, the TREN project, grounded in its multidisciplinary network and partnerships, is designed to carry out joint research activities on the following topics:

- Innovation in transition management and resilience concept from an evolutionary economy lens;
- Innovation in transition management and spatial planning through a territorial dimension approach;
- Resilience Capacity building in the aftermath of external shocks.

The ultimate goal of this research project is to construct an Open Access Toolkit (OpenAT) for the European Post-2020 Cohesion Policy in response to the widening spatial development disparities across Europe. Dedicated to policy-makers and policy-users (e.g. regional authorities, academics, stakeholders and urban advocacy groups), the OpenAT is expected to enhance the regional administrative capabilities to trigger, implement and manage Transition Management (TM) strategies towards resilient-building processes. To better support the implementation of TM strategies at different regional/local levels, the OpenAT will provide a set of indicators regarding: 1) context, 2) result, and 3) performance. In a broader sense, the OpenAT will serve as a “capacity building” platform able to not only spread knowledge about regional economic diversification, but also spur social innovation.

Grounded in a robust literature review covering evolutionary economics, resilience, transition management and spatial planning, the TREND project adopts a mixed method research approach. Quantitative data, including statistical, geographical and demographic data gained from official and public statistical data warehouse at different geographic levels (city – regions – country – EU- non-

EU), are interpreted with the support of qualitative data, gained through on-line and face-to-face interviews of public and private stakeholders; and by means of surveys, such as observation, reports and inquiries.

This mixed method research approach is crucial to case studies, which are to be developed through data gathering (e.g. interviews and surveys) and data analysis (e.g. social network analysis). It is also supportive of spatial analysis to help gauge the effect of the “space/place” on related/unrelated diversification through indicators, previously deducted from literature. These indicators will be later projected into GIS mapping database to help link the theoretical framework to the territorial/urban dimension of Cohesion Policy in an evolutionary perspective.

Theoretically, the TREN project bridges 1) Resilience, perceived as an ongoing process of change rather than a recovery to a preexisting or new stable equilibrium state (Simmie and Martin, 2010), 2) Diversification, defined as a leverage of regional resilience to absorb shocks, and 3) Evolutionary Theory based on continuing and progressive socioeconomic change (Krugman, 1996). The logic is, based on the evolutionary theory. Socioeconomic change is in essence an evolution process whereby regions increase their capacities to mobilize resources and knowledge in adapting to their changing socioeconomic environments (Sanderson, 2015). To effectively respond to crises and shocks engendered by the ongoing structural change across the EU and transform crises and shocks into opportunities, the regional capabilities in triggering, implementing and managing Transition Management (TM) strategies need to be reinforced by diversifying regional economies. TM therefore can be conceived as a medium for Entrepreneurial Discovery Process (EDP) by deepening the understanding of S3 in shaping the policies for regional economic development. What is crucial in developing transition agendas, it is critical, *mutatis mutandis*, in the diversification process, for regions to harness opportunities while absorbing shocks, thereby driving “resilience-building” processes. All in all, the TREN project puts forward an evolutionary development concept that integrates transition management and resilience building in various territorial contexts towards a reforming process of the post-2020 Cohesion Policy.

The TREN theoretical framework envisions the TM strategies as “co-evolving processes which progressively build up toward a revolutionary change on the long term” (Rotmans et al. 2001, Frantzeskaki & de Haan, 2009, Loorbach 2010). Originally adopted as a strategy to manage the “transition” towards a more environmental-friendly development model (e.g. decarbonisation, reducing emissions, etc.) in cities and regions, TM is adopted within the scope of this research project as a tailored approach to drive the diversification through the resilience-building process. In this backdrop, the regional economic resilience is conceived as “the ability of a region or urban system to change its structure and function rapidly and successfully in response to a shock” (Simmie and Martin, 2010). This definition marks a theoretical progress, as resilience is popularly perceived as the “capacity of a systems to retain its organisational structure following perturbation of some state variable from a given value” (Perrings, 1994, p. 30). Simmie and Martin (2010) have the merit to embed an evolutionary perspective in the realm of resilience. They define “adaptation” and “adaptability” as two key concepts:

Adaptation refers to the adaptive capacity of regions within their own strong specializations and established paths. This so-called “positive lock-in” brings benefits to a region in terms of positive local externalities, but is perceived to undermine the “adaptability” of a region simultaneously: the prime focus on adaptation and reproduction of existing local structures

would negatively affect the ability of regions to develop new pathways. This “negative lock-in” may arise due to a lack of potential local sources of recombination but also because of myopia, inward-looking local networks, institutional lock-in, and sunk costs. (Xiao et al. 2017, p. 17)

The rationale behind TM aims at adjusting and adapting towards long-term solutions and defines it as “a form of intelligent long-term planning through small steps based on learning and experimenting” (Rotmans and Loorbach, 2010). By deploying an explorative and design-oriented approach, the TM moves at the crossing of complex systems with governance. It tends to generate participative co-evolution processes towards triggering broader scale innovations through small-scale actions. However, its complexity lies in the multiple domains, scales and levels at which transitions occur. In compliance with a cooperative ethos, the TM approach aims at engaging different actors in the context of policy making. In the EDP process likewise, the so-called “front runners” (individuals, companies, local governments) are considered catalysts for supporting the transition process by spreading in wider circles a shift in mind-set labelled as “transition visions”. Those front-runners are invited to take part in the “transition arenas” where stakeholders intervene upon a multilevel networks logic. In the early phase, the arenas are entitled to develop transition agendas (strategies and tactics) according to common beliefs shared by smaller groups of participants. Afterwards, broadening participatory process, they set operational and reflexive activities under a cyclical framework. During each cycle, TM processes tend to contend with the regime assumed as “the dominant culture, structure and practice embodied by physical and immaterial infrastructures” (Loorbach, 2007) through four main steps of the cycle: pre-development, take-off, breakthrough and stabilization. TM processes generally take place under five phases (Table 3) (Frantzeskaki et al. 2011).

Table 3: Transition Management phases. Source: Frantzeskaki et al. (2011)

Phases	Key activities
1. Preparation & Exploration	<ul style="list-style-type: none"> A. Transition Team Formation B. Process Design C. System Analysis D. Actor analysis (long-list and short-list of relevant actors) incl. interviews E. Set up Monitoring framework
2. Problem structuring & Envisionaning	<ul style="list-style-type: none"> A. Transition Arena formation B. Participatory problem structuring C. Selection of key priorities D. Participatory vision building
3. Backcasting, Patways & Agenda Building	<ul style="list-style-type: none"> A. Participatory backcasting & definition of transition paths B. Formulation agenda and specific actions
4. Experimenting & Implementing	<ul style="list-style-type: none"> A. Dissemination of visions, pathways and agenda (transition narrative) B. Coalition forming & broadening the network
5. Monitoring & Evaluation	<ul style="list-style-type: none"> A. Participatory evaluation of method and content (process) B. Reflection on vision & strategy C. Monitoring interviews

TM processes tend to promote the emergence of niches defined as “potential sources of radical system changes (e.g. establishment of a new regime), TM aims to provide niche actors with the space and

resources for experimentation” (Rauschmayer et al. 2015). Consequently, “such niches protect radical innovations against market selection and institutional pressures from a regime and allow actors to learn about these novelties and their uses through experimentation” (Boschma et al. 2017).

Expected Results and Implications

Through a continuous refinement of the conceptual framework and assessment methodology for resilience building and evolutionary economy into a TM tailored-planning, the TREnD project will be able to correlate the theoretical approach stemming from the evolutionary economy topic with the necessity to give a practical explanation of resilience and transition in terms of indicators and metrics (Figure 2).

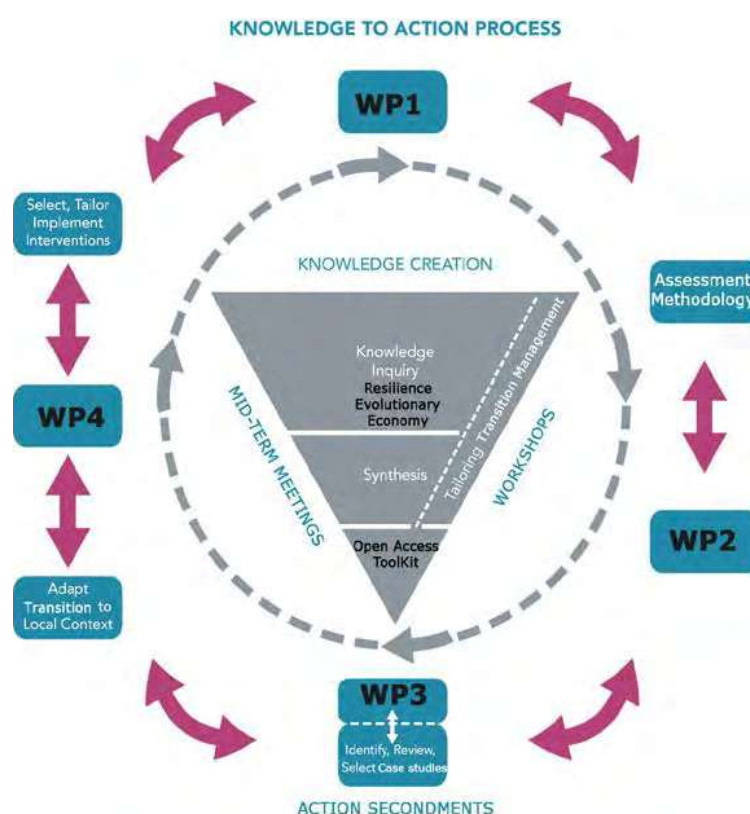

Figure 2: The work flow from knowledge generation to action. Source: The Authors.

The TREnD research project is first expected to produce a novel concept encompassing “resilience-building” processes and TM strategies based on the Evolutionary Economy’s assumptions. Grounded in the data gained through retrospective longitudinal studies addressing ongoing trends and, in a broader time framework, past or current transition trends both in the EU and US, the framework will identify main challenges, hindrances and drivers of transitions and resilience-building processes. The characterization of regions will be defined with a set of socioeconomic indicators concerning the past development trajectories (e.g. path dependency) and the local degree to shift towards a related/unrelated diversification. In so doing, it will pave the way to pursue ground-breaking objectives, to be achieved through a rigorous and evidence-based empirical work. With an evolutionary perspective, the analysis will be based on retrospective longitudinal studies addressing ongoing trends and, in a broader time framework, past or current transition trends both in the EU and US.

Second, the TREnD project's theoretical framework is to be linked to the territorial/urban dimension of the Cohesion Policy in an evolutionary perspective. In so doing, it will help unveil the impacts of the territorial aspects in regard of resilience-building processes towards new equilibria, namely, new territorial development patterns and trajectories. Much emphasis is to be put on governance aspects regarding the resilience building process, including local networks, transition arenas, and role of external actors. Meanwhile, the place impact on the diversification process is to be gauged by means of spatial analyses.

Third, an evidence-based and users-oriented framework is to be created, based on the selected case studies, with respect to the spatial factors and governance affecting the opportunities to set up local "path-reshaping" processes. The window of locational opportunities (WLO) disclosed in the aftermath of shocks are to be fully exploited to design tailored TM by analysing case studies with the "backcasting" approach. This will lead to the provision of a set of evidence-based guidelines on how to transform external shocks into latent opportunities to re-orient local development trajectories.

In a certain way, the starting point in designing the innovative bridge between regional economic resilience with transition is to apply a local/urban perspective to disclose the forces able to drive the evolutionary development at regional level. Finally, the OpenAT is to be constructed based on the interpretation of end-user's feedback and information, and on this basis the metrics of TM are to be upgraded and the resilience building to be implemented and tested through the OpenAT.

Conclusions

In the post-2020 European Cohesion Policy, policy packages need to better integrated and coordinated and delivered at national, regional and local levels to curtail increasing regional disparities. Therefore, a strengthened multilevel governance conducive to a more reactive and responsive public administration is largely needed in a knowledge-based society. This is because, public intervention is important to increase higher impact R&I outputs, leverage more knowledge and ideas converting into products and services.

This high experimentalism endeavour by TM processes seems to fit well with the need of cities and regions to drive economic diversification and discover new development trajectories. However, the extremely adaptive nature of processes, the long-term period framework (minimum 25 years), and the large variety of variables affecting the strategies might constitute relevant flaws of the existing TM concepts. In fact, TM processes do not show explicitly "clear-cut objectives or normatively defined principles to steer the process of transition dynamics towards a more sustainable world" (Rauschmayer et al. 2015). Finally, taking stock of past experiences, the large scale systemic changes due to TM still seem questionable (Loorbach, 2010). These are all the gaps in the existing concepts concerning transition management to be filled by the upcoming research activities of the TREnD project.

The TREnD project focuses on the creation of an open access toolkit on the basis of an interactive platform which shares data with different users, policy makers and end-users. The objective of knowledge transfers into actions created by research activities will be used in order to provide new services for local communities of entrepreneurs, local policy-makers and public authorities. The project addresses a theoretical framework aimed to bridge regional economic resilience with

Transition Management in an evolutionary economic perspective. Including the evolutionary approach toward the discovery of “novelty” is proposed through a strategic endeavour to challenge the current regime to disclose “niche markets”. In this view, the TREN D project will significantly contribute to the manifold literature streams which discuss the diversification upon the concept of related variety, relatedness, and niche/regime narratives. Unveiling the real forces/agents that at urban scale work in creating different forms of adaptation is supposed to reinforce the regional diversification towards an evolutionary dimension of Cohesion Policy.

Acknowledgements

This research work is part of the TREN D research project (Transition with Resilience for Evolutionary Development), which has received funding from the European Union’s Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No. 823952.

Spatial distribution characteristics of cultural tourism in historical regions: a case of Shaoxing Ancient City based on POI data

Tong Cai ¹

¹ *Tongji university, tong.cai@qq.com*

Abstract: As an important industry to achieve sustainable economic development, the role of cultural tourism has become increasingly prominent. The concentration and dispersion of various functions in the urban often reflect the distribution of different activities. It has become a crucial topic to consider how to respond to changes of urban function and balance the regional cultural protection and tourism economic development in historical areas for urban studies. In order to realize the comprehensive management and dynamic supervision, the article provides a method for analyzing cultural tourism in historical regions by using big data. In this work, we obtain the POI data of Shaoxing ancient city in China from Gaode map, combine them with GIS spatial analysis function and summarize the spatial distribution. In order to quantitatively identify the urban single and mixed functional area, the article also illustrates a way to reclassify the POI data and use the RGB color method to visualize the functional diversity index. The result shows that (1) With a tendency of decreasing from the road to the periphery, Shaoxing Ancient City function is relatively distributed in the marginal areas rather than in the central parts, especially in the traffic distribution square. (2) It is confirmed that the larger the functional density and diversity, the higher the public awareness of the historical blocks in Shaoxing Ancient City. (3) From the perspective of functional mixing, cultural function shows a high ability to be mixed with the tourism, but the spatial distribution of the two is still relatively discrete, which has not yet formed a good collaboration in Shaoxing Ancient City. (4) Compared with the network electronic map, the quantitative identification method provided by this study is more precise and accurate.

Keywords: cultural tourism, distribution characteristic, POI data, historical region

1 Introduction

Historical region is the birthplace and carrying heritage areas of special city's memories with a profound cultural background, also attaches great importance to residents' daily life. For many years, historical regions have always been a focus and difficulty in the protection of urban cultural heritage. Under the guidance of local government, most ancient cities are currently actively protected through developing cultural tourism, which seems to be a main trend to realize the regeneration of regional vitality and cultural revival. However,

as a dynamic cultural heritage, changes in urban functions brought about by tourism economic development cannot be avoided. Cultural tourism promotes urban economic development, but also brings a series of challenges including government's or resident's supervision, proportion of tourism and non-tourism economic, the choice of profitable subjects, urban development intensity norms and so on.

China, with thousands of years of history, has its own unique historical cities, regions and streets. Although local regional departments have tried to take various protective measures, that cannot avoid some embarrassing situations happening in these areas. We could easily find that some historical places are protected as a cold exhibition hall with no popularity and vitality, while others are urgent for "high-speed" economy developing without control. Excessive commercial development will accelerate a spread of "gentrification" or destroy truly historical landscape, regional context and genius loci. Eventually, it would probably be a biggest trigger of changes and differentiation in urban social communities (Zhang, 2017). How to search for a balance between protection and tourism development in accordance with changing functions in ancient cities? How to make history and culture live on through planning management? Apparently, finding a method to identify good ways of sustainable urban development has always been a crucial topic to consider in recent studies.

However, most of present traditional historical planning, relying on past statistical data and field investigation with high waste of labors, fees and times, are unable to quickly obtain the accurate spatial location or boundary information. With the deepening of the information network, many scholars have tried to explore the spatial distribution characteristics and laws of urban active points within the city through big data (Chi, Jiao, Dong, et al., 2016, Ning, 2016). In recent years, there have been more and more urban studies based on the data of POI (Point of Interest), which provides a new idea for functional identification for historical regions and spatial distributions analyzing between historical protection and tourism economy in the context of authenticity.

2 Data and methodology

2.1 Research area

This paper is based on the POI data from Gaode map in Shaoxing, China as an example. Shaoxing is one of the most ancient cities all over the world with a long history of more than 2,500 years. In 1982, Shaoxing was listed as one of the first state-list famous historical and culture cities in China with rich cultural heritages, which is called as "a natural museum without walls" until now. Suffering from several dynasties' expansion and evolution, there has been not much changes occurred in urban spatial patterns since Goujian City in King of Yue, even organization of modern cities has influenced traditional landscapes of Shaoxing(Figure 1). This research is focused on Shaoxing Ancient City (29°97' to 30°03'N, 120°56' to 120°60'E), with a total area of about 8 km².

2.2 POI data

The POI data of Shaoxing in December 2018 was obtained in the research. A total of 31,405 POIs were obtained, including 14 major categories, such as catering service, shopping service, science, education and culture service, scenic spots, public facilities, enterprises, etc. Each piece of POI data includes the information such as the name, category, address, latitude and longitude. From the perspective of urban management to be consistent with refined requirements, POI data in historical landscape sites can dynamically observe the city in time with its current description ability of facility locations at a microscopic scale. On the other hand, quantification and visualization of POI data can not only easily analyze quantitative functions of ancient sites, but also better reflect resource allocation characteristics of mixture areas to balance the relationship between urban historical protection and tourism economic utilization.

Figure1 Spatial patterns of Shaoxing Ancient City in dynasties

2.3 Methodology

The paper processed the POI data as follows: Firstly, according to the Gaode API platform, we obtained the all POI data of Shaoxing Ancient City in approximate latitude and longitude coordinate range, and then selected by Excel with polygon frame and using the ArcGIS 10.2 spatial analysis platform. Secondly, we tried to classify specific contents including name, type, address, latitude and longitude, etc. Referring to the definition of administration and public services (A) and commercial and business facilities (B) in “Code for urban land-use classes and Standards of planning construction use (GB50137-2011)”, the POI points that are not related to the research were removed, after which we got a total of 6101 POI data in Shaoxing Ancient City. Finally, POIs were divided into six functions including catering business, enterprises, culture education, hotel accommodation, local-consumer places and leisure-oriented entertainment (Table 1).

Table1 Main information of a POI data coding B023F02NIB

<i>item</i>	<i>details</i>
<i>POI code</i>	<i>B023F02NIB</i>
<i>Name</i>	<i>Landscape Life Square</i>
<i>Type code</i>	<i>060101</i>
<i>Type</i>	<i>Buying service</i>
	<i>Marketing</i>
	<i>Shopping mall</i>
<i>Reclassified function</i>	<i>local-consumer places</i>
<i>Address</i>	<i>No. 6 Yuecheng Beach, Shaoxing City, Zhejiang Province, China</i>
<i>Latitude and longitude</i>	<i>120.581254, 30.02023</i>

In order to facilitate the mixing of statistical functions, the research region was divided into 797 100m*100m grids as a research unit because of the spatial intersection of POI data types. Referring to a nature recognition of each functional unit, the index frequency density and type ratio were constructed to identify the functional

properties according to relevant researches (Chi, Jiao, Dong, etc., 2016). The formula for calculating the degree of functional mixing is as follows: $F_i = n_i / N_i$, $C_i = F_i / (\sum_{i=h}^6 F_i) \times 100\%$.

In this formula, taking POIs of type i as an example, we called it iPOI. n_i is a number of iPOI in a certain research unit. N_i is a total number of iPOI. F_i is a frequency density of iPOI in the total amount. C_i is a frequency density of iPOI, which is a percentage of the frequency density of all POIs in the research unit. To easily analyze the degree of mixture, taken the value of C_i in a research unit more than 50% as a criterion, after which the whole research units were divided into three categories as single-type, multi-type and no-data regions. If the value of C_i in a research unit was more than 50%, the unit could be evaluated as a single land property and determined by a type of POI. If the value of all C in the unit was less than or equal to 50% and larger than zero, the unit could be identified as a mixed property, which was determined by two mainly types of POIs with the largest proportion. If there is no POI in a research unit, the unit could be judged as a no-data region.

3 Spatial distribution characteristics of Shaoxing Ancient City

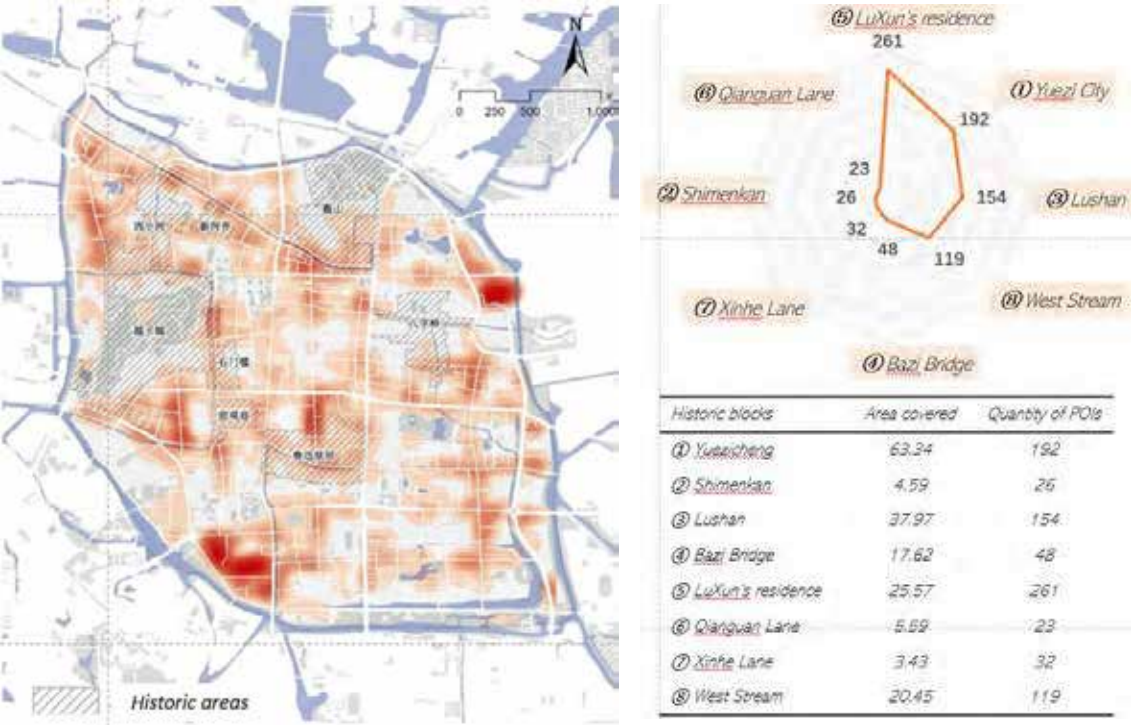

3.1 Overall functions

Based on the GIS platform, the POI point data is superimposed on the road network, water system, and mountain data to perform nuclear density analysis. It is found that the overall function of the ancient city mainly shows the following characteristics (Figure 2):

- the spatial agglomeration showed the characteristics of "large scattering and small concentration". It was obvious to find some structure patterns of scattering points in the center of the ancient city and agglomeration of edge areas. The peak of functional agglomeration density was located at the entrance and exit of the ancient city, such as the intersection of Jiefang Road and Huancheng Road on the south side, Huancheng Road and Shengli Road on the east side, Shengli Road and Huancheng Road on the west side. At the junction of the ancient city area and other areas, it is easy to attract commercial accumulation and different consumption by forming functional intensive regions.
- urban development in series was expanded and distributed along road axes. Density of functional agglomeration showed a gradient decline from roads to the periphery, while main city roads such as Jiefang Road radiate to the east-west was forming clusters around the edge. For example, Fushan Street and Xinjian South Street are clustered around newly built intersection blocks, radially connected by the edge of some historical streets.
- The historical block was surrounded by functional clusters. The higher the level of cognition, the more obvious function agglomeration and infiltration. According to the scope of the Year 2020 historical protection plan announced by Shaoxing Municipal Planning official website, there are eight historical blocks were officially confirmed, named as Yuezicheng, Shimenyu, Lushan, Baziqiao, Lu Xun's residence, Qianguanxiang, Xinhenong and Xixiaohe. As can be seen from Figure 3, every historical block covered a large number of cultural property by attracting accumulation of functions. However, due to the protection policy, the high-density function cluster was close to historical blocks without truly coincidence. Points of interest in a city mainly come from the network electronic map, so that each POI represents some degree of influence and attention. To some extent, the more POI data are gathered, the more intensive the economic, social and cultural activities in the region are and the more recognizable they are to the public. Through the spatial connection tool of GIS, the POI

data are linked with historical blocks. It was found that a total POI data of Luxun's former residence, Yuezhicheng and Jishan are ranked in the front with relatively high public notice, while relevant statistics of other historical districts were far apart. To add that, because Shimen occupies limited area, it was considered together with Yuezhicheng due to geography.

Figure2 Overall spatial distribution characteristics of Shaoxing Ancient City

3.2 Different functional types

Through nuclear density analysis of various functional areas, it was found that different functions was organized as different spatial distribution patterns(Figure 3).

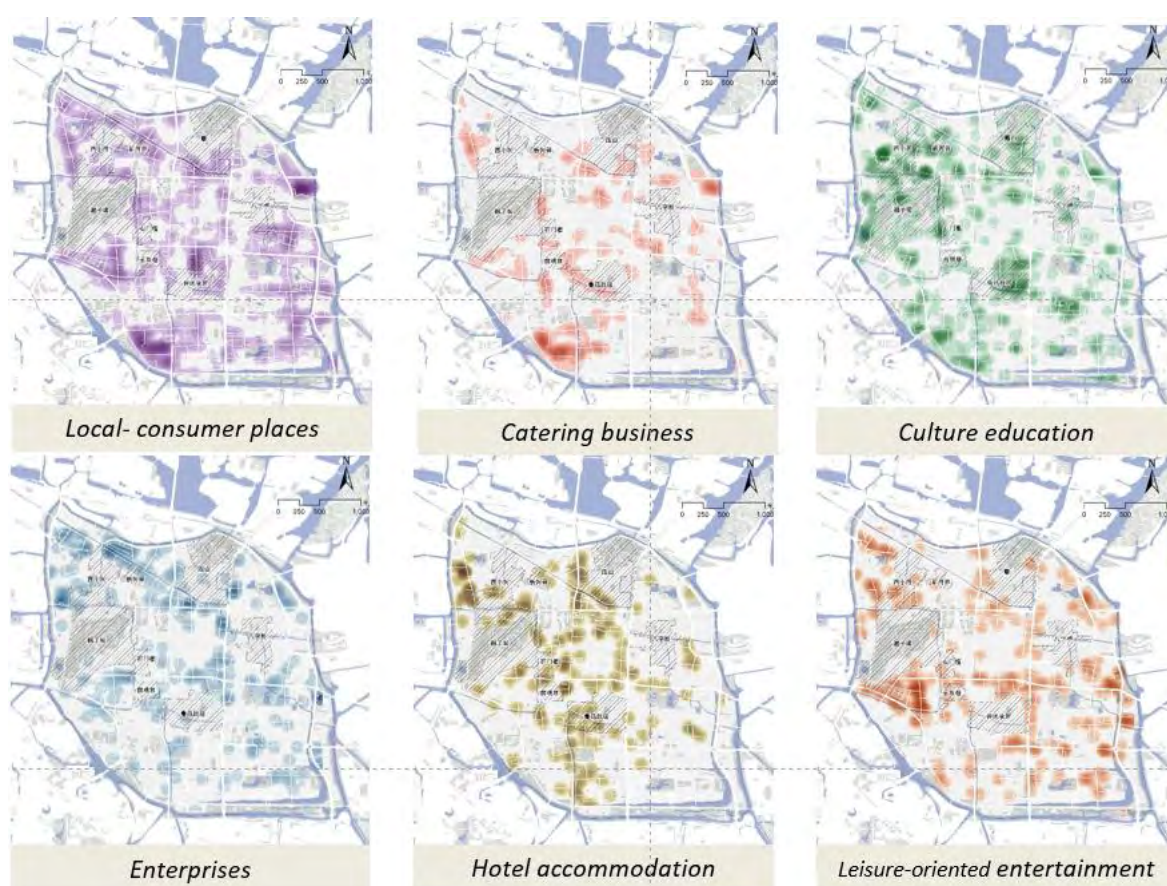

Table2 Quantities of different types of POIs in Shaoxing Ancient City

Catering business were mainly distributed in large shopping malls and characterized by point-like gathering. Catering varieties accounted for more than 60% of local non-local catering, teahouses, Jiangsu and Zhejiang cuisine accounted for about 23% of local restaurants, concentrated in historical districts or old streets. The cluster

was obvious at the junction of Xinhe Lane and Jiefang Road in the north of the company and pattern scattered in other places, which might be led to the reason about classification of logistics and transportation. Culture education includes social groups, education associations, schools, etc. Shaoxing has been prosperous in humanities for thousands of years and has a high degree of integration with historical blocks, but museums, exhibition centers and other functional facilities displayed to the public accounted for a relatively small proportion. Hotel accommodation was mainly located around Jiefang Road, indicating that tourists would more likely to choose main transport streets as a place to have a rest. Comparing with the current situation of land use, it was implied that hotel owners mainly relied on commercial facilities with low compatibility in residential areas. Entertainments for leisure and recreation show a typical characteristics of central distribution and peripheral concentration. Contrary to hotel accommodation, the spatial distribution of local-consumer place was widespread with better compatibility of multi-type land use, because it was mainly located near residential areas aimed at local people.

Figure3 Spatial distribution characteristics of different functions in Shaoxing Ancient City

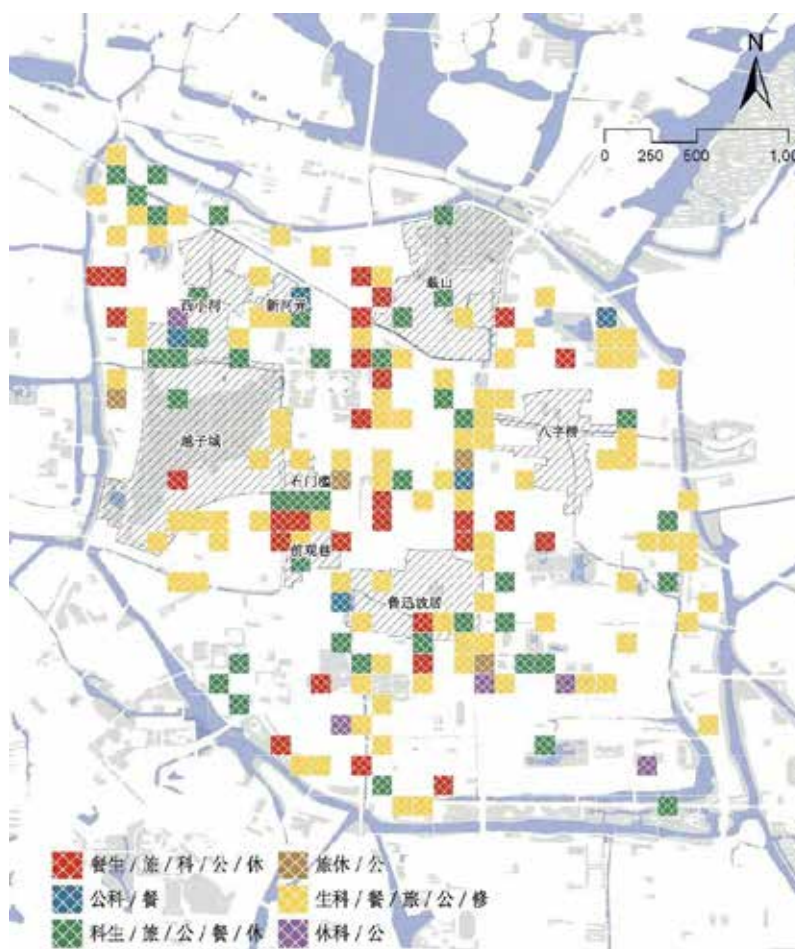

3.3 Units of functional mixing

According to statistics, there are 449 single-type functional units, 177 multi-type functional units and 171 non-type functional located in mountain or water sites. After further quantitative identification and visualization, the specific types of single functional area and mixed functional area can be distinguished.

- A single-type functional unit represents more than 50% of a certain POI type in a research unit, and its functional properties are determined by first-ranked type of POI data. In this paper, there were 6 single-type functional units, namely local-consumer place (54.8%), culture education (20.7%), catering business (15.8%), enterprises (3.6%), leisure-oriented entertainment (3.3%) and hotel accommodation (1.8%). Local-

enterprises, hotel accommodation and other functions is relatively low. It indicates that the former had a high compatibility, while the latter was relatively simple for the crowd.

Figure5 Multi-type functional units in Shaoxing Ancient City

4 Discussion

In recent years, the cultural development of Shaoxing Ancient City has entered a bottleneck period. According to the research report, residents and tourists are not aware of the historical environment of the ancient city as a whole, and the development, protection and display of cultural relics and historic sites are relatively simple (Zhu, Qian, 2018). In September 2018, the "Regulations on the Protection and Utilization of Shaoxing Ancient City" was approved by the Standing Committee of the Provincial People's Congress. The "Regulations" pointed out that there is a contradiction between the actual needs of the protection and utilization of Shaoxing ancient city and urban development, especially the problems of overall, physical state, activation protection and utilization. Therefore, it is imperative to re-examine the specific function use of Shaoxing Ancient City and analyze its protection and utilization.

- Generally speaking, Shaoxing Ancient City presented the spatial distribution characteristics of central distribution and functional agglomeration in marginal areas. Functional agglomeration density decreases from road to periphery gradient. It undertook the collection and distribution of external traffic at the junction of ancient and other areas, and was also a functional agglomeration area with emphasis on development and utilization.

- From the point of view of the protection of historical blocks, Shaoxing Ancient City paid attention to the original ecological protection, based on the living and shopping functions for residents, and there is no large-scale development and utilization. On the other hand, the public awareness of historical blocks is strongly related to the functional density and mixing degree. The public awareness hotspots of Lu Xun's former residence, Cangqiao Street and Shusheng's former residence are more obvious than other blocks, while the degree of functional expansion is low.
- The ancient city had abundant cultural tourism resources and high degree of mixability with other functions, but its development layout was scattered and shows obvious singularity, which had not yet formed the spatial layout of the whole city in series. In the context of the overall ancient city life, governments could try to take science and education culture as the guidance to promote the transformation and development of traditional residential space, and enhance the spatial penetration intensity of historical, landscape and cultural resources and external propaganda.

5 Conclusion

Existing research generally believes that the mixed use of urban functions can guide the orderly development and utilization of cities, increase interpersonal communication, improve regional vitality, and promote sustainable urban development. The complexity of cities and their internal structure make it more and more important to study the distribution of urban population density, and big data provide some new technical means for this theme. However, the traditional land use data is mostly planar and cannot accurately represent the actual situation of regional functional mixing. Based on the quantitative and visual analysis of the POI data of Shaoxing Ancient City, some conclusions could be drawn more easily.

The planning pattern and architectural art of the historical area have formed a unique regional cultural phenomenon (Ruan, Shao, Lin, 2002). Under the principle of urban authenticity, integrity and readability, the protection of historical ancient cities must be carried out. To carry out reasonable updating and utilization, it is also necessary to sort out the correct concept of understanding. Based on the objective data of POI, this paper needs to be further deepened and systematic, especially from the concrete empirical cases to analyze the relationship between social space and material culture involved in urban functional transformation. Only by linking the changes in historical space, cultural values and social consciousness can we truly show the “face”, “character” and “personality” of culture heritage through a good way of tourism economic developing.

‘What else?’: Community Perspectives on Tourism-led Urbanization in Spiti, India

Surajit Chakravarty

Indian Institute of Management Calcutta, schakrav@iimcal.ac.in

Abstract: The remote Spiti Valley in northern India, is experiencing a tourism boom, which, in turn, is fuelling a construction boom in the villages of the region. The region offers a unique landscape – a rocky high altitude desert with splashes of greenery. Rare wildlife can be spotted in winters, with the region under a cover of snow. Perhaps the most important component of the region’s cultural attractions are the monasteries of Tibetan Buddhism. Today the fragile Himalayan ecosystem is threatened by the rapid urbanization and increasing tourist loads. Social structures and cultural practices are under stress. Two questions lead this project. (a) What are the community’s aspirations and concerns with regards to tourism and urban development in the Spiti Valley? (b) Why, despite witnessing undesirable urban outcomes in numerous Himalayan towns, has very little changed in terms of tourism policy in this sensitive region? The study examines attitudes towards tourism in Kaza, a small town in the Spiti Valley, facing rapid urbanization as a hub for the fast-expanding tourism sector. Based on a survey of residents and business-owners (N=420), and in-depth interviews with key informants, the paper reports the principal narratives in the region on the themes of growth and sustainability.

Keywords: Sustainable tourism, Community based tourism, Himalayas, Small towns

Background

Spiti valley (also known as Spit) is located in the ‘Lahaul and Spiti’ district of the state of Himachal Pradesh in northern India. (Figure 1 shows a map of the area.) The town of Kaza is the main administrative center (known as a subdivisional headquarter) in Spiti. The valley can be accessed from two sides. The Eastern route, through Shimla, is an all-weather road that remains open throughout the year. The Western approach, through Manali, is not properly paved. Systems for clearing the snow in winter months do not exist. Consequently the route remains closed until well into spring when the snow begins to melt.

Spiti is known as a high altitude desert. Located at the height of 12,000 feet above mean sea level, Spiti features snow-capped Himalayan peaks, rock formations, wide valleys, lush agricultural patches amidst the dry rocks, pristine lakes, unique wildlife (most significantly the snow leopard), and perhaps most

importantly, solitude and the feeling of having left it all behind. The seabuckthorn plant is grown widely in the area and processed in various formats (soap, drinks, ointments etc.) for its health benefits.

The population is predominantly Buddhist. Monasteries are important social institutions. According to convention the second son of every family is sent to the monastery for religious training. *“The local population (ca. 10,000) belongs to one of the three Buddhist sects Gelukpa, Shakyapa, or Ningmapa, is related by blood, and shares a common Tibetan dialect”* (Mishra et al., 2003, p.595 original emphasis). Figure 2 shows the location of some of the main monasteries in the Spiti Valley. Handa (2014) provides an excellent description of Spiti’s society and ecology in a book-length examination of the region.

The economy of the region has primarily been ‘agro-pastoral’. “The main agricultural activities begin around mid-April with ploughing and sowing, following which the irrigation channels are repaired and the sown fields leveled for irrigating. The fallow lands are also ploughed around this time” (Mishra et al., 2003, p.598). In recent years tourism has risen sharply. In addition to spectacular landscapes of the upper Himalayas mentioned above, Spiti offers options for trekking and adventure sports, magnificent Buddhist monasteries, and a rich Buddhist-Himalayan culture featuring unique food, crafts and festivals. (Figure 3 shows Dhankar Monastery perched on a mountain top at 12,774 feet above sea level.) Numerous hotels and ‘homestays’ have opened up in Kaza and around the Spiti valley. Ancillary services such as tours, travel bookings, taxi and transportation, food and retail have also received a boost. Not surprisingly, Spiti is witnessing a construction boom at the moment as homestays and guest houses race to build new structure, add floors, or simply renovate, in preparation of the tourism boom. Meanwhile the lower Himalayas in India are littered with towns that have become victims of their own success. The larger concern driving this research is the need to break the cycle and find a way to keep Spiti and Kaza from going down the same path.

Sustainability of values, place and practice

Tourism development promises economic benefits for communities, especially in places with few economic resources, but often brings unwanted consequences for society, culture and the environment.

Perhaps more than any other economic activity, tourism has an intricate interrelation with natural and cultural heritage. Tourism depends on the availability and quality of heritage and related resources. At the same time, uncontrolled tourism development may lead to the degradation of cultural and natural heritage, ultimately eroding the potential for sustaining tourism. (Coccossis, 2009).

This relationship has been studied in numerous contexts and is well understood (Cater, 1995; Faulkner and Tideswell, 1997; Garrod and Fyall, 1998; Scheyvens, 1999; Neto, 2003; Coccossis, 2009; Hunter, 2009; Williams and Ponsford, 2009). Tourism activity, if not properly controlled, can easily diminish the value of the natural or cultural resources, from which it is generated in the first place. Garrod and Fyall (1998) inquire whether “the unfettered growth of tourism inevitable kill the goose that so many are hoping will lay them a golden egg?” (p.199). Known as tourism’s ‘resource paradox’ (Williams and Ponsford, 2009, p.396), this idea points to the need for models and practices that promote sustainability.

Several key ideas have emerged in response, such as ‘sustainable tourism’, ‘ecotourism’, ‘carrying capacity’, ‘community-based tourism’, ‘responsible tourism’ and ‘pro-poor tourism’. It is not feasible to conduct an exhaustive review of all the literature on these terms. Arguably the two broad concepts of ‘sustainable tourism’ and ‘community-based tourism’ have received the most critical attention. These are discussed in greater depth below.

By the 1990s, the dangers of unplanned growth were clearly evident in the tourism sector, as were the direct impacts on natural and cultural assets. The need for sustainability - of the resources *and* their long-term business potential – was perhaps felt urgently. In this context, the idea of ‘sustainable tourism’ attempted to bridge tourism promotion and sustainable development (Butler, 1999; Hardy et al., 2002; Cole, 2007; Clarke, 2010; Lee, 2012; Carr et al., 2016; Budeanu et al., 2016; Dangi, 2016). Defining ‘sustainable tourism’ (much like sustainable development) has been a contested matter. To put it succinctly, sustainable tourism aims to develop tourism while preserving the destination’s resource base for future development (Lane, 1994; Hunter, 1997).

Although a seemingly significant step forward in thinking about tourism, the idea of ‘sustainable tourism’ has been critiqued on various grounds. The following issues are the most prominent: (i) lack of a clear definition, (ii) difficulty translating principles into practice, (iii) parameters not easy to measure, (iv) undervaluing the role of the community, and, not least, (v) losing touch with the goals of ‘sustainable development’ (Cater, 1995; Berry and Ladkin, 1997; Garrod and Fyall, 1998; Hunter, 2009; Scott, 2011). These tensions are experienced all the more acutely in developing countries where resources scarcity is already a challenge and institutions of planning and control tend to be weak.

In particular it is important to note that there is broad consensus in literature that for tourism to be successful the local community must be engaged and invested in the planning and management of the destination. This understanding has given rise to the idea of ‘community based tourism’ (CBT). Proponents of CBT see the community - the guardians and stewards of the local tourism resources – as

the principal agents of sustainability, and beneficiaries of the tourism industry. The main objective is to empower communities, through equitable distribution of resources and benefits, by supporting collaborative practices and participatory methods. CBT is considered particularly important for building capacities and capabilities in poorer communities. Faulkner and Tideswell, 1997; Scheyvens, 1999; Simpson, 2001; Byrd, 2006; Salazar, 2012; Matarrita-Cascante et al., 2010; Giampiccoli and Kalis, 2012; Sutawa, 2012; Tolkach and King, 2015; Richards and Hall (2000) summarize the argument for community-based understanding of sustainability.

Communities are a basic reason for tourists to travel, to experience the way of life and material products of different communities. Communities also shape the 'natural' landscapes which many tourists consume....without community sustainability, tourism development cannot be expected to be sustainable (Richards and Hall, 2000, p.1).

Community based tourism has received its share of criticism with doubts have been raised about tokenism in participatory models, distortions in distribution of benefits, exclusion of others by the power elite, political manipulation etc. (Goodwin and Santilli, 2009; Joppe, 1996; Blackstock, 2005). Yet community participation in tourism development is seen as a vehicle for empowerment, sustainability and development.

The existing literatures on both 'sustainable tourism' and on 'community based tourism' miss out on an important aspect of sustainability. Most of the literature sees 'sustainability' (at any level) as comprised of social, economic and environmental dimensions. Durovic and Lovrentjev (2014) have compiled an extensive survey of literature, where each of the three dimensions is explored in depth.

In much of the literature, little attention is paid to the mutually constitutive interactions and interconnections between the three dimensions of sustainable tourism. Sorely missing from scholarship is a deep understanding of how society, culture and ecological systems are bound together *in* places and communities, *through* values, practices and everyday life. Theories and models of sustainability are likely to remain flawed, if the concept is approached as a set of discrete elements, that are measured separately using 'indicators', without appreciating their interconnectedness. This study attempts to show how adopting a socio-spatial outlook to understanding human ecology can help gain insights for the development of tourism.

Tourism in Himalayan towns

The Indian Himalayas are dotted with a number of attractive 'hill stations'. These small- and medium-sized towns (in comparison to metropolitan centers in South Asia) were mainly summer destinations for tourists from the plains. With investment in infrastructure and growing incomes of the middle class the

tourism sector grew rapidly since the 1990s. Unfortunately, while provincial (state) governments continued to push tourism, local governments were unable to keep up with the pace of urbanization. Unplanned urban growth, fuelled by entrepreneurial construction, became the bane of these hill towns. Studies from various town, across the Himalayan belt, tell the same story of tourism-led development leading environmental damage, lower quality of life, and, ironically, a diminishing quality of experience for tourists. Himalayan towns like Kullu, Manali, Shimla, Dehradun etc. have benefited tremendously from tourism, but have become overcrowded and polluted in the process. The promotion of the tourism sector seemed to have been done without forethought to issues of infrastructure, capacity, culture or environment. The warnings have been sounded by a number of scholars, specifically for the state of Himachal Pradesh, where Spiti is located (Jutla, 2000; Batra, 2001; Kirch, 2002; Kuniyali et. al., 2003; Singh and Mishra, 2004; Singh, 2008; Gardner et. al., 2015; Kumar and Pushplata, 2017). More literature is available for the Himalayan states of Jammu and Kashmir, Uttarakhand, Sikkim and Meghalaya amongst others. Many would argue that tourism centers in the Himalayas have lost their identity in the process of growing tourism. Water shortages, traffic jams, noise, poor air quality, deforestation and visual pollution are commonplace. But the development of tourism has brought jobs, taxes and business opportunities to these cities. Laissez-faire treatment of tourism has also, therefore, been popular amongst voters. Kaza is poised to go down the same path, exposed to what Holden (2009) calls the “environmental ethics of the market” (p.373). One of the last remaining areas untouched by unbridled commerce, and home to a unique culture and way of life, Spiti raises cause for concern.

Despite the phenomenon being repeated in all major hill stations, the ‘resource paradox’ problem has proven to be intractable. Elected representatives find it risky to apply any measure of control on an industry that brings prosperity to their constituencies. Capacity for urban and environmental planning is weak at the local level. Financial resources are limited. And once the door is opened investment floods in too quickly for regulation to keep up. There is a need for two bodies of literature to be considered in tandem. We know that tourism promotion in places like Spiti can cause great harm to the ecology and culture of region. There is also a growing understanding of the need to study the urbanization dynamics of small- and medium-sized towns. It is high time to give special consideration to small towns that have limited capacity for planning but must deal with the responsibility of managing high-value tourism resources, both cultural and environmental. Creative institutional solutions will be required. It might not be sufficient to rely on buzzwords that are not uniformly successful to begin with.

Methodology

Two questions lead this project. (i) What are the community's aspirations and concerns with regards to tourism and urban development in the Spiti Valley? (ii) Why, despite witnessing undesirable urban outcomes in numerous Himalayan towns, has very little changed in terms of tourism policy in this sensitive region?

This study uses mixed methods to answer the research questions and report comprehensively the nature of urbanization in the small rapidly growing town. A household survey (N=420) was conducted gauge the residents' opinions on tourism and development in the Kaza and the Spiti Valley. Survey respondents included 253 men and 167 women. The sample was selected by visiting homes (door-to-door), making sure all areas of the town were covered. The survey sought to garner perceptions on the effects of rapid urbanization, and prospects for the future of the tourism sector. 15 semi-structured in-depth interviews were conducted with residents to triangulate findings of the survey and to obtain a deeper understanding of their everyday lives and opinions. Not least, observations in the town of Kaza were compiled on annotated maps and complemented with photographic documentation. The next section discusses findings from the survey and interviews keeping in mind the idea of the 'resource paradox'. The analysis attempts to bring out the tensions between the local population's aspirations and trepidations.

Needs and opinions

The survey asked local residents to rate their satisfaction with service and facilities (on a scale of 1 to 5 (1 indicating poor and 5 indicating excellent). Figure 4 shows the various categories of services, along with the average scores awarded by men and women. The overall average is indicated for each category. Scores are low across the board, with 'higher education', 'mobile phone services' and 'access to the internet' receiving the lowest scores. The scores awarded by men and women were comparable in all cases. These results are discussed in greater depth in this section.

The survey shows that people are aware of the costs and challenges of economic growth. It is less clear if respondents understand the difficulty of obtaining economic growth without putting social and environmental sustainability at risk. When asked whether tourism will bring prosperity to Spiti, an overwhelming majority (88%) of the respondents answered in the affirmative. Respondents cited employment opportunities, growth of the size of the economy, and new business openings as the main benefits of the growing tourism sector. There is no doubt in the community that the tourism sector is the future of the region, and is necessary for achieving a better quality of life. The small minority that had reservations on the question indicated that more tourism would mean more pollution (waste, garbage, noise etc.), threats to indigenous culture, and increased pressure on scarce resources.

The same question was approached from a different angle by invoking a comparison with Manali and Shimla – small cities in the same province that have been overrun by tourism. Opinions were divided. It was noted by a large number of people expressed the need for caution. Manali and Shimla were reported as having better infrastructure and facilities (particularly for health and education), markets where “everything is available”, “fresh fruits and vegetables”, tourist attractions, greenery, jobs and business opportunities. The responses showed a sense of awareness amongst respondents that they were living in a backward, underdeveloped area, even in comparison with two medium-sized towns. At the same time, however, imagining Spiti going down the same path caused a great deal of concern. Ironically, Manali and Shimla were also seen widely as expensive, polluted, commercialized, overcrowded, and over-exploited. Respondents were wary that Spiti might face a similar fate. “Spiti must grow similarly – but sustainably – in a balanced way, limited way”. “Spiti should not get crowded”. “Preserve culture and environment”. Growth, but in a restricted, controlled manner, is a popular idea. This is discussed in greater detail later in the paper.

Table 1 summarizes the most frequently reported needs for the community. The table shows two groups of needs. ‘Primary needs’ were reported most frequently in the survey and stressed upon in interviews. ‘Additional needs’ were expressed by fewer respondents, but their saliency has been verified through observations. These needs still exist, even though people do acknowledge and appreciate the development works that have transformed the region over the last 20-30 years. It is widely expected that growth of the tourism sector could pave the way for other investment and infrastructure upgrades. The aspirations are tempered, however, by the fear of rapid change and its destructive effects. The second column of Table 1 shows the main concerns. Each point listed in the table is discussed in the following sections. The desire for a better quality of life is palpable, and so is the fear that rapid change might destroy everything that is beautiful in the region.

Primary needs

Water

The fieldwork for this project was conducted in the summer of 2018. The region (far beyond Spiti) was reeling under conditions of drought and chronic water shortage. (Figures 5 and 6 shows low water levels in Spiti.) Interviews conducted in these conditions show that the risks of exceeding the environmental carrying capacity of the fragile ecosystem are felt by the community in a direct and immediate manner.

Snowfall had been sparse in the previous winter and the Spiti river, fed by melting ice in summer months, was running low. In Shimla (erstwhile ‘summer capital’ of British India), a popular summer destination in the same province, water shortage was causing riots. The local narrative was clear that a large part of the blame lay with tourists and hotels. When water resources were scarce the tourism sector was seen as exacerbating the problem. In Spiti, numerous hotels and homestays have sprung up, particularly in the last 2-3 years, and provide valuable additional income to families. But they are at the risk of becoming victims of their own success when water runs dry. Although no comments were made against tourists on account of their contribution to water demand, respondents did point out that the situation was not sustainable unless reliable piped water supply is ensured to all homes. Both the amount and quality of water were mentioned in interviews.

Access and connectivity

Roads have been improved periodically in Kaza and around the Spiti Valley. Large sections, however, still remain unpaved. Moreover as traffic increases there are new concerns regarding capacity and safety. With regards to safety respondents brought up the issue of surface quality, influx of drivers not used to mountain conditions, and poor street lighting. Figure 7 shows a market street in Kaza. The road surface is not properly paved, with traffic and construction activity growing every summer.

Spiti can be approached from Manali and from Shimla. The approach from Shimla is in good condition and remains open throughout the year. The approach from the Manali side, however, is unpaved and makes for very uncomfortable rides. At several points along the way smaller automobiles run the risk of getting stuck in water, leading to traffic jams that last for hours. In winter the road from Manali remains closed as the snow cannot be cleared. These issues were brought up by respondents, along with the need for more regular air services, especially in the winter months. Kaza is served by a helipad for emergency landings. But residents would like to see more regular helicopter services to and from Kaza. Residents would also like to see more frequent bus services to nearby towns and to Shimla and Manali.

Education

When asked about their hopes for the next generation (open-ended question, no options provided), as many as 92% of the respondents mentioned better education. Through interviews it became clear that people rued the absence of an institute of higher education. The lack of education options, it was felt, was taking children far away from their homes. As a result, not only is the community losing youth and talent, but also its traditions and way of life.

It was also felt that the lack of business training was causing locals to be left behind in the tourism boom. This aspect is discussed further in the next section, on ‘employment’. Several respondents indicated that because of the lack of education locals are left with few options for securing their livelihoods.

Employment

The lack of work is the biggest worry for residents of Kaza after infrastructure shortages. Jobs are hard to find locally. The economy is growing fast due to tourism, but this has not brought the expected benefits to local people. Due to restrictions on acquisition of property on outsiders, it has become common practice for entrepreneurs from outside the region to lease properties in Kaza and around Spiti to operate businesses. Most of these businesses are in the sectors of food, hospitality, retail, tourist services (such as organized tours, adventure sports etc.) and social entrepreneurship. The businesses tend to bring employees from their place of origin – mainly due to kinship. Deeper motivations vary and could include trust, creating opportunities for younger members of the family, suppressed wages etc. As a result locals feel left out of the economic opportunities coming to the region. Further, as mentioned earlier, locals feel that they are not benefitting enough from either partnership or transfer of skills. One respondent was clear in his evaluation. “Bringing outsiders to work is not good. Locals should be able to find work and benefit from the tourism growth.” Another respondent seconded the opinion. “We would like locals to benefit from the business opportunities created by tourism.” The community is already discussing ways to insist on partnerships between locals and outsiders as an alternative to simply leasing land.

Communications and Internet

Another piece of critical infrastructure lamented by many respondents was mobile communications and Internet. Although mobile services are available, there is only one provider (government-owned BSNL) and coverage is patchy at best. Internet connectivity, through the same provider, is poor to non-existent. A tourism-based economy will find it difficult to prosper in the absence of reliable telecommunications and Internet services. Moreover the digital divide tilts the playing field in favor of businesses that have large networks and multiple offices, allowing sales and other business functions to be conducted elsewhere. Small local businesses will struggle to compete in such a market. It is also embarrassing for the larger polity for a section of the population to remain effectively disconnected the Internet.

Additional needs

The issues identified above were mentioned most frequently in the survey and interviews. In addition to these, several other needs were mentioned, with less regularity. These include better health care

(including more doctors and better local facilities), reliable electricity, better banking facilities, support for traditional agricultural practices, sports facilities, and a new petrol pump (gas station).

Many of the needs discussed above may be considered as falling within the domain of state welfare for a remote region with a low population density, and few resources. There is an expectation, however, that growth of tourism will add economic weight to the region, which could, in turn, propel the government to upgrade infrastructure and services. As one man put it in an interview, “If tourism grows but the people of Spiti don’t grow, then what’s the use?” The desire for greater tourism revenues is tempered with a great deal of anxiety regarding the unintended consequences of economic growth. Certainly rapid development threatens environmental quality in the region. It is important to note, however, that respondents feel a pressing need to guard the identity of the community and its individuals.

A way of life at stake

After discussing the improvements they hoped to see in Spiti, respondents were asked what they would like to not have change. The answers illustrate the connectedness of people, place and practice. The very identity and way of life of the community is threatened if tourism is allowed to grow in an unplanned manner, as has been the case in many other towns in the Himalayas. To be clear, the word ‘identity’ did not appear in the question. Further, not a single respondent used this word in answering the question. This was not an attempt by the respondents to define themselves as individuals or as members of the community. As indicated above, the responses represent a degree of reflection on the most cherished aspects of life in Spiti, to which people are attached, and which they consider worth saving. It is only upon analysis of the survey data that it becomes clear that for this community self-concept is tied very closely to their way of life.

Table 3 shows some of the responses received in the survey. But it would not do justice to the people of the region simply to enumerate these answers. It is important to consider the connections between these ideas, and the coherent narrative they provide of a sustainable and rich way of life. Three aspects of the way of life can be discerned from survey responses and interviews – (i) values, (ii) practices, (iii) the environment.

The idea of ‘peace’ is particularly important to understand Spiti society. The word is mentioned in the context of faith, community life, personal values, and negotiating everyday life in a difficult climate and sparse landscape. “We like the peace up here”, says one interviewee, referring at once to the mountains, the solitude, the pace of life, and the practice of faith. A strong sense of community, too, is a thread

running through the various aspects of the local way of life. One respondent, a businessman from outside Spiti, expresses his admiration for the people of Spiti. “People here are honest and nice. They will not give you an unfair deal to make a profit. The local culture is special. People help each other.” These values do translate to practices of agriculture and architecture, both of which were carried out traditionally with shared labor. The importance of community is evident in personal values, collective practices, and in the work of living in a high-altitude desert. The notions of ‘peace’ and ‘community’ are perhaps the most important pillars of the local way of life. It is no surprise then that when threats are expressed, they can be traced back to one of these two ideas.

Being at peace with nature is Spiti’s definition of sustainability. Mud-brick architecture, agriculture based on traditional crops following the natural cycle of snowfall and melting ice, sharing labor, protection of wildlife (particularly the Snow Leopard) are all examples of environmentally sustainable practices drawn from the idea of ‘being at peace’.

All anxieties expressed with regards to the potential negative fallout of tourism development (summarized in Table 2) may be seen as the fear of the collapse of one of the two pillars – peace and community. Community member expressed concerns of cultural changes occurring due to the influx of tourists. Monks at the local monasteries expressed similar views. A senior monk at Tabo monastery was concerned about the apathy of the younger generation. In particular, he is troubled by the preoccupation with digital screens, the growing culture of partying, and the influence of the drugs in the state (even though it has not yet become a major phenomenon in the Spiti region). “Our culture and traditions are being diluted.” Another respondent adds, “the locals are changing by looking at tourists.”

The consumer economy threatens to destabilize traditional communitarian practices, such as building houses by sharing labor. An outsider, who runs a hotel in Kaza, shared his insight regarding local culture and the risk it faces. “They are very content and self-sufficient people. More money brings more insecurity. You see more consumer options you start thinking about what you can buy and afford.” The potential risk of the consumer economy was also noticed by the monasteries. “These days people are spending their days looking at other people’s news and pictures. That is a world of lies. They are losing touch with their own life. Young generation has no time for the monastery. No time to participate in ceremonies. At the ceremonies also they are on the phone.” He says the last line with a laugh.

The effects of commercialization is not limited to personal values. There is a materiality to this social change. Concrete houses have replaced the mud brick houses that are the traditional architectural form in

this part of the world. Mud brick houses have thick walls, are good for retaining heat inside the house in winters, easy for people to construct for themselves by pooling their labor, and relatively cheap to build. But concrete is taking over, despite being less than optimum for the local climate. It is stronger, allows taller structures, and can be built by hired workers brought in from other parts of the country. The dilution of the values goes hand in hand with the changes in material culture, and, in turn, with environmental concerns.

The tension between economic growth and fear of loss of cultural values is not new.

Ambivalence, tensions and local resistance emerge in the process of commodifying culture at Goo-Moremi village. Some local people embrace the commodification of their culture into a tourism product because of anticipated socio-economic benefits whereas others resist cultural commodification as a result of fears that it may devalue their culture and belief system. (Mbaiwa, 2011).

Similarly, Joseph and Kavoori (2001), writing on Pushkar (Rajasthan, India), assert that “tourism is perceived as a threat to “tradition” and religion even while a large segment of the population is dependent on its economic benefits” (p.998).

In Spiti, the concern over “dilution” of culture and identity is deeply connected with everyday life and environmental sustainability. Moreover, there are already issues of distributive justice, inclusion and community engagement. Thus planning for tourism in Kaza and the Spiti region must be approached as the “wicked” problem that it is. It is not simply a matter of calculating the correct *number* of tourists. A very fine line separates the appropriate level of tourism exploitation from its excess.

A contribution of this study is to highlight the interconnectedness of social, cultural and environmental dimensions of tourist destinations. Although it is well established in urban planning, geography and allied fields, this lesson seems to be underplayed when it comes to tourism policy. Durovic and Lovrentjev (2014), for example, have compiled an extensive survey of literature, looking deeply at the social, economic and environmental dimensions of sustainability. There is, however, no acknowledgement of the ways in which these dimensions of sustainability are connected *in communities* through values, practices, and everyday life. Any understanding or evaluation of sustainability remains incomplete, if the concept is approached as a set of discrete elements, that are measured using ‘indicators’, and without a thick understanding of their interconnectedness.

Paradoxical prescriptions

The challenge of the balancing act is illustrated by the variety of policy directions being suggested by the various stakeholders. Caught between the desire to leverage tourism for the development of the region, and aware of the risk of destabilizing the way of life altogether, community members have curated a number of narratives that attempt to strike the balance between growth and sustainability. The three narratives discussed here are instructive for understanding the tensions at play.

Good tourist/ bad tourist

Opinions of community members regarding increasing versus controlling tourism seem evenly split. A recurring theme is the imagined good tourist/ bad tourist dichotomy. “Tourism is good, but some tourists are bad.” This, perhaps, is true of any popular destination. In Spiti, however, this truism is mentioned not simply as an analytical statement, but rather as a proposal for segregating the good tourists from the bad tourists. The narrative attempts, a bit crudely, to bridge the gap between wanting tourism and avoiding its negative consequences. It follows inevitably that people try to define ‘the ideal tourist’. In the words of one respondent the ideal tourist is “respectful and culturally sensitive”. Another voice added that “tourists must also understand this area and the people who live here.” While there is merit to promoting “responsible tourism” options, such a policy can hardly contribute to the selection of a certain type of tourist.

Regulate the number of tourists

This narrative points to a cleft in society. Those in favor of this option tend to be people who have already established a business. They only stand to lose their margins if competition increases, especially if bigger players arrive in the market. The vast majority of locals, still waiting to benefit directly from tourism or from state investment, seldom hold this view. In addition, many respondents also held tourists responsible for promoting a permissive culture, drugs, pollution, noise etc. Although mass tourism could cause or exacerbate these problems, regulating the number of tourists may not be a sufficient control. Nor can we be sure that there are no other policies available to contain such problems. Moreover, it still leaves open the question of the aspirations of those who have not yet benefitted from the lucrative tourism sector. It is useful also to remember that local representatives will be sensitive to voters’ demands.

The Bhutan model

Tourism in Bhutan is closely controlled to preserve the ecology and culture. Bhutan “took a cautious approach towards tourism, designing a policy of ‘high-yield, low-impact’ tourism, aimed at providing high quality service to wealthy tourists who are interested in and sensitive to Bhutan’s culture and traditions (Brunet 2001). The objective of the policy is to generate revenue and achieve economic self-

sufficiency, but prevent cultural pollution (Reinfeld, 2003). As a sovereign nation Bhutan is able to control the number of tourist visas issued, and is also able to set certain requirements (such as planning the trip through local tour operators) in order to obtain the visa. It is clear why the ‘Bhutan model’ appears attractive to anyone concerned with controlling tourism growth. It regulates the number of tourists, while ensuring expenditure, and also, to an extent, filtering through only those tourists who are really interested in the country. India, however, allows free movement of citizens within the country. Domestic tourists are by far the majority of visitors in Spiti (as in all major tourist attractions across the country). Granting access to a select few individuals is not an attractive idea politically or economically. Nor is it possible for any authority to insist on employing certain services to visit the area. Again, we see the desire for growth and professionalization of tourism, but without exceeding limits.

Conclusions

Infrastructure

The infrastructure needs that have been mentioned by community members in our extensive survey should be prioritized. Water, electricity, internet, mobile communications, health, higher education, roads and banking are indispensable – whether seen in terms of human development or tourism. In addition, there should be an immediate enhancement of the region’s city and regional planning capabilities.

Avoiding dependency

The title of this paper is derived from words spoken by a respondent in an interview. Speaking about the lack of higher education and the difficulty in finding jobs, he said his children would probably work in the tourism industry when they grow up. “What else?”, he added. This lack of choice points to the inevitable dependency that will be created on the tourism sector if the benefits are not diverted towards overall development of the region, including other economic sectors and traditional sources of income – including crafts and agriculture.

Community at the center instead of carrying capacity

Bringing revenues to the community and spreading the benefits to the entire community should be the economic goal of tourism development. The long-term growth of the entire community is more important than the profitability of the businesses of an elite minority (Brohman, 1996).

The more that local residents gain from tourism, the more they will be motivated to protect the area’s natural and cultural heritage and support tourism activities. If they do not benefit from tourism development, they may become resentful (Liu, 2003, p.466).

That said, however, the community should be able to continue to practice their way of life without having to succumb to tourist expectations. Promoting cultural tourism also runs the risk of essentializing and commodifying the local culture to suit the tourists' vision of authenticity. Writing on the successful transformation of Yogyakarta into a tourism destination, Dahles argues that "the policy of 'quality' tourism which offers carefully constructed and controlled tourist experiences" (2001, p.vii) led to losses in equity and welfare of low-income groups. As Richards and Hall (2000) put it,

[t]he realisation that the community itself has become an object of tourism consumption has in turn encouraged some communities to reproduce themselves specifically for tourists. Through the process of site sacralisation, whole communities can begin to identify themselves with the way in which they are 'named' and 'framed' as tourist attractions. (Richards and Hall, 2000).

But the choice is not simply between preserving a way of life and promoting tourism, or finding a way to do both at the same time. The real challenge facing policy-makers is to grow tourism in a planned manner versus letting it grow entirely under market forces. It is the latter approach that has destroyed other mountain destinations in the region. Preserving culture exactly as it is now (or as it was practiced by previous generations) may not be a viable option. Nor is it tenable, given the aspirations of the people, to allow society to get left behind in this age of digital divides. Local business, entrepreneurship, innovation, and capabilities will suffer. Planning the growth in a participatory manner will at least give stakeholders an opportunity to direct future growth, to inscribe their values in the vision, and to offer a strong counterpoint to consumerism.

Focus on interconnections

Based on the foregoing discussion - on the connectedness of values, practices and the environment – it is necessary that policies are made first and foremost to preserve the most essential elements of the traditional way of life. In particular, the state has to create institutions to support agricultural practices, local architecture, wildlife conservation, Monasteries, festivals and self-governance. Only on a strong foundation of these aspects of society can we build a model of tourism for Spiti and for other Himalayan destinations.

Acknowledgements

This research was made possible through generous funding from the Indian Institute of Management Calcutta. The author is grateful for the research support. The author also wishes to thank three research assistants who helped with data collection: Ms. Shreya Bansod, Ms. Akshara Shibu and Ms. Stuti Gangwar. Thank you for your commitment to the project. Not least, the author is grateful to Ms. Ishita Khanna and Mr. Norbu of Spiti Ecosphere for their hospitality and support.

How well can privately owned public spaces (POPS) facilitate social interactions in Taipei City? A case study of the community residents' daily life

Abstract

In Taiwan, the high-density urban environment is the normal urban form as many highly populated counties. The concerns of possible impacts of vertical-developed cities have long discussed for several decades. Since the 1980s, in order to improve the urban environment and increase open spaces, the Taipei City Government granted additional floor area bonus as incentives in exchange of the private developers providing privately owned public space (POPS) for public use. Nevertheless many studies identify that the openness and the publicness of most POPSs are lower than expected. However, other concerns such as the possible external costs of the urban environment i.e. the decline of public service quality, more energy consumptions, increasing residential density, and skyline destruction derived from the additional floor area bonus as incentives for POPS are still to be studied. Early local research regarding the POPS usually focused on the usage of such space, and has given advices on design details. There is a lack of discussion about the impacts on the social behavior of residents by the POPS. Hence, this paper will discuss the possible impacts of the POPS on the social interactions (social relation). We will conduct questionnaire survey and field studies at the selected communities with more POPSs in Taipei. The research results will expect to gather some information about how can POPS benefit residents daily life at the community level and provide policy feedbacks on future POPS in Taipei.

Keywords: privately owned public space (POPS), People-environment fit, social connection

INTRODUCTION

To achieve the goal of improving the urban environment and the capacity for disaster prevention, some building site owners in high density cities can apply for additional floor area bonuses (bulk reward) in exchange for converting part of the private property into privately owned public spaces (POPSs). It is considered as an

effective approach to improve the quality and quantity of existing open space system in many highly urbanized metropolitan areas around the world. In the case of the New York City, since 1890s, a lot of skyscraper builders have joint the competition to build building taller in height and larger in volume and resulted in degradation of urban environment and living quality. As a result, the 1916 zoning resolution came to create a sense of openness, also known as “light and air,” at street level. Further, the Voorhees draft in 1958 proposed the first concept about POPS. “In order to bring more light and air into streets surrounded by tall buildings, as well as to create more usable open space, a bonus device has been established to encourage the setting back of buildings from the street line.” (Kayden, J. S., 2000) Likewise, Taipei as the capital of Taiwan encounters similar problems of poor open space provisions due to the high density built environment and economic development pressures. In addition, the city cannot expand its border due to the limit of basin and range topography geographically. The urban grows close to saturation, so it cannot afford more construction of open space land. Hence, Taipei City Government has been seeking alternatives to improve open space system and adopting approaches of authorizing extra bulk bonus in exchange of POPSs since 1980s.

The promotion of POPS has been encouraged for nearly 40 years until now. However, there was lack of evaluations of the actual contributions that POPSs provided. Questions such as “does it achieve the goal of improving open space system?” or “how well-managed are these POPSs?” popped out frequently. More importantly, “how can those POPSs actual serve citizen’s social life?” Common problems discovered in the New York Cities are poorly management of the POPS environment and quite a lot of POPSs are not open to the public. Nonetheless, scholars and citizens have frequently questioned the effects of POPS. The common criticisms are: the restriction of social interaction, the exclusion of “undesirable” groups and the partiality for private benefits (Kayden, 2000; Mitchell, 2003). The most common critique is of their accessibility to the public. For instance, studies regarding the POPS mostly focus on user experience at the individual POPS sites. 2006). Moreover, in 2014, Taiwanese citizens held “Occupation of POPS Movement” owing to protest the authoritarian ban on entering privately owned public spaces.

Therefore, in this paper, we extend our series discussion of the actual contributions of POPSs in Taipei City. Since 2015, a three-phase study structured by three planning and design spatial level, city level, district level, and street block level has conducted. At the city level phase, we focused on understanding the spatial function of POPSs in the urban planning contexts to further confirm the planning goals and purposes of POPS from urban open space system perspective. A total of 483 POPS sites from 1983 to 2013

was our selected research target sites. In the second (district level) phase, we discussed the relationship between site planning, the pedestrians flow and accessibility of POPs. Finally, in the third phase, from user's benefit perspective, we focus on how can POPs contribute to connecting people's social life.

Literature Review

1. The Planning Regulatory Background of POPs

The intention for legalizing the establishment of POPs was good, but many have questioned the role of POPs in the whole open space system in a city due to the lack of instructions in the statutory plans such as master plan and detail plan. Figure 1 illustrates the related regulations for open space system in urban planning and POPs in Taipei city. It is clear that the location and function of POPs was not carefully considered and clearly defined at master and detail plan level. A POP is only an additional patchwork in the open space system. Also, according to the zoning plan and land use control regulation, there is no instruction regarding where and how to allocate POPs. Thus, there is no evaluation tool available for measuring the possible effect and contribution of each POPs.

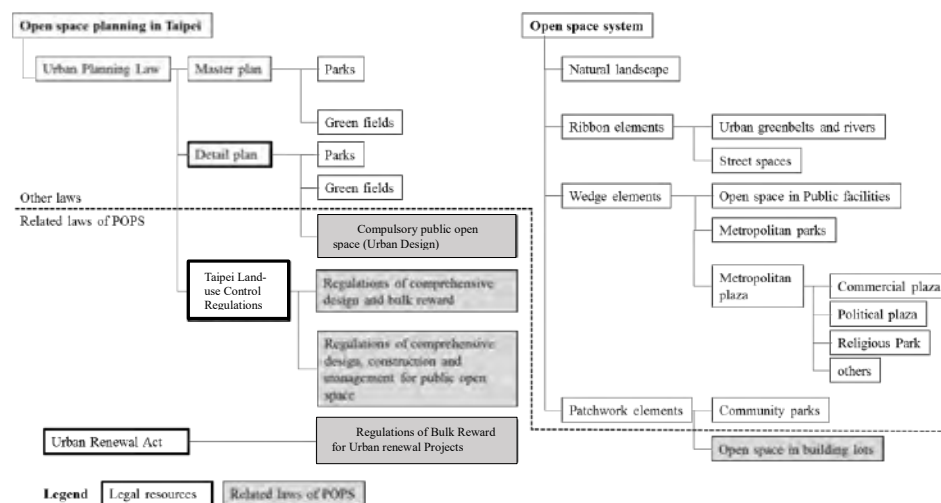

Figure 1. The relationship of POPs, regulations and open space system

As a result, in 1997, POPs became a concerning issue regarding to the location and poor managements. After that, regulations on Taipei Land Use Control were amended to cancel the bulk reward, extra floor area rewards for new residential building construction projects. Until 2014, doubts and concerns of POPs arose again and many reported illegal usage or poor management of existing POPs in order to avoid public

usage. On the other hand, over the past decade, the developed ratio of public open space in the statutory plan has only increased 7.9% from 43.0% to 50.9%. By 2014, there are still half of open space proposed in detail plan failed to develop. That is to say, the planned open space system has difficulty to be realized and also each district ended up with very low average open space. For instance, the green resources per capita of the five districts, Wanhua, Zhongzheng, Songshan, Da'an, and Datong, are lower than 10 m². These districts are mostly located in the eastern part of the city. They are all old developed quarters with poor public facilities in quality and quantity as well as lower social economic status. For such deprived areas, it is most impossible to provide public open space due to fully developed built environment. Hence, although current policies encourage urban renewal projects to provide POPS in exchange of bulk rewards, the actual amount and quality of POPS provided is still questionable.

We argue that although POPS has long been ignored by the statutory plan system, the ever existence of POPS is no doubt a trade-off between private floor areas and public right of POPS usage. To keep POPS open for public use is to practice public justice. It is also land owners' obligation to keep it open for public. In addition, the locations of POPSs were chosen on the basis of the laws without considering the entire planning scope.

2. Related research of POPS

Research on POPS traditionally tends to focus on different aspects of the issue: the legal approach discusses it in relation to floor area ratio incentive policies, and often cites New York City as a model of this system; from the perspective of Economics, the emphasis is on the shift of urban spaces from the public realm to private ownership; the Urban Design approach analyses the spatial arrangement of POPSs, and their relation to the built environment (Kayden, 2000; Webster, 2007; Wei, Z. C., 1994). In Taiwan, however, research on privately owned public spaces tends to be less complex, only discussing urban design aspect, quality of the urban environment, and user behaviour when evaluating the „publicness“ of such places, and pays less attention to issues of supervision and property rights (Tung, Y. Y., 1999; Chiang, W. C., 1993). Besides, research is mainly based on observation of individual cases, hence lacking in objective, quantitative indicators derived from a large sample, which arouses doubts of subjectivity, and makes it impossible not only to get a full view of POPS, but also to use the results as a basis of evaluating the publicness of POPS in general. Furthermore, since user preferences and behaviour differ significantly in Taiwan and in other parts of the World, therefore it is not possible to use international indicators to evaluate the

degree of public access to POPS in Taiwan (Wei, Z. C., 1994).

3. Person-Environment Fit (P-E Fit)

Person–environment fit (P–E fit) is defined as the degree to which individual and environmental characteristics match (Dawis, 1992; French, Caplan, & Harrison, 1982; Kristof-Brown, Guay, 2011). It is considered to be similar with ‘the theory of supplementary fit’. Based on compatibility that derives from similarity, a person fits into some environmental context because he/she supplements, embellishes, or possesses characteristics that are similar to other individuals in the environment (Kristof-Brown & Guay, 2011) It is also believe that urban dwellers could develop various P-E fit patterns according to their surrounding environmental settings. Thus, as Jane Jacobs emphasizing on appropriate design elements such as openness and inclusiveness in the public realm can create good place for people to meet, we argue that it is crucial to examine the P-E fit level of current POPSs to see what spatial pattern works and what don’t.

METHODOLOGY

1. Phase One: Evaluation of the spatial distribution pattern of POPSs and relationship between other public-owned open spaces

Many local research have examined the possible effect of the individual POPS on its local users and discovered problems in terms of limited usage and poor management of POPS in case study. On-site observation or questionnaires are most frequent methods adopted. However, only very few have debated about the relevance of entire POPS system with open space network. Spatial analysis was rarely adopted at city scale in discussing POPS issues. (Yoon & Srinivasan,2015)

This study is conducted at both urban and local scale to discuss the relationship between existing POPSs and the public open space system. Thus, we selected 6 administrative districts in Taipei as our research sites based on the amount of existing POPSs, similarity of spatial contexts and average open space per capita. (Figure 2) There are 315 public open spaces and 228 POPSs available in the selected research area. The average size of each POPS is 1314.25 m².

At city scale, this study discuss the suitability of POPS location in terms of overview on open space system in Taipei city by using bivariate local Moran’s I analysis. We adopted and revised the method by Yoon & Srinivasan (2015) and study the

relationship between the lack of public open space and the provision of POPS in each district. We would like to confirm and identify the types of the possible misallocation of the POPS in 6 districts in Taipei City. The result of Spatial Correlation analysis and bivariate local Moran's I analysis can identify the compatibility of open space system and allocation of POPS in each district. Four types of compatible combination are categorized. (Figure 3) In the phase two, at local scale, we further selected two types out of four in the previous stage to conduct field investigations on the spatial layout of each POPS in order to observe the level of openness and usage characteristics of POPS in different district according to the compatible types of public open space and POPS. Wanhua District, with lack provision of both public open space and POPS, and Songshan District, with both abundant public open space and POPS were selected as research sites in the second phase.

Figure 2 The Selected Research Districts and distributions of public open spaces and POPS

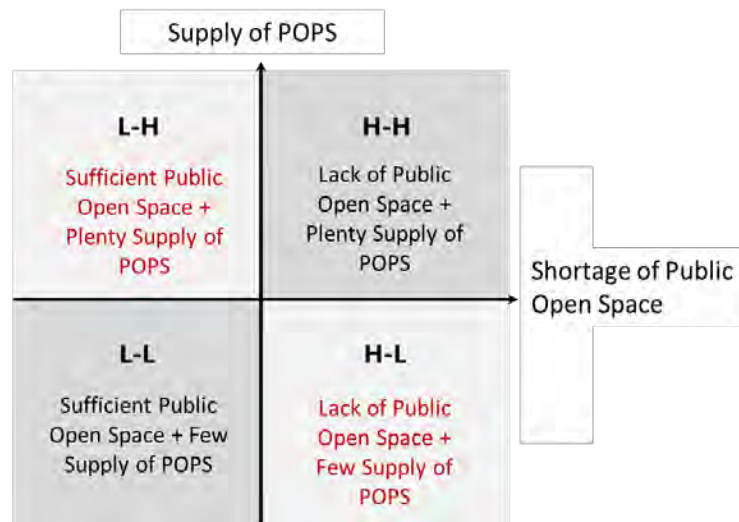

Figure 3 City-level Open Space System bivariate LISA analysis results

2. Phase Two: The Pedestrian flow and site plan of POPSs

Among the existing 483 POPS sites in Taipei City, we further use urban and local scales to discuss the publicness and accessibility of existing POPSs. In urban scale, we evaluate the accessibility and connectivity of the location of POPSs by using the Space Syntax Analysis in order to explore whether the POPS can enhance the pedestrian flows. In addition, at community context, on-site investigations of the design and usage of POPSs through Visibility Graph Analysis method in Shinyi District and Zhongshan District were conducted. (Figure 4) AutoCAD and Depthmap software were applied. (Figure 5) The main point of investigation is to document the actual quality of POPSs from user perspectives.

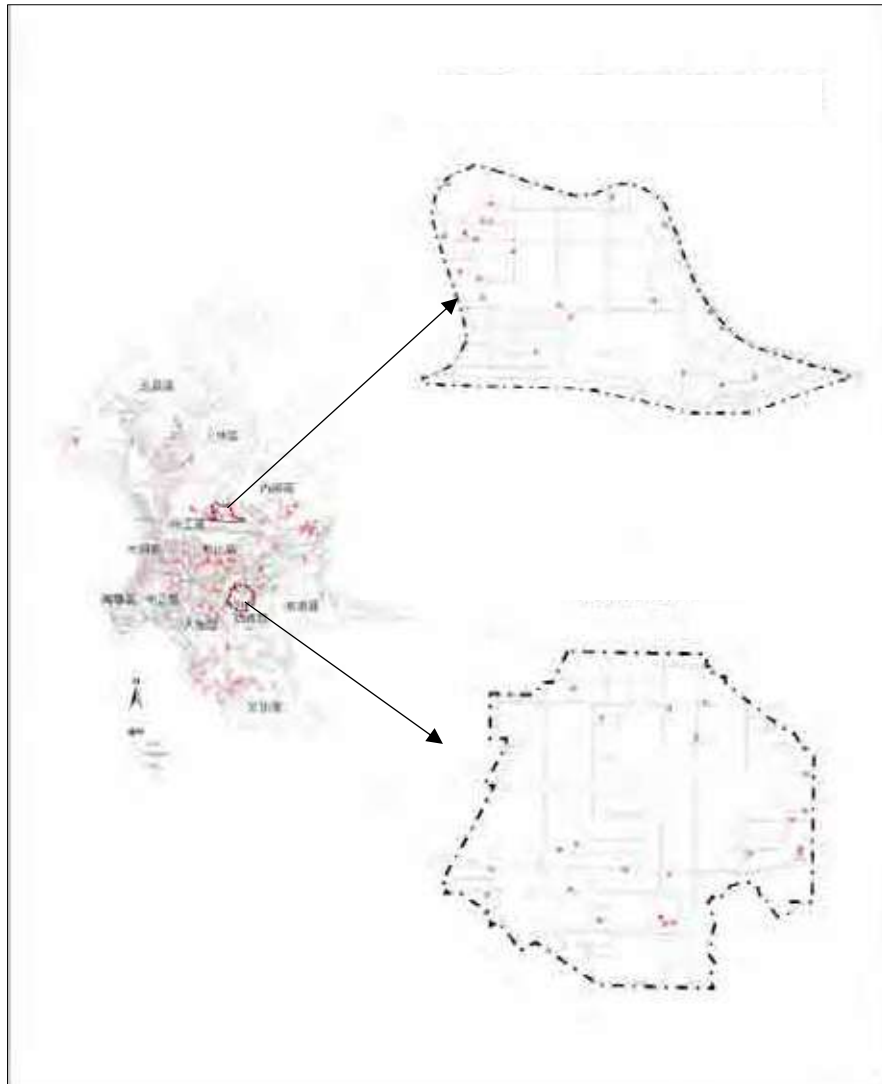

Figure 4. Site selection for Space Syntax Analysis

Figure 5. Visibility Graph Analysis

3. Phase Three: P-E fit evaluation

Owing to the lack of user-experience study feedback to the design guidelines of the POPS, as a result, design concepts applied in POPSs in Taipei City are mostly from developers' perspectives instead of users' perspectives. By applying the P-E fit theory

and environmental psychology, we argue that it is necessary to obtain the actual information of P-E fit level of POPSs in Taipei City. Through user's questionnaire and focus-group interview of local residents, we could identify the users' purposes and activities occurred in the selected POPS sites. Also what kind of design elements of the POPS facilitate the social connections among users and what failed.

RESULTS AND DISCUSSION

1. The relationship between POPSs and other public-owned open spaces

It is our argument that a good POPS should be able to compensate to the shortage of public-owned open space provision by the planning tools at city or district level. Hence, master plan or land use zoning plan should instruct the location choice criteria for POPS to instruct POPS happening at the preferable location that benefit the whole open space system. However, the result of bivariate LISA indicates that the current distribution pattern of POPSs has no correlation with the citywide open space system. The High-Low (H-L) area, which means the area lacks of both public open space and POPS, gathered in Wanhua district. However, the developed ratio of land use of open spaces is 99.5%, indicating difficulties to provide sufficient public open space by the city government. That is to say, the demand of open space in the Wanhua district is still high but we can only expect POPSs to meet the demand. On the other hand, the Low-High (L-H) area, which means that such area has sufficient public open space and more than enough POPSs, mostly locate in Songshan district. The spillover effect of oversupply open space can be also considered as a waste of resources. Therefore, whether POPS in Songshan district achieve the intended purpose, which is to improve open space environment, have to be verified by local scale analysis.

At local scale, the main point of field investigation is to obtain the spatial form and user behavior information in L-H and H-L areas to further initiate the dialog between quantity and quality of open spaces. Wanhua district belongs to H-L area, and it has a long development history and most land has already built up. Because it lacks of public facilities and public open space, the real estate price is lower than other district. There are only a number of POPS located in the Wanhua district mostly existed for more than 20 years. The design of such POPS 20 years ago were lack of openness and connections to public areas. Clearly, with limited available land to acquire as public open space, it is even more important to promote POPS in Wanhua district. As one of the priority areas for urban regeneration, land use plan of urban renewal project should

address the need for POPS and provide more incentives, i.e. bulk rewards, for private developers to provide POPS. Also, urban design code should require the design contexts of POPS to ensure the openness and publicity of the POPS.

On the other hand, most residents in the L-H area enjoy good open space environment in both quality and quantity. It has sufficient POPSs as well as public-owned open spaces. It might raise another concerns such as over-supply of open spaces and inequality of planning gain. For instance, most of the POPS located too close to other public open space and it will cause user competition and result in under-use of both good quality open space.

2. The Pedestrian flow and site plan of POPSs

According to the fundamental purposes of providing POPS, the location choice of open/public space can have significant impact on connectivity of the overall pedestrian network. In other words, the location and spatial configuration patterns of POPS in each development site can be a facilitator for the overall enhancement of pedestrian environment.

From the comprehensive survey of POPS conducted in our research, different design approach and spatial configuration patterns would affect actual usages of POPS. For instance, the plaza type POPS is more attractive for local people, but the utilization rate also related to its design for the level of pedestrian friendly. Furthermore, we compare the POPS developed by different developer, government and private, and realize that POPS developed by private developers usually has poor openness than the one provided by public developers.

Figure 6. Shinyi District Case: Pedestrian flow and POPS

The Space Syntax Analysis conducted in two districts where POPSs mostly clustered further confirms that the existence of POPSs in both districts enhance the connectivity and pedestrian flow. For instance, in the Shinyi District, by adding all POPSs to the connectivity evaluation, the average connectivity value (C_n) increases from 4.422 to 4.674. Also, the average global integration value (R_n) increases from 0.709 to 0.803. (Figure 7.) It is to say, at the district level, when considering granted permission of POPSs, local planners should take the location and the potential contribution to the overall pedestrian connectivity into account.

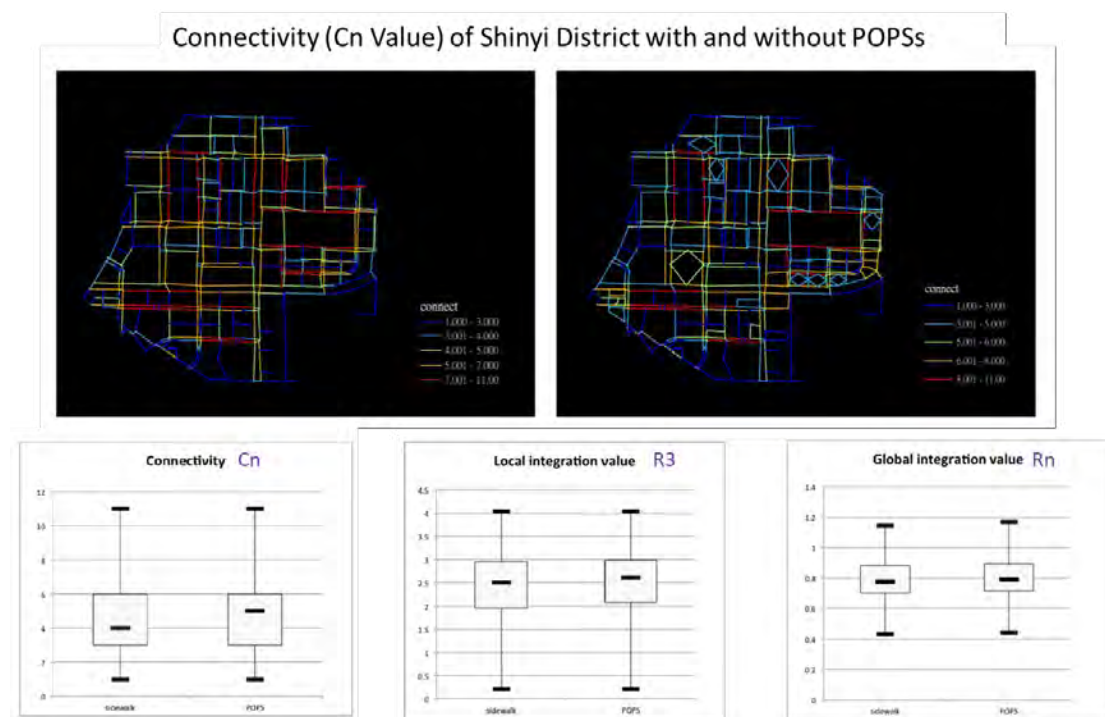

Figure 7. Space Syntax Analysis result of Shinyi District

3. The activities and the design of POPS

The other important expectations of POPS is to promote social interactions and activities at the single site level in terms of place-making. However, a place has to be visible first for people to have interactions in it. In the cases of Taipei city, we realize that although the regulations required the POPS to open to the public and property owners to design the place accessible for the public, most of them still intentionally 'design' to be less visible for users from outside. Eight spatial configuration types of POPS were selected to do the Visibility Graph Analysis in Shinyi District. Figure 8 illustrates the result of one case. The POPS in the following case was allocated at the

back-side of the main building and away from the main road. The visibility graph map indicates the POPS was not visible from the main road where most pedestrian would pass by without noticing the existence of such public space. As a result, very few activities occurred in the POPS and it is almost impossible to enhance the social interactions between POPS users.

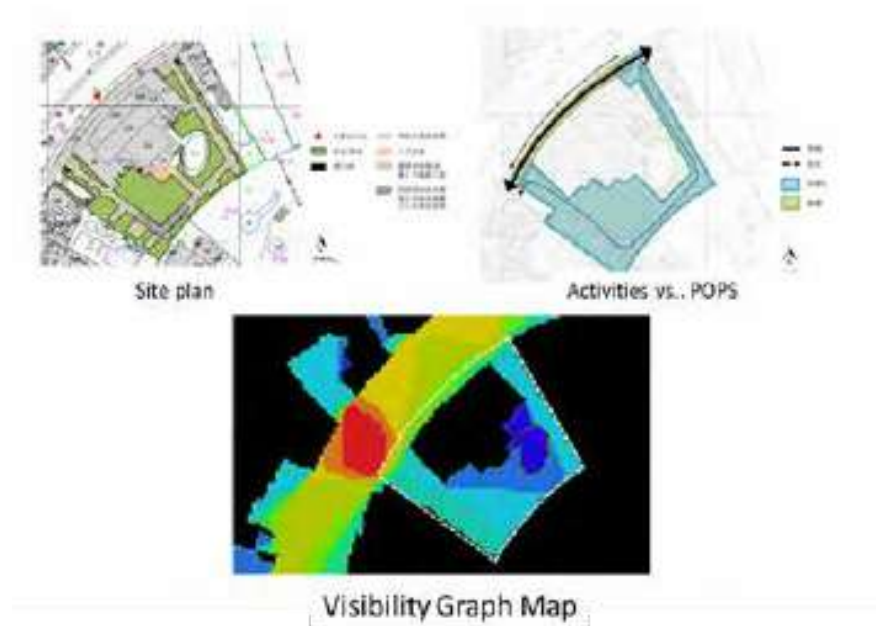

Figure 8. Visibility Graph Analysis

CONCLUSION

This paper presents the results of our 3-phase systematic research of the actual function of POPSs in different spatial level. First, we examined the relationship between existing POPSs and the public open space system in the Taipei City. Second, we evaluated whether the POPS can enhance the connectivity of public spaces and provide a better walkable path network for urban pedestrian at district level. Thirdly, we investigated the design and spatial configuration of POPS in each development projects to see if such space can enhance the social interactions.

The research results confirm that POPSs in Taipei fail to function in terms of fulfilling urban planning aim and enhancing public interests. At urban master plan level, there is no overall considerations of the possible collaboration between public-owned and privately-owned public space. According to the LISA analysis result, Wanhua district, the most deprived area, lacks both open space and POPS but Songshan district, the prosperous area in the city, has too many POPS and public open space at the same time. This raise a concerning issue of the fairness of public interests due to the

inequality of public space distributions. Hence, there is an urgent need for city-wide planning, design and locational guidance for POPS. From local scale investigation result, the plaza type POPS and POPS developed by government have better design quality than the other type and could stimulate more activities in it. Also, the location decision of the POPS in single building site should be further examined before the permission granted in order to ensure the visibility of such areas for all citizens. Finally, due to the housing price and real estate market will influence the developers' decision of providing POPSs, as a result, the distribution of POPSs don't match the demand of open space. Therefore, this study recommend that floor area incentive standard should be different according to the availability of existing open space. More incentives should be granted in the area which lacks of publicly-owned open space. The concept and purpose of open space system, both public-owned and privately-owned, should be included in detail plan as a guiding principles. In addition, in urban design review process, we should require proper location choice and design for future POPSs to facilitate the positive social interactions among users.

Analysis and Research of Urban Street Functions Based on GIS

: A Case Study of Xuhui District, Shanghai, China

Luning DAI

Abstract: In the context of the shortage of public space resources in large cities, the concept of "Street Space Renaissance" has been reintroduced, and the social attribute of urban streets as public space have been reemphasized. Street vitality is one of the main indicators to evaluate the social attribute of urban streets, and it is also the main target of urban street design and control in recent years. In this paper, GIS technology is used to evaluate the vitality of streets of different functional types, which makes up for the deficiency of ignoring the functional properties of streets when evaluating the vitality of streets by spatial syntax. This paper takes the Xuhui District of Shanghai, China as an example and comprehensively analyze urban facilities' POI data of different functions (commercial, office, residential and public service facilities, etc.) to identify the density, mixing degree and the dominant nature of the street functions, and using the three indicators to identify the characteristics of urban streets. The research found that: (1) In the area of Xuhui District, according to different types of infrastructures' POI data, the streets present different functional features. (2) At the overall level, the street vitality shows a certain correlation with the mixing degree and density of the street functions. For example, the streets in the northwest of Xuhui District bordering with Changning and Jing'an District are more active. On the contrary, the vitality of the streets' in the southern part of Xuhui District and the eastern part near the Huangpu River are generally weak, whose overall development are not perfect. (3) At the meso level of street vitality, the street sections at the intersection are more dynamic than the middle sections. (4) Xuhui District has the highest proportion of streets dominated by the functions of public services and public management, followed by commercial and business streets, and finally residential streets. In general, Xuhui District has strong public functional features and high public service capabilities.

Keywords: Street function, street vitality, street function density, street function mixing degree, the functional nature of the street, GIS, POI

1 Introduction

As the main carrier of urban traffic, the street mainly bears two attributes in the development process of the city: the transportation as the medium of communication and the sociality of the public space function^[1]. Different street patterns represent different social and economic needs. In the era of pre-management, the street forms all showed small-scale, network-interlaced features, accompanied by a narrow road width^[1]. This community-level street organization served the town life at that time, such as the Beijing City Square in Qing Dynasty of ancient China and the streets of medieval European cities^[2]. However, this street pattern has gradually declined with the rise of motor vehicles. People's requirements for regional accessibility have gradually increased. In order to adapt to large carriages and trams, the streets have gradually widened, and the infrastructure properties of the streets have gradually surpassed the public space. Social property dominates. People's feelings about the initial "city" culture of the street are gradually decreasing. In recent years, the concept of "revitalization of street space" has gradually been brought forward, and the social attributes of the streets as the public life stage of the citizens have begun to be re-emphasized by the public^[3]. The functional layout of the street determines the vitality and nature of the street, which in turn determines the value and atmosphere of the surrounding plots.

At present, the research on the functional layout of the street level is mostly related to the

vitality of the street. It is considered that encouraging the diversified activities in the street is an important method to improve the attraction of the street. The decrease in the diversification of street functions is the main reason for the decline of street vitality^[5]. At present, the quantitative research on street function and street vitality in academia is mainly based on the use of facility POI and mobile phone signaling data proposed by Ying LONG et al to establish street vitality quantitative evaluation methods^{[4][6]}, and there also are methods based on SD method and the field investigation method from the human perception to describe the street vitality more qualitatively^{[7][8]}. However, there is still not to many methods on quantitatively measuring the vitality of street functions and determining the nature of streets.

This study mainly uses the POI data of urban diversified facilities to determine the vitality of the street from the mixing degree of street functions (that is, the degree of diversification of street functions) and the density of street functions, and further determines the dominant nature of the street through the proportions of each function of the street. This paper aims to conduct a more comprehensive study of the function of urban streets from the above two dimensions, and then to discover the characteristics of spatial function layout of the study area through the street level.

2 Research scope, data and main functional indicators of urban streets

2.1 Research scope and data

(1) Research scope

The scope of this study is Xuhui District, Shanghai. Xuhui District is located in the southwestern part of Shanghai's central city. Xuhui is one of the central urban areas that completed the renovation of the old district in the early time. The railway, waterway, interchange and elevated roads in Xuhui District crisscross, so Xuhui is the main thoroughfare for the city center to enter and exit the districts including Minhang, Fengxian, Pudong New Area, Jinshan, Qingpu and other provinces such as Jiangsu, Zhejiang, Anhui, Guizhou and Guizhou. The interior construction and development of the streets system in Xuhui District is relatively complete, and the urban functions are more diverse and complex, which is more in line with the theme and requirements of this research.

Figure 1. Location map of Xuhui District, Shanghai

(2) Data source

① Road network: The road network of this study is drawn according to the main and secondary roads of Baidu map, and the node is interrupted for the research in the later GIS platform.

② POI map data: In the "Shanghai Street Design Guidelines", it is mentioned in the street function that "passenger transportation is mainly divided into four purposes: commuting, business, life and leisure." In the sixth chapter "Vibrant Street" suggests that functional compounding is one of the primary goals of street furniture^[9]. The classification of street function types by Long Yu et al. is divided into eight categories after screening for POI: government agencies, transportation, commerce, education, corporate, residential, green space and others^[4].

This paper sets up the street function evaluation indicators based on "Urban Land Classification

and Planning and Construction Land Use Standards (GB50137-2011)”, and divides the collected urban multi-type facilities into five categories (see Table 1).

Table 1. POI data classification of urban facilities in Xuhui District, Shanghai

Category	Content
A (Public Management and Public Service)	Administrative institutions such as government agencies, libraries, hospitals, schools, etc.
R (residence)	Residential
B1 (commercial)	Commercial service facilities such as shopping malls, supermarkets, restaurants, bars, beauty salons, pedicure shops, etc.
B2 (business office)	Business office building
G (green space)	Parks, street greens, etc.

2.2 Main function indicators of the street

Measuring the vitality of the street and judging the functional nature of the street in the area are the two ultimate goals of building the street function indicator system. Details as follows:

(1) Street vitality indicators - Street function density, Street function mixing degree

Based on the analysis of five types of urban facility POI data, this paper first measures the street functional density and street function mixing degree, and then derives the first-level indicator—street vitality based on the above two secondary indicators.

① Street function density, defined as the ratio of the total number of POIs to the length of each street within the 50m buffer range on both sides of the street.

② Street function mixing degree, according to the definition formula of Ying LONG et al, which can be expressed as:

$$\text{Diversity} = -\sum(\pi_i \times \ln \pi_i), (i=1, \dots, n)$$

In the formula, Diversity represents the functional mixture of a street, n represents the number of categories of the street POI, and π_i represents a certain type of POI.

The proportion of POIs in the street is normalized. The normalization method is the ratio of the number of POIs in the street to the number of all kinds of POIs in the researching area.

(2) Determination of the functional nature of the street

Defining a certain type of POI exceeds 50% of the total POI in the street radiation range, then this type is the dominant function of this street; if each type of POI on the street is more balanced, there is no more than 50% of the POI, then the street is determined to be a mixed type function; if there is a street that does not judge the proportion of the POI type, it is determined to be of an unknown nature.

3 Street vitality measure

3.1 Analysis by different function types

Based on the five types of urban POI data, namely public service and public management, residential, commercial, business office and green space, the characteristics of the sub-function types of urban streets are analyzed. Measure the number of POIs of each functional type facility in Xuhui District, and use the GIS platform to form a thematic map, and then analyze the spatial layout and characteristics of different functional types of streets (Figure 2).

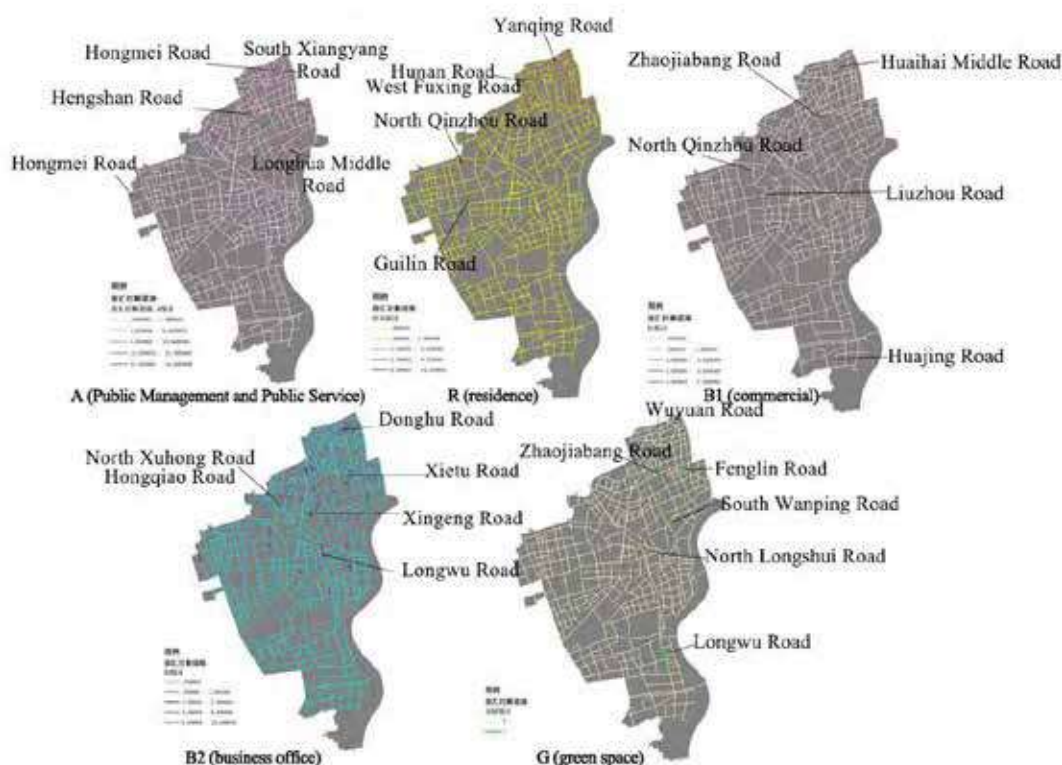

Figure 2. The quantity distribution of five types of facilities' POI in Xuhui District

(1) Public service and public management

The selection of public services and public management urban facilities in this study mainly includes administrative agencies, cultural facilities (schools and libraries), hospitals, etc. The analysis shows that in the Xuhui District as a whole, the number of public service and public facilities in the north is significantly larger than that in the south. The most prominent streets are Huaihai Middle Road, Xiangyang South Road, Hengshan Road, Longhua Middle Road and Hongmei Road. Among them, Hongmei Road is covered by Shanghai Xinmei Art Museum and some science and education cultural facilities in the Caohejing Development Zone. Hengshan Road is located in Xujiahui, Shanghai's vice center. It has relatively complete public service and public facilities. Longhua Middle Road The outstanding performance is due to the concentrated layout of various cultural facilities in Xuhui Riverside.

(2) Residence

The distribution of residential functions in the streets of Xuhui District is similar to that of public services and public facilities, mainly concentrated in the north; but at a more micro level, the streets with dense residential buildings are distributed in the periphery of public service and public facilities. The situation of planning layout in reality, such as Huaihai Middle Road.

(3) Commercial

The performance of Xujiahui streets' commercial functions is different from that of public service and public facilities which gather in the North District. From the entire Xujiahui area, each district has a prominent street in the number of commercial facilities: Zhaojiabang Road, Zhaojiabang Road is an east-west traffic trunk, with various types of commercial plazas and hotels, as well as Liuzhou Road in the Weihe area, and Huajing Road in the Huajing area. Forming the respective commercial centers of each large area meets the realistic requirements of planning.

(3) Business

The streets with more layouts of Xujiahui business facilities are offset to the south, including Longwu Road, Xuhong North Road and Hongqiao Road, Xingeng Road and Nandan East Road, and Donghu Road in the north. The Hongqiao Business District has a radiation impact in Xuhui District.

(4) Greening

The distribution of the streets in Xuhui District with a lot of greenery (parks) is mainly close to the Xuhui Riverside, forming a strip-shaped line. There are north to south including Wuyuan Road, Qijiattun Road, Fenglin Road, Wanping South Road, Longshui North Road and Longwu Road.

3.2 Street vitality measurement

The measure of street vitality is mainly considered from two aspects: the density of street functions and the mixing degree of street functions. Among them, ① street functional density refers to the ratio of the total number of various facilities within the 50-meter buffer zone on both sides of the street to the length of the street, ② the formula of the street function mixture is as mentioned above, $Diversity = -\sum(\pi_i \times \ln \pi_i)$, ($i=1, \dots, n$).

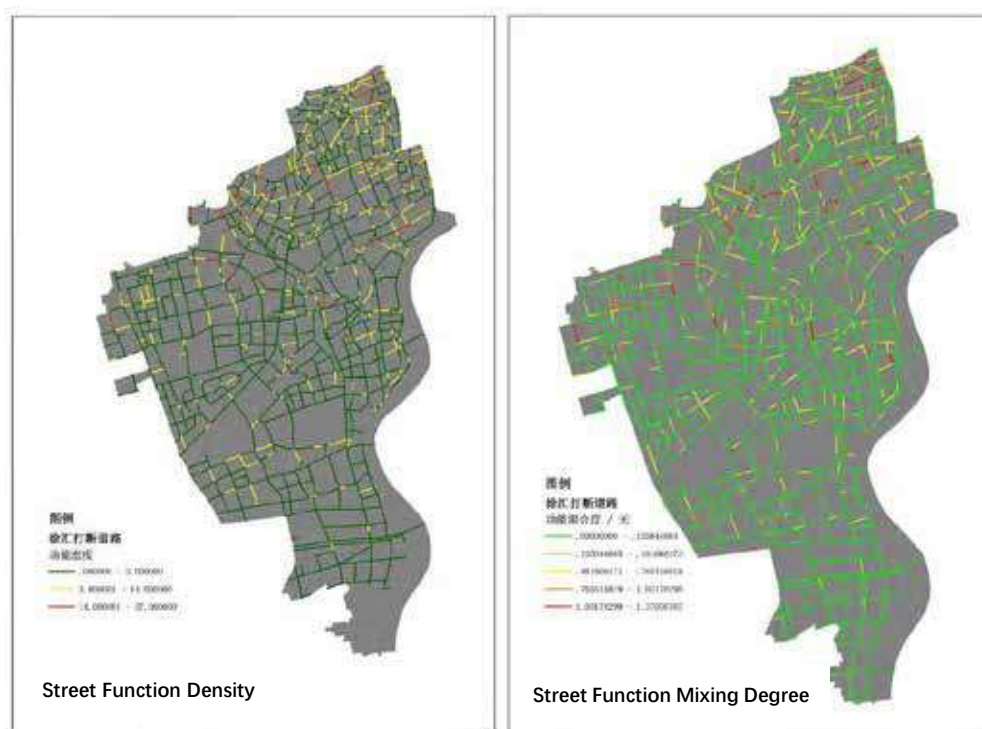

Figure 3. Street function density and street function mixing degree

The density and the mixing degree of street function map are formed by the superposition of five types of POI facility data.

Based on the above two sub-indicators, they are weighted and superimposed at a ratio of 50% each, and finally form a thematic map of street vitality and its nuclear density (Figure 4). From the maps, it can be found that Shanglin Road and Guilin Road around Huaihai Middle Road, Xuhong Road, Xietu Road and Caohejing Development Zone are all high-energy streets. From the analysis of the entire administrative area of Xuhui District, the northern and western parts of Xuhui District are areas with high street vitality, while the opposite is true for the southern part of Xuhui District

and the riverside area. Among them, the number of facilities in the southern part of Xuhui District (Huawei District) is very small, and the overall level is weak. The public service and public management and greening facilities in the Xuhui Riverside area perform well, but in residential, commercial and business areas. Functional development is weak, which directly reduces the function mixing degree of streets in the area.

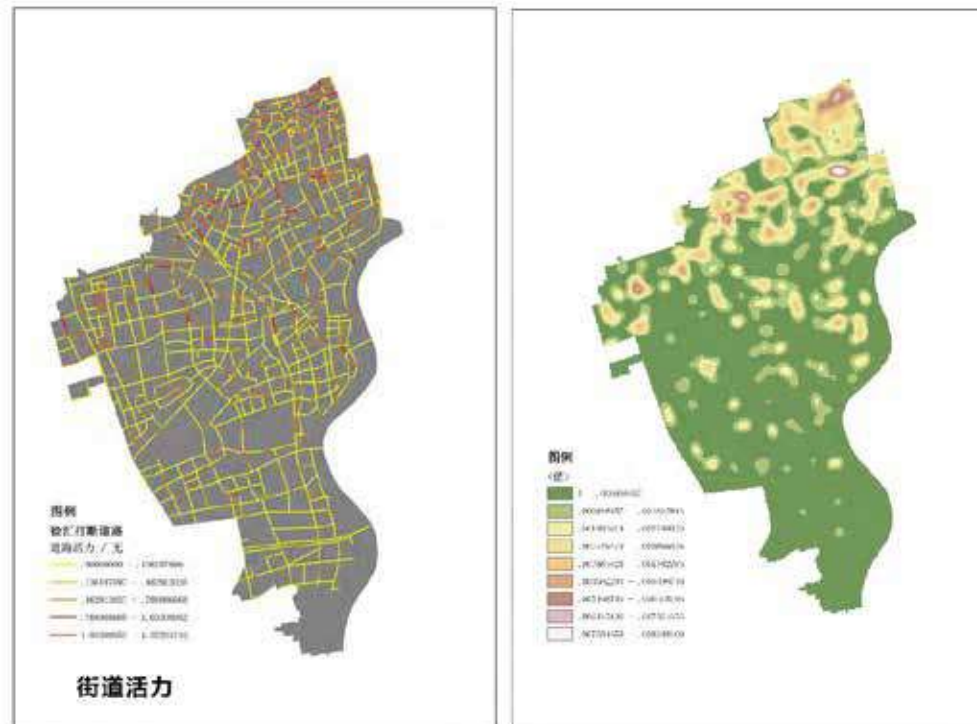

Figure 4. Street vitality and its nuclear density map of Xuhui District

Figure 5. Street vitality at the intersection of Xuhui District

When breaking the road, this paper breaks a street into three sections according to the intersections at both ends, and finds that even in the same street, the streets at both ends of the intersection are more energetic (Figure 5). This aspect reflects that in the layout of various types of facilities in the city, the overall tendency is to arrange facilities around road intersections with better accessibility to obtain higher popularity and consumption.

4 Identify the functional nature of the streets

According to the criteria for determining the nature of urban streets mentioned above, the nature of the streets in Xuhui District is divided into four categories (there is no street dominated by the functional nature of green space), and a thematic map of street nature is established on the GIS platform (Figure 6). After excluding streets of unknown nature, the results showed that the number of the function nature of public service and public management streets accounted for up to 50.64%,

the residential nature of the streets accounted for 15.18% of the total, the commercial nature of the streets the least, accounting for 0.28%, the nature of business office The streets accounted for 31.21% of the total.

Therefore, within the scope of Xuhui District, the number of non-profit public service and public-managed streets accounts for the largest proportion, followed by business and commercial streets with offices and markets, and finally residential streets. It is found that in the Xuhui District, the public social property of the street is strong. Most of the street functions in Xuhui District are for the public service. The number of streets dominated by residence is not large. In addition, there are very few streets dominated by the nature of commercial facilities. This shows that in the configuration of facilities on both sides of the street, the number of facilities mainly based on commercial shopping consumption is very small. This function is usually associated with other functions such as office and residence. Such as the use of configuration, such as Huaihai Middle Road K11 and other commercial office square development model.

At the level of the inner area of Xuhui District, the streets of various natures in the north are more balanced and more complex in the south. This is related to the development of the southern district, and various facilities, especially commercial and business office facilities.

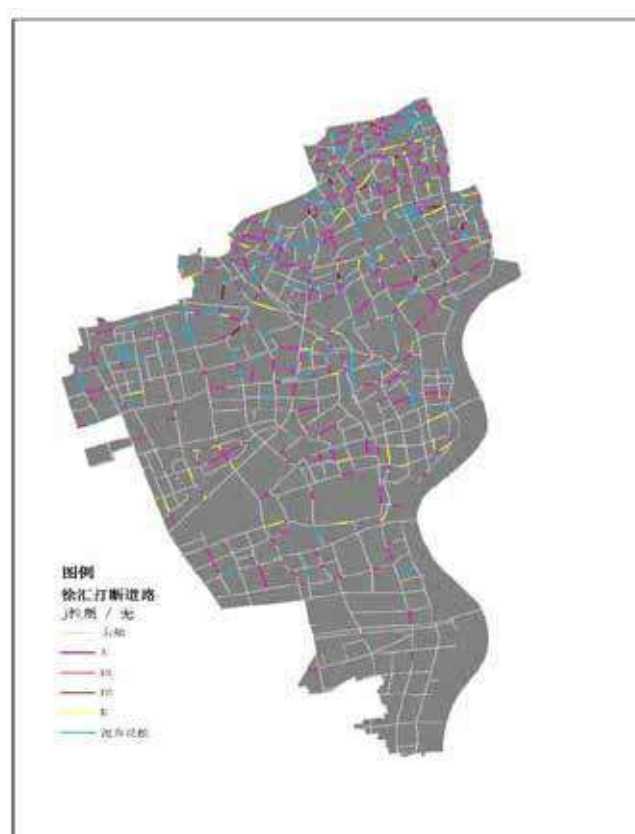

Figure 6. The functional nature of the street

5 conclusions and discussion

From the perspective of street function, this paper conducts quantitative measurement and judgment on the street vitality and street functional nature of Xuhui District in Shanghai through the analysis of POI data of various facilities in the city. This paper mainly uses the GIS big data

analysis method, which is different from the traditional method based on spatial syntax analysis of street vitality, and it is more explanatory than the latter^[4]. At the same time, this study aims to construct a street vitality assessment system at the urban level. The street function density and street function mix are the two main sub-indicators of street vitality; the two sub-indicators are based on five categories (public service). It is superimposed on POI data of different cities with public management, residence, business, business office and greening.

(1) Main conclusions

This study mainly draws four conclusions:

- ① In the scope of Xuhui District, the street functions under different types of POI data are different. The streets with outstanding public service, public management and residential functions are mainly concentrated in the north. And all small areas have several outstanding performance commercial streets. Streets that perform better in commercial are shifted to the south part of Xuhui District, and the streets with outstanding greening functions are distributed along the riverside.
- ② In the overall vitality of the street, the streets in the northwest of Xuhui District are adjacent to Changning District and Jing'an District. On the contrary, the streets in the south of Xuhui District and the riverside are generally weak, and the number of facilities in the city is small and the mixing is low. The overall development is not perfect.
- ③ At the local level of vitality of the street, the street sections at the intersection are more dynamic than the middle section in the street.
- ④ Through certain evaluation indicators, the functional nature of the streets in Xuhui District is identified. It is analyzed that the streets with the same public service and public management nature in Xuhui District have the highest proportion, followed by the commercial and business office streets, and finally the residential streets; therefore the function of streets' in Xuhui district of the district has strong public attributes and a high service capacity for the public.

(2) Disadvantages and improvements

In this study, only Xuhui District of Shanghai was selected as a single research object. Without horizontal comparison, other objects should be added to the future research to conduct comparative analysis of multiple cases, making the nature of the research object more prominent.

At the same time, the article has not tested the relevance of the segmentation type of POI data and the correlation between various POI data and street function vitality indicators. In the future, we can further study the impact of various POIs on the final street vitality index and conduct in-depth analysis.

By no place to public space: a new resource for Capua

Claudia de Biase¹, Irene D'Agostino²

¹ *University of Campania Luigi Vanvitelli, claudia.debiase@unicampania.it*

² *University of Campania Luigi Vanvitelli, irenedagostino0@gmail.com*

Abstract: Capua is one of older cities in Caserta province and today its socio-economic, spatial, social, economic and settlement disequilibrium is clear. The analysis done discloses functional, social and physical degradation of the city and the missing of identity, mixed with phenomena of urban disorder and social and environmental degradation. Very often, infrastructures and social services miss as well. This deficit of public space takes to the creation of denied territory, localized in urban and rural areas. The area of ex assistance camp for foreign refugees – Ex C.A.P.S., our case study, is between the historical centre and housing buildings realized over the 80s-90s. Thanks to Law Scelba (1952), ruling assistance to refugee, this area is destined to a "Campo di Accoglienza", used to host refugee coming from East Europe. Nowadays, the area is not destined for anything and is a state of abandonment and misses its identity. It is neither an empty nor a dismissed area. It might be considered a non-place, without any value, any functional link with the context and with no social aim. It is a marginal place since Institutions have ignored it for years. The aim is to revitalize this area starting from its criticalities, such as accessibility, green and parking areas, services, infrastructures and the missing of social integration through the creation of a big urban park full of utilities and housing buildings. As for accessibility, pedestrian, cycling and driveway paths have been thought to improve it. The last, and maybe the most important, criticality deals with the missing of social integration since the area is not functionally connected with the context. A mixed housing park has been created in order to overcome this criticality. No distinction between public and private buildings has been done in order to achieve a social, functional and housing mix against mono-functionality of peripheral areas.

Keywords: public space, disequilibrium, revitalization, mixité

Introduction

The following work aims at the creation of a recovery project for the area called Ex C.A.P.S., that is the ex assistance camp for foreign refugees, a public space taken away from the population and become denied territory. It is an area of 132,863 square meters, in the shape of a very elongated rectangular trapezium, located in the municipality of Capua along the Via Martiri di Nassiriya. The first phase of the research consists of a historical investigation that clarifies its evolution, its urban structure and in particular its resources and its problems. The second phase consists of a territorial study of the city of Capua in the PTCP, to understand the inclusion of the same in the provincial context and in particular to know the directives in place. After a territorial analysis, we moved on to the study of the existing and existing urban planning tools in order to understand the choices of the administrations and the related effects that these have had on the morphology of the city. The study of the area is the next step both from a regulatory and urbanistic point of view. Finally, a proposal is made for an intervention aimed at revitalizing the same and aimed at the development of sustainable tourism.

1. Capua: resources and problems

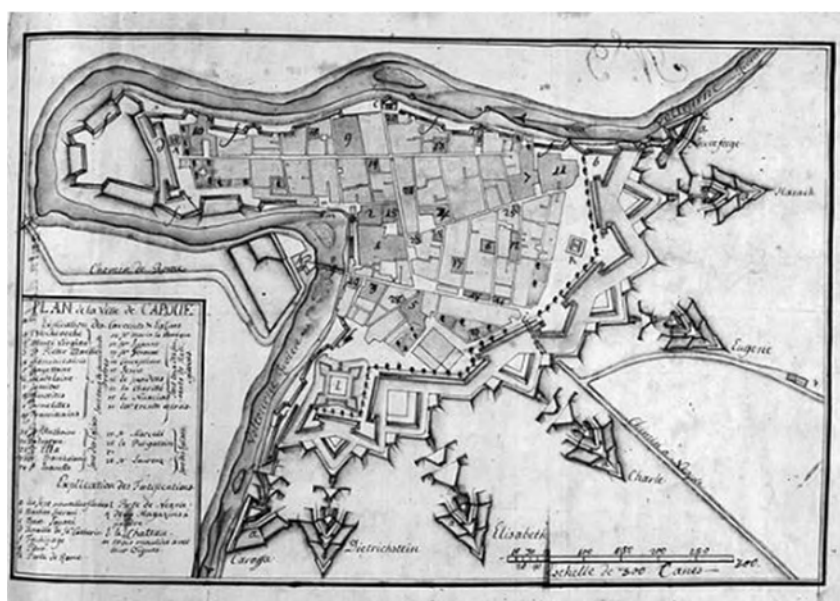

Figure 1. Plan de Capoue [Fonte: Joseph Jerome De la Lande, 1807]

Capua possesses considerable naturalistic-environmental and landscape assets that affect the municipal territory: the Volturno river and the area subject to landscape constraints at the foot of Monte Tifata and Monte dei Lupi, which also includes part of the hamlet of Sant'Angelo in Formis and the two SCI areas "Volturno e calore Beneventano" and "Monte Tifata" (Figure 2-3). Moreover, considerable historical and cultural heritage should not be underestimated: the architectural and monumental elements of value including the bell tower of the cathedral and the towers of the *federiciana* gate. In this context, a strong tourist-religious value is given by the nearby village mentioned above, where are located the Benedictine Basilica, a religious complex of medieval origin candidate to become a UNESCO¹ World Heritage Site, the cathedral of St. Stephen and Agatha founded in '856 but rebuilt in the tenth century. Therefore, the tourist potentialities of the territory are to be considered great, linked to the fruition of the rich naturalistic-environmental and architectural patrimony as well as to the rediscovery of the small historical centre rich in identity and traditions.

Figure 2. Basilica di Sant'Angelo in Formis

Figure 3. Monte Tifata

¹ The application was submitted by the National Commission of Unesco Italy, after a careful analysis in the context of the selection of Mibact.

The city of Capua, as Robotti (1996) writes, shows the liveliness and originality of a compact urban environment, an authentic small capital of the Campania hinterland². The courtesy of the context is enhanced by the uninterrupted presence of both the bishop's seat and the military complexes. In Capua, in fact, works ranging from the Roman age to the nineteenth century, such as palaces and green spaces, churches and convents, barracks and fortifications, merge admirably. All this is enclosed in the wide bend of the Volturno river and in the mighty sixteenth-eighteenth-century bastion walls. The first inhabitants were of Campania, Lombard, and Latin origin; they came in 856 from the Roman Capua, today's S. Maria Capua Vetere, an Etruscan town later destroyed by the Romans. This was rebuilt and had a flourishing life throughout the imperial period, but was devastated again after the invasions and destruction of the Visigoths and Vandals. The earthquake of 685 caused serious damages and changed its appearance. In 817 the ancient Capua became a gastaldato and later - in 841 - a modest county to the dependence of Benevento, but later the Saracens destroyed cities and surroundings. It was after such devastation that the Capuan community moved to the banks of the Volturno. Of another Capua, indicated with the name of Sicopoli, we have news around the year 823. It was a small town built near the sources of Triflisco on a hill of Mount Palombaro overlooking the plain of Campania and much of the valley in which flows the Volturno. After the destruction of ancient Capua, Sicopoli then began to take the name of Capua³. Abandoned Sicopoli, because of the numerous fires that made it unsuitable for defense, the community founded in 856, in just two years of work, Capua Nova in memory of their ancient city from which they fled after the looting Saracens.

Since the foundation of the new city (856), in fact, the importance of the strategic position of the settlement has been understood both with respect to the Volturno river and with respect to the two main road axes of ancient times, the Via Appia and the Via Latina. In particular, the relationship with the Volturno was decisive for the economic life of the city, as it was not only a defensive element but also a source of wealth, as it was navigable at least until the end of the Middle Ages, constituting a fundamental communication route for trade.

The prevailing original character of Capua is to be found first of all in its role as a fortress to defend the territory, which allows us to interpret the magnificence of the city and at the same time its peculiarity as a bulwark city. The Capuan economy, however, went into crisis after 1860, when the city was deprived, after the unification of Italy, of its strategic military role and, at the same time, the progressive restructuring of the transit routes and the development of the railways made it lose that prosperity linked to the favorable geographical position. Moreover, the interruption of the fortification works that the Bourbon government had undertaken led to a sudden drop in the demand for labour, which was an important source of alternative employment to work in agriculture. With the post-unification crisis of the ancient productive structure, agriculture remained the driving sector of the local economy, even if the particularly fertile soils produced to a lesser extent than their potential, due to the backward methods of cultivation, the absence of adequate irrigation systems and the existence of large swampy areas. The economic crisis was also reflected in the demographic trend: from 1871 to 1901 the population increased by only 969 units. The industries were few and small, being mainly small quarries and brick factories located in the outskirts of the city. The only large industrial plant was the Military Pyrotechnic Laboratory, moved in 1857 from Naples to Capua, located in the castle of Carlo V.

The loss of the ancient role upset not only the economy but also the structure of the city. The walls were now useless and harmful to urban development outside the walls of the old town, while the many buildings that housed barracks, convents and welfare facilities connected to them, deprived of their original functional use, were abandoned to progressive degradation or underwent a series of functional changes. In the period between the First and Second World Wars the social and economic situation went through a positive phase, as some large industrial plants were established. In 1938 the sugar factory was born, then the cellulose factory - which in 1948 gave way to the Pierrel pharmaceutical industry - and a series of plants for the

² Robotti C., 1996, *Capua. Città d'arte*, edizioni del grifo, pag. 7.

³ "Capuae quae est Sicopolis" as writes Leone Ostiense, *Cronaca*, libro 1, cap. 26.

processing of hemp and residual products. Since the 1930s, with the construction of the second bridge over the Volturno, the development of urban areas outside the city walls began. From that moment on, we can talk about a real historic center distinct and separated from the new neighborhoods. One of the districts that today, however, still are in situations of maximum degradation is that to the south of the city, where there is the former CAPS area.

2. Capua in the PTCP

The Territorial Coordination Plan of the Province of Caserta⁴ is based on the principle of environmental recovery and requalification to protect the physical integrity of the territory and the landscape (Figure 4).

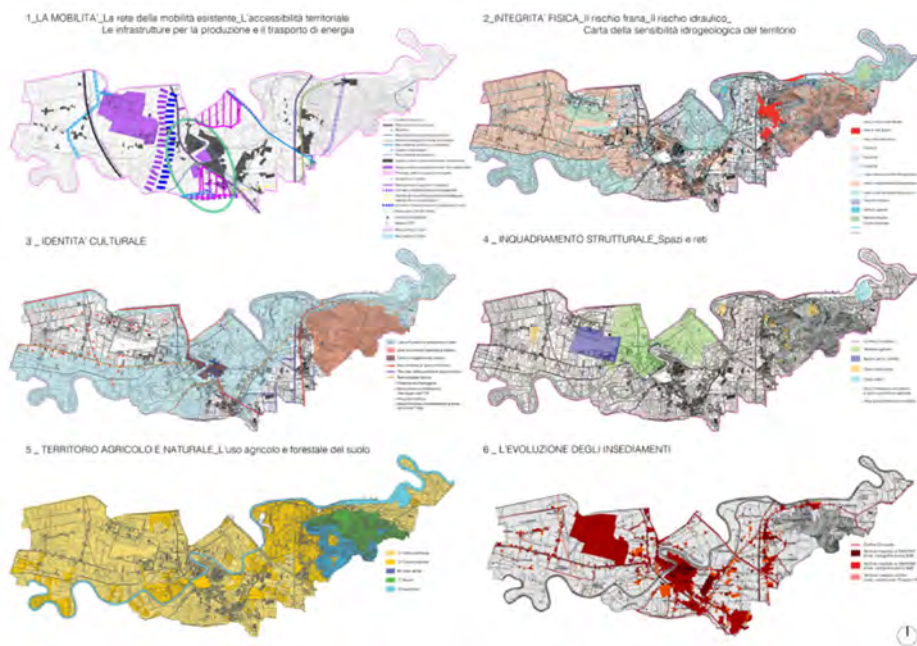

Figure 4. Summary of the Caserta PTCP [Source: author's work]

The analysis work at the base of the PTCP of Caserta has shown, first of all, strong socio-economic and territorial imbalances that characterize the provincial settlement structure. The PTCP divided the provincial territory into six settlement areas⁵ and the municipality of Capua falls within the "Settlement area of Caserta". This area is characterized by a deficit of public, a large amount of "denied territory" and includes the conurbation Caserta, formed by the interweaving of settlements grown around the Via Appia, from San Felice to Gate Caserta and Marcianise, Santa Maria Capua Vetere to the modern Capua. The first objective of the PTCP of Caserta concerns first of all the correction of the tendential settlement pressure that afflicts the areas of conurbation and defines a precise regime of sizing of the municipal plans aimed at stopping the population growth and the consequent congestion of the municipalities with higher density. The action of rebalancing is configured as an essential objective of the PTCP, starting from the consolidation of the settlement weights, which is required to contribute to all municipalities in the province to a certain extent, regardless of real growth and demographic trends⁶.

The PTCP also documents that the settlement imbalance has been accompanied by extremely worrying phenomena of urban disorder, environmental degradation and wear and tear of territorial resources,

⁴ Approved by Deliberation of C.P. n.26 of the 26 aprile 2012.

⁵ Rules of the PTCP, Title I. General provisions, Art. 2, Settlement areas.

⁶ Preliminary Report, PUC 2018, A.1.2 - Provincial Territorial Coordination Plan.

specifically resulting not only from the extent, but also from the morphology, of the settlement developments that have taken place in recent decades and their practical implementation, which is often approximate and out of control. These problems are being solved by focusing on a polycentric type of "discontinuity of inhabited centres in the countryside", based on the differentiation between open rural territory, to be taken away from any form of incongruous expansion, and "urbanised territory", to be reconstituted. It should also be noted that the "denied areas" of rural and open space are not only those polluted by illegal landfills, but also all those in which activities and buildings are located in clear contrast to the environmental values of the context, and in general all areas affected by critical issues that await urgent resolution.

The PTCP attributes a fundamental role to the rational re-use of the "denied areas" present in urban agglomerations, which are the same as the "denied areas" scattered throughout the open rural space mentioned above. They are all those areas belonging to both the urban system and the open space system, without a uniquely defined function and marked by clear signs of degradation⁷. The recovery of these denied areas is the instrument through which the receptive/habitative capacity of some districts can be increased, or the equipment and services can be integrated. In the municipality of Capua 114 denied areas have been catalogued (Figure 5), for a total of 125.45 ha and the PTCP has classified these areas in:

1. Urban areas;
2. Areas of infrastructure relevance;
3. Areas of open space;
4. Quarries;
5. Areas with waste accumulation;

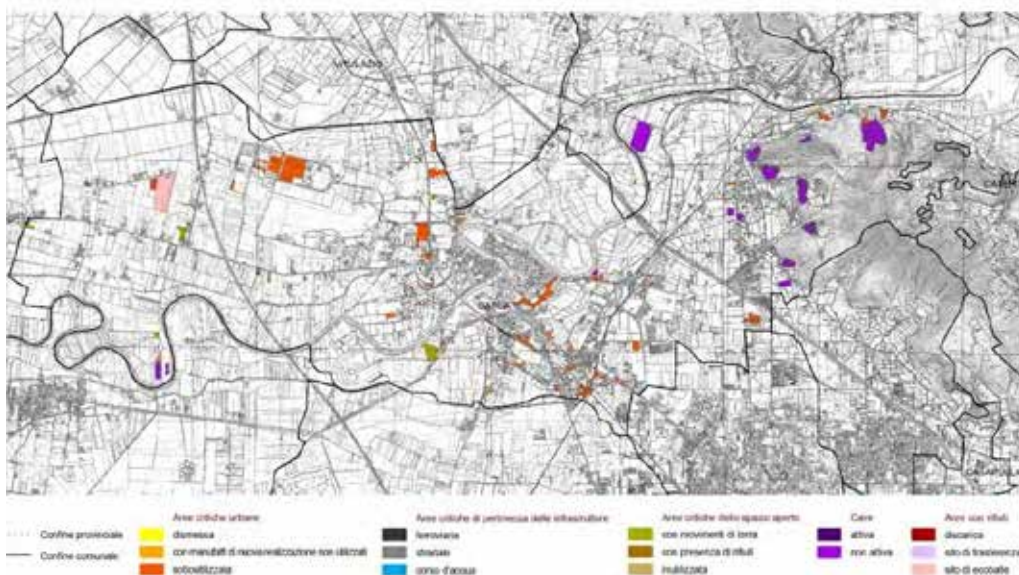

Figure 5. Mapping and classification of denied areas of Capua [Source: author's elaboration]

Analyzing the map, it can be seen that there is a strong prevalence of urban areas denied underutilization and prevalence of active quarries, but in the municipality there are other areas that although being abandoned and decommissioned are not present in the table of PTCP, as they are waiting for the programs of redevelopment

⁷ PTCP Caserta Report, *The territory of illegality, The denied areas*, p. 222.

and/or enhancement planned for these to be implemented. This is the case of the area under study, the ex C.A.P.S..

Another issue to be resolved in the PTCP is the lack of civic identity, often accompanied by a real lack of equipment and social services, which affects the suburbs and – more generally – the recent developments in the urban fabric of many municipalities in the province. As far as the historical centres are concerned, the PTCP provides for this:

1. recovery;
2. the rehabilitation and upgrading of settlements.

3. Capuan urban planning instruments: from the PRG to the PUC

The cornerstone of the urban planning instruments in force is the General Regulatory Plan (PRG) adopted by the municipal administration in 1972 and in force since 1976 (Figure 6).

Figure 6. PRG 1974 [Source: Municipality of Capua]

Downstream of the PRG, several residential interventions have been carried out with the instrument of the Zone Plan⁸. In addition, there are three variants specific to the PRG:

1. a first one adopted in 1977, in force in 1978 but returned by the Campania Region without a conformity visa, concerned only zone D3 for production activities;
2. a second one, adopted in 1986 and in force in 1987 but returned by the Province of Caserta in 1993 with negative results, concerned the establishment of the CIRA (Italian Centre for Aerospace Research);
3. a third, adopted in 1994 but returned to the municipality with negative results in 1996, concerned the production areas.

⁸ Article 19 of Law 328/2000 identifies the Zone Plan as a strategic tool for the governance of territorial social policies. The Plan is the instrument through which the Local Authorities redesign the integrated system of social services that the Area has, with reference to the strategic objectives, the tools to be used and the resources to be activated for its implementation.

From these problems, in fact, the need arose to prepare for the City of Capua a new tool for planning, management and regulation of future arrangements for the entire municipal territory, on the basis of the latest regional legislation constituted by the Regional Law n.16/2004 on "Rules on the government of the territory", the PUC (Municipal Urban Plan). Capua has been involved in three proposals of PUC:

1. The first proposal, in 2010, in which it was decided to start the drafting of the P.U.C. and the R.U.E.C. but, it was evaluated with "negative result" due to differences with the higher-order spatial planning and with the state and regional legislation in force. This concerned mainly the pursuit of a balanced and sustainable development of the settlement system; the redevelopment, reorganization, reprogramming of the territory and the settlements and finally the improvement and strengthening of transport networks recognizing the strategic importance of the same.
2. The second proposal, in 2012, adapted to the observations accepted, as well as to the opinions of the Superintendence, the authority of the Basin of the Liri-Garigliano and Volturno Rivers and the ASL Caserta, concerned mainly the preservation of the quality of the residential destination; the reuse of disused containers; incentives sustainable and environmentally friendly energy policies.
3. The third proposal, in 2018, which contains the key strategic points, such as the improvement of urban quality and living conditions, the revitalization of the existing city and regeneration of the built through the recovery of the old town and the redevelopment of the different districts of the city, in order to encourage a cultural tourism of the city; the impulse to socialization in order to make Capua an attractive and liveable city and finally the sewing up of the suburbs.

3.1. The disused area of the former C.A.P.S.

In the territory of the Municipality of Capua, located in a central urban area between the Old Town and the settlements built in the 80s and 90s, there is a large area of state-owned property known as "Piazza d'Armi" because in past centuries was used for military exercises by the many troops in the city. Within this area, there is also a large complex called "ex C.A.P.S.". (Figure 7) that from the early '80s until 1989, the year of the fall of the Berlin Wall, was used as a reception camp for foreign refugees coming, mainly, from the countries of 'beyond the curtain', mostly refugees waiting for visas to emigrate to the United States, but more frequently to Canada or near northern Europe⁹.

⁹ de Filippo E., Strozza S., 2012, *Vivere da immigrati nel casertano. Profili variabili, condizioni difficili e relazioni in divenire*, Franco Angeli, pag. 60.

Figure 7. State of play of the former C.A.P.S. area [Source: author's work]

However, at times, the centre also hosted the so-called Vietnamese "boat-people" and, between 1986 and 1988, a significant number of Polish refugees. Pugliese and Sabatino write about this area: "Moving on to the province of Caserta, it should be remembered that it immediately attracted attention as one of the first and main nuclei of foreign immigration in Italy from the beginning. This is due to various reasons including, not least, the presence of the Capua refugee camp where some immigrants, especially those from Eastern Europe, had settled"¹⁰. With the so-called "Scelba" Law of 1952, the procedures aimed at the creation of the C.A.P.S., to be located in Capua, on an area owned by the State, consisting of several buildings and their infrastructure, were started. Today, most of the area of Piazza d'Armi continues to be used for agricultural purposes, the area of the Camp for Foreign Refugees Reception, since its closure on 31 December 1990¹¹, has not been used officially, has not in fact a destination for use and for several years is in a state of complete abandonment.

All the Municipal Administrations that have taken turns in recent decades have had in their programs the ambitious goal of acquiring the municipal heritage not only the former C.A.P.S., but also the entire area of Piazza d'Armi. Thus they prepared programs and projects for the redevelopment of the site, which, for its strategic location, is a crucial point for the development of the city and the entire district:

- in 1998, the Municipality of Capua, for the first time, expressed its willingness to acquire the area called C.A.P.S. to allow the construction of a second level D.E.A. (Department of Emergency and Acceptance) hospital complex. In the state of the year, the P.R.U.S.T. (Programs of Urban Rehabilitation and Sustainable Development of the Territory) is proposed, in which the urban restructuring of Piazza d'Armi has been foreseen, foreseeing the realization of a great urban park surrounded and integrated by other structures and the forecast of the lodgings of the E.R.P. (public residential building);
- in 2002, the municipality of Capua, in addition to confirming the forecast of a hospital area to house the D.E.A. of level II already planned, provided for the location of a hotel and some areas of public housing type agreement;

¹⁰ Pugliese E., Sabatino D., 2009, *Emigrazione e immigrazione*, Guida editore, pag. 96.

¹¹ Calvanese F., Pugliese E., 1991, *La presenza straniera in Italia. Il caso della Campania*, Franco Angeli.

- in 2005, all the initiatives mentioned, unfortunately, did not reach a positive result, both for the intrinsic economic difficulties, but also, and above all, for the administrative-bureaucratic obstacles connected with the onerous procedure of acquisition of the state property area;
- in 2006, the Municipality ordered the start of the procedure aimed at the contraction of the loan for the above purposes, intended to finance the expenditure necessary "for the acquisition of the area called ex CAPS for the construction of the new hospital;
- in 2009, in order to redevelop the entire area, the Municipality expressed its intention to acquire the entire area owned by the State, with a total surface area of 132,863 square meters, in order to be able to create both the second level hospital structure and an articulated intervention of urban redevelopment and social activities;
- in 2010, a portion of the former C.A.P.S. area (about 38,160 square metres) was identified as an area of the municipal territory on which to build, as a variant of the PRG, Social Residential Building settlements;
- in 2013, with the enactment of Legislative Decree n. 69 of 21 June 2013¹², converted into Law n. 98 of 09.08.2013, and in particular, with the provisions of art. 56 bis¹³ on "state property federalism", it was decided that the Municipality had the opportunity to acquire the entire former C.A.P.S. area free of charge;
- in 2014, the Regional Director of the Agenzia del Demanio transferred, free of charge, to the Municipality of Capua, pursuant to art. 56-bis of Legislative Decree n. 69 of 21/06/2013, converted with amendments by Law n. 98 of 09/08/2013¹⁴, the full and absolute ownership of the property called "Ex Piazza d'Armi - ex Campo Rifughi rate";
- subsequently, in September 2014, the Public Works and Urban Planning Sectors of this Municipality completed the elaboration of the intervention program for the enhancement and transformation, after reclamation, of the area of municipal property called ex C.A.P.S., which provided for:
 1. the reclamation of the entire area as identified above (132,863 square meters);
 2. a programme for the enhancement and transformation of the area, providing for the subdivision of the entire lot into two distinct areas of intervention: the first, with a total surface area of 93,763 square meters, intended for equipment and services at local and territorial level. The second, with a total surface area of 39,100 square meters., is intended for residential construction, with a share of Public Residential Building (E.R.P.) equal to 70% of the total volume, of which 20% to be allocated to Social Residential Building (E.R.S.) and a share of Free Residential Building equal to the remaining 30% of the total volume;

To date, the PUC has confirmed the enhancement of the area with this "tool" introduced.

4. The C.A.P.S. area in the instruments in force

The area ceded by the State Property Office to the Municipality constitutes most of the original settlement of the area of the former C.A.P.S., with the exception of the area pertaining to the Chapel of San Cristoforo and the adjacent structures already used by the Pastoral Centre of the parish of S. Roberto Bellarmino, and the part occupied by the C.A.P.I. (Civil Protection Centre) of the Prefecture of Caserta. The area, located in the

municipality of Capua along the Via Martiri di Nassiriya near the Appian highway S.S.7, measures 132,863 square meters in total; it has the shape of a rectangle trapezium greatly lengthened. Numerous buildings, most of which were built in the 1950s, stand on the same particle. Part of the buildings have been demolished over the years and the resulting piles of unselected rubble are still present on site; the remaining part of the buildings are in a precarious state of maintenance and neglect. The lot has direct access from the municipal road via Martiri di Nassiriya, which runs along the border on the longest side. There are several buildings on it, built at different times, all in a very poor state of preservation and many even destroyed, with a total covered area of about 46,300 square meters and a total volume of about mc. 97,060 (Figure 8).

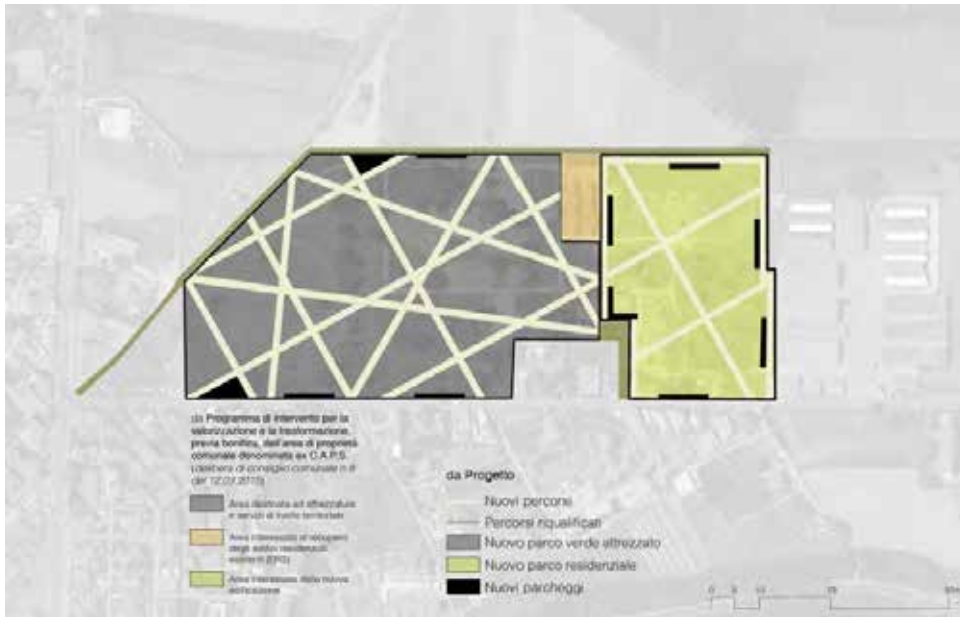

Figure 8. Performance elements of the former C.A.P.S. area [Source: author's work]

From an urbanistic point of view, in the current PRG¹⁵ (Figure 9), the soil is classified:

- for the most part as: "Br2" area, (Refugee Camp) to be renovated;
- for a part as: zone "I", equipped public park and green core;
- for the additional quota as: zone "G1", district collective equipment.

¹⁵ Approved by DPGRC n. 3889 del 26.10.1976.

Figure 9. Current PRG excerpt [Source: Municipal development programme for the former CAPS area]

In the PUC adopted in 2012¹⁶ (Figure 10), instead, the area is classified as zone "BR3"- Urban restructuring already planned, governed by art. 15 of the NTA, which reads: "The BR3 Zone includes the area of the former refugee camp (C.A.P.S.), including the share already identified by resolution of the Civil Code n.4. of 26.02.2010 for the interventions referred to in Article 7, paragraph 4, of Regional Law no. 19/2009 and subsequent amendments and integrations, intended for social housing. In this area are allowed interventions of urban redevelopment and restructuring for destinations of collective and social use.

Figure 10. Excerpt from the PUC adopted by resolution CC n.41-2012 [Source: programme of municipal development of the former C.A.P.S. area].

¹⁶ with deliberation of C.C. n. 41 of the 31.07.2012.

Finally, in the 2018 Preliminary PUC (Figure 11), the C.A.P.S. area, is part of the evolving city, namely the enhancement of the former C.A.P.S. is planned. In fact, the preliminary report speaks of the refugee camp as an area "today the object of reconversion and requalification programmes also for social housing purposes"¹⁷.

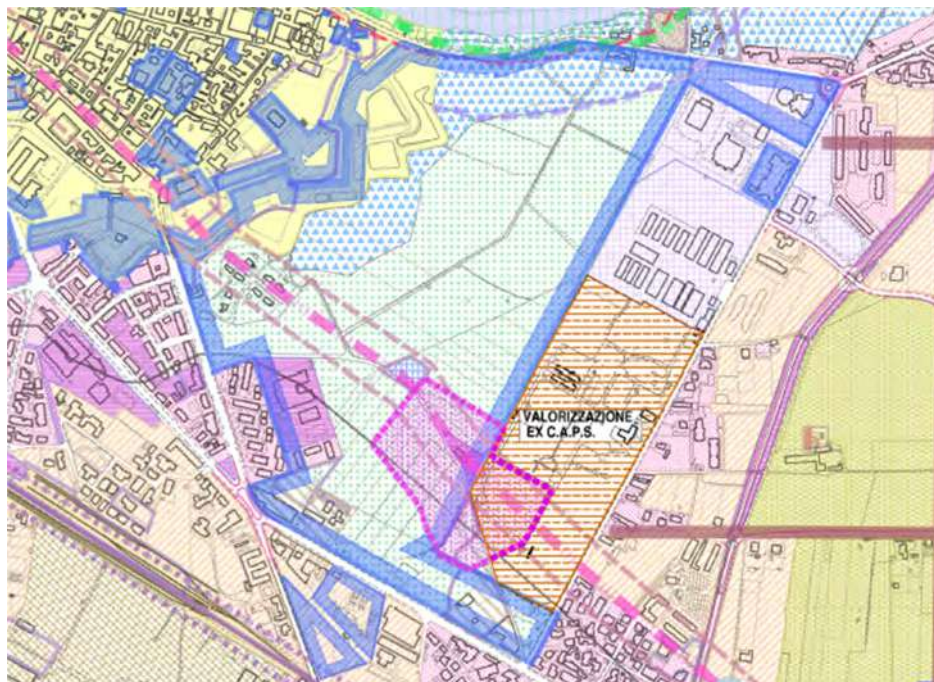

Figure 11. Proposed excerpt from PUC 2018 [Source: Environmental and settlement transformability]

The area is not affected by any type of superordinate constraint.

5. The recovery project

A careful urban analysis of the area, accompanied by historical research, has allowed us to identify the particular elements, potential values and the many critical points of the area, on which to base the guidelines of the recovery project. At the end of the cognitive process, this project aims to make up for the lack of public space that leads to the creation of denied territory, to revitalize an area of great degradation for the city and consequently to create a large public space, absent from the municipal territory, that leads to the development of sustainable tourism that combines urban park and widespread cultural heritage.

This area of 132,860 square meters, has strong critical elements: first of all, most of the buildings that were present in the area, are no longer existing due to a demolition occurred in 2016 for improper use of the same and illegal occupations by Roma families. Of the buildings present in the area of 2016, only two remain today, subject to building recovery (3,350 square meters). Secondly, accessibility is greatly reduced, since it is possible to access the area only through the main road, via Martiri di Nassirya. There are two other roads that do not serve as access to the area while surrounding it and are, via Lazzaro di Raimo, almost an open-air landfill and a road parallel to the main road, accessible only for a small stretch, while the remainder is a dirt road. The green in this area is practically non-existent, or rather, the area is now completely surrounded by greenery, but a degraded green and abandoned, such as to prepare for improper use and neglect. Further discomfort is given by the lack of parking, with the exception of the space in front of the entrance to the former refugee camp and the roadsides used as parking. Another important point is the inadequacy of neighborhood services, with the exception of the sports hall, the elementary school "Former refugee camp"

¹⁷ Preliminary report, PUC 2018, A.0.5.1 - *From the current PRG to the PUC: evolution of urban planning and its impact on spatial planning*, p. 18.

and three churches, the church of San Cristoforo, the Temple of San Roberto Bellarmino and the Sanctuary of San Lazzaro, there are no other standards. Finally, in order to revitalize this area, a large mixed residential park has been created, where the public, social, and private buildings will be included without any distinction between the types of buildings. In fact, the aim was to create a mixture of these in the pursuit of the social mix, so as to unite the housing functions by contrasting the monofunctionality typical of urban suburbs. As a functional mix and a building mix, they allow social mixing.

- the redesign of pedestrian and bicycle accessibility;
- the integration of services and equipment of the district, currently non-existent;
- the creation of a mixed residential park to restore life to an abandoned area, in order to promote social and functional integration;
- the creation of a large urban park to give new green spaces cared for and equipped for the population. (Figure 12)

Figure 12. Project sketches [Source: author's work]

urban one and the residential one, separate but connected. This urban redevelopment then enters the empty and abandoned spaces of the urban blocks so as to create an improvement in the quality of life and a strong increase in green areas for the enjoyment of all citizens, residents, and non-residents.

If this is generally the enhancement project, it is actually divided into two major projects: the equipped urban park and the residential park (Figure 13).

Figure 13. Masterplan of the recovery project for the former C.A.P.S. area [Source: author's elaboration]

5.1. The equipped urban park

Of the 132,860 square meters of the entire area, 90,410 square meters, from "Programme of intervention for the enhancement and transformation, after remediation, the area of municipal property called ex C.A.P.S." are intended for equipment and services of territorial level. An important functional recovery for the area has been thought of with the creation of an urban park equipped for the inhabitants of the area and beyond, a real pole of attraction (Figure 14).

Figure 14. The equipped urban park [Source: author's elaboration]

The main focus is the realization of a series of accesses, located on all sides, which serve as a connection between the area and the surrounding environment. On the main road, 7 accesses, 5 pedestrian and 2 cycle paths have been created; on via Lazzaro di Raimo 6 accesses, 3 pedestrian, and 3 cycle paths have been created and finally, with the redevelopment of the perpendicular road to via Lazzaro di Raimo, another 4 access points, 3 pedestrian and 1 cycle path will be placed. In other words, the cycle-pedestrian route represents the structuring element of the entire project. The whole project is equipped with parking lots, 3 for cars and 2 for bicycles, to fill the previous and total absence of the same. The green, of course, will be the master. In fact, there will be various green areas, located in various points of the park and having various functions, outside the main function of public green, such as:

- a large play area;
- a dog area;
- a large structure which will become a large restaurant with panoramic views of the ramparts;
- a large sports area, with football pitches, tennis courts and a track for athletics;
- a picnic area, which is a real meeting point and aggregation for families;
- a circular structure with a sinuous course which has various functions:
 1. Reading and relaxing sessions;
 2. Stage for theatrical performances or concerts;
 3. A real square, a meeting point in the core;
- paved surfaces, acting as a square, scattered throughout the entire lot, with large trees and circular seats that surround them;
- urban markets, located in 2 points of the park, with direct sale of products grown in nearby urban gardens, located in various areas of the area.

Other areas will be left to public green areas with expanses of trees. (Figure 15)

Figura 15. Project concept [Source: author's elaboration]

5.2. The residential park

The concept behind the residential park project was to pursue the social, functional and housing mix to eliminate the distinctions between the types of buildings, instead creating a mixture of public, social and private buildings, so as to unite all residential functions, creating a large residential park (Figure 16).

Figure 16. The residential park [Source: author's work]

Of the 132,860 square meters of the entire area, 42,450 square meters, from "Programme of intervention for the enhancement and transformation, after remediation, the area of municipal property called ex C.A.P.S." are intended to residential. Of the share of existing buildings, before the demolition, there are only two remaining construction, which are the subject of recovery program building (3,350 square meters). The remaining part will instead be allocated to new construction (39,100 square meters), of which 15% will be allocated to non-residential construction (services), 25% to Free Residential Building and finally 60% to Public Residential Building. The public and private residences will not be separated in this project, but on the contrary one of the central themes will be the search for the mix, both functional and social, mixing the functions of housing (public and private), with those of work, consumption, leisure, contrasting the monofunctionality typical of urban suburbs. This is not the traditional mix (services, residence, activities), but an innovative mix that includes leisure, sport, culture and entertainment, integrating functions not only within individual buildings, but throughout the city (multiuse city) so as to trigger a cascade of virtuous processes of revitalization and redevelopment of the surrounding urban contexts. It is possible to reach this park thanks to the opening of a long axis that connects via Martiri di Nassirya with its parallel, redeveloped. Perpendicular axes intersect on this axis, so as to allow access to the park from all points. All the buildings are equipped with greenery, pertinent car parks and a large underground car park. As planned, services have been designed in the area, such as the kindergarten and the ecological island to make the park liveable, organized and equipped.

Conclusions

This work aims to recover a very complex area that is neither an urban void nor an abandoned area. An area that has lost its identity, which has gone from being a reception camp for foreign refugees to being an area denied to social use. It could be defined as almost a non-place, a private place of value, of functional link with the urban context. In fact, it has now become a marginal place, mainly because of years of disinterest on the part of public institutions. The same institutions, only after years of neglect and consequent degradation, have become interested in the area. In fact, this condition began in the 90s with the closure of the refugee camp and ended only in 2014 when it was decided to proceed with the demolition of the buildings in the area, with the exception of 2 buildings subject to recovery and establish a program of valorization so far not completed. The urban project developed, adhering to the conditions prescribed by the program, gives precise solutions for each area (Figure 17).

Figure 17. Project masterplan with zoom [Source: author's processing]

If the specific aim is to give a new image of this area, it has been tried to demonstrate that it is possible to comply with the rules, the needs of the population, the identity of places and transform a non-place, from problem to resource for the city of Capua. Resource created through the recovery, the transformation of the former C.A.P.S. in a place no longer "EX", a place with its own life, converting this degraded area into a new urban centrality. A large equipped urban park and a residential park with all the related services and equipment have been designed, with a deep focus on greenery, accessibility and connections, trying to give this area a functional mix, characterized by the presence of large urban services; a mix that includes leisure, sport, culture, integrating the functions not only within the area, but throughout the city. The functional mix is accompanied by a social mix that was created through the residential park and where there are no distinctions of housing type but public, social and private buildings. They all are mixed together to counteract the monofunctionality typical of urban suburbs. All this has been designed to give this area a socio-economic as well as historical-artistic usefulness, so that this heritage becomes a tourist attraction; attractor of a sustainable tourism able to preserve the environment, the community, the economies and the local cultures. A set of practices and choices that do not harm the environment but enhance it, promoting sustainable economic development and also contributing to the improvement of the quality of life of resident

The impacts of sharing platforms for tourism on spaces and communities: the possible role of place-based regeneration processes

Abstract: Within the national and international scenario, the phenomenon of sharing economy in tourism is strictly linked to the “shadow hospitality” models, spread on platforms such as: Airbnb, Homelidays, Wimdu (Travel like e local), Vrbo (Vacation rentals by owner); Kid&Coe, HouseTrip, OnlyApartements. This new trend in tourism needs to be investigated in terms of impacts on local communities, public spaces and urban cultures. The so called “Airbnb effect” is influencing the housing sector, the typology of commercial facilities, and the local productive traditions. Several initiatives - both at municipal and communities level - started recently in European cities affected by these phenomena and different policies and measures were adopted for: protecting the housing accessibility, regulating the real estate speculation and stopping the expulsion of residents. In line with this perspective, the paper will discuss the following research questions: How to investigate the impacts of the shadow hospitality on cultural, social and economic environment of the urban areas affected by these phenomena? How a place-based regeneration process could contribute to re-balance economic opportunities and risks produced by sharing platforms in tourism, by dealing with the loss of authenticity of public spaces and the gentrification trends?

Keywords: sharing platforms; tourism; place-based regeneration; local communities

1. Touristification: lever for development or urban degeneration?

In the last decades, tourism encompasses multiple new destinations, thus becoming one of the fastest growing economic sectors in the world and a driver for socio-economic progress. Tourism has become one of the major players in international commerce, and represents at the same time one of the main income sources for many developed countries. “This global spread of tourism in industrialised and developed states has produced economic and employment benefits in many related sectors - from construction to agriculture or telecommunications” (UNWTO, 2018).

Tourism, and cultural tourism in particular, draws upon artistic, historical, environmental and human resources of the territory, and in turn contributes to local development and to the enhancement of the pre-existing heritage. The attraction of tourists ranks high in urban agendas, strategic planning documents and in policies geared towards the preservation and the enhancement of cultural heritage, job creation and the revitalization of stagnant economic sectors. As an economic sector, tourism constitutes a large portion of the economic output in well-established destinations and in art cities. On the other hand, marginal or economically weak areas seek to attract tourists as a panacea to counter depopulation and the dissolution of traditional economic activities. UNWTO forecasts international tourist arrivals to reach 1.8 billion in 2030 (UNWTO, 2011).

This tendency has been observed and analyzed in scientific literature across different disciplines and is widely accepted. It has been observed that tourism has brought both positive and negative outcomes in different geopolitical contexts. Whether – and to which extent – tourism is a sustainable industry is hotly debated (as seen in figure 1). On the one hand, more people than ever are able to visit art cities – as opposed to the privileged travelers of the *Grand Tour* – and the hospitality sector grows exponentially. On the other hand, however, tourism exerts an undeniable pressure upon morphologically and socially fragile area and endangers vulnerable cultural heritages. The latter risk stressed the need for a differentiated understanding of the phenomenon and for an appropriate management thereof. A recent survey conducted by the World Tourism Organization (UNWTO) and IPSOS (June 2019) finds that, generally speaking, urban dwellers are in average supportive of tourism. At the same time, it points to the urgency of identifying management strategies to address the emerging challenges that come with increased tourism demand¹. Looking at 15 countries worldwide, the UNWTO report shows a positive picture of local residents’ perceptions towards urban tourism, identifying what residents consider to be the best ways of managing rising numbers of tourists and highlighting different attitudes to urban tourism amid different socio-demographic groups². “In order to make sure that urban tourism continues to benefit local residents, it is fundamental to implement sustainable policies and practices. This includes the regular monitoring of residents’ attitudes towards tourism and factoring them in the tourism agenda.³” More specifically, with regards to potential measures to address growing tourism flows in cities, residents across the 15 countries consider ‘improving infrastructures and facilities’ as the most effective. In Hungary, 89% of respondents stressed this measure as the most adequate, followed by Italy (80%) and Argentina (79%). In a similar way, “creating experiences and attractions that benefit residents as well as visitors” is the second most preferred management strategy, and extremely popular in all countries (82% in Canada and Hungary; 75% and 74% in Argentina and Republic of Korea, respectively) (UNWTO and IPSOS, 2019).

¹ The UNWTO/IPSOS Global Survey is based on the IPSOS online omnibus survey conducted between December 2018 and January 2019. The research is based on the responses of 12,000 respondents in 15 countries – Argentina, Australia, Belgium, Canada, France, Germany, Hungary, Italy, Japan, Poland, Republic of Korea, Spain, Sweden, United Kingdom and United States of America

² Regarding the results of the survey, tourism’s impacts are valued most positively in Australia, Argentina, Sweden, the Republic of Korea and Spain. Young respondents (under 34) exhibit a stronger awareness of both the positive and negative impacts of city tourism, in contrast to older respondents (over 50) who perceive the negative impacts less. Younger respondents are also more likely to be in favor of more restrictive measures to manage increased tourism demand. Among older respondents, only 5% think that tourism promotion should be stopped, and only 8% favor limiting the number of visitors in their cities as compared to 12% and 16% of younger respondents. (UNWTO and IPSOS, 2019)

Figure 1. UNTWO Sustainable Development Goals. Source <http://tourism4sdgs.org/>

Recent debates highlighted the additional challenges posed by the diffusion of collaborative economy platforms in the tourism sector. This, together with cities competing to be included in the network of low-cost airlines, change the trajectories, the habits, and the supply of touristic destinations.

In this framework, the paper addresses one of the most discussed problems in recent years: the so-called *shadow hospitality*. Although this phenomenon is almost always identified with the platform *Airbnb*, the latter is only the most famous but surely not the only provider of tourist apartments. Other examples include: *Homelidays*, *Wimdu* (*Travel like and local*), *Vrbo* (Vacation rentals by owner); *Kid & Coe*, *HouseTrip*, *OnlyApartements*, just to name a few. In the absence of appropriate regulations, the supply of such accommodations has grown enormously and in a disorderly fashion.

In contrast to traditional hospitality management, the so-called “shadow hospitality” (HOTREC, 2014) eludes governments’ coordination and control efforts. Among these, particularly important are security and legality controls which otherwise apply to regular operators in the tourism sector. Shadow hospitality thus operates in legal loopholes and exploits the advantages created by deregulation.

According to a recent survey, carried out by the Italian hospitality association *Federalberghi*, 397,314 accommodations were available in Italy in August 2018 (Federalberghi, 2018). This shows an average annual increase of 37.6% since 2016, and of 45.7% since 2013, when the platform only had 60,589 flats available. Originally, *Airbnb* established itself as a provider of “shared” travel experiences, whereby tourists could interact with their hosts and thus as an opportunity to experience destinations in a more authentic manner and to explore the identity of the visited places.

Within few years, however, Airbnb has grown exponentially and turned into the opposite of what it once stood for. It is no longer a complementary source of income for households who diversify the hospitality supply and provide “authenticity”. Particularly in large cities and in well-trodden touristic destination, the growth of Airbnb is gradually leading to the emptying-out of old city centres and to the expulsion of their residents and of traditional activities. The abandonment of old city centres, in turn, leads to a loss in these places’ identities: whole districts have become dominated by hospitality and food enterprises.

Furthermore, the Federalberghi survey argues against several common conceptions about Airbnb. Notably it disputes that: Airbnb grow where the supply in hospitality is lacking; that it provide supplementary forms of the income for the owners; that tourists “share” their experience with the owners and finally that hosting be overwhelmingly an occasional activity. Often, landowners do not manage apartments and holiday homes themselves, but hire sophisticated firms to do so.

This assessment seems convincing. It highlights the problem and effectively calls on institutions to act. However, it does not point to the distortion of places determined by the arrival and diffusion of Airbnb: whole buildings almost without residents, and entire neighborhoods geared only to shops and catering for tourists. The following pages reflect on the evolution of collaborative platforms for hospitality in the tourism sector and on the dynamics that they are generating in the different types of tourist destinations. If geared solely towards the earning of short-term profits, we argue, tourism can impoverish cities and territories and destroy their identity rather than work as a factor of local development and as a channel for the enhancement of cultural heritage. The expulsion of the resident population in favor of tourism hospitality, the destruction of local traditions in favor of a standardized tourist offer, and the elimination from the market of traditional economic activities can be considered indirect consequences of the diffusion of platforms such as Airbnb. In fact, in attractive areas, these platforms seek to favor tourist flows by not respecting zoning regulations.

This scenario will be discussed here through a reflection on sharing economy platforms in the tourism sector. These are analysed in the context of growing reactions in cities where this kind of tourism has been growing the most. The paper ends with a proposal to elaborate a process of urban and territorial regeneration based on endogenous resources as a possible way to avoid the dispersion of cultural and social capital of touristic areas. This approach presupposes a “counter-cyclical” adaptation, so that the tendency may be still inverted and thus prevent re-generation efforts to result in de-generation.

2. Collaborative economy and sharing platforms: key aspects

The collaborative economy (Acquier, Carbone, & Massé, 2017) aims to generate value through relational capital. It is often linked to platforms (Evans & Gawer, 2016) that facilitate new entrepreneurial models by building a market open to the temporary use of goods or services. These are often provided by private individuals or firms (European commission, 2016). However, such entrepreneurial models are not always geared towards a tight relation between economic and social progress. In terms of identity, economy, and local communities, their impact on cities and territories is highly significant concerning the rights of the resident population, the protection of travelers, the social and occupational equity of the different urban areas, but has not been quantified objectively. The uncontrolled growth of tourist flows, the alteration of the real estate market, and the lack of

adequate regulations often diminishes the intrinsic value of the places and feeds into social conflicts as well as into imbalances in consolidated markets.

Whether fair and sustainable development in a territory is possible depends on its ability to create value, particularly shared value. According to Porter & Kramer, "The concept of shared value can be defined as policies and operating practices That enhance the competitiveness of a company while me advancing the economic and social conditions in the communities in which it operates. *Shared Value creation focuses on identifying and expanding the connections between societal and economic progress*" (Porter & Kramer, 2011).

In the light of these reflections, it seems useful to analyze the topic of the tourist fruition of the territory by looking at the contribution of the different economies which, thanks also to the use of new technologies and internet, have different tools to develop and spread quickly. This "chain reaction" generates changes in cities and territories, which have both positive and negative impacts on local development. "Sharing", "experience" and "circular" economy are growing economic forms which share some features. Generally speaking, these are oriented to new consumption logic. Within this logic, growth is oriented towards the internet and on the market's needs, as well as towards ever-changing communities and territories. In doing so, this new tourist supply seeks to offer unique and authentic experiences by at the same time optimizing the use of human, environmental, social, and economic resources.

Against this background, it is necessary to define how these new and less structured economic models impact on the planning and management of the territory. Mirroring the new and unpredictable changes in the relation between firms and territory, research in urban planning and economics has produced several research methodologies and approaches (Calafati, 2009; Polanyi, 2010; Zamagni, 2007). Territories are increasingly impacted upon by economic initiatives based on co-creation processes. The theories of reference for these practices are based on a multidisciplinary and multicultural contamination, as well as on horizontal interactions between actors and users. The aim is to experiment with more streamlined and flexible development models, thus mirroring societal changes.

In particular, the so-called "sharing economy" model (Schor, 2016) is booming, as shown by data on gross total revenues in the European Union of collaborative platforms and service providers (28 billion euros in 2015). Since 2013, there has been considerable growth. This bulged in 2015 following investments in large platforms, which has expanded the boundaries of their activities. A first estimate shows that the collaborative economy is increasing its turnover from 160 to 572 billion euro (European Commission, 2016)

In Italy, the phenomenon is growing, too. Recent studies (Sharitaly, 2016, 2017) have traced the sector's impacts and the growth in different branches of the Italian economy, including from housing to transport, from tourism to welfare, to culture, finance, Science and work. Through this research, Sharitaly seeks to gauge the potential of the sharing economy towards new forms of regulation aimed at collaborative users and entrepreneurs. These researches are collected in the annual report of the "Collaborative platforms map", along with further data on the sharing economy in Italy. From the data revealed 125 active platforms in 2017 (Sharitaly, 2017).

Also other economic phenomena, such as on-demand services, the “rental economy” and the peer-to-peer economy (Bauwens, 2005) and collaborative consumption (Botsman & Rogers, 2011) may fit in under the “sharing economy” umbrella. This empirical broadness expands the boundaries of its still growing theoretical and policy articulations (Friel & Rabbiosi, 2016).

Particularly, the collaborative platform (Cerreta, Daldanise, & Regalbuto, 2017), as an application model, enables the provision of differentiated services. Through technological support (e.g. websites or mobile apps), services can scale up, be useful and original. These platforms have the following common attributes: They are p2p (peer to peer); they allow the exchange or the sharing of goods, objects, money and spaces; do not select the staff; and they enable transactions through a reputation system. Also, platforms can be used to access a resource temporarily without cash transactions (as in Timerepublik), or with a money-mediated transaction (such as on Airbnb and Gnammo). Some make it possible to trade one resource in exchange for another without monetary transactions (such as Baratto Facile, Zerorelativo), or to use alternative currencies such as time and credits (such as Reoose, Timerepublik, Sardex). Others allow users to donate or exchange used item (as on Sharoola, Subito.it, EBay).

Within the framework of "sharing" platforms, the phenomenon of "Tourism and Shadow Economy" (Federalberghi, 2018; Hotrec, 2014) highlights two crucial aspects related to the growth of non-hotel hospitality services:

1. A normative aspect: Legislation to guarantee an actual sharing experience and to avoid damaging the local market. Regulations should adapt the current management rules and integrate them with new norms to protect customer, workers, and the broader community;
2. An urban aspect: The change in identity linked to the environmental, cultural, social, and economic impacts that the new models of hospitality have on cities and on their old city centers.

In this perspective, the diffusion and the increase of these models in the tourism sector shows how the sharing economy is becoming more and more rooted in urban life. This is because the new forms of digital technology connect people and goods through new forms of network which often may not be monitored. Unfortunately, sometimes this translates into a mere *rhetoric* of sharing, whereby the exchange of goods online promotes the otherwise very usual logic of profit maximization (Ferreri & Sanyal, 2018) rather than an authentic touristic experience based on actual cooperation between residents and "temporary citizens" (Comitato Matera 2019, 2014).

3. The “Airbnb effect” on European cities

Under the label of "collaborative tourism", a multimillionaire business has quickly established itself. The latter is based on two pillars (Acquier et al., 2017): Low-cost flights and Airbnb (along with several similar portals, such as HomeAway). As transactional-type platform, Airbnb has indeed been very successful within this strand of "platform capitalism" (Srnicek, 2017). However, this economic drive has amplified the negative impacts of mass tourism on cities.

The data below (as seen in figure 2) ranks European destinations by amount of listed accommodations, share of entire houses/apartments for rent, and incidence of listings with "high

availability" (i.e. for three months or more). It shows that about 40% of the hosts offers several apartments, and that 64% of users carry out this activity for more than 4 months/year. This business model has removed apartments from the regular housing market. In Europe, Airbnb's sales volume grew by 14% in 2015, and by 24% in 2017. In 2016, thanks to reservations in 191 countries, the worldwide turnover amounted to 1.7 bn dollars (Sole 24 Ore – Zanini, 2018). In response, several European cities have introduced restrictions and regulations.

City	Total listings	Entire house/apartment for rent	High availability
London	49,348	51.2%	58.8%
Berlin	20,576	50.0%	38.2%
Barcelona	18,531	46.6%	63.9%
Paris	61,152	86.9%	34.4%
Rome	25,275	60.1%	91.4%
Athens	5,127	83.2%	91.6%
Venice	6,027	74.9%	87.1%
Amsterdam	18,861	79.5%	28.1%
Brussels	6,192	64.6%	57.8%
Copenhagen	20,545	80.7%	37.6%
Dublin	6,729	47.0%	49.9%
Edinburgh	9,638	56.8%	57.4%
Madrid	16,313	63.4%	64.7%
Málaga	4,853	76.3%	85.3%
Mallorca	14,858	87.5%	94.4%
Manchester	868	41.3%	83.8%
Trentino	1,847	77.3%	92.0%
Vienna	7,893	67.3%	67.0%

Figure 2 Data on Europe's main tourist destinations (source: InsideAirbnb, April 2018)

Globally, the "Airbnb effect" has worsened gentrification. The contraction of housing supply and the increase in costs radically affects the social fabric of these areas, transforms entire neighborhoods into spatially widespread hotels and theme parks to the extent that, since 2014, large European cities introduced new regulations to sanction breaches to the preexisting zoning regulations. Among the first cities to adopt containment policies are Barcelona, Paris, Berlin and Amsterdam (Sole 24 Ore – Zanini, 2018). These cities acted to safeguard housing accessibility, regulate the market of listings and stop the expulsion of residents from city centers. Some cities have witnessed vehement protests against these forms of tourism, including demonstrations and street protests. The protests focused on the role of such platforms in fostering real-estate speculation and altering the historical and architectural character of the city.

These include cities such as Lisbon with its historic *Alfama* neighborhood, the city's original urban core where the poor lived outside the city walls. When residents are expelled by owners who seek to make profits with Airbnb, the traditional shops and craft shops disappear to make way for fashion stores or souvenirs for the visitors. In the same city, in the historic district of *Mouraria*. *Mouraria* is the birthplace of *fado* and crucible of lively and essential cultures of the "other" *Lisboetaes*: the

Brazilians, Africans, Chinese, Indians and the many others. Here, local associations resist the pressure of tourism and the reaction of residents has been triggered (as seen in figure 3).

Figure 3 Lisbon – Mouraria (source: the authors)

Similar processes took place in many European tourist destinations, such as Venice and Barcelona, where residents must seek new homes and where the lack of regulation of worsens conviviality and social fabric in the historical centers. Entire districts are transformed into tourist areas without authenticity (Corporate Europe Observatory, 2018). In Madrid from 2005, the city center has lost over 15,000 inhabitants. The influx of tourists in famous neighborhoods such as Lavapiés dilutes its identity as an ethnically mixed place.

The report "UnFairbnb" (Corporate Europe Observatory, 2018) shows how the platform contributes to the strong increase in housing prices and creates pressing neighborhood problems to such an extent that the issue has been the subject of new strategies in several European cities.

Barcelona no longer issues permits for short-term rentals in the *Ciutat Vella*, which caused a conflict between the municipality and the company, which had to pay a 600,000€ fine. The protests and clashes were eventually reconciled into an agreement between Airbnb and City Council in order to fight together illegal listings. In response to widespread protests, the municipality issued a special masterplan, the PEUAT – “Plan Especial Urbanístico de Alojamientos Turísticos” (Barcelona City Council, 2017). This plan, based on an analysis of the phenomenon, divides the city area in different zones: the city centre, where no new reception facilities may be opened (red zone). Other zones indicate less central areas where such initiatives are permitted, but in a limited fashion. In Paris the fight against for-profit real-estates, called "ATMs", ushered the so-called "compensation rule": This rule forces the owner of an apartment that has been withdrawn from the regular rental market, to buy a commercial property and turn it into housing. This rule was strengthened in 2014 thanks to two

provisions. On the one hand, it was stipulated that the newly purchased properties should be in the same neighborhood. On the other, property registration became compulsory.

In response to the rapid growth of the phenomenon, the city council of Berlin has frozen the issuing of new permits to rent apartments and houses in May 2016. From then on, it was strictly prohibited to use such properties for short-term housing and this resulted in a lawsuit between Airbnb and the city. After the victory in court, the regulatory framework has been reinforced by a bill that has increased fines for illegal listings, thus bringing back a total of 8,000 apartments to the long-term rental market.

The city council of Amsterdam initially signed an agreement with Airbnb to simplify the rental of apartments and houses but capped its duration to two months per year. In return, Airbnb should have helped the authorities to counter illegal hotel accommodations. However, the number of complaints was so high that it was difficult for the city to monitor them: most ads seemed to break the rules because the offered accommodations were available for more than two months. In 2017, despite company's willingness to cooperate, the authorities have arranged that all guests must register with them and, in January 2018, the permitted period was reduced to one month a year only.

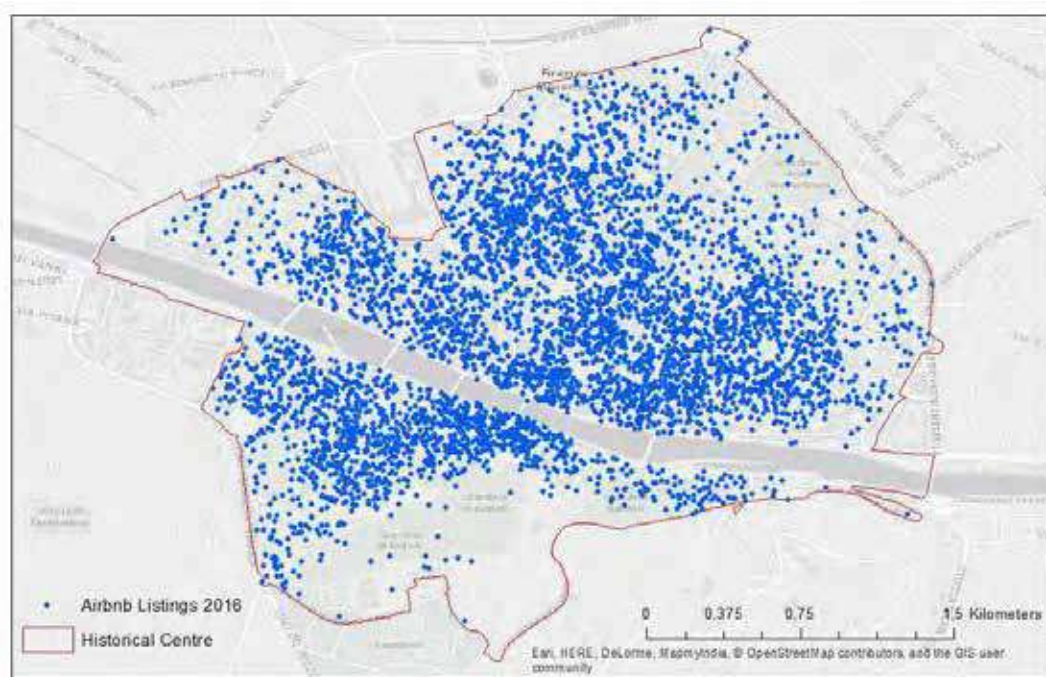

Figure 4 Spatial diffusion of Airbnb listings in the old center of Florence (source: LADEST, 2018)

Different sources label these transformation the “Airification” of cities (Ladest, 2018). These include International online data collection projects such as "Inside Airbnb" (Cox & Morris, 2018), an online tool that monitors the impact of Airbnb on urban communities, or AirDNA of MarketMinder (an integrated platform for vacation rental insights) and national searches such as that conducted by LADEST (Historical territorial Economic Data Laboratory) of the Department of Political Sciences of the University of Siena. These studies argue that low cost rents affect not only the traditional tourism business but also the morphology of the main historical centers worldwide. In Florence, one in five apartments in the historical center of the city is listed on Airbnb (as seen in figure 4) soon disappears definitively from the regular long-term housing market (Sole 24 Ore – Tremolada, 2017). LADEST

analyzed the spatial and economic aspects of the real estate market in several Italian historical centers, with particular reference to 13 cities: Bari, Bologna, Catania, Florence, Genoa, Matera, Milan, Naples, Rome, Siena, Turin, Venice, Verona. The search uses a large database to trace the listings on the platform in the years 2015 – 2016.

The phenomenon creates revenues without a real redistribution of wealth, since homeowners continue to gain whereas weaker social strata grow increasingly poorer. The SET network (Sud Europa di fronte alla Turistificazione – Southern Europe in the face of Touristification) seeks to investigate this phenomenon by analysing data about the downsides of “collaborative” tourism and to propose alternative courses of action. For example, in Florence’s old center, the SET network highlighted the dominance of multinational funds behind the city’s hospitality supply there.

In Naples, there are currently 8,714 Active Rentals. The largest rental channel are Airbnb (83%) and Homeaway (11%). 6% of the offers are listed on both (AIRDNA, 2019). The Municipality of Naples has not introduced any relevant measures. The only initiative worth mentioning is the creation of a Municipal Identification Code (Codice Identificativo Comunale – CIC) for non-hotel hosting facilities. Such a code, however, is neither mandatory nor incentivized. As a result, few homeowners get such a code, since doing so would likely mean having to withstand controls on sanitary facilities, construction permits, etc. The Municipality has recently produced a document for the “Estates General on Tourism” (Stati Generali del Turismo), called “Marketing plan for the strategic development of Naples as a [touristic] destination” (Piano marketing per lo sviluppo strategico della destinazione Napoli). The document has been commissioned by the managing company of the city’s airport, GESAC. According to the researchers of the SET network, however, the data upon which the document builds does not allow the definition of concrete guidelines for the strategic development of the city.

MISSION

The SET network (Southern Europe In the face of Touristification) is an initiative born out of the experience of some European cities which faced several negative effects of mass tourism. Its manifesto focuses upon the main critical aspects of Southern European experiences.

GOALS

To study the phenomenon and identify negative aspects. To propose data-based alternatives and analysis.

23 cities involved

ACTORS

Students
Retailers
Workers
Unemployed people
Professionals

BENEFICIARIES

Citizens (weaker social strata)

ANALYSIS OF THE SITUATION IN NAPLES

- Rents have increased by 9% in the old centre and in the surrounding areas.
- Local retailers were forced to close down, while shops for tourists and non-residents have become widespread.
- Activists at the labour help desk of the [social center] “ex OPG” signal the diffusion of illegal or underpaid labour in the tourism sector.
- Pollution caused by cruiser ships moored at the harbour – in turn due to the dock not being electrified.

Figure 5 Interview with Alessandra Caputi (SET network – Naples Chapter)

Within the Naples chapter of the SET network, of which Alessandra Caputi is a member (see interview in figure 5), the network's research concentrates on the legal framework concerning three types of non-hotel tourism (short-term stays, B&B, holiday homes) in order to elaborate – together with the city's II district - relevant proposals to be ultimately submitted to the Municipality. Within this European scenario, Airbnb has set up a national initiative to generate positive economies for territories and local communities, probably in response to the many protests moved against the platform.

The plan "Borghi Italiani" (Italian villages), sponsored by the National Association of Italian Municipalities (Anci) was developed in collaboration with the competent Ministry (Airbnb, 2017). This plan envisages the enhancement of more than 40 towns realities and of their underutilized assets both in inland areas and in historical villages. The initiative targets paths with limited numbers of hotel accommodations and which still have spontaneous and authentic forms of hospitality. The aim is to introduce travelers to small Italian towns with their landscapes and knowledge in order to promote sustainable tourism as an alternative to traditional routes and new forms of local economy.

The three pilot villages, where initiatives take place in networks between partners, municipality, associations and local communities (based on the model introduced by the municipality of Civita di Bagnoregio) are: Lavenone in Lombardy, Civitacampomarano in Molise and Sambuca in Sicily. The idea is to open up an accessible space through the platform. The profits are then devolved to the maintenance of historic sites and other cultural projects to support the village at national and international level. The dedicated website thus becomes a tool for territorial marketing for increasing the competitiveness and the attractiveness of these places. The municipalities concerned are: Aieta (Calabria), Apricale (Liguria), Asolo (Veneto), Barolo (Piedmont), Bevagna (Umbria), Bitti (Sardinia), Città Sant'Angelo (Abruzzo), Cividale del Friuli (Friuli Venezia Giulia), Dozza (Emilia Romagna), Étroubles (Valle d'Aosta), Furore (Campania), Mezzano (Trentino Alto Adige), Moresco (Marche), Pisticci (Basilicata), Poggiorsini (Puglia), Sabbioneta (Lombardy), San Casciano dei Bagni (Tuscany), Sperlonga (Lazio), Savoca (Sicily) and Torella del Sannio (Molise). Other twenty villages will follow suit and be promoted by Airbnb on social media through a dedicated communication plan.

Against the background of research and practices on urban and national tourism policies, we want to focus on this phenomenon, given the huge wealth of small centers and marginal areas that characterizes Italy. In this vein, the aspects linked to web communication are not sufficient to define a local action plan that is capable of innovating this heritage in order to make it economically, socially, physically sustainable and productive. However, we argue that an "integrated" transformation of the status quo of these areas may become a sustainable local development model, if it is geared towards creativity as a structural aspect of each dialogical or participation-based process that integrates the perceptions, the interests, as well as the human and social capital of a territory (Bozeman, 2007).

Airbnb itself, at least on this aspect, is currently trying to enter a less aggressive segment of the market. This segment is more in line with strategies aimed at rediscovering the territory through experiential and culturally Conscious tourism, i.e. one that is linked to local traditions and to material and intangible cultural heritage. Indirectly, this move works towards the valorization of the *heritage communities*. The latter, indeed, identify creativity as a relational and Community entity that succeeds

in producing multiple values, including economic ones, by using the potential of yet unexpressed heritage – Faro convention, art. 10 (Council of Europe, 2011).

4. Genius loci and place-based approaches to urban regeneration

The outlined scenario suggests that a tendency is under way. Although it has not yet been systematically investigated with appropriate comparative empirical investigations, its structural elements can be summarized. On the one hand, we mentioned market studies to trace the evolution of the forms of collaborative tourist hospitality. On the other hand, we offered an overview of interventions of local authorities on issues specifically related to its impacts on the socio-economic fabric of the cities. The resulting picture suggests the need for a regulatory system to "govern" the phenomenon, especially concerning the industry of tourist hospitality, the real estate market and the urban services sector. This new kind of tourism hospitality initially carried the promise to share benefits and to experience places in a more authentic fashion as opposed to mass tourism. In the absence of shared and up-to-date rules, this is turning into an aggressive business model. This model threatens to:

- Create conflicts and infringe on the rights of industry operators and of users;
- To frustrate the expectations towards a culturally and environmentally conscious tourism;
- Irreversibly alter the settlement dynamics and the defining characteristics of the tourist destinations (the *genius loci*).

Regarding the first issue, the analysis of local authorities, of the SET network and of the work of other similar NGOs, highlights the necessity of issuing relevant legislation in order to direct planning and balance the effect of market-led initiatives that heavily impact on communities and on those activities that are not strictly related to tourism. It also signals the presence of conflicts between traditional tourism operators and those active in the so-called shadow hospitality, as well as between traders and users, residents and visitors, and lastly between global and local strategies.

The second issue, which emerged by quali-quantitative and statistical studies, highlights the question of the traveler's perspective and the betrayed expectations of a non-standardized experience-tourism. The original ideas of these platforms – that of a non-standardised tourism, of a “traveller” who is in touch with local cultures and traditions – has been swallowed whole by a globalized business model managed by large multinational operators. In a similar vein, local communities lost the opportunity to grow culturally or economically through tourism. These betrayed expectations has translated in the rise of opinion movements, initiatives by local authorities, and also riots and adverse campaigns. On this point, the broad research and practice tradition on cultural tourism, slow tourism, and experience tourism, offers useful interpretations and solutions (Chambers, 1997; Faccioli, 2015; Fullagar, Markwell, & Wilson, 2012).

The third aspect, although strongly interrelated to the other two, presents peculiarities and complexity transverse to requires a significant cognitive, interpretative and operative effort. The question of identity, a controversial and multidimensional topic, is interpreted here in a key local identity as "genius loci" (Norberg-Schulz, 1980), i.e. as a set of relationships and interactions between city,

landscape, and people that help define the culture and the values of a community. Concerning the perception, the quality of the places, and urban design (Isaacs, 2000), shifting from the term “genius loci” to the “sense of place” describes an aspect that transcends the place itself and characterizes the atmosphere and the quality of its environment thus giving a feeling of wellbeing (Jackson, 1994). This is “the spirit of place” (Barnes, 2004). This approach interprets the concept of identity dynamically, i.e. as a tangible and intangible cultural heritage that changes with its community. The “genius loci” is thus understood as a dynamic process between conservation and innovation, and where perceptions are the main tool to ensure the authenticity of change (Jive'N & Larkham, 2003) within Urban planning (Hayward & McGlynn, 1993; Tibbalds, 1992).

Local policies, as well as national and supranational strategies, often combine measures for the enhancement of cultural heritage with the promotion of tourist fruition. This is seen as a fruitful avenue to acquire the economic resources necessary for its survival and for local development. At the same time, however, the pressure of tourist flows on fragile urban systems – e.g. in Venice – and phenomena such as *museumification* and *Disneyfication* - typical of art cities - tend to transforming their defining features into an oleographic stereotype. The combined effect of current trends in cultural tourist destinations, the distortions induced by the market, and the current dynamics urge us to clarify the relations among:

1. The diffusion of collaborative platforms in the tourism sector and in urban services;
2. The growing pressure of mass tourism on urban areas;
3. The dilapidation of social and cultural capital of large parts of cities.

Apparently, the positive cycle of tourism-led regeneration seems to be followed by the excess of touristification might produce negative impacts that overwhelm the positive ones. We suggest that defining the threshold to activate a counter-cyclical process is of paramount importance for qualitative research on the topic. These thresholds are fuzzy in nature and must be interpreted together within regeneration processes, as long as identity and territory are multidimensional components essential to activate innovative productivity processes (Cercola, Bonetti, & Simoni, 2009) and new models of value creation are important goals (Porter & Kramer, 2011).

In this perspective, a process of urban regeneration geared towards the enhancement of the endogenous physical, functional, economic and cultural resources may be the turning point of strategies, plans and policies that draw on the local identity and renew it by preserving and innovating them at the same time. This would allow to overcome the stereotype-identity pair that crystallizes and banalizes the touristic “product”. In this perspective, an important step towards a place-based regeneration process is to identify what defines the genius loci in terms of tangible cultural heritage – the physical elements i.e. the backbone of the cultural landscape – and intangible cultural heritage – the host of traditions, activities, and relationships that constitute the lifeblood of this landscape and of the communities that feed it.

Place-based strategies for urban regeneration must therefore adopt an integrated approach and identify the *genius loci* that local communities recognize in order to make the territory vibrant and authentic. This helps preventing the juxtaposition of stereotypes of a falsified identity. Recent international guidelines on the historical urban landscape issued by the Historic Urban Landscape (UNESCO, 2011), show the importance of synergy between landscape and integrated approaches to

transformations implemented in locally to guarantee the efficiency of the policies aiming both at the valorization of the genius loci and at the development of new forms of sustainability.

In line with HUL methods (UNESCO, 2011), it is crucial to analyze the system of relations linking the processes of urban regeneration to the valorization of the historical-architectural heritage (Esposito De Vita & Trillo, 2014), thus leveraging on the concept of culture and of sharing as activators of local micro-economies (Daldanise, 2017). Whether HUL strategies are successfully implemented depends, therefore, on the presence of a strong cultural base of the city, which stimulates cooperative approaches towards achieving a general interest oriented, on the one hand, to enhance and preserve the local cultural roots and, on the other hand, to increase local competitiveness in the global scenario (Imrie & Raco, 2003) through innovation.

These goals integrate themselves well with places-based approaches that combine public goods and services. Such services must be adapted to the place and stimulate and combine local preferences and knowledge through the participation of public institutions, also establishing links with other territories. This approach particularly highlights the role of places and of historical and architectural identity for local development (Barca, 2009). It does so by adopting a long-term development strategy in which the place in its entirety is considered, including the preferences of people, natural and cultural circumstances, social ties as well as informal and formal institutions. We consider this approach useful to nudge the collaborative platforms of the tourism sector back to their original experience-based goals and away from its distorted version based on easy profits and unfair competition. The Municipality of Matera, European Culture Capital 2019, seeks to prevent this tendency by defining, with the support of the CNR, appropriate measures to manage tourism flows attending the event. This city embodies a peculiar urbanisation process whereby the so-called “Sassi” (stones) – a cave system used for dwelling purposes – is now a UNESCO heritage site and the center of an extremely relevant cultural project (figure 6).

Figure 6 Matera (Italy) “Sassi” 2019, picture by the authors

In this context, a long-sighted administration is currently seeking to design policies to encourage tourism-led development in the city without damaging its delicate cultural, social and environmental tissue. Precisely this complexity makes Matera the ideal laboratory to test the feasibility of an adaptive, cyclical, and place-based regeneration. These preliminary reflections require further investigation to fully grasp the systemic relations and reconstruct the network of interdependencies between the actors involved. However, even this cursory overview sheds light on place-based regeneration as a possible reaction to the problems highlighted above. Drawing on the identity expressed dynamically by local communities, place-based regeneration will be able to protect the inhabitants and the various economic actors involved from some of the distortions mentioned above while at the same time activating the endogenous cultural resources. Re-generation, indeed, means to trigger a process that respects the profound identity of the places and of their communities, that allows the development of an authentic and sustainable tourist offer, and to avoid the trap of short-lived stereotypes.

Acknowledgements

The paper has been developed within the project “Place-based Regeneration Strategies” led by Gabriella Esposito De Vita at the CNR IRISS. In the context of a joint effort, Gabriella Esposito De Vita wrote the introduction (§1) and the chapter on genius loci the place-based approach (§4). Gaia Daldanise wrote the chapter on collaborative platforms and on their impacts in European cities (§2, §3). We thank Alessandra Caputi for the data produced by the SET network.

Reading the city through the lens of urban standards.

The case of Ponticelli, East Naples.

Alessia Franzese

Dipartimento di Culture del Progetto, Università Iuav di Venezia, afranzese@iuav.it

Abstract: In occasion of the 50th anniversary of the Decree 1444/68, an intense debate has refocused the attention to the original tension of the Law towards the right of the city. By the application of the Decree it has been possible to reconstruct a new geography of Italy, variegated and diversified. In this scenario, the south of Italy is conspicuous by its lack of equipment, that can't permit an evaluation of the social impact because it's an interrupted process. The purpose of the present study is to observe and analyse how the spatial welfare system of southern Italy has been built, examining the study case Ponticelli, in the eastern periphery of Naples. Through the outline of two stories, it will investigate the construction of the public city in the degraded areas, among tensions and social inequalities. The first one is an institutional tale, which looks at the process of application of the decree; the second one is an informal tale, which reads the practices and the processes of use and appropriation of these lands. Thus, the current paper aims to rethink about the validity of the normative tool in an urban and social condition characterised by continuous and uncertain evolution. Additionally, the research attempts to find alternative and spontaneous forms, bordering illegal practices that can be found in urban areas, in absence of public intervention, such as subsidiary processes of guarantee of the right to the city.

Keywords: urban planning standards, urban practices, land reserves

Foreword. What do we talk about when we talk about urban planning standards?

The urban planning standards are a normative device introduced in 1968 at national level through the Decree (DI) 1444/68. It was intended to ensure, through reference to a quantitative value (18 sqm/inhabitant), the creation of a specific category of public spaces and thus curb urban speculation occurred after the Second World War, improving the quality of individual and collective life. The collective equipment defined as urban standards – schools, parks and open spaces, collective services and car parks – therefore represent the formalization of a right to the city. They have been realized

mainly in growing areas, to equip the public city and to compensate for the lack of collective equipment within the already urbanized areas. They have therefore helped to build the periphery of the public city according to the modern urban model.

The instrument of urban planning standards, understood by local governments as a mere numerical quantity to be respected in the sizing of the zoning plan, is now ineffective in responding to the social and urban condition in deep global change, in continuous and uncertain evolution, according to needs and desiderata that characterize contemporary lifestyles in a very different way from those defined 50 years ago. Today, the theme of urban planning standards raises several questions concerning, on the one hand, the disjointed heritage of equipment, its management and reuse; and, on the other hand, the failure to implement that "collective infrastructure" as a guarantee of high levels of livability (Gabellini, 2001; Munarin and Tosi, 2011).

Historical Background. Fifty years of urban planning standards

"The patient research for the physical and concrete dimensions of individual and collective welfare started before the Welfare State" (Secchi, 2005) is still nowadays a crucial point of the urban discipline. The phenomenon of equipment of the city, as a heritage of '900, remains one of the main features of the contemporary European city (Munarin and Tosi, 2011).

In occasion of the 50th anniversary of the DI 1444/68, in the last year a debate has been animated in ministerial and academic domains, which refocused the attention to the horizons in the sense of the decree – the only national policy on the 'public city' about citizen rights recognised by the Constitution¹ – in the original tension towards the right to the city. Among the different initiatives, the academic group "Laboratorio Standard"² led a research which has: crossed the cultural and of interdisciplinary context roots of the Decree; it has also built reports on the role of the normative device in the equipment of different Italian cities and territories by means of the production of "standard spaces" as deposits of grounds as well as of collective and public artefacts (Renzoni, 2018); finally, the research group has developed possible experimental hypotheses towards a rethinking of the normative tool, that is able to adapt to the transformations and challenges presented by contemporary society³. National and local seminars⁴, meetings with representatives of the academic world and of the local and regional administrations have been the occasion to create an atlas of cases and questions, problems and innovative devices. Urban performance and quality, legislative reduction, and limits of the parametric value – unable to meet the increasingly complex needs and desires – are the concepts where the focus of the discussion on urban planning standards has been put today and in

⁴ For further information please visit: www.standardurbanistici.wordpress.com

the past decades⁵. The design of new maps as possible, some of them concern the change of the demand – variable, fragmented, dynamic – other maps deal with the dynamics of reuse/conservation/management of the supply (Gabellini, 2018) – inappropriate, obsolete, no longer just public but often of negotiating nature. Following the urban federalism, Regions from 1970s have taken different orientations, shaping a new Italian geography, which is variegated and diversified in terms of number of facilities, application of the procedure, used tools, urban forms created, practices of use, processes of regeneration of the inherited legacy from the application of the normative tool, innovations ‘within and beyond the logic of the standards’⁶. Consequently, a disarticulated national image has emerged following three patterns: first, the overproduction of “standard spaces”, that faces the problem of reconfiguration of the urban material inherited; second, the pattern crushed by the ‘pressure of the parameter’, unable to respect a too severe numerical value in the planning process; third, the pattern of under-equipment and informal city.

According to the logic of overcoming the urban planning standards, the “*progetto di suolo*” has been defined by Bernardo Secchi: “a large part of the *progetto di suolo* concern the standard areas, that is the areas meant to provide the city with collective equipment, that now are not linked tiles among each other [...]. However, the *progetto di suolo* does not reduce the public spaces to mere standardised quantities. Urban design and administrative planning practice, during the past decades, have shown how the principles and the objectives that rule the formulation of the law might be, in fact, betrayed” (StudioBresciaPrg, 1998). *Progetto di suolo* described by Secchi goes beyond the reductionist notion of to which urban planning standard has been attributed in urban planning practice, which is a non-secondary cause of semantic poverty of the contemporary city (Secchi, 2006). This latter, in turn, has generated fragmentation and lack of sense of urban parts space. Within the *progetto di suolo*, there is in between spaces, which cannot be eliminated or reduced to technical spaces (Secchi, 1986a); it shows attention to the dimension of everyday life, to the articulation of the space in sequences of recognisable, comfortable, and safe places. This kind of project does not only deal with quantities but with the quality of things, that is detail quality. “Recovering the spirit of the Decree, the *progetto di suolo* considers urban planning standards as materials which more most properly public and collective part of the city can be built” (StudioBresciaPrg, 1998). *Progetto di suolo* represents the ‘urban excipient’ (Munarín, 2010), in which it synthesizes collective infrastructure. “This is certainly the opportunity to deal with it: i.e. when the pressure for the construction of huge quantities of dwellings, in addition to the existing ones becomes weaker, while the pressure for the ‘modification’ of the existing is still strong” (Secchi, 1986a).

In this paradigm shift, where the city does not expand but rewrites itself, the city can be conceived as a recyclable resource. The topic of the transformation of parts of the city that have concluded a cycle of life, that are not going to work as in the past and are not going to host the same populations, leads to consider the recycle of the city as a fundamental strategy that crosses scales and themes of the contemporary urban question (Viganò, 2011). If on one hand the ‘cycle of modern’ can be considered

⁵ For additional details, please read: Collection “*Welfare urbano e standard urbanistici*”, (Roma: Officina); Contardi L., edited by, 1999, “Trent’anni dopo... Tornare a ragionare sugli standard urbanistici”, in *Urbanistica Dossier*, n.21; Falco L., 1987, *I nuovi standard urbanistici*, (Roma: Edizioni delle Autonomie); Falco L., 1977, *Gli standard urbanistici*, (Roma: Edizioni delle Autonomie).

⁶ Expression often used to classify the innovative aspects in the normative tool, in Caceres E., Chicco P., Corrado F. Falco L., Madrigal M., 2003, *Servizi pubblici e città. Gli standard urbanistici nelle legislazioni regionali e nella pianificazione locale*, (Roma: Officina).

as concluded, on the other, the entity of the legacy inherited from it, the legacy of urban planning standards, represents a central and crucial point.

To support this approach, there are the recent regional legislative measures on land use containment, to progressively reduce those parts of land that are not yet urbanised, in coherence with the European objective of no-land take by 2050. In this scenario, the guarantee of spatial quality in designing public space is considered as one of the main objectives of the legislative measures⁷. Nonetheless, for the interrupted, incomplete parts of the cities, where the cycle of equipment – an expression of the modern paradigm – has not come to an end and in which it is no longer possible to recover the gap between time, space and policies, which are the possible future cycles of life?

A Different-speed Italy

In its partiality, the “trip to Italy” described above shows a national geography “divided by the Apennine Mountains”, where “the great territorial room of the country”⁸ – the Padanian megalopolis – is characterised by comparable cycles of equipment of the modern public city, policies and reconfigurations.

The South of Italy is conspicuous by absence, lack of allocations, unfinished works, abandoned areas, (as a result of the reiteration of the bond of expropriation which was not been followed by an effective realization), unauthorised building phenomena (which make it the Decree impossible to apply). The political-urbanistic events which affected the Southern territories, the peculiar conditions of presence/absence of collective equipment only allow partial comparisons with other Italian cases.

Therefore, if on one hand the ‘standard spaces’ realised in the south raise shared questions, linked to the obsolescence of heritage, to the managing and designing of new cycles of life in terms of performance, according to the variation of the demand (as in the current national debate), on the other, the condition of absence – or suboption – of equipment does not allow to consider the evaluation of impacts and conflicts as a constant method of work and innovation (Gabellini, 2018), for a rewriting of these urban materials within regeneration processes, which cannot properly contribute to the debate on the revision of the legislative instrument, according to the parameters assumed on general scale.

Within the Black Box⁹: Ponticelli extra-ordinary city

Also in Naples, the decree on urban planning standards has contributed to shape the peripheries, fostering the process of urban polarisation, social and spatial inequalities in access to services and

⁷ In reference to the normative text of Veneto Regional Law L.R. 14/2017 “*Disposizioni per il contenimento del consumo di suolo*”, the first one region introducing the European indications in legislative normative in Italy.

⁸ See Clementi A., Dematteis G., Palermo P.C., 1996, *Le forme del territorio italiano*, (Bari: Laterza).

⁹ The title is referred to the intervention by Laura Lieto and Enrico Formato “Out of the black box. Per una critica degli standard tra eterogeneità e differenza. Il caso dei beni liberati a Napoli” during the SIU seminar “*Standard a misura. Regole, attori, esperienze*”, University Roma Tre, February, 16th 2018

facilities that should have improved the quality of individual and collective life. The inadequacy in the public managing together with the complexity of the city itself – here and elsewhere – have turned an inclusive and improving tool into a discriminatory and marginalising element.

The intervention on the existing identifies the city as a matter of facts conceived by another; the starting point is therefore “the logical understanding established by someone else” (Boesch M., 2018) to outline future paths of the possible: i.e. reading the signs of the territory in terms of palimpsest (Corboz, 1983) of formal and informal practices, regulatory and spontaneous, natural and anthropic.

In order to observe from the inside a phenomenon of equipment of a southern reality and investigate the possible causes for which analogous normative processes have led to different outcomes (Secchi, 1986a), the study case of the neighbourhood of Ponticelli, in the eastern area of Naples, has been selected. Ponticelli as “standard-city”, built according to specific relations (i.e. buildings height/street width) and quantities (i.e. squared meters/inhabitants) which represent the heritage of the modern principles. Ponticelli as a residential city, with a population of 50.000 inhabitants. Ponticelli as a palimpsest and mixture of urban history – ancient farmhouse district, agricultural areas, public city. Ponticelli as a land of heterotopia, urban space organised as a campus, which conceives the ground as mere support of elements, with specific functions and specific temporalities (Secchi 2006; Foucault 1984), a peculiar land between dissolution of the industrial city and harbour activities of the productive city.

Through the delineation of two stories the research aims to retrace the construction of the public city in an area rhetorically known as “urban hell” (Camerlingo, 1986; De Lucia, 2018), an area of degradation, tensions, social inequalities: a formal story on one hand, that looks at the institutional process of application of the Decree, on quantity and consistency of inherited spaces; an informal story, that reads the practices and processes of use and appropriation, on the other.

The Formal Story: blending place, plans, and policies

In the attempt of reconstructing a timeline, the process of equipping the city, that has crossed the plans, has been observed through the lens of urban planning standards, starting from the date of emanation of the DI.

The story begins in 1969 when an initial survey by a Ministerial commission, led by Minister Occhiuzzi, declares as illegal or abusive the near totality of buildings realized in Naples from the end of Second World War (De Lucia and Jannello, 1976), including public city settlements. This image shows the seriousness of the situation of emergency of “environment destruction and of the terrible conditions of life characterising a large part of the population. Where the near totality of buildings is illegal it is not conceivable demolishing the whole city”. Naples as an extra-ordinary city.

The story of Ponticelli area is the story of an ancient farmhouse and of an agricultural centurial plan¹⁰ (Pagano, 2001) transformed in a huge public city equipped with a delay compared with the Italian season of "great generation" (Secchi, 2005). A story that is made during the '80s, which sinks its roots in the first interventions Ina-casa¹¹ of the after War and crosses the plans followed through the time by means of rewritings of the Peep plan 167¹² from 1964 on. The first variant to the Peep plan, designed by architect Franz Di Salvo, is absorbed by the new zoning plan in the 1972. The settlement matrix was exasperatedly linked to the car, the lands were separated by the motorway road network through public equipment. "The periphery continued to be conceived as totally available as if they were working in the desert, ignoring pre-existing settlements, but creating a new urban image, technologically updated on the large-scale values" (Dal Piaz, 1986).

The zoning plan of 1972¹³ started a systematic transformation of the city in the tertiary sector, articulated in a series of headquarter centres, where Ponticelli was clearly privileged for number and consistence of the aforementioned centres and for the connections at the superior level. It considers the eastern side as a periphery supposed to host infrastructures, equipment, and services necessary to the whole city, without any particular care for the inhabitants who were already living there. "The new Ponticelli was proposed as a fragment of a 'different city', nestled in an urban city of bulky and unsuitable infrastructure installation". Peep settlements are organised as a marginal neighborhood, largely provided with public areas and public use areas but with no integration at all with the previous ones" (Dal Piaz 1986; Vittorini, 1986). In 1976 the "Piano Quadro dell Attrezzature" (Framework Plan of social Equipment) was drawn up as a tool to properly adapt the existing zoning plan to the regulation on the urban planning standards. It was never approved but it will contribute to the formation of the group "ragazzi del piano" (Corona, 2007), i.e. the young urban planners directed by Vezio De Lucia, that will develop, on the political wave of major Bassolino, a new idea of city with environmental matrix. This experience has been mentioned because it represented a formative moment of detailed knowledge of the Neapolitan reality, in particular, of discovery of its peripheries, leading to the drafting of the "Piano delle Periferie" in 1980. That is, a plan for the recovery of the historical centres of the ancient farmhouses, annexed to Great Naples by the end of the 1920s¹⁴, as "a construction of *the city within the city*, as a plan meant to create a continuous rethinking of the main hypotheses along which we moved in the 1960s with the construction of the public city" (Secchi, 1986a). The earthquake of November 23rd, 1980 represents a turning point for Naples as it changes times and perspectives of urban development of Ponticelli.

The earthquake has played the role of accelerator of all the processes of centre-periphery social redistribution already occurring (Benevolo, 1982; De Lucia, 1989). But above all the authority, the normative instruments, the extraordinary fundings of Special Law 219/81¹⁵ for reconstruction allowed

¹⁰ The Sebeto river valley, swampy in previous times, was characterised by a centurial structure of the territory with the rotation of "quinari" along the slopes of the Vesuvius as a testimony of the ancient process of agricultural appropriation of the volcano slopes and that marks, at the same time, a full appropriation of it (Pagano, 2001)

¹¹ Public social housing program.

¹² Public social housing program by the Law 167/62.

¹³ Last plan approved by the Ministry on March 31st. The day after urban planning domain is transferred to the regions.

¹⁴ "Since then, those lands started the downhill to the hell, progressively abandoned to degradation, without any service of public spaces"(De Lucia, 2018).

¹⁵ The title VIII of the Law L.219/81 (artt. 80-85) foresees the realisation of 20.000 dwellings together with the urbanising works mainly in napolitan territory; interventions made in a unitary way and in primary and secondary urbanization services also referred to the arretrated need; detection of the areas to expropriate in exception to the existing urban planning

the shaping, in record times, to a series of ordinary interventions elaborated in previous years (Camerlingo, 1986). The Piano Straordinario di Edilizia Pubblica (Pser)¹⁶, which incorporates the indications of Chapter VIII of the Law, allowed the realisation of ordinary plans through extraordinary sources, thus implementing the Recovery Plan for Peripheries (Piano delle Periferie) and carrying on the Peep 167 Plan for Ponticelli that, until then, proceeded slowly.

For the dimensioning of the urban planning standards, it was decided to increase the values provided for in the DI in order to meet the previous need of equipment and green spaces. The Pser allowed to produce the public city, with social equipment realised at the same time as the housing (Cederna, 1987). It is a historical turning point for the equipment of the whole city of Naples: i.e. 99 schools satisfy the demand of the whole periphery, 32 sport facilities, 95 collective equipment. Especially as regards the natural open spaces, there is a considerable increase: i.e. 30 among green areas, local and urban parks with an increase of 132,7% compared with the existing endowment, raising the quantitative data from 0.11 to 2.19 sqm/inhabitants. Despite the substantial increases, the parametric data of the city scale still remains rather underestimated. Naples as a city of absence.

In Ponticelli the Pser realises 3750 accommodations (30% of the total forecasts) through 3 consortia of cooperative and state-owned companies; for the equipment, the forecast is 20 sqm/inhabitant for the recovery plan and 38 sqm/inhabitant for the new built Peep plan. It can therefore be considered as a standard city. Investigating the forms assumed by the Peep plan realised since 1981, it can be stated that it derives from a second version of the Peep plan, in 1979. This latter abandons the ambitions of the ‘great signs’ of the 1960s in favour of a clearer and more elementary settlement organisation, a grid, in response to the very trivial criteria of managerial nature among the consortia. The emphasis is maintained on the interdistrict roads with motorway features, whereas the dimensions of the macroblocks tend to encourage the realisation of out-of-scale complexes, with the structuring element of “cis”¹⁷ as a central axis of the settlement. The areas are divided into urban sub-district areas, each of which hosting a share of equipment, not equally distributed. The Pser, that will only take action on some urban sub-district areas and on the completion of others (i.e. area 11 of Ponticelli), assigns a non-secondary role to the public equipment planned. In the designing of the planvolumetric map¹⁸ some limitations can be recognized, the effect of which setting are still visible today: “the aim is recovering the importance of the delimitation of spaces with “qualifying set” constituted by buildings, borders and fences; that is to say, the recovery of the importance of the delimitation of the city” (Vittorini, 1986).

normative with a building index of 200 inhabitants/hectare; expropriation increased up to 70% compensation; the mayor is nominated as special commissioner. The realisation times are exceptional: within 15 days the areas are detected, in the next 15 they are given in concession, by means of agreements, to cooperative companies and consortia that deal with expropriation, planning and assignment of the accommodations, according to the economic criteria established by CIPE (Comitato Interministeriale di Programmazione Economica).

¹⁶ For the data reconstruction referred to the PSER (Extraordinary Plan of Housing) the following literature has been consulted: Dal Piaz A., 1982, “Il programma straordinario nel quadro delle vicende urbanistiche della città”, in *Edilizia Popolare* n. 166; Di Biagi P., 1986, edited by, “Napoli. Costruzione e ricostruzione della città”, in *Urbanistica* n. 83; Pres. Cons. Min., 1988, *Il recupero dei centri storici della periferia napoletana*, dossier INU Conference, Matera; De Lucia V. 1989, *Se questa è una città*, (Roma: Editori Riuniti); Corsi E., Franco C., 1991, edited by, *Da terremoto al futuro. La ricostruzione a Napoli. Il titolo VIII della Legge 219/81*, (Napoli: Electa); Corona G., 2007, *I ragazzi del piano*, (Roma: Donzelli).

¹⁷ Integrated centre of services.

¹⁸ The instrument to which Peep plan was subjected within the Pser, for the realisation; for Ponticelli, the group coordinator was Marcello Vittorini.

In the 1990s, in Major Bassolino's time, a process of protection of the physical integrity of the territory and of environmental quality started, according to an ecosystem vision which anticipates of some by decades the concept of no land take¹⁹, conceiving the territory as a resource (Corona, 2007). During the first '100 days' several parks and facilities are completed and opened to the public (De Lucia, 2018) to the slogan "each neighborhood of the periphery must have a park as big as the Municipal Villa in Naples".

The zoning plan approved in 2004, currently in force, provides two different production paths of standard spaces: i.e. a direct one, through public-private agreement for public use equipment, or through the transfer of areas and the realisation of equipment in the implementing planning. The plan of transformation for Ponticelli includes a series of implementing acts with the purpose of 're-founding'²⁰ the eastern city of Naples, "made of a chaotic urban mosaic but provided with conspicuous resources of available public spaces". Since the end of the 1990s, there has been a collection of scenerios, visions, calls for tenders and projects for the Ponticelli area, which today can be considered as tensions towards the future, utopias that have never been realised. Most of them are 'standard spaces'²¹. Ponticelli as an interrupted city.

At the end of the first tale, there is a reference to the guideline document for the drafting of new urban plan, published in March 2019, where the issue of the urban planning standards crosses through the visions of city proposed. Above all, the passage "from public city to city of public use, to city of common goods and civic uses" is highlighted as an evolutionary key of the definition of "urban collective infrastructure": the forms of innovation on urban planning standards aim to capitalize on the experience of bottom up experimentation, recognised and institutionalised from the local government²² as forms of the management of city as a common good.

The Informal Story: between practices and spaces

The second tale is an attempt of field exploration. By shifting the point of view from zenith to horizontal, it tries to observe the territory through the lens of collective equipment at present tense, between practices of use and conditions of degradation. Even though still in an embryonal phase of the research, it is still possible to get a first description of "Ponticelli as a city of people", still partial and introverted.

Between gigantism of settlements and the oversized roads allocation, in an excess of separation, a series of obstacles – fences more or less permeable to the eye – encloses and detects the collective equipment, often vandalised, sometimes unused, squalid, devoid of maintenance and care, without any quality and comfort. The 'standard spaces', fragmented or united in clusters, often appear inaccessible

¹⁹ In the zoning plan, approved in 2004, the C zones, expansion areas, are absent.

²⁰ See Council of Naples, Report on the variant to the general regulation plan, chap.6 (pp. 468-475), on www.comune.napoli.it/urbana

²¹ The Sebeto Park, the PalaPonticelli, the House of Music, Culture, and Events.

²² It is here referred to the following deliberations: dcc 29/15 "Adotta una strada"; dcc 7/15, dgc 893/15, dgc 446/16 for the collective managing of public and the recognition of citizen experiences of self-managing of public spaces to the advantage of local collectivity; dgc 458/17 on the temporary use of abandoned public equipment, for the purpose of valorisation of the public, unused legacy through the creation of urban civic communities.

and unaccomplished but sometimes it is just a mere perception. The gap between quantity and quality of the collective infrastructure is all there. The dimension, the scale, the distance between “parchi urbani”²³, roads, facilities and people make the urban space suspended: “not contemplated, not foreseen, removed, mankind finds itself alone at the top of the work and then disappears” (Wu Ming, 2018). An uninhabitable city. Almost a city without inhabitants. Nonetheless, people are in fact there and they manipulate and appropriate space, claiming a right to the city that has been betrayed.

The state of apparent abandonment allows spontaneous practices to colonize places: i.e. forms of informal re-appropriation, more or less virtuous, like a shred of vegetable garden land that an inhabitant has cropped in a public park, opening a gate in the fence that separates his house from the park; other times illegal, like transforming a linked bound to an urban park in toxic waste landfill. Other ones can be recognized as place-making and bottom up processes. This is the case of De Filippo Park, a 12-hectares local-scale park, apparently another fence inherited from the modern equipment. Realised at the extra-ordinary time of Pser²⁴, inaugurated and closed due to a lack of funds for the maintenance, after a period of improper use by criminal system, in 2015 it is entrusted by the municipality to the day care centre for addictions by ASL (i.e. the Italian NHS), called ‘Centro Lilliput’, for the creation of an “urban garden of health”, for curative and social reintegration purposes of drug addicted people. The management for rehabilitation purposes is associated with the re-appropriation by the local community, through the signing of an agreement between municipality and committees of free citizens for the assignation of spaces to be adopted and re-cultivated. This ‘micro-tale’²⁵ of urban planning standards tells about a process of activation, triggering and care of collective equipment, whose main value is in the recovery of the local identity and in the pedagogical function of the urban space.

The ‘presence’ of a heritage of equipment, such as the Decree spatial deposit, is also associated to the rarefaction of the unused space, of the in-between lands (Russo, 2012) waiting for the hopes-utopias-tensions to come true in the form of urban projects. They are fragments of ‘third landscape’: i.e. this “reserves of land” bring back to the generative principle of the decree, where original character had the aim of guaranteeing to the cities a reserve of unbuilt areas of public domain, regardless of the effective realisation within reasonable times and in absence of a public land policy (Falco, 1987; Chicco, 2003).

Marginal Notes on the presence/lack of equipment

On rhetorics. On one hand, there is a perception “at first glance”: a city-neighborhood-dormitory, a social hell, the mediatic reputation. On the other, “the controversy that prevails over the analysis, the passion that does not leave space for doubt, the side taking that does not allow to deepen the issues, to make comparisons, to place every idea and result into a proper perspective” (Secchi, 1986b). From another point of view, the observation from above and from a closer perspective, through the

²³ . In Naples, the term “parco urbano” is usually referred to a cluster of residential buildings, usually enclosed within fences; they might be defined as “gated communities”.

²⁴ The sub-district 5, geographically barycentric in the Peep plan 167 in Ponticelli.

²⁵ The micro-tale has been reconstructed through interviews with professor Maria Federica Palestino, Diarc Unina, and with citizens that adopted areas within De Filippo park met there.

reconstruction of the normative events and the survey in the field, shows a daily reality that is made of the presence of equipment as a deposit of a physical heritage, of social networks, of forms of activism, of lands of possibility in form of waiting lands.

On urban planning standards. If the cycle of equipment according to the forms and methods provided by the Decree can be considered concluded, as it is linked to a limitless growing phase of the urban areas, the number gap, i.e. of the lacking quantities, however, cannot be recovered. If at a neighbourhood scale, the equipment has more or less satisfied the parameters established by the Decree, even though repeating the mistake of gigantism also for the equipment, the reflection needs to be brought back to the comparison between a local dimension of a presence (which is satisfied but still inadequate) and the urban and metropolitan dimension of absence (strongly underequipped), between quantity and quality, between standards and *'progetto di suolo'*. From this point of view, the case of Ponticelli can contribute to the national debate, showing comparable and common features to other Italian situations.

On urban planning. Thus, which kind of urban planning for the 'middle lands', still waiting? The storytelling of the two tales allows a definition of different images of the city: i.e. Ponticelli as an extra-ordinary city, only realised through actions and policies beyond the ordinary, but also extra-ordinary case for the phenomenon of equipment that has affected it. Ponticelli as an interrupted, incomplete, fragmented, awaiting city: a physical and political condition of inertia which generates segregation and social discomfort. Ponticelli infernal city, as an accumulation of urban wastes. Ponticelli as a present city, which reacts in a daily and spontaneous way to the condition of degradation and forgetfulness where it is relegated.

Non-conclusion

The image of an interrupted city allows to outline possible research perspectives. If the periphery can be assumed as a steady, historicised urban figure (Bianchetti, 2003; Russo, 2008), Ponticelli emerges in its hybrid position for the condition of presence/absence, unfinished, as an 'open work', where each part still has an uncertain status: if it is undiscussed which are the 'hard' parts (Secchi, 1984), the 'malleable' ones, in the inertia of the waiting, have hardened to the perception, structuring the urban landscape of this part of the city. "The quality of the space that crosses the time is not the neutrality (as defined by the modern project) but generosity, open structure, belonging to social networks" (Viganò, 2011). If "incomplete" can be considered as typical Italian style, we can assume 'freespace' as a verb or commandment that stimulates new ways of seeing the world, inventing solutions that provide for well-being and dignity of all inhabitants (Aravena, 2018): rewriting the city will mean being an open work, rather than a closed, accomplished system. The question 'time' becomes for Ponticelli a 'new urban question'. It is necessary to contrast the waiting of long term and wide-ranging planning with short timeframes and minimal interventions, contrasting to all that a greater flexibility in regulations, space and use. In a metabolic vision, assuming the postulate of Ponticelli as resource-city can allow to interpret the presence/absence of collective equipment as materials to be reinterpreted in new cycles of life. Can these materials define a new, albeit unsteady, image of the city?

Antifragile Practices to Design Social Dialogue in Contemporary European Public Spaces

Beatrice Galimberti¹

¹*Politecnico di Milano, DASTU, beatrice.galimberti@polimi.it*

Abstract: European territories are crossed by an uneven transition that highlights a new geography of inequalities, fragilities, and fragmentations. Public spaces are one of the core features of European culture and today a number of events undermines their everyday body-scale dimension, exacerbating risk perception. This paper shows some preliminary outcomes of my ongoing PhD research, that digs a new spatial-relational strand involving the concept of *antifragility*. Introduced in opposition to the notion of fragility, antifragility describes the capacity of getting better from shocks taking advantage of volatility by dealing with randomness, disorder, and unpredictability. Holding this perspective, the paper deepens some specific antifragility features (i.e. the ability of learning from errors, the capacity of gaining from disorder –maintaining a certain degree of uncertainty–, as well as optionality and redundancy as methods to reduce shock exposure). The spatial value and design potential of these features is investigated through some remarkable public spaces recently built in Europe, so to show not only the potentialities of antifragility as a design issue, but also that public space is still the best environment in Europe to activate new urban dialogues –considered as the sum of social actions and spatial forms that co-design publicness.

Keywords: Contemporary European public space; antifragility; social and spatial justice; new planning and design tools

1. Introduction. Public Spaces as a key-factor in rethinking European territories

Europe is now facing a profound transformation, whose outcomes have still to be built. Indeed, what is already visible about the current change is not encouraging: it makes Europe a network of territories in crisis (Bianchetti *et al.* 2015). This crisis is deeply diversified across European territories, highlighting a new geography of spatial and social fragilities, inequalities, and fragmentations. Further, it goes widely beyond the economic boundaries and its strict involvements, as it is a crisis of meaning that questions the issue of European –open– identity.¹

¹ “There isn't an all-European culture” (Hobsbawm, 2007), indeed, Europe hasn't a bounded identity, but an open one, made of multiplicities, differences, exceptions, incompleteness, and contrasts. European identity took shape over time through accumulation, addition, superimposition, rarely replacement or elimination. It is based on a strong urban culture,

Since a decade, public institutions, academia, private agencies, as well as practitioners and informal groups are working on an unprecedented number of studies, researches, awards, and activities concerning contemporary European public space. I argue that this proliferation is symptomatic and that it could suggest the centrality of public space in the general rethinking of European territories, in order to consciously face the current epoch-making transformation. Hence, on the one hand, public spaces are the *loci* of presence –even for the powerless–, and thus of relations as dialogue, conflict, sharing, reciprocity (Cogato Lanza and Pattaroni in Bianchetti *et al.* 2015), and, finally, of difference considered as a right (Lefebvre 1996; Cogato Lanza *et al.* 2013). In particular, difference has an intrinsic creative value (Bauman 2005) able to make life more intense, moreover public space is the place where differences can be supported in starting a meaningful dialogue. On the other hand, public spaces are one of the core features of European culture (CCCB and Gray, 2015) and they should be intended as repository of *mixophilia* as well as space of resistance to *adiaphorisation* phenomena, considering mixophilia as the ways in which the city prompts attraction and tolerance toward strangers and adiaphoria as moral indifference (Bauman, 2005; Bauman and Donskis, 2013).

During the last decade public spaces deeply changed. The increasing presence of new technologies transformed the way collective spaces are experienced, furthermore the transformation of uses made spaces more flexible, variable, and temporary than in the past, embodying a continuous and perpetual resignification (Tornaghi and Knierbein, 2015). Today, beyond the progressive cordon off of many public spaces, a number of events has increased the attention on the topic of urban public spaces control in Europe. The terrorist attacks all over the continent, as well as the institutional reactions to different forms of urban social contentions (Neguerela Del Castillo in Bianchetti *et al.* 2015) undermine the everyday body-scale dimension of public space, exacerbating risk perception and bringing mixophilia in danger of being lost (Bauman in CCCB and Gray, 2015). With the increasing sense of insecurity all the charming aspects of urban life, such as spontaneity, surprise for unforeseen, and adventure are jeopardised (Bauman, 2005). Thus, public space has become place of crisis representation, but, thanks to its open and inclusive nature, it is also the potential playing field of a change-maker social dialogue.

1. 1 Contents and contribution of this paper

Starting from these premises, this paper shows some preliminary outcomes of my ongoing PhD research, that intends to dig a new spatial-relational strand by testing *antifragility* (see section 2) as an operational design issue applied to public space, so to give rise to a highly transferable and applicable approach in architecture and urban design practice. The goal is not so much to produce new design tools, as rather to further articulate the “framework” (Lévy, 2007) of sustainability in spatial design disciplines (see paragraph 2.3). I argue that antifragility could be helpful to look at the current moment of fundamental change for society. In particular, when design of public spaces is concerned, it could be particularly useful to consider antifragility as a design issue. Indeed, being open to all, public spaces

considering urbanity as a concept of self-limitation of rights in respect to cohesion, feeling that city belongs to everybody, in a dimension of sharing (Zucchi, 2015).

are the places in which all the things that nourish antifragility –such as complexity, chaos, disorder, randomness, etc.– are more massively present.²

Thus the next section of this paper introduces the notion of antifragility from a theoretical point of view, presenting its origins, the reasons for which it is useful to discuss about fragility –and, consequently, about antifragility–, the relationship among fragility, antifragility, and robustness, as well as how antifragility could profitably substitute resilience in pairing with the framework of sustainable development. Then, by means of some remarkable examples of recently built or renovated public spaces in Europe, section 3 examines a number of antifragility features, that could be usefully applied in design disciplines, notably in architecture and urban design. In conclusion, section 4 presents some final considerations and opens up to future developments of my ongoing doctoral research.

2. Antifragility

By writing of antifragility I refer to Nassim Nicholas Taleb’s neologism, first proposed and widely examined in his book *Antifragile: Things that Gain from Disorder*, published in 2012. Taleb, statistician expert of randomness, probability, and uncertainty, introduced the term antifragility to describe the “functional opposite” (2012, p.17) of fragility. Namely, fragility and antifragility are intended as opposite poles of the same spectrum. The author states that the opposite of fragility is already present in our daily life, although no name has been previously coined to describe it. Robustness is commonly mistaken for the opposite of fragility, even if it is not. In keeping with possible misunderstandings, antifragility is sometimes confused with resilience, even if they are utterly divergent. This second section of the paper delves into the notion of antifragility and inquires how it differs from robustness and resilience. But before getting into these issues, a focus on fragility has to be done.

2.1 Why discussing about fragility?

The argumentation that follows focuses on fragility starting from a spatial example: the renowned public space of Superkilen. Superkilen is located in Copenhagen –more precisely, in the multicultural neighbourhood of Nørrebro– and it has been designed by the art collective SUPERFLEX together with a joint team of architects, urban, and landscape designers –BIG and TOPOTEK 1. During the 2000s Nørrebro was notorious as the most restive neighbourhood of the city, being the stage for violent social clashes. Thanks to an attentive municipal governance, an integrated urban and social development programme has been developed for Nørrebro, in order to work on social co-existence issues. The realisation of Superkilen (2007-12) has been part of this programme. Indeed, through a participatory process that involved people from all the ethnic groups inhabiting the neighbourhood, Superkilen transformed a 4 hectares wedge –*kilen* in Danish– in an intriguing system of public spaces that celebrate cosmopolitanism. Today, seven years after its completion, Superkilen is still widely considered as a successful case of participatory design, and violent clashes are just a bad memory. But can designers – as well as promoters and other stakeholders– assess the risk of negative events that could affect the

² These characteristics should refer at least to all open collective spaces of public property. Indeed, chaos, disorder, and complexity are strictly excluded from the so-called *privately owned public spaces*, that are silently multiplying all over the world. See the work of Jeremy Németh, as well as of Matthew Carmona *et al.* (2010, 2012, 2014).

conditions and usability of this place? Some measures can be undoubtedly taken to face the most probable negative events. However, even a common event as vandalism, riots –or a typical Danish flood– can happen in an unpredictable way or concomitantly with other situations, causing unexpected damages.

So, if it is not possible to robustly determine the consequences of a probable event, is it then possible to predict more rare events? For Taleb the answer is negative. Indeed, he argues that, by its very nature, risk is not precisely measurable, and a sheer number of circumstances are not predictable at all –being unexpected as black swans (2010). Thus, Taleb suggests a shift of focus from risk assessment, to the analysis of existing fragility features. Notably, Taleb avers that: “It is far easier to figure out if something is fragile than to predict the occurrence of an event that may harm it. Fragility can be measured; risk is not measurable [...]. This provides a solution to what I’ve called the Black Swan problem—the impossibility of calculating the risks of consequential rare events and predicting their occurrence. Sensitivity to harm from volatility is tractable, more so than forecasting the event that would cause the harm” (2012, pp.4-5).

To work on existing fragility features –and thus on antifragility solutions– means to make the most of what is already present. Fragility features are measurable and, furthermore, no prediction is needed. Hence, unlike risk assessment, a decision-making process based on fragility and antifragility features involves a *nonpredictive* logic: “By grasping the mechanisms of antifragility we can build a systematic and broad guide to *nonpredictive* decision making under uncertainty in business, politics, medicine, and life in general—anywhere the unknown preponderates, any situation in which there is randomness, unpredictability, opacity, or incomplete understanding of things” (2012, p.4).

Even though Taleb has never explicitly mentioned the work of Albert Hirschman, I suggest that Taleb’s *nonprediction* attitude has an interesting overlapping to Hirschman’s *possibilism*. Hirschman started to develop his notion of possibilism from his book *A Bias for Hope* (1971) in which he states that: “I have of course not been disinterested in claiming equal rights for an approach to the social world that would stress [...] the possible rather than the probable. For the fundamental bent of my writings has been to widen the limits of what is or is perceived to be possible, be it at the cost of lowering our ability, real or imaginary, to discern the probable” (1971, p.28). In the early 90s, during an interview published in the book *Passaggi di frontiera* (1994), Hirschman claimed that, throughout his career of Development economist, he has always been more interested in exploring the domain of *possibility* rather than the one of *prediction*. This means to focus the attention on the real –or perceived– possibilities that something –good or bad– may occur. Rephrasing with Taleb’s lexicon, this means to adopt a nonpredictive attitude, by working on fragility and antifragility features that are present in a specific situation –even when they are latent resources.

2.2 Fragility, robustness, and antifragility

Taleb affirms that fragility can be described as “*what does not like volatility*”, adding that “*what does not like volatility* does not like randomness, uncertainty, disorder, errors, stressors, etc.” (2012, p.20). Consequently, the opposite of fragility gains from volatility, as well as from randomness, uncertainty, disorder, errors, stressors, and so forth. To explain this theoretical statement, Taleb gives the example of a package to be sent (2012, p.40-41). Namely, a fragile package is breakable –so it should be handled with care–, while a robust parcel does not break –as it remains unharmed regardless of how it is handled.

Thus, robustness is not the opposite of fragility, as the opposite of a fragile package is a parcel that gets better from being mishandled. As no name has already described this condition, Taleb purposes to call it antifragility. As seen in Figure 1, fragility and antifragility are relative terms, they are opposite poles on a spectrum, while robustness is not part of it. Further, the perfect robustness is an ideal condition, but in real circumstances one can just be robust up to a certain point.

Figure 1. The relationship among fragility, robustness, and antifragility. Elaboration by the author.

Investigating the relationship among fragility, antifragility, and robustness is not an exercise of abstract thinking. On the contrary, it allows to bring into focus a wide range of practical implications that affect the decisions we make as well as, I would suggest, the spaces we design. Taleb argues that, in many cases, to acquire some antifragility features is more advantageous than to reach a certain level of robustness. Indeed, robustness is a safe condition, but it is not affected by context, while antifragility is context-sensitive, it is adaptive and able to deal with criticality. An antifragile system is ready to change and to take advantage of stress, disorder, imperfection, error, chaos, and chance. The next section of the paper exemplifies some of these aspects by means of spatial cases. But before coming to examples, the current section continues with some theoretical observations. The final aim is to clarify why investigating antifragility is a fruitful operation, indeed antifragility “makes us understand fragility better. Just as we cannot improve health without reducing disease, or increase wealth without first decreasing losses” (2012, p.11).

2.3 Antifragility, resilience, and sustainable development

In 2007, the French geographer Jacques Lévy wrote a short but significant article about sustainable development on EspaceTemps.net, an interdisciplinary online journal of social science. Lévy stated that “sustainable development is more of a framework rather than a standpoint within a debate. In other words, sustainable development is more of a language than a discourse”. The concept of resilience is frequently associated with the “language” of sustainable development (Rees, 2014). But, by looking at this pairing from the point of view of the flow of time, it is possible to identify an inconsistency between the two notions. Indeed, on the one hand, sustainability is literally the ability to sustain indefinitely over the course of time. Whereas, on the other hand, resilience –a notion originally coined in the domain of Systems Theory– is the ability to restore a previous condition after a shock. Thus, resilience concerns the capacities of re-establishing and reinstating, it involves a movement on a close path that permits to come back to the start. To come back means to openly contradict the linear becoming of time and, consequently, to be incompatible with a sustainable development inscribed in the linear becoming of time. On the contrary, antifragility is linked to the becoming process, as it involves the concepts of change and improvement. To design means to project an idea in the future, in order to build something never existed before. So, the notion of resilience could be profitably substituted by the one of antifragility in association with sustainable development.

2.4 Antifragility as a nomadic concept

Taleb considers antifragility as a highly transferable concept, emphasising its possible application far beyond the study of uncertainty. Throughout his book, he introduces heuristics that allow a system to gain a certain level of antifragility. These heuristics are transformative actions and they reveal traces of a design attitude that I try to start grabbing in this paper. Although just a few efforts have already been done to use antifragile heuristics in architecture, urban design, and planning, antifragility has already been fruitfully applied in several scientific fields as physics, biology, computer science, and transportation planning.³ The spreading of antifragility across different disciplines encourages its

³ An empirical systematic application of antifragility in architecture, urban design, and planning is still missing. One of the first efforts has been made by Tanzil Shafique from the pages of *Studio* (2015), where he proposed antifragility as a possibility to re-situate contemporary urbanism. Ivan Blečić and Arnaldo Cecchini have been working on the role of antifragility in urban planning field (2016, 2017, 2019). However, their work concerns the proposition of a general notion, no direct relation with public space has been inquired. Up to now, the only effort bridging antifragility to public space, is an article by Mark Brown (2017), an urban planner active in the United States who wrote germinal remarks on North American public spaces, focusing on security and flows issues. Further, Strong Towns, a movement active in US and Canada, dedicated a section of its blog to design-oriented reflections on Taleb’s book.

A cluster of interests has been aggregating around the relation between antifragility and design in critical contexts. In this sense *Fragile/Antifragile: Shigeru Ban + VAN, the Voluntary Architect’s Network* (exhibition by Microma, Turin, 2014) opened the way by using antifragility as a metaphor to describe the socially engaged work of Shigeru Ban. Camillo Magni has referred to antifragility to comment some contemporary architectures in the Global South for *Casabella* (2015). More recently, Cherubino Gambardella has considered antifragility among a list of concepts selected to describe some of the most interesting contemporary architectural and urban projects on peripheries all over the world.

comparison with the definition of nomadic concept. According to Isabelle Stengers' definition (1987), a concept is nomad when it *propagates* from a scientific discipline to another one. Stengers argues that *propagation* takes place in different ways. Indeed, the nomadic concept can be:

1. A metaphor: a concept used in a new field of study, even if its definition is still referring to the starting field of study –Stengers calls it propagation as diffusion;
2. A pure concept: a notion grafted in a new field of study, in order to build new theories in the new field and the definition of which can be given inside the new field of study, without referring to the starting one –Stengers calls it propagation as epidemic;
3. A pirate concept: an absolute interdisciplinary concept, free from any bond with local concepts and single fields of study.⁴

Thus, is antifragility a metaphor, a pure concept, or a pirate concept? As written at the start of this section, antifragility has been coined at the beginning of the current decade. Thus, the *propagation* is still ongoing. However, I would argue that, considering the current point of *propagation* in the aforementioned disciplines, antifragility is half-way between a metaphor and a pure concept. Indeed, antifragility is characterised by a number of widely applicable heuristics that make it a potential pure concept. As far as pirate concepts are concerned, they just set up a tight group, further, many external factors could influence the admittance within this group. Time will tell if antifragility could be a pirate concept. For the moment, I am interested in highlighting that antifragility is a potential operative concept for several disciplines, and, in particular, for design disciplines –including architecture, urban design, and planning.

3. Antifragility as a design issue

This third section of the paper presents a set of case studies. Each of them concerns a remarkable example of recently built or renovated public space in Europe, and it has been selected to investigate a particular feature of antifragility. The value of these case studies has already been recognised by international architecture critics, indeed two of them have been mentioned by the most important awards for contemporary European architecture: the *European Union Prize for Contemporary Architecture – Mies van der Rohe Award* and the *European Prize for Urban Public Space*. Furthermore, in this paper each case has been selected for its capacity to reinterpret a previous open space –through space and processes– in an innovative way that breaks with the *status quo*.

Up to now, this investigation involves a simplification, as these spaces have more than one characteristic that deals with the notion of antifragility. However, the choice of isolating a single feature for each case

On this topic, Gambardella –with *Annali dell'Architettura e delle Città foundation*– has organised *Periferie Antifragili* (conference, Naples, 2018) and *Metropoli Novissima* (exhibition, Naples, 2018).

⁴ For instance, the French geneticist Michel Veuille (Stengers, 1987) considers the notion of correlation a pirate concept.

is a first attempt to show the potential of antifragility as a design issue, as well as to understand that a number of antifragility features are already –unwittingly– present in spatial projects. In particular, the following paragraphs focus on some antifragility features mentioned by Taleb, as the ability of learning from errors, the capacity of gaining from disorder –maintaining a certain degree of uncertainty–, as well as optionality and redundancy considered as a method to reduce shock exposure. Among all the antifragility features already recognised, these are the most directly connected with spatial design. But this list is just a start, ready to be discussed and implemented.

3.1 Learning from errors. The case of *Place de la République* in Paris

Starting from the traditional recommendation *learning from errors* and its corollaries –according to which stressors, errors, and their consequences can provide powerful information–, Taleb avers that the fundamental heuristic of *trial and error* has to be kept in the foreground. Indeed, “the random element in trial and error is not quite random, if it is carried out rationally, using error as a source of information. If every trial provides you with information about what does not work, you start zooming in on a solution –so every attempt becomes more valuable, more like an expense than an error” (2012, p.81). Furthermore, learning from others’ mistakes is vital. For instance, if a single individual fails, its error can still be a lesson to be learned by its community.

The antifragile attitude is the one that, after slipping up, takes advantage of the lesson learned from its mistake, and moves on “enriched with a new piece of information” (2012, p.83). More in general, “antifragile loves randomness and uncertainty, which also means –crucially– a love of errors, a certain class of errors” (2012, p.12). By writing about “a certain class of errors”, Taleb refers to small and diffused mistakes, a frequent little variability, namely the opposite of an isolated major shock. He writes that “such variability helps improve the system (hence the antifragility). A week with declining earnings for a taxi driver [...] provides information concerning the environment and intimates the need to find a new part of town where clients hang around [...] a small (nonterminal) mistake is information, valuable information, one that directs him in his adaptive approach” (2012, p.97). *Fluctuat nec mergitur* (2012, p.113), as Latins said.

Fluctuat nec mergitur is also City of Paris’ motto and, during the recent renovation work for *Place de la République*, this motto was written in capital letters along the fences of the square’s building site. No writing could be more appropriate, as the renovation of Parisian *Place de la République* by French architects TVK is a true example of how to learn from errors, in particular from past errors –that is to say the previous configuration of the square–, as well as from current small mistakes –the daily variability– by means of a blog that acts as a permanent observatory of the square.

Originally realised during Haussmann’s renovation and located among the 3rd, 10th, and 11th *arrondissement*, during the 20th century *Place de la République* had been progressively downgraded to the level of a huge roundabout. It had become a sort of traffic junction among seven main urban axes. Both private and public transports had increasingly colonised almost all the surface of the Haussmannian square, making pedestrian space marginal and devalued.

In 2009-10 the City of Paris organised an ambitious competition to entirely rethink the square. TVK won the competition and, in 2013, the realisation of their design project was completed. The new configuration has remodelled *Place de la République* as the largest pedestrian square of the city –280 x

120 meters, approximately 2 hectares—, subverting the spatial proportion between transport area – reduced from 2/3 to 1/3 of the total surface— and pedestrian space –increased from 1/3 to 2/3. By so doing, the square harmonises the metropolitan scale of transportation systems together with the local scale of pedestrians, as well as the magniloquence of its Haussmannian dimensions with its everyday uses.

The square is conceived as a wide and continuous pedestrian surface, composed by different tones of grey concrete slabs and characterised by a “serene balance of the mineral element and a horizontal ground”, as TVK states on their website. The prevalent horizontal dimension is even underlined by the few vertical elements that are present, as the aligned masses of treetops that shade pedestrians, the 19th century monumental statue of Marianne that orients gazes and fluxes, and a café located in a glass pavilion that seems to float on a reflective pool. The entire square constitutes a *plateau* that TVK considers as “an urban resource, available and adaptable for different uses”. Further, the designers state that the entire redevelopment of Place de la République “is based on the concept of an open scene with multiple urban uses”. Indeed, today the square hosts a great variety of daily uses, as well as informal public gatherings, institutional parades, mass demonstrations and protests.

Figure 2. Place de la République: left, learning from past errors; right, studying current daily variability. Elaboration by the author.

As seen in Figure 2, TVK has not only learned from past errors by redressing the spatial configuration of the square, but, together with the City of Paris, they have also decided to continue learning from present configurations, uses, and mistakes, by establishing an open online blog that works as a permanent observatory of the square. In fact, the blog *republique.tvk.fr* is a dialogical virtual space that

documents the survey of the renewed space by means of pictures, videos, interviews, and drawings. Far from being a neo-functionalist tool, the blog reports daily uses as well as exceptional uses of the square, also documenting unexpected uses and temporary appropriations of the spaces. The aim is to provide the necessary adjustments to be made along the way, as well as to build a repository of information for future projects.

3.2 Gaining from disorder. The shared space of Sonnenfelsplatz in Graz

Errors and stressors are just two specific components of what Taleb calls *The Extended Disorder Family (or Cluster)*. Thus, by saying that antifragility gains from disorder, the author refers to “(i) uncertainty, (ii) variability, (iii) imperfect, incomplete knowledge, (iv) chance, (v) chaos, (vi) volatility, (vii) disorder, (viii) entropy, (ix) time, (x) the unknown, (xi) randomness, (xii) turmoil, (xiii) stressor, (xiv) error, (xv) dispersion of outcomes, (xvi) unknowledge” (2012, p.21).

In this paragraph I would emphasise a spatial interpretation of gaining from disorder and chaos. When someone is immersed in a disordered or even chaotic space, he/she has to compensate the surrounding sense of uncertainty by being vigilant and staying focused. The popular Shared Space approach goes in this direction. Indeed, it aims to design more liveable and human-sized streets by introducing a certain degree of chaos. To reach this goal, shared spaces seek to minimise the separation among pedestrians, cyclists, and drivers –in favour of the slowest– by removing traffic signs and by weaken the difference among sidewalks, cycle paths, and roadways. The absence of traditional street rules produces a greater sense of uncertainty. For instance, it is no longer completely clear who has the precedence at some point, thus drivers and cyclists are inclined to slow down, with a general increase of awareness and alertness. As it is well known, the first spaces of this kind were conceived in the early 80s by Dutch engineer Hans Monderman. Since then, they spread to the extent that, in 2003, *European Shared Space Project* was established, leading to the development of specific shared spaces policies and design approaches. Today this kind of spaces are widespread in Anglo-Saxon Countries as well as in Northern and Central Europe and, despite criticism, an actual reduction of accidents has been found.

As other Shared Spaces, Sonnenfelsplatz in Graz is interesting because it tests the importance of self-regulation in a chaotic context. Sonnenfelsplatz has been built by the municipality between 2009 and 2011 and, being part of the European Shared Space project, it has been the first case of shared space in Austria. The square is located in a neighbourhood strongly characterised by the presence of University’s buildings, and it is close to the border between the compact inner city and diffuse tissues. Sonnenfelsplatz –approximately 3.000 square meters–conveys five busy streets and has an average of 15.000 motor vehicles per day. In particular, during peak hours, it has an average of 1.000 motor vehicles, 3.000 pedestrians, and 600 cyclists per hour (Schönauer *et al.*, 2012). A quite crowded square for a city of 435.000 inhabitants. In order to make the square more liveable and to decrease the number of accidents, the municipality of Graz has introduced the idea of a shared space through a number of participatory sessions together with inhabitants, city users, University’s personnel and students, followed by live training phases on the field. The participatory process has led to a collective welcoming of shared spaces solutions, that have involved de-regulation of traffic as well as introduction of seatings. Further, the perimeter of the square has been delimited by an uneven sequence of stripes miming the projection of the buildings that delimit Sonnenfelsplatz, in order to suggest –but nothing more than suggesting– a safe area for pedestrians and cyclists’ rest.

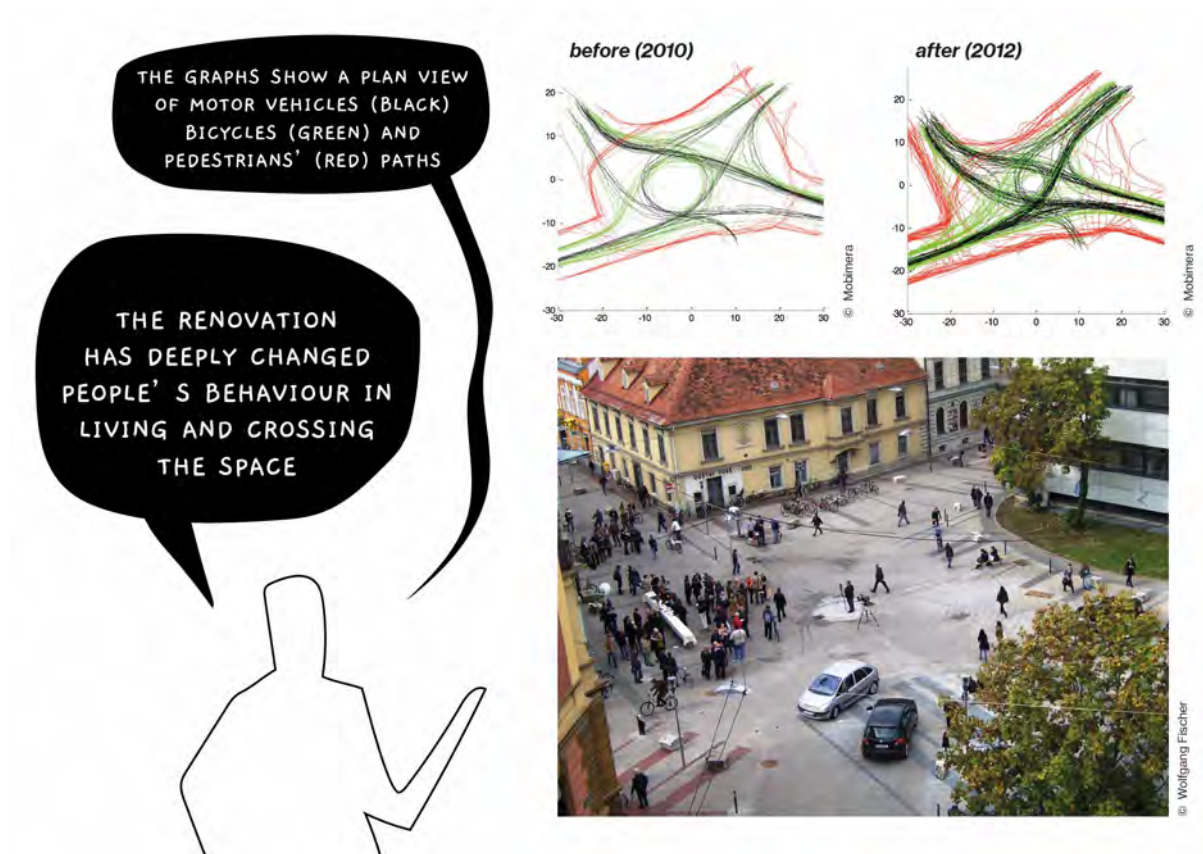

Figure 3. The shared space of Sonnenfelsplatz in Graz. Elaboration by the author.

Spatial self-regulation is not an invention of Shared Spaces. It is an ancestral behaviour. Nevertheless, shared spaces have the merit of its introduction in contemporary planning of public spaces. Besides, Sonnenfelsplatz is a useful case to be considered as it has been the subject of a traffic survey conducted immediately before and after its renovation (2010-2012). As seen in Figure 3, the survey was led by Mobimera –a Viennese consulting start up working in the field of urban road design and traffic organisation– and it showed that Sonnenfelsplatz redesign has deeply changed people's behaviour in living and crossing the space. Indeed, already in the first year after the renovation, drivers, cyclists, and pedestrians' paths smoothed in a more fluid configuration, motor vehicles systematically decreased their speed, the perception of safe areas deeply increased, car accidents significantly decreased and no accident involving pedestrians was registered (Schönauer *et al.*, 2012).

3.3 Optionality and redundancy to reduce shock exposure. The case of Superkilen in Copenhagen

An antifragile behaviour is the one that preserves the possibility of choosing, changing, adapting, and keeping options open. In this direction, Taleb states that “the fragile has no option. But the antifragile needs to select what's best –the best option” (2012, 197). Further, optionality –namely the possibility to have more options– “will take us many places, but at the core, an option is what makes you antifragile and allows you to benefit from the positive side of uncertainty, without a corresponding serious harm from the negative side” (2012, 184). In particular, the author introduces redundancy as a particular – simple– case of optionality. A redundant system has some kind of extra features, that could apparently

seem a waste of resources, but that can turn into precious reserves ready to use in case of need, shocks, unexpected events, and so forth.

In order to delve the spatial value of redundancy, I propose to return to the renowned case of Superkilen, already introduced in paragraph 2.1. Indeed, Superkilen is an interesting example of redundancy. Along approximately 700 meters of length, Superkilen keeps changing its morphology to establish a meaningful dialogue with its contexts. In this regard, one of the chief designers, Bjarke Ingels from BIG, says: “[w]hen we looked at the topographic map, there were somehow already three parts. We just transformed them into the *Red Square*, the *Black Market*, and the *Green Park*” (Steiner, 2013, p.25). Each part has a colour in its name, as it is the main colour that characterises its soil. Another of the chief designers, Jakob Fenger from SUPERFLEX, avers that the three coloured soils are “a sort of backdrop for the objects collected from different places” (*ivi*). These “objects” are the main feature of Superkilen. People of all nationalities living in the neighbourhood have been called to suggest an amazing and special object to represent their nation, culture, and tradition. Designers asked for objects “which usually furnish cities –ranging from litter bins, benches, manholes, bicycle racks, play and sport items, street lighting to ads (light boxes), bus shelters, a fountain, and even to sculptures” (*ibidem*, p. 13), and, after a process of selection, some objects have been directly transported from their country of origin and installed with the direct help of neighbourhood residents –thus triggering a deep sense of identification with the space–, while others have been reproduced on site with small variations. As a result, 108 objects and 11 new trees have colonised the space of Superkilen, creating “emotional connectivity” (*ibidem*, p. 16) and even “deliberate conflicting constellations, such as soil from Palestine and a manhole from Israel next to one another” (*ibidem*, p.18).

This process of summation, juxtaposition, inclusion, and incorporation of various objects has its roots in Cabinets of curiosities –*Wunderkammer*–, passing through English landscape gardens –as suggested by Martin Rein-Cano from TOPOTEK 1 (*ibidem*, p.30), and after through kitsch amusement parks as Tivoli Gardens in Copenhagen and Epcot Centre in Florida –as claimed by Rasmus Nielsen from SUPERFLEX (*ibidem*, p.31). Further, Bjarke Ingels from BIG adds that “[t]hings somehow fuse, and I think this was the case with Superkilen. I would like to call this ‘inclusivism’, [...] but different from the way that it does not become *Frankenstein*. In the beginning we said ‘lets the dogs loose and see what happens’[...]. There were moments of elegance and a lot of moments of incompleteness. But still, it has become much more tasteful than I had actually imagined” (*ibidem*, p.72). This kind of operation of summation is antifragile as it introduces an interesting degree of redundancy. Indeed, if a few of the 108 objects composing Superkilen are damaged, broken, ripped out, or simply under maintenance, they do not prevent to use the space, that will still be full of objects, uses, and possibilities. Further, many of the items are shaped so that they are versatile and can also be used for other purposes –i.e. a bench as a sport item, a bicycle rack as a game for children, and so forth. Superkilen’s redundancy of objects also provides a rich and varied experience of the space even if not all objects would ever be realised, in this sense Bjarke Ingels from BIG states this very clearly “The *Black Market* should get a bump. That is a quite successful little element. On the *Black Market* we wanted to create a little shelter. Unfortunately, this has not been realised yet, and it may never be. If it comes to the worst, I think the park can survive with just the bump” (*ibidem*, p. 25-26). Redundancy takes place also on a broader level. Indeed, the three parts composing Superkilen –the *Red Square*, the *Black Market*, and the *Green Park*– are deeply different from each other in terms of typologies of spaces, soils, materials, and so forth. Consequently,

the temporary impossibility to access one of the three parts –i.e. the *Green Park* after a typical Danish flood– will not prevent to enjoy the other two parts –featured by more impermeable soils.

4. Conclusion

This paper has investigated a number of antifragility features by means of recent projects of European public spaces, in order to start inquiring the spatial value and design potential of antifragility. As argued at the beginning of the third section, these features are just a start. Many others are presented in Taleb's writings and, more in general, in writings that have already tried to graft the notion of antifragility in other disciplines. Further, my work will not just be limited to the spatial interpretation of some features already identified. It will define features that make public spaces antifragile places to enhance existing local environmental and social resources, relate contexts, and generate new ecological and relational interactions as formative elements to strengthen culture and design of European collective dimension. To do so, two general considerations will be kept in mind all along the development of the work. The first one concerns the strategic role of public space. Indeed, if public space is a place of sharing, of reciprocity, and, ultimately, a space of democracy representation, then it has to be considered for contributing in framing a new bio-political project (Viganò, 2018) that will shape the future of European territories. The second one starts from the considerations of paragraph 2.3, notably from the suggested pairing between sustainable development and antifragility. In this sense, ecological and environmental dimensions are more and more inseparably intertwined at different scales with social concerns. Thus, a critical reading of contemporary European territories that considers overlapping dynamics and articulations among ecological, environmental, and social priorities, could be useful in understanding the nature of contemporary European public spaces.

Acknowledgements

Prof. Camillo Magni (Politecnico di Milano) has first sparked my interest in antifragility as a possible spatial design issue. Furthermore, several precious conversations with Prof. Elena Cogato Lanza (École polytechnique fédérale de Lausanne) have deeply helped me in considering antifragility as a potential entry point to approach and to inquire some questions related to contemporary European public spaces. At present, I am enrolled in *Urban Planning, Design, and Policy* PhD programme at Politecnico di Milano, my work is led under the guidance of Prof. Bertrando Bonfantini –with the collaboration of Prof. Andrea Arcidiacono and Prof. Eugenio Morello–. As I am a first-year student, my research questions are currently under definition.

³*Beijing Forestry University, zhangyunlu1986829@163.com*

Abstract: In China, historical and cultural blocks serve as the material carrier of traditional culture and resident life in the city, as well as an important area for protecting local culture, inheriting historical culture and displaying urban style. In the transformation and renewal stage of the city, the protection and renewal of historical blocks has become a hot topic of research and discussion. Based on the life and leisure needs of residents in historical and cultural blocks, this paper firstly interprets the concept of ‘collage city’, emphasizes the integration and coordination of spaces and surrounding population demand, land use function and style, and proposes a planning idea. Secondly, taking the Beijing Moshikou historical and cultural block as an example, realize the diversified and systematic public space system through the three-level planning of ‘node-tour line-region’. Meanwhile, we plan festival activities to promote neighbourhood relations and tourism development, and encourage community residents to participate in the planning process through time series construction. In the end, in the historical and cultural districts, the use of collage techniques to promote the integration of multiculturalism, coordinate the balance between tourism development and residents' lives, and achieve sustainable urban transformation.

Keywords: Sustainable urban transformation, Public space, Landscape technique, Public participation

1 Introduction

In China, historical and cultural blocks serve as the material carrier of traditional culture and resident life in the city, as well as an important area for protecting local culture, inheriting historical culture and displaying urban style. However, due to the rapid development of the city, the historical and cultural blocks have been built for a long time. Historical and cultural blocks generally have problems such as backward infrastructure, narrow living space and poor sanitary conditions. The weakening of neighborhood relations and the lack of public activity space, the harsh environment and the lack of care for vulnerable groups have led some aboriginal people to be unbearably and gradually moved out, eventually making the neighborhood community gradually lose its vitality. Memory ^[1]. Therefore, in the transformation and renewal stage of the city, the protection and renewal of historical blocks has become a hot topic of research and discussion. However, the current historical and cultural district renovation projects often focus on tourism development and economic benefits, and are not based on

the daily life of the original residents in the neighborhood. The reconstructed neighborhoods are too commercialized and socially isolated, eventually leading to these. The renovation project has not achieved the expected economic and cultural benefits, nor can it meet the basic daily living and leisure needs of the residents. Historical and cultural blocks often have scarce public space, not only in small numbers, but also in problems such as unreasonable distribution, low diversity, and inadequate functional facilities. Under such restrictions, the drastic new green space is neither realistic nor rational [2]. Therefore, on the basis of completing the protection and restoration of historical and cultural blocks, it is the main content of this paper to use multi-level and time-series public space system planning to reshape traditional culture, display urban style and enhance living environment.

2 The concept of “Collage City”

The concept of “collage city” comes from Colin Rowe's book *Collage City*, which he believes that urban form always changes in a small and gradual way, and the culture of the old town is different. The cultural accumulation of the period and the multiculturalism contradict each other to form a collage [3]. The concept of “collage city” opposes the demolishing of cities in the name of modernization. It believes that cities should self-renew in different segments without losing the whole, and should pay attention to the continuation of historical context and style. "Collage" is a design method that respects historical things. By using existing things and old things to create, you can perfectly integrate the future, present and past things to form new things. The core content of the “collage city” concept is summarized as follows [4]: 1. The city is a product of historical synergy. Anyone's understanding or influence on the city is fragmentary and partial, and the whole city is partly partial. Formed by patchwork. 2. Cities are complex and diverse, and space should be the product of society and people based on their interpretation of absolute reference and traditional values. 3. "Collage" on the level of urban "technology" means that spatial design should be based on respect for urban texture, deal with specific situations in a variety of ways, and achieve harmony with the surrounding environment, rather than conflict. 4. Actively advocate the "bottom method" to analyze and Cognitive cities. 5. “Collage” can be a strategy to impart reality, change, movement, behavior, and history through Utopia's ultimate unchanging vision.

3 The idea of public space planning in historical and cultural blocks under the concept of “Collage City”

3.1 Coordination with the needs of the population

For the diverse use demands of people, the public space features a variety of functions such as rest, exercise, children's recreation, cultural display, party negotiation, etc. Compared with large parks, the use of small public spaces is more humanized and closer to the daily life of community residents. Based on the concept of “collage city”, the planning of public space system in the historical blocks should fully coordinate the relationship between the public green space and the functional needs of the old city, and arrange the green spaces with multiple functions in the urban area to make the spaces of each function coordinate with each other. Emphasize the interactivity of each monomer between the public space system and ensure the functional integration of the space system to meet the diversity needs of the residents of the area.

3.2 Respond to the function of surrounding land

Due to the flexible layout of small public spaces, the service objects are nearby people, and the surrounding environment is complex. The surrounding areas of public spaces may be office areas, residential areas, and commercial areas. Therefore, the use of people and surrounding environment should be fully considered. Under the guidance of the concept of “collage city”, the relationship between green space and surrounding land should be fully considered, focusing on functional connection, texture integration and layout coordination to form an organic space system. The specific planning and design can determine the focus of the public space function planning according to the surrounding land use function, and consider the surrounding land use planning and green space system planning, thus exhibiting a multi-dimensional unified urban micro green land function carrier.

3.3 Setting off with cultural landscape style

The culture of historical and cultural blocks is the cultural accumulation of different periods and the interweaving of multiculturalism. When excavating the cultural characteristics of the historical blocks, it is necessary to continue the historical and cultural connotation and traditional style, and also to enhance the era of the old city. As a carrier of culture, public space bears the role of protecting cultural diversity. In the design of public space, the cultural features of the urban area are extracted, and the language and cultural meaning of the venue design are given to form a dynamic open space with urban regional characteristics. Incorporating local regional cultural characteristics into public space not only can display the unique characteristics of historical and cultural districts, but also help to increase the cultural identity and local sense of belonging of local residents.

3.4 Collaboration with the urban renewal plan

The construction of public green spaces is not only related to the effect of optimizing the surrounding human settlement environment in the near future, but more importantly, it will directly affect the reconstruction of the long-term pattern of green space in historical and cultural blocks. The planning and construction of public space system is an organic process of “point-to-face”. The “Collage City” concept focuses on sustainable and progressive public space planning and construction, and in this process, moderately and systematically protect and update the living environment resources of historical blocks. Promote the continuity and stage of the historical and cultural district renewal process through public space, and restore and revitalize the vitality and vitality of different historical and functional spaces in historical blocks^[4].

4 Multi-level public space system planning——taking Beijing Moshikou historical and cultural block as an example

4.1 Research scope

Moshikou Historical and Cultural Street is located in the northwest of Shijingshan District in Beijing, at the southern end of Xiaoxi Mountain, and belongs to the shallow mountainous area of the city. According to the scope of protection of the historical and cultural blocks of the model mouth determined by Shijingshan District, this study covers Shimen Road in the west, Jinding North Street

in the east, Fahai Temple Forest Park in the north, and Nankou in the south. It has Yongding River Canal. Through, the total area is about 56.8 hectares.

4.2 Spatial classification of potential construction

Through on-the-spot investigation, the “corner space” existing in the historical and cultural blocks of the model port is explored as a potential space that can be developed into a micro green space. As seen in Figure 1, according to the current land use function and utilization situation, these potential spaces are divided into forest land, park green space, courtyard space, streetside public space, waterfront space, parking lot, construction site, and waste land . These potential spatial layouts are scattered and have a public nature. On the one hand, they provide space for daily life and social interaction for residents, on the other hand, they are also an important element to highlight the characteristics of the community and human settlements in the historical and cultural blocks of the model. The conversion of these potential spaces into public spaces is of great significance for enhancing the living environment, community identity and belonging.

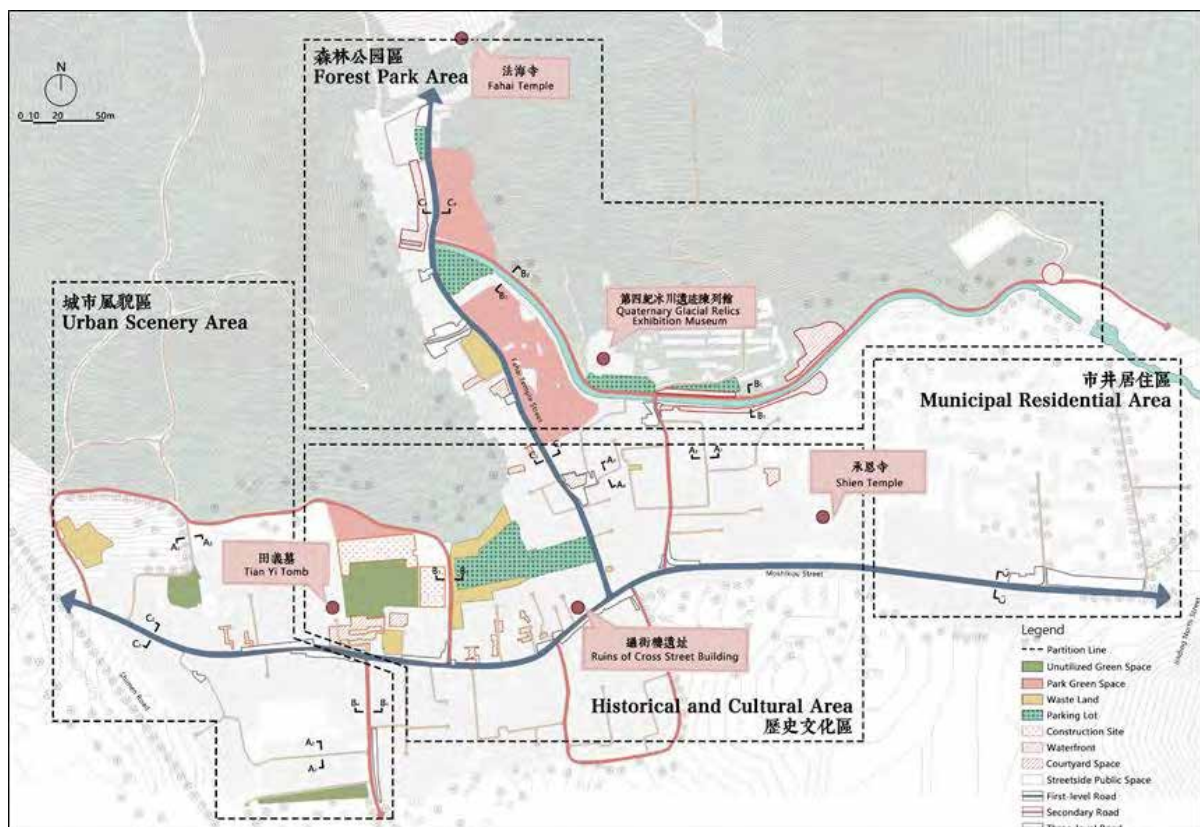

Figure 1 Schematic diagram of the current potential spaces

4.3 Node level public space planning

There are many “corner spaces” in the development of the Moshikou block. Converting these scattered point spaces into green space is a strategy for transforming the green areas from the node layer. Although these green spaces are not large, it is evenly distributed and easy to reach, and the transformation from the nodes can have an immediate effect. After evaluating the potential space within the site, it was found that the Moshikou historical and cultural block was partially in good

condition and has many public spaces (such as parking lots, cultural attractions, parks, shelters, etc.). As seen in Figure 2-4, different ways of creating catalyst nodes, combining green space and rationally utilizing free space are adopted for different situations.

4.3.1 Creating catalyst nodes

Public space has the role of “point-to-face”. Catalyst nodes can play a “catalytic effect” to stimulate and guide the surrounding resources and potential, thus driving the vitality of the neighborhood. Therefore, the potential space is screened and four micro spaces are selected as the catalyst nodes. The size of the four catalyst nodes is about 1000 m², which is suitable for the pocket park. It is suitable for public activities and can achieve the effect of point-to-face. The site selections of the catalyst nodes is located in the west, north, central and eastern parts of the site, and are at key positions in each zone, which can stimulate the vitality of all quarters. There are public service buildings or cultural relic sites around those sites, which have a certain flow of people and are more conducive to the attraction of the catalyst node. With the theme of interactive experience, green ecology, historical humanities and cultural creativity, the four catalyst nodes create four different thematic catalyst nodes, which become the vitality points in the block and create possibilities for attracting multiple formats. For example, in the interactive experience-themed catalyst node, the residential activity stage and the interactive tea seat are designed to provide social space and display space for residents and foreign tourists, and to promote and attract drama and dance and cultural products.

4.3.2 Sharing courtyard space

According to the public courtyard space of residents, the courtyard space is integrated, and each household both has its own space and public space shared by residents after designing and combining those fragment and separate spaces. Residents' demands for courtyard space is that they must have independent use space (such as placing sundries, planting flowers) and convenient public spaces (such as traffic, and sitting). Therefore, open the public courtyard space of residents, dismantle the simple houses and walls that are built randomly, re-dividing the private space and public space of the residents and improve the accessibility of the courtyards between some residents' courtyards or courtyards, and build a public space shared by residents. This type of public space is only used to serve multi-family residents around the courtyard space.

4.3.3 Reasonable use of free space

Reasonable use of free space is a reform strategy for parking lots and other abandoned spaces, that is, reorganizing the existing waste space and parking lot, releasing unused space, opening the wall to facilitate pedestrian entry in the street, and flexibility make use of the free space of the parking lot as a public space. According to the survey, the parking area of the model port is large, the greening is small, and the space is not fully used. Therefore, it is possible to release a space that is not effectively utilized, and a movable planting pond, a flower pond, a seat, and the like are placed in the space. When the parking volume is small, this space becomes a green leisure space for tourists and residents to stay. When the parking demand is large, the facility can be moved at any time to resume the parking function.

Figure 2 Interactive Experience Living Room

Figure 3 Green Ecological Kitchen

Figure 4 Collage Culture Wordshop

4.4 Tour line level public space planning

The streets and water systems in the Moshikou historical and cultural blocks have strong spatial characteristics. The integration of their potential space to form a continuous linear green space is the main strategy for tour line level transformation. The linear green space can enhance the connection between different public spaces, green spaces and cities, and expand the contact space and interface between the city and nature. At the same time, as seen in Figure 5, by integrating the potential space along the street and widening the street boundaries, the problem of pedestrians can be solved while accommodating public activities such as booth sales, cultural exchanges, leisure recreation, etc., adding certain infrastructure and creating rich and interesting street space. For the residents' streets and waterfront trails, two ways of renovating the street space and the façade and continuing the waterfront space were adopted.

4.4.1 Enrich street space and facade

After the preliminary investigation, it was found that due to the special geographical environment of the shallow mountain where the model mouth is located, the residential space and the street on both sides of the street have a large height difference, forming steep ridges, platforms and retaining walls, which cannot be used as a public space. Therefore, by optimizing the street façade and transforming the steps and retaining walls on both sides of the street, the streetside public spaces are created and the street boundaries are widened. The streetside spaces with high difference are taken as the object of reconstruction, the retaining wall next to the street is digested, the ramp is set, and the slow-moving road is expanded by using the high-end residential space. The use of walls and space under the steps for three-dimensional greening creates a public space where people can stay and create greenery.

4.4.2 Continuing waterfront space

Continuing the waterfront space is the transformation strategy of the space beside waterfront trails, that is, excavating the waterfront space on both sides of the river, and forming a continuous green

corridor through the integration of space. The Yongding River diversion canal in the Moshikou block is Between the block and the mountain. Although there are waterfront roads which can be used, the waterfront space is totally neglected, and there is no continuous green space and road system of traffic diversion. Space, increase seats, plants, small squares, scenic walls, pedestrian walkways, etc., to form a continuous strip of green space, to lay the foundation for the formation of green roads. By continuing the waterfront space, the waterfront green landscape can Be enhanced, so as to better connect people with mountains and waters, and to close the distance between man and nature.

Figure 5 Culture and Creative Corridor

4.5 Regional level public space planning

Through the transformation of the public space at the node level and the tour level, the points and lines of the public space are no longer scattered and isolated, but can form an organic green mesh system at the entire regional level of the pattern and history and cultural blocks, driving the organic updating of the block. From the perspective of the tour system, various types of point-like micro-green space connect the main landscape nodes of the city, ensuring the continuity of the green open space. They form a network that provides a richer function and a more diverse landscape for the urban green space to form a system for building a tourable space. From the perspective of ecological pattern, when the urban green lands develop to a certain scale to form a green network, the city and the shallow mountain are well connected, which will certainly exert positive ecological benefits, including mitigating the heat island effect, improving air quality, and increasing species diversity. And a series of positive effects such as reducing building energy consumption^[5], greatly enhance the high-density urban ecological environment, thus forming a green complex in the shallow mountain block. From the perspective of cultural shaping, the public space system carries a variety of neighborhood culture, and the historical and cultural system of the block is inherited and improved. Residents can carry out various cultural activities in the public space, thus forming a multicultural exchange and sharing space and cultural display space.

4.6 Event planning

By planning social organization activities, government organization activities and residents spontaneous activities, enriching the lives of community residents, it can also attract tourists, and the economic benefits brought can also be invested in the next step of construction, as seen in Figure 6. Activities include:

1.Social organization activities. Including the Arbor Day, Spring Tour, Beijing Design Week, etc., which can attract a large number of enterprises or colleges to participate in the construction of the Moshikou historical and cultural blocks, which can becomes the carrier of multicultural communication.

2.Government organization activities. Including community green plant distribution, plants science cognitive activities, talent competition, marathon competition and other activities. By organizing such activities, the government can enrich the residents' lives and promote the relationship between the neighborhoods, as well as enhance the visibility of Moshikou historical and cultural block, so that more tourists can know the Moshikou and join in protection and renewal work.

3.Residents spontaneous activities. Including spontaneous activities such as morning market, mountain climbing, and walking. Through the construction of the public space system, the quality of the green outdoor space of the model port will be improved, so that the historical and cultural district of the model port can better become a good place for residents' living and tourists to relax.

After the planning of the event, the residents of the community as well as the tourists and enterprises and the government can participate in the construction process , and it can also promote the neighborhood relationship. The economic benefits brought by the development of the tourism industry can also provides economic support for the further protection and renewal work of Moshikou block.

Fig.6 Events Planning

5 Summary

The transformation of the public space in the traditional historical and cultural blocks is mainly to attract foreign tourists, to make renovations in the public space of the neighborhood from the aspects of tourists' sightseeing and shopping experience, ignoring the quality of local residents' life qualities. Professor Pu Yisan once said that , “Once historical blocks have lost their traditional lifestyles and customs, they have lost their 'life authenticity'. Instead of the real people’s activities attached to these historical sites, In a sense, it is another kind of falsification behavior, and the block will lose its original historical charm.” The author believes that the construction of historical and cultural blocks should not blindly pursue the restoration of the antiques, and should respect the residents’ lives in the block. From the perspective of the needs of tourists, we will solve the various needs of the local residents, such as building living and leisure space, continuing the good cultural atmosphere, creating a beautiful and humane living environment, which also can meet the tourists' perception and experience of the venue living environment. .The public space planning idea based on the concept of “collage city” emphasizes the rational and coordinated systematic design plan. From the overall perspective, it proposes the plan according to the sequence and stage, pays attention to constructing a sophisticated and perfect public space system, and gradually promotes the healthy development of the block. This paper also hopes that this plan can fully mobilize the surrounding resources and potential, and make the neighborhood and the surrounding have a organic linkage, and build a public green space system of the city's overall area with a integration goal, gradually improve the urban green space system structure, and build a harmonious symbiosis between human-beings and nature.

Tourism ,public spaces and urban cultures

Urban Public Space Design from the Perspective of Environmental Behavior——A Case Study of the round-city-park in Xi'an

Taiwei Gu

Xi'an University of Architecture and Technology ,2467523706@qq.com

Abstract: Urban public space provides the place and environment for leisure, entertainment and social intercourse for residents, and it is an essential part of urban composition. In the process of building public space, we should pay full attention to the use value of public space to people and people's perception of public space. Through the use of various dynamic elements in public space, the space environment can play a guiding role in human behavior, and create a city public space that corresponds to the behavior of communication activities. Based on the theory of environmental behavior, this paper deeply interprets the interaction between space environment and human behavior, and analyses the characteristics of human behavior in urban public space. It also elaborates the influence of environmental behavior on public space in combination with Xi'an Circle Park, and explores the ways of constructing urban public space with local historical and cultural characteristics, so as to improve the quality of urban public space.

Keywords: Public space The round-city-park in Xi'an Environmental Behavior

Introduction :

With the development of the city and the improvement of people's living standards, the existing urban public space is more and more difficult to meet the citizens' cognitive and use needs of public space. With the development of environmental behavior, people gradually attach importance to the study of the relationship between human and environment. On the one hand, urban public space conforms to the characteristics of human perception and cognition, on the other hand, it also closely corresponds to the characteristics of human behavior, which can meet the needs of different levels of human beings. Therefore, relying on the theory of environmental behavior, the study of urban public space planning and design is in line with the new requirements of urban development. Through the study of urban public space planning and design, this paper summarizes the influencing factors and design principles of urban public space quality, and adds theoretical basis based on environmental behavior perspective to the field of urban public space planning and design. It is conducive to the future design, use, protection, management and development of public space, while positively affecting the new style of the city.

1.Origin and Research Progress of Environmental Behavior

The concept of "environmental behaviour" was first proposed by American scholars Prochansky and Iterson. Environmental Behavior focuses on the artificial environment, which pays attention to the relationship between environment and behavior, and studies the relationship between environment and behavior as a whole, emphasizing the interaction between them. Environmental Behavior is called Environmental Psychology, but the scope of Environmental Behavior seems to be narrower than that of Environmental Psychology. Environmental Behavior combines the relationship and interaction between human behavior and its corresponding environment. It pays attention to the relationship and interaction between environment and human's explicit behavior, so it is more applicable.

In 1968, the Association for Environmental Design Research was established in Europe. In 1969, the Journal of Environment and Behavior was published. Many research centers were formed and gradually became the largest number of academic groups engaged in environmental-behavioral research and application. By the end of 1950s and the beginning of 1960s, the study of environmental behaviour began to rise in Europe. In 1979, psychologist David Canter founded the Journal of Environmental Behavior, which and the Journal of Environment and Behavior are the two most influential periodicals in this field so far. Environmental Behavior began to be introduced into Asia in the 1960s. It was first studied in Japan and developed rapidly in the 1970s.

China started late in the field of environmental behaviour research. In the early 1980s, relevant theories and research methods were introduced from Europe, America and Japan, and began to be applied in the field of architecture. In the field of environmental behavior, Professor Li Daozheng's Introduction to Environmental Behavior, which systematically introduces the relevant theories of environmental behaviour, is the main theoretical book in the field of environmental behaviour. Professor Xu Leiqing's "Human Engineering and Environmental Behavior" combs environmental behaviour, and makes a detailed study of the theory and application of human engineering. Similar studies include Environmental Behavior and Human Engineering, compiled by Zhang Yuming, Zhou Changliang, Wang Hongshu, Liu Yuchu and Wang Xueyi, which has made in-depth studies on the theory of environmental perception and the theory of the relationship between environment and behavior. In addition, Professors Xu Leiqing and Yang Gongxia's Environmental Psychology and Professors Hu Zhengfan and Lin Yulian's Environmental Psychology play an important role in guiding the theoretical research of environmental behavior. With the development of environmental behavior in China, the number of books and academic papers on environmental behavior is also increasing.

In summary, the research practice of environmental behaviour in China is relatively late, and most of the research methods and contents focus on theoretical research content. The research of empirical cases still needs to be deepened.

2.Necessity of Organic Combination of Environmental Behavior and Public Space Planning and Design

From the perspective of human visualization, urban public space is not only designed and constructed by human beings, but also realizes its use function value by human beings. The relationship between them is an interaction and interaction.

Through the related theories of environmental behaviour, we can find that the main reasons for the limitations of urban public space environmental design are: in the early stage of urban public space planning and design, most decision makers and designers do not do enough in some basic research work, and they do not have a good understanding of the regional cultural background, user age and social

stratification, physiological and psychological demands and even social and economic development. The comprehensive consideration of the influencing factors such as the objective law of exhibition is not meticulous enough, which leads to that the public space environment presented in front of the users can not fully meet the various practical functional needs of various groups of people; at the same time, in the design process, the users are not placed in the main position of public space construction for relevant discussion and research, and the real meaning of "people-oriented" can not be penetrated. In the whole planning and design process.

Therefore, from the user's point of view, it is necessary to take environmental behavior as the basic theoretical support, and combine the research methods of literature review, case analysis, on-site investigation and comprehensive evaluation. Firstly, the specific design elements that may have a direct impact on the urban public space environment should be identified. On this basis, the behavior and needs of the users in the empirical cases should be analyzed and summarized. The results are summarized and refined, and more reasonable design strategies and objectives are formulated to meet the needs of different types of users for various activities, so as to maximize the use value of urban public space.

3.Study on the Development of Public Space of Xi'an Ring City Park

Xi'an Circum-city Park is located in the periphery of Xi'an Ming City Wall. It is a three-dimensional park which includes Xi'an City Wall, Moat and Circum-city Forest Belt in Ming and Qing Dynasties. Xi'an Circum-City Park relies on two elements of Moat and Ancient City Wall to construct. Because of the obstruction of the city wall, the development space is relatively small. In the South Gate of Xi'an Circum-City Park-Suzakumen Section, around the city wall, the Plaza central attractions are connected with a series of small attractions in the form of riverside walking belts. In some large squares, thematic sculptures are arranged to form large public recreational space through the combination of static environment such as landscape, sculpture, sketches and waterfront buildings. (Figure 1)

(Figure 1 Xi'an Ring City Park)

The biggest characteristic of Xi'an Circum-city Park is to design with the city wall, which not only retains the original style of the ancient capital, but also enlarges the urban public space. With the development of the times, the design methods of Xi'an Circum-City Park are constantly innovating and changing, forming the landscape of the city wall. With the gradual improvement of Park facilities, the number of tourists is also increasing. From the current effect, the city wall has become the symbolic structure of the park, the defensive function of the old city wall has changed, and it is well integrated into the urban public space.

4.Environmental Behavior and Space Analysis of Ring City Park

According to the questionnaire on the behavior of tourists in the park around the city, the age composition, sex ratio and purpose of tourists are studied and analyzed. It was found that from Monday to Friday, 48% of the respondents wanted to walk, 18% of the visitors wanted to exercise, and concentrated in the morning and evening. 24% of the visitors enjoyed the scenery, while the remaining 10% were friends gathering and chatting. On weekends, 52% of visitors are for walking, 12% for exercise, 30% for enjoying the scenery, and 6% for party, chatting and so on. (Figure 2)

(Figure 2 Questionnaire charts)

According to the theory of environmental behaviour, people have different requirements for the environment in every activity. Spontaneous activities and social activities are particularly dependent on the quality of the space environment. Most of the activities in public space are mainly spontaneous and social activities. In order to build urban public space, it is necessary to make rational use of the elevation difference of the site, plant diversified, and provide space for users to communicate with each other, so that people will not feel lonely, alienated, or uncomfortable, and then build a suitable dynamic space environment.

Spatial communication includes some space for communication, such as entrance space, square space, garden space, etc. In the design of the entrance area of the park around the city, considering the influence of people flow, traffic flow and other factors, a number of square lawns are laid out, which effectively realizes the transition from public space to semi-public space. Through the layout of the archway, visitors are attracted to the park by its unique appearance and historical logo. Array of trees at the entrance of Xi'an Circum-city Park. Under the big trees, people can stop and rest. Residents can talk and cool down. It is a more ingenious and applicable arrangement to make trees and not grasses, because this arrangement enlarges the use of space. In the objective form of material existence, the combination of vegetation and water surface elements can provide people with a more comfortable space environment in a long, wide and high range, and improve people's satisfaction.

At the same time, the tree array isolates the noisy urban main roads from the urban parks, and also serves as a transition from public space to semi-public space. Considering the difference of terrain elevation, different vertical elevation differences are often used in public space. Steps and retaining walls are used to layout the site and separate the space. The management facility building in the park around the city is a city landscape building which integrates urban green space and functions. At the spatial level, it is highlighted that the city wall, as the background of the park around the city, is the product of history and culture. Under the environmental conditions of the city wall and the famous historical and cultural city, attention should be paid to the distinction of primary and secondary, and the ups and downs and scattered space environment should be constructed.

The moat has a sinking hydrophilic entrance, new docks and landscapes on the South bank. These facilities are bricked and built by ancient methods. Near the bridge deck, there are new decorations and changes. On the basis of the original trees, many new trees have been planted. (Figure 3)

(Figure 3 City Moat)

Many theme sculptures have been added to the central part of the park. The setting of these landscape sketches has become the focus of the central square. There are some shaving burdens in the living customs of the old Xi'an people, as well as living scenes and appliances such as selling water, oil tea, storytelling, walking birds, Qin opera culture and so on. Concentrate on reflecting the commercial culture, catering culture, opera culture and folk culture of old Xi'an. When visitors come to the moat, they have a concept of Xi'an's life and culture. They can really feel the taste of the ancient city of Xi'an, recall the history and experience the contemporary era. (Figure 4)

(Figure 4 Sculptures in the Park)

In addition, the space environment should play a guiding and enlightening role in human activities. By combining the important natural environment elements such as water body and green space with people's activities, we can create more excellent activity space, enhance people's communication, and enhance the vitality of public space. The five-in-one "Wall, Lin, River, Road and Lane" has become an important landmark symbol with historical and cultural characteristics of Xi'an. Witness historical memory, store cultural spirit, enrich human experience, influence modern life, improve the overall environmental image of the city, and provide people with more leisure facilities and public goods of high social value.

Around the moat of the ring park, through the blending of wharf landscape and hydrophilic space, the paving way and decorative style of the ground and bridge deck conforming to the characteristics of cultural accumulation, retaining and supplementing the decorative echoes of trees and grasslands, and

actively giving play to the guidance of space environment to people's willingness and way of activities. In the design of the park around the city, the city wall, as the core of historical elements, often appears as a composition element. Through the intersection of different trees, high or low, the city wall presents in different forms in front of visitors. Looking from a distance, it seems that it is shaded by the big trees in front of it. Looking from a close angle, it is tall and lofty.

5. Discussion on Promotion and Development of Public Space around City Park

5.1 Complete and reasonable transportation system

Systematic integration of the traffic system around the city park, full consideration of the outdoor public space scale, create pleasant, comfortable pedestrian and space, create functional organic series, visually unique charm of the pedestrian system space, for people through walking to carry out exchanges, leisure, entertainment, shopping and other activities to create space conditions, foil the vitality of creative space atmosphere.

5.2 Overall Planning of Ground Form

The division of hard and soft media, the choice of material texture and the design of pattern and color will make people feel the space intuitively. Therefore, in the design stage, it is necessary to divide the functional space according to the basic elements of the node theme and the use function of the park around the city, through the application of different materials and the transformation of the laying style, to create the vitality of the ground space, and to guide people to carry out different types of behavioral activities from the side.

5.3 Overall Planning of Activity Sites

On the premise of guaranteeing its diversity, the public activity space in the park around the city should provide sufficient quantity, comfortable and safe activity facilities according to the users demand for behavior activities; at the same time, reasonable control and selection should be made on the site scale and layout according to different use functions, so as to carry out for users of different types, age groups and cultural backgrounds. Various types of activities create positive conditions.

5.4 Landscape greening is exquisite and diverse

Environmental landscape design should meet the needs of people's visual sensory enjoyment, and integrate the needs of people's behavioral activities into it. Through the rational collocation of plant vertical level and the rich change of seasonal color, and combined with spatial nodes and functional themes, the landscape facilities such as sketches and structures are designed to create a good ecological environment and achieve the overall upgrading of the environmental landscape.

Epilogue

Today, with the rapid development of urbanization in China, the quality assurance of urban public space is becoming more and more important. It is the material basis for promoting a healthier and harmonious social life. The overall quality of public space construction directly affects the city's comprehensive competitiveness and public satisfaction. Therefore, urban decision makers, builders and users all pay special attention to it. It is an important guarantee for building an environment-friendly city and realizing the scientific development of human settlements environment to excavate the characteristics of urban public space and improve the quality and taste of public space in combination with environmental behavioral research.

Abstract: Joint development is a collaboration construction between a transit agency and real estate operated by government and private individuals. Mostly focused on transit-oriented development (TOD) which ensures dense, walkable, mixed-use development near transit and at the same time improve the transit system. With China's national policy on prioritizing the public transit development, now is the critical time to achieve a sustainable urban form through implementation of Transit Oriented Development (TOD). Higher residential densities in the vicinity of transit station will make residents more likely to use public transit and support local economic activities. Based on the TOD principle of designing high-quality mixed-use areas that are pedestrian friendly, it facilitates socioeconomic and cultural diversity. A case in Jinqiao Community, Pudong New District, Shanghai, was chosen to better illustrate the win-win cooperation based on the involvement of social group in the TOD transformation case analysis. The proposal greatly contrasts with existing developments and try to integrate land use with transit and to include the public groups' ideas in the transit-oriented concept. The proposal greatly contrasts with existing developments in the way to develop transit-driven land and how the public groups' ideas are included in the transit-oriented concept. The public group encourages self-organization and promotes place-branding. Meanwhile, this third-party concerns about public participation, continues to play the role of public spaces in promoting a diverse, equal and democratic urban cultures.

Keywords: Joint development, Self-organization and place-branding, public participation, social group

1. Joint Development and Social Groups

Joint Development refers to a strategic orientation in which companies and their partners participate in market competition in a joint way in order to achieve their respective strategic goals. This strategic situation enables them to collaborate and complement each other and solve problems due to resources and many issues caused by insufficient ability. In urban development, it refers to the cooperation between transport agencies and real estate operated by the government and individuals. The main focus is on transit-oriented development (TOD), ensuring intensive, walkable, multi-purpose development while improving transportation systems.

Joint development is a development activity based on public-private partnerships that balance public and private demands. The risks mainly include risk sharing among partners, government risk control over projects, and joint development company (enterprise) control of project risks. [1] In traditional joint development, the government generally acts as a transportation planner and developer (enterprise) for real estate development. It is difficult to strike a balance between stakeholders, especially when they have different opinions or imbalanced interests. As a third party, social groups represent social forces,

can coordinate the interests of all stakeholders and make the project balanced, and achieve a balance between the state, the market, and the society, and its own experience also contributes to joint development.

Since the 1990s, statements about joint development and TOD have begun to appear in China's relevant research and planning practices. With rapid development of China's cities and the construction of transportation infrastructure, joint development has received increasing attention in China. Due to different national conditions, political systems, travel habits, and land systems, there are still limitations in current Chinese development and localization practices of joint development. How to rationalize the joint development based on Asian cities is the latest topic. On this basis, if we can introduce social groups in joint development, it is evidently a new opportunity for Chinese urban management.

2. Policy background

2.1. Policy Background of Pudong New District

The following paper will discuss the role of social groups under TOD mode in the background of Pudong New District in Shanghai.

Now that the urban sprawl of Pudong New District is finally achieving its geographic limit, existing urban neighborhoods are finding a way to absorbing its share of the region's growth, which stimulates regional planners to relocate land use patterns to better boost economy as well as residents' satisfaction of living standards. Accumulating number of citizens choose to pay higher rent to live closer to work and amenities. This trend helps increasing regional sustainability, but low-income transit riders in the suburban areas are thus sacrificed which exacerbates social and economic inequality. The district government has been working on the public transport system to adjust overall urban layout and solve the spatial contradiction.

Pudong New District has evolved an extensive public transport system during its past 29 years' rapid development. By 2020, the proportion of public transportation in Pudong Central District will be increased to 55%, and the average commuting time of residents will be shortened to less than 45 minutes¹ because of the efficient implementation of public-transport-priority strategy.

Some parts of Pudong New District are now achieving marginal benefits. On one hand, the lack of supportive land use policy inevitably led to the tidal flow of the employment population, the pressure of which cannot be alleviated by merely setting up traffic stations. This requires TOD mode to guide multi-functional land use mode in surrounding area. On the other hand, the macro-zoning act, merging of Nanhui District into Pudong New District in 2009 for example, has become a new trend in Chinese urbanization. Strengthening cooperation from north to south and reducing urban disparity through the means of public transport, TOD mode will be of great benefit to reintegrate the regional resources.

¹ Shanghai Municipal people's government, 2016, 13th Five-Year Plan of Shanghai Comprehensive Transportation.

2.2. Background of public participation demand in Pudong New District

At the same time, Shanghai shoulders the pioneering roles in experimenting public participation in community governance. Tremendous efforts have been taken to explore how bottom - up requirements could be practiced in an overall regional joint development.

'*Colorful Community*' initiated by Pudong New District government proposed the "multi-governance" mode, in which residents' autonomy serves as core content, professionalism that comes from social groups' participating, and finally a platform built by the government departments for indirect participation in community governance.

For example, more than 1000 residents participated in the Jinqiao Jiahong colourful community project. Based on responding to residents' needs, the design scheme built up a passage between residents and neighborhood committees, meanwhile the spatial experiences of residents on their way home were improved through a gallery, and the facilities for diversified activities are also provided for the community. (Figure 2-1)

Figure2-1 Residents participating in the design scheme

Source: http://www.sohu.com/a/288094096_728328

TOD mode and community participation have mature practicing modes abroad. Because of the commonweal of public transport, the benefits of public transport construction are very limited during the operation process, especially in the start-up stage. Meanwhile, public participation means sharing community responsibilities and results. For example, Bethel New Life, an autonomous social group based in a Chicago community, it builds a transit system and residential venues by raising \$10,000 through local churches. While resolving the financing problem, it also better combines residents 'wishes with TOD.

3. Joint development introduces social group “City 360” ——Taking Jinqiao Community in Shanghai Pudong New District as an example

3.1. Project

The case of this paper selects the comprehensive urban center of Jinqiao Community in Shanghai Pudong District as an example. The plot is the center of all major industrial blocks in Pudong New District, with Jinqiao Export Processing Zone in the south, Waigaoqiao Free Trade Zone (national level) in the north, large residential area in the west, and Cao Road industrial area in the east. The imbalance between housing and jobs leaving regional commutes slow and unreliable before the project.

Meanwhile, as the plot is adjacent to Jufeng Road subway station. Combined with the Pudong New District's superior planning, it supports the district-level public service facilities of Jinqiao Center and the professional production service functions of the surrounding modern industrial parks. It has the best conditions for joint development and TOD design.

Figure3-1 Industrial distribution around Jinqiao Community in Pudong New District, Shanghai

Source: Author's self-drawn

The focus of this case is on how to prevent the original neighborhood relationship under high development intensity in joint development. In Jinqiao community of Pudong, the main contradictions are the following three points.

Firstly, how traditional urban space and social relationships can be preserved. The original urban space is a traditional Chinese courtyard. Local residents are worried that the new design will destroy the original neighborhood culture and social relations. Secondly, the relationship between multiple groups is very tense. The formation of the master plan did not involve the residents' participation nor fully consider the interests of the residents. Therefore, the entire process cannot be supported by local residents. The removal of the original building encountered great obstacles. Third, the multi-actors are complex and so are their social relationship. The internal and external conditions of the original plot are thus complicated. On the one hand, the function of the upper planning must be satisfied. On the other

hand, the land has the conditions for TOD development. In addition, the composition of multi-actor is very complicated, including high-tech talents, nuclear families, low-income people, and landless farmers. Therefore, the requirements for functional integration and social attention are very high.

3.2. The role of City 360 as a self-organization and its place-branding

The City 360 is committed to taking the combined advantages of Shanghai Tongji University's comprehensive professional integration, starting with urban regeneration, using qualitative analysis (definition, classification, case and policy orientation) to identify problems, using quantitative analysis (research, data, Interviews) to analyze problems, using simulation processes (platform interactions, fixed-point uploads, resident votes) to generate methods and using big data methods to solve problems. Based on the reality and existing needs of China's leftover space, combined with case classification, the “City 360” platform was developed to build a core interactive platform based on big data and artificial intelligence, so that joint development from singularity to diversification.

City 360, as a social group, intervenes in its own program platform (see figure 3-2), through several simple options (such as spatial scale, green area, material, presence or absence, etc.) to generate drawings, and promote residents to participate in the production plan.

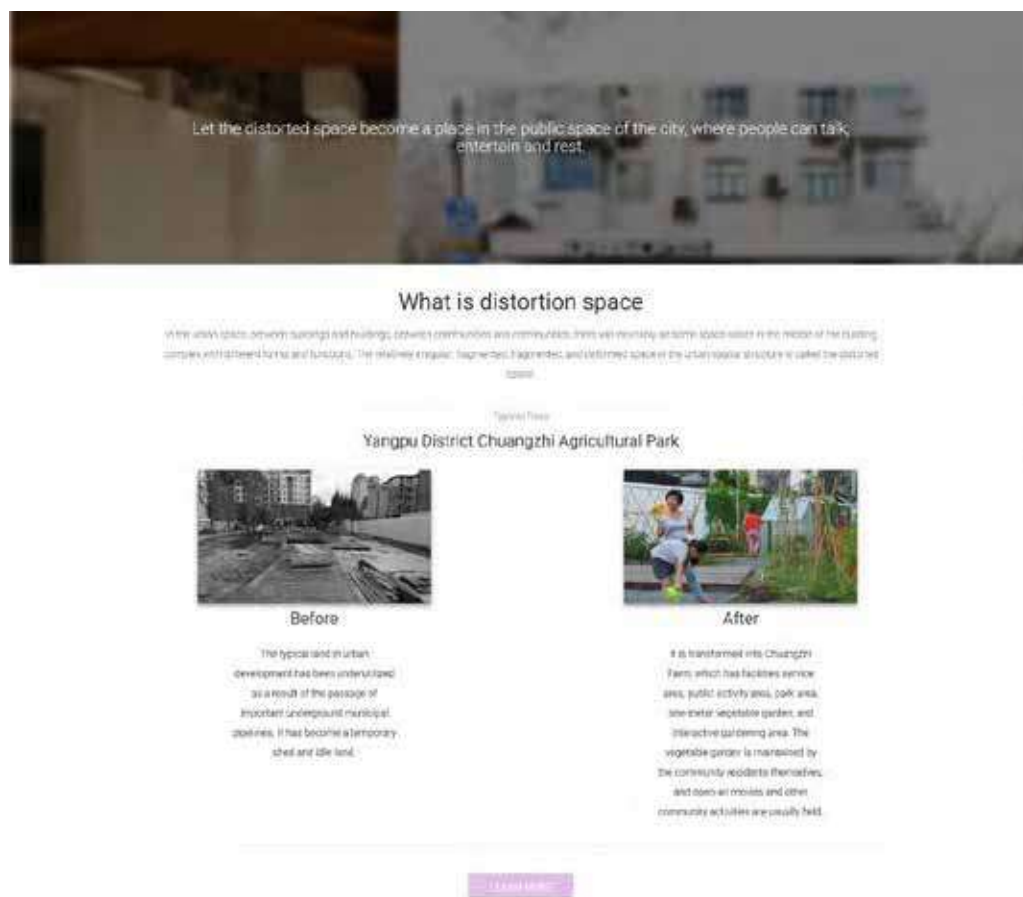

Figure3-2 Community demand docking platform based on big data and artificial intelligence - City 360

Source: https://www.city-tech360.com/city360_web/

This approach solves the problem well among the developer, the government and the local residents, because that the generated drawings are a good expression of local residents' wishes (see figure 3-3).

Figure 3-3: Residents meeting in Jinqiao Community, Pudong, Shanghai

Source: Photo taken by Author

In addition, in order to solve the comprehensive contradiction mentioned above, in terms of spatial form, on the one hand, the TOD node is adopted to adopt a high-intensity development mode. The office buildings, business offices and residences are connected by corridors, which formally reflects the uniformity of the courtyard and the continuity of the streamline (Figure 3-4).

On the other hand, the building adopts an enclosed space, which forms a good transition between the surrounding traditional space texture and the central business area. The architectural form is consistent with the surrounding small neighborhoods in terms of spatial form, and is transparent to the central public activity space, further strengthening the spatial and psychological connection (Figure 3-5).

3.3. Guidance strategy

City 360's attendance in the design and planning process results in a more efficient traffic-oriented joint development process and a better overall transformation effect. As a social group devoted to enhancing bottom-up public cohesion and spatial justice, City 360 in return gain itself place-branding. It is specifically embodied in the following 5 parts.

1) Spatial integration

In the whole design, the commercial complex set up at the top of the TOD transportation hub is taken as the regional landmark, as the skyline of surrounding area is governed by its height, which impressively strengthens the visual sense and highlights the regional identity. As for the core area, the square formed by the subway entrance and exit of traffic hub undertakes the highest density of people, estimated to be witnessing to over 48,000 daily boarding's. It will be an area unprecedented in the region and space of more urban diversity. Corridors are set up at specific points to connect commercial, residential and business areas in an all-round way, enriching the walking experience, giving green land back to the pedestrians of region, and solving the original traffic jamming and land splitting problem.

The pedestrian-oriented regional planning uses the 15-minute community-life circle as the basis for the program, allocating northern and eastern communities within 15-minutes' walk from the central public transportation hub, emphasizing the importance of infrastructure improvements to local residents, creating first and last mile connections that enhance the access and mobility of surrounding communities.

2) Public participation in decision-making

A successful TOD design needs extensive support from local residents. City 360 has played a role in connecting the public with the official, the regional planning with the resident' feedback. The whole process is critical to community involvement and adherence to local policies as well.

City 360 is committed to the needs of Jinqiao local residents and sensitive to the local identity and major industrial blocks nearby. Through exploring the travelling habits, consumption level and living needs of the original residents, the design more effectively reflects the requirements of the citizens, enhancing the geographical character of the design, and also widely increasing the public participation, promoting the creation of a pluralistic, equal and democratic community atmosphere. helps to rebuild the transport/land use language, in addition to a simple understanding of TOD, Metro and local leaders have allowed for a more detailed, sensitive and pragmatic approach to growth and resiliency.

3) Reciprocity of economic interests

Social groups can effectively balance the interests of all parties and use their own resources to communicate with other developers, which is conducive to obtaining extensive financial support to make up for the lack of funds at the early stage of the project and obtain good marketing performance

and long-term benefits. The gradual generation of regional benefits will inject economic value into the social groups in the medium term and later stages, achieving win-win interaction of economic interests.

4) Good cultural propaganda

As City 360 has the advantages of marketing planning, public relations media, exhibiting and large-scale event planning, this advantage will play an important role in the promotion of the core District. TOD transport hub has established a new regional landmark image in the open space, and landmark image is more conducive to attracting the surrounding office, business, transportation, culture and gathering the tourism crowds and their interaction. From residents' perspective, City 360 partnered with the local community to develop the first step in the public participation, and they worked together to develop guidelines that are sensitive to local issues. At the same time, the successful urban regeneration mode of the region will also enhance the branding of social groups.

5) Close responds to the policy

As the center of the main industrial sectors of Pudong New District, this planning unit takes public transport as the guidance and develops multi-functional land use pattern, which accelerates the establishment of an integrated structure for the joint development of urban and rural areas, and also promotes the development of "*city-industry integration*" and "*urban-suburban integration*"² under the policy guidance of Shanghai Municipal Government. Also, Shanghai has adopted a *15-minute community-life circle* as one of the most important measures to enhance the competitiveness of the city which is used as a tool in the TOD case to update the regional residential communities. Functionally, it not only serves as a comprehensive urban center in the north part of Pudong, but also serves as the production and service function of the modern industrial parks, responding to the policy guidance of Jinqiao as the city's Deputy Center in Pudong New District. On the whole, the policy adherence and planning strategy is pushed by City 360 as a social group, promoting democratic approach under the policy guidance.

]

4. Summary

This case, focused on relocating the original community, contrasts with existing developments and try to integrate land use with transit and to include the public groups' ideas in the transit-oriented concept. The process centralizes a platform organized by City 360 as a social group for bridging the developer, the government and the local residents. Meanwhile, this third-party concerns about public participation, continues to play the role of public spaces in promoting a diverse, equal and democratic urban cultures.

² Shanghai Municipal people's government, 2016, 13th Five-Year Plan of Shanghai urban and rural development integration.

The whole design takes a holistic view, recognizing that communities surrounding transit hub need far more exploration that deals with spatial and psychological connection, public participation, interests' balancing, cultural propaganda and policy responding. But the spirit is that it takes a closer look into people's behaviors, how to plan from a human scale, how people get around and finally how to approach a long-term community justice.

****pre-conference draft, please do not cite****

**** author can supply latest version of this work-in-progress ****

Abstract: The Museum of London (MoL) is one of the world's largest and best-curated collections. It was formed fifty years ago from the merger of two rivals: the archaeologically oriented Guildhall Museum, representing the antiquarian harvest from intensification of the central business district, which coincides with London's ancient core municipality; and the London Museum, metropolitan in scope, eclectic in its collections, oriented towards the scale and diversity of the modern city. From its formation MoL has sought to combine and reconcile these strands, making it - as IUAV expert Prof Donatella Calabi notes - a seminal example of a modern city museum. MoL's purpose-built home in the architecturally famous Barbican complex suffers from a fatal defect. Its entrance on an elevated deck is inaccessible, limiting visitor numbers. After several unsuccessful attempts to open up ground-level access, the museum has decided to relocate. MoL seized the opportunity to acquire two halls formerly belonging the wholesale meat market at Smithfield, in a prime visitor location close to the massively enlarged railway station at Farringdon, meeting point of London's north-south and east-west Crossrail routes. The new premises combine spacious ground levels under high domed roofs with deep cellars intended for cold storage of meat. Plans for the transition are well advanced with MoL scheduled to reopen its doors in 2023. The paper discusses the challenge of relocating the Museum from a purpose-built modernist structure on an elevated deck, to buildings that are larger and older, with street access from all sides; and the consequent choices for organisation and presentation of the collections. We see how those basic questions of urban museology which fuelled the rivalry between Guildhall and London collections a hundred years ago continue to exercise the MoL's curators today.

Keywords: city museums, London, urban history

Introduction

The UNESCO-funded International Council on Museums, ICOM, has a special sub-network of museums that are in and about cities, called CAMOC – the International Committee for the Collections and Activities of Museums of Cities. CAMOC publishes an online review three times a year and its annual workshops, hosted by member institutions around the world, have taken place in Moscow (2005), Boston (2006), Vienna (2007), Seoul (2008), Istanbul (2009), Shanghai (2010), Berlin (2011), Vancouver (2012), Rio de Janeiro (2013), Göteborg (2014), Moscow again (2015), Milan (2016), Mexico City (2017), Frankfurt (2018) and most recently Lisbon (3–4 May 2019), courtesy of the Museu de Lisboa. Though city museums are no more than a minute subset of the vast category of museums that are located in cities and sometimes named after them, they are often highly visible as bearers of a city's collective memory and contributors to its contemporary brand image. My paper discusses one of the oldest and largest city museums, the Museum of London. Though London hasn't so far hosted a gathering of fellow-institutions, it provides an important reference point for them, all the more so as the museum is in the process of relocating from its present purpose-built premises to a new and much larger home in a pair of former market buildings, with all that implies for a shake-up of the displays, the collections, and the entire scope and purpose of the museum.

In a comparative perspective, city museums can be said to have sprung from two distinct starting-points. On the one hand, they originate in early modern 'cabinets of curiosities', miscellaneous collections of items received, inherited or churned up out of the ground through the ceaseless process of urban development. Local patriotism has a strong antiquarian dimension. The demand to display and explain a city's memorabilia lies at the origin of many important collections. But interestingly for us, the other stimulus has come from the rise of municipalism and town planning movement, with its belief that cities are collective personalities who should actively shape their futures, and its corollary that citizens need to understand and appreciate

their civic past. Early twentieth century pioneers such as Patrick Geddes in Edinburgh and Marcel Poëte in Paris attached great importance to museums as promoters of collective awareness. In this sense, a city museum was to the municipalist movement as the great national capital collections were to the rise of the nation-state: a shrine to territorial identity.

The challenge of reconciling these different rationales continues to absorb curators and directors today, and is the topic of much museological discussion in CAMOC gatherings and publications: what priority should be given to display of archaeological collections ? Should material be chronologically ordered or grouped thematically ? How can the multi-ethnic diversity of modern cities be reflected and hegemony of dead white men avoided ? The museologist Rainey Tisdale, who describes herself as an ‘independent curator and think tank of one’, suggests that museums are finding it difficult to adjust to twenty-first century expectations and mores: many ‘seem to be operating under an outdated 20th-century model and are having trouble articulating and demonstrating their public value. The public doesn't necessarily want to learn what history museums want to teach them, and they don't necessarily want to learn in the ways that history museums are offering.’ Her diagnosis points towards a more people-centred approach, mirroring the diversity of contemporary urban residents (Tisdale 2013).

For an alternative perspective we need look no further than IUAV where for the past decade a distinguished Venetian, the historian and activist Prof Donatella Calabi (fig.1) has led an important comparative study of the role of city museums in Europe. Her prolific writings include major contributions to the history of the Venetian Republic, the cities, ports, shops, markets and streets of Europe, the historiography of cities and city planning, and the seminal work of Marcel Poëte. In her work we find an emphasis on the importance of the museum within the urban public realm, which is the topic of Track 15 of AESOP's 2019 Venice conference, Like Hannah Arendt, she sees the public realm both in terms of materiality of buildings and urbanism, and as a

dimension of human thought. Physically, she wants a museum to hold up a mirror not just to the historic core beloved of archaeology but to the larger reality of the contemporary metropolis in its entirety. Her focus on the built fabric leads naturally into the realm of maps, designs, drawings and images, and from there into the digital universe of virtual urban realities – a different but no less challenging path for museological practice (Calabi 2012).

2. *Origins of the Museum of London*

The history of MoL is engagingly narrated in Francis Sheppard 's book *The Treasury of London's Past* (1991). Today's institution originates in two very different collections. These echo the archetypal origin narratives of museum history, but with

an additional difference caused by the great peculiarity of London's local government history, in which the original mediaeval city corporation has resisted enlargement, retaining its territorial limits and its charters of autonomy while modern London has grown up around it. So when we speak about 'the City', or the Square Mile, we refer to a territory that corresponds more or less with the two-thousand-year-old Roman settlement of Londinium, and its thousand-year-old Corporation; whereas when we speak about 'London' we refer to the entirety of the metropolitan area inside its encircling green belt, with its subdivision into 33 boroughs since 1963, and its overall Mayor and Greater London Assembly since 2000 (Davies 1988, Hebbert 1997, Travers 2002).

Like many city museums, London's has its earliest origins in the collection of ancient objects acquired through the centuries by the historic municipality. As well as a port and a centre of commerce, the Square Mile began in the eighteenth century to develop a specialist vocation as an international financial capital. The continuous churn of redevelopment as homes and workshops were displaced by offices and trading floors brought to light a stream of archaeological findings. Shepherd describes the initial reluctance of the commercially-minded City authorities to engage with archaeology and accept stewardship of historic findings. From 1826 the library of the Corporation of London's mediaeval Guildhall did provide space for a fast-growing collection of 'antiquities and curiosities', but had no curatorial policy. For example, the City of London showed no interest in the astonishing Roman findings collected by the local antiquarian Charles Roach Smith (fig.2) which went instead to the British Museum in 1856. Not until the later nineteenth century was there a change of attitude in the City towards conservation of Roman and mediaeval remains, and acquisition of artefacts. In 1890s the library collection was organised for public display and opened as the Guildhall Museum, publishing its first catalogue in 1903.

Fig.2 Antiquities of Roman London collected by Charles Roach Smith

London's second city museum was launched in 1910. The London Museum was the brainchild of two wealthy aristocrats, Lord Harcourt and Viscount Esher, who had visited Paris together in 1890 and contrasted the scope and vitality of the Musée Carnavalet with the Guildhall Museum's parochial interest in the antiquities of the Square Mile. They conceived a museum for the whole metropolis, past and present, containing

‘everything which could be collected of historic interest connected with London from the earliest times: pictures, china, costume, arms, engravings, miniatures, snuffboxes, manuscripts . . .’

Harcourt brought plutocratic connections through his marriage to Pierpont Morgan’s niece, and Esher as a courtier brought royal patronage and the offer of accommodation in Kensington Palace, as well as loans of Queen Victoria’s collections of dolls, for whom she made the costumes, and sets of her ceremonial robes. Shepperd describes how the notions of a ‘royal treasure box’ and ‘London Carnavalet’ were fused under the inspired leadership of the Museum’s first Keeper, Sir Guy Laking, a fashionable playboy and collector of antique arms, whose father had been Queen Victoria’s physician and confidant (1991, 45). Laking robustly deflected complaints and legal threats from the City of London, who claimed a breach of the Corporation’s ancient chartered privileges. He had a flair for showmanship which quickly established the Museum in the public imagination. In 1912 when workers digging the foundations of the London County Council’s headquarters on the south bank of Thames opposite Westminster discovered the remains of a Roman boat, Laking supervised the excavation of the 22-ton keel and ribs and led them ceremonially back to his Museum at Kensington Palace (fig.3). From the Franco-British Expo at White City in 1908-9 he acquired some spectacular tableaux by the model-makers Thorp of London, including a display of the Great Fire of 1666 with electronic fire effects that remains popular to this day.

fig.3 Sir Guy Laking, First Keeper of the London Museum

The London Museum's positive policy towards collection was continued by Sir Mortimer Wheeler, Keeper from 1926 to 1944, who combined an outstanding archaeological reputation with a commitment to gather 'all classes of material from every period'. He pioneered the Museum's fashion and costume collections, and had a foresight to acquire a hansom cab at a time when such vehicles were still plying the city's streets. Relocated to Lancaster House, Wheeler built up the museum both as a visitor attraction and a centre for urban research. He brought in London Society, *Survey of London* and the Royal Archaeological Institute as tenants, but his proposal

in 1927 for a merger with the Guildhall Museum fell on deaf ears. The two establishments continued to exist in rivalry, tempered by an understanding that the Guildhall would limit its acquisitions to the Square Mile, leaving the rest to the London Museum.

Both museums were bombed out during the Second World War. The London Museum reopened in 1951 in its former base at Kensington Palace, readmitted by Royal Warrant on the understanding that its lease was temporary. Guildhall Museum reopened in 1955 in the Royal Exchange beside the Bank of England, likewise on an interim basis. The fact that neither of London's city museums possessed a permanent home revived discussion of a potential merger. Negotiations began in earnest in 1959, with central government acting as broker, and by 1963 a board of governors was already meeting, with Viscount Harcourt in the chair and six members appointed by the government, the Corporation of London and the London County Council respectively, each party being committed to contribute an equal share of capital and running costs (*Antiquity* 1963). A site for the museum's new home had been identified in the vast area destroyed by wartime bombing north of St Paul's Cathedral, beside the roundabout that terminated 'Route 11', the London County Council's dual carriageway along London Wall, and immediately to the south of the City Corporation's ambitious comprehensive Barbican redevelopment (City of London 1959). Legislation followed in 1965, building started in 1971, the Queen Mother laid the foundation stone on March 29th 1973, and 'the largest urban-history museum in the world' (Lewis 2019) opened its doors on December 2nd 1976.

The Museum of London since 1976

The Barbican was designed by the young architectural partnership of Geoffrey Powell, Joe Chamberlain and Christoph Bon. Followers of Corbusier, they conceived the entire site as a megastructure with residential towers, educational, cultural and social facilities linked by a series of elevated decks and walkways, releasing the ground and

subterranean levels for vehicle circulation, parking and storage. In the Modernist boom of the Sixties the Barbican's upper-level pedestrian system triggered proposals to extend the typology of podium and tower development across the fabric of London. Though these plans were quickly abandoned elsewhere (Hebbert 1991) a vertical segregation concept continues to dictate patterns of movement around the Barbican today.

The Museum of London was the work of another young architectural team, Philip Powell (no relation) and Hidalgo Moya. The design incorporated the Barbican's elevated pedestrian deck, with the complication that their museum had to be wrapped around the retained livery hall (at street level) of the Ironmongers' Company. No less committed Modernists than the Barbican designers, their approach was less dramatic and more humanistic and people-centred (Saumarez-Smith 1995). They preferred white walls to Brutalist shuttered concrete, believing that design should aim above all to avoid stress through a simple circulation plan, easy ramps between levels, full-length picture windows opening onto gardens, and 'attractive but unassertive' settings for displays (Powell & Moya 1966). In their concern with internal user comfort the architects gave less thought to the external aspect of the Museum of London, relying on a large drum containing a sunken garden in the middle of the Route 11 roundabout to give visibility (Fig.4).

fig.4 Powell and Moya's scheme in 1966

Unlike Powell and Moya's subsequent work at Wolfson College Oxford, or Chamberlin Powell & Bon's adjacent Barbican project, the design was not well received. The lack of a formal entrance at ground level proved problematic from day one, when the H.M. the Queen arriving to inaugurate the Museum had to enter via the shuttered steel delivery bay on London Wall. The roundabout rotunda with its sunken garden soon became rat-infested and was externally perceived as 'an ungainly building like a pillbox ready to repel invaders' (Owen 1998). The upper-level walkway system continued to baffle visitors, despite repeated schemes to improve signposting and way-finding. Staff were frustrated by the constraints of an internal plan designed explicitly to prevent 'museum fatigue' by making all visitors follow a single route through the city's chronology, from prehistoric to modern times (fig.5).

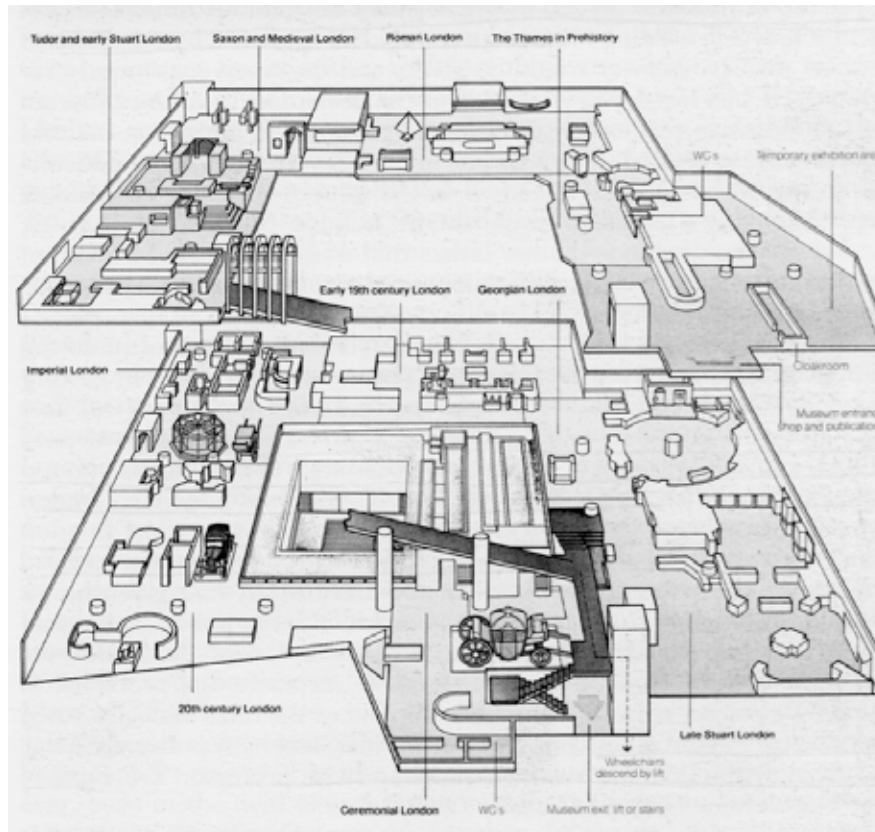

fig. 5 Powell & Moya's internal layout of the Museum of London

Since its opening in 1976 the Museum has had several refurbishments. The nineteenth century coverage was completely overhauled in 2001 under the directorship of the historian Simon Thurley (Werner 2001). His successor the architect and museum designer Jack Lohman initiated new galleries of Modern London, expanding the museum's display area by 25% (*Design Week* 2009). No sooner had they opened than a further phase of refurbishment and expansion was announced, involving building over the top of some surviving fragments of the city wall of Roman Londinium. The project was to be financed through the construction of a new office tower beside or over the main entrance on London Wall (*AJ* 2011). But in 2012 the arrival of a new director, Sharon Ament, brought a radical shift of strategy: instead of struggling to further expand the tight envelope of the Powell and Moya building, the Museum of London would find a new home.

The Move to Smithfield

Sharon Ament was recruited from the Natural History Museum where as Director of Public Engagement she managed annual visitor flows of over four millions. An exponent of 'stretch thinking', she aimed to double the Museum of London's visitor numbers from 900,000 to 2 million and expand the schools programme to reach every child in the city. In the tradition of Guy Laking and Mortimer Wheeler, she emphasized the need for contemporary as well as historical coverage, making her mark with acquisitions such as Thomas Hetherwick's Olympic cauldron immediately after the London Olympic Games of 2012, and 'fatberg' of congealed grease and wet-wipes that was found to be blocking the sewers of Whitechapel in 2017. Every aspect of her agenda for the Museum of London underlined a need for more space.

Fortuitously, the City Corporation possess at Smithfield a former market hall, derelict for forty years, that enjoys protected status as a historic building, having been saved from insensitive commercial redevelopment by the intervention of the House of Lords. The General Market dates from 1876, has a handsome domed interior generously illuminated by a clerestory lantern and is lined externally with street-facing shops and market traders' premises (fig.6). Its immediate neighbour, the Poultry Market, was destroyed by fire in 1958 and rebuilt in the 1960s with Europe's largest clear-spanning roof of reinforced concrete: this virtuoso shallow dome was engineered by Ove Arup and is also listed (fig 7).

fig.6 Smithfield : the General Market

fig.7 Smithfield - the Poultry Market

The Poultry Market is about to be vacated by the relocation of the wholesale meat trading to new facilities in outer London. In terms of location, the two buildings could hardly be better, sitting nearby the mediaeval foundations of the Charterhouse and St

Bartholomew's Hospital, and immediately beside (indeed partly over the top of) the Farringdon Station complex which is about to become a point of prime metropolitan centrality as the intersection between London's east-west Crossrail line and the north-south Thameslink (Hebbert 2014). Furthermore, the successful growth since 1990 of a rival financial office district to the east, at Canary Wharf, has encouraged the City Corporation to reconsider its priorities and emphasize other values besides the single-minded pursuit of commercial profit: there is a new emphasis on residential liveability, on quality of the public realm, and on the City's still remarkable concentrations of historic buildings, educational facilities and cultural performance spaces. Investment in the relocation of the Museum of London to Smithfield has become part of a larger rebranding programme known as Culture Mile. In a press release dated March 28th 2019 Catherine McGuinness (Policy Chair, City of London Corporation) is quoted as saying: 'Our ambition is to redefine the Square Mile - already established as a leading global financial centre - as a world class destination for culture, creativity and learning'. The press officer's Note to Editors adds: ' Culture Mile is a corner of London's working capital where creativity is fast becoming the most valuable currency' (City of London 2019). Symbolically, an art installation now marks the closure of one of the high level walkways which radiated from the Barbican (fig. 6).

fig.8 Korean house by Do Ho Suh on the Wormwood St walkway, April 2019

Work is now proceeding for the design of a new Museum of London scheduled to open in 2023. The principal architects are Stanton Williams, designers of the Royal Opera House Covent Garden and University of the Arts at Kings Cross, and since both markets are listed, the design team also includes the historic buildings specialist Julian Harrap whose projects include Nicholas Hawksmoor's church of St Anne, Limehouse, the Neues Museum Berlin, and Sir John Soane's Museum in Lincoln's Inn Fields. The physical resource at their disposal is enormous, since each market building has a deep basement for refrigerated storage, besides a multiplicity of exterior street-facing units. The present intention is to divide the spaces into six time-zones, 'imagined', 'temporary', 'deep', 'real', 'present' and 'past' (fig.9): interpretation strategies for each zone are being mapped out even as I write.

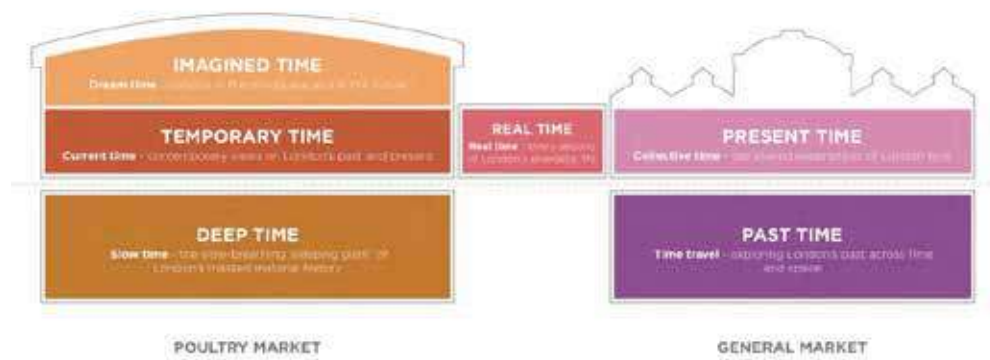

Figure 9 The Museum of London's initial master-plan for Smithfield

Over the summer of 2017 the museum launched its proposals to the public with a festival that celebrated both the richness of its historic collections and its rapport with modern living Londoners. The market buildings were dressed with billboards featuring portraits by Vicki Grout, leading photographer of the London grime scene (fig.10). The captions elided the name of the establishment into 'Museum of Londoners'.

Figure 10 : Smithfield General Market, Summer 2017

Conclusion

The Track 15 Call for Papers encourages us to think about the importance of urban public space. As explained above, city museums have developed in part as conscious effort to enrich the public realm and enhance the collective memory of the spaces and the townscapes that we share (Hebbert 2005). Donatella Calabi's work addresses the many museological choices that have to be made in curating and displaying city collections, the balance between archaeology, history, living memory, contemporary reality and the future, between tourists and locals, young and old, digital and concrete, morphological and people-centric. The Museum of London's imminent transition from the Barbican to Smithfield involves all these choices and more. That's why this paper can be only a work in progress. Watch this space !

Suitable renewal and space organization methods of historic town in the transition period: a case study in China

Wenjun Hou¹, Tianyang Ge², Jianqiang Yang³

¹ First Author: School of Architecture, Southeast University, hwjseu@qq.com

² Corresponding Author: School of Architecture, Southeast University, getianyang@qq.com

³ Professor, School of Architecture, Southeast University, yjqseuud@126.com

Abstract: China's urban planning and construction have stepped into a transition period, with three major characters, which are transitions "from efficiency demand to humanity demand", "from perceptual planning to rational planning", and "from incremental expansion to inventory planning", this bring new demands to urban space planning, especially historic towns in China. The previous planning approaches caused some problems to historic towns, some of them were turned into tourist attractions, some of them were abandoned by natives. Most of them are facing the problems: how to develop sustainably with the consideration of the natives? How to demonstrate cultural heritage in a proper way? With the demands of transition period, this paper studied a typical historic town in Jiangsu province, China. First, this paper summarized the three characters of the transition period of China. Then through the study on the typical case, the paper summarized the problems caused by the previous planning approaches, which were missing of the original life pattern, narrow use of resources and inefficient use of public space. In order to solve these problems systematically, studies were made on three key parts "resource understanding", "function activation", and "space organization". Firstly, on resource comprehensive understanding aspect, multi-dimensional resource understanding and excavation system were construct, which expanded resource understanding ideas, and offered resource discovery system, to adjust the old perspective of economic optimality. Secondly, on function activation and implantation aspect, a function activation system taking people and value as the double core was construct, which expanded function organization ideas, and offered a function activation system. Thirdly, on coupled spatial renewal aspect, an embedded planning model facing urban renewal was construct, which condensed spatial renewal main points, and improved renewal planning ideas.

Keywords: historic town; resource understanding; function activation; space organization

1. Research background

Suitable renewal of historic town is a worldwide hot research topic in urban and rural planning research fields, and is getting a continually increasing attention in China. China's urban and rural planning and construction have stepped into a transition period, that bring new demands to the related works on historic town. With the demands of transition period, how to develop sustainably with the consideration of the natives? How to demonstrate cultural heritage in a proper way?

2. Characteristics of transition period

There were three major characters of transition period, which are transitions “from efficiency demand to humanity demand”, “from perceptual planning to rational planning”, and “from incremental expansion to inventory planning”.

2.1 From efficiency demand to humanity demand

In 2017, General Secretary Xi Jinping emphasized in his report to the Nineteenth National Congress that China has entered a new stage, and the main contradictions in our society have been transformed into the contradiction between the people's growing need for a better life and the unbalanced and inadequate development. In his important speech on July 26, General Secretary Xi Jinping pointed out that people's lives have improved significantly, their yearnings for a better life have become stronger, the needs of the people have diversified, have multi-level and multi-faceted characteristics, and they hope to have better education, more stable work, more satisfactory income, more reliable social security, higher level of medical and health services, and more comfortable living conditions. Beautiful environment and richer spiritual and cultural life. "Good life" and "human needs" have become the key words to be considered in social development at this stage (Leung *et al.* 2019). How to plan reasonably based on human needs is an important direction to be studied in the transitional period.

2.2 From perceptual planning to rational planning

With the rapid economic development of China, problems such as the spread of urban diseases, the similarity of urban styles and features, and the decline of the quality of human settlements have become increasingly prominent. Academician Wang Jianguo believes that how to achieve future-oriented "sustainable development" through "rational planning" in China's urban development is an important issue that needs to be considered and solved at this stage of urban development (Wang, 2018). The traditional perceptual planning method has some problems in our long-term planning practice, such as implementation failure and subjective decision, which cannot meet people's requirements and expectations for the quality of life at this stage.

Academician Wang Jianguo, on the basis of analyzing the development frontiers of urban design at home and abroad, put forward that there is a new trend of urban design development characterized by digitalization. "Human-computer interaction" is an important development direction of urban and rural planning and construction in the new stage, which requires efforts and exploration in the direction of "scientific analysis and guidance of spatial planning". Academician Wang believes that the design process of "human-computer interaction" can emphasize the combination of value-based creative design and multi-source data management and control. Rational planning can solve the problems of insufficient systematic grasp and subjective judgment in traditional planning and design, and integrate database and quantitative planning into urban planning and control.

2.3 From incremental expansion to inventory planning

With the improvement of the understanding of land resource shortage and the reflection on the development mode of growth doctrine, the transformation of urban development from "incremental

expansion" to "stock optimization" has attracted extensive attention from the government and all sectors of society. The state has put forward the requirement of delimiting the boundary of urban growth. The 13th Five-Year Plan (2016-2020) pointed out that the efficiency of resource utilization should be greatly improved, the total amount of construction land should be effectively controlled, the increment of construction land should be reduced year by year, and the management of restrictive indicators should be strengthened, and the double-control action of total amount and intensity of construction land should be implemented. Incremental and stock planning have become the inevitable choice of urban planning (Yang, 2017).

In recent years, there have been some practices and explorations of stock planning, including a new round of general planning for Shenzhen, Shanghai, Beijing and other major cities, as well as detailed planning such as regulatory detailed planning, urban design and renewal planning.

Inventory planning conforms to the overall idea of the transformation of urban development from "incremental expansion" to "tapping the potential of stock" (Ge *et al.* 2017a). It is a kind of planning that takes the stock space of built-up areas as the object and optimizes the adjustment as the main content without adding new construction land. Firstly, the concept of inventory planning is based on the realistic background of strict control of new urban construction land at the national level. Secondly, the inventory planning takes the stock space as the object, including all the land and buildings in the built area, such as the land and buildings with good or bad use status. Thirdly, stock planning should fully respect and make use of the current situation, take optimization and adjustment as the main content, encourage "acupuncture-type" planning, and avoid large demolition and construction.

3. Typical case study and main problems

There were problems caused by the previous planning approaches, which were missing of the original life pattern, narrow use of resources and inefficient use of public space.

3.1 Location

As seen in figure 1, Hushu town is situated at the east of Nanjing, which is one of the economic prosperous cities in China. The research area is about 27.13 hectare. Hushu Town was founded in the Western Han Dynasty 2000 years ago. It began to prosper in Ming Dynasty, which played an important part in the development of economy of the city. Because of the spread of cities, it is facing the stress of land-use transformation and missing of the original life pattern. There are seven intangible cultural heritages. Nanjing salted duck and manufacturing method are the provincial intangible cultural heritages. Zhou Gang mahogany carvings are the municipal intangible cultural heritages.

Hushu town embodied the culture of Nanjing and is also one of the Hui communities in Nanjing. Due to the lack of guidance in construction for many years, the original texture of villages has changed, the decline and reconstruction of old buildings have increased, and the cultural ecology of old town has been damaged.

Figure 1 Location of Huahu town in Nanjing

3.2 Material space

There are lots of historic factors in Hushu town, whose history is connected with the main city. As seen in figure 2, historic factors include historic buildings, historic streets and alleys, historic trees and so on. According to the investigation, there are 1400 buildings in this town, which include one provincial, seven municipal and seven district-level protection units and other outstanding historic buildings. All the historic buildings were built before 1980. Because of lack of correct renewal methods, some of them are at the edge of damage, which were made of local material. And they scattered among the normal buildings (Ge *et al.* 2017b).

Figure 2 The overall style and features of Hushu town

3.3 Population structure and cultural tradition

According to the official data, there are about 3347 people in Hushu town, nearly half of which are external population. Most of the natives moved to the new town in the north. Only old and some poor people are still live in this old town. Some of the traditional festivals are kept here. But the traditional life-style changed a lot.

3.4 Missing of the original life pattern

The existing historical value-oriented method of functional activation lacks consideration of human needs, which tends to use museum and exhibition hall to show historical value. According to the survey, the existing functions of Hushu town were composed of protection function, tourist oriented commercial functions, low-quality residential function, and some even mixed with industrial production functions. On one hand, the existing functions can no longer meet the needs of residents for a better life, and there was a phenomenon of residents looking forward to move out. On the other hand, the existing function lacked the combination of various resources of the towns, and can't display the unique value of the town well.

3.5 Narrow use of resources

The focus of resources understanding is mainly on the historical value of built-up areas, while the value of a wider variety of resources is indeed neglected. On one hand, because lack of systematic understanding of the resources of the town, historic residential area in the center of the town suffered serious protective damage. The local government renovated some historic buildings on both sides of the main streets, which totally did not conform to the local architectural characteristics and destroyed the traditional style of the streets in the area. On the other hand, other available resources have been neglected because of insufficient historical value, many of them can be used to enhancing the vitality of the town.

3.6 Inefficient use of public space

Spatial organization of public space lacks systematic combing. Due to the lack of systematic sorting out of space, the blind expansion of space development has destroyed the traditional space texture, the traditional landscape along the river has been destroyed, and private construction has been serious. At the same time, the old town's internal traffic chaos, the original traditional bluestone pavement was replaced by cement pavement. Because inefficient use of public space, the living environment is difficult to meet the requirements of comfortable living standards.

4. Multi-dimensional resource understanding method

On resource comprehensive understanding aspect, multi-dimensional resource understanding and excavation system were construct, which expanded resource understanding ideas, and offered resource discovery system, to adjust the old perspective of economic optimality. multi-dimensional resource understanding and excavation system include comprehensive screening, classified evaluation and value extraction.

4.1 Comprehensive screening

The available resources can be divided into material resources and intangible cultural resources. According to the different classification criteria of “scale, time and form”, the material resources have many kinds of classification methods, as seen in table 1. The resources of the town can be divided into 18 sub-categories by interpreting them from the three dimensions. According to the dimension of time, intangible cultural resources can be divided into three categories: intangible cultural heritage, characteristic intangible cultural resources and innovative intangible cultural resources. Overall, the resources of the town can be divided into 21 sub-categories, and arranged in a certain order one by one, forming a list of available resources screening. The investigation and screening of resources according to the list can effectively excavate the resources of the town in an all-round way.

Table 1 Classification of available resources of historic town

Classification basis	Classification Contents
Scale division	Macro-resources, meso-resources and micro-resources
Time division	Historical resources and characteristic resources
Morphological division	Linear resources, planar resources, point resources
Carrier division	Material and non-material resources

After resource screening, it was found that the resources of Hushu Town covered 12 of the 21 sub-categories. Among them, there are many resources in many subcategories. For example, the medium-sized linear historical resources include two items: water network system and spatial pattern, and the micro-point historical resources include two items: ancient wells and ancient trees. Each item may contain several specific resource points.

4.2 Classified evaluation

In the process of resource classification and evaluation, it is necessary to carry out specific evaluation according to different resources. Firstly, classify the primary screening resources, merge the resources to be evaluated properly, and merge all the primary screening resources into several special evaluations according to the needs. Then, establish a targeted evaluation system according to the different evaluation contents. Each special evaluation method and evaluation system should be different according to the different objects and importance of evaluation.

Through proper classification and merger, all resources of Hushu Town are summarized into 6 evaluation aspects, including “historical context analysis, spatial pattern analysis, historical relics combing, street spatial evaluation, water network evaluation, and building evaluation”. In the process of delimitation of special evaluation, emphasis should be laid on different levels of importance.

4.3 Value extraction

Value extraction refers to the further refinement and generalization of available resources on the basis of resource evaluation, and the extract available resources and values into concise and clear items of resource value. Resource value abstraction is based on the results of resource evaluation. After evaluation, more than two resource values can be extracted from the larger value of resources. The smaller value of resources can also be combined with one resource value from several resource evaluation results. The significance of value extraction is to further sort out and summarize the

evaluation of resources, and to further clarify the value of available resources. By extracting the evaluation results of six resources in Hushu Town, the total value of resources is summarized as follows: typical example of Nanjing culture, ideal landscape form, and unique architecture.

5. function activation

On function activation and implantation aspect, a function activation system taking people and value as the double core was construct, which expanded function organization ideas.

5.1 Combining with resources to enrich functional contents

Integrating human activities into functional organizations can enrich the functions of historic town, such as natural value recognition based on sightseeing activities, natural value exploration based on learning activities, intangible cultural experience based on leisure activities.

5.2 Increasing human participation

The inheritance of town value can’t be separated from people's cognition, feeling and memory. It enriches people's understanding and experience of town value and is conducive to the display and inheritance of local value.

6. Space organization methods

On coupled spatial renewal aspect, an embedded planning method facing urban renewal was construct, which condensed spatial renewal main points, and improved renewal planning ideas, as seen in figure 3.

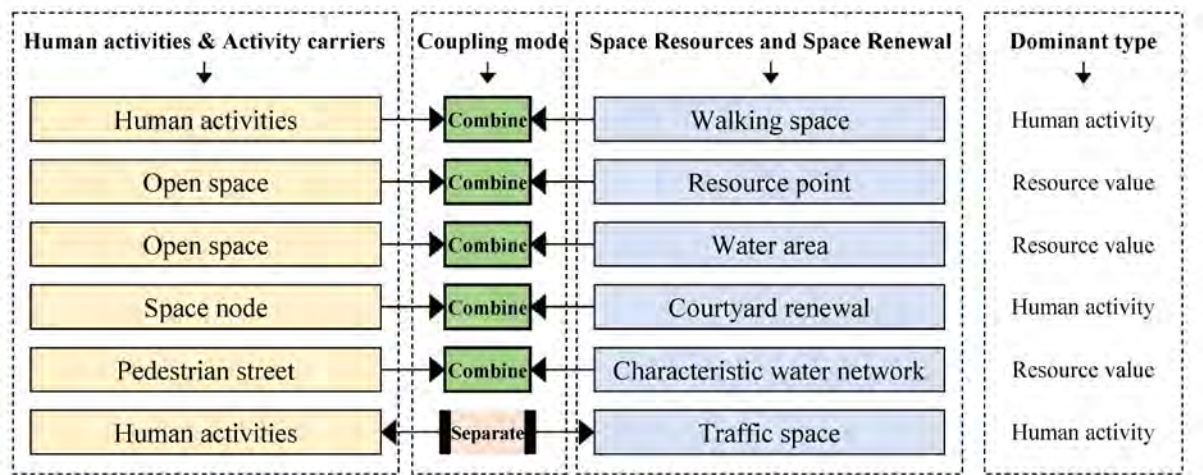

Figure 3 Embedded planning method facing urban renewal

6.1 Combine human activities and walking space

The combination of human activities and walking is a combination of linear elements and other elements, as well as a combination of functions and linear elements.

The planning emphasizes the combination of human activities and walking, and takes the walking system as the carrier of the spatial framework. On one hand, the walking system is the best carrier of public functions. On the other hand, the space and texture of historic town and streets are more suitable for walking. The main space nodes and active streets are processed on foot. Planning links all kinds of point and area elements in the town through walking system, including cultural protection units, characteristic buildings, historic wells, historic courtyards, water, open space and so on. The main public functions of the planning are also combined with the walking system.

6.2 Combine open space and resource points

The combination of open space and resource points is a combination of area elements and point elements. Planning emphasizes the combination of open space and resource points, including cultural protection units, historic courtyards, historic wells, excellent buildings and so on. Firstly, the combination of open space and cultural protection units will expand the open space. Secondly, combine open space with historic courtyards and historic wells. Through investigation and evaluation, it is found that there are two excellent historic courtyards and two historic wells in the town, and the location of historic wells and courtyards is relatively close. In combination of them, two new open spaces are added. Thirdly, combine open space and excellent architecture. Through the evaluation, it is found that there are nearly 100 excellent buildings in the town, and new open space is added in the dense areas of excellent buildings.

6.3 Combine open space and water resource

The combination of open space and water resource is a combination of area elements and area elements. Planning emphasizes the combination of open space and water resource. The water network system is one of the characteristics of the town. There are two large water pools around where a lot of human activities carried out. The planning combines the current water resource and expands the open space.

6.4 Combine courtyard renewal and space nodes

The combination of courtyard renewal and spatial nodes is a combination of area elements and area elements. Planning emphasizes the combination of courtyard renewal and spatial nodes. There are four areas in the planning core space: two cultural protection units and two water pools. Planning select the courtyards around the core space with better status to renewal, and improve the quality of the core space.

6.5 Combine characteristic water network with pedestrian Streets

The combination of characteristic water network and pedestrian streets is a combination of linear elements and linear elements. The planning emphasizes the combination of characteristic water network and pedestrian streets. Water network system is one of the important characteristics, which has the characteristics of distribution along streets and lanes. Planning protect the characteristics of the water network, following the spatial characteristics of its distribution along the street, expands the existing water network, and pays attention to its combination with pedestrian streets.

6.6 Separate human activity space from vehicle space

System coupling is not only the combination of systems, but also the separation of systems in space. The separation of human activity space and vehicle space is a kind of separation coupling relationship. The planning emphasizes the separation of the vehicle space from human activity space. Through investigation, it is found that the streets in town is not suitable for driving, and vehicle space will interfere with other space and functions, so the vehicle space will be limited outside the main space, and the driving and walking will be separated. There is a main street in town, which has a great impact on the quality of cultural protection and the surrounding areas through the core space; moreover, there are often various types of agricultural motor vehicles entering the town, which have an impact on the quality of the living space and cause damage to the bluestone pavement. Specific treatment methods include the pedestrian treatment of motor lanes and the construction of three parking around the town.

The Study on Spatial Interventions for Aging Communities in Tourism-oriented Historic Districts from the Perspective of Spatial Territoriality

Ying Hu¹, Zhongjie Lin²

¹Tongji University, Suzhou University of Science and Technology, 156797713@qq.com

²Suzhou University of Science and Technology, 1223267263@qq.com

Abstract: Aging-in Place represents the primary model of elderly housing in China. The current rapid urbanization has impacted the center city of Suzhou, one of China's most important historic towns, and its elderly communities. The populations have changed under this circumstance. The city has witnessed the influx of new migrants from other cities and provinces for economic opportunities and tourists from all over the country for its historic legacies on the one hand, and the outflow of young adults to the new districts and other cities surrounding Suzhou on the other. As a result, the elderly residents have accounted for nearly 45 percent of the total population in the Old City.

This paper examines the issue of spatiality for aging population using both qualitative as well as quantitative methods, and focus on Suzhou's historic district of Pingjiang. It reveals that the rapid commercialization and the increase of the tourist has squeezed the urban and community spaces of elderly populations, and the spatial ambiguity and disorder have created further conflicts between different demographic groups. All these are challenging the original Aging-in Place model. The paper analyzes the behavior logics behind these phenomena, and proposes several urban design strategies at the micro-scales related to different aspects of the current situation including place identity, territorial division, and symbiosis of population that are intended address, which hopefully could restore the environment for Aging-in Place.

Keywords: Spatial Territoriality; tourism-oriented historic districts; Interventions for Aging Communities

1. Introduction

The central historic districts in Chinese cities are full of tourist attractions, resulting in the mixed functions of tourism and residence in these communities. However, the increase of tourists in these historic districts has impacted the living function, which significantly hurts the interest of local residents.

Affecting by traditional concepts of providing support for the elderly and the reality of the facilities shortage for the elderly, Aging-in Place plays the dominant role in the life of city elderly in China. The current rapid urbanization has impacted the center city of Suzhou, one of China's most important historic towns, and its elderly communities. The populations have changed under this circumstance. The city has witnessed the influx of new migrants from other cities and provinces for economic opportunities and tourists from all over the country for its historic legacies on the one hand, and the outflow of young adults to the new districts and other cities surrounding Suzhou on the other.. For example, the aged residents in Suzhou Pingjiang district already reached 45% in total population. Their daily life, especially the quality life in public space, is negatively affected by the tourism development, becoming worse and worse.

In terms of the perspective of spatial interventions, this paper studies the living space for aging population in the historic district of Pingjiang, Suzhou. It focuses on following issues: 1) the public spatial living needs for the aged group in Aging-in Place model; 2) the evolution of public spatial characteristics in Pingjiang district and its influence to elderly residents; 3) the improvements of elderly's public space in Pingjiang district.

2. Research Subjects

Suzhou has more than 2500 years of history. As a famous historical street in Suzhou, Pingjiang Historic District sits in the north-east of Suzhou with outer city moat in the east, Lindun Road in the west, Ganjiang Road in the south and the East Baita Road in the north. It approximately covers a gross area of 116.5 hectares.(See as Figure 1) .This area, with traditional city layout, original local architectural style and the living habits, is the best preserved zone in ancient city of Suzhou so far(Wen Huachuan,2009). The core value of this region lies in the integrated preservation of the double-chessboard layout of Suzhou, with the streets and rivers going side by side while the water and land routes running in the parallel, making the true embodiment of Pingjiang Map of Southern Song Dynasty (1229 AC).

Pingjiang Historic District is abundant treasures of Chinese classical gardens and historical relics. Both Humble Administrator's Garden and Lion Grove Garden are the UNESCO World Cultural Heritage. Moreover, there are many museums, including the famous Suzhou Museum designed by I.M. Pei and the national cultural relic protection unit, Palace of King Zhong of Taiping Heavenly Kingdom. There are more than 40 ancient dwellings which have been put on the list of control and protection by local government. Some of them are the former residences of bureaucrats, rich merchants, or cultural celebrities, showing particular architectural features, such as the carving building in North Zhangjia Street and the Pan Mansion. With the remains of rivers, bridges, lanes, traditional dwellings, ancient memorial archways, old trees and wells, Pingjiang Historic District presents a charming picture of waterside town style, with small bridges over the flowing rivers

Figure 1 The location of Pingjiang Historic District

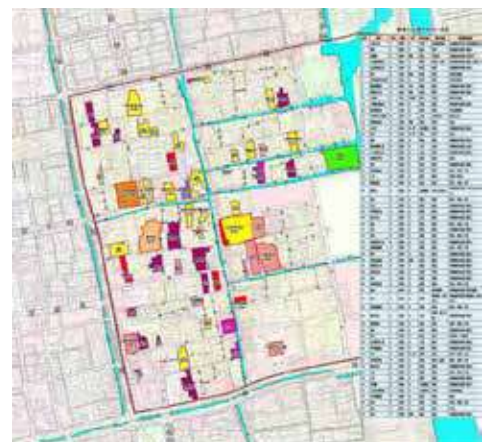

Figure 2, The distribution of Historic Preservation

and white walls and dark tiles. (See as Figure 2 and Figure 3)

Figure 3 The scenery of Pingjiang Road and Canal

In 2001, the overall protection of Pingjiang Historic District started, which aimed at the preservation of the original appearance of Pingjiang Street and preventing the destroy of environment. After 3 stages of protection work: the testing project (2001~2004), the environmental renovation project (2004~2006) and vitality cultivation and regeneration project (2006~now), the population density of Pingjiang Historic District reaches 16.1 thousand/square kilometers. The proportion of residents aged beyond 60 within the district turns into 45% in total population. These senior residents became the protagonist and their life style constitutes unique cultural features in the historic district. Most of them are low income families and Ageing-in Place model became their only choice for pension. However, the success of historic and cultural tourism in this area brings large amount of visitors in, which negatively impacts the local residents, especially senior residents. The most serious contradiction between tourists and elderly residents was caused by spatial ambiguity and disorder, because the increase of tourist has squeezed the public street space of elderly population. Hence, the elderly feels seriously threatened due to the spatial sense of belonging and domain has decreased continuously.

Before the tourism development in Pingjiang Historic District, an interdependent balance exists between the original district and the seniors who are living inside. On the one hand, local residents ensure the preservation of cultural inheritance and life style, promoting the level of preservation in historic districts. On the other hand, a livable district can provide elderly equipped infrastructure and cultural and culturally psychological dependence. Unfortunately, this kind of balance was gradually broken by the tourism development.

3. Research Perspectives and Methodologies

3.1 Territory

Territory is viewed as space occupied and defended by animals, where there are particular defensible resources. The act of possessing and defending territory from appropriators can be regarded as territorial behavior. Territory includes three types: Primary Territory, Secondary Territory, and Public Territory.(Zheng Ying, Gu Kouyuan, 2011)

Territorial Behavior is a very universal phenomenon in our society. J. Edney points out, “ This involves exclusiveness, marking, individualization and identity of physical space, possession, protection , exclusiveness, mark, personality and role.(J. Edney, 1990)

3.2 Alienation of Territory and Public Space

Territoriality is behaviors and cognitions embodied by individuals or groups, which is based on cognitions of the real spatial ownership. Different types of territories meet different motivations and needs. Therefore, people will select specific territorial types of public activities according to types and needs of participated activities. For tourism-oriented historic districts, territoriality refers to right statements of fictitious territories by residents, tourists and businesses that freely use or occupy the space. Territoriality can differentiate justifiable users and unjustifiable users in the area, allowing justifiable users relate each other to form a regional community.

Oscar Newman points out: Residents are willing to protect the space they feel they belong to and take some measure to control it from unauthorized intrusion.(Oscar Newman,1972)Being user entities in historic districts, residents, tourists and businesses always declare their rights for certain territories of public space. Such kinds of right announcement lead to different territorial behaviors and various ways of spatial use. Different territorial behaviors are the games among the three groups indeed and will engender the alienation of spatial usage. The group of residents is in a disadvantage position because of the capital power and government’ s guidance.

For these reasons, it is necessary to straighten out the mechanism of the interaction between space and behaviors, as well as to understand types of territorial behaviors and spatial characteristics of seniors in tourism-oriented historic districts. By moderately spatial interventions, the guidance of territorial behaviors will be set up, which ensures the transformation from spatial alienations to spatial justifiable usages by different groups and improves the spatial quality for aging communities in tourism-oriented historic districts.

3.3 Research Methodologies

This study applies with three research methods to investigate senior residents’ activities in Pingjiang Historic District, including behavior maps, questionnaires, and interviews. The survey checks out the public spatial utilization and population distribution in Pingjiang Historic District from 2013 to 2018. The research steps are as follows: A. Use degree of spatial satisfaction to evaluate the needs of space by questioning the public spatial needs of 361 senior residents randomly in Aging-in Place model within 6 years. B. Conduct the investigation on public spatial nodes in Pingjiang Historic District as observation points by using the method of behavior maps and observation approach, which helps understand the change of the public spatial utilization for elderly.

4. Research Results

4.1 The Changing Needs of Public Space for the Elderly

The water and land routes running in the parallel is the most important feature in Suzhou spatial pattern. The Chinese traditional public space composes of a series elements of street-lane-courtyard. Four levels of spatial composition exist in the daily living space of elderly residents: main street-lane-courtyard-building. Different degrees of spatial control lead into the unique spatial system for elderly residents: public-semipublic-semiprivate-private. Spatial elements, main streets, lanes and courtyards, together build the public space for seniors.

There are six public spatial needs for elderly residents in Aging-in Place model: spatial amount, spatial safety, environmental comfort, spatial accessibility, spatial separate and spatial diversity. From investigations on the public spatial utilization and population distribution in Pingjiang Historic District from 2013 to 2018, seniors shows different levels of satisfaction to six public spatial needs. The results of investigation demonstrate: the satisfaction degree of spatial amount declined from 3.56 in 2013 to 2.19 in 2018; the satisfaction degree of spatial safety decreased from 4.21 in 2013 to 2.08 in 2018; the satisfaction degree of spatial separate degraded from 4.64 in 2013 to 2.97 in 2018; the other three aspects of public spatial satisfaction almost stay the same during these 5 years.('As seen in Table 1)

year	amount	safety	comfort	accessibility	separate	diversity
2013	3.56	4.21	3.93	3.39	4.64	3.25
2014	3.23	3.56	3.77	3.47	4.52	3.23
2015	2.98	3.41	3.41	3.48	4.14	2.86
2016	2.21	2.34	3.48	3.25	3.31	2.95
2017	2.13	2.33	3.57	3.27	3.00	3.75
2018	1.93	2.08	3.31	3.00	2.79	2.92

Table 1 Public Spatial Satisfaction Degree for Elderly in Pingjiang Historic District

Above results show that spatial amount, spatial safety and spatial separate become the significant criteria for evaluating elderly's public spatial quality. Therefore, this paper mainly concentrates on reasons of survey results:

A. the increase of tourists

The elderly's daily public space has been continually invaded by increasing tourists, causing the decline of elderly's public spatial quality in spatial amount and spatial safety. According to the statistics, the visitors in

Pingjiang Road are over 4 million per year. The peak daily reception reached 60 thousand people during typical peak seasons and weekends. Huge amount of visitors has squeezed the public space for elderly residents, leading the sense of crisis for spatial safety.

B. the enlargement of commercial area

The commercial space spreads all over the Pingjiang Historic District, from streets and lanes to courtyards, which seriously disturbs the regular daily life of senior residents in their public space. From 2013, the commercial space keeps expanding from two sides of Pingjiang Road to those small lanes that are perpendicular to Pingjiang Road. Furthermore, the local homestay also increased dramatically every year. These commercial activities interfere with local residents' daily life space. Thus, those semiprivate spaces, such as lanes and courtyards, are totally exposed to visitors. Elderly lost their public spatial safety and spatial separate.

Those node spaces that can accommodate varied activities became the favorite places by retailers for business usages. Such kind of commercial behaviors also occupy the seniors' recreation space, which left many unsatisfied.

C. the tourism needs for local experience

Being the best preservation district in Suzhou, the original life style and local spatial experience are important factors in attracting tourists in Pingjiang Historic District. Visitors' curiosity about traditional living space causes more and more troubles to elderly. The spread of tourists to every corner around the district persistently disconcert those public space and life style for elderly residents. The original residential function was replaced by the homestays and hotels, leading tourists into the most private space for elderly and disturbing their daily use for public space. Hence, tourism not only causes problems of environment pollutions and noises, but also lowers the life quality in the community.

4.2 Territory Behavior of Public Space under the Co-existence of Diversified Groups

Tourism expansion in historic districts takes huge impact on locals. The composition of population turns from solely residency status into diversified groups, including residents, retailers and tourists. The usage of public space also transformed from fully owned by local residents to share by residents, retailers and tourists. Consequently, all kinds of behaviors in varied territories occur in space.

The territorial behaviors of different groups in public space present four types of "Occupation" on street and lane spaces: Space Possession, Space Occupancy, Space Invasion and Space Defense. Space Invasion and Space Defense are a set of relative concepts, representing the acts of declaring domain territory by a group people. Space Possession and Space Occupancy describe the ownership of space sovereignty in different time duration. The former one is a long term and permanent behavior to occupy space, which privatizes the space. The long-term outdoor storage of private stuffs or expansion of buildings will take over parts of public space. Although they still belong to public properties, others cannot use them anymore. For example, some retailers transformed the street space into parking lots or outdoor

Figure 4 Space Possession

teahouse. Space Possession becomes the main reason for breaking the continuous of elderly spatial public system, resulting in the space privatization and fragmentation.(See as figure 4)

Space Occupancy refers to those behaviors of stay in a short period, such as a rest taking, chess playing and Tai Chi playing. These temporary stay activities usually avoid public spaces using by others, which means current public spaces are difficult to be shared with others. Space Occupancy can either be the proper use of space, or be the alienated use of space. Thus, spatial ambiguity and disorder were created for elderly, which became the primary reason for those elderly residents who lack spatial belonging. The conflicts generated during the spatial use process among local senior group, the commercial group and the tourist group. This spatial use process represents the Space Occupancy process of different groups.

Space Invasion means someone enters into others' functional space and uses the space temporally. This is an injustice behavior for space occupancy, such as seniors have their daily activities in commercial outdoor teahouse, and tourists intrude into elderly's' private courtyards.

Space Defense is spatial restrictions for preventing others' Space Invasion, which represents a behavior of justice. For example, the installation of fence by retailers avoids non-consumers entering into the teahouse area. Local residents place temporary obstacles or markers to prevent the entering of visitors.

Through long-term observation on territorial behaviors in public space of Pingjiang Historic District, the typical territorial behaviors of different groups are shown as Table2:

Table2 Typical Territorial Behaviors of Different Groups in Public Space

Groups	Space Possession	Space Occupancy	Space Invasion	Space Defense
Seniors	<ul style="list-style-type: none"> ● Enclosure activity spaces 	<ul style="list-style-type: none"> ● Playing chess ● Playing Tai Chi and squaring dancing ● Having a rest ● Airing the clothes 	<ul style="list-style-type: none"> ● Non-consumers entering into the retailer's seats area for resting 	<ul style="list-style-type: none"> ● Placing temporary obstacles
Retailers	<ul style="list-style-type: none"> ● Delineation of parking lots ● Enclosure spaces with fences ● Arrangement of outdoor seats 	<ul style="list-style-type: none"> ● Placing merchandises temporarily ● Mobile booths 	<ul style="list-style-type: none"> ● Homestays entering into residential living space 	<ul style="list-style-type: none"> ● Placing fences
Tourists		<ul style="list-style-type: none"> ● Shopping ● Resting 	<ul style="list-style-type: none"> ● Entering into private courtyards 	

Above four territorial behaviors is the process of long-term interest game and district autonomy, causing the difference in usage of district public spaces by different groups. In this process, the power of capital is often stronger than that of society. The seniors in districts take in a disadvantaged position so that their activity spaces are squeezed and intruded. Finally, the loss of public space became the decline of satisfaction degree of public space and life qualities. Thus, the public spatial intervention for the aging group also decreased in this kind of historic districts.

4.3 Public Space Transformation for Aging Group Caused by Territorial Behaviors

After the rising of large amount of tourism and commercialization in historic districts, public space for aging group delivers the characteristics of fragmentation and ambiguity. This lowers the safety and belongs of public space. The main features are as follows:

A. the Change of Space System

The communication space among the elderly has shrunk sharply, which develops from early three-level spatial system (main street-lane-courtyard), to two-level spatial system (lane-courtyard). Some seniors only have courtyards as semiprivate space.(See as Figure 5)

Figure 5 the Change of Space System

B. Decrease in Spatial Scale

The commercial space keeps expanding along main street and river sides that are originally part of the public space for seniors. Behaviors of Space Possession and Space Occupancy turned the residential space into commercial space, reducing the amount of public space for the elderly.

C. Lack of Node Spaces

Most traditional street spaces are linear spaces and are short of node spaces. These existing node spaces are essential activity space for the aging group for the usage of morning exercises, evening exercises and squaring dancing. However, the massive influx of visitors caused the occupation of node spaces by retailers and tourists. According to the statistics, the node spaces for the elderly have reduced 50% since last 6 years.

D. the Competition for the Spatial Usage in Periods of Time

The investigation shows seniors transit trip rule in Pingjiang Historic District differs from other districts. Aging residents like morning activities from 7:00-9:00 and mostly they lack of public activities at night. Seniors in China love strolling and squaring dancing. These excises take in both morning period and night period. However, due to the Space Possession and Space Occupation by tourists and retailers for whole day in the historic district, the aging group in Pingjiang Historic District cannot enjoy the night public activities like seniors in other residential districts. 60% elderly dissatisfied with this phenomenon..('As seen in Table3 and Table4)

Table3 Statistical Analyses of Public Space Users (Weekends)

Table4 Statistical Analyses of Public Space Users (Work Days)

Above researches reveal that effective methods can be applied to restrict Space Possession and Space Occupation by tourists and retailers. The appropriate ways help reduce the Space Intrude to public space for the aging group, which also become the main approaches to improve spatial interventions for the elderly in historic districts. These effective strategies and methods will be discussed in what follows.

5. Urban Design Strategies from the Perspective of Territoriality

5.1 Separate Managements in Different Territorialities with the Spatial Limitation for Commercial Development

The expansion of commercial spaces is the main reason for contradictions and conflicts. Therefore, commercial spaces should be limited within certain areas, such as spaces along Pingjiang Road and Pingjiang River. This centralized layout not only maintains the existing organic culture style and residential space, but also improves the spatial performance and balances the economic development and local residential life. It's also necessary to restrict the commercial development in secondary lanes and original living spaces. Special development areas can be designed to enhance the vitality of districts, as well as to realize the economic performance. Spaces used for homestays and hotels can look for complete courtyards for adaptive design so that the fragmental interventions of space usage can be avoided. Moreover, this will reduce the interference with the elderly in semi-public and semi-private spaces.

5.2 Place Identification by Reintroducing Residential Life Style into Commercial Space

In most historic districts, tourism development becomes a necessary way to ensure the district vitality and economic development. Furthermore, it is also an important approach to share the tangible heritages. Urban design needs to consider the roles played by the elderly to maintain the exiting organic cultural style. Moreover, the design work should commit to create shared public places so that different groups can co-exist in different level of public spaces. Specific recommendations are as follows: Urban design should reduce the pursuit of maximum economic benefits in the main street and reintroduce life style of the aging group into commercial space; Lifestyle business can be moderately added into the street and lane spaces; Mixture of different businesses can accelerate the integration among residents, tourists and retailers, enhancing the place identity of the elderly.

5.3 Live Harmoniously by Accommodating Seniors and Tourists in Public Node Spaces

The participation of social activities is a significant way to improve the social capital of the elderly. Design work for active spaces can be achieved in primary node space in the district for providing public activities for the elderly, such as bridges, river banks and street pavilions. Meanwhile, activities can be planned within these spaces for the elderly and visitors to participate by community building, such as listening and singing the Pingtan, appreciating Kun drama and playing chess matches. By the end, the increase of public space participation behavior of the aging group can help achieve harmonious coexistence of different groups.

5.4 Enact Policies to Improve Social Responsibilities of Business Practitioners

The act of urban administration policies not only clarifies the spatial attribution, but also encourages the social responsibilities of business practitioners. In terms of different spatial needs for different groups, urban design methods can be applied to identify the public space attribution, especially spaces along Pingjiang Road and Pingjiang River. Thus, the design can reduce unjustifiable Space Possession and Space Occupation so that each group is in their proper place. Those business practitioners, who are willing to offer public space to the aging residents, should be rewarded in spaces, as well as give tax incentives. This kind of policy can guide businessmen to take social responsibilities.

6. Conclusion

Aging-in Place model within tourism-oriented historic districts is the important carrier to ensure the cultural inheritance. It promotes cultural connotation and realizes the harmonious coexistence of residence and tourism. This model builds an ideal life style in tourism-oriented historic districts. From the perspective of spatial territory, this paper analyses life style and public spaces in historic districts, which provides design and management ideas for urban planners, architects and government. The study not only improves the spatial interventions for aging communities, but also promotes the tourism quality in historic districts.

Sustainable tourism and public space - a case study of Skeppsholmsviken 6 in Stockholm, Sweden

Anna-Paula Jonsson¹, Tigran Haas²

2Associate Professor KTH Royal Institute of Technology, tigran.haas@abe.kth.se

Abstract: The visitor industry is considered a primary industry for Swedish economic growth today. Official strategies and goals for the industry focus mainly on quantitative aspects such as number of visitors, number of jobs in the visiting sector, or total revenues from the same. Despite a large body of evidence showing that urban tourism can have unintended consequences of a less desirable nature, public documents categorically present the idea of more visitors to Stockholm as something leading to positive outcomes. A discussion or mention of social or economic change to a city's residential character and heritage is hard to find in written or spoken discourse. By studying an on-going conflict related to a project that might bring more visitors to an already well-exploited area in central Stockholm, this paper aims to explore what role a society sustainable tourist strategy can or could play for decision making when urban development impacts public space. The paper employs complementary strategies of qualitative enquiry through interviews, discourse analysis and desk based research.

Keywords: Public space, sustainable tourism, economy of tourism, visitor impact management

1. Introduction

The economy of tourism has an important role to play in Europe's urban economies. In a post-industrial age where the number of hires in traditional industries is decreasing in parallel with growing numbers of urban residents, the visitor industry can add considerable economic value, particularly in the form of job creation and investments. Stockholm is doing well on this front; it is the leading destination for growth in Scandinavia and overnight stays are increasing steadily (Tillväxtverket, 2019a). This trend can be expected to continue given the above 5 per cent growth of non-European tourism to Sweden during the last few years, and the global growth of tourism, expected to stay at approximately 3 per cent per annum reaching 1.8 billion by 2030 (Tourism in Sweden report (UNWTO, 2011).

The combination of increasing visitor numbers arriving to consume space in our cities, together with the economic opportunities this presents to those benefitting from the visitor industry, inevitably translates into economic and social consequences for these spaces. One less attractive consequence is the challenge to high-quality public space, which in turn has impact on a city's social sustainability (Gehl, 2010). Public spaces may change in their conditions for accommodating different groups of people in a city over time. Changed conditions then also means changed conditions for distinct social and economic groups, for adjacent urban areas, and those visiting or passing through (Carmona, 2010).

Definitions for public space therefore remain fluid and contextual, and no universal grammar exists for public space, other than that it can be defined as a *public good*. What emerges instead are complex questions such as "Who is entitled to design and define public spaces? What are the impact such spaces have on our cities? How do such places create meaning for the people who occupy them? Should our modern public spaces remain public and public goods and if so, whom do they serve?". In tandem, the quality of public space is an important factor influencing whether a tourist returns to a city. Visitors generally experience a city by foot and increasingly by bicycle. They are usually attracted to streets and open spaces that are clean, safe, vibrant and attractive (van der Zwan, 2016).

Over tourism can substitute these qualities with overcrowding, decreased safety and increased littering. As observed in cities like Barcelona, Amsterdam and Venice, where over tourism as a phenomena is well studied, these externality costs are often born by local residents who resort to claiming their right to the city, i.e. public space, through angry protests and hostile behavior towards visitors (Brenner, 2009). Stockholm has only a few locations where mass tourism occurs during the summer season, one being the centrally located and medieval *Gamla Stan (Old Town)*, another being the city's Southern side of the Royal National Park, also known as *Djurgården*. While Stockholm is yet to experience over tourism on a citywide scale, local media has spotted signs of local distress by residents (Karnatz, 2019).

By studying an on-going conflict in the municipality of Stockholm this paper aims to make a critical investigation of whether a strategy for a socially sustainable tourist industry has a role to play in how the office for city planning in Stockholm manages developments that impact public space. The case relates to the expansion of a well-known amusement park located on Djurgården. The proposed expansion plans are developed by the city's urban planning department together with the amusement park. The city's urban planning committee oversees and ultimately approves or vetoes the plan. The current expansion plan has been criticized by residents and experts on heritage and urban planning due to its perceived excessive impact on the Royal National City Park's visual, cultural and spatial environment.

To provide a theoretical framework for the case, we turn to a set of critical urban theory lenses, shaped over time by constructivism. Theoretical concepts from tourism studies and visitor impact management theory are explored for phenomenal understanding of the research problem.

2. Urban conflict analysis

In the introduction to ‘Cities for People, Not for Profit: Critical Urban Theory and the Right to the City’, (Brenner, Marcuse, & Mayer, 2009), the editors highlight a need to construct “cities that correspond to human social needs rather than to the capitalist imperative of profit-making and spatial enclosure” (p.2). Critical urban theory has come a long way since its early versions, but the quote exposes its origins in urban Marxism, still evidently clear in the allusion to the socio-economic dichotomy of user-needs versus the capitalist imperative driven by profits.

Early forms of critical urban theory were spearheaded by post-Marxists like Henri Lefebvre (Lefebvre, 1968), Manuel Castells (Castells, 1972), and David Harvey (Harvey, 1976). Along the lines of classic Marxist theory, their work took opposing material interests of the capitalist ruling class and the working class as the heart of power struggles. This theoretical framework built around material asymmetries and economic determinism, also known as historical materialism, has a number of shortcomings, among them the rigid model of class struggle. It would allow for analysis of only a very narrow selection of conflicts in our contemporary urban spaces (Brenner, Marcuse, & Mayer, 2009).

Admitting that urban politics is highly diverse and inevitably situational has been key to for the theory to bring in the element of sociologically and culturally constructed dimensions of conflict and explain conflicts that earlier theories had a hard time to accommodate (Marcuse, Imbroscio, Parker, Davies, & Magnusson, 2014) (Brenner *et al.*, 2009). For example, social constructivism allows critical urban theory to account for cultural hegemony, as in the organization of consent, along the lines of Gramscian thought (Barrett, 1991).

There are hence a multitude of forces, power relations and politico-institutional arrangements that may contest, reinforce or support profit-oriented strategies in a city. The constellations formed in one way or another depend on each agents’ relation to the exchange-value (profit-oriented) or use-value (everyday life) of a given urban space (Lefebvre, Kofman, & Lebas, 1968) (Carey & Harvey, 1975) (Logan & Molotch, 1987) (Sassen & Lynd, 2017). This is helpful to understand why some public private constellations are formed around ideological and policy positions taken as natural and given, while they are in fact social constructs motivated by those who somehow benefit from them (Howarth, 2015). A clear example of this is the neo-liberal approach towards economic growth and urban development.

Differently from capitalism which is an economic system, neoliberalism adds a layer of complexity to capitalism by going beyond the mere profit making imperative (Chun, 2019). By consisting of “a theory of political economic practices” (Harvey, 2007:2), neoliberalism inherently generates power constellations and normative frameworks that, perhaps inconsistent with its supposed origins in liberalism, aren’t always liberal (Thorsen & Lie, n.d.). Based on the primary tenet that the state’s fundamental legitimacy is to safeguard private property rights and that markets are best regulated by their own market mechanisms, subscribers to these ideas are likely to adhere to the idea that growth is an end in its own right.

The emergence of neoliberal growth constellations has been contested by theories like Lefebvre’s ‘The Right to the City’ (Lefebvre, 1968) and later ‘Whose right(s) to what city?’ by Peter Marcuse (Marcuse, 2012). Lefebvre’s work, contesting the anti-social and homogenizing consequences of postwar Fordist urban renewal projects (Brenner *et al.*, 2009), goes hand in hand with Jane Jacobs efforts to save traditional urban neighborhoods in American cities. In a less theoretical but nonetheless less important manner, Jacobs vividly illustrated the

processes behind a wave of neo-liberal real estate and infrastructure reforms in the 60's and 70s that threatened and removed several traditional neighborhoods in New York, typical examples of vital local life made up of residents and visitors alike engaging in a plethora of activities, as preferred by residents themselves (Jacobs, 1961).

Hence, critical urban theory comes to terms with the present as well as with its historical legacy to understand the causes of things to be able to change them (D'Amato, 2006). In line with Marcuse's suggestion from *Cities for people not for profit*, critical urban theory is able to approach citizens' right to the city through a method of "exposing, proposing and politicizing" (Brenner *et al.*, 2009:37).

2.2 Urban Tourism and Visitor Impact Management Theory

The increasing affordability to travel by air and to stay in cities is placing unprecedented pressure on European cities, particularly those with historic city centers where mass tourism is more and more common (Goodwin, 2017). Early theories looking to account for the impact tourism can have on a destination includes Butler's model of the evolution of a tourist area (BUTLER, 1980) and Doxey's *irridex* (irritation index) (Doxey, 1975). As seen

Figure 1: Illustration of the Tourism Area Life Cycle (TALC)

in Figure 1, the former describes how a destination changes as their visitor industry grows and starts molding local characteristics. A critical point in this model is when a destination leaves the *Development* stage, when a well-defined tourist market area begins losing control of how the visitor industry impacts the city, and moves into the *Consolidation* stage. This stage is characterized by increased signs of resentment from local population, as residents are deprived of their neighborhood's authenticity and total numbers of visitors still increase (Upchurch & Teivane, 2000). This is a practical example of where social sustainability fails. If a destination's authenticity is substituted by commercial homogeneity easily found in other destinations, the given place loses its *unique selling point* (USP) for attracting visitors.

Doxey's *irridex*, on the other hand, describes the emotional stages of residents as visitor numbers increase and gradually saturate residents' environments (Doxey, 1975). Common reasons for increased levels of residents' annoyance is increased nuisance by rowdy and numerous tourists (littering, drunken behavior, loud talking and shouting at night etc.), traffic and infrastructure congestion, or extreme seasonality of visiting crowds. Both theories have their limitations but they illustrate a reality experienced by many destinations and can be useful for an analysis of social impact.

The concept of *carrying capacity* can be defined in economic terms as the maximum number of visitors that can be accommodated at a constant quality of their experience (Fisher & Krutilla, 1972:420). Excessive use of a city's resources will inevitably lead to a reduced quality of experience. Resources that must be used in a sustained fashion are both tangible and less tangible such as public space, infrastructure, authenticity, culture and heritage. When they are consumed in an unsustainable fashion, consequences can include overcrowding, crowding out and displacement of local residents, changes in the local character of a locality, 'trincetization' of the local commerce, wear and tear of public infrastructure, and increased rental costs (Glasson, Godfrey, & Goodey, 1995).

Figure 2: Graph of public opinion on capacity to serve tourists.

In Barcelona, some of these unintended consequences have characterized neighborhoods with high visitor frequency. The case of Barcelona illustrates how quickly public opinion can turn as a result (Alvarez-Sousa, Alvarez-Sousa, & Antonio, 2018):

3. Case

To understand the role of a sustainable tourism strategy vis-à-vis planning and public space we look at an ongoing case where a detail plan for exploration of a plot in central Stockholm is being developed. As seen in Figure 3, the plot is located in the red-dotted circle on Djurgården, encircled by the green dotted circle. Djurgården is located on the South side of the Royal National Park, and receives 15 m visitors every year. Visitors arrive mainly during the summer months. Djurgården is an area of both historic and economic importance. Historically it was part of the Swedish King's hunting grounds, and today it hosts a number of popular museums and scenic places in the park (located along the blue dotted line in Figure 3).

The Royal National City Park is classified as a national interest area due to its history and unique green space in the center of the city's urban archipelago. Due to its classification as an area of national interest, the park comes with a distinct legal framework, written to protect the space and heritage (Sporrong, 2018).

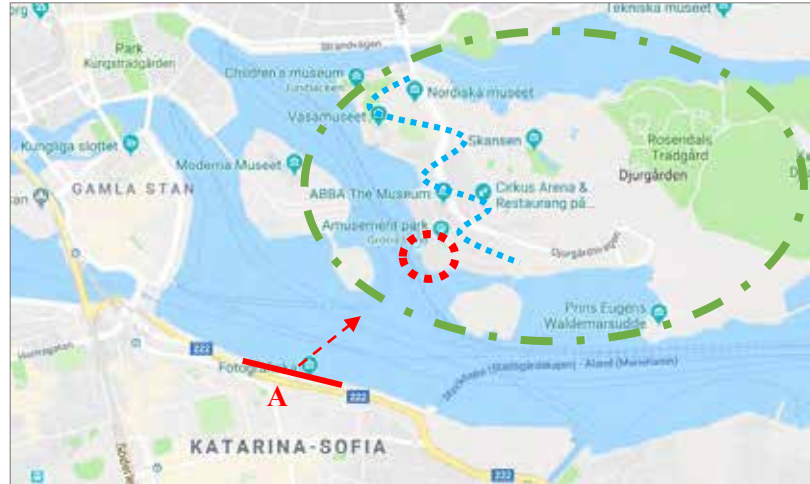

Figure 3: Map over Stockholm urban archipelago and part of Djurgården

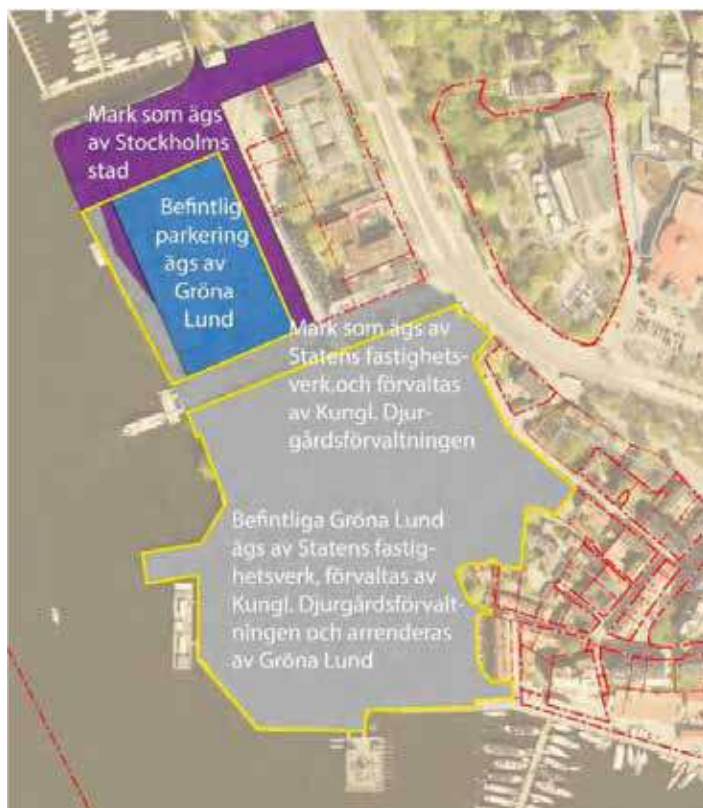

Figure 4

The owner and developer of the plot is *Parks and Resorts*, the owner of a number of Swedish theme parks. The plot under development (blue area in Figure 4) is adjacent to the amusement park *Gröna Lund* (located in the grey area in Figure 4), owned and managed by Parks and Resorts. The grey area between the water and the plot is a strip of shoreline Parks and Resorts has expressed interest to acquire and privatize. The purple space in Figure 4 is owned by the Stockholm Municipality.

Gröna Lund has been a part of Stockholm since 1883. Until 2006, when it was acquired by Parks and Resorts, it was managed as a family affair. Since then, the pace of densification of rides and constructions of new roller coasters and other attractions (currently 30 in total) increased significantly. The park is also host to an intense

Figur 5. Gröna Lund is located centrally in the heart of the Stockholm archipelago. Its visibility can be further illustrated by the view in Figure 5, seen as from point A in Figure 3.

entertainment schedule during the summers; around 70 evening concerts are held in the park during the summer seasons. Some events attract close to 20 000 visitors. At these times, traffic congestion and pedestrians cause large crowds and overcrowded public transport, particularly after shows.

The amusement park receives around 1.7 million guests, concentrated to the summer month when the park is fully engaged. During the winter months the amusement park is closed. Most

visitors come to Gröna Lund during evenings and weekends to go for roller coaster rides and to attend concerts. Parks and Resorts wants to expand the existing amusement park area into the plot that is to be developed. According to the current detail plan for what the plot would contain, the space would be used for similar rides and the sort of mechanic environment as the one occupying the existing amusement park area.

3.1 The conflict

Many characteristics of the conflict resonate with the *right to the city* theory where neoliberal interests conflict with residents feelings cheated on their space and heritage. While urban struggles for social justice and access to space have traditionally been characterized by a strong dichotomy of financial inequality, this case is different in that a group of influential residents has led the movement against the current detail plan.

The conflict regarding how the plot should be developed took its current proportions late 2018. It was around September/October when residents in the neighboring area of Gröna Lund took notice of the detail plan for the plot, its contents, and that it had reached its final stages of public audit before political approval.

A detailed development plan outlines and describes what the landowner is allowed to do and construct on the plot. The document is designed by the city's urban planning department (Stadsbyggnadskontoret), and approved by the city's urban planning committee (Stadsbyggnadsnämnden). The planning department is responsible for ensuring all concerned parties, including citizens, have a say when a development plan is designed. The process of allowing for input, critique or feedback on a detail plan is called *samråd*, and can be translated as *joint consultation*.

Aware of the advanced stage of the detail plan, the resident group organized themselves in an association called *Friends of Djurgården*, with the intent to change the technical content of the plan. They also engaged and gained the support from a number of local neighborhood societies specialized in urban planning and heritage, and urban planning and heritage expert organizations.

According to the residents association and their supporters, issues with the detail plan included planned permission to build new rides of a height that would impose excessively on the city's skyline (up to 60m high) and Djurgården's appearance; activities leading to increased and excessive noise pollution for neighboring residents; and an intensification of visitor numbers to the park during already overcrowded times. Part of the critique was a

claim that the property owner (Parks and Resorts) must be able to in a reasonable manner cater for their visitors rather than using the public space surrounding the park for large crowds leaving the park, or waiting in line to enter. By enlarging the Gröna Lund, residents feared crowds would further spill out on streets, sidewalks and green areas in a way that severely obstructs passage for children, pedestrians and people on bicycles.

Figure 6

Additional resistance to the detail plan is related to what was perceived as misleading illustrations of what the detail plan could come to materialize into. As seen in Figure 6, the original photograph from the detail plan illustrates a white, translucent roller coaster on the new plot to the left. The red thick rectangle was added to indicate height of 60m high rides. The thin line indicates 35 m height to show how much below what was technically allowed the plan chose to show, and it

serves to outline the area along which construction could be developed. Discontent over this led the Friends of Djurgården and their supporters to file a lawsuit to the Parliamentary Ombudsman claiming the visual content was not realistic in demonstrating what the proposed technical framework would actually allow for.

Finally, the plan suggests privatizing the shoreline, which is unusual in Stockholm; direct access to the water is generally considered part citizens' rights as part of the city's public space. There are several previous cases where private landowners on Djurgården have allowed public access to residential land along the shore, to ensure this principle. The solution proposed in the detail plan, to ensure pedestrian access along the shore, would be a footbridge for people to walk on, about 20m away from the shoreline.

In their attempt to change the content of the detail plan, the residential association led an effort to meet with staff from the planning department, politicians from the planning committee, and representatives from the County Administrative Board. A Facebook page was initiated to raise awareness of the cause.

Instead of proceeding to approval by the planning committee, the detail plan is now under development with the planning department again. Once reassessed, the plan will once again be made public for feedback before passing on to the planning committee for its evaluation and potential approval.

4. Results and analysis

To collect information on whether a socially sustainable tourist strategy exists in Stockholm and whether it could influence the planning and management of public space, the methodology of choice was discourse analysis. Spoken and written language was collected through interviews and desk based research of mainly reports and newspaper articles as content for analysis. Interviews were held with all relevant stakeholders, including the developer, the municipality and the opposing civil society groups. Experts and stakeholder organizations from the visitor industry were also interviewed.

4.1 Policy Framework

The policy framework for Stockholm's tourism industry is mainly composed by the Ministry of Enterprise and Innovation (Näringsdepartamentet), and the Swedish Agency for Economic and Regional Growth (Tillväxtverket), in collaboration with government owned promotion company Visit Sweden AB. Specific for Stockholm is Visit Stockholm AB, a daughter company to Stockholm Business Region, owned by the Stockholm municipality.

Other important actors for a sustainable tourist strategy are business associations like Visita AB and Royal Djurgården. They provide services such as technical assistance and strategy support to businesses from the visiting industry. Visita, together with the associations for trade and transport industry, as well as Visit Stockholm, own Swedish Tourism (Svensk Turism AB), a private company and partner of the state and the state owned marketing company Visit Sweden AB.

The planning department and planning committee have little or no relation to stake holders from the visitor industry, nor do political officials have experience with working with Visit Stockholm. Mobility and increased visitor numbers are hardly spoken of according to those interviewed, and none of the above named organizations tend to be contacted for consultation during the development of detail plans. Executive capacity and mandate to plan for the built environment is located with these departments, separate in structure and practice from those promoting and targeting increased visitor numbers in the city.

4.2 Whose right to what city?

Several actors from the area of heritage and planning who were consulted by the planning department and the developer during early stages in 2015 feel disappointed by the state of the development process as it stands today. This is compounded by a regret of not having asked more questions about the proposal and what it would entail and allow for in detail from the start. A sense of feeling 'naïve' and that 'one should have known' were mentioned several times.

Generally, however, opinions of the amusement park are positive. Its management has been known as being collaborative over the years, and most people interviewed agree that 'the kids need a place to have fun'. What is seen with less optimism is the gradual development of a family owned amusement park into a corporately owned mechanical entertainment center driven mainly by what is perceived as profit expectations and a desire to expand. Similarly, many share that the omission of important information on what the developer intends to develop, combined with the image description mentioned in section 3. (Case), points to a lack of honesty from public officials in the planning department, and a desire to liaise with developers to meet their requests, rather than the interests of civil society. As a result, those who signed the lawsuit did so as much as an act of principle to correct not only an immoral issue of not complying with technical requirements of a detail plan, as an opposition to the actual height of the rides.

Additional complaints about the planning department were illustrated by reference to reports and journalistic material scrutinizing questionable approaches to developing detail plans (Ingo, Berglund, & Perner, 2018) (Andersson, 2016). Claims are made that rather than regulating and leveraging an investment friendly climate to promote holistic growth on a city wide scale in Stockholm, the planning department has overseen developments and investments guided by exchange-value instead of standards for urban planning to maximize increased use-value for residents.

Perhaps this is related to what some people refer to as perceived arrogance and lack of interest for wellbeing by the planning department. When claims related to wellbeing are made, for example the right to rest at night, officials have been said to respond to such claims by stating higher noise levels at night as something unavoidable when living in a city. Similarly, when asked how one is to explain how a proposal can anger citizens to such a degree, the answer does not consist of a motivation of why the technicalities of the detail plan have been designed in a given manner, rather, the view is that it is impossible to please all stakeholders. The consequences of the current plans could hence mean increased stress levels for those living on Djurgården; however, the needs of Gröna Lund are perceived to be prioritized by officials from the planning department.

4.3 Social sustainability and carrying capacity

While the words ‘sustainability’ and ‘tourism’ do coincide in most tourist strategies for Stockholm, the term *sustainability* seems to refer to environmental aspects almost exclusively. Some references are made to social sustainability by the Swedish Agency for Economic and Regional Growth (Tillväxtverket, 2019b), but interviews produced little content in the way of concrete steps to achieve buy-in from residents, how to transform residents into a *host community*, or cost-benefit analysis.

This is a questionable way of strategizing for sustained visitor quality given there is wide consensus that visitors come to Sweden for the Swedish life style, even for banal things like looking at dads with strollers¹. Most visitors coming to Stockholm, local or national, have interest in accessing heritage in some way (Glasson *et al.*, 1995). A city like Stockholm has its own morphology in the shape of watersides, structure and traditions, which provide a framework for identity for the visitors and residents alike (Glasson *et al.*, 1995) (UNESCO, 2013). Edward Relph (1976) develops the idea of place and identity as:

“While place meanings are rooted in the physical setting and its activities, they are not a property of them but a property of human interaction and experiences of those places” (Relph, 1976:47)

To put a price tag on what cultural heritage and historical architecture is worth; the recent Notre Dame fire was enlightening. Over a 1 billion Euros were collected, the bulk from brands intimately related to the historical city brand of Paris. In other words, a USP worth preserving.

While political official and representatives from the municipal planning units were in general not familiar with the complexity of over tourism or the possibility that we could see it here, actors from the visiting industry’s private sector organizations showed a clear preference for quality over quantity. The expressed this by, for example, questioning strictly quantitative goals such as “doubling the number of overnight stays” or increasing

¹ so called *latte-pappa*, the stay at home fathers seen with their strollers while meeting up with other baby daddies to have a latte.

revenue by 80 per cent. In a few cases this also came with critiques of Visit Stockholm's quantitative focus: "What do they really say about growth or wealth?"

One of the difficulties when developing detail plans for Djurgården is how to interpret the legal framework for which developments are allowed in the Royal National City Park. While the framework is based on values intent on protecting the park and its environment from disruptive changes, concrete regulations such as height limitations are absent. Rather, directives are rather loose, such as expressing that new construction is only allowed as long as it does not intrude on the park landscape or cultural milieu. This leaves much room for interpretation of the master plan, which is ultimately of the planning department's discretion since no external advising organizations or experts have a veto over their detail plan decisions. An example of room for interpretation is that the master plans indicates existing actors in the event area of Djurgården, including Gröna Lund, are allowed to "develop". This is interpreted by the planning office as the right to expand with few limitations on height and density, and privatization of the shoreline. The latter, however under used under current circumstances, constitutes public space.

Interviews with stakeholders accompanying the development plan, many of which have engaged with the preservation of the Royal National Park for many years, align with a case of 'popularizing' an area associated with heritage to be one of broader appeal unrelated to any specific aspects of heritage or identity. As expressed by Glasson *et al* in his book from 1995, "it is a process that inherently comes with simplification of a given location's depth or story to tell. Contrary to how one might interpret such a process of 'democratization' of space, it transforms a city's heritage – which belongs to all its residents – creating a space instead designed for a specific group" (Glasson *et al.*, 1995). In this case, that specific group is the visitors of the amusement park Gröna Lund.

5. Discussion

Studies of how tourism influences cities is nothing new, it has been the topic of researchers for many years (Canestrelli & Costa, 1991) (BUTLER, 1980) (Van Der Borg *et al.*, 1996) (Glasson *et al.*, 1995). Nevertheless, social impact, as one of the more complex aspects of impact to measure, is only now beginning to gain traction in policy and strategy formulation. Public officials in a number of cities are agreeing that it is naïve to look at the visitor industry as one that should roam free from oversight, strategies and management. Even in the capitalist mecca of the world, regulations concerning commercial activity are put up to protect a location's character (San Francisco Planning Department, 2014). When it comes to regulating receiving capacity, the number of cities regulating Airbnb rentals is increasing; Barcelona, Amsterdam, Paris and Los Angeles are a few with municipalities creating stricter legislation for the platform industry (Lagrove, 2018).

However, in cases where local governments speak in terms of sustainable tourist strategies, it is done admitting sustainable is a concept that is linked to tradeoffs. To the distraught of residents, these are often the ones carrying the onus of the tradeoffs before more creative solutions to conflicting interests and regulations are put in place. This often occurs after economic and social externalities have reached a more permanent nature in the form of crowding out of local economic activity and local residents, or touristification of neighborhoods (Bakker, 2019). Planning then becomes remedial and reactive (Doxey, 1975).

The municipal planning office and the marketing agencies promoting growth of the visitor industry are conceptually and ideologically distant from the idea of regulation, improving reinforcement of regulation that controls the impact of tourism on local economy and social fabrics. Perhaps this is due to weak data on how the city is reacting to the increased number of visitors. The city needs instruments that can provide adequate data that overnight stays and airline arrivals simply cannot do. The managerial toolkit policy makers require must include forecasting capacity that can tell us something about qualitative information (cultural and economic behavior, for example) rather than the quantity of tourists we are receiving. Using tracking techniques is one way. Royal Djurgården is doing something of the kind already as a first innovative step to ensuring socially and environmentally sustainable development of the park's full potential.

It is perhaps due to place dependency that noticeable awareness of qualitative goals and aspects of growth was found when speaking to professional associations such as Visita AB and Royal Djurgården. Such actors are important partners for the city's planning office as increased collaboration could harness the interest in preserving the quality and authenticity of Stockholm while catering to needs for sustained and adequate growth in parallel. Place dependent actors conditioned to a certain environment have nothing to gain from over tourism. There are other examples of this. In Venice, the most powerful lobby group against the unregulated existence of Airbnb is the association of hotels. Crowds over a certain point is simply not good for business.

Successful examples of sustainable management of public space vis-a-vis both residents and visitors require participation of all impacted stakeholders, as well as management, enforcement and communication by relevant authority (van der Zwan, 2016). Denmark is another example where tourism strategies aiming for quantitative goals have been substituted by destination strategies with a more qualitative focus. Differently from a tourist strategy, a destination strategy goes beyond the idea of the 'tourist' as a separate stakeholder, and approaches urban management in a holistic way in that planners recognize that increased mobility of both local, national and international travelers needs to be observed for socially sustainable planning (Wonderful Copenhagen, n.d.) .

The focus on quantitative goals, rather than qualitative aspects in strategies for Stockholm's tourist strategies points to the absence of a socially sustainability for the visitor strategies. The lack of communication and coordination between the planning office and the departments developing the visitor industry weakens the social

sustainability of how Stockholm is developing further. As observed, this causes developments to emerge that fail to consider needs of the city's main attraction; its authenticity and local culture. Lack of coordination also undermines one of the pillars of the Visit Stockholm's tourist strategy, namely to make residents 'informal hosts'. This goal is less likely to be attained while another government department develops proposals for the visitor industry that make a considerable group of residents and citizens disappointed, angered and cynical about they operate.

Failing to appreciate a holistic approach to how to create urban growth will continue feeding beliefs of immoral and partial behavior on behalf of municipal representatives. For each case of popular resistance to infrastructure development that disregard public space, infrastructure limitations or architectural heritage, instead leaning in favor of private developers' interests, the question of sustainable urban development is likely to increase in its level of political urgency. In a worst-case scenario, it can turn into a politically divisive issue instead of something that unites residents.

Residents and tourists alike increasingly look for a unique and authentic experience. To deliver this a destination must take on tradeoffs in economic growth in some locations and for some stakeholders. When properly managed, historical landscapes can leverage tourism and the service sector to increase welfare, while motivating protection and endurance of economic and social diversity, as well as a place's residential character. It is therefore a fair claim to say that to attract a sustainable and desirable visitor industry, while validating those who call it home, carefully protecting and managing the identity of a place becomes an imperative (Ashworth & Voogd, 1990) (UNESCO, 2011).

The questions we are left with is how a practical framework that enables a socially sustainable strategy is to look. What can be induced is that effective visitor management requires effective communication and collaboration between potentially conflicting interests. One way of doing it could be to include representatives from the visitor industry as an assessment area in the early stages of deciding whether a request for a detail plan should be approved for full development. What structures are conducive to allowing for this, and how effective is collaboration without executive mandates? It remains to be seen; the first step for the municipality of Stockholm is to consider what a socially sustainable strategy could look like.

Suppressing urban creativity: displacement of the art spaces out of the mainstream cultural scene of Istanbul

Guzin Yeliz Kahya

¹*Erciyes University, yelizkahya@gmail.com*

Abstract: Istanbul's contemporary cultural scene has been struggling with the displacements of long-established cultural assets due to the applications of top-down urban redevelopment and renewal projects. In particular, the stigmatization of the city's long-established cultural spaces as a non-profit places and the de-functionalization of their buildings through long-term closures and neglect have appeared as a political strategy of urban policy makers to legitimize the replacements of public spaces by profit making private spaces. In this paper, as focusing on one recent case of the displacement of the Emek Movie Theatre that has symbolically important place for Turkey's local cinema scene through the application of urban renewal project, I investigate the reasons that the survival and resistance tactics of the bottom-up agencies failed to evolve planning processes into a communicative and collaborative structure. It is aimed to evaluate the drawbacks of the non-communicative and non-collaborative governance structure arising in the urban policy scene of Istanbul in the generation of urban creativity. The study will underline the importance of non-mainstream cultural scene in the development of Istanbul's creative and innovative capacity along with contributing to enhance the status of bottom-up urban players in the public spaces of cities. Thus, it draws an attention towards sustaining urban environments with the vision of innovative and positive nature of bottom-up urban practices, and contributes the debates on how the urban processes in Istanbul are democratized by the participation of bottom-up urban actors in formal planning and urban development processes.

Keywords: bottom-up urban actors; urban regeneration; top-down urban planning; urban governance

Introduction

Cultural heritage and assets are more implicated in the policy structures of cities in parallel with more prominent emphasis on innovation, knowledge and economic competition within policy issues. They play instrumental role in positioning cities as a cutting edge creative city that competes with other global cities (Trosby, 2001; Florida, 2002; Chhabra *et. all.*, 2005; D'Auria, 2008;). Contemporary modes of urban governance, on the other side, increasingly rely on the agencies other than formal governmental structures (Carley, 2000; Schmitter, 2002; Haus and Heinelt, 2005, Bennett, 2009); however, cities continue to confront with the challenges of maintaining a satisfactory urban governance model that can aid to improve the quality of complex urban projects as well as complex decision-making process. These urban projects include big and distributed infrastructural projects, new routes for new transportation centers, highly contested environmental projects as well as the

projects that require major changes in cultural heritage and assets of cities with the concept of creating new commercial areas. The bottom-up agencies add new dimensions in these urban redevelopment processes as the actors of urban change with the capacities of creating new places and enhancing community relationships. That subject has been already discussed in various cases (Vivant, 2010; Colomb, 2012; Bain and Landau, 2017). The exemplified cases in these studies show that bottom-up agencies act as a catalyst for creating adoptive and responsive pathways to changing and challenging urban conditions. The case study of events in Berlin organized by the interdisciplinary cultural centre Zentrum für Kunst und Urbanistik demonstrates that the intermediary role of artists in urban development have challenged the exclusion wrought by the overriding forces of global capital through co-opting artistic creativity to increase citizen involvement, transparency and legitimacy in urban development processes (Bain and Landau, 2017). In this regard, urban governance that can able to involve bottom-up actors, who provide real support to integrate creative insights to this kind of complex urban projects would foster scenarios of community engagement and collaboration, and thus, add adaptive and co-evolutionary flexibility to urban environments.

The urban renewal and regeneration projects in Istanbul that were subject to civil response shows that the city still faces malfunctions in the governance of multiple stakeholders from civil society in the social and cultural dimension of urban development. The national government structure in Turkey still has a significant influence on metropolitan development through policy making although transition to global economy has led to reduction in government's proactive role in the economy and society (Uzun, 2007). The urban renewal and urban redevelopment projects increasingly rely on spatial and cultural heritages of the city while the operationalization public-private partnerships in these projects has been gaining importance. These projects, however, illustrate that these partnerships cannot operated through forms of governance. Indeed, the types of collaborations with the actors from civil society have been visibly neglected.

This paper aims to discuss the disablement of governance mechanisms in the decision-making processes during the Renewal of Serklydoryan urban plot and re-build of Emek Movie Theater in the proposed new shopping mall in Beyoğlu, Istanbul which was subject to policy intervention of public-private partnership. Through the examination of non-communicative and non-collaborative attitude of the local and central planning bodies towards the long-standing bottom-up response towards the top-down processing of that project, the paper considers the only strategy of local and central governmental bodies to allocate all historical and cultural heritage in the urban core to private commercial developments as a suppressing factor on enhancing creativity at local level even though Istanbul's frequent reference to creative city and growth exemplars.

Istanbul's Creative City Approach and Self-Generated Cultural Dynamics

The changing and challenging conditions of 21st century stimulate new developments in Turkey's cultural and creative scene. The use of the 'creative economy discourse' in Turkey was first taken up national level by the Turkey's government in the beginning of 2000s. Turkey joined the eEurope+ Initiative for developing strategies and an action plan to become an information society in 2001. The policy-oriented cooperation projects that aimed at strengthening infrastructure for knowledge based urban development were proposed as concrete objectives of Turkish cities. Virtually increasing number of cities in Turkey uses the concept of creative city (or one of its variants) in their politics,

policy, advocacy and practice. The e-Turkey initiative was established as a part of this attempt. Economic growth in Turkey between 2002 and 2011 also contributed to this initiative.

In this vein of Turkey's liberalization and creative economy interest nationwide, arts and culture started to be not considered marginal to economic life and not dependent on public subsidy. Promoting culture and investing in cultural industries appears in the policy agendas of the city to compete in the contemporary knowledge-based economy. Government bodies were moving towards enhancing the socio-economic impact of cultural life while enhancing creative industries. Turkey's cultural scene has also witnessed an increase and diversification in the number and type of cultural actors starting from the late 1990s. Along with the established state-owned cultural associations and institutions, the private and semi-private initiatives also accelerated in different forms of cultural spaces (Ertürk, 2010:9; Bakbasa, 2010:14). This stimulated collaborations with private and governmental institutions for taking shared actions in cultural scene.

Istanbul, as globalizing city, has adopted to use creative industries as strategic tool for urban management for last two decades (Öztürk and Çıracı, 2015). Istanbul Greater Municipality made first cultural and creative industry classification in two groups of activities in 2005: culture based activities and business services. This can be considered an attempt to understand the city with the contribution of the economic activity stemming from creativity and culture to the city's economy. This classification includes the commercial forms of culture and creative activity (culturally industrialized entertainment activities_, like theatre, music and film) and also the service businesses like advertising selling creative skills to other businesses, manufacturing businesses that feed into cultural products and the retail of creative goods). This tendency was also motivated by the fact that Istanbul has been selected to be the European Capital of Culture (ECoC) in 2010. A series of arts events and cultural festivals have been taking place during this special year, and an important symposium, Creative Cities and Industries in the 21st Century, was scheduled for November 2010. The government allocated large amounts of funding to create new cultural offerings and to host year long cultural events. This upspring in the city's cultural scene stimulated the formations of new cultural actor-initiated interventions, notably the emergence of bottom-up art organizations. The bottom-up groups had chances to build new organizational arrangements to establish their own autonomy and to allow ways of interaction with the public in the city. Consequently, new models of cultural actors found their place in the city's cultural scene. Their emergence in the city's cultural scene, in turn, increased the local capacity to mitigate and adopt new realities and challenges for local cultural scenes.

Despite this course, however, the enabling conditions for the development of self-initiated mechanisms started changing after 2010. Public investments and the organizational excellence in building the infrastructure for cultural and creative industries in Istanbul dramatically drew back. The government could not reap the expected political benefits of holding the title of the ECoC. The government was even negatively publicized due to the lack of preparedness in the face of some social challenges.

The country's significant shift towards more liberal and out-ward looking economic policy also dominantly operated through the subsequent urban transformations of that decade, culminating, especially in large cities, in the development of shopping malls as alternative retail spaces to traditional markets and stores on a shopping street (Erkip and Özuduru, 2015). The related legislation on 'The Protection of The Deteriorated Historic and Cultural Heritage through Renewal and Re-use'

(act 5366 released at 2005) has been put the historical and cultural heritage of Istanbul to controversial position (Enlil *et. all*, 2011). Istanbul's urban landscape has been rapidly marked by private- public partnership driven urban renewal projects taking place especially in its historic sites. Based on this law, eleven urban areas within historical and architectural value have been subjected to the urban renewal projects; and six of them, Tophane, Tarlabası, Persembepazarı, Cezair Street, Galata Tower and Beyoğlu Municipality and their surroundings and the Serklydoryan urban block, are located in Beyoğlu (Çoşkun, 2016: 56). As regards to the issue of revival of unused and decaying cultural heritage in Beyoğlu, the projects worked on similar urban models re-program and rebuild the existing built fabric with the new concept of retailing, which occasionally embodied itself as big shopping malls integrated into new offices, residences, entertainment and cultural centers.

For many critics (İslam and Enlil, 2006), the intricate machinery of this law and its legislations did not trigger positive effects on urban protection and reinforcement of social dignity and equality since the independent small retails and existing neighborhood or building dwellers were left vulnerable and insecure and usually unorganized and there was a lack of integrated urban policy for developing strategies to make the dwellers and retailers resilient. Hence, it is frequently declared that the local authorities have exposed mere control on the use of the deprived areas of Istanbul through arbitrary expropriation. In this way, these properties either private or public would have been endowed to the new users. Through employing urban renewal and re-use projects, the property ownerships were easily exchanged; and this paved the way for putting the private interest over the public good in these places.

It is clear that there is a significant challenge caused by the emerging multi-voice economic and cultural scene in the city on the future of urban commons and the central and local planning bodies' creative city initiatives and plans and their underlying rationales about regeneration of cultural heritages. Currently, the empowered agents in the cultural and urban scene, including municipality, private sector and central government nor took important steps for institutionalized dialogue on constitution and implementation of urban and cultural policy areas or generating vision of civil life adapted to the city's changing economic life. The lack of institutional mechanisms also prevented developing a collaborative decision making processes for proposing solutions for enhancing creativity in the city.

The case of renewal of Serklydoryan urban plot and re-build of Emek Theater in new shopping mall

The phenomenon of renewal of Serklydoryan urban plot and re-build of Emek Theater in new shopping mall was long-before on the agenda of urban policy makers; and its sell for commercial development has been vocalized in media since 1994. In 2005, the *Emekli Sandığı* (Retirement Fund-ES) announced to sell the Serkldoryan urban block (Yapı Dergisi, 2005). The implementation of new project, however, was delayed until 2010. Along with the renewal of Cerle D'Orient building under the Law on Protection of Cultural and Natural Property, the re-build of shopping mall on the remaining part of urban plot, where the Emek Movie Theater was located, have anticipated from its beginning by civil society. The civil response not only came from the professional bodies that approached susceptible to the contractual practices between public and private subjects and design practices but also individuals and social groups frequenting the theater, in particular, cinemagoers and cinema-workers including artists, producers, and audiences. This civil opposition depends on two

major concern: (1) the transfer of public property to private ownership to re-build and to manage it as a private property by operationalization of built-transfer-operate model would produce range of physical and social displacement processes (2) the relocation of theater on top the newly-build shopping mall would undermines the authenticity of the theater building and cause the loss of information of collective value. These impacts prompted civil society to form movements to engage and speak up about the increasing impacts of harsh urban regeneration projects they were facing. The civil society groups were organized under some initiatives; *Emek Bizim İstanbul Bizim (Emek is ours İstanbul is ours)* and *İstanbul Kültür Sanat Varyetesi* were leading the processes. Despite these events; the iconic cinema building was demolished in 2013. Later on, Kamer Construction Company completed the urban renewal of Serkldoryan urban plot in 2016 through re-constructing a new shopping complex covering all the land of this urban plot. In this complex, the Serkldoryan building was only kept through restoration, the back part of the building including the Emek Movie Theater demolished and rebuild as a part of shopping complex. The Emek Movie Theater is now on the top floor of this new shopping complex, Grand Pera.

The case that the strong social response against the project could not have evolved into an influential civil society-based organization in city planning points out different dimensions of crisis between municipal bodies, city leaders and civil society: (1) de-personalization of local and central governmental bodies to the right of society on the future of cultural heritages sites (2) obstacles preventing the civil initiatives to evolve from social movement to soft-infrastructure at city level. Although the influence of civil society groups would play significant role in devising new policies in regeneration of cultural heritage sites, the personal engagement of the citizens and the commitment of national and local governments to cooperate with civil society groups seem to be still rather marginal in the process of Turkey's urban planning practices.

The enduring role of Serkldoryan urban plot and Emek Movie Theater in Beyoğlu's urban everyday routine

The Emek Movie Theater on *Yesilcam* Street (formerly *Devaux*) was located on the Serkldoryan (Cercle D'Orient) urban plot in Pera, which has been actively part of urban social life since the second half of 19th century. The Pera neighborhood, northern extension of Galata neighborhood was mainly Levantine neighborhood with the establishments of churches, schools, institutions and new associations. In 1884, the construction of Cercle d'Orient (Serkldoryan) building in the heart of Pera made this urban plot unique destination of bourgeois urban life. The building was one of new social associations for Ottoman-elites and non-Muslim Levanters came together to socialize (Baruh, 2016). In 1896, the Ottoman Bank took the building from its owner Abraham (Karakahya) Pasha since he did not pay the borrowed the money back. The bank owned this building until 1919. During this period, the whole urban plot accommodating the Serkldoryan building with its backyard become to used as a recreational and cultural center as the dead-end street next to the Serkldoryan building decided to widen and open towards back of the urban plot. The Staking Place was built at the back of the building in 1909. It was actively used for not only for skating but also other performative activities such as talks, circuses, sports and cinematographic performances, and the skating palace was then converted into a theater in 1918. Lately, the use of electricity in Istanbul has initiated the opening of movie theaters in the same urban plot.

After the decline of Ottoman Empire and the first years of the establishment of Turkey Republic, this

urban plot continued to be a recreational spot in the cultural life of the city; and it began to transform into a movie theater zone. The establishment of Melek Movie Theater (Emek) in the Staking Palace building was dated back to 1924. Two other cinemas (Ipek/formerly Opera and Sumer/formerly Artistik) located in this urban plot in 1930s. These two movie theaters with their renewed names served as movie theaters until 1955. The major changes in the cultural and social landscape of Beyoğlu were happened due to the decline of non-Muslim communities living in Istanbul. The wealth tax of 1942 has changed the general profile of property ownerships in the district and caused economic disempowerment of non-Muslim communities. As a result, The Serklidoryan urban plot with its all-cultural and commercial facilities has brought by the municipality (Aktar, 1996). The transition of the urban plot from private to public, however, did not prevent the cultural and commercial importance of the plot. There were still active three cinemas, eight commercial stores at the entrance floor of Serklidoryan building and the social club.

It is widely stated that the economic decline and leaving of non-Muslim population and the settlement of Anatolian immigrants in the empty places caused the decline in both urban environment and cosmopolitan cultural life of Beyoğlu. However, the rise of local cinema industry from 1930s till 1980s held some synergy in Beyoğlu despite the city's declining cosmopolitan profile. According to Kula (2015), it was still privilege to go the Melek Movie Theater and eat some cake in the Inci Patisserie in 1950s even though Beyoğlu has experienced decline in his cultural life. This urban plot was sold to the Emekli Sandığı (Retirement Fund-ES), the main social insurance institution for public servants of Turkey in 1957, and the institution has renewed all the three-movie theaters in the urban plot. They have continued to serve as movie theaters as Emek, Ipek and Kucuk Emek Movie Theaters. The Ipek Movie Theater has then taken over by the Istanbul Municipality Theater, and served as a comedy theater hall until 1975. Similarly, the Kucuk Emek Movie Theater was used for Municipality Concerts.

The Serklidoryan urban plot and its surrounding became a heart of the self-emerged movie theater urban zone in Beyoğlu. This zone was accommodating 11 out of 30 movie theaters in the city from 1920s to 1950s. Some of them were closed; some were re-named and new ones added on the list during this period. It has, indeed, enlarged towards proximate locations with increasing numbers of movie theaters (Özlü, 2016). Besides movie theaters, the related facilities and all the networks were established around this area, and this urban area, namely Yesilcam has actively functioned as a heart of movie industry of Turkey. There was also increasing number of local movie production companies in Yesilcam, and approximately 300 movies have been locally produced and distributed other cities in a year in 1950s.

Besides being a movie theater, the Emek Movie Theater has gained specific symbolic value with events, public gatherings and screened movies it housed. It housed leftwing concerts and screening alternative movies for years. The art pursuers formed bottom-up civil society groups have had a key role in shaping these events. The theater's progressive causes have provided the backdrop for small, courageous revolts: the first big public 1 May celebrations after the military coup of 1980 took place there in 1987. The Emek, it has turned out, was more of a meeting place strengthening sense of community in cinema scene than a movie theater. At this point, the theatre created a loyal 'public' coming regularly to this place, following the events and meeting people who think like themselves. This place was not a given public space; however, it might be considered as place with public role through bundle of network relations produced through collective actions (Fırat and Bakçay, 2012).

Globalization period led the cinema sector in Istanbul to re-structure itself with the inclusion of international companies and the rise of television and advertisement sector after 1995. This reflected on the spatial organization of the cinema sector. The clusters of production companies have begun to spread through the centre of metropolitan area. The central role of Beyoğlu in the film industry has been decentralized as a result of the location preferences of production companies in Şişli and Beşiktaş neighborhoods (Dursun, 2009). The social and cultural life, however, tended to not spread out as much in these recently developed creative precincts. There was still a strong tendency for locating art festivals or cultural events in city centers with strong historical and cultural links; and the Beyoğlu urban area was still a prominent figure in terms of engaging cultural and art activities. Until 2010, the Istanbul International Film Festival used the long-lasting movie theatres in Beyoğlu, most of which were demolished today, like Emek, Yeni Rüya, Atlas, Beyoğlu and Yeni Melek movie theatres (Say, 2016:28). Although the audiences of these events could be defined as very small proportion of Istanbulites, defined as middle or upper-middle class, these theaters have been stages for stories not seen either publicly funded and commercial private cinemas. The Emek Movie Theater has housed the opening and closing ceremonies of the festival for almost 30 years until it closed its doors to the moviegoers in 2009 due to the decision of renewal.

The bottom-up response to the renewal of Serklydoryan urban plot and the re-build of Emek Movie Theater in the new shopping mall

Since 1994, the speculations on the sell and rebuild of the Serkldoryan urban plot as a new commercial site encountered persistent opposition not only from professional chambers, non-governmental organizations, but also from the civil society. In particular, the civil society groups include both individuals and community groups frequenting the Emek Movie Theater and its surrounding urban environment in their daily urban practices and the ones demanding their right to decide over the fate of the city whose cultural and historical heritage. Here, an attempt is made to critically re-visit the existing debates on community groups' cultural heritage right activism in urban renewal and redevelopment process.

In 2010, the one-day use of the theater for the opening ceremony of Istanbul Film Festival staged political action and social protests against the demolition of the Emek Movie Theatre taken by the Istanbul Film Festival audience. Following the aborted three years of building between 2010 and 2013, there was ongoing legal battle against the implementation of the project. Several platforms including architects, planners, art critics, academicians, and art historians have founded to raise awareness and garner support against the project. Moving the theater without comprising the quality and value of its original set-up on the top of the newly built shopping mall is the mantra for this project to legitimize the renewal plan in the public sphere. The apparent lack of transparency in planning process, however, could not satisfy the civil society groups' and the professional chambers' concerns.

The Emek Bizim Istanbul Bizim Initiative was one of the leading figures in forming creative protests against the project. In 2011, they led the event that has occupied the Demiroren Shopping Mall, which was constructed in similar way opposite the Emek Movie Theater. In their slogans and banners, their right to the other neo-liberalized spaces, especially those replaced non-mainstream cultural spaces were highlighted (Özdüzen, 2017). In March 2013, the initiative occupied the theater while the contracting company was de-constructing the existing theater structure to rebuild shopping mall. This

initial unauthorized event organized by the initiative demonstrated that there was still time to save the theater from demolition. This event has followed by creative protests with the involvement of various community groups, including cinemagoers, cinema workers, artists and local residents. Public gathering and speeches by prominent figures has made. In April 2013, their protest was faced with extremely tight response with water canons and teargas from the police. This direct state intervention results in the evolution of political activism against the project transformed many of citizens into critical and activist cosmopolitan individuals. More people also fuelled the creation of a collective identity and a network of solidarity and resistance. The following wave of resistance and protests launched the Occupy Gezi Park Upspring in May 2013.

Conclusive Remarks

The case of the renewal of Serklydoryan urban block and re-build of Emek Theater in new shopping mall becomes a great example of the civil society's attempt to participate in urban planning, particularly in the controversy urban regeneration areas. Other relevant cases from Istanbul also support the idea that there is significant civil concern towards the strategy of local and central planning bodies that allocates all historical and cultural heritage in the urban core, including theaters, residences, public and private properties designated for other uses, to private commercial developments without engaging any negotiation with civil groups. This case also presents that the role of civil society groups encompassed the shared-values and lifestyles of citizens through gatherings, meetings and protests. Even though these groups have received support among citizens, the governmental bodies did not choose to recognize the voice of community and engage their attempts in urban regeneration process. This process, however, progressed in a destructive manner through undertaking reactive strategy.

It is important to highlight that this missed opportunity to create a base for a participatory planning approach prevents accommodating civil society aspirations for future of the Emek Movie Theater. Over the past decade, diversity of bottom-up practices are increasingly, on the whole, actualized in many cities around the world by different initiators, such as community groups, political activists, artists, entrepreneurs, individual volunteers and so on. The ones that aim to maintain their own positions to the challenge of urban problems can provide new forms of urban space uses, improving their urban living conditions and creating new urban commons. The presented case in the paper, however, prevents the capacity of bottom-up agents to adopt and to influence urban processes and local planning bodies; and the suppress of their creative capacity created barriers for the emergence and survival experimental urban space uses and solutions punctuating the city's landscape. The challenge of proposing adoptable urban model in Beyoğlu that can adjust the disturbances related to the emerging city marketing discourse requires battling the structural disadvantage of globalized retailed system in the city. The bottom-up tactics producing new images and narratives can come up with new opportunities for traditional small businesses to be up their game in the sector. If the civil response to urban regeneration is translated into a system of variety of urban actors interacting within network of governance, this system can generate truly differentiated and special solutions for urban developments.

This not only about finding good solutions for urban redevelopment but also dealing with the complex issues in an ongoing networked, fragmented and empowered world. In case of the Emek Movie Theater, the present reality was dynamic and volatile, due to the two insights derived from the

involvement of changing views. The urban transformative practices of civil initiatives interlinked with the some parts of local citizens, but there was tension arising with municipal authorities and the private contractor. Urban creativity in much broader terms –not just about creative solutions for urban environment, but also about how these multiple views engage and interconnect. It is related to the self-directed organization building processes that are created by participants. Under this condition, different priorities and capacities can be negotiated among different stakeholder and modes of co-existence in space be conditioned. Hence, utilizing bottom-up responses in urban planning processes that enable direct participation of civil society into urban planning should be understood as a framework for flexible and open structure for developing ideas.

In terms of extending limits of democracy in society, creating dialogue and interaction among various actors, even the ones with opponent perspectives, is essential. Besides that, the ways of challenging neo-liberal urban development logics –processes often oriented towards privatization and financialisation of urban space_ highly depend on the capabilities of civil society to self-organize and demonstrate alternative survival strategies and tactics. The ways that bottom-up groups foster new engagements with urban space and places, are therefore, essential power of expression of creativity at local scale while framing creativity in public imagination, at the same time, is essential driver of urban neo-liberal policy tool. Together, these two approaches offer diverging perspectives on, and expectations of, urban creativity. Hence, urban creativity is interpreted differently local administrators and civil groups. The former frames it as possibilities of making alternatives for virtues of economy while the latter generally uses it as socio-spatial practice of embedding themselves into locality. In this presented context in Istanbul, creativity seems to be interpreted as big urban redevelopment projects by the formal planning bodies, but social virtues of creativity were neglected. A dichotomy between the central and municipal planning bodies' strategy of suppressing opponent views and the ineffective efforts of bottom-up groups to creating dialogue with formal planning bodies prevents intermediary role of bottom-up response to emerge not just as the inscriptions of various visions of the theater associating individuals and social groups frequenting the theater, but rather develop relationship building processes between diverse groups and urban actors for maintaining mode of co-existence within the place.

Alternative Urbanism in the Historic City Centre: A Transnational Perspective on Theory and Practice

Ameera Akl¹, Krystallia Kamvasinou²

²*School of Architecture and Cities, University of Westminster, kamvask@westminster.ac.uk*

Abstract: Historic city centres are characterised by the tension between the local, represented by authentic spaces of everyday life, and the global, responding to the needs of tourism industry and capital flows. Under the neoliberal paradigm, state-led urban regeneration projects often benefit developers and private investors with little regard to the socio-economic dynamics of existing communities. Recently, this approach has been challenged by alternative practices of placemaking that represent a transition from top-down imposition of urban change to the co-production of space. Such practices are characterised by a more temporary, flexible and tactical approach to the design of space. They represent a collective desire that involves several actors, from local residents and business owners, to civil society organisations and design professionals in the role no longer of the exclusive author but as facilitators and mediators of change. Observing the development of such practice in the western world, and the corresponding theorisation attempts developed mostly by western scholars, this paper looks further to its applications in the global South, with evidence drawn from empirical research in London, UK and Cairo, Egypt. The paper suggests that alternative urbanism may be indicative of a longer-term transition towards a more equitable urban planning practice.

Keywords: alternative urbanism; place-making; co-production; community

Introduction: Alternative Urbanism

In recent years, there has been a growing interest, both theoretical and practical, in small community-based urban interventions that have been proliferating in cities around the world and their potential contributions towards activating and reshaping urban spaces. These urban practices indicate different ways of acting and thinking in relation to urbanism that pays attention to ordinary local city spaces of everyday life such as repurposing overly wide streets, vacant lands, highway underpasses, parking lots and other little-used or abandoned spaces (Loukaitou-Sideris and Mukhija, 2017). Such spaces or what Groth and Corijn (2005) describe as ‘places that are not coded for market-led development’ (506) open possibilities for urban design experiments, artistic expression and informal improvisations allowing a more vibrant everyday urban life. Even in prime locations in city centres, innovative interventions in vacant lands temporarily ignored by investors are argued to be catalysts for urban development that rework orthodoxies of conventional urban planning (Tonkiss, 2013). The approach of intervention is based on the efficient use of existing resources, local skills and knowledge to revitalise the cityscape. Alternative to neoliberal large-scale flagship regeneration projects largely based on the sanitisation and aestheticisation of space, such practices are characterized by emphasis

on the lived experience of public space to be enjoyed by all through a more creative, flexible and tactical design of space.

Despite originally emerging as urban activism in opposition to official prioritisation of economic gains and indifference towards local socio-spatial dynamics, these practices are now seen as tools for urban regeneration garnering the attention of developers and local governments, especially after the global economic downturn of 2008. Carried out formally under the conditions of austerity, such practice has enabled the synergy of two seemingly oppositional forces, community and development needs (Kamvasinou, 2015), leading to a co-production process where various stakeholders participate: from local residents and business owners, to civil society organisations and design professionals in the role no longer of the exclusive author but as facilitators and mediators of change.

Along with the development of such practice in the Western world, there are corresponding theoretical attempts mostly by western scholars to conceptualize and interpret these projects. In the academic literature, these community-oriented urban interventions are given diverse names among which tactical urbanism, temporary urbanism, everyday urbanism, or open-source urbanism. The shared characteristics across these practices are that they are mostly small-scale or incremental, cost-effective, relatively short-term and participatory, whereas the majority of published work addresses mostly case studies in Europe and North America. While citizen-led urban practices have been dominant for years in the global South as survival tactics born out of need, they are differentiated from what Devlin (2017) describes as ‘desired informality’ promoted by western scholars to capture the essence of the traditional humane city enlivening the public realm. In less developed cities, informal actors repurpose the seemingly abandoned or little used plots of land to acquire the basic necessities of life (Bayat, 2012). However, in recent years such citizen-led activism has been further manifested in the global South through a surge of urban actions involving local communities, experts and international collaborations reclaiming and revitalising ordinary spaces while embracing existing informalities and creatively setting them on the legitimate path. Even though planning institutions in many areas in the South still hold to outdated modernist clean sweep planning ideas, creative collectives mediate between the conflicting interests inventing opportunities for transformation (see Watson, 2009).

Placemaking, diversity and inclusion

Placemaking is a term that has its origins in the works of planners, urban designers and geographers such as Jane Jacobs (1962) who advocated for community-based urban design and lively neighbourhoods, Edward Relph who explored Place and Placelessness (1976), W. H. Whyte who famously researched what contributed to the successful social life of public spaces (1980), and Dolores Hayden who discussed Placemaking, Preservation, and Urban History (1988). Together with creating a distinct identity, these people-centred approaches underlie many of the current works on placemaking in research and practice, including those of the Project for Public Spaces, a consultancy carrying on the work of Whyte on small urban spaces. They have led to Urban Design being termed ‘the art of placemaking’.

Placemaking is an important dimension of regeneration projects. According to Project for Public Spaces, it is a collaborative process by which we “maximise shared value”, promote “better urban design”, or facilitate “creative patterns of use, paying particular attention to the physical, cultural, and social identities that define a place and support its ongoing evolution” (Project for Public Spaces, 2007).

Cities need spaces for diversity, social mixing and inclusion, where people meet, interact and even ‘clash’ (Dines and Cattell, 2006). Streets, squares, parks and other public spaces constitute the ‘public realm’ and such spaces link to the economy, the environment and human health (Carmona, Magalhães and Hammond, 2008). In multicultural societies such as London’s and Cairo’s, not only the design of

spaces is of importance but their control and management through private, public or community organisations. Placemaking brings together diverse actors (including design professionals, planners, elected officials, residents, and businesses) to improve a community's cultural, economic and social environment.

Local heritage is often used in regeneration projects to provide continuity, distinctiveness and a sense of belonging amidst new development (Adams, 2014), as people's attachment to an area is often motivated by their memories (Dines and Cattell, 2006). As Relph has put it "authentically made places", as opposed to places "invented or imposed", "arise when the physical, social, aesthetic and spiritual needs of a culture are adapted to particular sites, and this can happen unselfconsciously through vernacular practices, or self-consciously through thoughtful design" (Relph, 1976, 67-68).

If Placemaking is the more formal planning and design of urban space to include not just physical interventions but moreover the social and identity aspects of urban space and the communities therein – creating a place, place-shaping is similar in intention but usually more bottom up, temporary and tactical. It is incremental and organic and may lead to placemaking, but it's also more precarious and vulnerable to change and erasure. One of the key tools of alternative urbanism is place-shaping.

Under globalisation, with our cities under increasing demand, innovative approaches to the use of space have embraced temporary place-shaping (Hou, 2010). Place-shaping strategies and tactics can lead to a set of development-led placemaking strategies with the purpose of redeveloping the site while ensuring the legacy of temporary uses (Andres, 2013). Nowadays spaces can sometimes be activated almost instantly, with the aid of digital place-shaping through social media and civic engagement - the Occupy movement events in London in 2011-12 and the Egyptian uprising events at Tahrir Square in Cairo in 2011 demonstrate exactly this.

The cases we present here focus on alternative urbanism as the ability of spaces to adapt to societal, governance and physical change and the role of small urban interventions towards the longer-term shaping and reimagining of our cities.

Cairo Case Study

This alternative urban paradigm is manifested in one of the most significant central areas in Cairo, namely 'Downtown Cairo', through spatial interventions known as 'Downtown Passageways' that were initiated in 2014. The idea of the project was to revitalise the pedestrian passageways in-between buildings as alternative spaces for developing the old decaying core of Cairo.

Downtown Cairo has been the urban centre of the city, with major cultural, commercial, administrative and political activities. It was established in the late half of the nineteenth century along the lines of Haussmann's Parisian model with exquisite historical architectural styles, elegant public squares and wide boulevards, but has been experiencing significant deterioration over the past decades. Public spaces have been either securitized and underused; or extremely congested with informal encroachments, mobile vendors, clothes racks and food stalls. Moreover, being the home of the Egyptian Uprising in 2011, it witnessed unprecedented demonstrations which added a layer of complexity to the use and meaning of its public spaces. Besides the tension that arises from being the urban centre of the city with different competing interests, heritage assets, businesses and touristic attractions, downtown Cairo has gained after the revolution a national symbolic meaning of urban activism and political expression.

In post-revolutionary Cairo, after almost three years of political instability (2011-2014), the development of Downtown Cairo surfaced in the official discourse, particularly nostalgic towards Downtown's golden age with an intention to promote tourism. This nostalgically-driven approach led to more attention towards restoring architecturally significant facades and cleaning up undesired uses and activities. Emphasis on cosmetic issues would transform the area to an open air museum catering

for tourists and elites, but alienating existing communities (ElShahed, 2007). The state's plan of 'museumification' started to manifest in painting old buildings and sidewalks, white washing graffiti, and an enormous flag in the middle of Tahrir Square, the heart of the Egyptian uprising, along with tighter security, forced removal of street vendors and restricted car parking (Rabie, 2016). On the other hand, the private sector had another approach for development, particularly Al-Ismaelia for Real Estate Investment company, which is a major stakeholder owning more than five percent of downtown. El Shafie, the cofounder of Al-Ismaelia, believes in building a creative city narrative that would position downtown Cairo among the major urban centres in the world, reclaiming its lost place in global competitiveness (Rabie, 2016). Al-Ismaelia has supported creative industries in downtown such as independent art spaces, street performances and art festivals. It also has been working on buying and renovating abandoned cinemas and theatres; and leasing vacant properties for start-ups and small businesses. Both approaches of the state and the private sector raised concerns among the public regarding gentrification. The third vision of developing downtown besides the government and the private sector's is that of activists trying to find a common ground between the government, the private sector and local communities. Community-aligned activist professionals in urban design, planning and arts collaborated and established firms positioning themselves differently in relation to the formal planning system. Cairo Laboratory for Urban Studies, Training and Environmental Research (CLUSTER), a research platform and urban design practice founded by the urbanist Omar Nagati and the curator Beth Stryker, is an example of these professional entities particularly interested in downtown urban issues. Being based in one of Downtown's main streets, the CLUSTER team consider themselves a part of the local community. They can be described as practical activists who, while being keen to support less powerful underserved groups, are against demonising private investors.

The Passageways project started as a mapping and design exercise as part of an urban design studio led by Omar Nagati in one of Cairo Universities. The aim of the academic project was to propose realistic and creative urban solutions to revitalise Downtown's passageways.

The CLUSTER team led by Omar Nagati and Beth Stryker turned the academic coursework into practice, through which they established their firm after the initial conversations with the local community. CLUSTER proposed the concept of in-between-ness as an alternative framework for urban development, referring to a variety of spatial gaps between buildings ranging from passageways, commercial arcades and setbacks to courtyards, dead end streets and pedestrianised zones (Nagati and Stryker, 2016). Such spaces represent an urban typology that is less visible from the main arteries of downtown and the official public realm, allowing a more vibrant everyday urban life mediating between the formal and informal (Nagati and Stryker, 2016). In an interview with Nagati (2018) he said that without compromising security or traffic, the passageways can accommodate creative possibilities such as bike lanes, book fairs, vegetable markets and arts exhibits, nurturing a nuanced dimension of publicness.

While the CLUSTER team had a broad vision for revitalising the downtown area as a whole through its passageways, they did not have the capacity, power or resources to implement the whole idea. Nonetheless, they were willing to apply their approach partially for the experimental advantage of implementing small changes with an intention to induce activism, create social networks and potentially cause positive ripple effect (Nagati, interview, 2018). The opportunity came for CLUSTER when foreign Danish organisations provided a fund to regenerate Cairene public spaces after the revolution. Two passageways, Kodak and Philips, were proposed by CLUSTER as a pilot project under this fund. They supplemented the fund with small amounts of money from Al-Ismaelia, the Real Estate Development Company, local shop and property owners (Nagati, interview, 2018).

For the purpose of this paper, the transformation of one of the two passageways, Kodak passageway has been traced. It is in a prime location, and highly securitized as it lies across from downtown's

Jewish synagogue and close to multiple banks. Before intervention all the shops overlooking the passageway were vacant except two, and the passageway was mostly underutilised (Nagati and Stryker, 2016).

The redesign engaged Egyptian and Danish University students, artists and the local community. It involved re-tiling the passageway, incorporating tree planting, benches and gardens. Design elements were subjects of contestation and intensive negotiations; compromises were necessary (Nagati and Stryker, 2016). For example, one of the landlords complained that benches would bring ‘undesirable’ people or activities. He threatened to surround these benches with barbed wires if CLUSTER insisted on them, but Nagati convinced him to give the project with its benches one month as a test period after which the benches would be removed, which never happened (Nagati, interview, 2018). Also, municipal authorities objected to integrating benches for security reasons, thus the design was amended to present them as raised lighting features rather than explicit benches, which was officially approved (Nagati, 2018).

The renovations have produced an unexpected uniqueness triggering passers-by’s curiosity attracting them out of their daily routines. The cosiness of the space with its seats and green landscape transformed the passageway into a mini-park encouraging people to sit, meet and take a break from their harsh days. When asked what is different about this space, one of the passers-by stated the passageway “feels like home”; another said it is “serene and alive”.

In the following years CLUSTER collaborated with Al-Ismaelia a few times to organise events and curate exhibitions in the passageway and the surrounding vacant shops, which significantly added to the liveliness of the space, attracting a wide range of visitors. Such creative events have produced interesting public encounters and created a suitable environment for social interaction. The passageway and the surrounding shops have taken on an ‘edgy’ character enriching the experiential dimension of the area. Over time, the vacant shops have transformed into well-known venues supported by significant web presence. Moreover, the temporary art installations in the passageway implemented by Al-Ismaelia Company have attracted a wide range of users across different age groups and from different social backgrounds that have interacted with the art pieces. For example, in April 2017, a swing and spring-inspired decorations were installed which was a quite a novelty in Cairene public spaces. The passageway transformed then into a ‘must-visit spot’ in downtown Cairo. The narrative of creativity was further enforced by the activities of the users of the space and their interaction with the public installations. For example, the scenery intrigued a couple of university students to sit for hours to sketch the space.

Another substantial consequence of the renovations is the opening of Eish and Malh Restaurant around the corner, which quickly became one of the favourite restaurants for locals and tourists. In collaboration with CLUSTER, the like-minded owners of the restaurant organised a community Ramadan Iftar in the passageway which brought the community and representatives from the municipal authorities together (Nagati and Stryker, 2016)

After five years of the intervention, Kodak passageway is still in a good condition as it has been looked after by the local community. A board of tenants, property owners, and businesses was set after the intervention to manage the space. Although a public space, driven by their sense of ownership, they gather money monthly for gardening, trash collection, electricity water and general maintenance (Nagati and Stryker, 2016) The surrounding community are very proud of their passageway that became the ‘living room’ of the area. The space also received recognition from the local government, for example it was selected for launching events and exhibitions as one of the key sites to celebrate the International Heritage Day. Also, the minister of Tourism visited the space that was hosting a photography exhibition around the theme of promoting Egypt to the world.

London case study

King's Cross is a central London area and one of the largest redevelopment sites in London covering 67 acres of land. It has a rich historical past with 19th Century heritage assets ranging from industrial buildings, such as the Granary building, to fully operational and revamped train stations (St Pancras and King's Cross), and the Regents canal, originally introduced in the 1820s to link the city to Birmingham and the new industries of the Midlands but currently being used for leisure purposes. By the beginning of the 20th century the site was an array of 'stations, sidings, railway buildings and related warehouses', crisscrossed by railway tracks which were removed in the 1980s: 'The adjacent neighbourhoods housed the working poor and the destitute. It was not an attractive place but it worked' (Bishop and Williams, 2016, 23). The area went through decline in the mid-20th century; after the Second World War, changes in freight transfer rendered the goods yards obsolete and led to unemployment and deprivation for the local communities. Before the first redevelopment proposals were voiced in the 80s, the area was "notorious" for vacant wastelands, crime, prostitution and drugs, but also attracted nightclubs and artists as the rents were cheap (Bishop and Williams, 2016, 25). It also had a range of emerging and vocal community actors.

Various masterplans were proposed in the 80s including Norman Foster's in 1989. However, they did not materialise due to a combination of technical and financial constraints, unfavourable market conditions and resistance from the local community. In 1996 the King's Cross Partnership was set up as a public/private partnership between Islington and Camden Councils, Railtrack and London and Continental Railways (LCR), and community representatives. They sought a development partner that would have a participatory approach and ability to work with stakeholders, among other things. Developers Argent, who had successfully delivered Brindleyplace in Birmingham, won the competition in a joint venture with St George, a housing company, but they eventually parted in 2004 and Argent carried on the masterplan. The presence of two conservation areas, an important collection of historic buildings and industrial archaeology meant there was a legal requirement for a detailed application assessing the impact of the development on them (Bishop and Williams, 2016, 74); the development clearly took these into account and turned them into assets for placemaking, linking to the history of the place and local identity, and attracting tourists. English Heritage, the then advisory body for listing buildings, was involved in the process from the outset. The famous Gasholder no 8, Grade-II listed, now forms the centrepiece of the new Gasholder Park, which is bordered by a unique triplet gasholder hosting new housing – both historic gasholder structures were dismantled and reconstructed on a different part of the site. Another asset of heritage value that was respected and supported was Camley Street Natural Park, a small nature reserve and ecological heaven on the canal that had been preserved in the 1980s through successful campaigning by local activists.

Of interest to us is that strengths of the masterplan included the respectful and creative treatment of heritage assets and the focus on a diverse public realm throughout the lengthy process of redevelopment (2008-2020). Making physical and psychological connections for the local people to access the site, particularly during its construction, by introducing relevant uses on the edges and in the centre of the development was key to its success and acceptance (Bishop and Williams, 2016). This came up strongly during the extensive public consultation too, which pointed to the need to address social and economic issues including unemployment and health in the local community and particularly young people, and for 'meantime' social projects to be incorporated into the longer-term regeneration process. Temporary uses had always been part of the history of the site, particularly during the years of decline; now public spaces such as Granary square were open to the public as new civic spaces before even the buildings were occupied or built, and temporary uses such as the Skip Garden were brought in to link the different stakeholders and communities together and with the new development. The success and longevity of a temporary project such as the Skip Garden therefore owes a lot to the supportive approach of the developer.

The Skip Garden was inaugurated in 2009 in the early construction stage of the development. It is run by the sustainability education charity Global Generation (GG) and has received support from the two local authorities, Camden and Islington, local businesses (e.g. The Guardian newspaper) and the developers of the King's Cross masterplan. It consists of gardens planted in skips and maintained by young people, often from local schools, employees from local businesses and other volunteers. It was initiated by Jane Riddiford, currently CEO of GG, and the CEO of developers Argent who supported "the idea that business and activism don't have to be either end of the spectrum" (Riddiford, interview, 2013). The gardens are portable so they can be moved around the site as the development progresses through its phases. The skips represent, and were donated by, the construction companies on site (Kamvasinou, 2015).

The first Skip Garden was opposite St Pancras Station and lasted for two years (2009–2011). It moved to another part of the site awaiting development in 2011. In 2012, it moved to its third location just off York Way that hosted the Garden until May 2015 when it moved to Tapper Walk near a much shorter temporary art project, a natural swimming pond; the garden is still there in 2019.

According to Riddiford, the project is "about 65% grant funded and probably 35% through commissions, through venue hire, through the business training days", or more generally through "relationships with businesses". Part of it focuses on the Generators – young people in their late teens who join for a year and go through a programme of public speaking and learning about green issues. Through this the project can reach out to local businesses who then will actually pay to do workshops and offer internships to local young people (Kamvasinou, 2015).

The main focus of the project is to educate in the importance of sustainability. GG's aims and educational philosophy go beyond the physical site, while the 'skip' design relates to the particularities of the development site. A number of workshops and educational events have been built over the years, gradually allowing for more public accessibility, encouraging social interaction and educating about the origins of food. The project runs workshops on gardening and food growing, runs the local school Business BTec and works with the nearby textile department of the University of the Arts which is based in the Granary building. Companies such as the Guardian newspaper were looking for links with the local community and partnered up in a training scheme for their staff. The Garden has also attracted tourists and visitors to the site, who may have heard about it through the web or discover it through guided tours. This diversity of types of people or age groups has gradually come to be "the main marker of the project" (Richens, interview, 2013, cited in Kamvasinou 2015, 196). Although the garden has not been totally or always publically accessible, funded or managed, it contributes to the diversity of the public realm and placemaking through its ethos and the activities it supports.

Comparative remarks

The two case studies show several similarities and differences, and provide evidence to the application of alternative urbanism ideas in two very distinct cultural contexts. We now turn to examining some of these here, on the basis of a framework linking alternative urbanism to placemaking. This framework includes the synergies and challenges of co-production; the role of tourism; and activating urban space through place-shaping.

Co-production: synergies and challenges

Through a negotiated common ground, the Passageways project allowed the coming together of real estate developers, activists and the local community. Al-Ismaelia Company already had the intention to renovate the passageway aiming to create a coffee shop and co-working hub (Hassan, interview, 2019). Due to problems in officially licencing these uses, the proposal of the activists opened an alternative possibility for development and raising the value of their property and the whole surrounding area, while making use of local activism and winning the trust of the community. This

has helped to enhance Al-Ismaelia's public image that was linked to gentrification. In a personal interview with their head of marketing communications, she said their team operate under the slogan 'downtown for all' (Adel, interview, 2019). They promote this vision in all their community events to prove their good intentions which do not negate the importance of economic benefits to them. The vacant shops owned by the company hold temporary exhibitions open to the public for free and short-term rent-free leases are offered to creative local businesses on a condition of implementing pop-up creative installations in the passageway for the public. For example, the initiative of 'Downtown Goes Green' was launched where recycled materials were used in pop-up decorative art. Nevertheless, when interviewed about the reasons CLUSTER collaborated with Al-Ismaelia only a few times, the activist Nagati involved in the passageway project said they wanted to keep their neutral position within the community avoiding to be viewed as prioritizing economic interests over local needs.

Kodak passageway is a co-produced space by professionals and the local community. It was co-designed and people have contributed with their resources and knowledge both during implementation and through the continuous inclusive appropriation of space over time. Despite the involvement of investors, the local community retained control and ownership over the space, while nurturing a vibrant public realm and unique lived experiences for both locals and tourists alike.

On the other hand, the position of the Skip Garden in Central London highlights the possibility of producing fertile temporary 'edgelands' even within the context of high value business and an existing and successful ongoing regeneration project. The initiators were realistic about the prime location and the fact that they would have to be flexible and enter a dialogue with the developers to pursue their aims.

Consequently, the project has gained the support of the developers (although it was not part of the masterplan) and the two local councils of Camden and Islington. GG as a Charity runs the project and engages the private sector as well as local councils in supporting its funding while working towards establishing longer-term training programmes to self-fund in the future. Socio-culturally the project engages "local communities, including the local business and corporate communities, but also communities of interest: those wanting to learn more about food growing, sustainability and ethical business" (Kamvasinou 2015, 202). In kind support comes in many ways, including the donation of the skips from the construction companies on site, but further, through local businesses offering job opportunities or internships to local young people.

The concept was the brainchild of Paul Richens, a gardener. No designers were involved in the initial incarnations of the project, however temporary pavilions have been designed by architecture students from UCL at the latest site. The care and maintenance of plants also depends on the contribution of people participating in the gardening workshops. The Garden has supplied the nearby restaurants on Granary square with planters, while ongoing exchange exists with the University of the Arts textile department who use plant dyes from plants grown at the Skip Garden.

With regards to sanctioning the interventions, the two projects represent different challenges and approaches. In the Cairene context, the activist professionals followed a tactical approach to sanction the Kodak passageway project. The project's narrative was reframed for the authorities claiming that it was aligned with their beautification approach, restoring order to downtown after the political instability, while concepts of inclusiveness and diversity were understated (Nagati, 2018). The project obtained seven approvals from different authorities including electricity, water, traffic, security, and heritage preservation authorities and others; each time the design was reframed and presented so as not only to satisfy their technical requirements, but to also align with the authority's vision of development (Nagati and Stryker, 2016). Nagati (2018) explains that even the collaboration with foreign organisations was carefully presented as support for the local municipality.

Regarding the programmed events taking place in the passageway, CLUSTER took the risk of not obtaining official approvals particularly from the security apparatus when they organised the communal meal. Nagati (interview, 2018) points out “sometimes we have to take the risk”. Although the local municipality was collaborative, the idea was not welcome for security reasons which led to an argument with security personnel on site but resolved quickly (Nagati, interview, 2018). Similarly, the building and tenant relations manager at Al-Ismaelia company confirmed that they did not seek approvals for the temporary installations in the space. Nevertheless, they did not include any physical signs of advertisement for their company in the passageway to avoid legal trouble (Mostafa, interview, 2019). The head of marketing and communication shared her observations with me about the change in the attitude of the security forces existing in the surrounding area over time. They got used to people congregating in the space, enjoying their time and pausing for pictures in a space in which previously holding cameras was considered suspicious (Adel, interview, 2019).

On the other hand, the Skip Garden started as a temporary project but has managed to endure and contribute not only to the development site but to policy change. “GG have a three-year [renewable] temporary lease for renting the land, with no rental costs, the expense being borne by the developers in full. As a Charity they also benefit from tax rates relief” (Kamvasinou 2015, 193). The temporary lease has serious break clauses, to protect the developer as well as determine the liabilities and the appropriate health and safety requirements, both for working with young people and school children, but also for working on a construction site. It was one of the first of its type, and pioneered the development of what is now in the UK called a ‘meanwhile lease’ (Kamvasinou 2015).

Tourism

While Egypt in general has faced a substantial decline in the tourism sector since the uprising as tourists feared coming to Egypt due to several terrorism-related incidents, Kodak passageway represented a touristic attraction to the few tourists visiting Cairo. This is evident in the number of international visitors rating Eish and Malh Restaurant on TripAdvisor. Also due to significant web presence the space received recognition in artists’ networks attracting international artists and volunteers to exhibit their work and participate in the events such as ‘From Rags to Riches’ workshop which continued for a whole month in one of the vacant shops overlooking the passageway. Al-Ismaelia Company installed ‘I love Cairo’ signboard - a common rhetoric promoting tourism in major cities in the same way ‘I love London’ for example is on souvenir mugs and t-shirts. The signboard created a hot spot for pictures taken by tourists or locals that are usually uploaded on social media platforms attracting more people. ‘Internal tourism’ has been clearly enhanced: more people, especially younger generations, come from different parts of the city to downtown just to experience the space. Moreover, the minister of tourism’s visit is a formal recognition of the potential of the space to promote tourism.

The Skip Garden has an active and frequently updated website and has initiated promotional videos. This web presence has brought on site people from all around the world, including for example Brazil and China, which is “quite extraordinary, and wouldn’t have happened twenty years ago...That’s one of the major things, that suddenly you’re not just a local player but you’re a world player as well” (Richens, interview, 2013). Events organised there also help spread the word, and the information centre at King’s Cross run by the developers also promotes the project through guided tours. As the King’s Cross development nears completion, more people start flooding in and discovering its assets, including the Skip Garden – a different position compared to when it all started, when catalysing community engagement with the development site was the target.

Activating space and placemaking

Over a period of 10 years, as a mobile garden, the Skip Garden temporarily activated the sites it occupied through place-shaping activities but in the longer run it contributes to placemaking through

establishing longer term relationships between people – businesses and community. Its aesthetic is rather makeshift compared to other public spaces in the development, which are much more designed and polished (see Granary square, Cubitt square, Gasholder park) but that offers an alternative way of doing things that is still well-considered and serious. The Garden is still going strong ten years later and has become part of the identity of the new place, attracting both locals and visitors alike.

However it is unclear if the Skip Garden will stay on when the King's Cross development is completed. Some of the ideas for its future are, for example, to make use of green roofs on the new buildings or barges on the Regents canal. This highlights the precarious character of alternative projects but also the importance of flexibility.

Similarly, the Kodak Passageway project situates placemaking between two modes of intervention regarding time. The first incorporates permanent landscape alterations, while the second involves both spontaneous and programmed temporary activities or installations that leave no traces in the existing surfaces or structures. In both modes of intervention, throughout the process people were drawn out to the streets building social networks which triggered chain reactions and further interventions catalysing urban development in a long-term perspective (see Lerner, 2014). Therefore, alternative urban practices are sustainable in terms of creating a network of actors, as collective appropriations are expected to continue responding to new opportunities and new aims. Even temporary transformations of a space, which terminate by the end of the activity, do not always return to the pre-existing form but morph into something new (Dovey, 2016).

Both projects suggest “a different public realm to that proposed by mainstream urban design in the context of the neoliberal city, where emphasis is on commercial activity and which is often eroded by privatization and the exclusion of lower-income groups” (Kamvasinou 2015, 203). Activities that connect rather than divide, such as art, social events or gardening, create a public realm where people can meet, interact, reach each other and ultimately overcome their preconceptions and assumed differences. The often makeshift nature of the alternative urbanism projects, as opposed to the high-end public projects in city centres, makes it easier for some people to physically engage with them through designing, constructing, using or being responsible for their upkeep; they assume ownership and can see the impact on their everyday lives and neighbourhoods. “This diversity is much needed in the public realm of today because it caters for a variety of people with different disposable incomes, social status, ethnic background, age, gender or, more generally, interests” (Kamvasinou 2015, 203).

Conclusion

This research sought to address the potential of community-based urban interventions as a phenomenon and how it is reflected in theory and practice from a transnational perspective. As Friedman (2010, 161) has put it, “there is no single, best method [of placemaking]; each way is culturally attuned and has its own historical trajectory”. The versions of alternative urbanism we have presented here confirm this. Both our cases, however, point to a transition from top-down imposition of urban change to the co-production of space generating uncommodified urban spaces that are not solely controlled and maintained by the state or the private sector. Within the historic centre of the city, in both Cairo and London, Kodak Passageway and Skip Garden projects represented catalysts for urban development away from the conformities of mainstream urban regeneration projects. At the same time, they empowered local communities to become key participants in this transformation. In both cases, there seems to be a shared transition towards more acceptance of initiatives that are not part of the official plan – of the developer or the state. Although this has led to policy change in the case of London, in the form of the meanwhile lease, such transition in planning policy is still awaited in the case of Cairo. Alternative urbanism is not a universal form of action as the idea has been articulated to address different problematic urban settings in different ways. The alternative approach proposes injecting informal activities to enliven sanitised contexts and conversely embracing informal landscapes to enhance the use and quality of deteriorated environments without pushing away the poor or prohibiting everyday improvisations. Alternative urbanism as a concept places design at the

interface between the formal and the informal: it creates a lived space open to individual and collective appropriations reflecting the complexity of the city and suggests a transition towards a more equitable urban planning practice.

Research on the improvement of urban public space vitality based on the concept of social resource sharing—taking Tianlin community in shanghai as an example

Qianwen Li¹

¹Tongji University, 15316099679@163.com

Abstract: Based on the concept of social resource sharing, this paper takes Shanghai Tianlin community as an example and proposes feasible suggestions on how to improve the vitality of public space in the stage of urban accumulation and development. The Tianlin Community is located in the east of Xuhui Innovation Industry Park which brings a rich cultural and scientific resources together in the downtown of Shanghai. With the increase of land prices, the widening gap between the rich and the poor is obvious and the serious closed community phenomenon have led to the problems of weak public continuity and low vitality of the public space. The author selected 20 different public spaces in this area and evaluated them with five criterion: surface, identity, commerce, leisure and accessibility. By the usage of Grasshopper, a five-minute network of local connections with different degree was finally formed and found: (1) The area is not accessible everywhere and fragmented in different parts; (2) The area has some spaces in need for certain qualities while there are other spaces around have corresponding quality which can help to balance. In order to improve the accessibility of these 20 points of interest and sharing the public resources, the author tried to propose strategies of connection and balance to enhance the vitality of the public space in the Tianlin community: (1)Based on the current situation, increase the public access and visual corridors between the semi-closed community and the closed community; (2) According to the evaluation of surface, commerce, leisure and identity, provide various equipments in four categories to improve the wickest points. Through such strategies, it is possible to achieve a fair social resource sharing of the public space to the greatest extent, while at the same time solving the unbalanced development of different regions.

Keywords: public space; vitality; accessibility; closed community; social resource sharing

0. Introduction

In China, when talking about the vitality of urban public space, it is necessary to mention the public space inside the community area where people live in every day. There is a saying that "residence changes China", China is a large country with a population of 1.39 billion. In order to improve the quality and fun of people's daily life, the transformation of its daily public space is crucial. In other words, where, when and what the residents are doing in the city determine the vitality of the urban public space to a certain extent.

However, closed communities in China are a very common phenomenon. The lack of open-type models in communities has caused a number of urban and social problems, making

residents living in the same community unable to enjoy a completely equal outdoor public space, one of the important reasons that has led to the decline of the vitality of urban public space. In the face of the national policy of “promoting the block system and gradually opening the closed community and danwei courtyards”. How to change the situation, the unfair public space causing by the closed community will also be a big problem that China needs to face for a long time in the future.

This paper will first discuss the formation process of China's closed community and the urban public space problems caused by it. Taking the transformation of Shanghai Tianlin community public space as an example, this paper introduces the current situation of the use of public space and proposes some transformation strategies to enhance the vitality of its public space. I hope this article can be a reference to China's future urban public space development.

1. Background

In February 2016, in order to further strengthen and improve the urban planning management work, the Chinese government issued an important document of “Several Opinions on Further Strengthening the Management of Urban Planning and Construction”, which proposed that the new community buildings in China should promote the block system in the future and no closed community will be built. The completed community and danwei courtyards should be gradually opened to achieve internal publicization of roads and promote land use and utilization. The proposal of this policy shows that the state is paying more and more attention to the fairness and justice of urban public space. If the closed community is not conducive to the use of public space, then conversely the open block is an important solution to improve the vitality of urban public space.

However, the social development model of China's closed community has lasted for more than half a century, it is very different from the formation of the gated community in Europe and America. Now suddenly opening up the closed community which has been built, it will inevitably face conflicts with the current Property Law. More importantly, this is completely contrary to the concept of “deep house courtyards”. Chinese people have been pursuing for long, which is one of the typical concepts in traditional Chinese culture. In the past, Chinese urban residents have experienced siheyuan, danwei courtyards and now the closed communities, the only constant situation is "closed." It is no exaggeration to say that there is no home for the Chinese to have a room with no wall. Therefore, opening up the closed community is definitely not a one-step process, and it is necessary to constantly explore the transformation mode of the transitional stage.

2. The formation process of a closed community in China

2.1 Superblock mode

Tracing back to the history of China's community planning, it can be found that the concept of the community originated from the Soviet Union during the period of large-scale industrialization and was completely transformed in China. In the 1950s, after the Korean War, China formulated its first five-year plan (1953-1957), attempting to carry out comprehensive industrial modernization. The Soviet Union provided direct assistance which

including technology, equipment and labor force for 156 key projects in the "First Five-Year Plan." Therefore, China naturally began to seek experience in architecture and urban planning from the Soviet Union and the socialist countries in Eastern Europe (Huang, 2016). The superblock model from the Soviet Union was first used for experimentation which is Stalin's favorite. It emphasizes symmetry and enclosing space, but there are countless shortcomings. For example, residents living inside have only west windows and have to face the streets, a series of problems such as noise, pollution, and air convection generating here. Therefore, the pattern of the superblock soon was abandoned.

2.2 Microdistrict mode

As Chinese urban planners focused more on the economy and utility of community, a Soviet model called microdistrict caught the attention of planners. Actually, the microdistrict model was essentially indistinguishable from the superblock model, which is a basic unit of urban community with a relatively complete cultural and welfare facilities and surrounded by urban main roads.

2.3 Danwei courtyards

In the 1950s and 1970s, there was a big change in the development of community in China. At that time, a large number of communities emerged and the most widely accepted community planning model at that time was the danwei courtyards. Subject to the urban planning concept of the Soviet Union, China, which is learning from the Soviet Union, also put forward the slogan of "production first, life second". But we did not simply imitate the Soviet Union, we invented a unit model with some kind of Chinese characteristics. The Soviet Union allowed the distance between the community and the workplace to be no more than 40 minutes of commuting time. In China, the unit (Li,2017) was integrated into a place where living and working were integrated, then the danwei courtyards was born. However, the units built in the 1950s were not equipped with walls. Since the 1960s, various units have started building fences and walls. Danwei, as economic entities that combine production and consumption, are inevitably exclusive. The society is not equal, as the unit needs to rely on the wall to protect its own land and resources from the invasion from other area of the city, and also some other danweis.

2.4 Commercial housing mode

The failure of the planned economy and the decade-long Cultural Revolution have subsequently caused serious housing shortages for a long time. After the implementation of the economic reform policy in 1978, the Chinese government also implemented a series of reforms on real estate. The task of community development gradually shifted from the government to the private developers, and the commercial community development model gradually emerged. Although the planning department did not force developers to build closed communities, the development model of "who develops and who provides the facilities" set by the developers make it necessary for them to build private houses such as community and commercial buildings in the sites and they are also responsible for the common parts of roads, parks, and leisure facilities. The cost of the developer's construction part is shared by all the owners of the community, so the developer must make the public ownership of these

public facilities inside of the community. At the same time, the property management company introduced by the community has also played a role in promoting the closed community. According to some scholars' research, in 1991-2000, 83% of the communities in Shanghai were closed in this way.

3. The issues of public space development caused by closed residential

3.1 Social security issue

The closed community has greatly improved the security of the community by establishing the fence wall and the management of the property management companies, but it has increased the crime rate of urban public space outside the community. There is an old saying in China that "the skin does not exist, the hair will have nowhere to attach", and the complete separation of roads and communities has led to many unattended streets in cities. On the other hand, the security of public space is mainly achieved by neighborhood monitoring. A sufficient number of pedestrians and abundant street life are the main means to ensure the safety of urban public space. The closed communities greatly limit the natural surveillance of the inner public space by the police and the public.

3.2 Class isolation issue

E. Saarinen (1943) has proposed that "housing should mean home and a healthy environment, not just the walls and roofs made up of shelters from the wind", which means that the house shouldn't be limited as a living function (Lv,2006). It is also an important place to operate social relationship. Closed communities are manifestations of people's distrust of each other and even exacerbate the contradictions of different social classes. People of different classes live in different closed communities and social circles. Such social isolation has caused social unrest, resulting in people's selfish, xenophobic, and prejudicial characters, which seriously threatens the social harmony and the fairness of public space. Spatial justice is the foundation of urban vitality research, which is the key point for improving urban vitality (Cheng,2019).

3.3 Split urban public space

The formation of the closed residential is just like a cell whose cell wall protects the interior space well, but cuts off the connection between the internal and external space. Many public spaces with strong continuity have been cut off by these residential. Residents in the same community but not in the residential cannot enjoy the same public space. For example, some riverside green spaces will be blocked by residential, and people cannot walk or run along the river. Therefore, people can only do some activities in parks and squares, the scope of activities is very limited, which is also one of the important factors affecting the vitality of urban public space.

4. Exploring ways to improve the vitality of urban public space in community——Taking Tianlin community as an example

4.1 Introduction of Tianlin Community

4.1.1 Location

As seen in figure 1, our site is located in Xuhui district, southwest of downtown which is famous for its strong economic and culture, what was considered as the French Concession in the past. Huangpu River is an important canal in Shanghai and its formation is closely related to the flood-discharge of Taihu lake. The river flows from Panlong port to Huangpu River and Puhui Tong surrounding the bigger area of the site is part of this flow. The project site is situated in the northeast corner of the area.

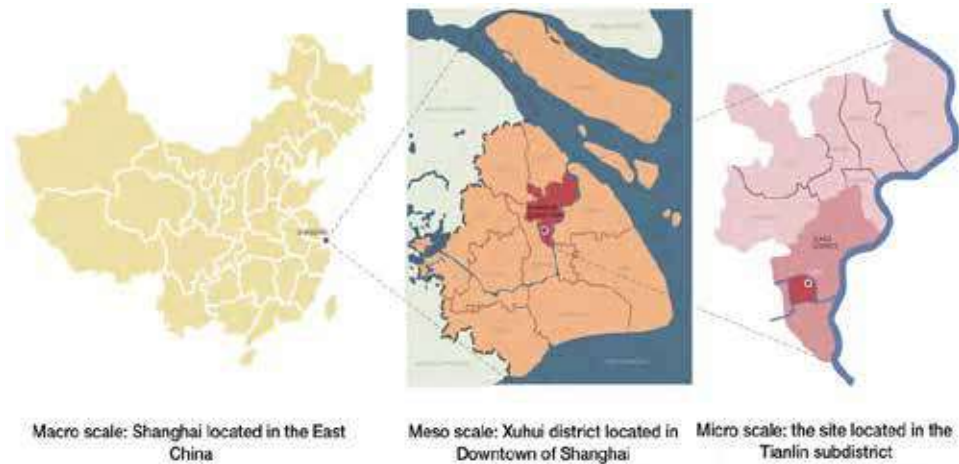

Figure 1. The location of the site from macro to micro scale

4.1.2 Built environmental factors

(1) Typology of residential buildings

The types of buildings in the Tianlin community are obviously different. Through field interviews and a large amount of network data collection, the height, shapes and year of construction are summarized. As seen in figure 2, most of these residentials are high-rise buildings, the newer the buildings, the higher the building's height and the old residential mainly distributed in the west of the Tianlin community. By comparing what we feel from the interview, we can also find that the more the residential buildings are of a lower height, the more the inhabitants are closer and know better each other. The more the community buildings are older, the more the inhabitants feel the sense of community as they know each other in comparison to new residents who have moved here recently. It is obvious to know that the built environment can affect the social relations among residents here.

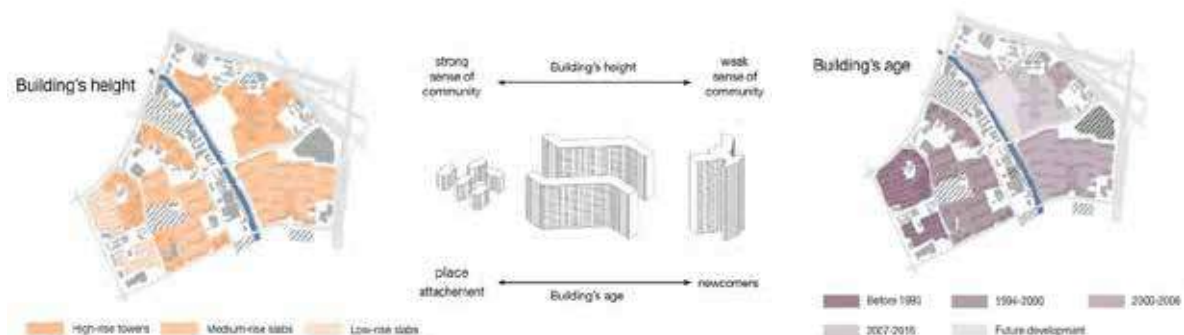

Figure 2. The typology of residential buildings in Tianlin community

(2) Resource analysis

The area is covered by bus system operating around 23 different bus lines while the metro provides 5 lines nearby: line 1, line 3, line 4, line 9, line 11 (Figure 3). It's sure that the Tianlin community has very convenient transportation resources for people to come here. Besides, the site is mainly supplied with restaurants, banks, cafes and shops. However, these commercial services are mainly distributed on the boundary of the site. There are not many destinations of that kind within the inner area which is composed of different residentials.

Figure 3. The resource analysis of the site

(3) Law of people's activities

By monitoring from 10 am to 8 pm, a total of six time zones of Baidu Thermal Map, we can easily find that people are mainly attracted by commerce, office and metro stations to move around the area but most of the time they spent in the boundaries of the area without getting inside (Figure 4). Especially during rush hours, there is the biggest flow of people around the site.

Figure 4. The law of people's activities in different time from Baidu Thermal Map

4.1.3 Public space

(1) Public space plaque selection

The area has around 20 points of interest which were chosen by a subjective criteria from the site survey (Figure 5, Table 1). Some of them are well-designed, suitable for leisure, commercial activities, others lack equipment, identity, have more greenery or are more lively. One of the main problem is that these areas have a different level of accessibility as there are big gated residential within the site and semi-public spaces in most cases not accessible to the inhabitants.

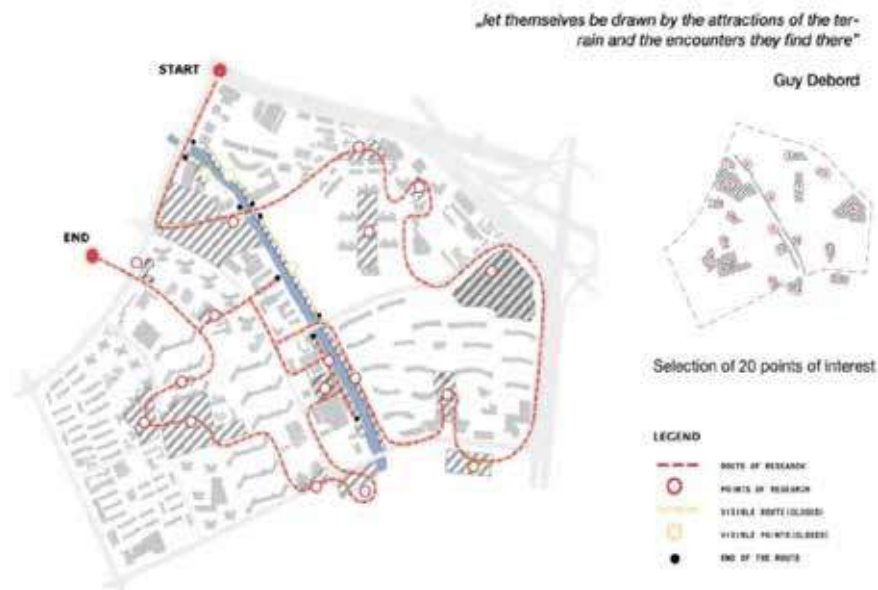

Figure 5. Public space plaque selection

1	Parking lot next to the bridge	2	Closed waterfront linear greenery	3	Greenery slope
4	Closed linear greenery	5	Community center	6	Community greenery
7	Greenery inside the gated community	8	Ikea	9	Waterfront behind the flower market
10	Open waterfront	11	Flower market	12	Square inside the gated community
13	Shopping mall	14	Waterfront of eagle park	15	Commercial front
16	Tianlin central park	17	Greenery inside community	18	Space between two apartments
19	Urban living room	20	Commercial corner		

Table 1. Selection of 20 points of interest

(2) Accessibility of public space

Due to the establishment of closed residentials, the accessibility of public spaces within the Tianlin community is very poor, and many places cannot be arbitrarily passed through. And these public spaces are not systematic. Different gated forms of gated residentials make up most of the space in the area (Figure 6). Furthermore, only streets can be classified as real public space. Gates prohibit a free access for people to many spaces of the area. Therefore, the public space in which people living in the Tianlin community can operate is very limited. As seen in figure 7, there are different arrangements along the canal, from a well-design public spaces, frequently used, to a waterfront not accessible for public. Many residents living here have never even visited the waterfront space adjacent to Puhui Tong.

Figure 6. The accessibility of residentials

Figure 7. The accessibility of waterfront

(3) Summary of public space features

From our first impressions and further analysis of the waterfront seems to be a clear division and imbalance between different sides of the Puhui Tong which is the consequence of the built-environment but also lead different lifestyles: Older-Newer, Traditional-Modern, Permeable-Impermeable, Downscale-Upscale, Shared-Private, Local-Globalized. The types of public spaces within the Tianlin community are very abundant, but there are also large differences and low levels of integrity. On the whole, the frequency of use of public space is uneven, and generally low, as the vitality of space is truly low.

4.2 Concept—Social resource sharing:providing opportunities for the inhabitants to rediscover their place of living

4.2.1Goals and Vision

The concept of social resource sharing is a concept proposed for the closed community which bring about the separation of urban public space. Through this concept, the utilization rate of urban public space resources can be effectively improved, and the waste of idle space can be reduced. At the same time, it can also effectively activate people's awareness of the protection of the public environment, so that everyone can rediscover their place of living. In

other words, we would like to create a neighborhood that apart from meeting inhabitants' desires in terms of comfort also provides opportunities of a better life by getting them in contact with new experiences and people rather than mere existence (Figure 8).

Figure 8. The metaphor of the concept

4.2.2 Methodologies

The site is totally divided into several parts, especially between west and east, as a consequence of the built-environment and different lifestyles. After the site survey, obviously the 20 buttons can be divided by two dimensions (Figure 9): One is the landmark, which are designed for all, attracting people also from outside (places embedded in public space). And the other is the urban living room, the place for the community to socialize, gather together (places embedded in private, semi-public space). After we evaluate the 20 points of interest from surface, identity, commerce, leisure and accessibility, we can visualize the site that need more design according to each of criteria. We find that the spatial attributes of different urban public spaces are quite different and lack close relationship with each other, which means that there is a serious problem of separation in public space in Tianlin community.

Figure 9. Two dimensions of the 20 points of interest

4.3 Reform Strategy for Enhancing the Vitality of Public Space in Tianlin Community

4.3.1 Connect: Enhance the correlation among public spaces

We can easily find that the area is not accessible everywhere and fragmented in different

parts. So what we would do is to provide new paths to link the twenty points in order to make the whole area more accessible, not only where there is a need for new design but connecting all the areas of the intervention.

According to the 5-minute life circle, we defined threads with the usage of grasshopper based on the 5 min walk radius (340m), and create a five minute network of local connections (Figure 10). The external manifestations of these connections can be bicycle lanes, walking paths, jogging paths or just a visual corridor, which in turn forms a relatively continuous and logically public space system. Then the next question is how to attract people to visit the 20 public spaces along the space path we designed, to rediscover the living space they live in.

Figure 10. A five-minute network of local connections

4.3.2 Balance: Balancing the spatial attributes between public spaces

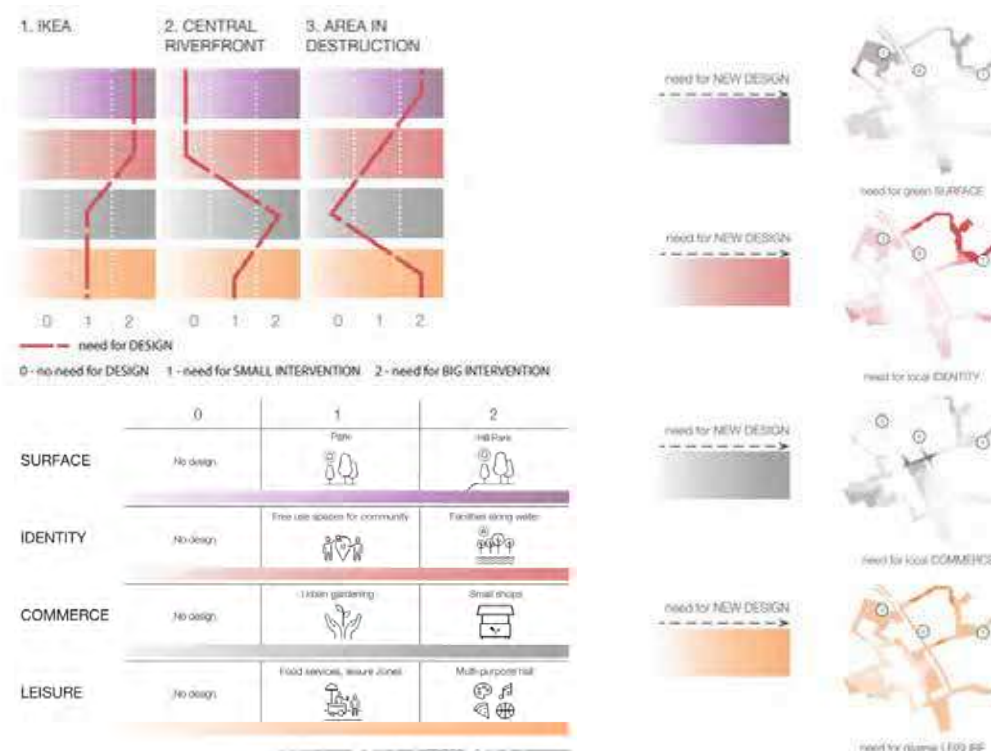

Figure 11. Reform strategies of balancing the spatial attributes between public spaces

The area has some spaces in need for certain qualities while there are other spaces which

have this corresponding quality. According to the evaluation of surface, commerce, leisure and identity we provide various equipments in these four categories to improve the wickest points so that there will be a certain balance between the various public spaces (Figure 11). According to the evaluation of the status quo, we divide the degree of each point needs to be designed into three levels: no need, need for small intervention and for big intervention. Take the central waterfront for an example, the current surface and identity is good enough, so what we need to intervene is to provide more commercial facilities to attract people to visit here. On the other hand, the quality of its leisure space needs to be improved, providing more leisure activities for people to enhance their public space, it can be food service and also multi-purpose hall. And for the commercial service of area in destruction is very good enough, but its scores of surface and leisure is really low, indicating that this area needs to improve its environmental function and quality.

5. Conclusions

The popularity of closed communities in China is the result of historical factors, social development and many other factors. Although, it satisfies the pursuit of safety and living environment quality within the community to some extent. Such development is limited and the negative effects on urban public space cannot be ignored also. If we compare the city to a giant organic organism, then the closed community can be regarded as a parasitic body with incomplete functions. Its wall is equivalent to a semi-permeable membrane, which filters and blocks the exchange of energy and matter. However, the closed residentials, must rely on external functional organs to function properly (Zhang and Wang, 2013)

Therefore, through the concept of social resource sharing, we continue to unblock the community and enhance the continuity of urban public space. This matter is related to the fairness and justice of the urban public space, but also reorganizes the separated social relations, allowing people to get out of closed work and living spaces, to promote interpersonal communication. These practices are of great significance to comprehensively enhance the vitality of urban public space, and hope to provide reference for the future development of Shanghai's public space.

Recent developments in Cultural planning as an approach to build creative cities

Raghavendra kattimani

Research Scholar, at Department of Architecture and Planning, Indian Institute of Technology Roorkee, India, email:raghavendraskattimani@gmail.com

Abstract

This study is basically a review of works of cultural planning across the world and particularly relating it to the urban planning, and other disciplines related to urban planning. This paper discusses about the different definitions and dimensions of culture in the urban planning practices. From the definition of culture to inclusion of culture in urban planning which involves a multipronged approach. It has looked into this through published works and best practices followed in different parts of the world. Culture of place is understood through cultural assets which are classified into tangible and intangible. Implication of classification of these assets is looked upon through the lens of urban planning policies and different development sectors related to the planning and management of cities. Some of the examples from Europe, Canada, and USA and Asia are taken into consideration. At the end observations are analysed for the suitability of the cultural planning theory for adoption in urban Indian context and future possibilities.

Key words: Cultural planning, Urban culture, Creativity, Creative city

Introduction:

Out of some of the literature about cultural planning, first to mention is the 'idea that cities ought to refashion their economic and development policies and planning regimes with an aim to become 'creative cities' (Landry, 2000). Prof Landry is the one of the few instrumental people in globalizing the idea of creative cities and cultural planning, where he emphasized on investment in the field of cultural capital for natural development of cities. City's cultural capital would transform into creative capital and act as an engine of growth in that particular place. Cultural identity is a very unique to any place or a city. This Idea of identity though culture brings a healthy competition among the cities in terms of development of creative capital. Each city has the pride in its diversity of cultural spaces and cultural capital, the supposed 'creative class', who are imagined as a vital demographic group to capture as in-migrants, for the investment and innovation, they bring with them (Florida, 2002). This intellectual human capital and their contribution brings value to a place. The cultural transformation through migration of different people of different background, ethnicity, occupation, geography would help in building the new age cities with balance diversity in the time of globalization. This would help in improving the knowledge based economy of the city as it's a symbol of cultural tolerance and acceptance. Another critique would be that creative transformation in places fuel gentrification, especially in the inner city...as deindustrialization gains pace in European cities (Gibson and Homan, 2004). This is in contrast with the Florida's idea of rise of the creative class help bridging the gap between old and new. These debates look into the culture as a traditional art form rather than the generator of economy, in terms of sound human capital with creative benefits. Mr. Landry looks upon culture as the lifestyle of every citizen of a city, the way we live influence our surrounding also the vice versa hold true that surrounding influence the way one lives and shows creative abilities through cultural activities. This is where the planning of cities, cultural and creative capital art related.

Review and critique on cultural planning that represents a relatively straightforward urban planning, economic, social geography, observation and theoretically informed theories related to America such as Fordism and post-Fordism, agglomeration and cluster theory, etc. (Gibson and Kong, 2005). One can see idea of cultural planning and economy related to it is also an effort to brake from the shackles of industry driven cities. It might have taken some time to finding the gap of culture in the madness of industry driven cities. Recent literature shows this ideas of culture and cultural planning are gaining popularity in the middle of critiques. Especially economy of culture is a subject of brainstorming among scholars. Turning from normative cultural planning to other dimensions of culture and creative capital of cities (Markusen, 2006) Globalisation, industrial towns and post modernism, idea of creative class, these theories only look at city culture as capitalist driven commodity which cannot be held true, as the culture plays wider role in day-to day happenings of a city while helping its sustenance.

So First we will try to understand different meanings and contexts of culture and try to find out answers for some questions, Such as what is culture? What are the types of culture? What are the cultural assets and why do we need to plan for these cultural assets? What is cultural planning and creative city and how these both are related? How creative city concept evolved? Why creative industries have to be incorporated in planning policies? How to quantify Cultural assets and Creative industry's significance to analyse potential and opportunities? And will discuss about some Best Practices around the world for Cultural planning. Will discuss about the tools and techniques used and practiced around the world to incorporate culture in planning and Cultural tourism. The focus will be to address how it has to be done.

Definitions and Notions

Meaning of Culture as mentioned in Webster's dictionary, culture is originated from the Latin word "Cultura" Which means "cultivation". Roman orator Caesar described the word Culture as the "Cultivation of the soul". There are many other scholars gave a wide and acceptable definition of culture relating it with urban spatial studies. Culture is "Universal human capacity". (Taylor,E.B. 1974) which is a generalized definition, it signifies universality of culture. "Culture is the folk-spirit having a unique identity and culture is the cultivation of waywardness or free Individuality" (Velkley, Richard, 2002). This signifies the identity of a city is its culture which is nothing but the way of life of that place.

Broad Classification of culture:

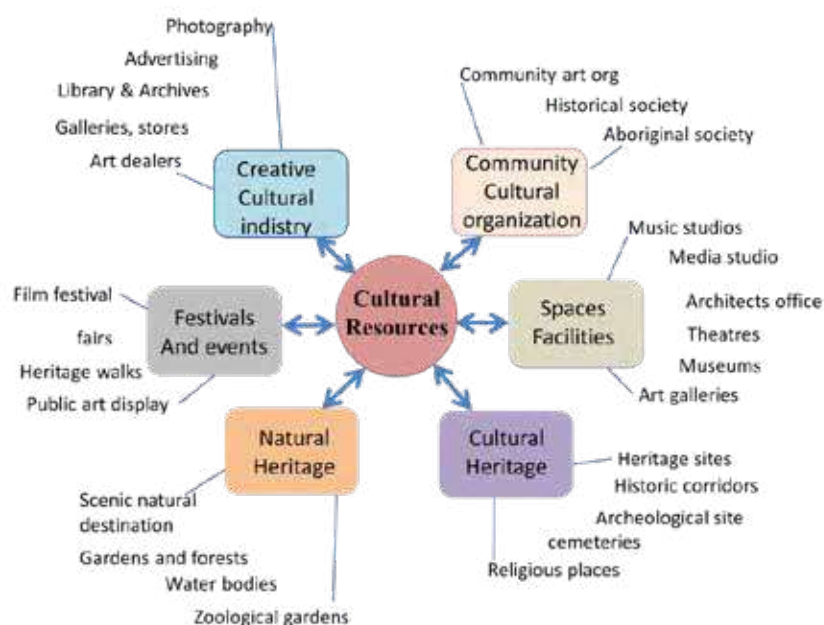

Figure 1: cultural resources.

The figure 1 is prepared based on different generic sources. Mainly from cultural plans of city municipal corporations of Chicago, Hamilton (Canada) and Barcelona. It shows enormous possibilities of inclusion of culture into urban planning process.

Culture can be classified Based on various parameters, The Basic and Broad classification can derived as shown in figure 1. Considering the culture a way life, Rituals, Values, Beliefs, Costumes, Laws, Architecture, Festivals, Gatherings, Natural Heritage, Native Industries, Spatial identities etc. can become cultural elements. Depending on the Definition of culture, these elements vary with the context of place and study. Culture can be elaborated differently with different knowledge domain. But broadly it can be divided as mentioned above, based on Geography such as Asian, European, American or African again considering smaller geographical areas as French, Punjabi, and Tamil etc. Likewise Different languages, Ethnicity, Wealth such as High and Low, Based on Different Time Period as Gothic, Indus valley, Greek civilization etc. And Last but not least the Power and Political Culture which can influence all other cultural aspects. For example Democracy, Communism, Monarchy, etc.

Cultural assets can be classified broadly into two categories that are: 1) Tangible assets - Physical artefacts, Built and Natural Heritage. It is also called as material culture. 2) Intangible assets - Such as language, customs, traditions, rituals, sense of place etc. Different techniques can be used to map the culture. Which, we will discuss with some examples and Best practices.

Relation between culture, creative city and urban planning.

So, what is a creative city? Charles Landry in his book “Creative City” says, “In simple terms creative city is the one where innovation happens”. The idea behind this is, there is always more creative potential in a place than known. This notion of creativity lies in the culture of opportunity given to every individual to be part of problem solving community of city. Every individual gets an opportunity to present his imagination and knowledge to address a problem of city one lives in. It can be addressing the transportation problem, Homelessness, improvement educations facilities, recreational facilities, conservation of nature and Heritage, or it could be a solution to hygienic living. Where these idea come from? The culture of the city and the community are reasons for the problems as well as solutions for place to develop. The idea of creative city is to bring in the existing potential of culture to the forefront of urban planning and development process. To establish the relation between economy, culture, other urban dynamics and policies. To be a creative city the soft infrastructure includes: A highly skilled and flexible labour force, dynamic thinkers, creators and implementers (Markusen,2001). So one needs the creative minds who would bring innovation in the field of urban sectors. Urban components Social and Physical infrastructure to works on need creative brains as the software, So this clarifies culture led creativity is crucial for better development of urban centres. Now let us look into the existing system where culture is omnipresent and how it is perceived in the current urban planning scenario

Recently Municipal organizations across cities have tried to inculcate a culture into their development schemes and have formulated definitions of cultural planning based on expert studies “Cultural planning is often explained as a strategic approach to urban cultural development; an approach that involves the ‘mapping’ and leveraging of a wide range of ‘cultural resources’ (arts, culture, and heritage)” (Kovacs 2011). UNESCO has approved two documents (2001 and 2005) on this subject. In 2001 the Declaration on Cultural Diversity, it emphasises on the acknowledging the cultural wealth of a place and it implication on diversity and human rights. In 2005, the Convention on Cultural Diversity, It advocates the need for diversifying the production means of goods and services to the local level rather than centralising it to some countries for short term economic greed and selfishness of capitalist countries.

The UN Habitat State of the World's Cities Report, 2004, notes, for example,

“...the growing trend of refurbishing and re-branding cities as cultural havens - a creative attempt by many local governments to revitalize economies in need of urban renewal mechanisms....Whether or not a city has a cultural heritage to draw upon, or merely a survivalist's need to succeed, banking on the financial draws of culture – be it artistic, historic, athletic or religious - has proved to be a blessing for many urban officials and planners... On the assumption that culture can be a motor of employment growth...”

UNESCO creative cities framework, 2012, classifies Cultural assets of a city into two broader categories that are 1) Tangible assets - Physical artefacts, Built and Natural Heritage. It is also called as material culture. 2) Intangible assets - Such as language, customs, traditions, rituals, sense of place etc. which by far now has been reflected in many scholarly works. Through available scholarly literature one can say that recently it is happening around the world. Many local governments are trying to address the gap of culture in the urban planning process to tap potential of culture in transforming urban scenario through cultural plans. To mention a few examples, Toronto, Chicago, Barcelona, London, Vancouver, Paris has cultural plans prepared for a period of ten to twenty years. Other cities in different continents such as Thailand, Singapore, Sydney, Doha local bodies have adopted mechanisms to include cultural assets into urban planning strategies.

The Barcelona cultural plan was envisaged in 2009, planned for 10 years. Underlines three goals 1) to create environment in a city which brings different communities together for inclusive progress 2) Ease of equal access to cultural places, goods and services 3) To encourage every citizen to express their ideas for the public problem solving. These goals bring in more number of people with different background and different development domains together which increase the cultural interventions in the development of the city. Often it talks about accessibility of more programs and facilities for all the citizens of the city. This is more of a Policy document outlining different schemes and programs for inclusiveness.

The Mayor's Cultural Strategy for London 2012 London cultural strategy emphasize upon six categories that are Education, skills, career, Infrastructure, environment and the public realm. *“...Education considered as strategic approach that helps to coordinate existing activities, build links between cultural institutions, schools and local authorities and raise awareness of the high quality provision on offer...”*. Skill based careers offer a wide range of opportunities in cultural sector leading to own business rather than youngsters opting for company jobs. “Great outdoors” initiative to improve public space, streets, water bodies, green spaces, Public art which would enable public communication and interaction are included as a strategy.

Chicago cultural plan 2012, Emphasizes on the broader civic impact of cultural activities and communication through culture, through community development programs for economic growth. Similarly Sydney's cultural strategy 2014, is sector based, the emphasis is given to cultural tourism and the tourist experience of the city. The entertainment industry is the main economic generator of the city's creative industries. So now look at the international framework provided by the United Nation's cultural arm, UNESCO, gradual progress in the field of cultural strategy and development relating it to urban planning and economics is apparent in the last 3 decades. Which can be substantiated by scholarly literatures.

The rise of idea cultural Planning in Europe and USA is acknowledged by number of academic works and also by some of the city authorities. Academicians and researchers have been trying to distinguish between

art policies of industrial towns and culture as the engine for the growth of a city. There evident is the difference between arts policy and idea cultural planning. It is often asked whether the cultural planning is not simply ‘a fairly traditional arts policy’ with another name (Stevenson 2005). This is a matter of discussion and critique since the early 90s (Kovacs, 2011) that how cultural policy is not merely related to arts it can be much more than that. It has been three decades since the idea of cultural planning emerged in contemporary world. Most of the research available on the topic is non empirical and based on mapping and available economic statistics. The advancement in terms of cultural asset mapping is limited to spatial mapping of tangible assets but there is not much advancement into how these result can be incorporated into existing development plans. The most of literature found seek to move away from the idea culture as art policy (Mills 2003, Kovacs 2011) to culture as an approach to build new cities where creativity of citizen help cities to develop. This clearly shows in spite of push for cultural led urban planning, urban policies have been adopting economy focussed cultural inclusion rather than cultural based urban planning approach.

Considering the Indian Scenario, the Union government has a Ministry of culture which are responsibilities limiting to Arts policy and conservation of historic monuments and Ministry of Urban development is totally a different set. All different departments at top government level work in isolation for example body responsible for conservation of monuments looks after monuments without any regards to the regional aspirations of the place those monuments are situated. The tourism department looks into the profit side of the monuments without considering the broader infrastructure and natural resource backing. This scenario is also seen in many other European and Asian countries. So the policies made by the central government serve as examples of city municipal corporations, even if local bodies have a better understanding of their cities. So the bottom approach for the policies regarding urban development is the need of the hour for cultural based development. Since the land is a state subject in an Indian Federal system, some of the states have passed different culture and conservation guidelines for the municipal local bodies. To mention few, Delhi urban arts commission, Jaipur heritage guidelines, Mysore heritage development plan, Ahmedabad heritage city guidelines etc. Most of these city guidelines focus exclusively on heritage conservation and tourism focussed development. However, good, these are for Heritage conservation since these do not emphasize on living culture as the heritage. Also urban planning bylaws and guidelines are prepared without due consideration of living cultural assets.

Possibilities in the cultural planning

Looking through the above literature, some of the basic questions would arise. Is there a framework for inclusion of cultural assets, both tangible and intangible in urban development process? What are the policy preferences are in place to consider culture as the driving factor not only as arts policy? Can we relate culture with spatial dynamics in city planning? Is there a method to quantify cultural assets so as analyse its impact on urban dynamics such as transportation, social infrastructure? Would culture help in better development of human capital in terms of Quality of life? Does Culture influence creativity leading to innovation, thus helping the development of a city into a better civilization?

Hypothetical idea of the relation between Culture, cultural assets, urban spaces, urban economy, sociology, Cultural geography, urban planning, governance mechanism, could broadly be established diagrammatically as drawn below in table 2. This leads to the next stage of the further research in the field of culture and urban planning.

The possibilities

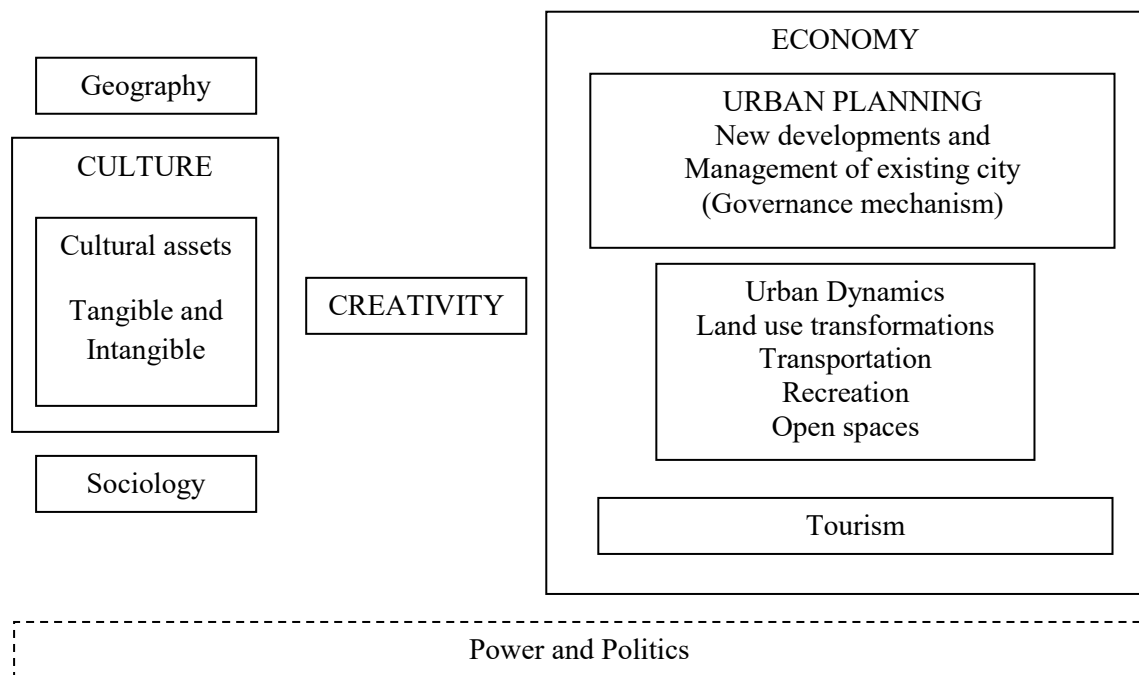

Table 2. The hypothetical relation between Culture and urban planning

1. Tourism, public spaces and urban cultures

Recording, evaluating and management of tangible and intangible cultural heritage, through a decision-making multi-criteria analysis

Eleni Linaki¹

¹PhD Candidate, National Technical University of Athens (NTUA), eleni.linaki@gmail.com

Abstract: Nowadays, we live and act in cities fulfilled with urban spaces, architecture and of course heritage culture, expressed by tangible and intangible assets. The last decade, the economic crisis, shows that cities and global heritage is demolished, damaged or in danger. This paper tries to identify culture in multilevel way, through space to global. As tourism is concerned with cultural (culture routes, touristic heritage attractions cities), this project aims to record culture from object to plan, including tangible and intangible assets. The paper, proposes a table, separated in tangible and intangible categories such as buildings, oral traditions, biodiversity etc. That's a first step of a fully record of the heritage of a city. In a step below, criteria indicators are placed in each category, concerning to a decision-making analysis called MAUT. With this system each city can have a record, evaluation and knows which culture assets must save, manage, promote or protect first. The mainly idea of this project is to propose a new innovated system about urban culture, including multilevel heritage analysis and a new management system, which can be used for tourism, urban actions etc.

Keywords: tangible assets, intangible assets, multicriteria analysis, culture

Introduction

Every city is a place, fulfilled with motivation, emotions, people, has a past, a present and a future time and energy. In this concept of the three parameters, time, place and energy, we have the rhythm of a place, grouped into programmed events, where the above-mentioned triptych, interferes with alternations, repetitions, etc., through the dynamics of each place. Thus, urban spaces are transformed into spaces of action and manifestation, into new spaces that are completely mutated. Static urban space is not always the same and commonly used. It gives its place to new events, structures and explorations, new possibilities of opening, producing new rules and fluxes of interaction within these constantly changing urban entities. affect the vitality, publicity and sharing of urban spaces (Antchak, 2018).

The above description refers to the city and automatically creates an inner and outer contour space, in the form of repeatability, ephemeral, etc. Each form has a shape and limits its content. Tangible forms are all dimensional, as a non-dimensional form is not meant in the intangible world. Each form has a center on which its composition depends. Such a form is also the place, expressed mainly through the city. Every new form-city-place we are in for the first time, invites us to meet it, so that we can then

describe it and categorize it. To get to know a new place, we use an experiential personal experience. We carefully examine and observe to determine its characteristic features, details and properties (structure, form, etc.). So, we know through experiential experience and personal judgment, we form one and then we know it to others.

In this perspective its city has a past, a form and it's a new experience both tangible and intangible. So, its city has a culture and heritage to show, to protect and manage. Culture and heritage are two mean full words, acting in everyday life. Beginning by the theory that culture is much more than the legislation of it and the main conventions and declarations, culture is everywhere. In the way we speak, we form our cities through the years, we act, laugh or the customs we have. In other words, culture is an attempt to preserve and save the old without affecting the progress of the cities and the future of them. Heritage is the transfer, of the culture, from generation to generation. Is more than ethics but is included in culture. Culture is a completely expanded and tricky concept that is constantly being renewed, revised and incorporates new inputs of interpretation from mankind, art, folklore, architecture, etc.

Besides, the word "polis", from which culture emerges, is a place of speech and myth, where each city creates its own speech and myth, at a reasonable and spiritual corresponding level creates an identity. Cultural identity, is something wider than culture, is the result of a collective historical experience of many fields, creating a common value set. The coexistence of the people, in which this value and social ensemble are composed, is the creation of a city, a place (Stefanou, 2000). As a space of interaction and experience of a value set, a city is always an "on the move" object, which brings together citizens and through their co-operation helps to develop the individual consciousness that leads to the collective consciousness of the place.

In this paper, and after this introduction, we will try to describe more extensive, the meaning of tangible and intangible cultural heritage and propose a new system based in multicriteria analysis for the purpose of protecting, recording, evaluating and managing the cultural heritage.

Tangible and intangible cultural heritage

First, it's useful and needed to identify the meaning of tangible and intangible culture. According to the dictionary of the Greek Language Center, culture is: *"all the material, spiritual, technical achievements and performances that are the result of man's creative powers and abilities and which are expressed historically in forms and forms of organization and action of society as well as the creation of (material and spiritual) values "* We see, therefore, that culture is treated as one, initially, a set of incriminating categories at a practical and spiritual level, as it concerns techniques but also forces and capacities that act through society. Two sets of cooperation, one related to the result of the forces and one in relation to the organizational structure of society. The basic source of the two systems and sets, man, the driving parameter and the entity of all the elements, the creator of civilization, in a perpetual continuum and evolution of life. These two forms created through the years the tangible and intangible cultural heritage.

The tangible heritage concerns to material culture, as buildings, monuments etc and has a variety of legislations, conventions beginning after the Second World War, after a huge number of monuments, treasures and cultural elements lost or destroyed. So, the prevention, the legal framework and the

protection were an immediate need. Tangible heritage, from the protection of the individual monument, to the protection of the perimeter environment and then whole historic and traditional settlements, is commonly known in cities and worldwide. The protection of intangible heritage started many years ago, as intangible assets are more difficult in understanding, recording and management.

The term "intangible cultural heritage" is considered to represent an "English translation" of the Japanese expression "*mukeni bunkazai*" (Lenzerini, 2011). In the Western world, the word "intangible" according to the Dictionary means: *a. Which does not have a material existence; ANTI Material: The spirit is immaterial. Yields and intangibles. b. (for a material body) so very transparent, ethereal, as if it were immaterial: the intangible forms of Byzantine hagiographies.* We observe that this word is given the essence, the transcendent, the non-material body, and the association with the spirit is important. In the form of linking intangible civilization, we begin by establishing and adopting the view that culture is a product of humanity, structured and shaped, taking shape over time, and the resources of that were exemplified by culture. At an early stage, all assets were intangible. The first legislation about intangible culture was the Unesco Convention on the "*Safeguarding of Intangible Cultural Heritage in 2003*" defines intangible cultural heritage as: "*practices, representations, expressions, knowledge and techniques - as well as the tools, objects, handicrafts and cultural sites associated with and which communities, groups and, where appropriate, individuals recognize as part of their cultural heritage*" (Article 2 (1)).

The Convention provides for the creation of two lists: (a) the Representative List of Intangible Heritage and (b) the Inventory of Immature Heritage in an Emergency Preservation State for expressions that are on the verge of extinction or significant alteration. (Unesco, 2003, para. 11-28). Greece ratified the Convention in 2006 and has so far incorporated into the "*Representative List of the Intangible Cultural Heritage of Humanity*" five elements of intangible cultural heritage. Specifically:

1. In 2013, Greece, along with Spain, Italy, Croatia, Cyprus, Morocco, Portugal, have enlisted the Mediterranean Diet as an expression of the intangible Cultural heritage that characterizes the Mediterranean.
2. In 2014, the know-how of Traditional Masticulture in Chios was placed on the same list.
3. In 2015, the Tinos marbles crafts
4. In the year of 2016 the Momorous, a custom of Kozani, Western Macedonia, was included in the catalog
5. In 2017, the registration of Rebetiko, folkore Greek music, was approved
6. In 2018 Greece and seven other countries (France, Switzerland, Spain, Italy, Croatia, Cyprus, Slovenia) joint the catalog, for the Art of Xerolithia, which is a technique of buildings wall stones without cement and binder.

According to those, we believe that cultural heritage is initially recognized as a place and then identified in it, initially its intangible elements and subsequently the materials, for their efficient management (Pocock et al., 2014). The main correlation of intangible and material culture is the realization that culture as a conquest was always at the same time immaterial and material, and that

this separation is for mainly state reasons and that these two resources can be readily understood by both experts and non-experts.

Based on all the above considerations, we conclude that culture, in fact, is commonly a dual nature of intangible and tangible assets, that are involved with varying degrees of intensity in each resource. This awareness, with the parameters of the resilience and breadth of these resources, can lead to a better management where intangible and tangible assets are intertwined and interdependent.

Types of culture

Culture has many different expressions and forms that have emerged in the course of time. As the first goal of this paper is to record resources, tangible and intangibles, this chapter is an attempt to register multiple categories, with the aim of creating a repository of tangible assets, separated in natural and man-made assets and intangible assets. This repository will assist in creating the registration system, which is discussed in the next chapter.

We notice that from the beginning, the world consists of an immaterial substance which is becoming matter. Starting with the natural resources, the earth's elements, the green places, the blue surfaces and thus the biodiversity that create the environment and the space in which man developed and began to design his place. They are the original components of creation, without which civilization and man could not evolve. Unesco for the creation of 22 development indicators defines certain categories for the listing natural heritage. As a natural heritage, it states: (a) physical characteristics consisting of natural and biological formations or groups which have an excellent value of aesthetic or scientific value, (b) geological and geographic formations and precise demarcated areas, which are the biotope of endangered animals and plants of exceptional value in terms of science or conservation. However, this classification is somewhat limited. So, in order to make a various typology of nature resources, we put analytical categories of the natural resources, that a scientist finds in a place such as: ground morphology, geotherm, seas, lakes, waterfalls, etc.

Secondly, we continue with the typology of the man-made assets. It could be argued that natural resources are the activating factors of creation, the background, the raw material that man has ever intervened mildly or more vigorously, composing what we call man-made assets that include intangible and tangible cultural assets. The cultural heritage of mankind is based mainly on man-made assets, as it becomes more manageable and comprehensible through the creations of man.

The most well-known and understandable tangible and man-made cultural resource and one of the most important forms of cultural heritage is the architectural heritage, which resides in a single or cluster of buildings and ecclesiastical buildings with influences from different periods. But besides the city and the protected elements, the countryside and its elements are also important for the cultural heritage of a place, whether they are crops, fields, green areas, ie natural elements with little human intervention, or human activities such as livestock farming, beekeeping etc. The building blocks of a city or countryside area are the smallest unit of understanding, as the building is the evidence of the history of a place as it is depicted in various forms. Every period expresses something different and, over the years, it is judged to be pleasant or unpleasant with the realization that it can change over time. The museum is an artistic and educational space. It collects the "worthy" or "saved" material elements of the past. Moreover, educational buildings, as a knowledge place, is another powerful

avenue for learning the heritage. It takes place from childhood and lifelong, through schools, spectacles, and museums that are powerful pillars of civilization. From the point of view institutions and museums, in the term that Hjerppe used in 1994 as "Memorial Institution", covering institutions, museums, organizations etc. trying to preserve the heritage, prevailed (Solanilla, 2008).

Another example of cultural heritage in building is the industrial heritage consisting of building structures and equipment, objects of industrialization and the industrial revolution that emerged first in Europe and then in the rest of the world. A major issue for buildings in the city and the countryside is the architectural remains, which are scattered existing buildings in a poor or desolate state that have been abandoned. They are important or humble remnants of a period (Dillon, 2013), which play an important role in the historical continuity and course of a place, as well as in the whole of a city or nation. Finally, important for each place is the archaeological heritage, the archaeological sites and excavations, elements of whole cities, that have been found through the years and smaller elements of the history of a place such as heirlooms, books, costumes, utensils, ecclesiastical etc.

Those and some more categories were used to create the categories of human creations in the category of tangible assets. In order to classify the intangible cultural heritage, the categories of the 2003 Convention, were used, for reasons of plurality and because intangible is remaining a difficult and non-well-known research field, as the paper already shown.

Development of the multicriteria analysis system

In this chapter, we will analyze the system of recording and evaluation, as it was formulated in the context of the research and the methodology of approaching the present dissertation. For the creation of the system, the original structure of thinking and creating this, we form it in the context to be a simple, easy-to-manage system that would be in direct use and provide valid and optimal results. Thus, the steps to identify this are the following:

1. After the analysis of multicriteria systems, these tests in the context of recording and evaluating the intangible and material cultural heritage of a place, for the selection of the best method
2. Develop a general philosophy of the system, in terms of its purpose, content and outcome
3. Development of the system in two distinct stages. These stages are recording and evaluation
4. Organization of the two stages with their constant interrelationship
5. Create an evaluation system using mathematical models, analyzed through gradual milestones
6. Explanation and creation of a manual, which is presented in this chapter

The first assumption of this paper, which is defined at all stages of the system, is that in this system, throughout the writing process, we used the categories of the chapter :types of culture and all our assets tangible and intangible are legally understood as the cultural heritage of the place and engraved in the collective consciousness of individuals as part of it. The notion of ownership or shared heritage

between two places has been affected in the context of interpretation, performance and creation of the system. This happened, because of the multiple issues that this option creates, as we think that it will be caused misinterpretations or system misconceptions. Thus, in the two distinct stages of the recording and evaluation of the multicriteria system, to be interpreted below, only the cultural objects of the site are selected at the registration stage, while at the evaluation stage targeted criteria are set in each category. The system is easily understood by four main steps.

1. First, we created a table, separated in tangible and intangible with the analyzed categories etc. That's a first step of a fully record of the heritage of a city.
2. In a step below, criteria indicators are placed in each category, concerning to a decision-making analysis called MAUT (Multiple Attribute Utility Theory).
3. Each criteria has the same calibrated system and the user, following the analysis evaluates the criteria from 0 to 4, regarding to the culture significance.
4. After this, easy mathematical models are used, and the system is evaluated, giving the culture significance by number.

Conclusion

The aim of this paper is to clarify the terms of tangible and intangible culture to redefine them and to class them by introducing the concepts of the environment, humanity and society into the context of culture. This thesis is a doctoral thesis, so its analysis is expected to be completed and attributed in two years from now. The creation of a multicriteria system is a new attempt to link civilization with a system of evaluation and recording which has not been used so far. Multicriteria systems are usually used in cultural programs for protecting threats, risks, analyze materials of buildings etc. With this proposal system each place can have its own record of tangible and intangible culture, which it can be evaluated. In this way, the government, groups or operators of culture or anyone involved in cultural management can manage, save, and know through a calibration the importance of the assts of each place.

The Research on Formation Mechanism of the Rural Red Culture Tourism Industry Cluster and Application

-- Reflections from the Comparative Analysis of the “Revolutionary Resort” Xibaipo Town and “Green Dot” Dashi Town

Shiqi Liu¹

¹*Tongji University, ShiqiLiu47@163.com*

Abstract: Red culture tourism has emerged as a new theme tour in China. Developing red culture tourism industry is a special way to activate economic and revitalize cultural for the villages in old revolutionary area. In fact, when red tourism intervenes in rural development, some villages can form red culture tourism industry cluster. In addition to the villages' own resources, social network condition and market demand, the policy regulation and planning guidance behind are also important. By taking “Revolutionary Resort” Xibaipo town as an example, whose red tourism have developed into a rather mature stage, we firstly studied the overall distribution of the red tourism industry cluster, and analyzed the formation mechanism. Then, we used Xibaipo town as a comparison case. With the help of the National "Green Dot" Rural Revitalization Competition platform, we analyzed the practical problems in the development of red tourism resources in the Guangan village, Dashi Town, Sichuan Province, and put forward the industrial cluster model of "Cultural Innovation" and "Scientific and Technological Innovation" to promote the benign development of rural agriculture, society and ecology. Hope to provide a new idea about the red resources' development for the villages in the old revolutionary area in the future.

Keywords: rural revitalization; red culture tourism industry cluster; formation mechanism; comparative analysis

1 Introduction

Rural development is important in China now. In the revolutionary era, as China took the special revolution road of “urban encircling the city”, the country has preserved many valuable red cultural resources. Furthermore, in the new era of knowledge economy, the development of industrial clusters not only exists in the manufacturing industry, but will also emerge more in the service industry. So, the development of the red tourism industry cluster is also the new way and idea for the future economic and cultural revitalization of the rural areas. This paper established an analytical framework for the formation mechanism of red tourism industry clusters, and analyzed the Xibaipo, a “Chinese revolutionary holy site” with mature red tourism industry clusters, and compared it with Guangan Village, which also has red cultural resources. We hope to propose appropriate countermeasures for the development of the red cultural tourism cluster in Guangan Village in the future.

2 Literature review

2.1 Industrial cluster

In 1990, Michael E. Porter used the concept of "industrial cluster" for the first time in **The Competitive Advantage of Nations National Competitive Advantage** to describe the group formed by enterprises and related institutions that are close in space, have business relevance and are linked together through mutual communication and complementarity. With the development of knowledge economy and the improvement of people's consumption level, enterprises have higher and higher requirements on technology. Traditional industrial clusters' way of reducing costs through specialized division of labor already cannot satisfy the production demand. Innovation becomes the key factors to survive in the competitive environment (Wang, 2007). Under this background, Chinese scholars put the innovation development of clusters or the innovation of industrial clusters on the agenda, and have more clear division between the industrial cluster and industrial agglomeration. Agglomeration is the process of actual operation, the cluster is a phenomenon form or strategic method (Wang, 2007). At the same time, the tourism industry agglomeration with enterprise sharing behavior and rooted in local enterprise network is real industry cluster (Feng and Miao, 2009, Yin and Liu, 2010). Later, we have a comprehensive understanding of industrial clusters. The essence of industrial clusters is not only an economic network, but also a social network (Tian *et al.* 2013). It is not only geographical agglomeration, but also contains the logic of knowledge, production and sales (Liu, 2011). As seen in Table 1.

Tab.1 Analysis of industrial clusters in the age of new knowledge economy and traditional industrial clusters

Category	Traditional industrial cluster	Industrial cluster in the era of knowledge economy
Attributes	Economic.	Economy, society, culture, etc.
Aims	Costs cutting.	Continuous innovation to meet consumer demand.
Method	Professional division of labor, mass production.	Relying on innovation networks, corporate interaction and division of labor.

2.2 Tourism industrial cluster

Although there is no clear answer about whether the cluster concept can be applied to tourism industry, there are many supportive views. In 1998, Michael E. Porter affirmed that industrial cluster theory can be applied to the tourism industry, and called tourism, agriculture, chemical industry and textile industry together as the four industries having the most obvious industrial cluster phenomenon. Earlier in our country, Long is an early scholar who put the concept of industrial cluster into practice in the field of tourism. He pointed out that the cluster in specific geographic areas should include a series of entities closely related to the leading industry, and points out that in the case of Yunnan the main body at the core of the ecological tourism cluster is nature reserve (Long *et al.* 2002). Judging from the economic development situation, it is an inevitable trend for industrial clusters and trade clusters to develop into service industry clusters, and industrial clusters will blossom everywhere in the service sector (Qian, 2007). on the other hand, for the need of the development of tourism industry, rural tourism industry is highly correlated and needs to establish a huge network organization through industrial agglomeration(Liu,2009). In reality, after nearly a decade of development, rural homestay clusters, such as Moganshan homestay industrial cluster and Huanggongwang suburban village homestay clusters, have been developing rapidly in recent years (Zhu, 2018). The author thinks that the above cases and studies can show that tourism industry cluster is established and will have great development potential in the future.

As for the definition of tourism industry cluster, it is generally agreed that the tourism industry cluster should have the core tourism attractions, and the tourism-related organizations should concentrate in the region, gathering together through the complex network relations (Shen, 2011, Ma and Lu, 2014), and Ma highlighted

the importance of the creativity, and points out unlike manufacturing longitudinal economic ties form the upstream and downstream of industrial agglomeration, and horizontal industrial agglomeration of the same kind pursuit of scale economy, tourism industrial cluster is a transverse combination of different forms of industry, demand and the tourism market platform shared are the keys to connect production factors (Ma and Lu, 2014). As seen in Table 2.

Tab.2 *Analysis of tourism industry clusters and manufacturing industry clusters*

Category	Manufacturing industry cluster	Tourism industry cluster
Motive force	Scale production, industrial division of labor, innovation.	Core attractions, shared market platforms, regional brands, policy promotion, innovation.
Method	Horizontal similar industry agglomeration, vertical economic upstream and downstream industry agglomeration.	Horizontal accumulation of industrial based on tourism demand.
Development trend	From mature to transformational development.	From budding to vigorous development.

2.3 Rural tourism industrial cluster

As for the definition of rural tourism industrial cluster, it is a consensus that tourism related enterprises and organizations satisfy tourists with rural culture and resources to let them experience rural culture, landscape and rural life gather in rural space (Shen, 2011, Xu, 2013). Furthermore, innovation of rural tourism industry cluster is important. (Xu, 2013). Conceptual Comparison of Industrial Clusters, Tourism Industry Clusters and Rural Tourism Industry Clusters can be seen in Table 3.

Tab.3 *Summary of the industrial clusters, tourism industry clusters and rural tourism industrial clusters*

Concept	Characteristics
Industrial clusters	Complete industry chain, industry scale, sharing behavior, dependence on innovation and local social networks. Existence; It is the inevitable trend of economic development.
Tourism industry cluster	Core attractions, cater to tourism needs, network organizations, shared tourism market, regional brands, innovation.
Rural industrial cluster	Taking rural culture, landscape and life as the core resources to cater to the needs of tourism, in order to share the tourism market and regional brands, rooted in the innovation of local social networks.

2.4 Formation mechanism

Concerning the important driving force for the development of the rural industrial cluster, the social capital is the key. During the knowledge economy age, the interaction of enterprises, social network and the symbolism of the products for industrial cluster development is particularly important (Wang, 2007), Tian studies the current situation of the social network of Kashgar tourism industry cluster (Tian *et al*, 2013). Huang comprehensively expounds the formation mechanism of rural tourism industry agglomeration in Guangxi from the perspective of spatial agglomeration, social network and economic externalities (Huang, 2014). Liu pointed out that social

capital is the micro-core driving force of rural tourism industry cluster, and he studies the three cluster evolution models of the rural tourism industry cluster in Hangzhou, embedding and converging. He valuably points out the important role of the government in its operations (Liu *et al.*, 2015). On the other hand, the driving force of economic is also very important. The sharing market and regional brand are the two key development factors. Ma explained the profit maximization model from that perspective of economics, and took Baiyun Mountain in Song County as an example to summarize the formation of the tourism industry cluster into four stages: "factor improvement, brand promotion, market sharing, and business agglomeration" (Ma and Lu, 2014).

2.5 Development mode

Based on Chinese conditions, scholars have given suggestions on the development of rural tourism industry clusters. First, Long believes that the village itself needs to improve the literacy of knowledge and culture. it must learn how to "self-rescue" and improve the utilization efficiency of the resources invested from the angle of social capital's initiative (Long *et al.* 2002). Followed by Qian's view about for the industry's own demand, China's rural tourism clusters should form homogenous services, mainly resort-based rather than tourism-oriented services, and the new industry cluster is mainly promoted by the local government in the future (Qian, 2007). At present, the rural public awareness is weak and the relationship is relatively loose. Perhaps the villagers can spontaneously lead to the rise of the rural tourism industry, but governments' intervention and operation later on is indispensable (Shen, 2011), and there is also a research perspective on the optimization of rural tourism industry cluster structure, which shows the important role of government in innovatively transforming resource-dependent agglomeration (Xu, 2013).

2.6 The driving role to rural development

At the economic level, rural industrial clusters can drive the development of the rural economy and increase the income of the villagers. From the perspective of resources, it can strengthen the overall landscape of the village, which is conducive to the rural areas gaining competitive advantage in tourism development (Shen, 2011). Especially, it can effectively reduce the phenomenon of "tragedy of the commons" of tourism resources (Han, 2016). From a social perspective, rural tourism industry clusters can further build and extend social networks in rural areas due to their comprehensiveness and openness, which is conducive to the future self-organized entrepreneurial behavior of villagers (Liu *et al.*, 2015).

3 Method

3.1 Basic principles

Through the preliminary theoretical research, the five aspects are the selected—regional brand, cluster component, resource level, social network and government regulation—as the conditions for analyzing the basic formation demands of the rural tourism clusters in China. As seen in Figure 1.

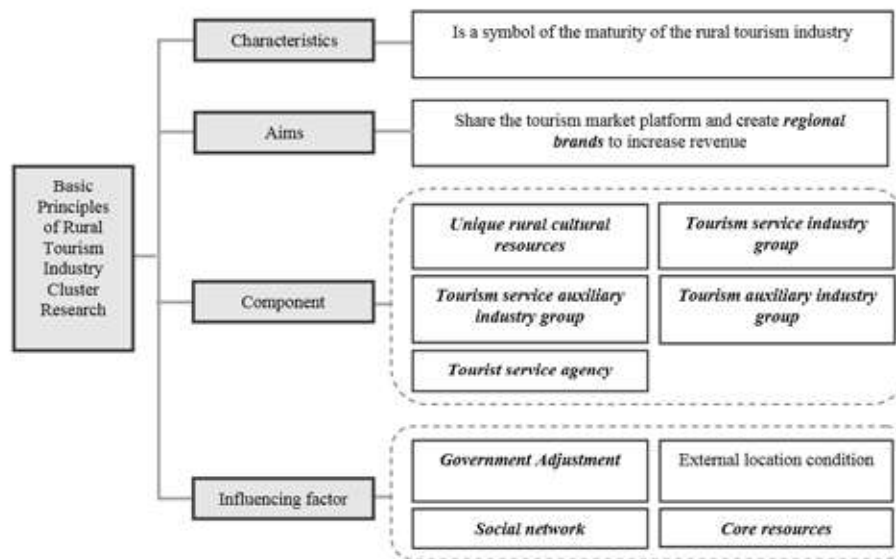

Fig.1 Basic analysis conditions of China's rural tourism industry cluster

3.2 Research framework

In terms of research mechanism, Porter's competitive advantage theory and diamond model are reasonable method from the perspective of consumer (Bao and Fang, 2006). Yang used the Michael Porter Diamond Model selecting unique elements—the rural cultural landscape, tourism service industry group, tourism service auxiliary industry group, tourism auxiliary industry group and tourism service organization to further explained the rural tourism industry cluster (Yang, 2008). It is believed that for the development of rural tourism, the perspective of consumers' needs is very important. So it is a very classic and correct choice to select the Michael Porter diamond Model for research. As seen in Figure 2.

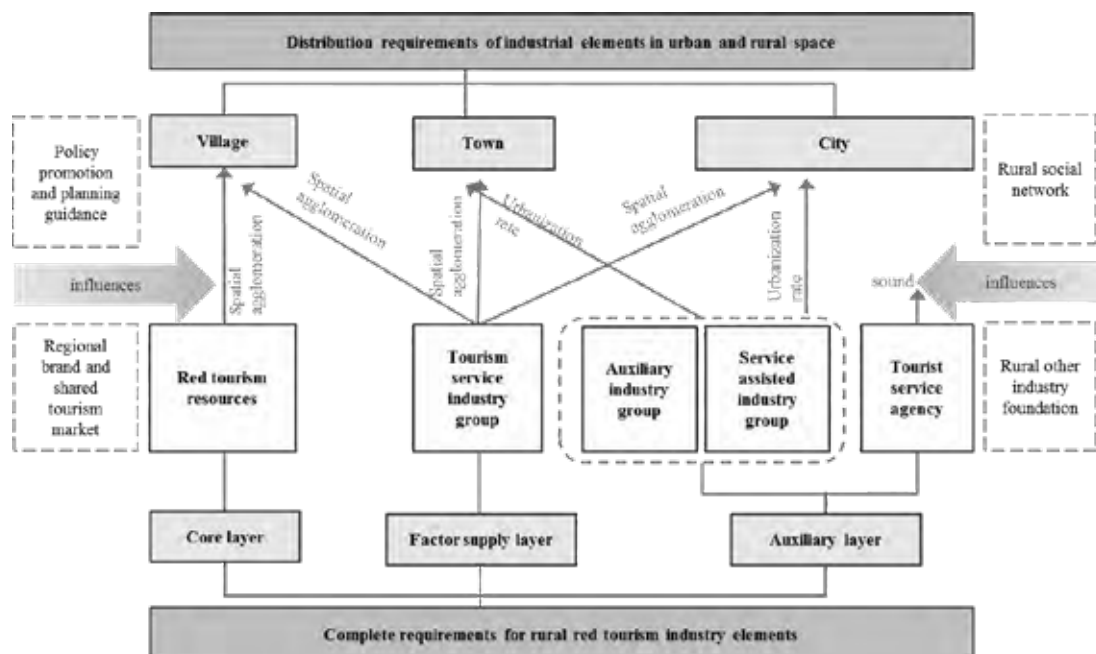

Fig.2 Analysis framework of rural red tourism industry cluster mechanism based on Porter Diamond Model

The study considers that the rural red tourism is different from the general rural tourism industry. It is reflected that its red tourism resources is the core, it relies heavily on government policy support and planning guidance, and rural industrial facilities can be shared with other rural. Therefore, adjustments are made on the basis of rural tourism industry cluster theory. Firstly, the necessary elements of the formation of the rural red tourism industry cluster are decomposed into three parts: core element layer, supply layer, auxiliary layer, and the elements are implemented in the three spatial scales as city, town and village. Judging whether the red tourism cluster in the village of Xibaipo is formed by these three spatial level elements. Secondly, through the interpretation of important policies, development history and the comparison of the industrial status of surrounding villages, we consider the reasons for the formation of the original red tourism industry cluster in Xibaipo town. Finally, under this framework, we made a comparative analysis with Xibaipo to judge the conditions and shortcomings of Guangan Village to develop the red tourism industry cluster in the future, and proposed countermeasures.

4 Comparative analyses

4.1 Xibaipo town, "revolutionary resort"

4.1.1 Basic information

Xibaipo town, located in Pingshan county, Shijiazhuang city, is one of the five revolutionary holy places in China, and it is a dual-excellent area for developing red tourism and rural tourism (Tian *et al*, 2016). **The Master Plan of Big Xibaipo (2011- 2020)** has determined the geographical concept of the Big Xibaipo, the space scope contains five towns, two villages and Gangnan reservoir in Pingshan county (Xie and Liu, 2013), Xibaipo Town is a tourist town dominated by red cultural resources. So we identify Xibaipo Town as the main spatial scope of this study. As seen in Figure 3.

Fig.3 Township distribution map of Xibaipo town area Model

Xibaipo town has jurisdiction over 16 administrative villages, 28 natural villages. The town government is located in Chenjiayu village. Xibaipo town is 40 minutes away from Pingshan county and 1 hour away from Shijiazhuang city, which has very convenient transportation. Therefore, the research objects of "City" are

designated as Pingshan County and Shijiazhuang City, "Town" is Xibaipo Town, and "Village" is 16 administrative villages.

4.1.2 Judgment of the red cultural tourism cluster

The core element layer is analyzed from the distribution of red resources. Three core red resources groups are formed in the Xibaipo town area, namely Xibaipo town center-Xibaipo village-Dongpo village group, Gaijiatun village-Chenjiatun village - Jiayu village - Baili Village Group and Liangjiagou village - Beizhuang village Group, followed by Nanzhuang Village with the former site of the Organization Department of the CPC Central Committee. As seen in Figure 4 (left).

The supply layer analyzes the distribution of tourism service industry group. From the four aspects of hotel, catering, convenience store and parking lot, there are actually only Dongpo village, Xipo village, Chenjiayu village, Liangjiagou village-Beizhuang village formed a tourism service industry group. There is no service industry distribution in Gaijiatun village-Chenjiatun village-Jiayu village-Bali village group and Nanzhuang Village with red tourism resources. As seen in Figure 4 (right).

The auxiliary layer is analyzed from the urbanization rate and the service of tourism institutions. In terms of urbanization rate, the urbanization rate of Shijiazhuang City in 2018 is 63.16%, and the urbanization rate of Pingshan County in 2017 is 51%, indicating Shijiazhuang and Pingshan County are both now in the stage of urban and rural integrated development, public finances are strong, the gap between urban and rural public services is small, and the city has greater capacity in assisting rural(Zhao *et al*, 2016). Therefore, for the villages of Xibaipo Town, Shijiazhuang City and Pingshan County are both Can provide some auxiliary support for it. In terms of tourism service agencies, Xibaipo is operated by the Xibaipo Scenic Area Management Committee and the tourism service agencies are officially operated.

In general, the urbanization rate of the cities around Xibaipo town is relatively high, and the scenic spots are operated by regular tourism institutions, indicating that Xibaipo Town are qualified in the auxiliary layer. Combining the core elements and the supply layers, Dongpo village, Xipo village, Chenjiatun village, Liangjiagou village and Beizhuang village meet two conditions at the same time, which can be preliminarily judged that these villages have formed a rural red tourism industry cluster.

Fig.4 Cluster map of red scenic spots (left) and tourism service industry (right) in Xibaipo Town

4.1.3 Policies and development incidents

In 1935, when the Gangnan reservoir was built, many villagers from other places moved to Xibaipo town, forming the migrant village. The social network of the village was unstable, and the development of industry

and agriculture was restricted by the terrain. The whole area lacks vitality. In 1955, Hebei provincial museum, together with the local government, began to prepare for the construction of Xibaipo memorial hall. Xibaipo village and Dongbaipo village began to develop (Cheng and Cheng, 2013). In 1956, Xibaipo Township (Chenjiatun village) was gradually expanding. Construction of Gangnan reservoir started in 1958, completed in 1962. As the main source of drinking water in Shijiazhuang and the capital Beijing, Gangnan reservoir instead of providing valuable waterfront space for the development of Xibaipo tourism, it has imposed strict restrictions on its development and construction (Tian *et al*, 2016), which is also the reason why the county in the northeast and southwest of red scenic area has not been developing red tourism related industries. In 2010, Pingshan county put forward the construction of "Big Xibaipo" target in order to speed up the pace of urban and rural integration, and proposed the construction plan—the Xibaipo, Dongbaipo, Liangjiagou and Chenjiayu the four administrative villages merging into one in the heart area, On both sides of town center building three key village, to strengthening radiation level of red tourism cluster in the center and to promote the development of village in the two-winged (Yan *et al*, 2010). It is hopes that the new residential construction is combined with the local rich ecological tourism resources. As seen in Figure 5.

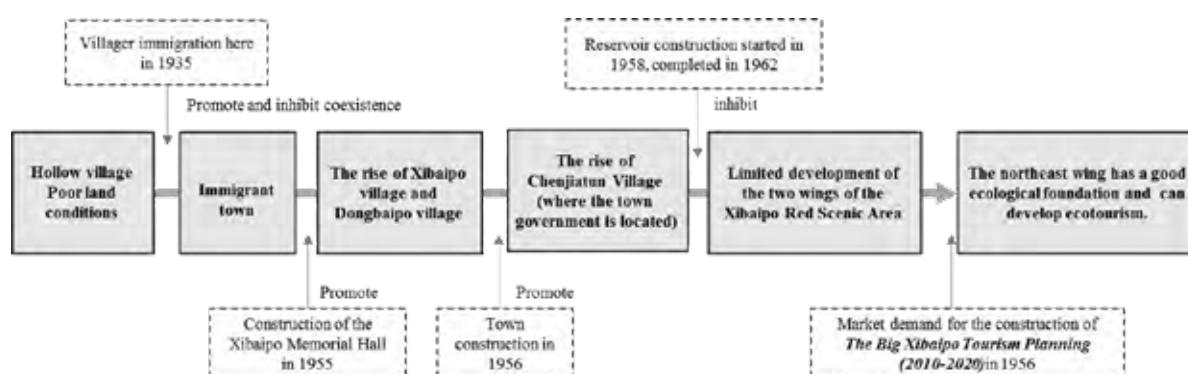

Fig.5 The overall development experience of Xibaipo township

4.1.4 Related industries in surrounding villages

At the current stage, Xibaipo town has four functional divisions, with a mountain sanctuary in the north, a red industrial cluster in the middle, a national forest tourist area in the northeast corner, and a traditional agricultural area in the southwest. On the whole, since the northern part of Xibaipo town is affected by the mountain, with the south part restricted by the reservoir, the development is relatively cramped. Under this circumstance, the north can only develop eco-tourism based on ecological resources. For the southwest part there is no better advantage, and it can only maintain the original traditional agricultural development. As seen in Figure 6.

Fig.6 *Distribution of main types of rural industries in Xibaipo town*

4.1.5 Summary of motivation

The construction of the Gangnan reservoir in the township and the Xibaipo Red Tourism core scenic spot led by the government are two important factors affecting the development of the local industry. They play a dual role in driving and restricting the rural industry in Xibaipo town. In the early stage, the villages were promoted by the construction of the core red tourist scenic spot. However, later on, when the red industry area of the whole area is ready to develop, the safety requirements of Gangnan Reservoir limits the rural development in the two wings of the core red scenic area. The villages on the northeast side rely on a better ecological base to develop a national forest ecological park, while the traditional agriculture on the south side does not match the quality and specifications of the central red scenic spot, with development limited. From the perspective of motivation, the villages in Xibaipo town can be classified into four categories: red tourism policy promotion, township construction policy promotion, endogenous demand, endogenous demand and policy orientation, and ecological security restriction. Secondly, the government's strong ability to regulate and control Xibaipo town can, to a certain extent, make up for the lack of social capital in the immigrant villages of Xibaipo town. The side shows that the red tourism cluster in the area was established.

4.2 Guangan village, "green point"

4.2.1 Basic information

Guangan village is located in southwest of dashi town, Pengxi county, Suining city, Sichuan province. It is 5 kilometers away from dashi town, and near the south of Chuanshan district. The location is very convenient. On August the 29th, 1929, Jixun Kuang announced the uprising in Niujaogou village and established the first red army of workers and peasants. The site of the Niujaogou village where Jixun Kuang uprising for Sichuan province was elected as the provincial key units of cultural relics protection. As seen in Figure 7. With the implementation of the comprehensive plan of modern agricultural industrial zone, an important strategy for rural revitalization in Suining, the development of Guangan village is facing a new opportunity.

Fig.7 *Guangan village's Jixun Kuang Uprising Site (left), former headquarters (right)*

4.2.2 Comparison of forming conditions

Xibaipo town was originally a small village with red resources, but later gradually developed into a town, which is close to the development condition of Guangan village. By comparing Guangan village with Xibaipo town, we firstly found that the core tourism resources and regional brands of Guangan village are not as important as those of Xibaipo town, and the largest regional impact can only reach to the provincial level. Followed by the auxiliary layer, both of Shijiazhuang city and Pingshan county have entered the stage of urban and rural integrated development, while Suining city has just entered the urban-rural integration stage, with Pengxi County still in the stage of urban-rural unbalanced development. The recent support for Guangan Village will be

weaker. Like the original of Xibaipo town, the hollowing out is serious, and the social network is unstable. However, Xibaipo town have a strong embedded development from the state-province-city-county-town different levels of governments, and the economic and social network built by them can make up. Guangan village does not have such development conditions. It needs to find another method. In the end, Xibaipo Town has many ecological restrictions, while Guangan Village hasn't, and the surrounding agricultural foundation is good. As seen in Table 4.

Tab.4 Comparison of the formation conditions of village red tourism industry cluster

Important condition		"Revolutionary Resort" Xibaipo Town (initial condition)	"Green Point" Guangan Village, Dashi Town
Horizontal industry element	Core resources layer	National famous revolutionary memorial site and 100 national patriotic education demonstration bases.	The site of the Niujaogou village where Jixun Kuang uprising for Sichuan province is the provincial key units of cultural relics protection.
	Factor supply layer	Close to the original town area, 5 minutes drive (now Chen Jiaxuan).	Close to Dashi Town Township, within 10 minutes by car.
	Auxiliary layer	The urbanization rate of Shijiazhuang 2018 is 63.16%; the rate of Pingshan County in 2017 is 51%. Basically it is in the urban and rural integrated development stage, the rural auxiliary capacity is good.	The urbanization rate of Pengxi County in 2018 was 36.94%, which was in an unbalanced development stage. The city has weak support for rural support.
Social network		Immigrant village, social network is instable.	Hollow village, social network is instable.
Government regulation		State-province-city-county-town government regulation.	City-county-town government regulation
Regional brand		Ten nationwide major revolutionary bases.	Sichuan Provincial Red Tourism Aorta.
Other factors		There are many restrictions on ecological protection—the construction of Gangnan Reservoir in the west, the protection of the mountain in the northwest, the good forest resources in the northeast of the town, with agricultural foundation in the south.	There is an agricultural foundation. The village grows walnuts, and the surrounding countryside grows rice, rapeseed, alfalfa, pear, watermelon and other fruits and vegetables.

4.2.3 Problems

Compared with Xibaipo town, Guangan village's red tourism industry cluster will faces three major problems: how to use red cultural resources, how to deal with the recent development of Suining City and Pengxi County's poor support capacity; how to seek sustainable development while the social network is unstable, and the government's strong involvement is not possible. We put forward strategies for the above problems.

4.3 New method

4.3.1 Thinking the ecological base

Guangan village cannot solely rely on red resources. Compared with Xibaipo Town, the top ten revolutionary bases in China, the red resources of Guangan Village are of limited importance and influence in the whole country. It is necessary to use the existing foundation to build a red tourism industrial chain with the red cultural sites of Niujiaogou, constructing walnut ecological chain with local walnut garden and Suining agricultural ring line, and propose the strategy of developing with red tourism as the core and cooperating with local industries.

4.3.2 Construct a new social network

The reconstruction of local social network in Guangan Village requires the power from multiple parties. At the same time, it needs to be developed in stages, and three keywords can be used to summarize them, namely “red”, “walnut” and “valley”. In the early stage of rural development, cultural innovation was carried out with red resources to attract schools, NGOs and travel agencies to provide them with services such as red cultural tourism, eco-farm experience, and Small and Beauty Agriculture experience. Through B2B cooperation model, we can improve the rural social cooperation network. At this stage, we also pay attention to the local development of walnut agriculture. In the medium term, the scientific and technological innovation focused on the walnut ecological chain, and the green industry and education are expanded to attract enterprises services, high-efficiency and experimental bases. Guangan village will provide modern agricultural experience, finance, and logistics services for them. Through the B2B and B2C models, the village will develop the social network relationship between local villagers, enterprises, and governments. After completing the dual innovation development stage, they can return to the local rural construction to create a higher quality environmental quality for local residents. Let them have a better sense of belongings.

4.3.3 Organization revitalization

Guangan Village needs to revitalize grassroots party organizations. As the location of the red cultural site, the local has a solid foundation of party organization. At the stage of red culture, it can carry out the construction of a learning-oriented and service-oriented foundation party. In the stage of green industry and education development, it can carry out the construction of innovative, learning-oriented, and service-oriented party organization. In addition, under the leadership of grassroots party organizations, rural infrastructure construction can also develop steadily.

5 Conclusion

On the basis of theoretical analysis, this paper draws on the perspective of the Michael Porter Diamond Model to study the mechanism of the rural red tourism industry cluster in Xibaipo town, a national revolutionary holy land. It is except that Xibaipo Town is an immigrant village in the early stage of development, and short board of social network vacancies (strong government regulation brings about this shortcoming), other aspects of development conditions are very good. Furthermore, we selected industrial factors, social networks, government regulation, regional brands and other conditions to make a comparative analysis with Guangan village which also have red tourism resources. It shows that Guangan Village can't compete with Xibaipo Town in the importance of red core resources. and Pengxi County's future support services for Guangan village is limited. Similarly, the problem of hollowing out in the Guangan village is serious, and the government's ability to regulate and guide the future is unknown. So, the red tourism industry cluster in Guangan Village cannot copy the development mode of Xibaipo Town, and cannot rely solely on the government and red resources. In response to the problems faced by Guangan village, we proposed three strategies—building a dual core of rural red resources and ecological bases, building a new social network with "red cultural innovations" and "green technology innovations", building a learning-oriented, service-oriented, and innovative grassroots party organization to achieve organizational revitalization. We hope it will provide a new idea for the development and utilization of red resources and rural revitalization in the method of tourism industry clusters in rural areas in China.

A Study on the Development Trend and Transformation of Shanghai as a Creative City in the 21st Century

Xiaojiao Ma¹, Weiqiang Wang²

¹*Tongji University, zuckerwatte0425@163.com*

²*Tongji University, wwq@tongji.edu.cn*

Abstract: In the 21st century, under the wave of globalization, society is entering an economic development model with knowledge and creativity as its capital. Against global convergence, playing local characteristics of the city itself is the key to improving the city's competitiveness. This model of creating a city image with creative economy and stimulating economic development through creative industries has adapted to the requirements of post-industrial society for urban transformation. Therefore, it has been strongly supported and promoted by many governments, and has rapidly swept the world – “creative city” has gradually become a new paradigm for urban development. Based on the data of the Shanghai Statistical Yearbook for the past ten years, this paper visualizes creative investment, creative achievements and creative workers at the creative economy level, and hierarchy structure, proportion and salary at the creative class level, and creative immigrants, homosexual index and creative ideas at the creative city level. Thereby it analyzes the development trend of Shanghai as a creative city at various levels in the past ten years, and summarizes the advantages and disadvantages of its development. This paper found the advantages are that the national level has a large investment in research and development in Shanghai, a large number of patents granted, a rapid development of creative industries, and a leading index of creativity across the country (except Beijing). The shortcoming is that the number and proportion of the creative class is not big enough. At the same time, Shanghai as an international metropolis, the openness, inclusiveness and diversity of the city are far from enough. In these respects, we analyze the creative city—Helsinki's successful experience, meant to guide Shanghai's future development strategy and transformation as a creative city.

Keywords: creative economy; creative city; creative class; urban culture

Introduction

In the 21st century, under the wave of globalization, society is entering an economic development model with knowledge and creativity as its capital. The industrial transformation of the city is becoming more and more important. It opposes global convergence, and the local characteristics of the city itself are the key to improving the city's competitiveness. This model of creating a city image with creative economy and stimulating economic development through creative industries has adapted to the requirements of post-industrial society for urban transformation. Therefore, it has been strongly supported and promoted by many governments, and has rapidly swept the world – “creative city”. This has gradually become a new paradigm of urban development (Gan Lin, 2012). Looking forward to 2035, Shanghai will basically be built into a remarkable global city, a city of innovation, a city of humanities, an ecological city, and a socialist modern metropolis with world influence. This

is the development of Shanghai's urban development in the 21st century. Goals and visions (Shanghai Municipal People's Government, 2018). How to become a city of innovation and how to become a great creative city that can attract a large number of creative classes will become a new challenge for the development of our city in this era.

At present, most of the domestic and foreign research related to it is aimed at the public policy of developing creative cities at the national level, the development experience of European and American cities as creative cities, and the creative industries developed in Shanghai in recent years along with urban renewal. For Shanghai itself As a whole, the overall development trend of the creative city in the past decade, including the advantages and disadvantages, is relatively small. Therefore, this article first briefly introduces the basic concepts of creativity, creative economy, creative class, creative community, and creative city. Then, I consulted the Shanghai Statistical Yearbook in the past ten years, and creative investment, creative achievements, and creative workers at the creative economy level. At the creative level, the hierarchical structure, proportion, salary, and the immigration, homosexual index, creative industry and other statistical data at the creative city level are visualized, and the development trend of Shanghai as a creative city at various levels in the past decade is analyzed and summarized. At the same time, from the six aspects of lifestyle, social activities, diversity, authenticity, identity and local quality, the creative capital: Helsinki's successful experience, to provide some feasible suggestions for the future development of Shanghai's creative city.

1 Related concepts

1.1 What is Creativity?

Creativity is a very open concept that can be interpreted in a wide range of ways. It seems that any action aimed at solving a problem or improving the situation is a reflection of creativity (Klaus Kunzman, 2012). Charles Landry writes, "Creativity has many qualities. It is a history of deep experience in the past. It subverts widely accepted things, challenges customs, and tries to create new experiences, rather than absorbing and identifying existing ones in advance. Experience. Experience always exists in a predetermined pattern or theme, leaving little room for personal imagination. Conversely, creative cities have to create their own space, it can be loose, ambiguous, uncertain and unpredictable Sex, ready to adapt (Charles Landry, 2009)."

1.2 Creative Economy

The concept of "creative economy" first appeared in the US Business Week in August 2000, after which John Hawkins explored the global impact of the creative economy in his 2001 book, Creative Economy. Define the creative economy as 15 creative industries (Richard Florida, 2010). Richard Florida (2010) thinks so, "Creativity is the most important economic driver, knowledge and information are creative tools and materials, and innovation is a creative product. This product can be expressed as a new technology product, too. Can be a novel business model or method."

1.3 Creative Class

The rise of the creative economy has had a profound impact on the division of social groups or classes (Richard Florida, 2010). The striking feature of the creative class is that its members are engaged in the work of "creating meaningful new forms" (Richard Florida, 2010). In this regard, Richard Florida (2010) believes that it is mainly composed of two types of groups, the "super creative core" group (including scientists and engineers, university professors, poets and novelists, artists, actors, designers and architects, and The pioneering group of thoughts in modern society) and the group of "innovation experts" (including high-tech industries, financial services, law and health care, and business management groups). The other classes corresponding to it are the agricultural class, the working class and the service class.

1.4 Creative Community

For the creative community, Richard Florida believes that “the place must be open, there must be diversity, there must be an open gay community, and people there have different races and ethnicities. There are different ages. The people in the paragraph are living, and they are easy to accept young people, and the appearance of those people is not the same (Richard Florida, 2010).” That is, the creative area can provide interesting lifestyles, social activities, diversity, inclusiveness (such as accepting homosexuals), authenticity, ability to reflect identity, recognition, ability to have unique local qualities, and so on.

1.5 Creative City

Successful creative cities have the following characteristics: hard factors (creative physical space such as museums and exhibition halls), urban history, individuals (leaders, stars, etc.), open communication, network connections, organizational capabilities, urban cultural image, mature Cultural and creative industry clusters, art and media education, technology environment, cost of living (affordable housing, etc.), pleasant atmosphere, etc., these characteristics can attract creative people, as well as various creative enterprises, thus driving the city's creative economy development (Klaus R. Kunzmann et al, 2013).

2 Shanghai 21st Century as a creative city development trend

2.1 Creative Economic Level

2.1.1 Creative Investment Index

In the 21st century, Shanghai's creative economy is developing rapidly. R&D investment in the creative sector has grown exponentially, the number of licensed patents has continued to grow, and creative industry workers are steadily growing. Simultaneous development of technological innovation and creative work will become one of the main driving forces for Shanghai's economic growth.

In 2000, total R&D expenditure was about 7.673 billion yuan, and it increased to 93.614 billion yuan in 2015. The total R&D investment during this period increased by 11 times. In 2000, research and development institutions, universities, and enterprises did not have high R&D expenditures. From the perspective of growth rate, the highest is the R&D expenditure of enterprises, followed by R&D expenditures of scientific research institutions and research and development funds of higher education institutions.

Fig.1. Significant growth in creative investment: research and experimental development (R&D) funding

2000-2015

(Source: Shanghai Statistical Yearbook 2004-2016)

2.1.2 Creative Achievement Index

From the beginning of the 21st century to 2015, from the year-on-year curve of R&D results, although there was a slight downward trend in 2004 and 2013, the overall situation continued to grow. In 2000, the number of authorized patents in Shanghai was only 4,050, and it increased to 60,623 in 2015, almost 15 times more than the 20th century American mentioned by Richard Florida in *The Rise of the Creative Class*. Authorized patent growth.

Fig.2. The growing creative achievements: the development of patents 2000-2015

(Source: Shanghai Statistical Yearbook 2004-2016)

2.1.3 Creative Workers Index

Compared with R&D investment and creative achievements, the increase in the number of creative workers is not very large, but it is also a growth trend. Technological innovation practitioners, such as scientists and engineers, increased from 18,365 in 2005 to 45,196 in 2015, an increase of 2.5 times. In particular, from 2008 to 2009, the largest increase, an increase of 15,000 people. The number of people in culture, sports and entertainment has been fluctuating up and down, with an overall increase of around 20,000.

Fig.3. The number of creative workers increased slightly 2005-2015

(Source: Shanghai Statistical Yearbook 2004-2016)

2.2 Creative level

2.2.1 Hierarchy structure and proportion

In the 21st century, the creative class in Shanghai is rising and its number is growing steadily. From 1,633,700 in 2005 to 331,270 in 2015, it has roughly doubled, and the total number of employed people has increased by about 4.5% in total. The increase is not large. For the creative class, Shanghai should also be in the future. Adjust public policies to attract more creative people.

From the overall chart, Shanghai's labor class still plays an important role, both in terms of quantity and proportion, at the highest position, followed by the service class, the creative class, and finally the agricultural class. The number and proportion of the agricultural class are decreasing year by year, while the number of labor class and service class is increasing year by year. The difference is that the proportion of the service class has increased, and the proportion of the labor class has decreased in recent years. There is a tendency for the number and proportion to gradually approach.

Nobel laureate Robert Lucas believes that productivity due to the agglomeration of human capital is a key factor in regional economic growth, calling it "the out-of-bounds effect of Jane Jacobs" (Richard Florida, 2010). Therefore, in the future, Shanghai's urban development expects that the proportion of creative and service groups will increase substantially, and the proportion of working class and agricultural class will decrease. But this does not mean that the service class will replace the working class, because the meaning of the service class is mainly to support creativity. Class and creative economy. This trend means that creative people will start to recognize the lifestyle and atmosphere of Shanghai and can gather here. It is accompanied by creative companies that need manpower to choose Shanghai. The synergistic development of the two will drive Shanghai's economic development.

Fig.4. Hierarchy structure 2005-2015

(Source: Shanghai Statistical Yearbook 2004-2016)

Fig.5. Hierarchical structure 2005-2015 (% of total employed population)

(Source: Shanghai Statistical Yearbook 2004-2016)

2.2.2 Salary level

The chart shows that the creative class has been at the highest salary level for ten years, followed by the service class, the working class, and the lowest is the agricultural class. On the whole, due to the rapid development of China's economy, all sectors have shown a sharp growth trend in the past ten years, with the creative and service sectors growing fastest. In 2005, the average salary of the creative class was about 33,000, and it increased to 90,000 in 2015. In 2005, the average salary of the service class was about 23,000. In 2015, it increased to about 68,000. In the past ten years, both classes have increased their wages by about 2 times.

Fig.6. Average salary level of people at all levels 2005-2015

(Source: Shanghai Statistical Yearbook 2004-2016)

2.3 Creative City Level

2.3.1 Immigration Index - Urban Openness

A large number of studies have shown that the immigrant population has a positive effect on the economic development of the country and the city (Richard Florida, 2010). Wall Street Journal reporter Baska Zachali's "Globalization of Me" mentioned that "opening up to immigrants is the cornerstone of creativity and economic growth." He believes that the success of the national economy is in line with the entire country. The openness of creative talents and dynamic people around the world is directly related (Richard Florida, 2010). I think the same is true for cities, that is, the degree of urban economic development is directly related to the openness of creative talents and dynamic people around the world.

The following picture shows the trend of the number of migrants in the past ten years according to the Shanghai Statistical Yearbook. It can be seen that from 2009 to 2010, regardless of the resident population, there is a relatively large increase in the proportion of migrants and migrants, indicating a large amount during this period. The immigrant population flooded into Shanghai. This is because in 2009, the Shanghai Municipal Government issued a notice on the "Trial Procedures for the Hold of the Shanghai Residence Permit" to Apply for the Permanent Residence of the City, That is, the eligible entrepreneurs and employees in Shanghai can meet the requirements. Apply for Shanghai household registration. From 2010 to 2015, the migrant population is basically in a relatively stable trend. It may be due to factors such as high housing prices in Shanghai and difficulties in settlement. The increase in foreign population is very low.

2.3.2 Gay Index - Urban Inclusion

Richard Florida (2010) mentioned in his book that he and Gates conducted a comparative study of the creative/high-tech industry distribution and the homosexual index rankings, and found that the homosexual index is an effective indicator for measuring diversity. Because of the usual situation, the colony that can accept homosexuals also has a relatively open attitude towards other types of people (Richard Florida, 2010). That is to say, in areas with high gay index, the degree of openness, diversity and tolerance of the city will be relatively high. Such an area plays an important role in stimulating creativity and high-tech growth.

Since China's overall openness to homosexuality is not high, there is basically no accurate research data. Therefore, it can only be based on the data in the 2015 Blued Big Data White Paper. Blued is currently a popular gay friend dating app, and the number of users is very high. It accounts for 84.57% of the domestic gay apps, which is relatively more telling. The data shows that the number of Blued users nationwide has increased

significantly in recent years. On the one hand, it reflects the popularity of APP, and on the other hand, it shows the growth of this group and the demand for social. In terms of user rankings, Beijing was the highest, followed by Guangdong, Jiangsu and Shandong (no data rankings were found later). Shanghai is geographically close to Jiangsu. In theory, the number of users should be high, but it is not ranked in the top four users, indicating that Shanghai is not very tolerant of the diverse population. At this point, Shanghai, as an international metropolis, should make a difference and strive to create a more open and inclusive urban environment. Only in this way can Shanghai attract more creative people.

At the same time, I believe that the increase in immigration is not high, and the homosexual index is not high. These may be directly related to the results of the previous increase in the creative class, and further research is needed in the future.

Province	Blue users nationwide ranking
Beijing	1
Guangdong	2
Jiangsu (near Shanghai)	3
Shandong	4
...	...

2.3.3 Creative Industry Agglomeration Index - Urban Culture Level

Based on the development status of urban creative industries, the identification of creative industry clusters with corresponding funds and supporting support is a relatively simple and fast way to achieve effective results in the material and space level, accompanied by a large number of urban material space renewals in recent years. Transformation, this kind of government-led industrial cluster development model is widely used in major cities such as Beijing, Shanghai, Suzhou, Xiamen, etc. According to statistics, at the end of 2015, Shanghai has certified 126 municipal-level cultural and creative industrial parks, covering a total of 17 districts and counties in the city. At the end of 2017, Shanghai issued "Several Opinions on Accelerating the Innovation and Development of Cultural and Creative Industries in the City", and proposed that by 2035, it will fully build a cultural and creative industry center with international influence.

2.3.4 Creative Index

The 2017 China Urban Creativity Index (CCCI2017) was jointly completed by the School of Management of Shenzhen University, the Research Institute of Cultural Industry of Shenzhen University, and the National Cultural Innovation Research Center of Shenzhen University. The results show that Beijing, Shanghai, Hong Kong, Shenzhen, Hangzhou, Guangzhou, Chongqing, Suzhou, Tianjin, and Taipei rank among the top 10 in the 2017 China Urban Creative Index. It can be seen that Beijing and Shanghai are leading positions in creative cities nationwide.

Fig.10. Creative Index Ranking 2015-2016

(Source: 2017 China Urban Creativity Index (CCCI2017) released data)

In view of the development trend of Shanghai as a creative city in the past ten years, the advantages are that the national level has a large investment in research and development in Shanghai, a large number of patents granted, a rapid development of creative industries, and a leading index of creativity across the country. In other cities (except Beijing), etc., the shortcoming is that the number and proportion of the creative class is not big enough. At the same time, as the international metropolis of Shanghai, the openness, inclusiveness and diversity of the city are far from enough. In these respects, we can learn from European and American cities, such as Helsinki, to guide Shanghai's future development strategy and transformation as a creative city.

3 Localization of Creative Cities: Drawing on the Capital of Creativity: Helsinki City Development Strategy

3.1 Overview of Helsinki Development

Helsinki is the capital and largest city of Finland. At the end of 2016, the population was about 635,000. Helsinki is considered to be a very livable city and a vibrant cultural city and destination. In 2012, the New York Times commented on the city like this: "Design! Design! Design! Design is the DNA of this city." (Klaus R. Kunzmann et al, 2013) Now, Helsinki has clearly developed into a science, art, creativity and innovative cities and creative industry centers with excellent service (Klaus R. Kunzmann et al, 2013). Finland's Greater Helsinki 2050 vision is from urban urban life, urban life attraction, economic and employment growth, sustainable urban transport, entertainment, urban natural and cultural environment, sea area and urban internationalization. New requirements.

3.2 The basic characteristics of a creative city - Helsinki related experience

Richard Florida (2010) states in the book *The Rise of the Creative Class* that the basic qualities of a creative city are: a lifestyle with creative culture; a "third space" for social activities; And inclusive; the authenticity and uniqueness of the city; the realization of its own value and identity; participation and local quality. Helsinki, as a successful creative city in the 21st century, is well represented in these six aspects. Correspondingly, Shanghai can get some inspiration from Helsinki's way of shaping the characteristics of creative cities according to the current development status.

At the lifestyle level, Helsinki hosts a large number of cultural events as well as festivals, celebrations, etc., and is instructed by influential cultural institutions to form a strong urban culture and artistic atmosphere. People here can easily find activities and places that suit them, such as interesting musical performances, exhibition galleries, performance venues and theatres. The public's satisfaction with cultural facilities is as high as 94% (Klaus R. Kunzmann et al, 2013).

Social activities and diversity levels, such as the former Cario workers' settlement in the north, are known for ethnic restaurants, bars and sex shops. There are a large number of students, Bohemians and residents who like beer, and it is also a concentrated area for middle-class IT workers (Klaus R. Kunzmann et al, 2013). People here are open-minded and can accommodate people of different nationalities, races, ages and sexual orientations. Among them, "Carlio Manufacture" was transformed into a studio for 19 young artists, and also provided services for locals such as shops, galleries and cafes, which provided "the first place to interact with acquaintances or others. Three spaces" (Klaus R. Kunzmann et al, 2013).

At the identity level, Helsinki supports cultural activities and art education through a number of regional cultural centers, providing artists in all fields with affordable venues to display their works, so artists can realize their

value here. Another example is the Araba beach area, which has transformed the former glassware and ceramics factories into attractive creative residential areas. At the same time, through government intervention, it provides artists with the corresponding needs, that is, developers are required to invest a portion of their investment in art investment. Etc (Klaus R. Kunzmann et al, 2013). These practices will enable people here to establish their own identity and actively build the community into a community that can recognize their identity (Richard Florida, 2010).

In terms of the authenticity and local quality of the city, the city should create its own characteristics of culture, geography, history, facilities, environment and activities. Although the city of Helsinki has a cold climate and a poor geographical location, and because it is located in a very polar night, the lack of sunlight in winter can easily cause seasonal depression. But by discovering the potential of urban resources, the “Light Power” campaign, which calls for people to take a serious look at lighting, has become a festival for shops, galleries, streets, parks, museums, and even factories and construction sites. The venue has attracted many international cooperation and a large number of tourists, becoming a new city brand in Helsinki (Charles Landry, 2009).

3.3 Localization Construction - Shanghai's future development strategy and recommendations.

First of all, Shanghai will continue to promote the development of creative industries, but in the future, it is necessary to reduce the development of “commercial real estate” and “fragmentation” of creative industrial parks, and gradually integrate the industrial chain of creative industries in the district.

Secondly, it creates Shanghai's own urban characteristics from the aspects of history, regional culture and artistic activities, and provides the public with more space for social activities, so that people can find their own lifestyle here.

At the same time, Shanghai should treat foreigners, homosexuals, young people, etc. in a more open and inclusive manner, that is, to show the diversity of international metropolises.

Finally, the government should actively adopt policy interventions to provide affordable housing, venues, etc., for entrepreneurs, where they can achieve self-worth through their own efforts, and can be rooted in Shanghai to obtain A sense of identity and belonging, and so on. These will attract creative classes to live and work from all levels, which means that companies and resources that require manpower will gather here. In this way, people, companies and resources with different professions and abilities will gather in Shanghai at the same time, which will produce sufficient effectiveness to promote the growth of Shanghai's economy in the future (Richard Florida, 2010).

Conclusion

The 21st century is an era dominated by creative classes that promotes urban development with a knowledge economy and creative economy. In order to attract creative class, the city needs to build an environment conducive to creative development, that is, open, inclusive, diverse, and identity, to provide a suitable lifestyle, social activities, local quality environment. These innovative urban traits are essential to Shanghai's future creation of a global city of excellence. At present, the number and proportion of creative people in Shanghai is not big enough. The openness, inclusiveness and diversity of their cities are still far from enough. These need to be adjusted and improved through urban public policies. In the future, under the guidance of the creative class, Shanghai will become a city of innovation, a city of humanities and an ecological city. It will become a socialist modern metropolis with world influence. This is our common vision.

(Note: All charts are drawn by the author based on shanghai yearbook data and network data)

UN Habitat's participatory initiative to public space design involving residents, refugees and local authorities: the case of Naba'a', Bourj Hammoud, Lebanon

Christine Mady¹

¹*Notre Dame University-Louaize, christine.mady@ndu.edu.lb*

Abstract: This paper explores the process of engaging participants in designing a public space in a neighbourhood with socially deprived people from different backgrounds. The space was designed by locals and refugees, with the support of the local authorities. The paper investigates the extents to which placemaking, initiated by a third party could generate a civic space that combines people through everyday needs stemming from the context, and being addressed over time, rather than in a fixed design outcome. It examines the intervention initiated by UN Habitat Lebanon in Bourj Hammoud municipality at the eastern boundaries of administrative Beirut, and specifically within it, the area of Naba'a. Studying this public space initiative within Naba'a addresses marginal neighbourhoods that are in need of ameliorating the living conditions, and improving the quality of life for the population. UN Habitat's intervention comprised mediation between municipality and residents, and collaboration with the local residents and refugees within one neighbourhood in Naba'a, and framing their needs for an open public space. UN Habitat engaged the municipality in supporting the locals in executing this public space. The presentation argues that this process enabled place attachment for people with no official claim to an urban area.

Keywords: public space; social cohesion; place attachment; Bourj Hammoud

Introduction

Currently many urban contexts witness conflicts, displacement and the influx of refugees with limited access to services and job opportunities. These people often reside in marginal neighbourhoods, which are not visited by outsiders, reducing the opportunity for encounter (Netto *et al.*, 2018) and 'unplanned interaction' between disparate bodies and things (Amin, 2012: 71, Watson, 2006). This paper focuses on the process of public space provision and design in marginalised neighbourhoods that goes beyond securing a physical location (Tornaghi and Knierbein, 2015), and takes the challenge of activating and maintaining the space. In this approach, through a third party's initiative, local authorities, local residents and refugees are engaged in the decision-making process for designing a public space. The paper frames this approach through a relational perspective (Lehtovuori, 2010, Tornaghi and Knierbein, 2015), which allows for the understanding of the space contextually as a process intertwined with the local daily social practices (Knierbein, 2015). This understanding

considers the meanings, qualities and values attached to spaces (Healey, 2006), while enabling diverse people to jointly build space attachment.

The selected case study is one neighbourhood in Nabaa', Bourj Hammoud municipality, to the east of the capital city Beirut, Lebanon that has witnessed since World War I perpetual population flows and shifts causing instability and poor living conditions.

The following section examines marginal neighbourhoods and implications for their users and public spaces. The framework of a relational perspective on public space is then presented with the aim of understanding which processes could mitigate issues arising in public space design within marginal neighbourhoods. The next section focuses on UN-Habitat's participatory approach within a 'counter flow' relation and its application within a deprived neighbourhood.

Marginal Neighbourhoods and Public Spaces

The provision of public spaces is highly associated with their success in promoting or regenerating cities. Central public spaces reflect 'the legitimacy of the local administration' and are often considered 'nodes for social cohesion' (Madanipour, 2004: 269). Yet public spaces in marginalised neighbourhoods are usually neglected by local authorities and investors due to various reasons (Madanipour, 2004) ranging from the absence of commitment if residents are not voters, to the lack of interest in investing in a neighbourhood with poor environmental quality of urban space and residents with low purchasing power. The spaces are then either closed, inaccessible or highly securitised and controlled. Alternatively, self-regulatory mechanisms emerge for coping with the lack or the poor state of public spaces such as avoidance of the space by the residents (Barolsky, 2016) leading to the lack of encounter opportunities (Kwan, 2009) and often segregation. This segregation is reflected spatially but also in their social, economic and everyday life activities (Healey, 2006, Selim, 2015). Residents are disadvantaged and do not have equal access to job opportunities, facilities and amenities (Netto *et al.*, 2016, 2018). Yet they seek refuge within such neighbourhoods not by choice but rather by the lack of it. The population in such neighbourhoods is socially fragmented, forming 'a mosaic of difference trapped within a limited space ... and with limited capacity to connect to the outside world' (Madanipour, 2004: 271).

In the particular case of Nabaa' this neighbourhood is populated with disadvantaged residents consisting of locals or refugees who face social exclusion. On the one hand, refugees are often perceived as a security threat and a competitive workforce (Madanipour, 2004, Healey, 2006). On the other hand, the local residents can equally experience social exclusion due to different forms of vulnerability, for example age, disability, employment, ethnicity or other (Madanipour, 2004: 270, Selim, 2015). The vulnerability and poor living conditions that residents share lead to avoidance or lack of interaction, especially if 'most are preoccupied with sorting out some of the basic problems of life, their capacity to deal with others becomes more limited' (Madanipour, 2004: 271). Different forms of expression and the difficulty of communicating among residents cause tensions, and in some instances generalisations and prejudices about people that are perceived as different (Madanipour, 2004).

Tensions and schisms are visible in such a marginal neighbourhood's public spaces, especially if dominated by one group, sometimes requiring the intervention of security forces (Barolsky, 2016).

The decline of public spaces and lack of encounter among residents leads to their detachment from the place (Dines *et al.*, 2006, Lehtovuori, 2010). Some residents withdraw from the neighbourhood's urban spaces when feeling unsafe, intimidated or discriminated. Yet there is evidence that these perceptions can be reversed by increased everyday contact and interaction (Selim, 2015). This requires residents' mobilisation and collective engagement in the process of providing public spaces that meet shared interests and needs (Madanipour 2004, Lehtovuori, 2010). Through collective action, residents are enabled to 'de-alienate' public spaces (Knierbein, 2015: 54) and establish communication channels among themselves. Through the exchange of 'local knowledge' (Healey, 2006: 111), communication facilitates understanding, learning and acknowledging different ways of using, organising and valuing space (Healey, 2006: 112), which affect spatial practices and expressions. Discussing 'the management of co-existence' in shared space requires communication (Healey, 2006: 111) that is transformed into action. Over time, this may enable forging social links in public spaces beyond kinship or one's community (Healey, 2006), which is essential in a fragmented society. This is achieved through their shared engagement in shaping that space within their neighbourhood (Madanipour, 2004: 282) and establishing place attachment over time (Dines *et al.*, 2006, Lehtovuori, 2010). This attachment is dynamic and can switch from negative to positive depending on social relations and experiences as well as the presence of support available in the neighbourhood in the form of social networks, local facilities and reference points (Dines *et al.*, 2006).

Public Space Design and the Relational Perspective

This paper uses a relational perspective to explore public space as a process within a context with socially constructed meanings and practices, rather than as a product, a physical stage or a container of activities (Lehtovuori, 2010). This approach enables the analysis of material and immaterial aspects of public space by critically examining the relation of the social, political, historical and cultural context and its impact on people's lived practices within the public space process (Tornaghi and Knierbein, 2015). Within this perspective, individuals are given voice and are recognised as 'communities whose emotional and lived involvement in place making is not an option, but a fact' (Tornaghi, 2015: 35). These actors adopt 'a radical proactive attitude in the reconfiguration of institution-citizen relations in light of environmental and social justice' (Tornaghi, 2015: 35). This approach fosters 'links to be created between the dynamics of civil society (including conflicts between individuals, groups and different social spheres), political decision-making, and planning and design practice' (Tornaghi and Knierbein, 2015: 2).

UN-Habitat's role goes beyond giving voice to people (Miessen, 2010: 14); it rather works to ameliorate a crisis situation in a marginalised neighbourhood, and forge a lasting collaboration. UN-Habitat is keen to raise awareness on public space not only at the level of communities but also at the level of local authorities, highlighting the significance of learning from local knowledge and collaborating (see UN-Habitat, 2017b). 'Public space has surfaced as a top priority and a dire need, it is not only about asphaltting a space and fencing it with walls, it is about a social need' (social development coordinator, UN-Habitat, personal communication, 25 January 2018). There is a sense of 'responsibility' from the part of UN-Habitat and the local authority to improve the citizen-institution relation. UN-Habitat has an 'interest' in giving voice to vulnerable people and learning from insiders (Till, 2011). Their approach could be considered as 'entering participation from the side' (Miessen,

2010: 16), and engaging various stakeholders in decision-making. This is achieved through the neighbourhood profiling process and learning about the intricacies of the political, economic and social characteristics of the context under study (Miessen, 2010). In turn this insiders' knowledge guides the public space process, which combines people's needs with the municipality's vision. The next section examines UN-Habitat's public space design in a neighbourhood in Nabaa', Bourj Hammoud. But what was specific in the choice of Nabaa'?

Introducing Nabaa' in Bourj Hammoud

Bourj Hammoud is the eastern suburb of the capital city Beirut, which until the eighteenth century was agricultural and marshland. This terrain hosted Armenian refugees towards the end of the First World War, following Ottoman persecution, within shelters in a grid iron layout with narrow streets (Harmandayan, 2012).

A second wave of refugees included Lebanese, mainly from the south and east of the country during the civil war period 1975–1989. Similarly, Lebanese-Armenians also fled into Bourj Hammoud seeking refuge, and investing in commercial activities. This transformed the area into a commercial hub but also caused the out-migration of those economically better off (Harmandayan, 2009). The area's proximity to employment sources, and the affordability of housing caused the influx of economically and socially disadvantaged people of various backgrounds including Lebanese and foreign transient workers (Harmandayan, 2009). Historically and spatially, this population diversity and turnover resulted in social fragmentation.

In addition to population dynamics, planning decisions capitalised on the road network (Salam, 1998), leading to the division of Bourj Hammoud into a northern industrial waterfront area and a predominantly residential southern area, characterised by deteriorated housing stock with commercial streets dissecting the urban blocks (Harmandayan, 2012). In particular, the south-western part called Nabaa' is characterised by high population density, poor services, the lack of public spaces and a degraded urban environment (Harmandayan, 2012).

Within such a context Nabaa' still witnesses episodes of population influx, and is considered a hub for the disadvantaged. The most recent dynamic is the influx of Syrian refugees. Since 2015, about 61 per cent of the population are Syrian refugees, about 34 per cent are Lebanese and Armenian, and the rest are foreign workers. Irrespective of their background, the population is characterised by low income, and renters suffering from rising rent prices due to the housing market monopolised by few real estate dealers (social development coordinator, UN-Habitat, personal communication, 25 January 2018).

The neighbourhood under investigation in Nabaa' (Figure 1) is located at the crossing of three main roads and next to a school and mosque (UN-Habitat, 2015: 9). It comprises three blocks with 48 buildings and an estimated 2,044 residents in 2015 (UN-Habitat, 2015: 9). The sidewalks are in poor condition, with only commercial activities, and little greenery. The intersection of the three main roads is considered as a square, and the internal roads as the neighbourhood's public spaces (UN-Habitat, 2015: 9).

Figure 1: Location of Bourj Hammoud east of Beirut

To investigate the current public space provision in this neighbourhood, I conducted interviews between January and November 2018 with the social development coordinator at UN-Habitat who was in charge of this process, and reviewed available reports by UN-Habitat (UN-Habitat, 2015, 2016, 2017a, 2017b).

Intervening in Nabaa's

After conducting a rapid assessment in 2015 in Nabaa' followed by detailed neighbourhood profiling of Bourj Hammoud in 2016, UN-Habitat determined the imminent need to initiate a public space process and ameliorate living conditions in a highly congested area hosting refugees. This decision, which was supported by a successful public space programme application (UN-Habitat, 2017a), equally stemmed from the need to decrease tension among residents; this tension was manifested both verbally and physically. The local Lebanese residents claimed that safety and security deteriorated with the arrival of the refugees, and so did services including electricity and solid waste management. The municipality indicated that refugees had an economic impact by opening shops and competing with the locals. The school principal indicated that arguments among Lebanese and Syrian parents were recurring. The Syrians complained of prejudgement by the Lebanese, harassment of some females and money theft in some cases. So what was this public space process?

The Committee

In March 2016 a local committee of 11 members was formed with the help of a local female activist and under the guidance of UN-Habitat who requested that the members represent the neighbourhood with its social tissue including gender, age, role in this neighbourhood and nationality. The committee held regular meetings, and represented Lebanese and Syrians and included a municipal council

member, persons affiliated with the various political parties existing in the area, (for more information on various struggles in Lebanon refer to El-Khazen, 2000, Hanf, 1993, and Khalaf, 2002,). Particularly for contestations in public space refer to Mady, 2012, Fawaz *et al.*, 2009, Bou Akar, 2012, Bollens, 2012, and Deeb and Harb, 2013) two principals of local schools, a mukhtar or head of the locality (a mukhtar is a representative of the local government in charge of administrative tasks) and two activists from the area. In the local committee meetings, the significance of a public space process was highlighted, and residents were made aware that the municipality is a partner along with them in the process. As the majority of residents in Nabaa' are not from Bourj Hammoud, they have no voting rights within this municipality according to the Lebanese electoral law. This has led some residents to believe that their needs are neglected because they are non-voters.

The Intervention Site

One of the committee's first tasks was to aid UN-Habitat in identifying possible intervention sites. Several vacant lots were found at the south-western periphery of Nabaa', yet they were privately owned. Searching within the blocks, the committee identified a lot which was municipally owned though small in surface area, 200 square metres. UN-Habitat then got permission from the municipality to proceed with the implementation of the public space project on it. There was an obstacle, however, the domination of the lot by a drug dealer who defined his territory with a tent, a small van, tables and chairs where men often gathered. The dealer was a foreign worker whose sons were imprisoned, yet was under the protection of local influential persons. The local committee and the municipality worked for almost a year to relocate him away from the neighbourhood. In February 2017 and following the mayor's last warning for evacuation, the public space implementation began. Note that this could not have been achieved without the consent of the local political party representatives, after identifying this lot as municipal and seeing the benefit in offering it to the residents as a public space (social development coordinator, UN-Habitat, personal communication, 23 March 2018).

Minecraft as a Participatory Tool

Once the intervention site for the public space implementation was determined, UN-Habitat was ready to start the process of public space design by mobilising and engaging the community (UN-Habitat, 2016). Within the presented case study, UN-Habitat opted to use Minecraft as a participatory platform (UN-Habitat, 2016), which since 2013 has been implemented in other contexts, yet not in Lebanon.

Minecraft is a computer game that uses building blocks to visualise design ideas. UN-Habitat used it as an engagement tool following seven steps, first by building the model of the location using Google Earth and available maps. The second is to offer training to a group of participants from a UN-Habitat expert. The third is to hold workshops with community participants to give instructions on Minecraft and establish dialogue regarding the purpose of this process and the significance of public space. The fourth is forming groups of 2–4 participants each sitting at a computer, where ideas were collected and discussed, missing amenities were identified, similarities and differences in approaches were later compared. The fifth is constructing the actual Minecraft model generated by the participant groups within the 2–4-day workshops. The sixth is sharing the models with stakeholders, discussing, prioritising and ranking the proposals; this is further explained for Nabaa's case. The seventh is

converting the final Minecraft model into architectural work, estimating the cost and preparing for bidding then implementation (UN-Habitat, 2016). Minecraft was seen as a useful tool for building cohesion since it enabled residents to share their everyday knowledge of the neighbourhood including their experiences, their values and cultures, and use this knowledge as ingredients in a joint public space design process. This established a socio-spatial and contextual link that was useful in forging an understanding of what constitutes a public space for different users.

The public space process in Nabaa' is a pilot project, introducing a participatory approach that is not common in Lebanon, let alone involving Lebanese and refugees. Some adjustments in the seven steps of Minecraft approach were necessary to fit within Nabaa's context. These related to modelling, language, information dissemination and workshop duration. To produce the site model, Minecraft programmers were sent surveyed maps and photographs of the location. UN-Habitat game facilitators did not speak Arabic, except one urban designer who worked in UN-Habitat in Sweden and was trained on Minecraft facilitation. The engagement process took approximately four months, including networking with the community and disseminating the information provided during the workshop. While the Minecraft training sessions usually take four days, the facilitator was alerted that in the Lebanese context and culture, participants would not dedicate that much time. Therefore, information usually shared in the first Minecraft session was instead disseminated in the focus group, allowing for shorter workshop duration. These groups also served to reveal the needs and opinions of residents.

The focus groups took the form of a one-day discussion organized in the neighbourhood school. The groups were formed with the help of the local committee, in particular the female activist, and according to the selection criteria given by UN-Habitat to represent the neighbourhood residents. This was possible as this activist has lived in the neighbourhood for 18 years and gained the trust of residents. She was the gatekeeper whom all authorities and NGOs contacted for support. The groups had five themes: children, adolescents, youth, men and women, and each group was then asked to nominate members for the Minecraft workshop. The five focus groups comprised 120 participants who roughly represented 120 households within a catchment area of five minutes' walking distance from the location. Roughly an equal number of males and females participated and the groups comprised Lebanese and Syrian from different social backgrounds (ranging from homeless to employed).

Tensions between both nationalities surfaced during the focus group discussions, in some cases shifting to problems they were facing and projecting them on the public space discussion. The main issues of contestation were the drop in commerce for the Lebanese as Syrian shops selling cheaper products were frequented by the Syrian refugees; housing rent skyrocketed after the arrival of the refugees with an increase in demand and a limited supply, the willingness of Syrians to share apartments and split rent; issues of insecurity with the arrival of refugees and women feeling unsafe to go out; incidents with Lebanese and Syrians leading to prejudices and generalisations. After continuous discussions, these issues were resolved by UN-Habitat as follows: empowering the Syrians and allowing them to explain their case in front of the Lebanese; reminding the Lebanese of their own war struggles, and that refugees are obliged to flee and hence require support rather than adversity; using as examples public spaces in other refugee-receiving countries such as Germany, in which public spaces are equally accessible by Germans, Syrians and Lebanese without discrimination (social development coordinator, UN-Habitat, personal communication, 15 January and 23 March 2018). The latter was in response to a request to either provide separate public spaces, or temporally segregate the

space's use by nationality, knowing that the space is too small to hold many users. UN-Habitat responded by explaining that the management of the space will assure an equal opportunity and access to all residents to use it (social development coordinator, UN-Habitat, personal communication, 15 January and 23 March 2018).

In July 2016 the Minecraft training started and included 24 participants representing the five focus groups. Around ten groups with six to seven members participated (social development coordinator, UN-Habitat, personal communication, 25 February 2018). The training took place at the UN-Habitat HQ in west Beirut during two consecutive days. Participants were roughly equally divided in terms of gender, but predominantly Lebanese. Syrians, especially females, had some cultural constraints, such as women requiring the permission or accompaniment of the husband, and children not being allowed to go without a parent. About 30 per cent were Syrian and 70 per cent Lebanese in a neighbourhood where 61 per cent were Syrian. However, this did not prevent collaboration within the groups. A 50-year-old woman who could not use the computer was supported by younger group members. One homeless young man was very creative in the ideas he proposed, as was another drug addict. The Syrian children were often more active and creative in their proposals than Lebanese ones. The participants worked in groups of three, and some were allowed to work individually when they did not integrate well in the group. Many different proposals emerged: a Syrian child proposed building his house; some proposed building on two stories a garden and library.

It took the participants one-and-a-half days to complete their designs. Facilitators of each group then summarized the components of each proposal. It is worth noting that participants worked together in mixed groups, not minding their differences and focusing on their design proposals. On the second day, the work of the groups was presented to the local committee. Each group had one participant who presented the group's ideas and the discussion was with the local committee, while the facilitator, an architect, registered all ideas and counted frequencies (turned to scores). Participants felt proud that their work was taken seriously by the local committee including the municipality. The site planning was the combination of ideas with high scores from all groups, which became the basis for the Minecraft model. Participants were made aware that individual designs could not be executed so as not to favour one group over another. This was to ensure equal opportunities for the shared ideas to be implemented. They were also informed by the local committee regarding the feasibility of their ideas (trees, green surfaces, toilet, two storeys and so on), and provided with explanations about the rejected ideas. For example, the proposal to have a two-storey project including a small library was dismissed after explaining why it cannot fit within this tiny lot. The local committee validated the model with UN-Habitat to arrive at a final design, which took a week after the workshop. Some changes were made, for instance bollards proposed to mark the space's edge were replaced by a fence upon the request of the committee, although against UN-Habitat's intentions to keep the space open. The UN-Habitat facilitator then converted the key proposals into a Minecraft model, which the UN-Habitat architect later visualized through perspectives and drawings representing the design components. These included land levelling, flooring, landscaping, fixing sidewalks, furniture, trees and vegetation. The components corresponded to walkways, a resting area, a play area, trees and greenery, screening the adjacent building, lighting and toilets. During the discussion, residents decided not to have the toilets, as the space is very small, and embedded in their neighbourhood, which meant they could use utilities within their houses instead.

The discussion ended around August 2016 when the design and execution drawings with the corresponding bid documents were prepared by UN-Habitat and handed over to the municipality. One condition was to involve workers from Nabaa' to ensure the engagement of the neighbourhood residents during the implementation process. Between August 2016 and March 2017 the municipality started the procurement process. The selected bid included only local workers, such as the contractor, the builder and others. Meanwhile, UN-Habitat kept visiting the area to reassure people that the implementation was ongoing and that it was adopted by the municipality. The local committee continued its involvement in the process; one female activist had an active role in resolving problems arising during implementation. For instance, she was able to detect people who falsely claimed they worked in implementing the public space and asked for payment.

In August 2017 and under the auspices of the municipality, 'Nabaa's Garden – Bourj Hammoud' was inaugurated. Local catering was provided (ice cream vendor) and a show for children was organised (Figure 2). The lively event attracted many people from outside the neighbourhood.

Figure 2: Location of the neighbourhood in Nabaa'

Post-Implementation

The inauguration had an impact beyond the neighbourhood itself with positive and negative effects. On the positive side, some NGOs working within Bourj Hammoud and Nabaa' are using the space for meetings after gaining permission from the municipality (YMCA, Kafa and Himaya). The space is now well-known and popular, and is mostly active when open. On the negative side, some children started fighting over the monkey bar and the municipality did not abide by the space management agreement, and the grass and trees withered. To resolve these issues, the bar was removed and opening hours reduced (Figure 3). To some extent, the belief that the municipality neglected the neighbourhood due to residents' inability to vote seemed to hold true. UN-Habitat's response to this was to rethink the space with the residents' help. This reflects the principle of counter flows, where input from different scales is continuously sought and used to manage the public space.

Figure 3: Location of the lot before and after the public space implementation

The agreement was to have two municipal wardens in two shifts, morning and afternoon. In reality, there was only one, a policeman. Yet after the opening, the space was closed for some days, after which one of the local committee members negotiated with the municipality to open the space from 8am to 2pm. These opening hours were not suitable for the Lebanese children who finished school around 2pm. Only Syrian children had an afternoon school shift and could benefit from the space in the morning. Instructions on how to use the space were posted at the entrance and included the exclusion of food, ball games and access to youth as decided by the local committee. The space was dedicated for resting and for children to play safely away from cars.

To date and after implementation, UN-Habitat has been engaged in further learning from residents about their needs from this space and establishing a sense of ownership. This includes considering: the opening hours, the warden, maintenance of the provided amenities, greenery and safety. Based on residents' feedback, the space was upgraded in spring 2018, and some design elements were changed. The concrete benches, which are less likely to be vandalized or damaged than plastic or wooden ones, were relocated as they are set too close to each other. The grass, which dried out, was replaced with rubber tiles that are safe for children. The concrete benches and walls were painted with graffiti. (social development coordinator, UN-Habitat, personal communication, 23 March 2018). The trees that dried out were replaced with trees in pots, which give shade and do not require much irrigation. The tree pots and sand pits for children will be reused old rubber wheels collected from the area. In terms of safety and visibility, two water tankers used to park just next to this space blocking the view. In their place the tree pots were placed to maintain visibility. Solar lighting fixtures are installed and the whole neighbourhood is benefitting from them. Light wire fences were installed rather than walls. The space's flooring was expanded towards the road, that is, out of its limits, thus extending it into the neighbourhood.

Meanwhile, negotiations with the municipality continue regarding the opening hours and management of the space – either provide a municipally assigned warden for the afternoon session, or assign a local who would be paid by the municipality or funded by UN-Habitat.

Conclusion

The bleak image of a degraded and socially fragmented neighbourhood was transformed. This was possible due to the relational approach, which enabled an ongoing process of communication and collaboration among the municipality, residents and refugees. Within this context, 'the core feature of a relational public space is change' (Tornaghi and Knierbein 2015: 15), which is manifested through the initial engagement of various actors in the space's implementation, the use of the space for social practices beyond the confines of the neighbourhood, and the upgrading that followed. It is an attempt to counter stagnation and residents' perceived neglect of their neighbourhood by the municipality, and equally mix residents rather than suffice to live parallel lives leading to prejudices. This dynamic engagement of individuals has both benefits and shortcomings. It is an interweaving process that starts with reading the spatial and social fabric of the neighbourhood, identifying individuals, establishing social networks, and involving them in placemaking, empowering them to gain a sense of ownership and place attachment, nurturing over time and space a process of social cohesion.

The recently designed space became one component of the nearby facilities that form a fabric weaving across the neighbourhood. This new place established a station in people's everyday practices, providing immaterial benefit through gathering and contributing to wellbeing, specifically for housewives. Also, the space was recognised at a wider urban scale by engaging residents but also outsiders, and accordingly pinning the neighbourhood on the city map.

The relational approach together built a process rather than a product. There is no expectation that the design will solve all the neighbourhood's problems. Yet using the design as a shared basis for the residents is seen to enable encounters, everyday practices, and possibly have the potential to gradually dissolve prejudgements and establish affinity and coherence among disparate residents. This

marginalised neighbourhood with its palimpsest social and spatial urban context provides the ground for reflections on similar contexts in globally.

Along the river Cormor, re-linking landscapes and public facilities in the region Friuli Venezia Giulia

Abstract: In Italy, the drawing of policies for an Urban Agenda has only recently re-gained attention on the national level. However, while the discussion still focuses on metropolitan and inland urban contexts concerned by major transformations or abandonment trends, the ordinary framework of small and medium cities and villages – building the most of Italian territories – tends to remain at the background. These situations prevail in Friuli Venezia Giulia, where the 71% of Municipalities count less than 5.000 inhabitants. Many urban centres stand nearby the system of rivers, which structures a variety of landscapes from the mountains to the sea. Since the 2000s, a number of Municipalities from the valley of the river Cormor have started re-thinking their economies, taking slow mobility as the driver for sustainable tourism. With the support of a citizens' Association, they are now working on a River Contract, a non-compulsory tool for the participatory construction of strategic/planning instruments combining environmental protection with sustainable local development. This is the context of the activities that the Master Course in Architecture of the University of Trieste has recently carried out in collaboration with local stakeholders. The design of the southern extension of a horse and cycle track along the river gave the opportunity to re-frame the issue of tourism in a larger planning perspective, aimed at enhancing the relations between the river, and the small/medium urban centres it goes through. Results offer new planning visions that: interpret the Cormor as the spine of a network of ecological services; foster the reuse and re-connection of existing public facilities; re-define the topic of 'slow tourism' according to the specific characters and lifestyles of these contexts.

Keywords: river landscapes; ecological services; slow mobility; public facilities

1. Introduction

In Italy, over the last years, the drawing of a national Urban Agenda has re-gained attention (Calafati, 2015, ed.). More recently, and in the view of the 2021-2027 European programmes, the evaluation of the results that have marked the period of policies and projects just behind us has been accompanied by reflections on a growing differentiation of urbanisation features all across the Country (Munarin and Velo, 2016, eds.; Urban@it, 2018). With reference to an increasing variety of development speeds and trajectories, this differentiation will make the *customization to the contexts* of future governance and planning tools a particularly complex task, both on national and local levels.

1.1 'Middle lands'

In Italy, the map of abandonment and of territorial situations in conditions of environmental, economic and socio-demographic fragility is increasingly articulated and widespread. Even urbanised territories

that have historically been at the centre of the dynamics of production and modernization are changing their nature. This process sees the interweaving of trends of selection and decline, of marginalization and slow emergence of new opportunities that, however, struggle to find full expression in new development paths (Borghi, 2017, ed.; De Rossi, 2018, ed.). In the background a broader reflection lies. In Italy and in Europe, today's definition of 'city' lends itself to different interpretations, as evidenced by the analyses of national research networks (Balducci *et al.*, 2017a, eds., 2017b, eds.; Alleanza Italiana per lo Sviluppo Sostenibile [ASviS] and Urban@it, 2018). Many Italian regions are divided into numerous Municipalities. Characterized by a dispersed urbanisation made by small centres, these territories are crossed by practices and rituals that, due to their spatial extension, appear in some ways 'metropolitan', and that with denser urban contexts share the issues of the crises afflicting the contemporary Western world. «Urban planning is fully involved, even shaken by the current mutation: the gradual shattering of proven ways of doing is accompanied by a serious difficulty in questioning its principles in relation to a new interpretation of what happens in the cities and territories, in what is now identified as the urban *tout court*» (Gabellini, 2018)¹.

In this sense, the case of Friuli Venezia Giulia is representative of situations that recur at national and European levels. In this region there are not real metropolitan cities; the 71% of Municipalities count less than 5.000 inhabitants, with an overall standstill of population and growing aging trends; there is only one medium-sized city (Trieste), and three small capital cities (Gorizia with 34.411, Pordenone with 51.139, and Udine with 99.518 inhabitants) (Regione Autonoma Friuli Venezia Giulia, 2018a). The contexts of Friuli Venezia Giulia belong to the many '*middle lands*' that dot the national territory. With this term we allude to situations that, while consistent and pervasive, do not fall within the parameters and perimeters of the most dynamic *metropolitan areas*, nor within those established for the most marginal *inland areas*, both at the core of the national and regional policies for the territorial cohesion established by the European Union programmes 2014-2020². Our interest in 'middle lands' derives from what in Italy today appears a «strategic, political and cultural disinvestment» in the urban peripheries of small and medium-sized centres, as well as in the many places of a «province that is made of polycentric urban and productive fabrics» (Carrosio, 2019: 13). In these contexts the number of inhabitants and the equipment of services still hold on (albeit with difficulty), the situations of economic crisis and decommissioning are still limited (and therefore, perhaps, easier to govern). Nonetheless – due to the difficulties in identifying and accessing specific financing channels – it is strong the risk of being left alone in the face of increasingly complex environmental and socio-economic challenges, and therefore of slipping into more serious conditions of marginality and hardship³.

1.2 A different perspective

Friuli Venezia Giulia is the context of the activities that the Master Course in Architecture of the

¹ From here on, all the translations from Italian texts are made by Elena Marchigiani.

² The reference is: to the National Operational Program (PON) *Metropolitan Cities 2014-2020*, adopted by the European Commission with Decision C (2015) 4998, and addressed to Torino, Genova, Milano, Bologna, Venezia, Firenze, Roma, Bari, Napoli, Reggio Calabria, Cagliari, Catania, Messina and Palermo; to the National Strategy for Inland Areas (SNAI), which involved 72 project areas (1.077 Municipalities) identified as «peripheral» and «ultraperipheral» with respect to the distance from the poles of urban services (Barca, 2012, 2016; Barca *et al.*, 2018; Carrosio, 2019). For an overview of the purposes and implementation of these programs, see: www.agenziacoesione.gov.it. Date of access: 31/05/2019.

³ In Friuli Venezia Giulia these risks are made even harder by the abolition of the provinces: the intermediate government bodies between the Region and the Municipalities. By virtue of its autonomous status, Friuli Venezia Giulia was in fact the only Region in Italy (together with Sicily, equally autonomous) to implement the Law no. 56/2014, dealing with provisions for Metropolitan cities, Provinces, unions and merging of Municipalities. Today, there is therefore no intermediate level institution that is able to coagulate the interests and perspectives of territorial development among Municipalities that generally have a few thousand inhabitants.

University of Trieste has recently carried out in collaboration with local actors and Municipalities⁴. In this region, many urban centres stand nearby the system of rivers stretching from the mountains to the sea. The focus of our reflections is the sequence of urbanised spaces, including both small centres along the river Cormor, and the peripheries of the middle-sized city of Udine bordering the watercourse⁵. These areas were selected in order to cover a significant sample of *intertwined river and urban landscapes*: from the northern foothill sector, where the Cormor runs in the middle of the reliefs topped by small villages; to the ‘dry plain’, where Udine conurbation lay, and – apart from the Cormor – the minor water network is mainly underground; to the southern ‘wet plain’, where the water system comes to the surface, and the urbanisation becomes more scattered.

The stakeholders’ request to design the extension to the sea of a partially existing – but lacking of maintenance – horse and cycle track along the river gave us the chance to *re-frame the issue of tourism in a larger planning perspective*. Our aim was to help local stakeholders re-discover hidden and forgotten connections among the water landscapes and the settlement structure, in order to re-imagine the accessibility to the river banks as a driver for the development of new circular economies, services and spatial equipment spreading on wider urban and rural territories. In more general terms, our goal was to re-read the ‘middle lands’ not as ‘hanging’ territories, but rather as an *opportunity to imagine new development paths*. What these places still lack are in fact project-oriented representations, capable of giving visibility to resources that – due to their discontinuous and heterogeneous characters – are still underestimated by current economic and tourist dynamics. With the students, we built maps and pictures that helped us see these spaces in a different way: the river no longer as a simple longitudinal track or a trivial back of cities and rural sites, but as a complex and structuring system, once again linked to the contexts, and able to put into play the many underused areas along its course. In this sense, didactic and research work provided territorial and site specific design inputs to: interpret the Cormor as the spine of a new network of ecological services working in-between the scales (territorial, urban and neighbourhood); reuse and re-connect a rich framework of existing public facilities (green spaces, areas and equipment for mobility, social and health assistance, education and culture); re-define the topic of *slow tourism* in relation to the particular nature, sensitivity and lifestyles of these contexts. Mostly and above all, our aim was to draw *place-based interpretive frames and visions*, helping local actors build deeper reflection and discussion towards future policies and projects.

2. Territories on the edge

Coming out of the glacial hills, the river Cormor crosses the urbanized plain and reaches the Adriatic Sea, through a sequence of in-between urban and rural situations. The most evident character of this variety of *intermediate spaces* is the peripheral and residual character of areas, artifacts, practices and uses, with respect to the more compact and central nuclei that give shape to the settlement structure.

2.1 Sequences of intermediate spaces

⁴ The reference is to the Urban Planning and Design Atelier II (academic year 2018-2019), at the fourth year of the Master Course in Architecture. The atelier was coordinated by Elena Marchigiani, with Paola Cigalotto and Andrea Peraz. The didactic activities were organized in the frame of a formal agreement between the Department of Engineering and Architecture of the University of Trieste, the Municipality of Tricesimo (in the former province of Udine), the Valley of Cormor Association.

⁵ Specifically, we worked on 9 Municipalities from the former province of Udine. From the north to the south (the first figure refers to the number of inhabitants; the second to the territorial surface in square kilometres): Tricesimo (7.687; 17,7), Tavagnacco (14.981; 15,4), Pagnacco (5.059; 14,9), Udine (99.518; 57,2), Pasian di Prato (9.363; 15,4), Campoformido (7.891; 21,9), Mortegliano (4.969; 30,1), Pozzuolo del Friuli (9.927; 34,4), Castions di Strada (3.767; 32,8) (Regione Autonoma Friuli Venezia Giulia, 2018a).

Upstream, the initial part of the river course is closed between small hill towns; it forms an environmental mosaic, made of places that are characterized by high biodiversity and a strong topographical articulation. When entering the areas interested by our design explorations – between the Municipalities of Tricesimo and Pagnacco – the built-in path course of the Cormor keeps the buildings at a distance: the water is almost inaccessible, while on the summit of the hills the ancient centres stand; only some of them reach the edges of the river terraces. In the plain section – between Tavagnacco and Campoformido – the stream enters Udine conurbation. Its meanders cross several times the highway, along which large public facilities are located. Urban settlements border the watercourse on both sides: here the riverbed offers a precious pause in the urban structure, and an environmental corridor for the hinterland of the capital of Friuli. Downstream, the landscape opens up and the Cormor flows next to small ancient centres and their most recent expansions. From the Municipality of Mortegliano to that of Castions di Strada, the watercourse is punctuated with abandoned manufacturing buildings (industrial archaeology, mills and spinning mills, former military areas, etc.). In addition to freshwater prairies and natural wetlands, the stream touches the remnants of ancient plain woods and many floods mark its history; for this reason, the final stretch (running through the reclaimed lands) has been channelled to the sea.

The three transects where our design explorations took place – Tricesimo/Tavagnacco, Udine/Campoformido, and Mortegliano/Castions di Strada – correspond to a large variety of river landscapes, with different degrees of urbanization and naturalness. However, they show some common features. Despite the presence of areas of environmental interest, the lack of explicit relationships with the neighboring urban contexts, over time, has contributed to relegate them to a marginal position with respect to the overall functioning and use of these territories. A common character is the location on the edge of a ‘territorial machine’, that here still finds it difficult to reverse on contemporary development trajectories (Maciocco, 2006). At a first glance, there are no exceptional environments, great tourist and cultural attractions. The minute and ordinary elements of spatial identity are weakened by the crisis of the socio-economic conditions that, in the past, have ensured their construction and management. Standing on the border between the city and the countryside, the water and the land, these *counter-spaces of the contemporary city* risk being reductively interpreted as «*places that don't matter*» (Rodríguez-Pose, 2018), where transformation puts aside the selective and imaginative abilities of the project, to give space to the inevitability of abandonment and/or anonymous urbanisation trends (Figure 1).

However, these interpretative drifts can be avoided by taking a different approach. Since in these places it is not easy to identify striking aspects with a propelling role, the first move is «*to re-centralize the margin*» (De Rossi, 2018: 6): by making our glance more attentive, we have to search for the local conditions on which to graft *trajectories of internal metamorphosis*. In this perspective, the relationship with the river – that, up to the recent past, was vital for productive activities and communities – can once again become an opportunity to qualify activities (agriculture, tourism, housing, etc.), by focusing on their synergies and capacity to answer the demands for a *better quality of life* (Lancerini, 2005; Marchigiani, 2010). This quality finds today a fundamental ingredient in the landscape (Council of Europe, 2000). Coherently to this approach, our design work re-read the *river landscapes* as a discreet but relevant presence creating well-being conditions; as the pivot of transformations that are rooted in places; as the medium and generator of a plurality of practices, performed by many actors who can be involved in the development of local territorial systems (Lanzani, 2005).

Figure 1. On the left the river structure in the region Friuli Venezia Giulia (in red, the Cormor). On the right, the river Cormor and the settlement structure. The 3 transects of design explorations belong to landscapes 2, 3 and 4-5. Source: P. Cigalotto.

2.2 And yet something moves: towards the River Cormor Contract

The opportunity to work on the Cormor landscapes was given by the collaboration with local stakeholders who, over the last years, have been engaged in the construction of a complex strategic process. Since the early 2000s, a number of Municipalities along the river have started to jointly reflect on the opportunity to work on the enhancement of the basin, the sustainable management of water resources and the settlement of new economic activities. Thanks to European cooperation funds, they succeeded in refurbishing the northern part of a horse and cycle track – named *Ippovia del Cormor* – bordering the river⁶. With the support of the Valle del Cormor citizens' Association, these Municipalities are now engaged in the definition of a River Contract: a large scale tool for a shared construction of long-term strategic and planning instruments, where environmental protection combines with local development, and the horse and cycle track is extended to reach the lagoon on the Adriatic Sea.

The objectives of the EU environmental regulations stand at the core of this tool⁷. In Italy, in 2010, the *National Charter of River Contracts* defined them as «processes of negotiated and participatory planning aimed to reduce the eco-landscape degradation and to upgrade the river basin/sub-basin areas». The contract is built locally, between public administrations, private subjects and citizens involved at

⁶ The project *Ippovie In@natura* was financed in 2005 by the EU Programme Interreg II Italy-Slovenia. From Buja to Tricesimo, 35 kilometers of paths bordering the river were re-paved and tourist information billboards were arranged at the entrances to the track.

⁷ The reference is, in particular, to: 92/42/CEE (Habitat Directive), 2000/60/CE (establishing a framework for Community action in the field of water policy), 2007/60/CE (floods directive). See: <https://eur-lex.europa.eu/legal-content/EN/TXT/?qid=1559029419256&uri=CELEX:32000L0060>. Date of access: 31/05/2019.

different levels; the intent is to define and implement local development paths, whose «propulsive heart [...] is the reconstruction of a shared vision for the hydrographic basin. This representation has to guide the signatories of the contract in developing a project that is coherent with the real potential that the territory expresses»⁸. Although the River Contracts are a non-mandatory instrument, at the national level they obtained legal recognition with the Law no. 221/2015 (environmental provisions to promote green economy measures and to reduce the excessive use of natural resources), through the introduction in the *Environmental Code* of a specific article (Legislative Decree no. 152/2006, art. no. 68 bis). Even if the focus is the management and protection of water bodies and basins, the awareness of growing territorial fragility and the spread of hydrogeological instability processes (due to the effects of urbanisation, poor maintenance and climate change) are at the base of the progressive orientation towards multi-objective actions, in which safeguard, development and participatory governance integrate (Bianchini and Stazi, 2017).

The process towards the construction of the *River Cormor Contract* was fostered by the adhesion, in 2015, of the Friuli Venezia Giulia Region to these initiatives⁹. A further incentive was the possibility to access regional funds that – although not clearly planned – in the future might be addressed to the implementation of a strategic and shared framework of actions. The process started in 2017, with the organization – by the Valle del Cormor Association – of participatory activities open to local communities. The preparation of the Document of Intents for the River Contract started in May 2018. The agreement with the University of Trieste and the design activities developed with the students between October 2018 and January 2019 strongly interacted with this process. In April 2019 the signing of the Document of Intents was started with the coordination of the Municipality of Tricesimo, and the involvement of the Friuli Venezia Giulia Region, the Reclamation of the Friuli Plain Consortium, and the Valle del Cormor Association; up to now half of the 25 river basin administrations have signed.

The objectives set out in the Document of Intents cover different fields of action. They not only consist in the protection of the environment, the prevention of the hydro-geological risk provoked by the floods that periodically affect the basin, the reduction in the level of water pollution due to urban and agricultural activities. They also deal with the tourist enhancement of these territories, whose location in the proximity (albeit, once again, on the edges) of important regional, national and European cycle routes offers unprecedented perspectives (the reference is, in particular, to the Alpe Adria cross-border itinerary)¹⁰. Specifically, the ‘Cormor system’ is seen as an opportunity for developing sustainable tourism through the reuse of a network of existing inter-estate roads. The horse and cycle path is interpreted as a *widespread infrastructure for slow territorial fruition*, with a high potential to re-activate local economies: accommodation and catering equipment, also connected to the sale and

⁸ The National Charter of River Contracts was drafted on the occasion of the V National Table of River Contracts, held in Milan in 2010. See: <http://nuke.a21fiumi.eu>; <http://www.contrattidifiume.it>. Date of access: 31/05/2019.

⁹ The Regional Law no. 11/2015 (about organic regulation on soil protection and water use), defined and structured the process of negotiated planning for the River Contracts; with the resolution of the Regional Council no. 1448, 28th July 2016, Friuli Venezia Giulia formally adhered to the *National Charter of River Contracts*, launching activities aimed at promoting and supporting their diffusion on the regional territory.

¹⁰ In the Regional Landscape Plan approved in 2018, the completion of the Cormor Horse Trail up to the sea is part of the project for a regional slow mobility network. The trail is identified as a complementary component to the primary Alpe Adria cycle route, which is mostly already infrastructure, and runs from Tarvisio to Grado. On a wider scale, this regional network is part of the Bicalitalia and EuroVelo routes (Regione Autonoma Friuli Venezia Giulia, 2018b; see in particular document *E3. Scheda della Rete della Mobilità Lenta*).

consumption of typical products; sporting events; trails offering the experience of a variety of landscapes, from the mountains and the hills, to the lagoon and the sea.

3. New representations, between the water and the land

The activities developed with the students aimed to enlarge the design perspective from the areas directly related to the river, to the urban and rural landscapes the Cormor runs through. The Document of Intents is in fact only the first step of a process that should lead, on the one hand, to a Strategic Document where a medium-long term scenario integrates large scale spatial planning into local development policies; on the other hand, to a short-term Program of Actions, where the methods, times and economic resources that are necessary for implementation are defined.

With reference to this process, our contribution consisted in *anticipating spatial visions* supporting the recognition and the regeneration of systems of places and activities linked to the river and to its 'middle lands'. Taking tourism and slow mobility as the drivers for raising the quality of local living conditions, we worked on spaces dedicated to occasional practices and to residents' daily movements, on the reuse of dismissed areas, and on the settlement of new services and forms of production.

3.1 Research by design

Reflecting with local actors was fundamental. Even within the short time of a semester, the Urban Planning and Design Atelier was conceived as a gradual approach to the contexts, their voices and demands for transformations. The aim was to place ourselves in a hybrid field, between training, action-research and public engagement. What interested us most was exploring *locally rooted opportunities* for economic and social re-development. During this process, professors and students were accompanied by representatives of the Valle del Cormor Association and of the network of Municipalities adhering to the River Contract.

We started by combining the *analysis of local and regional planning tools*, with *participated visits* to the study areas, where we walked, talked to local technicians and politicians, listened to inhabitants, observed and reflected in places. No less important was *moving across the scales* of urban planning and design, to capture different dynamics and relations between the river and the territory. The presentation of intermediate results to local stakeholders prompted us to synthesize ideas into new representations of existing resources and of their enhancement potentials. We were convinced that discussing and, eventually, sharing images for the future had to be essential ingredients of our planning practices.

3.2 River landscapes as complex ecologies

All through the Atelier, students and local actors were invited to re-read the river contexts as complex ecologies. Going beyond the dimensions of the environment and soil protection, the potentials of these landscapes refer to broader sets of factors that the project is asked to critically interpret and re-arrange.

In order to safeguard, restore, enhance and manage river landscapes it is necessary to recognize and construct multiple correlations among many material and immaterial elements of the territory. By taking the concept of landscape as a general frame for a plurality of systems and processes, this approach allows to recognize the primary value of the interconnections between the river and the urban settlements, the strengths and the opportunities resulting from the synergies between the natural elements and the evidence of local culture. Until a recent past, the water system has been an important

reference for the localization of irrigation ditches, factories, mills, furnaces, economies related to the use of water. Although a large part of this estate has been abandoned, planning its reuse with respect to its identity and historical values can offer new perspectives. When working on the river landscapes, the project must also be able to cope with the weaknesses and threats that specifically affect these contexts. Let us consider the frequent presence in the riverbeds of (mostly abusive) landfills; or the waste of ecological and landscape resources provoked by urban settlements and agricultural activities that often spread to the banks of the watercourses. These processes can be contrasted by giving space to a growing demand for leisure activities to re-appreciate the values of nature; and by re-interpreting the places along the waterways as strategic nodes of new systems of collective spaces and environmental connections to the surrounding areas. In the same way, particularly significant alterations – such as the presence of artificial basins – can be re-read as design opportunities when re-framed in wider scenarios for a sustainable tourist use.

Due to all these considerations, building new visions for the river landscapes meant focusing on the different functions (and values) that these contexts can specifically perform:

- *ecological functions* (rivers as excretory systems; ecological corridors; areas where to govern risk factors and territorial fragility);
- *social functions* (rivers as spaces perceived and enjoyed by local communities; common goods; components of systems of equipment and services addressed to stable and temporary, static and moving populations);
- *economic functions* (rivers as places of economic activities, different from intensive production and agricultural exploitation);
- *cultural functions* (rivers as gates through which re-discover and enhance the history and the identity of the territory, and as attractors of new tourist flows).

3.3 Not only tourism and cycling... but also collective equipment and services

During the Urban Planning and Design Atelier, the local actors' request to draw the extension of the Cormor horse and cycle trail was integrated into a more complex vision. Working on the relationships between tourism and cycling forced us to define extensive *re-equipment strategies*. In this sense, our investigations searched for areas and materials for *light 're-infrastructural' projects*, that had to be pertinent to the sensitivity of the contexts on which we were operating.

The territories crossed by the river Cormor were re-interpreted as components of a *network of greenways*: «communication routes reserved exclusively for non-motorized journeys, developed in an integrated manner which enhances both the environment and quality of life of the surrounding area» (European Greenways Association, 2000). This key emphasizes the many potentials of slow mobility: from its being a means to favor access and enjoyment of those 'minor' and 'undercurrent' landscapes that only a slow fruition allows to appreciate; to its being an opportunity to encourage *loisir* practices, oriented to re-activate and to 'put into circle' sustainable territorial economies. In our region the growing of cycling supports this reading: between 2015 and 2017, along the Alpe Adria cycle route, transit increased by the 46%¹¹.

¹¹ These figures were disseminated by the Association Ulisse-FIAB, with reference to the 19th report on German cycling tourism prepared by ADFC (German Cyclist's Association). See: <http://www.ulisse-fiab.org/?p=9277>. Date of access: 31/05/2019.

However, *cycling is not just a tourist practice*. As in the past, and now again – due to the economic crisis and to a growing (albeit in Italy still timid) environmental sensitivity – moving by bicycle (and on foot) fosters tourist tracking on dispersed urban territories. Moreover, by observing the practices that are generated from a daily use of the bike, we often «recognize specific and new uses of space [...] that mix tradition, innovation, trends and multiculturalism». In our Country, the growth of these seasonal and daily movements «is tracing interesting geographies telling how economic realities, local administrations, stakeholders and individuals [...] have been able to respond and re-propose products and services of particular innovation and excellence» (Velo, 2015: 1663). When specifically working in urban contexts of thin and polycentric grain, «dirt roads, river towpaths, informal landscapes between buildings, areas of programmed floods, drainage basins and collective open spaces become the elements that constitute an additional *layer* of porosity within the city» (Velo, 2016: 332).

According to these issues, we invited the students to integrate the green and blue network of the greenways with the *system of collective equipment and services* that punctuate the edge territories of Cormor. In this way, the aim to re-embed the river to its contexts merged into the more general objective of making «cities inclusive, safe, resilient and sustainable», at the core of the *2030 Agenda for Sustainable Development* (United Nations, 2015), and of the next season of European funding programmes. Thanks to our surveys, we could see how the fragility of the territories along the river and of the communities that inhabit them were also connected to growing deficiencies in the maintenance of public spaces and equipment for daily living; to their inadequacy to answer to the needs of moving and changing populations; to their being closed to the contexts (i.e. the fences that generally surround the schools), and difficult to access. Moreover, re-designing and re-framing this – still implicit and not effective – *public city network* into new territorial visions could offer new solutions to face the current chronic scarcity of public funds, through more systemic urban regeneration actions.

Working in an integrated manner on the banks of the river, on the edges of urban settlements, on rural spaces, and on the leftovers of peri-urban agriculture was therefore a stimulus to take the project of the cycle route as one of the main ingredients of *a new spatial structure*. The importance of the cycle route was increased by its capacity to hold together different populations and social practices, and to foster the definition of new services both for outsiders and insiders. Moreover, the design of the route was a prompt to re-think the uses of existing public spaces and of their spatial connections; to update the legacy of urban policies that, over time, have built the «material quality of welfare»: green areas, areas for mobility and parking, social-assistance and educational-cultural services. In this sense, our design explorations also provided inputs to re-furbish large quantities of equipped spaces that have been provided by *planning standards* since the last century; spaces where the «individual and collective practices that give body to the ‘quality of life’ of women and men in their daily experience of inhabitants and users of the city» take place today (Pasqui, 2017: 139). Identifying the itinerary for the cycle route therefore stimulated us also to imagine new types of standards, in order to face climate and environmental emergencies through the planning of *ecologic services*, and to give answers to social demands and requests for economic re-development¹².

¹² The anniversary of the Interministerial Decree no. 1444/1968 on planning standards offered the opportunity to reflect on this pillar of urban planning and on its possible evolution. Many research groups have dealt with these issues; among them, the *Standards Laboratory*. With the support of the Italian Society of Urban Planners (SIU), it involves: University of Trieste (Sara Basso, Elena Marchigiani); Politecnico di Milano (Cristina Renzoni, Paola Savoldi); IUAV Università di Venezia (Alessia Franzese, Stefano Munarin, Maria Chiara Tosi); Università di Roma Tre (Mauro Baioni, Giovanni Caudo, Nicola Vazzoler). See: Renzoni, 2018, ed.; Marchigiani, Savoldi, to press, eds.; <https://standardurbanistici.wordpress.com/eventi-attivita> (last access: 2019/05/11).

4. Tailor-made design, across the scales

Our investigations in the Cormor 'middle lands' continuously moved between different scales and observation perspectives. If developing strategies and projects rooted in the contexts was necessary to reveal their latent identities, we did not want to fall into a 'localistic' approach.

We therefore started from a large scale, in order to draw a general master plan holding together the landscapes between Tricesimo (to the north) and Castions di Strada (to the south), and synthesizing the many functions – ecological, social, economic and cultural – that the river system, as a whole, can play. At the same time, we focused on a site-specific scale. Our aim was to recognize the territorial components with which the different transects of the river landscapes enter into contact; the risks of their degradation and simplification; the opportunities that their enhancement can offer to re-activate local resources and energies.

4.1 Tailors and jewellers

In the process of continuous displacement of our gaze, we have been encouraged to re-think not only the forms of the project, but also the role of the designer.

In the 'middle lands' the «centre/periphery, or city/countryside *cleavage*» which «seemed to have largely gone out of use in mature modernity» (Revelli, 2017: 45) still appears firmly present, not only in the spaces but also in the imaginary of actors and local communities. By making our externality a point of strength – and trying not to slip into the banal re-proposal of recipes that had been elaborated elsewhere – we imagined ourselves as tailors, called to mend fabrics of material and immaterial relations that time had consumed. As artisans engaged in a patient work of re-copying, unstitching and re-putting in place the contexts we were investigating. We were aware that *these territories needed a particular care*: similarly to the clothes put aside – but we are attached to – they had to be re-worked in order to respond to changed aesthetic and functional needs.

During our surveys we also cultivated the awareness of moving across places that are very rich of resources: the river first, but also the variety of landscapes, the diffused fragments of naturalness, the environmental networks developing along the minor hydrographic network, the many artefacts of a history of land construction and of economic and social investment. We therefore also imagined ourselves as jewellers, committed to re-nestle the little gems we had encountered. Our task was to define favourable conditions for *embedding into the tales of these territories* processes of innovation, new daily wanderings between the river and the cities, practices of an 'ordinary tourism' that takes the distance from the acritical importation of standardized models.

4.2 A new infrastructure for a collective city

Some specific questions addressed our design explorations: how to imagine the Cormor landscapes as the backbone of ecological and functional strategies aimed at structuring and 're-infrastructure' the territory; how to draw a spatial framework capable of re-composing a collective city on a vast scale; how to contribute to the overturning of hierarchies, and to the transformation of the watercourse from a back to a centrality generating new connections and public facilities. The overall vision drawn by the students' master plan outlines original geographies, in which the Cormor re-gains the role of reference for living and moving in contexts of varying thickness which, perpendicularly to the river, creep into

urbanised and rural areas. In this way, a new complex infrastructure of spaces for collective use takes shape, branching out in a sequence of side transects and chains of equipped places.

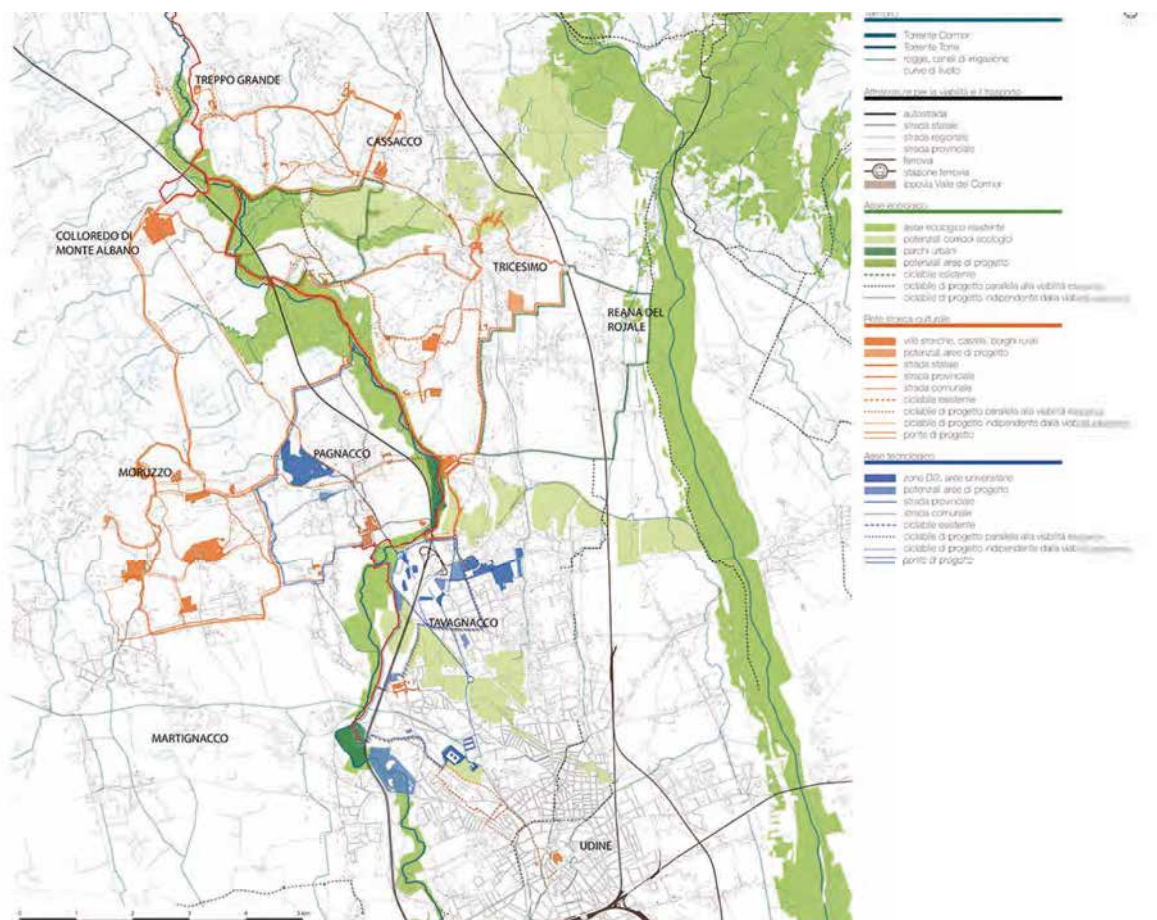

Figure 2. The master plan (transect 1: Tricesimo/Tavagnacco). Source: P. Barbiani, M. Caiffa, M. Collenz, S. Di Ferro, L. Lauricella, I. Morgera.

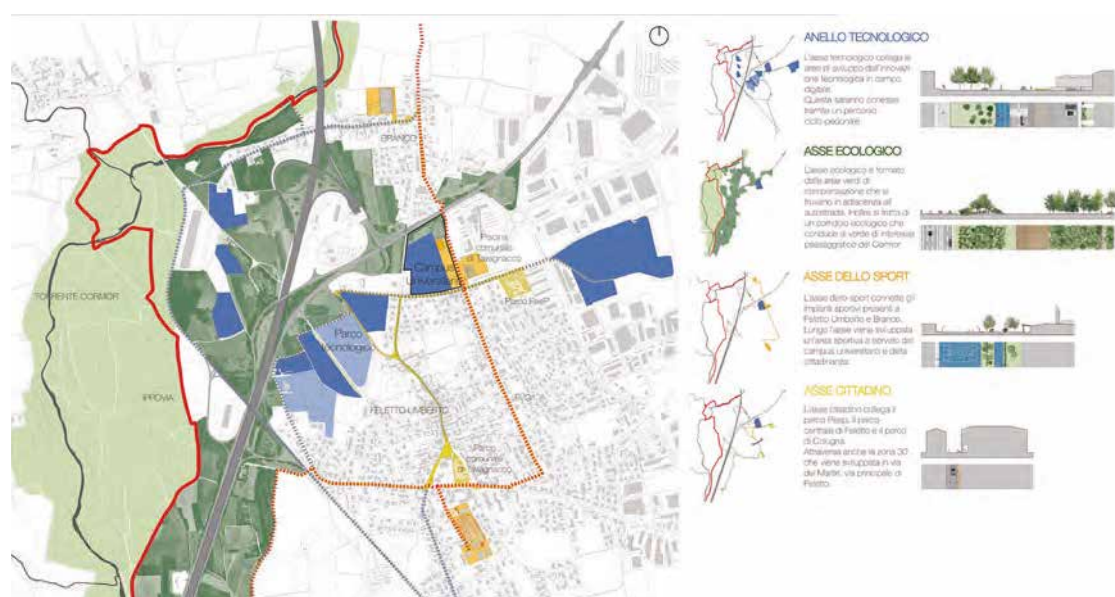

Figure 3. Axis of innovation. Source: M. Collenz, S. Di Ferro, L. Lauricella.

In the northern section of the 'Cormor system' the master plan proposes an image made of *arches and buttonholes*. Two green transects (the 'arches') overwrite the sequences of crops and areas of landscape interest that, by crossing the plain, ecologically connect the rivers Cormor and Torre. They are integrated by a circuit of cycle paths (the 'buttonholes'): a system of links between the main path (already built) on the river bank, the rural villages, the villas and the castles on the hills, the small railway stations in the area (Figure 2).

Within the conurbation of Udine – in the Municipality of Tavagnacco – this circuit finds a graft in what the Town Plan identifies as a new system of services and centrality of territorial scale: an '*axis of innovation*' comprising a succession of areas perpendicular to the river, intended to host a science-technology park and a university campus. The circuit connects the new campus to the existing equipment (neighbourhood parks and sports facilities), and becomes the occasion to transform the streets that penetrate the densest residential fabrics into '30 km zones'. Even more importantly, the definition of new territorial and ecological connections addresses the choice to design the campus according to sustainability criteria (from water management, to the use of devices for saving and producing energy from renewable sources); as a space that is permeable to the city and to the landscape, where one can find new sports and cultural activities, designed for a flexible use by students, tourists and residents (Figure 3).

The aim to *overcome the functional and spatial separation from the contexts of large plots for territorial equipment* similarly directs the work on the surroundings of the 'citadel of sports', to the north of Udine. In the riverbed of the Cormor river, the design of the landscape bordering the cycle lane is meant to reduce the impacts of the nearby highway, through the creation of drainage basins, reed beds, and the insertion of wood strips. These green infiltrations further extend, to scratch the impermeable surface of the paved areas around the citadel of sports. Not far away, along the cycle path, a sequence of shared vegetable gardens, areas for the sale of agricultural products, recreational and sports activities, draws a new type of public space, whose articulation helps to bridge the functional and perceptive gap with the huge scale of the existing equipment (Figure 4).

Figure 4. Citadel of sports. Source: P. Barbiani, M. Caiffa, I. Morgera.

In the central section of the watercourse, the cycle route passes from one side to the other of the Cormor, often keeping a distance from the river banks. In its waving movement, the path frequently approaches the edges of the city of Udine, where strong differences in the grain both of residential fabrics, and of urban and neighbourhood equipment can be recognized. In these contexts, the master plan proposes the image of a *necklace of parks*. The strategy of re-coupling the cycle itinerary to the places of everyday living translates into the identification of a network for soft mobility, connecting the suburban track to the main city centre. Along the network, the reuse of a series of still vague open spaces concurs to re-design the fringes of Udine, Pasian di Prato and Campoformido. Structured like a comb, the green itineraries form a sort of 'bicycle ring road': a fast connection for tourists and citizens, who can thus reach the leisure areas along the river avoiding the busiest radial roads, and enter the city moving along safe routes to access to urban equipment and services. What makes this journey attractive is precisely the variety of urban situations and collective spaces – new and existing – that it intercepts (Figure 5).

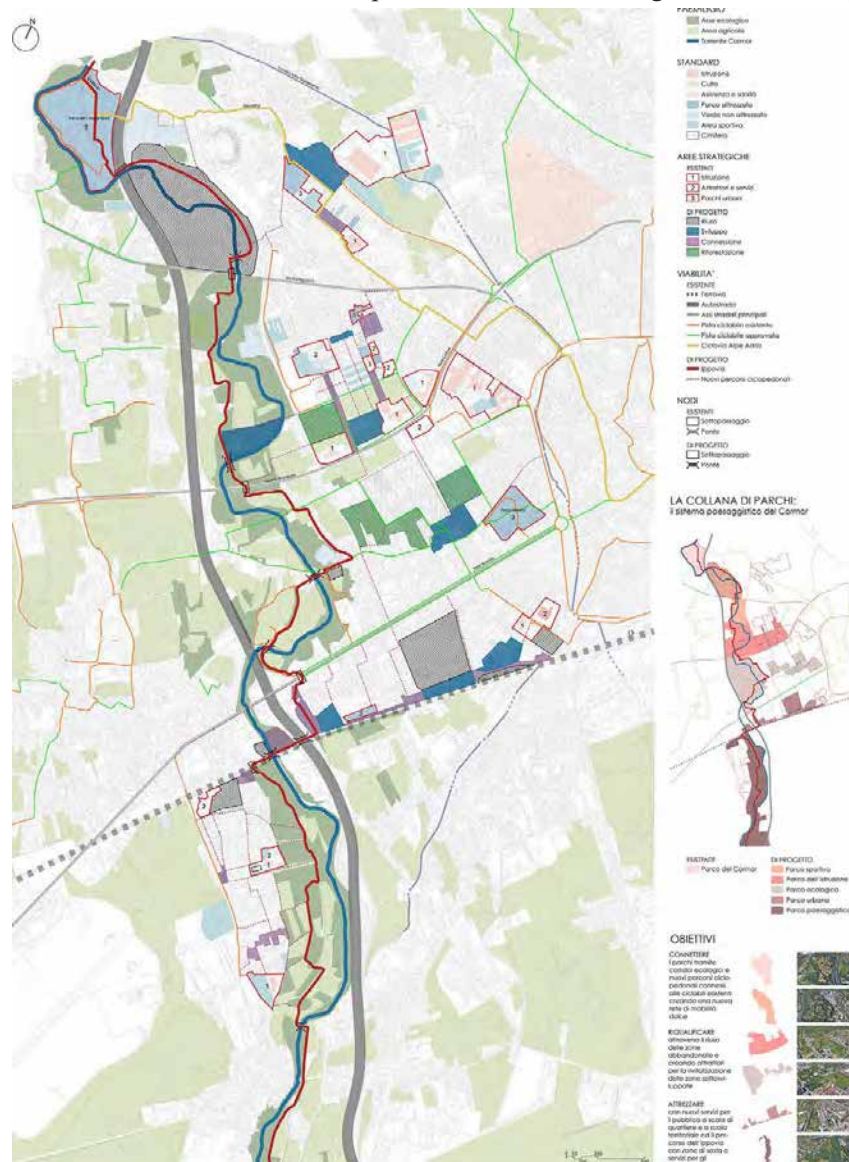

Figure 5. The master plan (transect 2: Udine/Campoformido). Source: G. Bearzotti, G. De Conz, T. Linternone, T. Lippiello, M.T. Manzara, V. Novello, N. Pigat, G. Zei.

In the north, the choice to place one of the new parks nearby a large social housing district ('Peep Ovest') is supported by a generous presence of areas realized as planning standards (gardens, schools of different levels, social and health services), and by the project to further develop an existing centre for higher education. Stretching from east to west, the new green spine is connected to the river by a branch of the main cycle path, which is obtained by re-sizing and re-arranging the section of the road that currently divides the schools from the housing district. Additional mending elements are given by the extension, in a north-south direction, of strips of open spaces from within the neighbourhood to the sports areas and the vegetable gardens conceived as *services complementary to the school cluster*, open to tourists and residents. What comes to light is a green carpet, where the Cormor plays again the role of primary frame (Figure 6).

Moving to the south the focus is, even more explicitly, on the urban extensions of public facilities, on the '*spatial chains*' where daily movements take place between dwellings, work spaces, services and leisure (Basso, Marchigiani, to press). Radiating out into peripheral tissues that are characterized by reduced articulation and limited spatial quality, the *design of a new soil* (Secchi, 2000) builds new ecological services. It is starting from the recognition of a fragmented presence of green plots that, again in the outskirts of Udine, students' design explorations propose a widespread park, linking a large garden (parco Moretti), the cemetery, schools and sports fields, abandoned areas. The park is made of different types of forest which are meant to improve air quality and microclimatic conditions; in the middle of urban woods, a further branch of the bike path runs, finding new equipment for children, youngsters and tourists near the riverbed (Figure 7).

Figure 6. Peep Ovest. Source: T. Lippiello, V. Novello, N. Pigat.

In the current economic and demographic standstill, *dismantling processes* pierce the settlements, affecting buildings and surfaces of different sizes, that are in competition the ones with the others with respect to a possible re-insertion into the 'city life cycles'. In Udine – as in the rest of the region – many military areas are today waiting for reuse. The proposal to create a third urban park concerns an area that, perpendicular to the river, intercepts a settlement of barracks to be discarded. Extending

immediately south of one of the main access roads to the city (viale Venezia), the military site overlooks a large void spreading along the railway. In this neighbourhood, the lack of equipped open spaces combines with the presence – in the direction of the city centre and near a minor network of urban streams – of important public facilities (schools, offices, a museum), that the park concurs to make more accessible through slow mobility. When reaching the barracks, the *green filament* attacks their fence; it *triggers the regeneration* of the large plot through the location on its edge of public spaces and services, as outposts for the future development of businesses and light production activities within the whole area (Figure 8).

Figure 7. Urban woods. Source: G. Bearzotti, T. Linternone, M.T. Manzara.

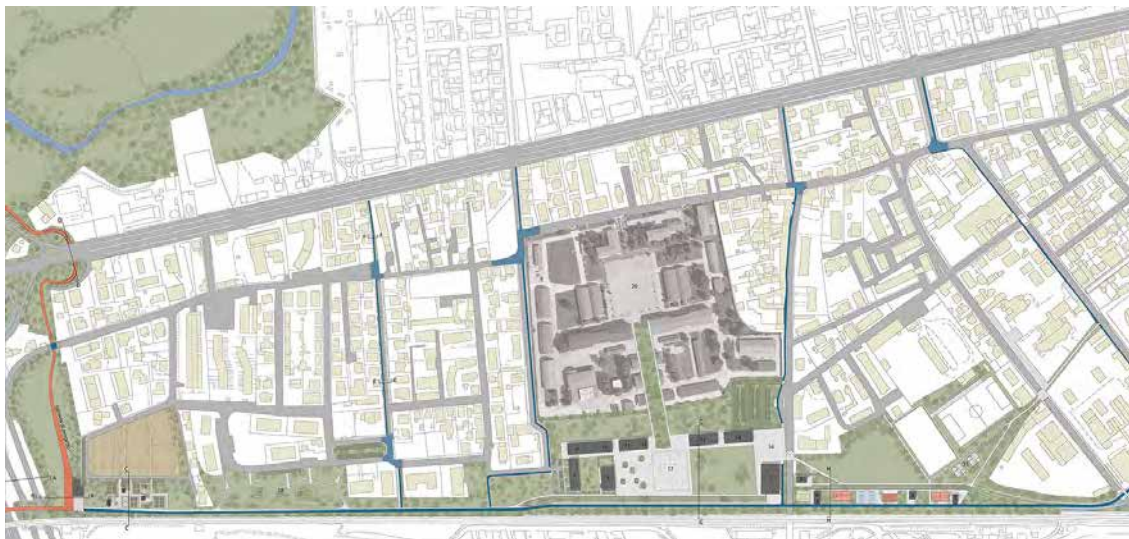

Figure 8. Former barracks. Source: G. De Conz, G. Zei.

In the territories of the Municipalities of Pesian di Prato and Campoformido the urban landscape is completely different. It tells the story of a residential enclave (Villa Primavera), originally conceived as a neighborhood of high building and space quality, and today impoverished by the abandonment of those small private commercial and sports facilities that were meant to enrich daily life in a green suburb. However, the legacies of public policies remain: a swimming pool, a church, schools and a sports area. On the western edge an articulated mosaic of landscapes borders the Cormor basin:

agricultural plots, stable meadows, protected natural areas and biotopes. Looking at the neighborhood from the point of view of the river, the project for the last park of the ‘necklace’ fosters an *articulated – even though minimal – regeneration strategy*. The main cycle lane finds space in the dirt roads running in the riverbed. Its branches enter the neighborhood; stimulate the re-thinking of the spatial and functional organization of the residential roads network; put into a system and enhance a multiplicity of small green areas, hedges and tree-lined rows that currently appear as offcuts without any meaning or use (Figure 9).

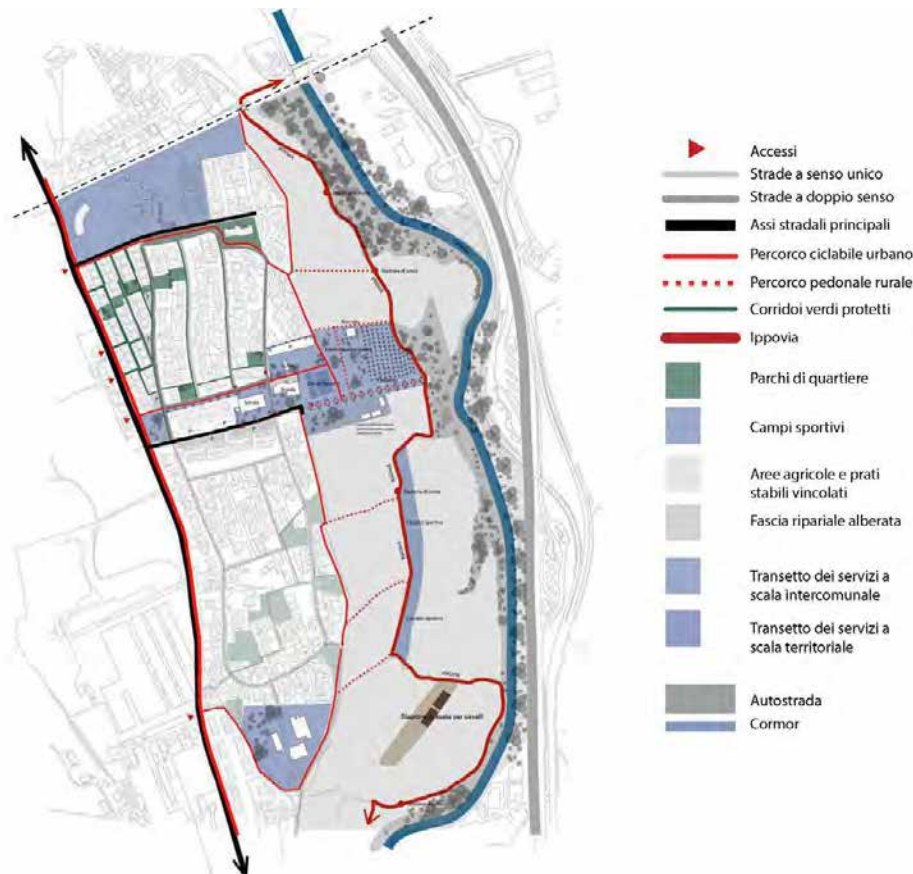

Figure 9. Villa Primavera. Source: L. D’Onofrio, P. Ridolfi.

Before reaching the lagoon and the sea, the Cormor relates again to urban landscapes in three Municipalities of the the lower Friuli: Pozzuolo, Mortegliano and Castions di Strada. Still full of meanders up to Pozzuolo del Friuli, the river flows channelled to the south. Its course blends into the minimal frame of the rural landscape. The settlement structure consists of small-sized centres, whose ordering principle is given by the frame of the roads. In this section of the watercourse the bike path is still to be traced. Building representations that could orient its design proved to be a particularly complex operation. To identify resources, these territories had to be *read in braille*, through layers that only a very careful examination, a 'tactile' approach and slow walking can unravel. However, here more than elsewhere, the project of the cycle route offered the opportunity to demonstrate how tourism and slow mobility can be a driving force for imagining «new development models, consisting of circularity of processes, self-organization and co-presence of diverse economic forms» rooted in the rural history of these territories (Carrosio, 2019: 30). To this end, the master plan proposes an image made of *stitches and mending*. The main cycle route follows the frame of dirt roads next to the Cormor; a network of secondary routes innervates in the surrounding contexts, to grasp places and points of view, break the monotony of the landscape, and re-construct ecological corridors between the areas of environmental interest (Figure 10).

building, where the installation of a small covered market, rooms for events and accommodation facilities are foreseen (Figure 11).

Equally attentive to the rediscovery of agricultural tradition is the project for the territories north of Mortegliano where, until the most recent past, the landscapes of the cereal production could count a lot of varieties. The northern entry point to the cycle route is once again a pole of sports facilities (a horse centre), built inside a former military powder magazine. Riding towards the urban center, the itinerary meets a new *agricultural and educational park* dedicated to the organic farming of many species of corn. The park follows the geometry of the existing fields; arranges the crop varieties according to their heights so as to orient the eye towards the most valuable visuals; thickens the hedges and the trees on the sides of the internal paths, where equipment supporting pedestrian and cycle use is settled. In contiguity with the park and a secondary canal running between Udine and the sea, the presence of a small abandoned mill offers the opportunity to create a bar and a resting point, exhibition spaces and research laboratories (Figure 12).

Figure 11. Spinning mill. Source: C. Furlani, G. Tomasin, F. Zotti.

The last section of the cycle track runs in the territories of Castions di Strada, where the Cormor splits into two arms, forming a drainage basin to be further extended. Here, with even more evidence, the design of the network for slow mobility becomes the engine of an *ecological 're-infrastructuring' process*. The creation of new water basins offers the opportunity not only to imagine reed beds for the treatment of pollutants produced by agricultural activities, but also to design a more extensive landscape project, aimed at enhancing and re-linking the wetlands that characterize this section of the river landscape. Reforestation actions give thickness to the system of environmental connections, and capillary radiate in the new rows and hedges along the roads and the dirt roads. Also in this case, the *green and blue network is integrated with territorial re-equipping strategies*, and the private management of new services is targeted towards occasional users and inhabitants: an old hydraulic booth is converted into a refreshment area; on the edges of the urban centre, a small residential expansion provides additional places for outdoor sports, education and culture services; entering the

agricultural landscape, a visitor center finally offers the opportunity to learn the history of the territory and to practice educational activities for schools (Figure 13).

5. And the reflection goes on

The *learning by doing* process we have described offers many clues for reflection both on teaching and making research through the project, and on more general issues related to spatial planning in the 'middle lands' .

5.1 The utility of trespassing

Taking sustainable tourism as the engine of territorial ‘re-infrastructure’ and ‘re-equipping’, what we developed with students and local actors was a twofold exercise: on the one hand, we tried to break the boundaries between single spatial and functional areas, in order to identify new possible relationships among places, uses, activities and economies; on the other hand, we set aside ordinary teaching methods, to put us in direct tension with the contexts, with those who inhabit them and are engaged with imagining a possible future. Thanks to this exercise, the approach of *research by design* taught us much: most of all, the need to update the education of an architect and an urban planner, by working both inside and outside the university classrooms.

Through a *learning process based on border crossing* we developed competences that are no less important and complementary to those of spatial design. Diving ourselves in the contexts, listening to common expertise, building empathic relationships with the places and with the people, cultivating the willingness to self-discard our positions, spurred us to reflect on how design-oriented knowledge can also make use of forms of collective learning, supporting technical data collection and elaboration. We often learn *by trial and error*, when we abandon situations and roles that are more familiar (the ‘comfort zones’), to enter lands that we have not explored yet. For this reason, the reduction of transversal, reflexive and communicative competences – those that today are defined as *soft skills* – to theoretical and codified formulas of teaching and learning seems counterproductive. On the contrary, widening the field of training contexts is a fertile way to reason on how to cultivate the sensitivity to innovate our tools through the direct interaction with increasingly problematic (*wicked*) spatial, environmental and social conditions. This sensitivity marks the difference between the acquisition (and transmission) of simple technical expertise, and the development of the ability to perform a professional practice that must be as competent, as relational and critical.

Nonetheless, during our experience, we often experienced the inadequacy of our (verbal and graphic) languages to translate and to communicate in a clear and effective manner what we had learned, and we wanted to deliver to a public discussion. No less strong was the students’ frustration in understanding how their prefigured spatial arrangements were nothing more than tentative and temporary proposals, within a much longer and articulated path of *framing and re-framing* of actors and points of view, situations and problems, solutions and tools. However, experience strengthened our awareness that building collaborative contexts, where the issues of complex and integrated design can meet those of teaching and active research, can be very useful. Even though difficult, these opportunities can in fact stimulate processes of collective imagination, build new synergies, points of contact and hybridization between the energies and the knowledge of the university, and the questions, the practices and the competences emerging from the territory.

5.2 Towards and Agenda for the ‘middle lands’?

These synergies are even more necessary when we work in contexts that are similar to those we were investigating, and whose features recur in many other situations in our Country. In similar territories, the conditions in which the local subjects – first and foremost institutional – today act appear to be far from favoring a strategic thought. For many Italian Municipalities it is difficult to access the funds finalized by the European Union to promote sustainable trajectories of urban and territorial development (Cappello, 2015, 2016). Even when addressed to inland areas – as happened in the programming season that has now come to an end – these funds have in fact excluded the here described ‘middle lands’. The

limited dimensions of the administered contexts and of the technical staff within the local authorities, together with the contraction of resources for the outsourcing of projects, inevitably create further and significant factors that impede participation in exceptional and complex financing channels. However, it is our conviction (and of the actors with whom we are still collaborating) that, even in the coming years, the resources allocated at European level (together with their wished national and regional integrations) will constitute one of the few effective levers to aggregate dispersed territories around projects for a sustainable development.

It is starting from these considerations that our work took as guiding principles the sustainable development objectives established by the *United Nations' 2030 Agenda* (United Nations, 2015), and now assumed as the basis of the European programming 2021-2027 (European Commission, 2018: art. 4). These objectives set a reference for the construction of spatial and environmental regeneration programs and projects, joining actions aimed at reactivating abandoned places, governing decline of population dynamics and migration flows, awakening dormant economies.

Nonetheless, these are far from simple tasks: they push the administrations of different levels to perform a complicated exercise of rethinking the future, of building medium and long-term visions that can enable them to effectively use both ordinary financing resources, and the extraordinary ones that hopefully will soon be destined for cities and territories.

Although it is clear that, without adequate support – both procedural and financial – the small Municipalities of the ‘middle lands’ will find it very difficult to go far, planning the future requires high doses of commitment and trust.

It is precisely with this obstinate and positive approach that we joined local administrations and civil society's actors in the construction of a vision for the River Cormor Contract. In this vision, the green and blue infrastructures where the slow mobility network is settled do not only constitute the structuring principles of a new environmental project, but they also equip a spatial support for imagining new and different development trajectories. These trajectories are aimed at promoting quality and well-being, combining the creation of new services and economies for both tourists and inhabitants. With our design explorations we proposed new representations, in which the territories on the edge – of water and countryside, small and medium urban centres – could regain centrality, while remaining far away from the «'having to be' [...] that have been determined inside the cities», as well as «from the typical urban projections on these territories, depicting them as a kind of *friendly society* with traditional, patrimonial and tourist values» (De Rossi, 2018: 8).

The Cormor master plan and the in-depth studies on the spatial transects that mark its course also offered further insights to reflect on how the guiding vision of the River Contract can find concrete implementation, even independently of the uncertain access to extraordinary financing channels. Due to their often minimal and incremental nature, the project actions defined with the students are not disconnected from the themes and methods that are typical of ordinary urban planning. We would therefore like to think that the work done, if shared by local administrations, may constitute an invitation to convincingly cross the boundaries between the fields of urban planning and of territorial development programmes, and to use the procedures and tools of local planning to try to *anticipate large scale and integrated visions*. In the current «wandering phase» (Gabellini, 2016: 144), when ever faster and complex environmental, social and economic changes associate with increasing political and financial uncertainties, helping territorial actors construct in advance project agendas is a contribution that universities and research can (and must) deliver to the territories that welcome and stimulate them.

Who lives heritage: investigation on the impact of tourism flows and heritage protection in the use of public space.

Chiara Amato¹, Francesca Paola Mondelli²

Abstract: The study turns to a theoretical reflection on the outcomes that the heritage protection over the last decades had on the use of public space and urban life, trying to compare the effects that have been observed on different urban models such as large metropolitan cities and small historic towns. The aim is to investigate the different responsibilities that contribute to the process of moving urban life away from historical and heritage sites, studying, among these, the impact of mass tourism.

Keywords: tourism, heritage, public space, landscape

Introduction

It has been a long time since the protection of the heritage, both in urban areas and in smaller towns, has been increasingly accompanied by economic interests triggered by the strong tourist flows that characterize our time. The implications of this phenomenon can be traced on several fronts: from the hardships caused by a real estate market increasingly oriented to temporary rentals, to the musealization of small historic centers that, on the Italian territory, are emptying of inhabitants and filling up with seasonal tourists, unable, on their own, to revive the places or to substantially reactivate the local economy. In this context, the public spaces of big cities do not avoid the consequences of mass tourism.

Tourism, in recent decades, has been the industry that has perhaps more than anyone else changed numbers, nature and purpose, from aristocratic travelers of the Grand Tours between the seventeenth and nineteenth centuries, to the masses of people of all nationalities surrounding the main monuments of the world. Through the twentieth century and the technological evolution of the media and transport, the progressive lowering of travel costs and the disappearance of distances, mass tourism has invaded the centers of major capitals. International tourist arrivals in the world have grown almost uninterruptedly: from 25 million in 1950, to 278 million in 1980, passing through 528 million in 1995, up to over a billion in 2013 (and according to UN estimates, the sector, which will continue to grow by an average of 3.3% per year, is expected to double by 2030, up to 1.8 billion per year).

Assaulted are the most important and significant capitals, the UNESCO sites, which for some time was blamed for declaring the mummification of cities by marking them as "World Heritage", and putting them into the spotlight of mass tourism (from the article "La maledizione dell'UNESCO", Sciortino 2019, Panorama¹). A tourism often concentrated in some parts of the year, paralyzing some parts in the heart of the city, morphologically not suitable to accommodate the flow of people we see walking through the alleys of our historic centers.

The other side of the coin is the paradox that sees small historical masterpieces, smaller towns such as small towns in Lazio, or small towns in the inner Cilento, desolate and abandoned. These centers, rich in history and heritage, are outside major touristic routes, difficult to access (lack of a quick connection to the networks of rail or public transport, or large leaps in altitude due to the morphology of many smaller centers) and so difficult to discover even for those tourists interested in different experiences, slower and of higher quality, compared to those of major destinations.

Over the years, some of them have become true ghost towns, often becoming targets to speculators who, by buying almost the entire historic centre, have transformed them into luxury theme hotels and open-air wellness centres, effectively erasing all the connotations of the city in what thus becomes a mere scenario.

For abandonment and depopulation, congestion and mass invasion both produce a chain of disappearance of memory and identity and the death of our cities. If, in fact, we take up again the Socratic thought according to which man is composed of the physical body, material, and soul, immaterial, and apply it to our cities, we understand that the part of immaterial and invisible city is not only people living there, but the mixture of tales and stories, memories and principles, languages and desires, institutions and projects that have determined its current form and that will guide its future development. And as Settis reminds us in his "Se Venezia muore", cities die for three reasons: when a ruthless enemy destroys them, when a foreign people settle there with force chasing away the natives, or when the inhabitants lose memory of themselves, and without even realizing it they become foreigners to themselves and enemies of themselves.

The periphery in the historical centres

Gentrification and depopulation are thus the two extreme phenomena that afflict the Italian historical centres today. To define these phenomena it is necessary to keep in mind that the recurring cyclical nature of economic crises, the instability of markets, the processes of late industrialisation and deindustrialisation, climate change and deterioration of ecosystems have transformed the traditional perspectives of urban development and settlement and socio-economic dynamics at all latitudes.

Since the second post-war period we have witnessed a strong industrialization of the Italian territory, which has produced already at the end of the '80s a territory characterized by a system structured around poles of attraction, the provision of primary services, or large cities, which experienced phenomena of polarization, congestion, limited accessibility. Around them, gravitate belt areas characterized by a metropolized territory (Indovina, 2009), a fragmented and widespread urban continuum, dependent on economic dynamics and commutism from the large main nucleus, which invades the rural space, contaminating it with unusual functional mixtures, dismantling the structural plots (Macchi Cassia, 1992). The resulting territory has the pathological characteristics of an enormous proliferation of settlements in widespread form with flows of multidirectional private mobility (Ricci, 2005).

¹ http://www.inu.it/wp-content/uploads/Panorama_Unesco_22_maggio_2019.pdf

The progressive expansion of the belt areas around the attractive poles and the corresponding territorial disequilibrium contribute to delineate the so-called internal areas, defined by the Unit of Evaluation of public investments as "areas far from the centres of provision of essential services such as education, health, mobility, connectivity, characterized by processes of depopulation and degradation", which today constitute 61% of the national territory where, however, less than 20% of the Italian population resides (ISTAT, 2016), a percentage significantly reduced compared to the first decades of the 20th century. The present differences are not only due to the classic North-South gap, but also to the many factors inherent to the unequal development between town and country, between mountain and plain, between coast and hinterland (Marchetti, 2017).

In such a context, the very notion of "periphery" no longer measures the physical distance of a place from the central area, but rather recalls the characteristics of "economic and social marginality, building degradation and lack of services". (Bando "Periferie" DPCM 25 May 2016) typical of the development of large urban areas as a whole. These peculiarities are also found within the historical stratification of urban systems, structures and open spaces, which is the main reference for the identity and self-representation of local communities.

In recent decades, in fact, the profound socio-economic processes of gentrification and turistification, which characterize in particular the historic centers of large cities, have led to the escalation of problems related to the deterioration and impoverishment of contexts of historical value, with increasingly evident effects of removing the memory of places and local identities. These elements are associated with processes of abandonment and disposal of spaces, complexes and facilities that are no longer functional or appropriate in the context in which they are inserted (large hospitals, markets, theaters, cinemas, meeting places and spaces of relationships), due to the emptying of the catchment area, difficult accessibility or structural obsolescence.

These state assets are now subject to privatization and incompatible reuse, transformed into supermarkets or large stores, following the legislative decree 85 of 2010, the rule on the so-called "federalismo demaniale" signed by Calderoli, Berlusconi and others. This makes it possible for the City to sell all public state property, 536 pages of property of immense value that now the municipalities can put in the hands of private individuals.

Perhaps the island of Certosa will never be sold, but only because it costs too much and pays too little, not because it is a common good, and the mere price of all state property makes Italy in fact a giant supermarket (Settis, 2014). But the city, with its buildings and its heritage, also has a soul, the so-called invisible city.

Crossing the Alps and stopping in France, the report "L'economie de l'immateriel" considers immaterial values (which cannot be valued) as the basis for tomorrow's growth: "there is an inexhaustible wealth that is a source of development and prosperity: the talent and passion of women and men", we read on the first page. Talent and passion triggered and nourished by cultural memory. The report was commissioned by the Ministry of the Economy (2006, Chirac presidency) and concludes that intangible values *"hide an enormous potential for growth, which can stimulate the economy of France by generating hundreds of thousands of jobs, and preserve as many as would otherwise be in danger"*.

Big congested centres

Venice

The symbol is undoubtedly represented by the City of Venice. The territory of the City of Venice, according to the current administrative division, comprises in addition to the lagoon city, a large area of mainland, which includes Marghera, Mestre and other areas, such as the airport of Tessera. And it is here that the population has headed in recent decades, especially the younger generations and students who move there from all over Italy. Despite the internal movement, in this area taken as a whole population has fallen by as much as 100 000 inhabitants from 1971 (363 062) to 2011 (263 996), but the data are much more dramatic if you look only at the

historic center, from 108 426 in 1971 to 56 684 in 2014. As Settis recalls in his "Se Venezia muore", only the terrible plague epidemic of the 1600s had reduced Venetian population by half in this way. Since the 1970s, a new plague has been spreading, with an increasing number of elderly and exodus of residents, a low birth rate, a continuous contraction of population, and a city that is running away from itself.

As the city empties, the wealthy around the world buys houses, pieces of Venice to use five days a year, distorting the market and creating a price system that expels the Venetians and causes a gentrification perhaps unique in the world. Meanwhile, every year eight million tourists flow into the streets for thirty-four million presences, against a maximum "load capacity" of 12 million (Tattare, 2014): in other words, for every inhabitant of Venice there are 600 floating visitors, deeply altering the economy, demographics, but also social and physical balances. The city is now dominated by a tourism monoculture that exiles the natives and binds the survival of those who remain and the city itself almost exclusively to the intention of servicing the tourist, with b & b, restaurants and hotels, parties ad hoc, in order to transform their residence in the old city in a profitable extra-hotel activity. Often a small contribution to the tax is one of the pros of living in Venice. While everyone in the world dreams of living a bit of the magic the city has to offer, are countless the Venetias that have sprung up all over the world, the Venice of the north, the Venice of the south, the 27 Venetias scattered in the United States, starting from the famous Venice beach, the Venetias of the east, which is punctuated India, Japan, China.

The image of Venice today represents a model of life, exportable and exported more than any other in the world. The aggression against the city is like an embrace of love, but that progressively tightens and damages parts of the city surrounded by the grip. In recent days we have seen the impressive images of the cruise ship that hit the boat along the Giudecca canal², making even more evident the risks and incompatibility of the system of exploitation of these places, denounced almost prophetically at the Art Biennale, by the artist Banksy in the performance in St. Mark's Square of "Venice in Oil" (Figure 1).

Figure 1: Venice on Oil, Banksy

² <https://tg24.sky.it/cronaca/2019/06/02/venezia-incidente-nave-crociera-video>.

But the people of Venice are not tourists, not even the most careful who spend a few days or weeks there. It is not that of those who own but do not live in the crowd of second and third houses. *“Neither can be what men and women must be for a city: the living blood that circulates in the veins that are streets and squares, the guardian and creator of memory, a community that identifies the physical form of the city and its ethical reason.”* (Settis, 2014)

Rome

In this context, Rome also represents an emblematic case, both as a city and as a historic centre. The territory of its municipality is today the largest in Italy, with a population of 2,865,000.

The 2008 General Regulatory Plan includes the historic centre as part of the wider Historical City, which includes the integrated whole of the central historical area inside the Aurelian Walls, the urban parts of the nineteenth and twentieth century consolidated expansion, and the individual sites and buildings located throughout the municipal territory. These have a historical-cultural identity defined by particular qualities, recognizable from the point of view of the structural characteristics of the urban system and those of the morphological, architectural and use of individual fabrics, buildings and open spaces, also with reference to the sense and meaning they assume in the memory of the communities settled³. Rome is in fact the largest open-air museum, where every church, every suburban villa, every historical road axis tells a piece of the story and the image of the city. In 2016, thanks to the Extraordinary Jubilee of Mercy, called by Pope Bergoglio in March 2015, there were 20 million arrivals and 40 million attendances, with an average staying, however, has gradually decreased to 2-3 days.

But the Rome of mass tourism is the Rome of its historical center; unique in the world not only for extension (1.470 ha, inside the Aurelian walls) and for the importance of its heritage (UNESCO site since 1980), but also for the extraordinary intensity of tourist flows (14.7 million tourists in 2017⁴), the center of Rome in recent decades is suffering massive phenomena of abandonment by the original inhabitants and gentrification (the population has risen from about 424000 in 1951, to about 133590 in 2012⁵), population aging (old age index equal to 227) and radical transformation of the socio-economic structure.

The number of visitors in 2015 in the archaeological complex of the Forums alone is impressive, 6,600,000 people, especially considering that the entire population of the Lazio Region, in which Rome is located, does not exceed 5,900,000 inhabitants and that the second most populated municipality of the same region, after Rome, is Latina and has 125,000 while that of the Roman area is Guidonia-Montecelio which has 89,000.

In the City of Rome is concentrated 88% of the accommodation activities (hotels and extra-hotel of the entire Province of Rome), and comparing the data on tourist attendance 2014-2015, it is clear that in Rome and its province is concentrated more than 85% of the presences recorded throughout the Lazio Region.

³ Municipality of Rome, General Regulatory Plan, approved by CC 18/2008, NTA, Art. 24, co.1.

⁴ Tourism and labour market observatory.

⁵ Roma Capitale. Statistical Office. Data for 2012 related to the I Municipio.

These data undoubtedly depend on the fact that Rome, for the very high concentration of assets, is a privileged destination for tourism on a global scale, cause but also effect of the reduced influx of tourists in the rest of the region, despite the very high presence of historic centers, museums, archaeological sites and points of interest (Cerasoli 2017).

This situation of massive tourism has important consequences in the use of public space in cities of art such as Rome, precisely. Today, in fact, the elements that physically make-up the squares and streets of the historic city, are the same as in the past, but lack the gestures, habits that gave body and life to that public space (Caudo, 2017). In a city like Rome, tourist flows reach such a volume as to transfigure the public spaces of the center, pushing the inhabitants to look elsewhere for new places of encounter that they can appropriate. As the monumental spaces of the historical city become victims of the substitution of the inhabitants in favour of temporary travellers, the identity of these places is lost and in fact these spaces are taken away from the citizens. In large cities, where there is certainly no problem of depopulation, as in more internal villages, there is the problem of social separation and the "migration" of public life from historical squares to more marginal and unconfigured spaces. The historical squares have been in some way "abandoned" by the citizens, who prefer to move to neighboring places, hidden corners in which to seek a greater identity and belonging of which many better known places have been emptied. In Trastevere, as well as in the areas of Campo dei Fiori or Piazza Navona (Figure 2), those that were the monumental public spaces and therefore designed and configured for the public life of the city, are reduced to a fictitious artifact, for the sole purpose of contemplation, almost denying the interaction with the actors who live the space, and therefore seek in places not configured the possibility of living freely the city, informally (Cianci, Mondelli, 2018).

Figure 2: Roma interrotta, Pasquale Iaconantonio

If it is true, in fact, that on the one hand tourism has increased the protection of heritage, it is also true that this protection has gone so far as to make heritage, and the space in which it is placed, an object of exclusive use of the tourist himself, effectively taking away the historical places from the life of the city and those who live there. Rome is an emblematic example in this sense. If it is true that many other cities of art in Italy have been invaded and transformed by the tourist industry, subjecting their structure and identity to the economic aspects of the tourism industry, no one like Rome has had the need to coexist this aspect with all the functions related to its role as capital. This means that the historical and monumental center of Rome is in a sense forced to live an superimposition of actions and flows that are twisted especially during the daytime, mixing tourists, workers,

students and so on. It is precisely this role of the city as a metropolitan city in which millions of people flock every day to "limit" the damage of tourism to a certain extent, and at the same time to make particularly necessary good practices for the reintegration of city life in historical, archaeological and monumental spaces.

If in Venice the city has abdicated to an almost mono-thematic and completely branded use of its urban space, triggering a process that has almost completely emptied the lagoon of its inhabitants, in Rome this can not happen and exactly for these reasons the city lends itself to become a fertile ground for initiating a debate and propose strategies that review in heritage sites opportunities for public space for use of the city and its inhabitants, counteracting the extreme musealization of the historic centers.

The attention that in recent years is focusing on the results that tourism is causing on the real estate, transforming most of the houses in temporary accommodation designed for travelers, must extend to the repercussions that this phenomenon has in the open spaces of the city. The idea of democratising space is therefore central, and only in modern times is it understood as "public" and therefore thought of and designed for the life of relationships and the needs of those who live in the city. Most of the squares that make up our historic centers, in fact, were not born in order to provide citizens with places where they could live the life of relationship, but were more than anything "the palimpsest of arrogant and egocentric representations of the powers that have dominated the city from time to time". (Cellini). Are we not now facing a new kind of "arrogance" in which economic interests dominate the city by materially selling its historical and artistic heritage and taking its spaces away from the citizens? It is necessary to reconsider the role of patrimonial protection in function of the city, tracing a strategy that balances the management of the patrimony with its usability by the inhabitants, avoiding the risk of a loss of identity and memory and therefore of the "death of the city".

Abandoned small towns

The other side of the story instead represents all those small "valuable" places, historical urban centers that belong to the heritage of the minor centers, located almost always in the so-called "internal areas" of the Italian territory, which see - with naive short-sightedness - tourism as a panacea of their decline and abandonment.

This archipelago of ancient territorial garrisons, which is the backbone of the country, after the end of the Second World War has been affected by significant phenomena of abandonment. Forgotten, it has gradually become fragile, suffering the dismemberment of the network of interactions that for centuries had radiated sap to the whole system, transhumance, supply chains, ancient paths, pilgrimages, represented the networks of territorial relations that had kept alive the local economies for centuries, which urban polarization and globalization dynamics have almost erased.

Today, the smaller historical centres of the internal areas, except in isolated cases, present common pathologies, linked to the inability to respond to the needs of contemporary living (Abbate, 2011), mainly due to the marginality of these centres with respect to production processes, the lack of services and the criticality of connections.

The lack of financial resources in the smaller municipalities, certainly not facilitated by national and regional policies, absorbed by the chronic "emergencies", has allowed these minor urban realities to turn into ghost zones, or, in rare cases, into large real estate investments in tourism, linked by a double thread to exogenous economic dynamics.

It is therefore necessary to work with the existing materials to reverse the erroneous approach that does not consider the internal areas as a resource or an opportunity, but as a problem or a residue concerning the peripheral lands, to react to the progressive marginality, conceiving these places as a ground for social and productive experimentation, protagonists in some way of a cultural and economic rebirth.

The primary objective in these contexts is to highlight the territorial heritage of these areas, understood as the set of long-lasting structures produced by the co-evolution between the natural environment and human settlements, whose value is recognized for present and future generations (Marchetti, 2017). Territory understood as a cultural landscape, as an expression and outcome of the complexity of nature and culture and therefore as a product of history, immediate expression of the identity of a place and its inhabitants, whose components thus become the invariants of places and communities, trace of history and matrix for a historicalised and contextualized evolution (Carta, 2002).

This extension of meaning not only concerns the formal, civil and symbolic aspects, but also the time of belonging of the resources and their location in contemporary territories, thus representing an extension of temporal, spatial and meaningful interest. The traditional field of analysis of the physical city has in fact extended from the historical centre to the existing city as a whole, to involve the entire "historical territory" of which it is part, in search of the "widespread and often dispersed plot of the traces of man" (Amato, Bevilacqua, 2018).

It should be kept in mind, in fact, that mass tourism often results in putting at risk and altering the value of the Italian landscape. The landscape balance that characterizes most of our country is an invaluable value whose protection we try to operate at multiple levels. The passage that led to the enactment of the conceptual extension from historical centre to historical territory (Gubbio Charter, 1960, 1990), reaffirmed by the European Landscape Convention, has been further innovated with the concept of "historical urban landscape" that UNESCO introduced with the "Vienna Memorandum" in 2005 and that at the end of 2011 was consolidated in a special "Recommendation". Its field of application concerns the recognition of the quality of an urban landscape whose strength is in the widespread, capillary and living presence of a heritage that is not reduced only to protected historical areas and buildings, but refers to the physical, geographical, historical context in which it fits, resulting in a synoptic and organic vision of the heritage that opposes the idea of discontinuous and isolated emergencies (Settis, 2002).

In the polycentric territorial system, the smaller historical centres perfectly embody those landscapes of everyday life mentioned in the European Landscape Convention as territories capable of projecting and "making perceptible to the settled communities values of a proper identity matrix" to be preserved, avoiding homologating interventions that "safeguard stones but not people and traditional functions" (Cervellati, 2009).

If on the one hand these valuable characteristics that the national and European regulations tend to protect are precisely the attractor that makes Italy one of the most visited countries in the world, on the other hand the "bel Paese" consists of a territory that is difficult to lend itself to the management and assimilation of such large tourist flows, especially when it comes to the most internal areas.

The case study of the small towns of the inner Cilento

To deal with and analyse the issue, this contribution refers, by way of example, to the area of the Cilento National Park, a sub-region of Campania which, with regard to the debate on the internal areas, is a particularly interesting reality and perhaps unique of its kind. Its large size and distance from the most important metropolitan areas, make it a region with a rural identity that only in recent decades has tried to invest in tourism by exploiting the heritage inherited from the Greeks, Etruscans and Lucanians. However, this momentum has most of the time moved without an adequate awareness of a heritage that goes far beyond archaeological sites but that includes the rural landscape of the Park in its entirety, leading to the serious consequence of making gestures that have endangered its intrinsic value (Cianci, Mondelli, 2019).

In fact, the historical centres that make up the Cilento Park are an emblematic example of this marginal situation in which many Italian historical centres fall. The Cilento, in fact, is a large slice of territory located in the south

of the province of Salerno, while remaining a peripheral area in a region, Campania, already rich in coastline, cities of art and tourist attractions worldwide. This administrative situation, if on the one hand it has never launched the Cilento towards the possibility of a consistent modern development, has had, on the other hand, the welcome side effect of at least "limiting" the effects of the building pressure on the whole territory, delimiting it only to some coastal centers.

Tourism, mainly concentrated in the coastal strip, is kept away from what is the historical and cultural value of the inland villages, causing also the negative consequence of increasing the insediative pressure on the coast, often compromising the landscape value of the Park. The morphology of the Cilento territory is exactly what over the centuries has dictated the lines of settlement development, alternating periods in which the proximity to the sea was functional to communications, with phases in which the need for defense led the population to retreat into more rugged and controllable territories.

It is precisely those same topographical characteristics (Figure 3) that in ancient times allowed the rise of the Cilento centers, to be today an obstacle to their contemporary development, making difficult connections for the inhabitants and also driving away the tourism that could discover them. The settlement structure formed in the Middle Ages that gave rise to the small towns that now characterize the Cilento landscape has long been preserved unchanged, until, starting in the 70s, mass tourism has changed significantly the appearance of the valleys and coastal areas, through the emergence of new urban expansions devoid of that relationship between anthropogenic forms and natural environment that constitutes the value of the Park of Cilento. The need to promote a new type of tourism, alternative to the seaside one that only concerns the summer season, is therefore felt not only in order to repopulate the most inland areas, but also in order to preserve the landscape and contain the risks arising from the territorial changes made in recent decades.

Figure 3: small town in Cilento National Park

Very significant, in this sense, is the Landscape Plan of the Park of Cilento, which among the objectives also identifies the "awareness of the local community to the importance and value - including economic - of the landscape and historical pre-existing". This aspect wants to emphasize the implications that a greater awareness and enhancement of the historical and cultural heritage of the smaller towns can have on the territory, providing the opportunity not only to reactivate the tourism sector more widely throughout the region, but also to give a new impetus to the primary sector, recalling the interest in the rural vocation of the Cilento interior, which never

before in this historical period could rediscover an important opportunity for economic development and repopulation of the region. The abandonment of traditional activities, in fact, are often the cause of the disappearance of the characteristics of a particular landscape, with the consequent loss of cultural value and attractiveness of a territory for tourism purposes. Therefore, it is essential to preserve the link between the territory and the population that lives there intact, keeping alive the traditions and enhancing the activities on which these small societies have been based and developed, counteracting the tendency to depersonalize the smaller centers operated in the contemporary era.

Conclusions

On the basis of what has been said so far, we can point out that it is possible and necessary to relate to the consequences that tourist flows are having in large cities that are congested on one hand, and in small inner cities that are endangered by them, either because of abandonment and marginalisation or because of a functional transformation that affects their cultural identity, on the other hand. There is no doubt that the planning of local territorial development must work putting at the core of the operations the protection and enhancement of the landscape according to a method that is not static or merely conservative, but identifying in the productive and economic activity of the places an important tool with which it is possible to dynamically preserve the landscape, attracting tourism inward and reactivating local economies. Tourism, in fact, can and must be in any case one of the tools for development and revitalization, but never the only source of economic support. Because in the latter case it is easily transformed into an element of degradation. In this way it will be right, then, to promote tourism in inland areas, also in order to unload and decongest the large cities of art, which on the contrary need to find their own dimension beyond the "urbs", the physical structure, and reconsider the value of "civitas", or the society that lives there, and that gives substance to the concept of the city itself.

Tourism is changing the historical centres of our cities, perhaps forever. It is said that "beauty will save the world", but not only, as Settis says, beauty will not save anything and no one if we do not know how to save beauty, and with it, culture, history, memory, the economy, but will gradually destroy cities that were previously resilient. (Cecchini, Blecic).

Public Space as Protest Space: Between Visibility and Insecurity

Ute Neumann

TU Kaiserslautern, Germany, ute.neumann@ru.uni-kl.de

Abstract: Public space in the European City is, by definition, a place of political publicity, debate and open exchange of opinions. Social movements use public space to create visibility and to express their political, social, or ideological perspectives and demands. Looking at the situation nowadays one can observe cleavages between right-wing and left-wing groups on the one hand, and an increasing eventisation of protests - a "pleasure for the state of exception" or "event-driven protest" - on the other hand. What do these developments mean for public space and its inherent qualities? How do protesters assess the situation? Based on the results of quantitative surveys of participants two types of protest are contrasted: 1) a conflicting political demonstration march 2) a less conflicting and more festivalized Christopher Street Day parade. The results show significant differences in the visitors' structure, motivations, the individual perception of the events and the perception of security and presence of police. The framework conditions of protest have an effect on public space: If they implicate security risks and instrumentalize or abuse the purposes of specific groups, there is a considerable impact on its accessibility, usability, and political quality.

Keywords: public space, protest, visibility, insecurity

Introduction

Political and social protests are omnipresent in public spaces of cities. They represent a central form of political participation outside parties and institutions and draw attention to current social and political conflicts. Protest topics and forms are diverse. They range from peaceful, festivalised parades to violent protests with massive riots. Media representations often focus on violent conflicts between controversial groups or between demonstrators and police, as in the case of the G20 protests in Hamburg/Germany (Hunold *et al.* 2018). Violence, fires, and looting (Rucht, 2019) also occurred repeatedly in the context of the protests of the yellow vests in France against President Macron's reform policies. Overall, changes in the protest culture are observed in Germany (Rucht and Teune, 2017): an increasing form of violence can be observed (Hutter and Teune, 2012, Nassauer, 2016) on the one hand, but on the other hand also an eventisation, an increase in "event-driven protests" and the "pleasure for a state of exception" (Betz, 2016, Blickhan and Teune, 2003).

Social movements and protests are usually investigated with regard to their origins, conditions, and contents. The "Patriotische Europäer gegen die Islamisierung des Abendlandes" (PEGIDA, Patriotic Europeans against the Islamization of the Occident) protests and their counter-demonstrations in Germany, as an example of conflictual demonstrations between right-wing and left-wing political

groups, are discussed from an identity-theoretical perspective. In addition, the focus is on the social composition of the participants, their motivation, mobilization, protest experiences, and political positioning (Patzelt, 2015, Vorländer *et al.* 2016). Research on parades such as Christopher Street Day (CSD) usually focuses on identity constructions and gender stagings (Kates and Belk, 2001). Spatial interactions and, above all, limits to the use of public spaces as settings for social movements are given little consideration in research. This article aims at filling this gap.

The current discussion on public space is concerned with various developments that endanger its qualities. At present, privatisation tendencies and increasing subjective feelings of insecurity are discussed as limiting the usability of public spaces. Exclusive practices lead to the fact that not all social groups can make equal use of their civil rights. The conditions for protests in the public sphere are also changing with increasing uncertainty and changed controlling options. Two contrasting case studies illustrate the importance of context of protests and their different effects on the usability of public spaces. Both can be located in the context of visibility and uncertainty and will be discussed in a final step.

Public Space: Heterogeneity and Visibility

Public sphere and the right to demonstrate are fundamental principles of democratic society and an essential element of cities and their culture (Schäfers, 2006). The central element of this public sphere is the principle of general access to places or assemblies. Publicity also implies transparency for all citizens with regard to matters of public interest. It is a prerequisite for generating (public) opinions and a way of bringing issues into public debate or onto the political agenda (Neidhardt, 1994). Speakers and audience meet, topics are visible and negotiated. The public sphere is thus a necessary condition for the effectiveness of social movements.

Public spaces are (ideally) freely accessible to all citizens and are therefore characterized by a high degree of heterogeneity among the population groups (Bahrdt, 2006, Sennett, 2008). They offer opportunities for the most diverse encounters, the expression of individual lifestyles, cultural differences, and the open exchange of opinions. Public spaces can be places of representation and can be described as "stages of visibility" for various political, social, or ideological points of view (Gusy, 2011).

The public character of a space, however, is only created by the people who use it. . "… what makes a space public – a space in which the cry and demand for the right to the city can be seen and heard – is often not its preordained 'publicness'. Rather, it is when, to fulfill a pressing need, some group or another takes space and through its action makes it public" (Mitchell, 2003, 35). Individuals or groups must occupy space, show presence to be represented and compete with other interests. . "… the desire of other groups, other individuals, other classes, together with the violent power of the state, laws about property, and the current jurisprudence on rights all have a role to play in stymieing, channeling, or promoting the 'taking' and 'making' of public space and the claim to representation" (Mitchell, 2003, 35) Negotiation processes for the demands for use of cities and their public spaces become necessary. "Cities not only breed contention; they also breed control. In their ongoing struggles to maintain order and power, local states and their partners develop strategies and techniques to direct the ebbs and flows of contentiousness constantly bubbling up from the urban grassroots. The city is a generative space of mobilizations and, because of this, it is also the frontline where states

constantly create new governmental methods to protect and produce social and political order, including repression, surveillance, clientelism, corporatism, and participatory and citizenship initiatives” (Uitermark *et al.* 2012, 2546). Cities are places where mechanisms of control, regulation, and order of political and social life in general and of social movements in particular are developed.

The symbolic occupation and appropriation of public space represents a claim to power and also creates atmospheres. Protest movements use the public space as a stage to generate attention and visibility. Parades and demonstrations are an expression of how people with shared political or ideological interests come together, form collective identities, and, at the same time, differentiate themselves from contrary views. Protest and social movements are closely connected to the concept of "mass" and the mobilization of masses (Rucht, 2012). Masses of people generate visibility and attention through their mere presence. With regard to protests and social movements, it is a matter of mobilizing "masses" and persuading them to stand up for or against something, to draw attention to social conditions, and exert influence. "Collective protests" strive to reach a broad public and generate public attention and sympathy (Rucht, 2012). A symbolic effect is produced by a large number of participating people (Balisitier, 1996). The central goal of street protest is to create presence, both concretely in space and time, and in form of resonance and effect in the media.

Media contribute to the production of visibility of various political and non-political interest groups, as well as socially relevant topics and areas of conflict, and generates a mobilizing effect. The presence of groups and topics in the media can activate supporters as well as opposing groups (Fahlenbrach, 2009). However, the kind and selection of media representations influence the reception and social perception of protest events. Content is moved to the foreground or to the background, depending on the interests involved. For example, the perception of the demonstrations on May 1st in Germany is shaped by media coverage and largely focuses on the outbreak of left-wing violence (Blickhan and Teune, 2003). This can lead to distortions and scandalisation (Rucht, 2003) and ultimately affect the subjective feeling of security of media recipients. But still it is the occupation of physical space that gives visibility to a protest. Reporting, dissemination, and mobilization via the Internet and social media take on a complementary function.

Current conditions of public spaces as protest spaces

The role of public space in the European city is discussed anew on a theoretical level: changed framework conditions regarding fear of crime, respect, trust, social heterogeneity, and polarization processes have to be introduced into the discourse. At present, the peaceful, tolerant, and stylized public appearance is countered by developments that move the issue of security in the foreground (Koopmans *et al.* 2005). Terrorist threats, xenophobia, and insecurity can also be associated with fear of staying in larger crowds. Transformations of public spaces through increasing privatization and surveillance also give security a new significance (Selle, 2010). These developments can contribute to more security in cities or intensify social divisions and feelings of insecurity (Minton, 2012), and restrict freedoms.

Insecurity

The heterogeneity of its users has always made public space a place of encounter with the other and the unknown, which can also generate feelings of insecurity and uncertainty. This unfamiliarity goes

far beyond the fear of crime (Wehrheim, 2009). Uncertainty caused by otherness can be explained on the one hand by a "knowledge gap" (ibid., 38) towards the foreign, and on the other hand by the perceived endangerment of existing social orders (ibid., 39). Thus, the meaning of security can also be thought of in two dimensions: 1) as protection in the sense of unharmedness, 2) as "security of expectation" (ibid., 40). This distinction is also effective in protests when different lifestyles and worldviews meet.

New threats today include cross-border, transnational activities, and sources of danger, criminal networks and organizations, and extreme violence with extreme consequences (Albrecht, 2010). A divergence between the objective security situation and the subjective perception of security can be observed. This subjective component plays a central role in the discussion about feelings of insecurity in public spaces; i.e. they are not only rational, but strongly emotional. Explanation approaches for the individual perception of insecurity can include victimization experience, the representation of crime in the media, and in a generalization thesis, which associates fear of crime with general fears of life (Albrecht, 2010). The perception of police patrols as well as age and gender also play an important role at the individual micro level with regard to fear of crime (Lüdemann, 2006).

The PEGIDA demonstrations in Germany and their venue, the urban public space, can be seen as a projection surface for fears (Keller and Berger, 2017). Fears and worries play a central role in the narratives of the PEGIDA movement. The communication of fear is a central strategic instrument in the PEGIDA movement and the expression of fear in public space is political action. This has made it possible to mobilize people and reach the "concerned citizen" (Keller and Berger, 2017). Fueling fear of specific social groups can have an effect on the subjective perception of (in-)security in public spaces. The PEGIDA movement takes the freedom of assembly in public space. At the same time it restricts the freedom of others (counter-demonstrators, citizens, migrants). Security and freedom are in a tense relationship. The safety of one person can restrict the freedom of another (Keller and Berger, 2017).

Privatization

Free accessibility and freedom of use are preconditions for free and visible articulation of opinions by all members of society. Communication and dissent require public space in which the freedom of speech of the citizen is not restricted by private interests (Kohn, 2013). However, the "right to public space" is controlled by the regulatory practice of the dominant social system (Ruppert, 2006). The possibility of using public space as a social and political space is defined by legal provision, spatial design, surveillance, and policing practices (Ruppert, 2006). Public space is increasingly developing into a contested space "where ambiguities of proprietorship, of aesthetics, of social relations (class and gender in particular), and the political economy of everyday life collide" (Harvey, 2006, 19). Particularly economic interests are at odds with the ideal of a public space (Mitchell, 1995, Neumann, 2016). Public space is in danger of losing its character if control by private interests prevails.

Protests in transition? Between violence and eventization

Increasing violence

In Germany, the number of protests is increasing, partly due to the growing number of asylum seekers which cause right-wing protests to increase massively. At the same time, counter-movements emerge

that advocate a tolerant, cosmopolitan society (Daphi and Deitelhoff, 2017). Above all, confrontational forms and violence have increased (Hutter and Teune, 2012, 2017). Studies have shown that the willingness to "civil disobedience" among protesters is growing (Rucht et. al. 2010). In the autonomous left-wing scene, militant actions such as arson attacks, attacks on police officers, or neo-Nazis are not uncommon. During demonstrations of the extreme right, confrontations with police are usually avoided. Attacks on people who are marked as foreign or belong to the left-wing scene are, however, part of everyday life (Rucht and Teune, 2017).

During demonstrations, the police is confronted with the dilemma of protecting the right to demonstrate for all on the one hand and preventing and punishing crimes on the other hand. The police's actions are regarded critically (Kanzler *et al.* 2003). Donatella della Porta has defined the term "Protest Policing": "the police handling of protest events - a more neutral description for what protestors usually refer to as 'repression' and the state as 'law and order'" (della Porta and Reiter, 1998, 1). The dichotomy of the term becomes clear in this definition: on the part of the state and the police, "protest policing" is understood as the enforcement of law and order, on the part of the protesters, the impression of repressive up to violent intervention of the police predominates. Police action itself can become a political issue, because the practice of protest policing influences the chances of political groups to articulate themselves, mobilize sympathizers and exert political pressure (Winter, 2006, 259). Article eight of the German Basic Law protects freedom of assembly as an essential element of democracy and ensures that people can come together without hindrance and assert their right to freedom of expression (Arzt and Ullrich, 2016). Police checks and surveillance aiming at maintaining public order and security are sometimes at odds with this, as police measures can restrict this freedom of assembly, or intimidate participants. This creates tension between the legal situation and police practice. If the presence of the police is understood as a demonstration of power, as a potential restriction of the freedom rights of the demonstrators, this can generate conflict potential (Winter, 1998). Protests and conflicts also arise when public space is restricted in its use as a demonstration space.

Eventization

Protests are extraordinary events. They are not always exclusively politically motivated or conflictual. As an "event-driven protest" (Betz, 2016), political demands can also be combined with an excitement and fun character. This not only changes the atmosphere of protests, the expectation of fun and joy can be the motive for participation and have a mobilizing effect. Participants expect community, sociability, and a feeling of belonging (Betz, 2016, 272). Initiating social change does not have to be the only objective, but can act as legitimization (Betz, 2016). Dancing, costumes, or performative elements can be the expression of this protest.

Earlier social movements, such as the homosexual movement in the beginning of the 1990s, still rejected fun elements, such as the carnivalesque parade of Christopher Street Day, as they question the political seriousness (Dobler and Rimmel, 2008). This seems to have been put aside with the emergence of the "event-driven protest" (Betz, 2016). Rucht (2003) diagnoses an increasing implementation with entertainment elements at the political demonstrations of the trade union on May 1st in Berlin, a development to a "fair interspersed with political elements" (Rucht, 2003, 50f). Even during riots in Berlin-Kreuzberg, forces of attraction and repulsion of sympathizers, activists hungry

for excitement, neutral activists, passers-by, residents, and police were observed as in a magnetic field (Casquette *et al.* 2003).

Case Studies: Demonstrations and parades

Demonstrations and parades can differ in their atmosphere, size, dynamics, mobilization, course, composition, or topic etc. For this reason, they should always be viewed in relation to their specific context (van Stekelenburg *et al.* 2012; Klandermans *et al.* 2014). Within the framework of the project "Organized Pedestrian Movement in Public Spaces (OPMOPS)", funded by the German Federal Ministry of Education and Research, demonstrations and parades are investigated. Two contrasting protest forms serve as case studies: regular demonstrations in the small German town of Kandel and the CSD Parade in the German city of Mainz.

Both protest forms use public space of the inner city to create visibility and convey political messages. However, they differ in the size of their venue, the conflictual nature of the protest, and their atmosphere. Kandel serves as an example of a political demonstration in which the clash of right-wing and left-wing groups leads to conflicts. CSD in Mainz shows the described tendencies towards an eventization of protest. CSD was originally a festive day of commemoration and demonstration for the acceptance of and against discrimination against homosexuals, bisexuals, and transgender people (LGBTI). Due to its size and the character of the event, it often has a tourist significance as a carnivalistic and excessive celebration (Markwell and Waitt, 2009). Nevertheless, the parade itself and the visibility of the difference in way of life can also be understood as provocation. Feelings of insecurity, rejection, avoidance, and even aggression can be observed when heterogeneous lifestyles are questioned.

Political demonstrations in Kandel

Kandel is a small town with about 9,000 inhabitants. In December 2017, a 15-year-old girl was murdered there by her ex-boyfriend, an Afghan refugee. In January 2018, right-wing political alliances called for a demonstration in which around 1,000 people participated. The protests were politically motivated and were primarily directed against the immigration policy of the German government. Resistance then formed counter protests: a middle class alliance, largely composed of Kandel citizens and supported by churches and trade unions, aims above all at sending a signal against right-wing attitudes and right-wing marches in the city. Furthermore, individuals as well as regional and supra-regional groups participate in a politically left-oriented alliance. It represents diversity, tolerance, and humanity and opposes hatred, racism, and exclusion. The right-wing demonstrations and counter protests in Kandel have been taking place since early 2018 at least monthly. The death of the girl was instrumentalized and forms the starting point for nationally organized right-wing protest, visible in the formation of the group "Kandel ist überall" (Kandel is everywhere). Kandel became a stage and synonym for a right-wing protest against Chancellor Merkel's German refugee policy and against immigration. The monthly demonstrations are accompanied by large police forces, physical and verbal attacks and crimes.

Christopher Street Day (CSD) in Mainz

Organized and registered by the association "Schwuguntia e.V.", the 25th Christopher Street Day in the German City of Mainz (approx. 200,000 inhabitants) took place in June 2018. Unlike in other

cities, only pedestrian groups (no trucks) take part in the march in Mainz. They demonstrated against inequality, exclusion, and discrimination, and for equal rights of all people. The intended renunciation of trucks and loud music emphasized on the original character of the demonstration and the political message, rather than on a fun and experience character. In addition to a march through the city center, which was registered as a political demonstration, a supporting program consisting of music, information stands of groups from the LGBTI community, rallies, and gastronomy was offered on a central square in the city center. This underlines the event character of the CSD, which not only pursues political motives, but is also a place of celebration, meeting, and entertainment. CSD in Mainz can be characterized as hybrid. The parade is not only a political demonstration, a symbol of equality in society, and an expression of belonging and identity, but also a colorful parade of parties and music.

Methods

The following results are based on two standardized quantitative surveys conducted by the Department of Urban Sociology at the University of Kaiserslautern in 2018. Participants at CSD and demonstrators in Kandel were interviewed face-to-face on various aspects of the perception of the demonstration, the police operation, and various other aspects. At the demonstration in Kandel in October 2018, a total of 99 participants from different protesting groups were interviewed. The total number of participants was about 700. Of these, 300 were supporters of the right-wing alliance, and 400 people took part in two counter-demonstrations and smaller pickets at different locations in Kandel. In June 2018 a total of 162 participants were interviewed at CSD in Mainz. According to the organizer, about 2,000 people participated in the demonstration march through the city center of Mainz. The results are supplemented by results of participatory observation.

Social structure and group size of visitors

The participants surveyed at the CSD are on average significantly younger than those in Kandel. There are also differences in the gender ratio: More men were interviewed in Kandel. Surprisingly, the proportion of highly educated people was the same in both surveys. With regard to socio-structural characteristics, the case study in Kandel reveals differences between the respondents according to alliances. The respondents from the left-wing alliances are younger than the right-wing demonstrators. There are also clear differences with regard to education. Respondents from the left-wing alliances show the highest education (Table 1).

Table 1: Comparison of visitor structure

	CSD n=162	Kandel n=99
Average Age (in years)	26	47
Male (in %)	44	58
Higher Education * (in %)	68	67

Source: Own Surveys; * in Germany: Admission to Universities of Applied Sciences and higher

There are also clear differences in terms of group sizes (Figure 1): Individual visitors are clearly underrepresented among the CSD respondents. The proportion of groups of 5 to 8 persons, and especially of larger groups of up to 20 persons, is significantly higher than at the demonstrations in Kandel. This may be due to the stronger event character of the parade. In Kandel, larger groups play a comparatively minor role. More than a quarter of respondents are individual visitors, which shows the greater relevance of individual political interests and motivations.

Figure 1: Comparison of Group sizes

Source: Own surveys

The people interviewed at the CSD were asked to rank associations with the parade to derive visitor types in a further analysis. The "hedonist" (21% of respondents) associates CSD first and foremost with the aspect "party, music and colorful parade". The "politically motivated type" (31% of respondents) primarily associates CSD with a political demonstration and chooses this aspect in the first place of the required ranking. The "mixed type" (48% of respondents) cannot be assigned a clear motive. The results show the differences in visitors' motivations and underline the hybrid character between event and political demonstrations.

Individual perception

The participants' perception of the parade or demonstration provides information on the atmosphere, subjective feeling of security, and attribution of meaning. By means of a semantic differential, on a five point Likert scale, respondents expressed their perception of the demonstrations in Kandel and the perception of Christopher Street Day in Mainz using opposing pairs of adjectives, where 1 is an absolute agreement with the positive term, 3 is "neither nor" and 5 is an absolute agreement with the negative term. The result is visualized using the mean value.

Figure 2: Individual perception - Kandel vs. Mainz

Source: Own surveys

Figure 2 clearly shows that both curves predominantly move to the positive adjective pairs. Viewed individually, the CSD is perceived as safe, cheerful, harmonious, and cosmopolitan. This underlines the positive atmosphere in which not only the political message, but also community, openness, experience, and fun are important. The demonstration in Kandel is perceived as important, interesting, and safe. The most obvious negative perception is visible in the adjective pair „harmoniously/full of suspense“, which reflects the rather tense situation when opposing groups meet. The protest situation in Kandel is described as clearly more stressful, sad, provocative, and tense than the CSD. This is due to aspects of topic and to the confrontational situation between demonstrators and counter-demonstrators.

The comparatively positive results in Kandel are partly due to the fact that all political groupings were considered cumulatively in the graph. Differences in the perception of the demonstration between the various participating groups, especially with regard to perceived provocations, can be observed: Since the counter-demonstrators were able to interrupt the demonstration of the anti-migrant demonstrators in Kandel with whistles and vuvuzelas and were not pushed back by the police, the vast majority of people from the politically right-wing alliance felt provoked. This heated the mood and directed aggression not only against the opposing groups, but partly also against the police. There are also differences in perception with regard to perceived security or insecurity. Respondents from the left-wing alliance perceive the demonstration in Kandel as safer than people who belong to the right-wing alliance. This may be due to the numerical dominance of the counter-demonstrators.

Perception of the police operation

Police deployment in Mainz and Kandel differed widely due to different conflict structures: On demonstration days in Kandel, the police regularly deploys several hundred emergency forces from federal state and nationwide. Police forces are confronted with different interests, not only of demonstrators and counter-demonstrators, but also of persons not involved, like residents, tradesmen, politicians, or representatives of the media. Police presence at the CSD was many times smaller. There were only 15 police officers on duty, mainly for road safety.

Figure 3: Perception of Police Operation

Source: Own survey

In Mainz and Kandel, the overall perception of police deployment was positive: comparatively appropriate, de-escalating, friendly, and justified. In all respects, the assessment at the parade in Mainz was more positive than at the demonstrations in Kandel. Here, too, it should be noted that differences between the alliances can be observed in Kandel: The left-wing alliances consider the police deployment to be more negative and, above all, rather unfriendly and exaggerated. The counter-demonstrators were kept at a distance by the police. This can be interpreted not only as a security measure but also as a restriction of personal freedoms (Figure 3).

Discussion

The inner-city public space provides the stage for both the protests in Mainz and Kandel. Centrality increases the visibility of protests. The ritual character of protests serves to strengthen their meaning. Rituals are necessary for community building and they contribute to the formulation and perpetuation of positions (Rucht, 2003). Especially in Kandel, where the protests take place at least once a month, this ritualization contributes to the visibility of the protest and to the support of the respective demands. Symbols can be seen as characteristics of rituals. They serve as a point of reference for collective identities and at first glance represent a specific view (Casquete et. al. 2003). Group-specific symbols connect people in social movements and also serve as a distinction to "others". But symbolisms also serve to create visibility and to classify people or things. At the CSD in Mainz, the rainbow flag dominates as symbolism, but identity is also staged with costumes. Also in Kandel,

different groupings can be distinguished from each other on the basis of clothing, banners, flags, etc., but without carnival elements (Figure 4).

Figure 4: Demonstration march Kandel (left picture) and CSD in Mainz (right picture)

Source: Own photograph 2018

Protests and social movements create specific atmospheres. The perception of the atmospheres by the demonstrator differs with regard to the character of the protest. Further influence is exerted by the perceived grievances, group identifications, possibilities of participation (empowerment), and the perceived aggression of the police (van Leeuwen *et al.* 2016). Since the perceived atmospheres can have a positive or negative effect on the behavior of participants in protests, possible emergence or avoidance of conflicts, for example, can also be controlled (van Leeuwen *et al.* 2016). While the atmosphere in Mainz can be described as cheerful and relaxed (which can also be attributed to the fact that there were no counter protests or other conflicts), the atmosphere in Kandel was much more tense and marked by the conflicts between the groups. Police was in attendance with a large number of forces, which on the one hand served to avoid and control conflicts, but on the other hand also fomented conflicts, namely when individual groups felt at a disadvantage with regard to policing strategies.

The positive perception of the demonstrations in Kandel in October is surprising and does not correspond to the image conveyed by the protests in the (social) media. There were riots during several demonstrations in Kandel earlier in 2018. According to the Ministry of the Interior, overall 178 criminal charges against participants were committed in 2018, mainly violations of the Assembly Act, attacks on police officers, or bodily injuries. Compared to other demonstration days, the situation during our surveys in October was more tense, but less aggressive. Nevertheless, media focus on the image and mood of a temporarily insecure public space occupied by right-wing groups, resulting in conflicts and violent confrontations between opposing political groups. Even if scandalisation cannot yet be spoken of here, there are certainly effects on subjective feelings of (in-)security.

Unlike the peaceful and cheerful protests in Mainz, the issue of insecurity is part of the demonstrations in Kandel. An important role is certainly played by the narrative of insecurity in public space (Keller and Berger, 2017), which is currently often used by right-wing political groups to stir up fears of attacks. This technique is also utilized by the right-wing alliance in Kandel. Feelings of

insecurity during demonstrations and parades arise from two perspectives: 1) insecurity, in terms of a perceived danger of assault and violence, for example when opposing groups meet; 2) uncertainty of expectation through the encounter with otherness, different views and lifestyles, groupings, and behaviors.

A mere dichotomous distinction between amused protest in Mainz and conflictual protest in Kandel, however, is not tenable. Counter protest can take different forms and also take up fun elements: A "people's bingo" took place in Kandel as an expression of a peaceful counter protest by the left-wing groups. Within hearing and sight, parts of the counter-demonstrators reacted to the use of certain terms and formulations in the context of right-wing demonstrations. The form of the protest action contains a fun component and an entertainment value, but also stereotypes are made visible and counteracted.

The effects on usability of public spaces by protest can vary considerably. For the demonstration march in Mainz, public space was temporarily converted and closed to traffic. The public character of Gutenbergplatz, the starting and ending point of the parade and the central meeting place, was not limited as there were no access restrictions. Due to its touristic importance, the CSD in Mainz can have a positive effect on the city, as a sign of diversity, heterogeneity, and experience of the extraordinary. For the citizens of the small town of Kandel, the demonstration days however represent a major break in everyday life. Public life and the usability of public spaces are limited. Shops close earlier and streets are temporarily closed so that detours have to be accepted. The effect is primarily limited to the demonstration days. But the empirical studies indicate that the nature of the demonstrations affects the city as a whole because images are transferred: Mainz as a diverse and cosmopolitan city, Kandel as a conflictual city, occupied by right-wing political groups. If "Kandel" is associated with right-wing protests, this has a negative effect on the image of the city, which can have negative consequences for both citizens and businesses. The representation in the media contributes to it in particular. Not only are the death of the girl, but also the city and its public spaces instrumentalized for political purposes. On demonstration days, public space in Kandel is a contested space: residents, tradesmen, demonstrators, counter-demonstrators, and police officers are involved.

Conclusion

David Harvey (2006) described public space as a contested space. The struggle for visibility is in the hands of those with the greatest power of expression. The more, the louder, the more conspicuous, the higher the visibility. The struggle for space does not only take place between opposing groups but also between demonstrators and police. Negotiation processes are difficult when the mood is tense. In a sense, police can be seen as a mediator between visibility and security in public space. They enable groups to assert freedom of assembly and thus create visibility and at the same time avoid insecurity for all participants. At the same time, they have a regulatory power that can restrict the freedoms of use of public spaces.

The effect of protests on public space, like the protests themselves, is context-dependent and case-by-case analyses are required. Individual perspectives of participants and their respective motivations play a role in the transported atmospheres. The example of CSD shows that an "event-driven protest" can contribute to supporting the qualities of public spaces. Heterogeneity and diversity are promoted and demanded. In accordance with the normative dimension of public spaces, however, opportunities

for participation and accessibility may not be restricted. This danger arises if experience orientation, consumption and commercialization become central motives of protest organization and participation.

Protests in public space are repeatedly confronted with the processes of negotiation. Without question there is an interplay of visibility and uncertainty: on the one hand, public space is used as a stage for representation and visibility; on the other hand, the clash of opposing groupings, ideologies, and lifestyles can lead to the emergence of uncertainties and insecurities. The creation of security, in turn, can lead to curtailments of protest possibilities and thus to restrictions of visibility. The more conflictive a demonstration, the higher the police deployment. This means that use of space is more restricted by barriers. Opposing groups are spatially separated from each other. Freedoms of space usage are restricted.

In conclusion, further research and comparisons with other parades and demonstrations are necessary to arrive at generalizable conclusions. Above all, a strengthening of (socio-) spatial perspectives in protest research would be desirable. Planning disciplines hardly play a role in the discussion about public spaces and social movements. It is precisely the aspect of space, in its physical and social function that plays an important role with regard to security and visibility.

“Tourism, public spaces and urban cultures”

Urban Regeneration and (over) tourism in China: Exploring Alternative Tracks in Suzhou’s Historic Centre

Christian Nolf¹, Yiwen Wang¹, Mengchuan Liu¹

¹ *Department of Urban Planning and Design, Xi'an Jiaotong Liverpool University*

Abstract: The booming development of cultural tourism in China has a significant impact on historic cities. While offering favorable opportunities for urban regeneration, tourism also poses a direct threat to the quality of life and the authenticity of urban cultures. This paper takes the historic center of Suzhou as an illustrative case to explore how alternative, spatially decentralized and time-distributed forms of tourism can contribute to the long-term and sustainable regeneration of historic cities and benefit local communities. Through conducting a design investigation of Suzhou, this research explores in particular the role of urban planning and design in aligning tourism development and urban regeneration agendas. The exploration reveals that, as opposed to exclusive and reductive city branding practice, a diversification of the tourism offer can multiply the distinctive identities of Suzhou’s historic city and contribute to its regeneration. It also advocates the potential role of urban design as an instrument of exploration and mediation in heritage-led regeneration projects in China.

Keywords: Cultural Tourism; Urban Regeneration; Urban Design; China.

Cultural tourism in Chinese cities and its impact: Suzhou as an exemplary case

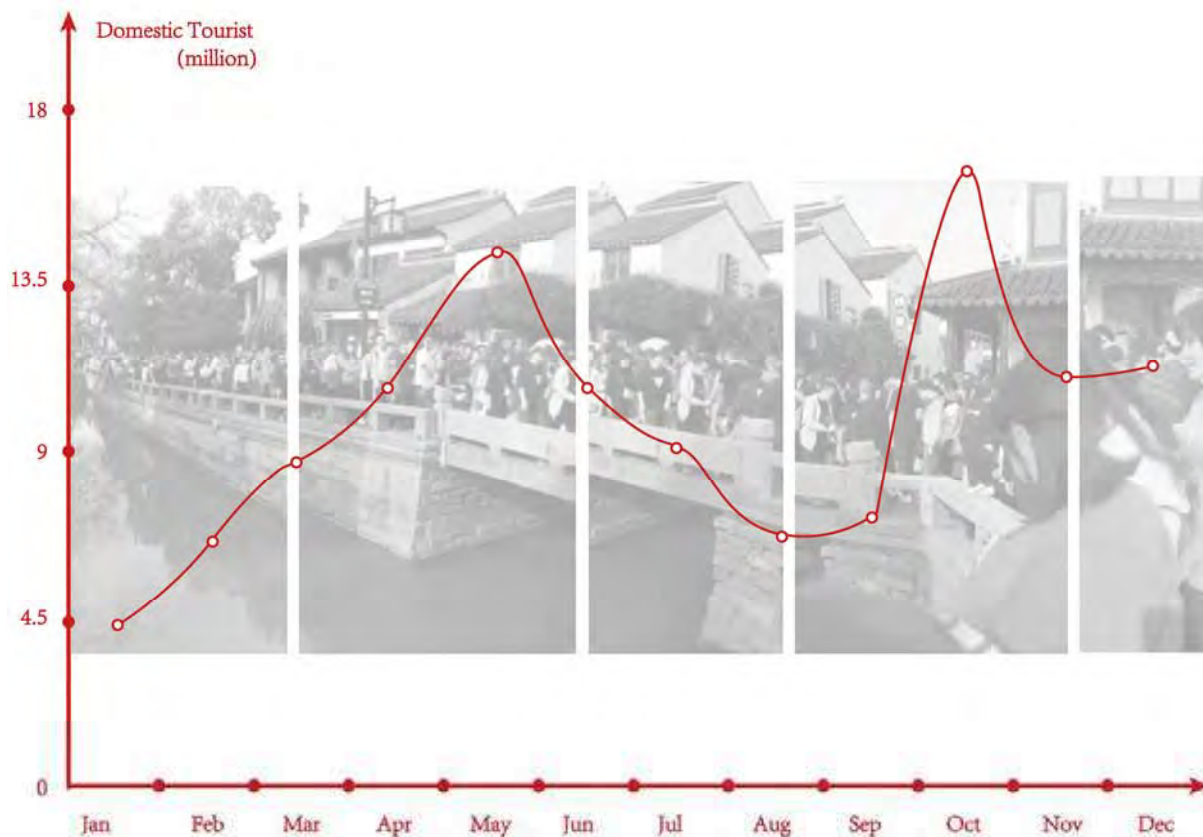

Figure 1: Accounting more than 100 million tourists every year, the influx of domestic tourists in Suzhou is mainly concentrated in two peak periods corresponding to national holidays and favorable climate conditions.

Suzhou is a megacity of 13 million people located in the heart of the Yangtze River Delta. Founded 2500 years ago, its historic center is very famous for its typical canal-streets and ancient gardens inscribed as World Heritage. Covering 15 km² and currently inhabited by 230,000 people, Suzhou old town is a main touristic destination that attracts a staggering number of visitors. Out of the more than 100 million people visiting the city area every year (STB, 2018), it is estimated that about a quarter visit the old town (Yin *et al.*, 2014). Among these, the vast majority (98%) are Chinese, coming from the local or surrounding provinces (Jiangsu, Shanghai and Zhejiang). The other 2% are foreign tourists, who still represent 1.5 million people, mainly coming from Japan, Korea and the USA.

The economic impact of tourism is equally massive. Ranked between the 10th to 20th most popular touristic destination in China according to various listings, Suzhou contributes up to 5% to the gross tourism revenue at national level, which was estimated in 2017 to 4570 billion RMB, or an 11% portion of China's total GDP.

Domestic tourism in China is in addition evolving very quickly, fueled by the emergence of the middle class and facilitated by new high-speed rail transport connections. Over the last five years (2012-2017), domestic travels in China had increased by 70%, or a 10% yearly increase. Over the same period the number of domestic tourists in Suzhou had increased by 6% every year, and generated an 11% yearly growth in revenue [Note 1].

While undeniably bringing considerable economic benefits to urban conservation and regeneration, the development of tourism in historic city centers across the world also presents serious threats. When exceeding a certain capacity, excessive growth of tourist numbers can generate negative and long-lasting impact on the livability of a place. As a global phenomenon, the adverse effects of over-tourism have been described and cautioned by the World Trade Organization (WTO, 2004). These negative effects include the abuse of natural resources and pressure on urban infrastructure and services, such as congestion and an over-proliferation of hotels, facilities or retails aiming at visitors. In addition, the promotion, marketing, branding and management of tourism can affect the diversity and authenticity of local life and culture.

In China also, the negative impact of mass-tourism on historic cities has been increasingly observed and acknowledged. In his study on Lijiang, a historic town recently listed as World Heritage, Huang (2013) describes how direct environmental nuisances such as traffic congestion and noise are accompanied by indirect and long-lasting impact on housing prices and urban services. He adds that the artificial importation of pseudo-traditional customs (such as floating river lanterns) to excite tourist interests have misrepresented the authenticity of the local culture.

Lijiang is not an isolated case. Several other researches have reported on how excessive development of tourism has affected the livability, heritage and traditional culture of local cities and forced the displacement of homegrown populations (Gang Xu, 1999; Li M. *et al.*, 2008). On the national level, it appears that most tourism strategies and management plans of Chinese cities have been applying standardized solutions for mass tourism (China Tourism, 2016). Tourism plans essentially focus on the city's major tourist attractions, with an exclusive attention to tangible elements and little consideration of the intangible aspects of the local culture (Li, 2000; Mao and Liang, 2013).

Retrospective of Chinese historic cities: from urban renewal to heritage-led regeneration

The “touristification” of Chinese historic cities is the latest stage in a succession of shifting attitudes towards ancient urban centers over the past decades. In the wake of the open-door policy of 1978, the industrial and economic development of China was accompanied with a massive wave of urbanisation. In Suzhou for instance, the built-up area was multiplied by more than 11 times between 1980 and 2010 (Wang *et al.*, 2015). In this process, most historic centers were initially neglected and suffered decay and degeneration. Overcrowded and poorly maintained, historical houses got deserted by the local middle-class population who could afford relocating in some new development areas on the urban periphery. This vicious circle aggravated the living conditions of historic city centers and worsened their attractiveness.

In reaction, from the 1980s, the question of urban renewal became a formal part of the agenda at national and local levels. Very typical in China is that local governments have played a leading role as both redevelopment advocate and project manager (Zhai, 2010). Three main successive types of urban regeneration strategies in China can be distinguished:

First, a demolition-reconstruction model, which prevailed between the 1980s and the 1990s. Also known as ‘old city renewal’ (jiucheng gaizao), this phase aimed primarily at solving urgent housing and safety issues. It replaced traditional urban fabrics with new housing types that met sanitary and fire protection standards, while sometimes ornamented with a reinterpreted expression of local historic architecture style (Yin, 2012). In this renewal process, as exemplified by the total replacement of Tianjin’s historic center, features of traditional urban fabric were forever lost.

Second, a commercial place-marketing model, which is incarnated by Xintiandi in Shanghai (1997). Based on the preservation of a few emblematic historic buildings, such projects use heritage conservation as a branding

tool to support real-estate development agendas. Economically successful in Shanghai, this regeneration model has been copied in several other places in China [Note 2]. However, these projects are also vigorously contested and accused of generating social exclusion and gentrification, while compromising the integrity and historical significance of the built heritage (Fan, 2014; Zhong and Chen 2017).

A third phase emerged in the 2000s and has focused on heritage-led regeneration – often termed ‘culture-led’ in China (Xia and Wang, 2010). According to Xie (2017), the growing influence of the notion of authenticity advocated by UNESCO explains China’s changing approaches to heritage conservation in recent years. After years of demolition and reconstruction, the new paradigm of conservation principle is now “to repair the old as to appear old” (Xiujia Rujiu). Authenticity is not only associated to preserving essential qualities of urban form, materiality or uses and functions. It also encompasses immaterial qualities such as the arts, culture, history, lifestyle and intangible assets of a city. This combination makes historic city centers a fertile ground for cultural tourism, and culture-led regeneration as a powerful strategy to achieve economic growth (Russo and Borg, 2002).

The link between urban conservation and tourism in Suzhou

Figure 2: the comparison between Suzhou’s Tourism Plans (2011) and Conservation Plan (2013) indicates a clear correlation.

The evolution of Suzhou’s historic center over the past decades reflects the three phases described above. While its historical fabric dating from the Song dynasty (9th - 13th c.) onwards had remained largely intact until the early 20th century (Xu, 2000), the center of Suzhou has since then been subject to profound transformations. A series of turbulent events (wars in the first half of the 20th c.; the Cultural Revolution in the 1960-70s) followed by sanitation and modernization programs in the 1970s-1980s led to the demolition of courtyard houses replaced by standardized walk-up apartments.

Subsequently, the local authorities issued its first protection plan in the 1980s and initiated reconstruction programs of historic elements, such as the city wall. The successive conservation plans have gradually broadened in scale and scope – from protection listed buildings and gardens to entire streets and areas, and finally controlling development by imposing restrictions on building height and style. The latest conservation

plan introduced in 2013 defines protection zones that cover almost a third of the city center's area, and includes some heritage-themed itineraries interconnecting them.

A comparison between the urban conservation and tourism plans reveals a clear correlation. Even though produced by two separate government authorities depending of different ministries [Note 3], heritage conservation and tourism development in Suzhou's historic center are closely interrelated. The review of Suzhou's official tourism channels confirm, for the historic center, a culture-led strategy essentially based on the promotion of the historic and traditional features inherited from the Ming and Qing dynasties and depicted in some famous scroll paintings.

On the link between urban conservation and tourism, the regeneration of Ping-Jiang Road district in Suzhou is often regarded as an exemplary case of integrated urban revitalization in China (Yin, 2012; Xie, 2017). Initiated in the late 1990s, the plan not only preserved and refurbished important parts of the traditional fabric, houses and public space. It also enabled to a majority of local residents to remain living in place thanks to the provision of basic infrastructures and an advantageous housing allowance program. For several years, the renovated historic area had combined successfully a coexistence of tourists and inhabitants in a relative balance.

Two decades later, however, the regeneration project became a victim of its success. Over-promoted on postcards and featured in successful television drama, Ping-Jiang Road is almost entirely bordered with souvenir shops and is the chronic theater of tourist traffic jams. Recent interviews conducted in the area indicate how local inhabitants suffer from the excessive commercialization of their neighborhood: the reduced accessibility, the closing of the vegetable market, and the recent conversion of the local temple house into a fancy teahouse / bookshop are the signs of tourism gentrification affecting their living environment (Vannoorbeeck and Attuyer, 2019).

Next to Ping-Jiang Road, a few other places designated as scenic areas tend to attract masses of tourists without positively contributing to the local life. In contrast, the rest parts of the city remain unexplored by visitors. Protected as heritage, these historic areas are subject to strict rules of conversation that limit the possibilities of radical changes, although adaptation and remodeling may be necessary to improve the living conditions.

Figure 3: contrast between overcrowded and commercialized scenic spots and decaying neighborhood.

The emergence of alternative forms of tourism

Suzhou is neither the only nor the first historic city facing the intricate challenges of tourism development, urban regeneration and livability. Lessons can be learned from numerous international cases and strategies addressing similar issues (Mason, 2015 ; Gotham 2005). One possible way to prevent the negative impact of tourism is to limit it. Perhaps inspired by Venice's installation of gates for tourists in 2018, Suzhou since very recently (23rd April 2019) imposes a reservation system on aspirant visitors to book their visit to popular attractions one to seven days in advance (The Humble Administrator Garden, Lion Garden, and the Suzhou Museum). Another possibility is to increase the pricing of attractions as a way to increase exclusivity and filter accessibility. Although they may solve problems in the short term, these approaches also precludes the possibilities of channeling popular tourism growth as a catalyst for urban regeneration.

Another type of response is to stimulate alternative forms of tourism. The notion of alternative tourism has been developed from the 1990s as a response to mass-tourism (Pearce, 1992). As a trend, it corresponds to a general diversification of tourism interests facilitated by lower transportation costs, relaxed regulations on (international) travel, and, more recently, the development of social media and online platforms of collaborative economy (Dredge and Gyimóthy, 2015). Prospective tourists can now plan their own travel individually and personalize their route by tailoring it to their needs without the intermediate of travel agencies [Note 4].

Among the several forms of alternative tourism that have emerged, some are focused on achieving a positive interaction with the local cultures and people. "Experience-based tourism" (Tzortzaki, 2018), "In-Depth tourism" (Chen *et al.*, 2009) or "Slow Tourism" models generally valorize local customs, products, traditions and travel experience as part of the destination's attractiveness (Honoré, 2004; Heitmann *et al.*, 2011; Lumsdon and McGrath, 2011) [Note 5]. Other alternative forms of tourism such as "Sustainable Tourism" (Edgell, 2016) or "Community-Based Tourism" (Blackstock, 2005) more explicitly aim at making the hosting community actively engage with and thereby benefitting from tourism development.

Interestingly, several values advocated by alternative tourism models meet the recommendations on tourism development coming from the heritage conservation and urban regeneration side. Guidelines from UN-Habitat or UNESCO's framework for Historic Urban Landscapes (HUL) also insist on enhancing indigenous and local culture, economy and products, and reiterate the pivotal role of local communities in regenerating their physical environment.

Integrating tourism and urban regeneration: defining a framework

A possible synthesis addressing both tourism development and sustainable urban regeneration is offered by a recent report of the World Tourism Organization (UNWTO, 2018). This report, based on the perception of "overtourism" (Ali, 2016) by residents in several European cities, proposes eleven integrative strategies to manage and promote dispersal of tourism flows in urban areas in order to make them inclusive, safe, resilient and sustainable:

- Strategy 1: Promote the dispersal of visitors within the city and beyond
- Strategy 2: Promote time-based dispersal of visitors
- Strategy 3: Stimulate new itineraries and attractions
- Strategy 4: Review and adapt regulation
- Strategy 5: Enhance visitors' segmentation
- Strategy 6: Ensure local communities benefit from tourism

- Strategy 7: Create city experiences for both residents and visitors
- Strategy 8: Improve city infrastructure and facilities
- Strategy 9: Communicate with and engage local stakeholders
- Strategy 10: Communicate with and engage visitors
- Strategy 11: Set monitoring and response measures

While complementary, these strategies can be divided into three main types of recommendation. A series of strategies (1, 2, 3, 5) focuses on the tourism experiences in both space and time. Another series of recommendations (6, 7, 8) centers on the involvement of the hosting community in tourism development and the benefits it can generate for urban regeneration. A third group (4, 9, 10, 11) relates to monitoring, management and regulatory aspects.

Together, these recommendations are in line with the evolution from mass tourism (destination based, pre-organized, all-inclusive packages) towards alternative and diversified modes of tourism characterized by free individual travellers in search for authentic and place-based experience and in consideration of the ethical and sustainable aspects of tourism development. Even though the mass and standardized tourism model still dominates in China, the trend for alternative tourism is likely to develop in the future, give the growing influence of social media and smart tourism (Kim and Wang, 2018). The eleven strategies can therefore serve as a valid framework to explore how the management of tourism growth can be integrated with the sustainable regeneration of historic cities in China.

Design exploration: seeking alternatives in Suzhou

Presuming that tourism in Suzhou will continue to grow, this research proposes a design investigation addressing in particular the role of urban planning and design in aligning tourism development and urban regeneration agendas. It takes the guidelines of the World Tourism Organization on Tourism Growth (UNWTO 2018) as a framework and Suzhou's historic center as an exploration field. The study area has been limited to the historic center, where the contrast between high concentration of tourism and poor living conditions is most striking.

The design exploration employs a triple strategy: 1) to multiply and diversify the number of touristic attractions; 2) to enrich the travel experience; 3) to modulate the seasonality of tourism peak flows. These three strategies on space and time are complemented by a fourth determinant – how visitors can navigate across an expanded spectrum of available activities.

For each strategy, a detailed analysis of the current condition was conducted based on a combination of documentation, fieldwork, interviews and interpretative mapping. In the Agency of Mapping, Corner (1999) describes mapping as a performative research method that allows, through graphic operations of selection, omission, isolation, codification and associations, to uncover realities previously unseen or unimagined.

Based on the mappings' findings, specific proposals for developing alternative forms of tourism are formulated. With the express purpose to promote the values of authenticity, sustainability, and equity, the proposals also draw on international precedents and theoretical conceptualizations of the city from an experiential and perceptual perspective.

Design exploration 1: multiply and diversify the number of touristic attractions

The first strategy is to multiply and diversify the number of touristic attractions. This strategy aims at decongesting the few overcrowded spots of Suzhou's historic center, but also at dispersing peak flows in space and time (strategies 1 & 2). Besides tourist attractions, a wider palette of 'places of interests' may as well contribute to a segmentation of visitors (strategy 5) and potentially enrich city experiences for both residents and visitors (strategy 6).

In the historic center, tourists currently tend to agglomerate at a few tourist sites: the World Heritage Gardens, two historic streets, and two reconstructed city gates along the city wall [Note 6]. Labelled as "top attractions" in international, national and local rankings, these attractions are the most popular on social media (Kim & Wang 2018). Over-commercialized and often overcrowded, the immediate surroundings of these sites suffer from the influx of tourists, many of which travel in groups and may not necessarily contribute to the local economy. On the other hand, the rest extensive area of the city are left blank on the current tourist map, suggesting they are featureless and uneventful even though they are potentially of comparable interest.

We argue that alternative attractions can be defined according to various selection criteria. One possible criterion is the notion of locality and authenticity. Supported by the slow-, community-based and responsible tourism models, the focus on authenticity and locality are seen as potential vectors for supporting the local economy, strengthening cultural identity, and encouraging direct interaction between visitors and guests.

In order to identify 'places of interests' in the historic centre of Suzhou, this research draws on various non-mainstream sources, such as Suzhou-based online platforms or local certification labels attesting the quality of established businesses. As a result, several maps were created, featuring traditional shops, small opera playhouses, craftsman workshops, or local residents' favorite restaurants.

Another possible set of alternative places of interests are the sites currently vacant or underused. As a 25-century old city constantly in transformation, Suzhou invariably has some temporarily neglected spaces, such as abandoned factories, construction sites awaiting permits, or shopping malls deserted by customers. Temporarily reclaimed and refurbished, these sites can play a role in absorbing the surplus of tourists during peak periods, while serving the local community with improved city infrastructure and facilities, which is the 8th strategy proposed by UNWTO.

Many other alternative points of interest can be imagined, based on selection criteria such as natural assets or viewing points. In all cases, the definition of alternative tourist sites should remain an open and dynamic process. The mapping of these alternative places of interests reveals new spatial logics, such as thematic clusters or linear patterns that urban regeneration can align with and capitalize on. As a tool for urban regeneration, the creation of new places of interests that serve alternately visitors and locals' needs can eventually inspire and help prioritizing interventions on public space.

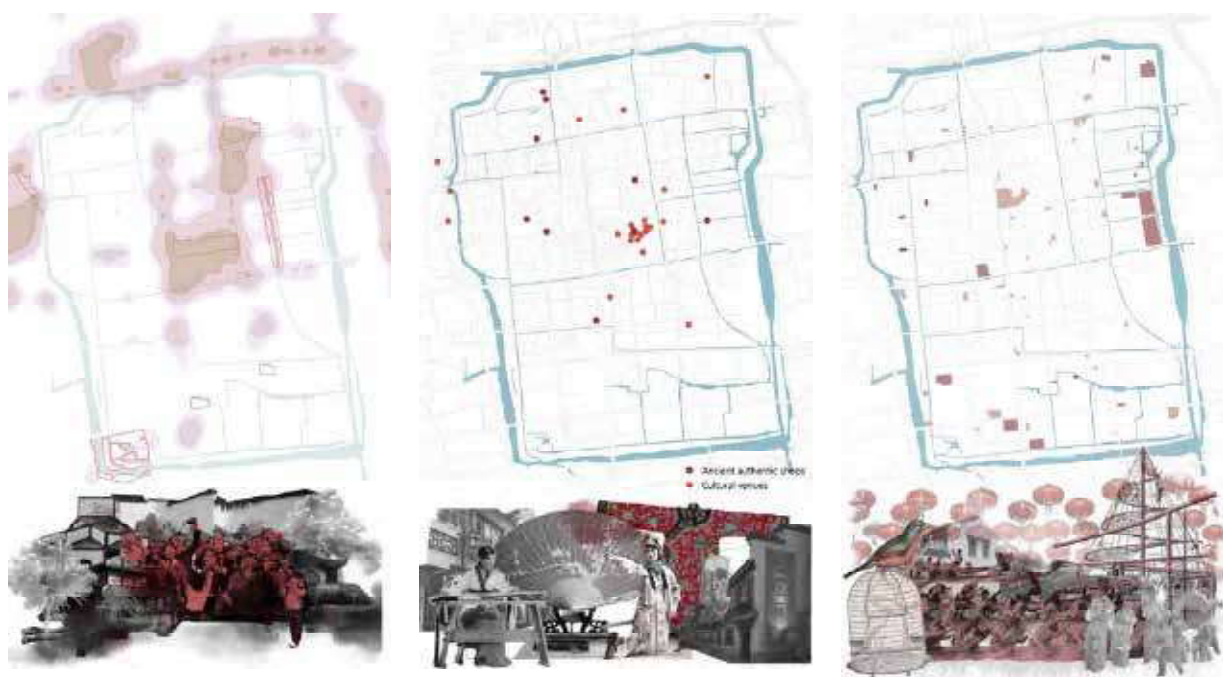

Figure 4: mapping existing and alternative attractions: a) (top) axonometric view of Suzhou with rooftops potentially offering a panoramic view on the city; (bottom, from left to right) b) mapping of the current mainstream spots (outlined with red contours) and concentration of population on a national holiday afternoon; c) typical Suzhou stores over 100 years old and traditional craft and culture places (opera, wood sculpture, embroidery, etc.); d) currently vacant or underused sites and buildings that could potentially host events.

Design exploration 2: stimulating alternative itineraries

The second strategy to address tourism growth in Suzhou is to stimulate new itineraries. Responding to UNWTO's third recommendation, this can also help disperse visitors and create city experiences for both residents and visitors (strategy 1 and 7). The notion of alternative itineraries is strongly encouraged by the models of slow tourism and experience-based tourism that emphasize on travel itself as a way to experience a place's cultural characteristics, to appreciate the everyday landscape, and to interact with its inhabitants.

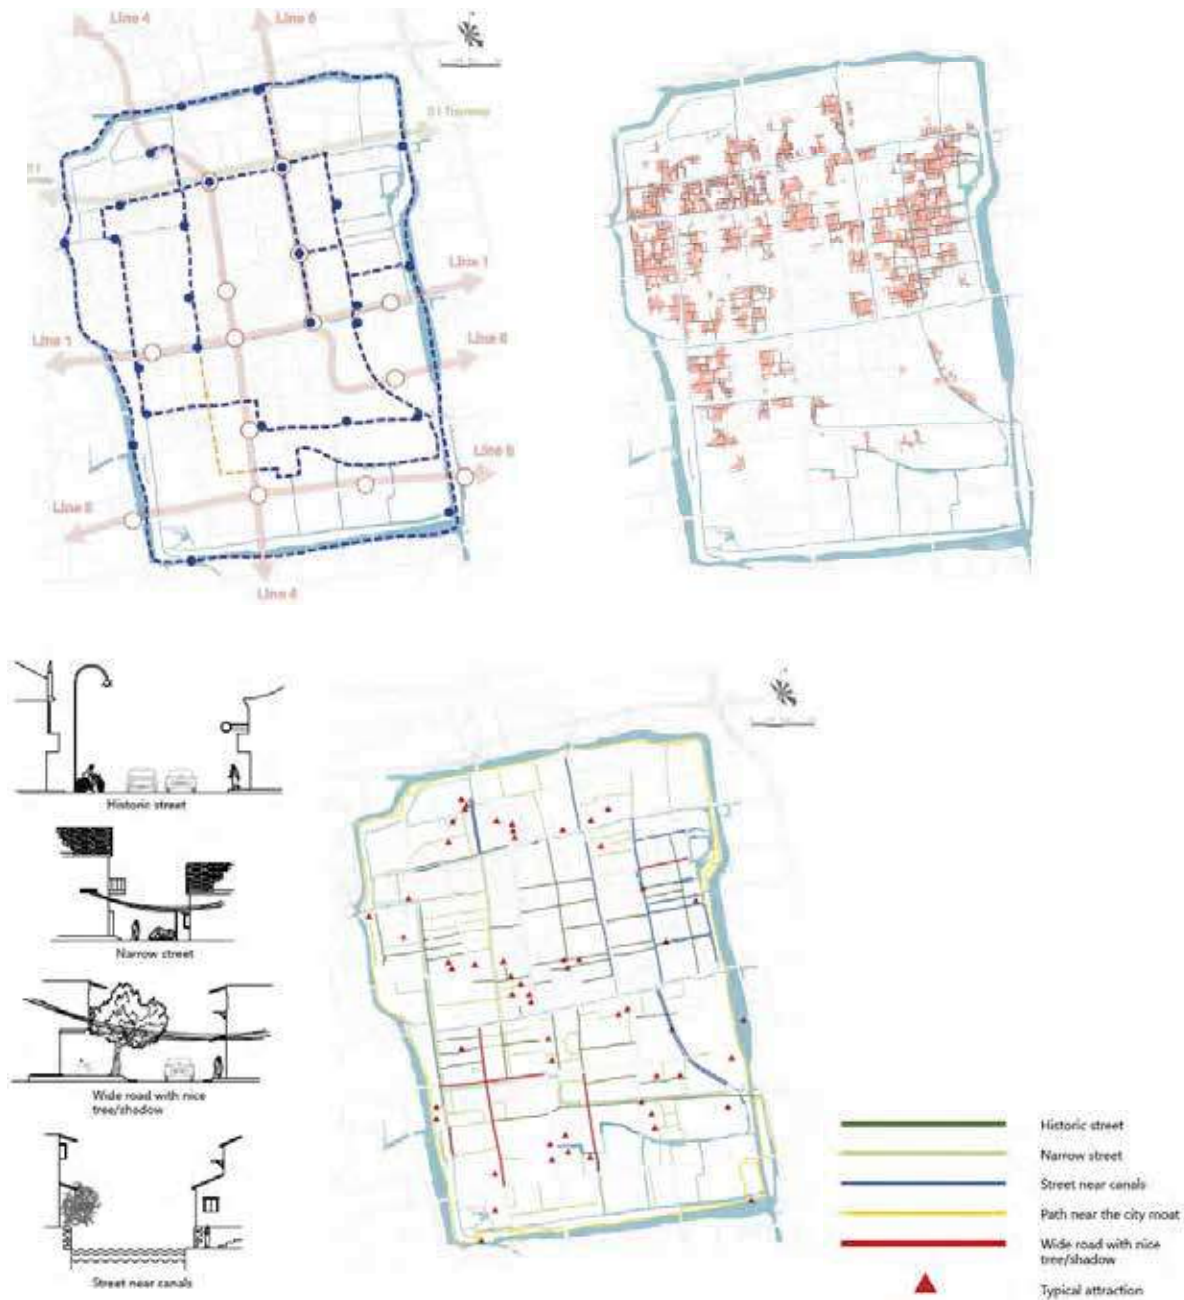

Currently, flows of tourists in Suzhou are mainly concentrated in a few historic streets and the immediate surroundings of main attractions. As visitors mainly go around by metro or private tour bus, the distance from one main attraction to another is far and not easily reached on foot nor facilitated by the bike infrastructure system. Very recently, the city begins to run a tour bus system and has been adding new lines connecting the different tourist sites. However, passing through the main arterial roads only, these itineraries offer merely a very partial view to the richness of Suzhou's urban fabric.

As an alternative, this research compiles an inventory of 'streets of interests' based on their potential for travel experience. Among the various evaluation criteria, the physical features of a street are essential in determining the comfort and perceptual value of an excursion. In this regard, Suzhou is characterized by a few avenues planted with trees, and a series of canal-streets [Note 7]. This mapping also reveals partially disconnected patterns that can potentially be reconnected through urban design approaches.

Another important criterion in the selection of an itinerary is the scenic experience it provides. Theorized in Cullen's *Townscape* (1961) or Peter Bosselmann's *Images in Motion* (1998), the quality of an urban walking experience is highly dependent on the scale, spatial diversity and articulation of the different atmospheres it crosses. In this regard, the dense network of narrow alleys sneaking across Suzhou's urban blocks from the Ming and Qing period offers a very rich experience: opening sporadic views on interiors, punctuated by small bridges over canals and shaded by trees hanging over courtyards, the mesh of tortuous pathways is full of surprises that contrast with the regular and predictable rhythm of the main street pattern.

The third possible thematic categorization of the streets is related to Suzhou's local history and toponymy. In her study of the city's morphology, Xie (2017) recalls that numerous streets and bridges of Suzhou were named after famous families or people. As such, the street pattern of Suzhou not only conveys historical and social meaning but also can be seen as a 'story-scape' for the curious visitor to explore (Kaufman 2009).

Here again, the set of criteria to choose alternative itineraries is endless and can be tailored to individual preferences. From an urban regeneration point of view, however, this investigation offers the possibility to reflect on how the designation of alternative thematic itineraries for tourists can be coordinated with investments that meet the residents' needs. The pedestrianisation of streets around schools could for instance perfectly meet the tourism mobility agenda.

Design exploration 3: Diversifying tourism offerings throughout the year

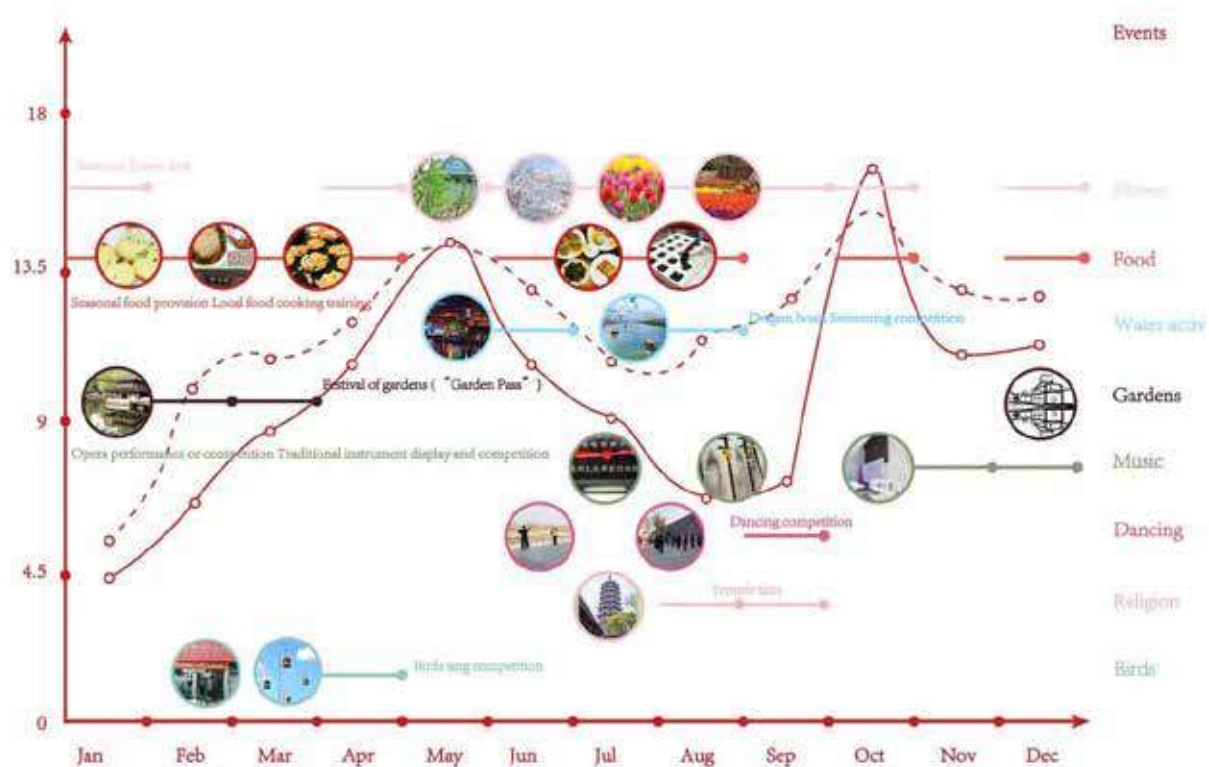

Figure 6: Chronological mapping of existing and proposed seasonal events that may contribute to a more balanced modulation of tourist influxes during the year.

The third strategy is to diversify tourism offerings into day vs. night, and weekday vs. weekend activities, featured by seasonal changes and punctuated by annual festive events. This responds to UNWTO's second recommendation to promote a time-based dispersal of visitors. Time dimension can be addressed at different scales. On a weekly and daily timeframe, tourism is logically concentrated in the week-ends and the daytime, with relatively limited activities after 8pm. On a yearly scale, the frequentation of tourists in Suzhou is relatively unbalanced, with two peak periods in May and October. This is principally explained by seasonal factors and national holidays, with no other particular linkage to Suzhou events. In contrast, the lower season is mainly in the cold winter and hot summer time, when the climatic conditions are not optimal to enjoy the mainly outdoor attractions of Suzhou.

To redistribute the influx of tourists on a yearly timeframe, several possibilities are offered. Starting from the annual calendar of flower blossoms, harvests, crops, rituals, pilgrimages, and symbolic dates, a series of alternative events can be imagined that are rooted in Suzhou's cultures, traditional houses and/or meaningful places. During the high season, decentralizing activities by using vacant sites scattered throughout the city can invite tourists to get off the beaten paths. Cordoba's Patios Festival in Spain (Cordoba, 2019) provides a good reference for Suzhou to hold a similar event prompting inhabitants to renovate their house courtyard and open it to visitors. Such initiatives, coordinated and supported by the city authorities, can contribute to develop locals' sense of pride and simultaneously foster a community-based and bottom-up dynamic of urban regeneration.

In the lower season, new events could celebrate some of the typical Suzhou customs and intangible heritage through festivals, seasonal markets or biennales. In the cold winter period, birds singing competition or gastronomic events could for instance reuse former industrial buildings, while during the hot summer times canal walks and boat rowing can help reinventing the historic link between the city and its canals.

Suzhou Drift as navigator

The systematic mapping of alternative places of interest, itineraries and events described above enriches the attractiveness of Suzhou with a wide variety of spatial and temporal opportunities. The fourth part of the design exploration of this research explores how tourists can be guided across the augmented city. Assuming that the trend towards individualized and experience-based types of travel will continue to grow, and taking advantage of new instruments associating GPS to social media, this opens up a possibility to develop an interactive navigation tool.

We develop and frame the concept of “Suzhou Drift” to support intuitive, individual and experience-based types of travel. The notion of Drift draws from the *Dérive* – proposed by the Situationist International in the 1950s-1960s – as “a mode of experimental behavior to create new situations, (...) a technique of rapid passage through varied ambiances guided by intuition” (Debord, 1958).

As a navigation instrument supplemented by the additional parameters of alternative attractions and itineraries elaborated in the previous sections, “Suzhou Drift” can customize routes according to personal interests and seasonal conditions. The simulation of Suzhou Drifts can cater for the need of different types of users/travellers and recommend several possible routes to explore the city. These possible itineraries can also be imagined in sequential perspective drawings as if on a Suzhou scroll, illustrating the variety of assets that the city can offer to adventurous visitors.

Complementary to the application-based information, some light physical design interventions in the public space such as signage, street furniture or temporary public art installations can make the city more legible, walkable and enjoyable while functioning as open invitations to some of the itineraries and alternative attractions.

Figure 7: A simulation of ‘drifts’ during one day in Suzhou by three typical users profiles (a young backpacker; a family with children; a senior couple) illustrate the variety of assets that the city can offer.

Conclusion

This research has explored the implementation of a triple strategy for tourism development in Suzhou and elaborated on their possible implications in practice. Based on findings from this design exploration, three recommendations are proposed to inform the practice of tourism planning and urban regeneration in China and achieve a better integration of the both.

Firstly, the diversification of tourism is an opportunity to reveal the complexity and multiple identities of a city. The inquiry for alternative attractions and itineraries in Suzhou reveals several features that have been so far neglected. Beyond the postcard image of gardens and canals advertised in official tourism branding, Suzhou's historic center has an enormous wealth of tangible and intangible assets inherited from its long history. Tatters of the traditional urban tissue are finely intertwining within the regular blocks and punctuated by a scatter of former industrial buildings and sites. With their own scale and characteristics, these contrasted urban atmospheres coexist as different cities in the city. While the existing culture-led regeneration practice in China has tended to brand one exclusive 'legitimate' identity and orient design guidelines accordingly, we argue that the recognition of multiple urban identities – be they spatial, cultural or social – is important. Not only for the diversification and segmentation of tourism, but also to accommodate the plural needs of the local communities.

Furthermore, the potential of alternative tourism as a strategic and transformative agent of urban regeneration should be recognized and exploited. Because of its dynamic and cyclic nature, tourism has changing and renewed needs that are a priori not always compatible with the incremental and linear process of urban regeneration. Nevertheless, the design exploration of Suzhou exemplifies how the creation of events and temporal re-programming of parts of the city can serve as a transformative agent, as a testing tool to inspire, trigger or help prioritize more permanent planning choices for the regeneration of historic cities.

Finally, the methodological value of urban design as an exploratory instrument could be further expanded and enhanced. As a discipline, urban design in China has until now been confined to an executor role of masterplans and regulatory design codes. Arguably, urban design offers a large palette of tools that help grasp the complexity of the historic city and to envisage its future. The practice of urban design can associate quantitative information with a qualitative reading of the specific typological, morphological, and usages characteristics of the city. It can also develop interpretative, temporal and narrative descriptions of the city that can in turn inspire potential projects. In regeneration processes, intense cooperation and exchanges are needed between communities, tourism, spatial planning and business stakeholders. In this context, exploratory urban design can be instrumental to create a middle ground and support the development of shared visions.

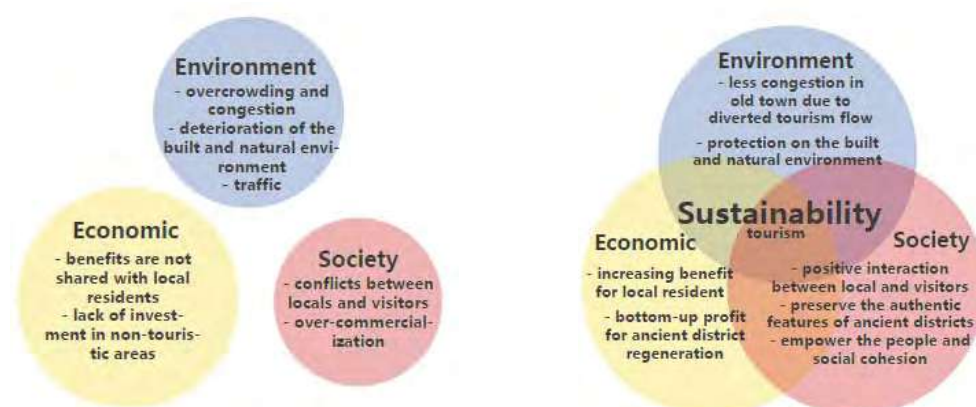

Figure 8: Comparison between the issues generated by a mass-tourism, and an ideal scenario of alternative tourism positively integrated with sustainable urban regeneration.

Limitations and suggestions for further research

Although potentially instrumental in China, the exploratory approach by design is nevertheless not sufficient to ensure a balance between tourism and sustainable regeneration. A key challenge remains how communities can positively take advantage of tourism development. In an ideal scenario or virtuous circle, alternative and decentralized tourism can lead to improved physical environments, empowered hosting community and greater social cohesion. In reality, however, numerous cases of touristic cities affected by an excessive Uberisation of hospitality services show that alternative and decentralized tourism models, when not regulated, can lead to serious risks of gentrification (Arias-Sans, 2015; Gant, 2015).

From interviews conducted with officials of the Suzhou Municipal Administration of Tourism (SMAT), it appears that the current tourism development model, while encouraging decentralized and alternative tourism, relies essentially on the dynamics of the market. For further research, it is recommended to investigate how governments can assume a coordinating role to ensure a collectivization of the profits generated, and reinvestment in distribution in the form of refurbishment or training programs.

Finally, considering that the local population of the historic center of Suzhou is characterized by an overrepresentation of seniors and migrant workers, it is also recommended for further research to explore how participatory and coproduction mechanisms can be encouraged and implemented.

Abstract: In many regions, an unbalanced dichotomic development based on core and peripheral areas has increased territorial inequalities affecting places, communities and economies. The peripheralisation processes are causing several disadvantages, in terms of socio-economic negative trends, abandonment of cultural heritage and increasing of environmental risks. The CNR IRISS research aims at investigating approaches to contrast marginalisation trends and support balanced development processes. Starting from a first screening of scientific literature, different fields of study have emerged, ranging from regional sciences to geography and urban studies, from economics to social studies, and different terms have come out such as internal areas, inland areas, and inner peripheries. The aim of this research phase is to implement a systematic literature review to explore the multiplicity of terms related to unbalanced development and peripheralisation processes, to investigate possible connections with different scientific disciplines and/or geo-political contexts also by analysing the evolution of the debate over time. This work presents a testing phase aimed at verifying the adequacy of the selected methodology and selected items and at sharing them with the scientific community in order to consolidate and enrich the methodological framework, and to organise the follow-up activities.

Keywords: territorial inequalities, peripherality, systematic literature review, data collection

Introduction

Reducing territorial inequalities is a key challenge for achieving sustainable development strategies, as highlighted by international scientific debate and political agenda. In many contexts, socio-economic and political dynamics have excluded some territories from mainstream activities, increasing gaps within regions between core areas and peripheral areas. The dichotomy between leading and declining areas results in negative trends for the second ones, in terms of abandonment and depopulation, lack of jobs and opportunities, reduction of essential services, accessibility issues. These processes produce negative impacts on well-being and quality of life of the local communities and contribute to the increasing vulnerability of the historic heritage and the environmental resources.

The ongoing research project “Innovative Strategies for Regenerating Small Villages and Inner Areas” deals with this debate by focusing on place-based regeneration strategies in territories that suffer marginalisation processes, with a specific in-depth focus on Italian context in which the inner areas amount to about 60% of the national territory. In these contexts, landscape represents a relevant asset as demonstrated by the high presence of excellent sites such as Protected Areas, National Parks and Sites of Community Importance. Starting from

this evidence, the research focuses on landscape to verify its role as driver for activating regeneration processes in inner areas, through a co-design approach aimed at improving synergic planning between top-down policies and bottom-up initiatives (Oppido *et al.*, 2019; Oppido *et al.*, 2018). The research activities are carrying out both by developing a first empirical case study of the Italian context through an Action Research protocol and by deepening an international theoretical framework. The key goal is to explore how to implement approaches for contrasting marginalisation trends and supporting balanced development processes, within the framework of the Italian National Strategy for Inner Areas (Barca *et al.*, 2014) that promotes a place-based approach for regenerating these contexts. The Italian inner areas have been identified through a methodological study based on the distance (in minutes) from the centres offering basic services and they are characterised by demographic decline, ageing population, low economic performance but also by a relevant territorial capital – human, cultural and natural capital – often untapped. The Strategy is implemented within a multilevel framework, involving national, regional and local tiers, considering local communities key actors for the goals, and it is part of the Cohesion Policy, according to the European expectations aimed at supporting all regions in enhancing their economic and social potentialities (Barca 2009; Commission of the European Communities 2008; OECD 2016). These policies recognise the unbalances between central and marginalized areas as a key issue in Italy and Europe in terms of social inequalities as well as of risks of losing the inestimable cultural and environmental value of the resources present in human settlements that over time have lost the critical mass capable of attracting and retaining population and productive activities. This known problem, which has been dealt with in literature and in local, national and transnational policies, requires a deepening of the ontological framework and of the interpretative aspects, in order to have a solid working basis, even in the linguistic and geo-political differences.

Building the theoretical framework of the research, literature review has highlighted the presence of multiple terms in scientific and political debate such as marginal areas, peripheral areas, inner areas, inner peripheries, inland areas – all terms referred to unbalanced development dynamics and peripheralisation processes (Kinossian, 2017; Küpper *et al.*, 2017; Lang *et al.*, 2015; Wirth *et al.*, 2016).

With reference to this terminological multiplicity, the aim of this research phase is not to establish a state of the art about a specific term but to implement a systematic literature review to explore the selected terms related to possible connections with different scientific disciplines and/or geo-political contexts also by analysing the evolution of the debate over time.

The first focus developed by the researchers was about the concept of “peripherality”, of which the core discussion concerns levels of accessibility (ESPON, 2009; Schürmann & Talaat, 2000; Spiekermann & Wegener, 2006; Vickerman *et al.*, 1999). This spatial meaning has been progressively linked to socio-economic performances, connected with distance from the main centers of activity (Kühn 2015). This change determines that places not geographically remote could be peripheral in terms of relationships with economic networks, highlighting the role of lack of connectedness and weakness of interaction (Copus *et al.*, 2017). From a first screening of scientific literature and policy documents, the conditions of marginalisation are linked to the exclusion from physical, social, economic, institutional and cultural network (ESPON 2017).

This relationship with socio-economic dynamics, rather than geographical characteristics, makes these processes changeable and transitory. However, it is useful to point out that overemphasizing the analogy between peripherality and socio-economic performance leads to confuse these territories with lagging areas (Copus & Noguera, 2016). «[...] the concept of inner peripheries which is emerging is not simply a Central European analogue of the kind of “economic potential” peripherality observed in Northern and Western Europe, but rather one which has more in common with the discourses on social exclusion and well-being» (Copus & Noguera, 2016). The discussion progressively focused on the complexity of variables to be considered, not simply related to location: «Geographical remoteness, as such, therefore does not cause marginalisation, nor does central location promise prosperity» (Bock, 2016, p. 5). From this perspective, «[...] the peripheries are

considered the outcome of complex processes of change in the economy, demography, political decision-making and socio-economic norms and values» (Naumann & Fischer-Tahir, 2013, p. 9), by highlighting the role of inadequacy of infrastructure, health facilities and educational services in terms of quality of life. These conditions trigger negative trends such as ageing, out-migration, reducing human capital and therefore the capability to generate local development, with the risk of progressive territorial de-generation processes (Sassen 2014).

Terminological differences also derive from different geographical areas. «However an additional source of terminological confusion arises between the Anglophone research tradition, which is used to the idea that the “periphery” is indeed around the (Northern and Western) edges of the country, and that of the Mediterranean and Iberian countries, where major cities are located on the coast, and peripherality is associated with “the interior”, or “inner areas”» (Copus & Noguera, 2016).

This brief overview shows the richness of the debate and the multiplicity of the implications related to the spatial and non-spatial features. The complexity of the topic is also highlighted by its multidisciplinary, including several disciplines involved such as regional and urban planning, economics, social studies, environmental studies, transportation. The screening of literature and political documents has allowed identify the recurring terms, obtained by combining the adjectives inland/inner/interior/internal/marginal/non-core/peripheral with the substantives area/context/territory/landscape and their plural.

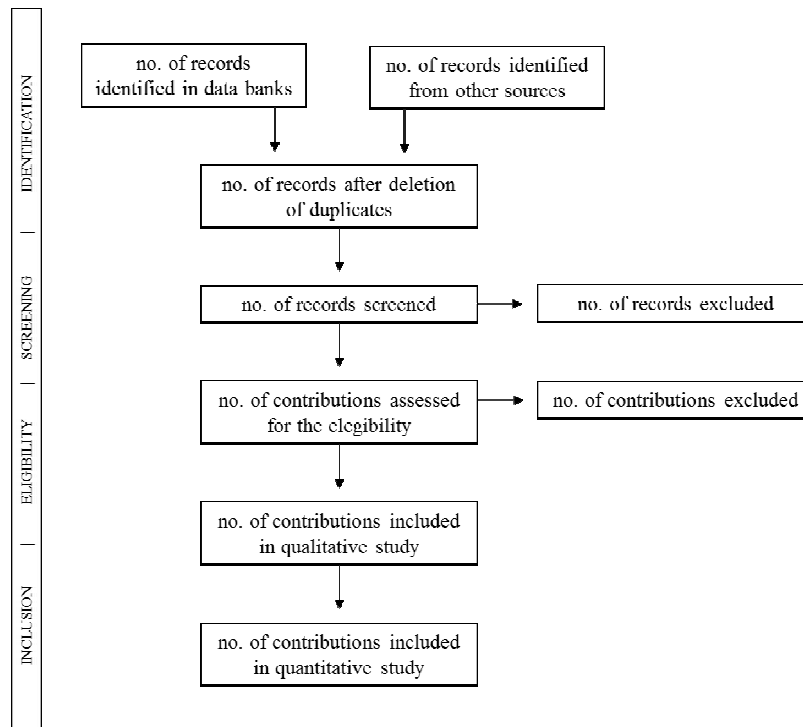

Following this introduction, the paper describes the adopted methodology for a systematic literature review, illustrates the data collection, analyses the first findings in order to discuss with scientific community about the current testing phase and to program the research follow-up.

Methodology

The systematic literature review is a method used to identify the state of the art in relation to specific research topics. Most used in clinical research, it represents a way to develop studies characterised by integrity and transparency. In the case of this work, this method has been used to: explore and deepen the multiplicity of terms within different scientific disciplines and geo-political contexts, reflect about the topic through studies and research developed over time, and propose original research initiatives to contribute knowledge in this research and operative scope (Perroni et al., 2015). Specifically, this work describes a testing phase of the methodology to be shared with the scientific community in order to consolidate and enrich the methodological framework, and to refine investigated terms.

A codified systematic review consists of «[...] a clearly formulated question that uses systematic and explicit methods to identify, select, and critically appraise relevant research, and to collect and analyse data from the studies that are included in the review. Statistical methods (meta-analysis) may or may not be used to analyse and summarise the results of the included studies» (Glossary of Cochrane Community 2019). The flow chart in Figure 1 describes the adopted systematic review approach coherently with the PRISMA Statement (Moher et al., 2015), which includes 4 phases: identification, screening, eligibility, and inclusion.

Figure 1 – Flow chart for a systematic review (Moher et al., 2015)

Data collection

Researchers structured the data collection process in order to explore the multiplicity of the selected terms within different scientific disciplines and/or geo-political contexts, and to propose an original perspective in the field of place-based regeneration.

As already anticipated in the introduction, authors' previous studies highlighted a preliminary set of terms on which apply a first testing round of a systematic literature review. In order to have the highest level of alternatives starting from these emerged items, researchers have combined all adjectives (inland, inner, interior, internal, marginal*, non-core, peripher*) with multiple substantives (area*, context*, territor*, and landscape*) (Table 1).

Table 1 – Matrix of adjectives and substantives creating terms for the testing phase

	inland	inner	interior	internal	marginal	non-core	peripher*
area*	inland area*	inner area*	interior area*	internal area*	marginal area*	non-core area*	peripher* area*
context*	inland context*	inner context*	interior context*	internal context*	marginal context*	non-core context*	peripher* context*
territor*	inland territor*	inner territor*	interior territor*	internal territor*	marginal territor*	non-core territor*	peripher* territor*
landscape*	inland landscape*	inner landscape*	interior landscape*	internal landscape*	marginal landscape*	non-core landscape*	peripher* landscape*

Working on a systematic review means to search multiple databases doing a laborious and time-consuming activity with a successful outcome. Taking into account the research of Bramer et al. (2017) about the optimal combination of databases needed to conduct efficient searches in systematic literature reviews, authors should have selected at least Web of Science and Google Scholar to guarantee adequate and efficient coverage of the research topic. The Web of Science platform offers to scientists a tool to develop, modify and save structured advanced research – called as query – through field tags, Boolean operators, parentheses. A plus value of this platform is the opportunity to frame the query within the Web of Science Categories, permitting to filter subject categories of every journal and book covered by Web of Science Core Collection. This is an important point to make specific query, avoiding a massive collection of suitable contributions. The Google Scholar's advanced research does not enable to refine results because it is not possible to isolate subject categories but only to search for author or journal/book. Representing this work a phase of testing, authors have used only the Web of Science putting off the manual research on Google Scholar for a more consolidated phase of the research.

Researchers structured the Web of Science search considering:

- only works in English language to guarantee an international profile of the research;
- the maximum timespan (1965-2018) covered by Web of Science to include the policy evolution;
- scientific articles, books, book chapters and conference proceedings;
- all databases from the Web of Science Core Collection (Citation Indexes).

Researchers started the advanced search organising specific queries for all the eight subject categories selected: Agricultural Economics & Policy, Regional & Urban Planning, Social Issues, Cultural Studies, Demography, Urban Studies, Development Studies, and Economics. After, they proceeded to draw up queries for each column of the matrix (Table 1), for example:

ts=(("inland area*") OR ("inland context*") OR ("inland territor*") OR ("inland landscape*"))

and organised a separate history for each ones in which it is combined with every subject category (Figure 2).

Figure 2 – The saved history for INLAND query

Authors used the software Mendeley to archive contributions. The programme is directly linked to Web of Science so the migration of the data was easy and automatically excludes duplications. This operation permitted to move from a package of supposed 716 units to 461 ones. All the data related to these latter were transferred to an Excel grid structured as follow and in which elements were input in chronological order with an assigned ID (Table 3).

In order to complete a testing phase, the first 100 lines with a published abstract have been evaluated for the eligibility and then included in a quantitative synthesis.

Findings of the testing phase

Authors developed preliminary quantitative findings of the testing phase in which the first 100 units with an edited abstract were assessed for the eligibility (from #027-1990 to #137-2008). This sample showed 80% of eligible units and 20% to be deleted from the database mainly because, nevertheless the subject category and query was respondent, contents were not relevant for this research (Figure 3). For this reason, the discussion proposed below was developed on 80 units developed from 1990 to 2008.

Figure 3 – Percentage of eligible contributions

First general findings were developed on the four specific categories: discipline scope, geographical scope, typology of the contribution and typology of collected items (Figure 4-7).

As expected, the main discipline scopes were Urban and Regional Studies and Economics, followed by Social Studies and Multidisciplinary Studies. Any units were collected in Geography, Transportation, and Environment discipline scopes (Figure 4). In the timespan tested, the scientific debate was concentrated in European countries and in Asia (mainly in China), followed by Africa, North America and Australia with similar concentration of

units (Figure 5). This debate was developed mainly through a case study approach while there was a lesser percentage of theoretical approach testifying the lack of defined framework of research topic (Figure 6). With regard to the collected items, four of them emerged as the most collected: peripher* area*, marginal* area*, inland area* and inner area*. During the timespan 1990-2008, the item peripher* was cited in almost the half part of the units (Figure 7). In this set, the items recalling the concept of the urban periphery were excluded – coherently with the research aims.

Figure 4 – Frequency of discipline scope

Figure 5 – Frequency of geographical scope

Figure 6 – Frequency of contribution typology

Figure 7 – Frequency of collected items

Starting from these first findings, authors considered to dedicate a specific quantitative synthesis of the four most collected items: peripher* area*, marginal* area*, inland area* and inner area*. In terms of item frequency during time, authors selected three five-year timespans: 1991-1995, 1996-2000, 2001-2005. Constantly, peripher* area* and marginal* area* exceed the others with a prevalence of the first one. Related to these two items, the scientific production is concentrated during the timespan 1996-2000 (Figure 8). In the next phases of the research, it will be clarifying to explore this quantitative result through a qualitative analysis.

Figure 8 – Frequency over time of the four most important items

To have an idea about frequency of the four categories until now collected, a brief quantitative synthesis is presented in Table 4.

Table 4 – A quantitative synthesis of the most collected four items

Item	Timespan	Typology of product	Discipline scope	Geographical scope
inland area*	1993-2005	case study	Economics	Asia
inner area*	1995-2007	case study	Urban and Regional Studies	Europe
marginal* area*	1990-2007	case study	Economics and Urban and Regional Studies	Europe
peripher* area*	1992-2008	case study and theoretical approach	Urban and Regional Studies	Europe

Discussion and Follow-up

The aim of the research is to explore multiple items emerged from the literature review, referred to unbalanced development dynamics and peripheralisation processes. This paper deals with a testing phase of a systematic literature review in order to verify the adequacy of the selected methodology and selected items with regard to the research goal. With this purpose, authors presented the methodology, the data collection and the testing phase to start discussion and to organise follow-up activities.

First evidence from the testing phase allows to highlight presence and frequency of selected items in discipline scope, geographical scope, contribution typology. With regard to the four most important items, frequency over time has been pointed out and the quantitative synthesis shows that the European countries is the main context involved in the debate and the discussion regards mainly case studies. By exploring the next timespan (2009-2018), it will be interesting to verify if theoretical approaches is codified, e.g. after the ESPON program started to affect the issue of inner peripheries.

In addition, the testing phase has pointed out that the Italian context has affected the first selection of items by the researchers. Analysis of some contributes, collected through the systematic literature review, shows the

presence of additional terms referring to specific phenomena in other continents, such as inner city in the Asian context. This gap will be filled in the next phase.

With reference to the follow-up phase, the research agenda includes the following activities:

- Sharing this work with the scientific community, first during the Aesop Annual Congress 2019 in Venice and then through research social networks (Academia, ResearchGate), in order to consolidate and enrich theoretical and methodological framework, and items investigated. Later, this work will be implemented through consultation of scholars and politicians.
- Exploring other studies about systematic literature review that can guide the methodological phases.
- Hypothesising to amplify the set of substantives, now referred mainly to the physical environment (area, context, landscape, and territory), with more social items, e.g. including community.
- Consolidating the set of items and phases of the methodology and re-apply the methodology also including the manual Google Scholar's advanced research for all the timespan 1965-2018.

Acknowledgements

The research activity is developed within the research project “Innovative Strategies for Regenerating Small Villages and Inner Areas” coordinated by Stefania Oppido at CNR IRISS.

Abstract: The relationship between the built environment and people's health has been a frequent scientific subject. The ageing populations of many developed countries has further increased the interest in this relationship. At the core of these studies is the assumption that, as people age, they become more sensitive to the physical space they live in, which can form barriers or, on the contrary, contribute to active life styles. But the role the institutions for older adults can assume in this context, and how their location and surrounding built environment can affect their users' mobility, has often been ignored by this discussion. This paper focusses on this relation, by analysing 17 care facilities in Portugal. For this analysis, interviews were conducted with 36 professionals and 137 users, and *in locu* assessments of their location was made. Through this methodology, it was found that the proximity to primary services is fundamental for an active lifestyle in institutionalized older adults and their integration in the neighbourhood. Particular attention should thus be paid to the broader location of these facilities in the urban context, and not only to the assessment of the surrounding environment's walkability levels.

Keywords: Ageing; built environment; care facilities, proximity, active lifestyles

Introduction

The impact of the built environment on people's health has been acknowledged since the XIX century. In particular in Europe and the USA, the urbanization processes of the industrial revolution was accompanied by epidemics of infectious diseases (Hall 1980), leading to the integration of public health issues in spatial planning regulations which allowed for more ample and green spaces, better ventilation and insulation or the separation of urban functions. The joint consideration of spatial planning and public health continued to be relevant in the following decades, but tended to weaken after the Second World War, with a decrease in infectious diseases and a "shift of power and resources to therapeutic hospital-based health services" in the medical field (Kidd, 2007, p.170). More recently, the relation between these two areas gained a renewed impetus, as broader health definitions became accepted and as the impacts of housing types and locations on the physical, mental and social well-being became evident (Kidd, 2007).

The aging population of many developed countries has also increased the interest in the relation between the built environment and the public health of older people. At the core of this interest is the assumption that, as people age, they become more sensitive to the physical space they live in, which can form barriers or, on the contrary, contribute to healthier and more active life-styles. Within the discussion concerning the relationship between the built environment and aging, mobility and accessibility are fundamental. In fact, more than designing dwellings according to older adults' needs, the idea that all the surrounding built environment must be planned according to their needs has been put forward (Burton and Mitchell, 2006). Prompted by the idea of aging in place, which aims to keep older adults in their original residences even when there are significant changes in their living conditions (Martins *et al*, 2012), initiatives such as elderly-friendly communities, age-friendly cities, livable communities or streets for life emerged.

By assuming that older people should stay in their communities as long as possible, these initiatives tend, however, to neglect the broader role elderly care facilities can assume in a society. Over the past decades, several studies stressed the impact of institutionalization in older adults, pointing to the depersonalizing effects of such environments. In the 1970's, Kahana (1973) noted that the accounts of the living conditions in institutions for older adults tended to invoke images of 'Dante's Inferno'. This perspective is still recurrent. Despite this, institutional settings are a valid (and sometimes the only) solution for a substantial number of seniors. And not just for those who are increasingly becoming dependent, live alone or lack family support – although these tend to be the main users (Freitas and Scheicher, 2010). Understanding the effects of environmental settings on older adults is therefore of utmost importance to assure them a better quality of life.

Studies concerning the location of these institutions are, nonetheless, scarce, leaving many unanswered questions. The goal of this article is to analyze the location and the neighborhood environment of senior institutionalized settings and the way in which they influence the behavior of their users.

Material and methods

Seventeen non-profit day-care centers and senior care homes were analyzed in the district of Aveiro (table 1), between 2015 and 2017, twelve of which located in predominantly urban areas and five in non-urban areas, according to the classification of the National Statistical Institute. For this analysis, a mixed methodology was adopted that included *in loco* observations and semi-structured interviews with professionals and users.

DC: Day-Care Centre SC: Senior Care Homes

For the interviews, a set of topics which are relevant to understand the users' experiences and perceptions, such as the most relevant services and activities or constraints and motivations. Were developed. In each institution the interviews were applied to two or three professionals and an average of eight users, totaling 36 professionals and 137 users. The majority of the interviewed older adults were female (67,2%) and the criteria for being included in the study were: a) to be a user of the institution; b) to be able to speak coherently; c) to be able to move without the assistance of others; d) to be willing to participate in the study. The ethical recommendations of the Helsinki Declarations for research involving human subjects were followed.

A preliminary visit to each institution's neighborhood environment was conducted in order to map other facilities and services, as well as to detect potential barriers in terms of accessibility within a given distance. This process involved: i) the analysis of services/functions within a given radius of the facilities; ii) the analysis of the features of the surrounding built environment.

Regarding the first (i), several authors have pointed out the impact that the availability of services in the proximity to older adults' facilities can have on their mobility (see, inter alia, Day, 2008; Burton and Mitchell, 2006). This analysis draws on the concept of catchment area (or ped-shed), meaning the maximum distance a user is willing to make to access a given service (Newman and Kenworthy, 2006). This means that all persons within the catchment area have a reasonable access to those services or facilities, measured in distance (metres) or time travel (minutes). In this study, the services and amenities within a 400 m and 800 m radius from the facilities were identified.

Regarding the influence of the build environment on the number of trips made by older adults (ii), it is important to consider the global quality of the neighborhood environment and the barriers that might exist in potential routes. Following Santinha, Costa and Diogo (2018) it was possible to distinguish five factors that influence seniors' willingness to walk:

1. *Connectivity*, which assesses the presence of a continuous network of routes, without barriers, and which guarantee a good connection between the main poles of attraction and to public transportation;
2. *Convenience*, which means a network that is as direct as possible, combining pedestrian routes, sidewalks, crossings, mixed traffic streets and pedestrian zones;
3. *Comfort*, associating a plain and pleasant movement to a sensation of calm in a space without restrictions and with attractive and high-quality pavement, urban furniture, shelters and resting areas;
4. *Conspicuity*, which refers to the extent to which a facility, a route or an object is noticeable, eye-catching and legible; and
5. *Conviviality*, which expresses the goal of taking advantage of attractive spaces, architectural and cultural variety to stimulate social interactions.

In this study, these factors were used to evaluate the neighborhood environment of the institutional setting. For this, three observable criteria were defined for each factor and were evaluated from a binary perspective: positive or negative (see the results for a complete listing of the criteria).

Results

Location

The assessment of the services and amenities within 400 m and 800 m of the considered facilities included six major categories: food related services; open public spaces; general services; health and well-being; transportation; and others. Table 2 shows the availability of services within the catchment areas of 400 m and 800 m. Findings show that the amount of services cannot be directly equated with a rural or urban location.

Nonetheless, the facilities in urban areas tend to be close to more services than the non-urban ones and, in particular, have better access to open public spaces or general services.

Table 2: Share of institutions that have at least on service/amenity in their service area (%)

Urban design factors influencing mobility

The assessment of the build environment regarding its walkability for the senior population was made for five factors, each one comprising three observable criteria (Table 3). The assessment for a criterion given was then summed up to provide an overall score for each factor and institution. The factors with the worst scores were convenience and connectivity, given a tendency for inadequately sized walking areas (namely narrow or absent sidewalks), insufficient crossings and natural and topographic barriers. The highest scores were observed for comfort, conspicuity and conviviality, with positive marks for the criteria related to the overall quality of the urban design, such as the presence of urban barriers, the amount of lighting or signalization. In these dimensions, a criterion that stands out for its negative score is the amount of street furniture for resting, which was considered insufficient in most facilities.

Table 3: Assessment of the environment surrounding the facilities

	Predominantly rural					Predominantly urban																	
Institution	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	Total

Users' perspective

Regarding the role of the urban layout for the elderlies' behavior, the interviews showed that in almost all institutions the users leave the facility on foot. Although walking for leisure or recreational purposes is very common, most of the trips are made with a destination in mind like accessing a specific service. The services mentioned most frequently in the interviews were cafeterias/pubs, post-offices, churches, hairdressers and pharmacies (in this order). This is in line with what was shown in figure 3.

Notwithstanding the broad tendency for leaving the institutions through active modes of transportation, several limitations were identified by the interviewed. These barriers mostly concern insufficient sidewalks, traffic, the lack of resting opportunities or high gradients.

One aspect that characterizes the mobility pattern of the elderly interviewed is the limited use of public transportation. This is mainly due to their distance (only six of the institutions had a bus stop within 800 m as shown in table 3), their limited frequency, the lack of experience of most of the older adults in using this type of transportation and also because transportation is often provided by the supportive care facilities.

Perceived walking behaviors of the interviewed older adults are, in general, related to the environment surrounding the facilities (as shown in table 3). In fact, older adults stating that they scarcely leave the institutions, are mostly from those institutions that present the lowest scores regarding the five urban design factors.

Conclusions

The general findings of this study show that institutionalized older adults value mobility, active lives and social connections, and leave the building by active modes of transportation, if the built environment of the institution's surrounding area provides appropriate conditions – which was not the case in many of the analyzed institutions. In particular, the quality of the sidewalks, the slope of pathways, the presence of urban barriers and the absence of places for resting (benches) form barriers to a more active life-style by older adults. It was also possible to conclude that walking for transportation occurs more frequently than walking for leisure, thus highlighting the importance of services and amenities in the proximity of the institutions.

These findings can provide useful insights for policymaking. When dealing with the challenges of aging and institutionalization, public policies must therefore take into account, not only the scale of the institution's environment, but also the institution's neighborhood environment, in close collaboration with other stakeholders, namely the institutions' directors and personnel. The extent to which institutions succeed in understanding older adults' requirements and provide an environment capable of addressing their needs, is a key issue to reduce stress and the pace of decline associated with institutionalization.

Negotiated Public: Investigating the Streetscape of Beijing's Old City

Wenwen Sun¹

¹*Delft University of Technology, W.Sun-1@tudelft.nl*

Abstract: The emergence of conflictual practices in the street life of Beijing's old city has challenged the conventional use of the concepts of public and private in the design of public space. This paper proposes a novel way of reading and understanding the street as a public realm under negotiation by exploring the controversial and conflicting spatial practices and ambiguous social expressions of a traditional type of street in Beijing, namely the *hutong*. It argues that the street is best understood as a dynamic public realm negotiated through common agreement, spatial conflict, and ephemeral intervention. This argument hopes to open discussions towards a more localised and comprehensive understanding of public space in Chinese cities.

Keywords: appropriation; negotiation; public space; the streetscape

Introduction

This paper's interest in renewing the way to read and understand public space in Chinese cities emerged from the observation of the enormous spontaneous and undefined activities taking place in the old city of Beijing. For instance, the hanging of personal laundry above the designed public facilities on the street defies the formal expression of urban public space; similarly, people inhabit the street by bringing out their chairs and tea tables from their living rooms, as if the street were their private ground. At first glance, the design principle of public space is not able to grasp the nuances and complexities of such a socio-spatial condition, where people exhaust the maximum availability of public properties and resources.

The deficiency, in my opinion, lies in the theoretical perspective in our contemporary design thinking of public space in Chinese cities. The current theoretical debate on the Chinese city has touched upon the particular characteristics of public space related to the Chinese urban culture (Lu, 2006, Li, 2014). In the design processes, however, there remains a generalisation of understanding the street as an obvious and legitimate public realm, assuming a rather consistent public behaviour. Other possibilities for a conceptual change also in the design practices of public space are not fully recognised and explored.

In this paper, I want to propose an alternative conceptual expression of the street as a negotiated public realm, in which the public is conditional and dynamic. In order to do so, this paper has conducted a

qualitative study of a specific type of street—namely the *hutong*—which is the alley aligned with traditional courtyard houses in the old city of Beijing (Figure 1). The living culture of the Chinese and how they perceive the public and private dimensions of their living environment find their full expression in this traditional urban typology. By using the methods of drawing, photograph, and interview, this paper investigates the spatial and social practices in the *hutong*, discussing three ways of negotiation in the making and using of the street space: common agreement, spatial conflict, and ephemeral intervention.

Figure 1. A typical example of the *hutong* (Source: author photo)

The Common Agreement: Negotiation in the Using of Public Space

Let us explore this new perspective of negotiation concerning using the street as public property from its most basic meaning: setting up a common agreement (Oxford English Dictionary, 2019). That is to say, the public or private use of spaces in the *hutong* is initially operated by agreements among residents themselves rather than determined by land property as in Western cities. The logic of the common agreement, according to my exploration, is the main cause of the so-called ambiguous status of land ownership and the privatisation of public space.

Street appropriation has been a common practice in the history of the Chinese city. As depicted for instance, in literature, the *hutong* in Beijing was commonly inhabited by shops displaying commodities for public viewing and purchase in the past. Swedish art historian Osvald Sirén (1924, p.8) addresses this phenomenon in his book *The Walls and Gates of Peking* that ‘a good deal of the business is transacted in the street, by the shopkeepers as well as by itinerant vendors, particularly at the food shops which display their delicacies outside’. However, some Western scholars have considered such a practice as the privatisation of public space and criticised it as displaying ‘a lack of public spirit’; the assumption was that people in the city lacked senses of responsibility and respect regarding public properties and public rules. As shown in the book *Chinese Characteristics* written by the American missionary Arthur Henderson Smith (1894, p.110), one of the earliest Western texts that present Chinese culture to foreign readers, appropriating public spaces was such a common practice in Chinese cities at the time that it was disturbing to a Western eye. ‘The wide streets of Peking are lined with stalls and booths which have no right of existence,’ as Smith complains, adding that ‘...the space opposite to the shop of each belongs not to an imaginary “public” but the owner of the shop’.

I would argue that the prevailing of space appropriation in the *hutong*, which seems firmly embedded in the Chinese tradition of living, is an initial result of the common agreement in negotiating the right to use spaces. There are many ways to establish a common agreement in the *hutong*. A typical example is making a personal statement in the public street by displaying private belongings such as home furniture, vehicle, and laundry. The places where people make such a statement are often peculiar: the crossing of two alleys, the street corner, or the front door of their house, where they have the best view towards the various things going on in the surroundings (Figure 2). Next to displaying personal stuff, we find

Figure 2. People sitting at the crossing of two streets and talking to the passing-by (Source: author photo)

simultaneously different approaches in making agreements. When a conflict of interests occurs in using the shared spaces between two neighbours in close proximity, people set up a rule in a more implicit way and sometimes even by a long-term effort to defend the territory. In an interview, a *hutong* resident identifies the unique pattern of bike parking in front of his door: the left side is fully parked while the right side is empty (Figure 3). ‘This is because,’ he explains, ‘the neighbour living in the right door does not want bikes parking next to his door, while we do not care so much.’ About how this became a common agreement in the community, he puts further, ‘maybe he once kept moving away bikes from his front door for about two months, and this is perhaps how he set up this rule.’

Figure 3. The bike parking on both sides of the door (Source: author photo)

The perspective of the common agreement illustrates that the street has been negotiated to become a public realm or a private territory not by land property or public rules but rather by autonomous spatial practices. Sometimes the common agreement is made explicit by personal occupations of the street space, and in other cases, it is more veiled behind the social scene of the community.

The Spatial Conflict: Negotiation in the Contention of Public Space

The second act of negotiation I want to specify is spatial conflict, which refers to the conflictual spatial practices occurring in the public street due to the diverging needs and interests of different social groups. As Donald Appleyard (1987) notes, ‘...streets have always been scenes of conflict. They are and have always been public property, but power over them is ambiguous’. These conflicts manifested in spatial practices have transformed the street into a battleground, where people exercise their power, as what Sharon Zukin (1995) claims, to experience, to conceptualise, and to control those spaces.

The spatial conflict takes over in the negotiation process when people fail to set up a common agreement. One of the conflictual points I have discovered through observation and interview is the catch basin for rainwater in the *hutong*. In many places, the water wells supposed to be used for drainage have become the dumping points of left-over food; such a practice not only blocks the rain water but also deteriorates the street environment. To stop this uncivilised behaviour, the residents first attempted to negotiate through written communication by putting a sign on the wall: ‘do not pour rubbish to the catch basin’. However, this strategy to set up a common agreement failed to change the situation, and eventually, people have to put a cover on the catch basin to physically prevent the rubbish dumping (Figure 4).

Figure 4. The covered catch basin and the warning sign on the wall (Source: author photo)

Taking a close look at the urban transformation process in the past years, we could understand that the spatial conflict is also a result of the emerging inequality in the right to public spaces caused by external forces. In Beijing’s old city, the rise of real estate development since the 1990s and the massive building process of tourism since the 2000s have been decisive in this sense (Beijing Municipal City Planning Commission, 2005). Notably, the cultural values embedded in the historical city generated an opportunity for developing tourism: within five years, many traditional courtyard units were sold to wealthy real estate developers and private owners (Fang, 2000a, 2000b). The locals were gradually pushed aside, and the limited public facilities in the old urban areas were taken over by the boosted domestic and international tourist trade. The economic benefit brought by tourism development has dramatised the spatial issues in the *hutong*: both posh courtyard houses as restaurants or offices and crowded shantytown style living units exist in one urban block, displaying a polarised economic and social condition with both global business elites and the urban poor (Zhang, 1997).

Among the changes in the social and economic landscape of the *hutong*, representatively, the arrival of automobiles has generated a crucial point of spatial conflict. Since the 1980s, the *hutong* has been forced to accommodate cars despite its limited traffic capacity. Car occupation intensified the issue of space scarcity in the *hutong* and resulted in various social confrontations articulated by the conflicts in space. One eye-catching phenomenon is the placement of old and broken bikes underneath the back window of a house or along the street. These bikes, which seem like ‘pieces of installation art’, are placed purposefully by some *hutong* residents to stop car packing next to their windows (Jia and Wu, 2014, p.104). As displayed in this street scene (Figure 5), the juxtaposition of the rusty bicycles and an expensive car on the potential sidewalk showcases people’s struggle to refine the condition of being invaded by a privileged use of the street by certain groups.

Figure 5. Broken bikes lying on the ground (Source: author photo)

We can understand from these objects negotiation through the spatial conflict is a radical and spontaneous attempt to resolve contentions in using public spaces and to maintain a social balance in the *hutong*. The public street is taken for granted by people as shared resources, but only if shared equally. By reframing the privatised urban spaces into public resources again, the spatial conflict has emphasised the characteristics of the street as a social arena mediating conflicts among the claims and interests of different social groups.

The Ephemeral Intervention: Negotiation in the Making of Public Space

The third way of negotiation, which I call the ephemeral intervention, is to my understanding the most relevant to our design perspective of public space. We used to think in the fixed categories of design and appropriation, but this context has urged us to change our perspective towards the equal importance of the two in the making of public space. Rather than the permanent intervention implemented from formal design proposals, the private-driven ephemeral intervention does not have a legal right of existence, and neither does it last long. Initiated by people, it is a practice that temporarily exists but has the potential to catalyse a change of spatiality in the public realm.

The ubiquitous laundry drying, a remarkable characteristic of the *hutong*, might be one of the most illustrative examples of the ephemeral intervention. For the locals, public facilities such as utility poles, trees, and cables are available materials for setting up a laundry drying space. As in this situation (Figure 6), the iron pole used for electricity is perhaps too smooth to tie a string, and thus a small piece of wood has been added on top to resolve the problem of friction. This additional spatial device, as an ephemeral intervention, has changed the nature of the pole from a public facility to a domestic tool. By ephemeral interventions like laundry drying, people reappropriate and restructure the street space to adapt to their daily needs of domestic life.

Figure 6. (Source: author photo)

In the *hutong*, the two types of interventions — the permanent and the ephemeral — co-exist and collaborate in the making of public space. There are good examples that illustrate the controversial results of this collaboration. One of them is the street corner connecting the main street to the small alley, a favourite place to stay and to gather among the *hutong* residents. While the public sector implemented a top-down restoration of the area by paving the ground with bricks, the ephemeral intervention took over the social design of the place. On the one hand, the corner space is not pleasing to the eye because of a dirty ground with a stack of trash, and its dark and oily surface indicates a lack of responsibility among the residents; on the other hand, the dirtiness does not prevent people from claiming the space. Chairs and tea tables mingling with bike parking and even with

discarded waste — the whole set up of things presents a fluid situation, where the officially designed public space is easily overturned by a set of positive and negative appropriations (Figure 7).

Figure 7. The ephemeral interventions extracted from the space and highlighted in red (Source: author photo and author drawing)

Besides the ground pavement, the refurbishment of the urban historical centre has equipped some places with designed elements such as stone benches and landscape sculptures. According to the residents, a large part of those interventions come from the municipality to block the open facades of the illegal shops and caf  s in the *hutong*. Using hard material like stone reveals the intention of the designer to introduce a permanent intervention to the street, aiming for a positive change in the quality of public space. It turned out that these benches are only occasionally used by the passing by tourists and most of the time occupied by the laundry drying activity: as the line above the bench hanging bedroom items shows (Figure 8). The bench's hardness and the laundry's softness have not only created a striking visual contrast but also manifested a conflict between the designer's ideal and people's perception of the space. In the two types of the spatial interventions, the juxtapositions of objects, combinations of activities, and collisions of ideas have constituted a new spatiality: a spatiality that articulates the public realm as a social arena under constant negotiation between different actors in the development of urban projects.

Figure 8. The drawing has mapped the two types of interventions from the photo: the bench and the vegetation as the permanent interventions and the hanging laundry as the ephemeral intervention. (Source: author photo and author drawing)

The prevailing of the ephemeral interventions in the hutong has showcased that the making of the public realm is by nature a dialogue between public agencies and citizens. While the authority imposed its will to shape the urban environment, the people simultaneously pose their claims to the city; while the designers offered their insights on the public space, the citizens tend to restructure it with their spatial

practices. Such realities also challenge us to re-identify the significant limitation of architectural and urban projects in shaping the social behaviours of people in the public realm.

Conclusion

The paper has offered a new understanding of the street as a public realm under negotiation and has briefly discussed three ways of negotiation as common agreement, spatial conflict, and ephemeral intervention. When looking at the street activities through the lens of negotiation, we recognise the complex and dynamic nature embedded in the using, contention, and making of the public realm.

The idea of common agreement, the primary form of negotiation, invites us to think about another way of defining the public and the private territories in Chinese cities. We have been focusing on parameters such as ownership, accessibility, and public laws to define what is public and what is private. Now we should start to question the availability of public space as something conditional, fluid and bound with specific cultural norms.

The practice of spatial conflict urges us to pay attention to the characteristics of the street as material conditions enabled by contentions over the evolved social inequality. Space is a product of social action, and the reordering of space is also a reordering of social relations (Lefebvre, 1991, Lu, 2006). The spatial conflict — alleviating or intensifying the contentions in the use of the street — embodies the nature of public space as the arena that mediates social issues and different interests as well as a result of the issues and divergence.

The perspective of ephemeral intervention challenges us to reconsider the approaches and actors in the shaping of public spaces. By re-defining appropriation as an ephemeral urban intervention, we understand better the design of public space as a matter of common and dialogical practices. It could, I believe, open up different views on the design of public space in Chinese architectural and urban practices.

Moreover, the results of this paper correspond to the contestation of ‘a unified public, the desire for fixed categories, and the rigid concepts of public and private space’ (Crawford, 1995, p.4), which has been ongoing since the 1990s. This paper, however, has used an utterly different example from the early scholarship that has mostly concentrated on American cities. Especially given the qualitative methods employed in this research, the reflections on the phenomena of negotiation are limited within a certain scope of scholarly perspectives and will not show the whole picture of public space in Chinese cities. But it hopes to steer future discussions towards a more localised and comprehensive understanding of public space and to help practice act in and respond more adequately to the conditions of Chinese cities.

Study on The Characteristics and Changes of Street Cultural Attributes in Mingcheng District of Xi'an

Bowen Tian¹, Yumen Lei²

1 Xi'an University of Architecture and Technology, tbwyoo@qq.com

2 Xi'an University of Architecture and Technology, 623875226@qq.com

Abstract: As an important part of a city, streets are not only the arteries of transportation, but also the carriers of history and culture. The cultural attribute of streets highlights the connotation of cities to some extent. Exploring its characteristics and changing rules is an important way to study urban culture. This paper, taking Xi 'an Mingcheng district as the research object, through the historical data query and the current situation matching, based on the ArcGIS platform, the three types of cultural space and the four important periods of the street pattern are coupled and analyzed, obtaining the street culture property during the period of the overall features and classification, finally summed up the cultural attributes of Xi'an Ming city streets. The research shows that the number of streets with cultural attributes in Mingcheng district of xi 'an is gradually decreasing, and the fluctuation of cultural index is decreasing. In the research on different types of streets, religious streets maintain a steady state, educational streets continue to increase, and humanistic streets decrease significantly.

Key Words: Xi 'an Mingcheng district; Streets; Cultural attributes; Change research

Introduction

Street is the road space carrying the urban traffic function. As the flow of elements within the city, the composition of street space cannot simply be regarded as the superposition of all streets, but should start from the study of urban intention to explore the correlation between the space formed by the enclosure of residential buildings on both sides of streets. Cultural space is a place with certain material space scope, which is generally recognized by people, where cultural production and consumption gather, and where urban cultural characteristics are concentrated. Cultural attribute is one of the important attributes of the street, which is reflected in the number, scale and accessibility of the cultural space on both sides of the street. By studying the relationship between street and its related cultural space, it reflects the change and development of street's cultural attribute. Cultural confidence is a more fundamental, deeper and lasting force in the development of a country or a nation(Zhao and Sun,2016). As an important carrier of cultural confidence, street's cultural attribute reflects city's cultural characteristics to some extent. Therefore, it is the only way under the national cultural strategy to sort out the relationship between streets and cultural space in Mingcheng district of Xi 'an and study the cultural attributes and changes of streets, as well as the necessary way to study urban development.

Xi 'an, known as Chang 'an, Fengyuan and Jingzhao in ancient times, is one of the four ancient capitals of China. Together with Rome, Athens and Florence, it is one of the world's famous historical and cultural cities designated by UNESCO and has a high value of historical and cultural research. As an important birthplace of the Chinese nation, the ancient capital of thousands of years and the starting point of the "silk road", its status is very unique and lofty in the whole country and even the whole world. Xi 'an Mingcheng district is located in the core area of Xi 'an city. During the Ming and Qing dynasties, Xi 'an was expanded to the east and north based on the Tang dynasty, and built walls to defend the city. During this period, a basic urban pattern with bell tower as the core and four main streets running through each other from east to west and north to south was formed(Lan,2016). This pattern has been retained till now, and has evolved into the Mingcheng district which can best reflect the historical and cultural characteristics of Xi 'an. As the most special urban space in Xi 'an Mingcheng district, street space contains important historical and cultural development characteristics of Xi 'an. Taking streets as the starting point, this paper summarizes the characteristics and changing rules of street culture properties, and provides references for the spatial system optimization and development strategies of Xi 'an Mingcheng district.

1. The connotation and type interpretation of street culture attribute

Fernand Braudel once said, "Small streets and alleys can take us back to the past. Even with the rapid development of the economy today, those material civilizations still speak of the past."(2008) Taking a comprehensive view of the development history of eastern and western cities, streets, as the first interface to display cities, are the entry point for people to understand a city, from Miletus of Hippodamus to the Roman walled city, from the medieval European new town to the baroque and classical dynamic champs-elysees. From Lu dafang's < Tang Chang 'an diagram> to Zhang Zeduan's Riverside Scene at Qingming Festival. The urban streets created by the continuous inheritance of thousands of years of urban history in China and the west run through the historical changes of human society from beginning to end and are engraved with the common urban memory of mankind. With the acceleration of modernization and the establishment and popularization of the modern traffic system with motorized traffic as the main body, the traditional urban street system in China has been systematically destroyed. The traditional interpersonal communication mode no longer exists, the inheritance of street space culture is forced to be interrupted, and the traditional cultural space is gradually blurred.

Xi 'an Mingcheng district has largely retained the development of Xi 'an during the Ming and Qing dynasties. It is an important historical and cultural protection core area of Xi 'an city and an important witness of Xi 'an history. Therefore, the study on the street cultural attribute of Xi 'an Mingcheng district is the key point to explore the development history of Xi 'an city and an important way to explore the wisdom and thoughts of ancient people. This study aims at the research ontology of streets in Mingcheng district of Xi 'an. According to the research foundation of domestic streets and the unique historical features of Xi 'an, the streets are divided into religious streets, educational streets and humanistic streets by combining different cultural attributes. Among them, the religious streets refer to the street through each type of religious beliefs and religious ritual and related activities of religious cultural space (contains Buddhist culture as the kernel of the Buddhist temple, islamic culture as the kernel of mosques, Taoist culture as the core of Taoist temple and began was introduced into China in late qing dynasty and formed a certain scale, the kernel for western Christian, Catholic church, etc.) and model of religious culture of the streets; Educational streets refer to streets with educational and cultural atmosphere built through

cultural Spaces with educational functions (including county schools, government schools, Confucian temples, academies, tribute schools, examination houses, schools formed by the reform of the education system and modern educational facilities, etc.) in the Ming district. humanistic streets refer to the street through all kinds of bearing city spirit, bear the function of cultural exchange and communication with humanity feelings class cultural space (include all kinds of ancestral temple, temple, bearing the function of regional cultural exchange halls, as well as modern citizens with lifting city palace of culture, science and technology museum, museum, art museum, memorial hall, etc.) and the shape has the cultural atmosphere of the street.

2. Research routes

2.1 Research idea

In this study, the definition of Xi 'an Mingcheng district mainly consists of five parts: the main district, East area, West area, South area, North area (Figure 1) .

Xi 'an Mingcheng district streets show a checkerboard distribution, and this distribution feature has been continued until now. The cultural space of Xi 'an Mingcheng district has the characteristics of large span, large quantity and wide distribution. In view of such characteristics, in the research process of changing characteristics of street cultural attributes in Mingcheng district, Xi 'an, firstly, based on existing historical data, the composition and distribution of road network structure and cultural space in different periods in Mingcheng district were sorted out. Secondly, the changes of street cultural attributes are interpreted. Finally, the author explores the historical causes of the changes and gives relevant suggestions. In the part of the interpretation of changes in

Figure 1 Scope of study

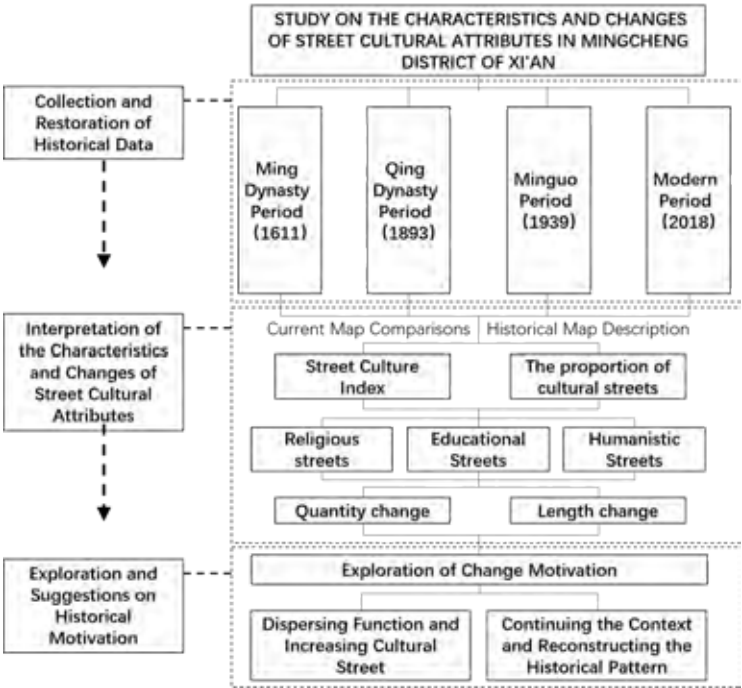

Figure 2 Research framework

street cultural attributes, there are two levels, namely, the interpretation of overall changes in characteristics and the interpretation of classification changes in characteristics. The cultural attributes of streets are further subdivided into religious attributes, educational attributes and humanistic attributes. On this basis, the types of streets are divided to explore the changing characteristics of religious streets, educational streets and humanistic streets. Through three steps and two levels of research, is the best way to explore the characteristics and changes of street culture in Xi 'an Mingcheng district (Figure 2) .

2.2 Data sources

From the early Ming dynasty to the present, according to data collection and analysis, cultural space changes in the Ming district of Xi 'an can be divided into four specific periods: Ming dynasty period (1611), Qing dynasty period (1893), Minguo period (1939) and modern period (2018). In these four periods, the urban development of Xi 'an was relatively stable and the urban characteristics of each period were distinct. Therefore, the cultural space of Xi 'an Mingcheng district was studied based on these four periods. Among them, Shaanxi provincial capital map of Ming dynasty(Figure 3), Xi 'an Fucheng map of Qing dynasty (Figure 4), existing road traffic map of Xijing city of Minguo(Figure 5) and 2018 map of Xi 'an Mingcheng district of modern times(Figure 6) are all represented. Translating historical map compared with current situation of Xi 'an topographic map, and the Qing Qianlong "Xi 'an government record", the Qing Jiaqing "Xianning county annals", the Qing Jiaqing "Changan county annals", the two counties of Xianning Chang 'an renewal ", "Xi'an Ming and Qing dynasties dictionary", "Minguo period, Xi 'an dictionary", "Xi'an education "and other documents as a basis point, on the streets and three kinds of cultural space location and size of accurately setting, thus obtains the accurate streets and cultural space distribution, and further integration of various periods street culture characteristic figure.

Figure 6 map of Xi 'an Mingcheng district of modern times

3. Analysis of characteristics of street cultural attribute change

3.1 Overall combing

3.1.1 Street combing

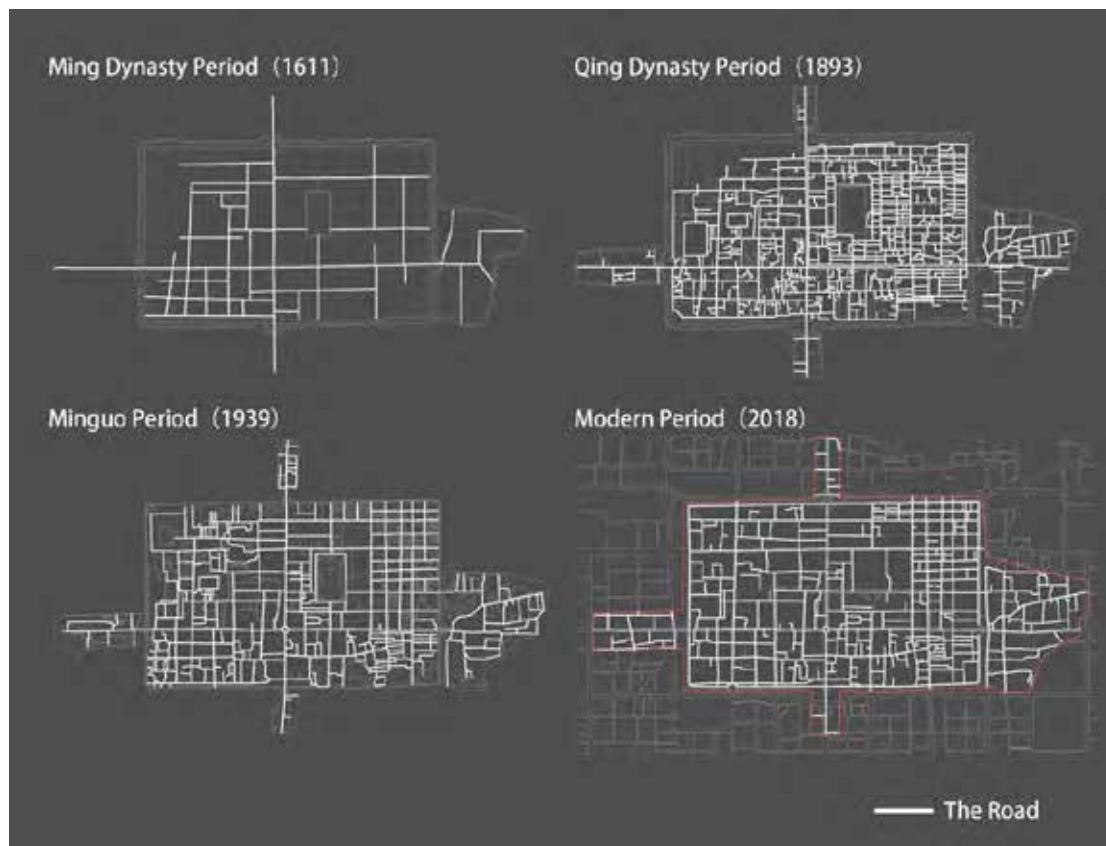

Figure 7 Street Layout Map of Each Period

The streets in Mingcheng district of Xi 'an in the four periods were summarized to get the street distribution map in each period (Figure 7), and the length of streets in each period was statistically analyzed. Among them, the total length of streets in the Ming dynasty is about 43238.4 meters, the total length of streets in the Qing dynasty is about 153175.1 meters, the total length of streets in Minguo period is about 120432.8 meters, and the total length of modern streets is about 150324.0 meters. However, due to the war and political instability in Minguo period, the development of infrastructure was backward and the street length decreased (Table 1).

Table 1 Road Length Statistics Table

Period	Ming dynasty	Qing dynasty	Minguo	Modern
Total Street Length	43238.45	153175.08	120432.82	150323.97

3.1.2 Cultural space arrangement

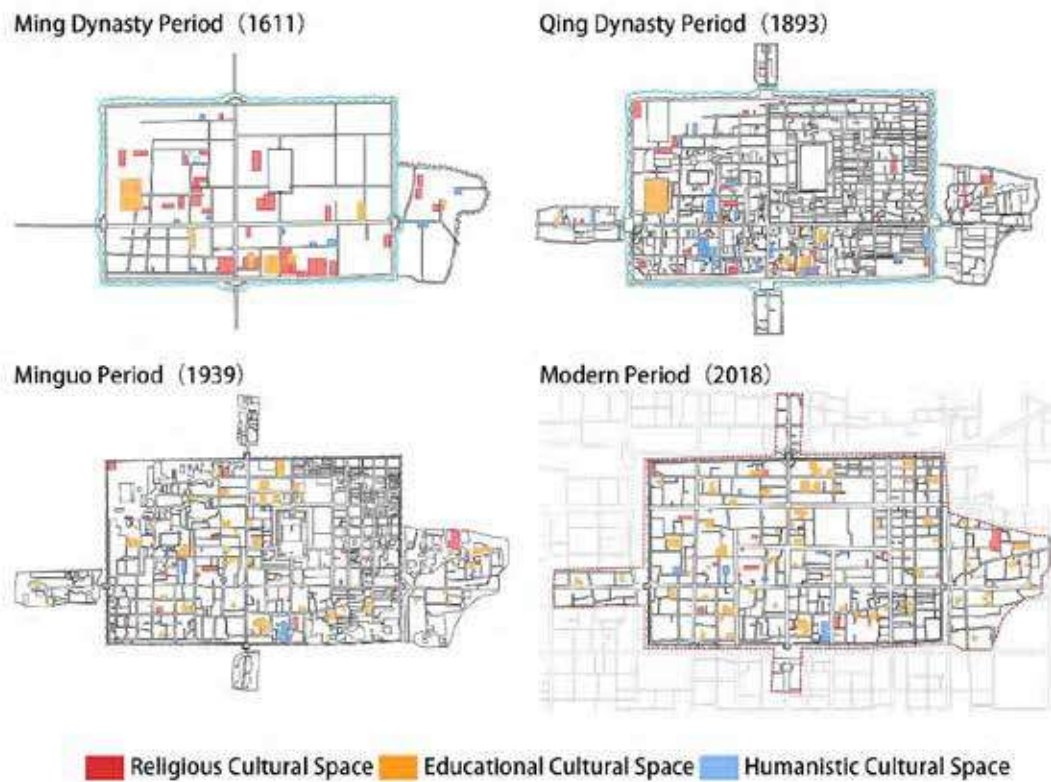

Figure 8 Cultural Space in Each Periods

The distribution of three types of cultural space in the Ming district of Xi'an in the four periods was analyzed in detail, and the cultural spatial distribution map of each period was obtained (Figure 8), and the scale of each type of cultural space was statistically analyzed. Among them, there were 57 cultural Spaces in the Ming dynasty, 205 in the Qing dynasty, 80 in Minguo period and 123 in the modern period. The number of various cultural Spaces is shown in the following table (Table 2).

Table 2 Statistical Table of Cultural Space Quantity

Period	Number of Religious Cultural Space	Number of Educational Cultural Space	Number of Humanistic Cultural Space	Total
Ming dynasty	35	8	14	57
Qing dynasty	39	9	157	205
Minguo	28	44	8	80
Modern	32	69	22	123

3.2 Analysis of overall change characteristics

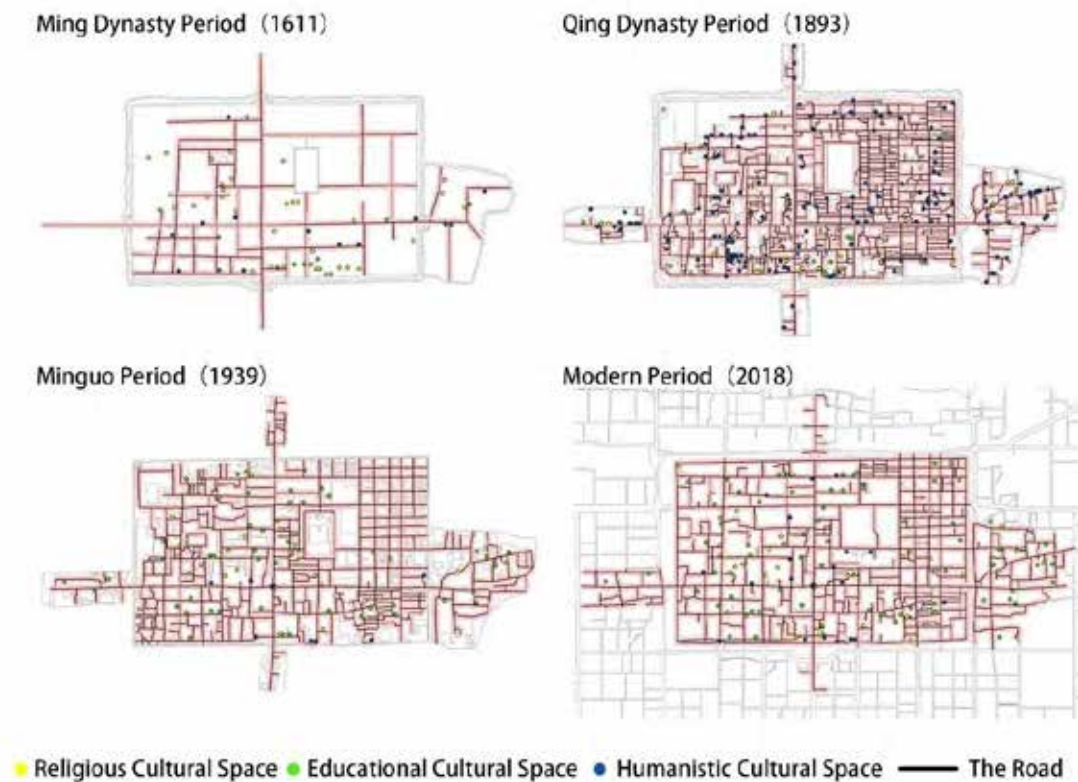

Figure 9 Overall Distribution Map

In order to further study the cultural attribute characteristics and changes of streets in each period, combined with their definitions, the streets in the four completed periods and the cultural spatial distribution in each period are coupled for analysis. By ArcGIS software to the streets as the object, establish a radius of 50 m buffer, and on this basis, the connection of three kinds of cultural space, street buffer calculated each period within the scope of cultural space, the number of street culture and concluded the period index and streets with cultural attribute variation characteristics, and further analysis and research for different types of street (Figure 9).

3.2.1 Analysis of changes in street culture index

The street culture index refers to the ratio of the total number of cultural Spaces in the buffer zone with a radius of 50m in each street in each period to the total length of streets in that period, which is a quantitative characteristic of street culture attribute. The calculation formula is: :

$$X_c = \frac{Y_c}{L} \times 10000$$

Xc refers to the cultural index of a certain period, Yc refers to the total number of cultural Spaces within the buffer zone of the street during the period, and L refers to the total length of the street during the period.

The street culture index of the four periods of Xi'an Mingcheng district is calculated, as shown in the following table (Table 3):

Table 3 Statistical table of cultural index

Period	Total Street Length	Number of cultural spaces within the buffer zone	Cultural Index
Ming dynasty	43238.44764	39	9.019750276
Qing dynasty	153175.0753	273	17.82274299
Minguo	120432.8152	103	8.55248628
Modern	150323.9727	157	10.44410929

It is found that the street culture index of Xi 'an Mingcheng district shows a trend of increasing first, then decreasing and then increasing, and the overall trend is a sharp decline. In the four periods, the street culture index of the Qing dynasty was the highest (17.82) and the street culture index of Minguo period was the lowest (8.55). From the Ming dynasty to the Qing dynasty, the street culture index increased by 8.8. From the Qing dynasty to Minguo period, street culture index decreased by 9.27. After the founding of Minguo period, the cultural index slowly increased to 10.44 in modern period, showing the characteristics of the gradual revival of the cultural attributes of streets in Mingcheng district (Figure 10).

Figure 10 Cultural Index Change Map

3.2.2 Analysis of street change characteristics with cultural attributes

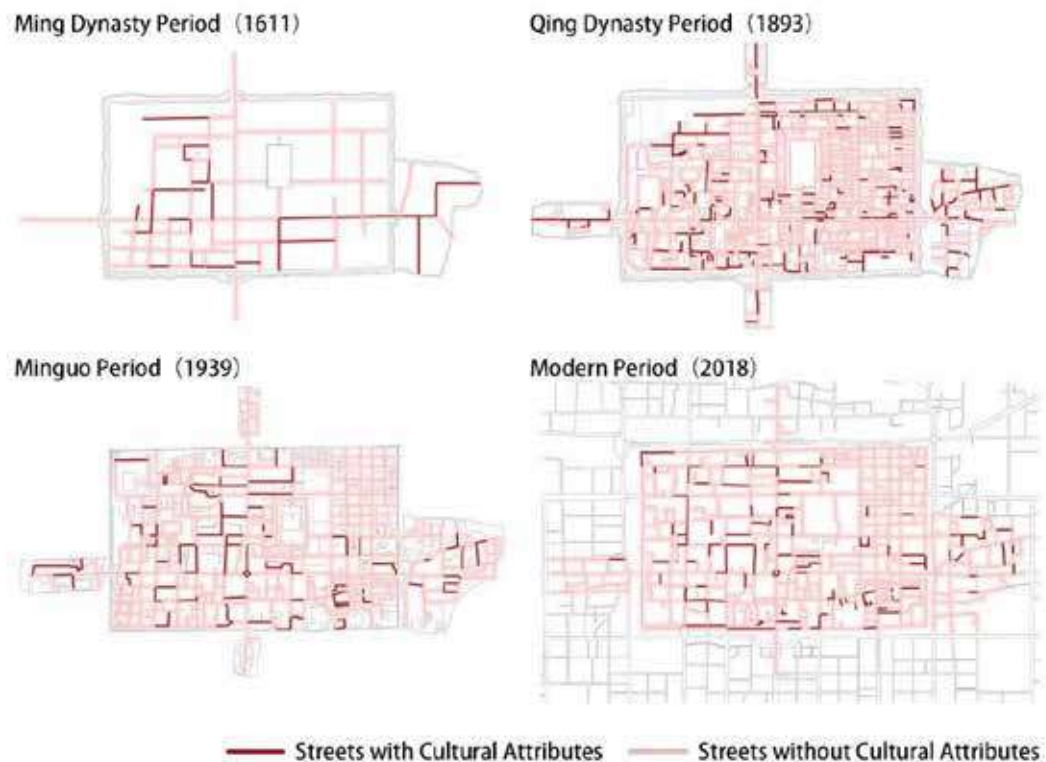

Figure 11 Street Change Map with Cultural Attribute

The cultural attributes of streets in different periods are counted, streets with cultural attributes are extracted, and the distribution map of streets with cultural attributes is obtained(Figure 11). Meanwhile, the total length of streets with cultural attributes in each period is statistically analyzed, and the following table is obtained(Table 4).

Table 4 Street Change Table with Cultural Attributes

Period	Ming dynasty	Qing dynasty	Minguo	Modern
Street Length with Cultural Attributes	12783.29	29575.7075	21939.33141	23689.01534
Total Street Length	43238.44764	153175.0753	120432.8152	150323.9727
Proportion	29.56%	19.31%	18.22%	15.76%

It can be concluded from the analysis that the length of streets with cultural attributes in different periods in the Ming district is similar to the change law of cultural index, showing an overall trend of first increasing and then decreasing and then increasing. The total length of the Ming dynasty was about 12.7 km, and it grew to about 29.6 km in the Qing dynasty. The Minguo period was greatly reduced to 21.9 km and 23.7 km after the founding of China.

Figure 12 Cultural Street Statistical Map

However, by comparing the ratio of the street length with cultural attributes to the total street length in each period, it can be found that the proportion of the street length with cultural attributes in the Ming district shows a linear trend of decline. The Ming dynasty accounted for the highest proportion, at 29.56%, while the Qing dynasty declined to 19.31% and Minguo period to 18.22%.Streets with cultural attribute length in different periods of time have increased under the condition of reduction, the overall proportion have continued to reduce, weaken gradually said clearly in urban streets cultural attribute, city streets whole culture continues to decline, the generation that not only unable to meet the needs of urban residents, but also seriously affected the heritage and development of the Xi 'an city spirit and context(Figure 12).

3.3 Analysis of changes in religious stre

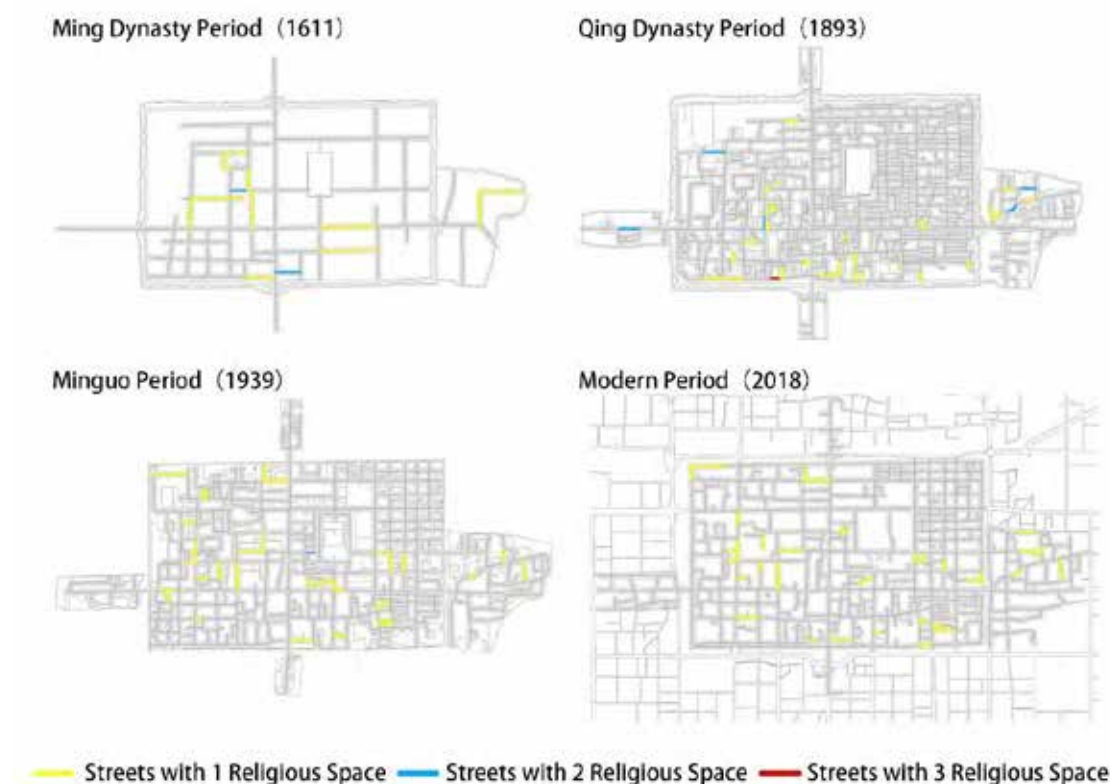

Figure 13 Characteristic Map of Religious Street Change

Religious streets were extracted from the streets with cultural attributes in different periods, and the change characteristics of religious streets were obtained (Figure 13). Meanwhile, the size characteristics of religious streets in different periods are statistically analyzed, and the following table is obtained (Table 5):

Table 5 Religious Street Size Statistics Table

Period	Ming dynasty	Qing dynasty	Minguo	Modern
Quantity of Cultural Space	35.00	39.00	28.00	32.00
Number of streets	13.00	42.00	37.00	45.00
Total length	6713.17	5768.77	7789.43	7907.11

The research shows that the number of religious streets in the Ming urban area presents an overall rising trend, and the change trend is relatively small after the Qing dynasty, with the overall number stable at about 40, indicating that the religious streets basically meet the residents' needs after the Qing dynasty. The analysis of the total length of religious streets shows a trend of decreasing first and then increasing, but its growth rate gradually slows down with the social development, which indicates that religious streets basically meet the needs of residents. According to the classification of religious streets by the number of religious Spaces within their scope, it can be found that there are less religious streets in the Ming, Qing and Mingguo period with two or more religious Spaces, which have a higher integration degree. However, modern religious streets all contain only one religious space, which indicates that the distribution of religious cultural space is gradually equalized for residents in different areas to use.

3.4 Analysis of changes in educational streets

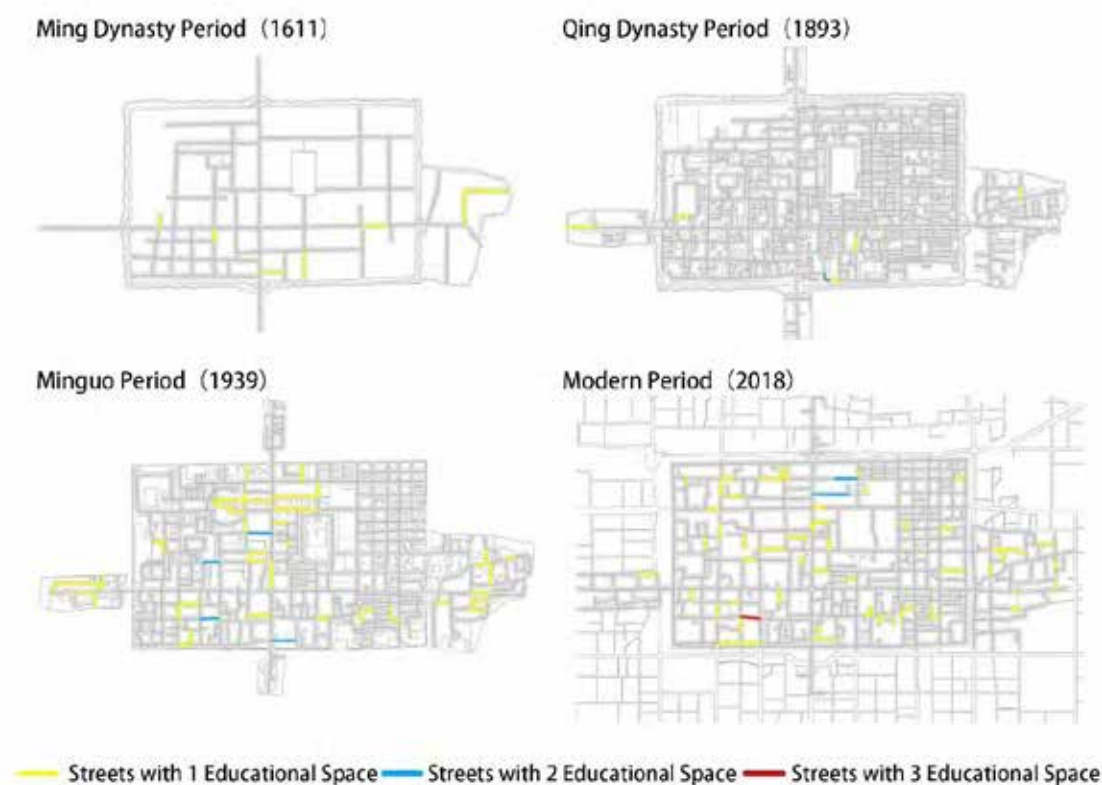

Figure 14 Characteristic Map of Educational Street Change

The educational streets with cultural attributes in each period were extracted and the change characteristic map of educational streets was obtained (Figure 14). At the same time, the size characteristics of educational streets in different periods are statistically analyzed, and the following table is obtained (Table 6):

Table 6 Educational Street Size Statistics Table

Period	Ming dynasty	Qing dynasty	Minguo	Modern
Quantity of Cultural Space	8	9	44	69
Number of streets	6	6	47	76
Total length	2740.97	1235.08	12191.35	12601.32

The research shows that the number of educational streets in Mingcheng district continues to rise, and it increased greatly during Minguo period until the number of 76 streets in modern times. The total length of educational streets is analyzed, and the overall trend is decreasing first and then increasing, but the total length of educational streets grows slowly after the founding of China. Combined with the growth of its number, it can be seen that the characteristics of educational street gradually develop from long and less to short and more. It can be found that with the development of the times, the number of streets containing multiple educational Spaces gradually increases, indicating that the number of educational cultural Spaces gradually increases, and the distribution develops from centralized layout to decentralized layout.

3.5 Analysis of changes in humanistic streets

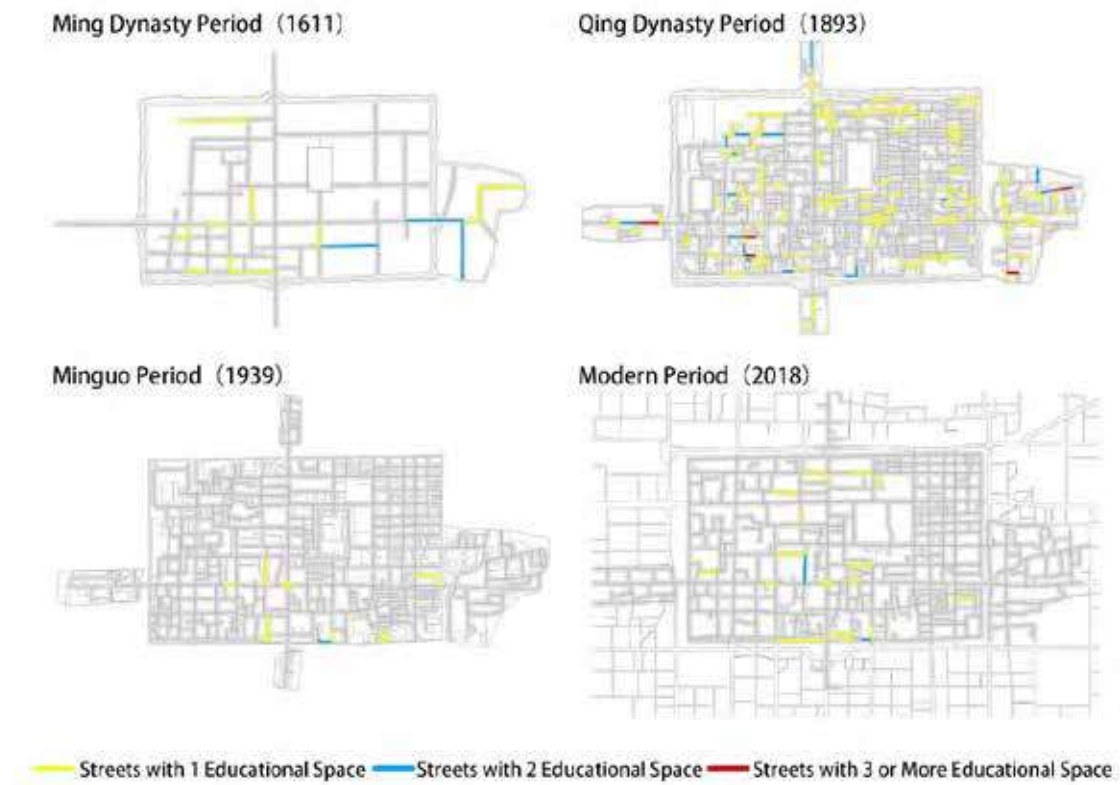

Figure 15 Characteristic Map of Educational Street Change

By extracting the humanistic streets with cultural attributes in each period, the change feature map of humanistic streets is obtained (Figure 15). At the same time, the size characteristics of humanistic streets in different periods are statistically analyzed, and the following table is obtained (Table 7):

Table 7 Humanistic Street Size Statistics Table

Period	Ming dynasty	Qing dynasty	Minguo	Modern
Quantity of Cultural Space	14	157	8	22
Number of streets	15	183	13	30
Total length	7821.05	24201.59	2758.94	5996.63

According to the research, the number of educational streets in the Ming district first increased and then decreased, reaching a maximum of 157 in the Qing dynasty, but decreased to 8 in the Minguo period. The analysis of the total length of humanistic streets shows a trend of increasing first, then decreasing, and then increasing. In the Minguo period, the length of humanistic streets also decreased sharply, from 24201.6 meters in the Qing dynasty to 2758.9 meters. After classifying humanistic streets according to the number of humanistic spaces within their scope, it can be found that the number of streets containing multiple humanistic spaces in the Qing dynasty was relatively large, while the number of humanistic streets increased gradually after modern times and presented a decentralized layout.

4. Historical motivation exploration and Suggestions

4.1 Research on the causes of changes in street cultural attributes

Since the Ming dynasty, the change of cultural attribute of streets in Mingcheng district of Xi'an has shown the characteristics of decreasing quantity and proportion. However, the change motivation of different types of streets in different periods is not the same, which is closely related to the political and social changes in different periods. Generally speaking, the causes of cultural attribute changes of streets in Mingcheng district of Xi'an can be summarized into three aspects, including social factors, economic factors and institutional factors.

Among them, the influence of social factors is mainly manifested in three aspects. First, demographic impact. Since the Ming dynasty, the population in the Ming urban area increased, and the residents' rigid demand for cultural space increased accordingly. Therefore, the number of streets with cultural attributes increased greatly during this period. With the population reaching saturation in Mingcheng district, the increase rate of streets with cultural attributes decreases, and the number of religious streets remains basically stable, indicating that residents' needs have been met. Second, the nature of the city. During the Ming dynasty, Xi'an assumed the position of an important military gateway to northwest China. During this period, its urban function was mainly military defense, serving as an important defense checkpoint and border gate in northwest China of the Ming dynasty. Therefore, in this period, Xi'an fu street cultural attributes are relatively weak, more assume the traffic and military defense attributes. With the change of dynasties, the Qing dynasty brought a relatively stable social form, and during this period, Xi'an's functions gradually changed from mainly military to diversified. During this period, Xi'an assumed more functions as an important economic and cultural center in northwest China, and a large number of assembly halls and ancestral halls were built, leading to a large increase in the number of humanistic streets in this period. Third, social stability. During the Ming dynasty, Xi'an's social stability was weak, and the street cultural attribute was weak, which was more of a military defense attribute. With the improvement of residents' spiritual demands brought by the political stability of the Qing dynasty, a large number of humanistic streets have been promoted to some extent, which makes humanistic streets become the first of all kinds of streets in the Ming district of Xi'an and the most important part of the cultural system of Xi'an streets. In the period of the Ming dynasty, the decrease of residents demand levels of political unrest, residents took on faith and city spirit of humanity class cultural space is gradually disappear, part of the conversion to education class cultural space, the other part with the historical process, so as to make the humanities class street a substantial reduction in the size, in Xi'an street culture system is also gradually forgotten(Ren,2005). With the rapid development of Xi'an after the founding of China, social stability has been greatly improved, and the number of streets with cultural attributes in the Ming district has also increased significantly, with the most obvious feature being the increase of educational streets and humanistic streets.

The influence of economic factors on the evolution of cultural space is mainly reflected in the fact that economic development increases residents' diverse demands for street cultural attributes. Qing Guangxu period, the humanities class cultural space due to its special worship(Ren,2005), such as for agricultural economy and the health of body and mind and such sacrifice, carrying the residents is yearning for a better life and hopes, with the economic development, residents' desire for the agricultural harvest and hall on the demand of the business income, lead to contain a industry protection function of humanistic

class cultural space in short supply, thus derived according to different requirements of humanities class cultural space, such as Xiangzi temple and Mashen temple, further makes the humanities class streets are widely distributed in this period and larger scale.

The influence of institutional factors on the evolution of cultural space is mainly reflected in the influence of educational street. During the Guangxu period of the Qing dynasty, the educational system was reformed and the imperial examination system was abolished. From 1905 to 1910, various kinds of modern education were concentrated. During this period, educational cultural space was gradually transformed(Xun,2002). During the period of Minguo, with the introduction and rapid development of new education, its educational ideas, methods and contents were greatly changed, which made the scale of educational streets rise steadily during the period of Minguo. Thoughts after the founding of new China, the scientific planning to guide urban construction in China, to meet the needs of residents of education function, education class cultural space as the main bearing of education function, on the premise of the pursuit of equal public services, to meet the demand of the whole, this kind of cultural space scale gradually improve, making education class gradually become the cultural attribute of Xi'an street street in the largest part of the body, the equal demand also contributed to the equal distribution of education class street makes education core gradually disappear.

4.2 Conclusions and recommendations

The cultural attribute of streets is of great significance to the Mingcheng district of Xi'an. Its existence satisfies the multiple demands of residents for cultural belief in different periods, and is the witness of Xi'an history, the bearing of city spirit and the sustenance of people's belief. In the streets with cultural attributes, humanistic streets, as the spiritual fortress of the city, will play the most critical role in the overall urban context and spiritual inheritance. This article through to Xi'an Mingcheng district contained in the Ming dynasty, the Qing dynasty, Minguo, the modern characteristics of four periods and street culture attribute changes were analyzed, and the main draw two conclusions: Xi'an city street culture present the first index increase after decreases and then increases variation characteristics, and the streets of the cultural attribute length of the period, gradually reduce the proportion of the total length of the street, Secondly, in the research on the three types of streets with cultural attributes, the overall number of religious streets changes slightly, and their length tends to decrease first and then increase. The overall number and length of educational streets show an increasing trend. The overall number of humanistic streets reached its peak in the Qing dynasty, which was greatly reduced in Minguo and slowly increased after the founding of the People's Republic of China. Finally, the study shows that there are three factors influencing the cultural attributes and changes of streets in Mingcheng district of Xi'an, including social factors, economic factors and institutional factors.

Xi 'an, as the ancient capital of thirteen dynasties, is the prominent cultural attribute, and Xi'an's history cultural should be the leading cultural attribute. Humanistic street is the largest, most extensive and most representative street type with cultural attributes. On the one hand, humanistic street symbolizes the historical memory of the city. However, with the development of The Times and the transformation of functional requirements, this type of street has been almost completely annihilated, and this phenomenon is the typical epitome of the loss of urban context and urban culture in Xi'an, especially in the Ming district. In view of the evolution characteristics and causes of cultural space in Xi'an Mingcheng district, highlighting its historical and cultural attributes, the following Suggestions are put forward for the

construction of Xi'an cultural system:

Dredge the urban functions in the Ming district and increase the humanistic streets. Combined with the development needs, the excessive commercial and residential functions in the Mingcheng district are removed to further increase the cultural space of humanities in the Mingcheng district, thus increasing the number of humanities streets. Current residents demand for humanities class street is no longer sacrifice function is given priority to, so it needs to be more suitable for today's urban residents use the function of the implant, such as reading books, museum exhibition points, green square, etc., to add more with different combining the characteristics of era cultural street, through the transformation of urban space, room to improve energy, choose for residents to provide a variety of cultural function.

Reconstruct the historical pattern, continue the urban context, strengthen cultural confidence. Xian Mingcheng district's old history and culture, optimizes the cultural space distribution, comply with the Mingcheng district in the old city renewal, in the history of important nodes or the culture of the city center for centralized core construction, combined with the network, set up the historical and cultural street network and system architecture, continuation of ten dynasties the ancient capital of context, the Mingcheng district into a centralized demonstration of the city culture and city museum, improve urban cultural self-confidence, enhance urban identity and a sense of pride, to build Xi'an unique history card, heritage city history, show the city spirit, and inspire vitality.

In this paper, considering the factors such as the data collected, only to Xi'an Mingcheng district within the scope of urban streets change characteristic and the cultural attributes of related research, but in today's Mingcheng district of Xi'an city account for only part of the overall scope, therefore, the properties of Xi'an within the scope of the whole street culture combing research is relatively insufficient, is expected to be further perfected.

Exploring port-city relationships through event-led urban regeneration

Enrico Tommarchi¹

Abstract: Policy makers in European port cities have been keen on bidding for mega events (MEs) in the last thirty years, as a means to boost or sustain processes of urban regeneration and development. Despite MEs are an increasingly regular feature of urban and cultural policies in these cities, little effort has been put in exploring the outcomes of event-led urban regeneration on the conflicting and deterritorialised liminal space that is the port-city interface. This paper presents some of the findings of a PhD research about the spatial and socio-cultural relationships between ports and cities and the impact of event-led urban regeneration on these links. The experiences of Rotterdam (EURO 2000; European Capital of Culture 2001), Genoa (1992 Specialist Expo, European Capital of Culture 2004), Valencia (America's Cup 2007 and 2010; Formula One European Grand Prix 2008-2012) are put in conversation in relation to the recent case of Kingston upon Hull (UK City of Culture 2017). The analysis of these experiences helps to problematise a range of issues including the 'cultural' role of port authorities, the spatiality of event-led regeneration at the port-city interface and issues of authenticity and cultural demaritimisation.

Keywords: culture-led regeneration; European port cities; event-led regeneration; port-city relationships

Introduction

In the last thirty years, mega events (MEs) have become a key feature in urban policy in many European port cities, in relation to the opportunities that such events may offer in terms of urban regeneration and development. This appears to be particularly the case for European port cities, which had witnessed deindustrialisation and the migration of working port areas outside their traditional urban location. Glasgow (European Capital of Culture 1990), Barcelona (1992 Olympic Games and 2004 Forum of Cultures), Genoa (1992 Specialist Expo and European Capital of Culture 2004), Marseille (European Capital of Culture 2013) are examples of how MEs have been used to address waterfront redevelopment in a context of changing port-city relationships. Although there is a recognition that port-city relationships are rapidly evolving and possibly retightening after a period of growing separation between cities and ports, little attention is devoted to exploring how MEs, and their considerable transformative power, impact on these complex and changing links.

This paper presents the framework and key findings of a PhD research aiming at exploring port-city relationships from the perspective of regeneration triggered by MEs (event-led regeneration) and by cultural activity (culture-led regeneration). In particular, the study aims at investigating the mutual relation between MEs

and the spatial and socio-cultural components of these links between port and cities, through a comparative analysis of MEs in four European port cities.

Firstly, a selective literature review about the evolution of port-city relationships is connected to the growing body of literature about culture-led and event-led urban regeneration. Secondly, the research design and methodology of the study are briefly outlined. Thirdly, background information on the four case-study cities is provided. Fourthly, the connection between MEs and the socio-spatial and socio-cultural aspects of port-city relationships are explored and discussed, in relation to the evolution of port-city links.

Ports, cities, culture and MEs

Port-city relationships have been explored by geographers and port specialists in particular since the 1960s, when Bird (1963) proposed the Anyport model to interpret the evolution of these links from a spatial and functional perspective. The Anyport model assumed the migration of working port areas outside their traditional location at the heart of their cities as an inevitable step in the evolution of ports. This because ports would need wider spaces and increasingly specialised infrastructures that could not be provided within historic harbours. As a matter of fact, containerisation, increasing vessel size, the need of deeper waters and greater accessibility were amongst the factors that fuelled port migration in many European port cities in the late 20th century (Hayuth and Hilling, 1992). These technological developments produced redundant port facilities in central locations on the waterfront and made ports less depended from local labour markets (Hoyle & Pinder, 1992; Ducruet et al., 2010 in Hall and Jacobs, 2012).

Research on port-city relationships from the 1980s to the 2000s (e.g. Hoyle & Pinder, 1992; Meyer, 1999) tend to underline the growing physical and functional separation between ports and cities and the consequent weakening of traditional links. However, Hoyle (1988; 1989; 2000) developed a model of port-city relationships that, in its latest version, suggests a current phase of retightening of these links. The literature on port-city relationships in the last two decades acknowledges that these relationships are evolving on different grounds. Ducruet and Lee (2006) proposed a model based on the role of ports in transnational maritime trade (intermediacy) and the role of cities within global urban networks (centrality). Contemporary port-city links are understood as a combination of complex interrelation (Wiese and Thierstein, 2014; Daamen and Louw, 2016), where the spatial driving force is now the city (Wiegman and Louw, 2011).

Hayuth (1982) first described the port-city interface as the liminal space between cities and ports, which raises issues of sustainability. This concept has been developed by further research (e.g. Notteboom *et al.*, 2013) towards a view of this geographical liminal space as “a pluralistic community of actors” (Daamen and Vries, 2013, p. 6). Since the 1980s, this space has been substantially transformed through processes of waterfront redevelopment. Pioneering experiences in US cities such as Baltimore and San Francisco inspired similar schemes in European cities such as London, Barcelona or Liverpool. Many of these schemes made use of culture-led urban regeneration (Bianchini and Parkinson, 1993; Evans and Shaw, 2004), where flagship cultural facilities, activities or events were used as catalysts for waterfront redevelopment and strategic repositioning.

European port cities such as Barcelona and Genoa have also made use of event-led urban regeneration, where MEs were devices for concentrating investment and producing massive urban transformation. MEs can be understood as “large scale cultural (including commercial and sporting) events which have a dramatic character, mass popular appeal and international significance” (Roche, 2000, p. 1). Examples are the Olympic Games, the World and European Football Cup, the European Capital of Culture (ECOC). MEs can also be viewed as pivotal moments along long-term trajectories of urban development and regeneration through culture (Evans, 2011). Policy makers in European port cities appear increasingly keen on bidding for MEs with the aim of diversifying the local economy and changing external perceptions in relation to the negative image of ports associated with pollution and poverty. For example, the competition for the title of UK City of Culture 2017 involved eight port

cities in the country. Nevertheless, the literature on culture- and event-led regeneration does not recognise the specificity of port cities.

Methodology

A comparative case study analysis of port-city relationships in the context of MEs involved four European port cities, namely Kingston upon Hull, Rotterdam, Genoa and Valencia. The case of Hull was approached as a pilot study to test and further develop the research methodology and to benefit from the fact that the analysed ME was being celebrated in the early stage of the study.

The other three case studies were selected seeking commensurability albeit allowing a certain degree of diversity of instances, in order to avoid “theoretically uniformed choices” (Storper and Scott, 2016, p. 1124) and “self-fulfilling reasoning” (Abu-Lughod, 2007, p. 401). An initial scoping review of experiences of MEs in Mediterranean and Northern European port cities was followed by a shortlisting process which considered a range of issues including demographics, role of candidate cities in national and European urban networks, timeframes of MEs, language barriers. Ducruet and Lee’s matrix (2006) mapping port-city relationships was also used.

Cultural political economy (Jessop and Sum, 2001; Sayer, 2001; Jessop 2010) was deployed as a high-level framework to explore power relations behind MEs at the port-city interface. A bespoke comparative strategy including elements of Tilly’s variation-finding and encompassing comparative strategies (Tilly, 1984; Robinson, 2011) was adopted to perform the comparative analysis.

A range of practical research methods were used in the analysis. A preliminary desk research was followed by a traditional policy analysis, examining event programmes and relevant planning documents. Forty-four interviews with key informants across the four case-study cities involved senior officers from city councils, port authorities, major cultural organisations, culture companies and event teams, as well as experts and academics. A small number of street interviews – approximately 5 to 10 in each city – was also carried out in waterfront areas and at the port-city interface, involving residents and visitors. These interviews were not aimed at producing quantitative data. Rather, they were used to validate information from other sources and to outline research hypothesis to be tested through the other research methods. Finally, non-participant observations, photographs and mapping were also deployed.

Four examples of port cities of culture

This section presents a brief overview of the four case-study cities. Each sub-section briefly outlines geographical and historical settings, pre-event regeneration strategies and event-led spatial transformation at the port-city interface.

Hull

Kingston upon Hull, or Hull, is a port city on the Humber Estuary, in Northern England. After peaking at more than 300,000 inhabitants in the 1930s, its population steadily declined in the following decades and recently rose again to 260,000 inhabitants. This was due in particular due to migration from Eastern Europe, albeit the ethnic composition of local population remained predominantly white British. In its 800 years’ history as a port city, Hull became the third largest port in the country in the 1930s. Shipbuilding – Hull is the port where the *Bethia*, later HMS *Bounty*, was built – and whaling were replaced by distant trawler fishing in the second half of the 20th century. However, overfishing and territorial waters disputes with Iceland – the so-called Cod Wars – led to the collapse of Hull’s fishing industry since the 1970s. This caused a slow and steady socio-economic decline, which made Hull one of the worst performing UK cities in terms of employment, education, deprivation and

health figures. Because of this steady decline, negative external perception and preconceptions have characterised the image of Hull up until the mid-2010s.

Since the late 1980s, urban regeneration focused on the city centre – which had long been considered as underperforming in terms of retail activity – and the waterfront. The city's old docks were redeveloped and Hull Marina (Figure 1, left) was opened in 1983. Victoria Dock was redeveloped in a residential area in the late 1980s and 1990s, while the aquarium The Deep (Figure 2) at Sammy's Point opened in 2002. The regeneration of the city centre was nonetheless halted in 2010 due to the impact of the economic crisis. The early 2010s also heralded a major development for the port of Hull, where Siemens located a £300 million wind turbine manufacturing facility (Figure 2), which contributed to generating additional jobs in the city.

1. Hull Marina (left) and Humber Street at the Fruit Market (right)

2. The Deep (left) and Siemens' wind turbine manufacturing facility (right, background).

In this context, Hull City Council bid twice for the UK City of Culture, in 2010 and then in 2013. The UK City of Culture (UKCoC) was proposed in 2009 and launched in 2010 with the aim of allowing other cities in the UK to benefit from the positive impact of cultural MEs, as happened in Glasgow. European City of Culture 1990, and Liverpool, European Capital of Culture 2008 (DCMS, 2009). The first UKCoC was Derry-Londonderry in 2013, followed by Hull in 2017. Although no major regeneration schemes were part of Hull's UKCoC bid, the event did have a transformative impact and contributed to boosting investment (e.g. £100 million invested by the City Council only) in the improvement of public realm, the refurbishment of cultural facilities such as the Ferens Art Gallery and the New Theatre and finally the regeneration of the Fruit Market (Figure 1, right).

Rotterdam

Rotterdam is the largest port in Europe, stretching for roughly 50km from the city centre to the North Sea. It is the second largest city in the Netherlands, with a population of roughly 630,000 inhabitants, and it is part of the urban region known as Randstad, which includes the other three major cities Amsterdam, The Hague and

Utrecht. Nearly half of Rotterdam's residents are foreign born (Entzinger and Godfried, 2014), in particular from former Dutch colonies, Turkey and Morocco.

The city and the port of Rotterdam were devastated during the Second World War and went under a long process of reconstruction in the following decades. In the 1990s, Rotterdam was facing the typical challenges of a declining industrial city, including deprivation and unemployment, and was in the shadow of Amsterdam. The transformation of Rotterdam from an industrial port city to a culturally vibrant port metropolis was initiated by both the City Council and the Port Authority. On the one hand, the City Council adopted a long-term strategy of attracting middle-income households to balance the social composition of the local population; on the other hand, the Port Authority realised that port competitiveness also depended on the attractiveness of the city itself, as ports require more high-skilled professionals (Aarts et al., 2012; Vries, 2014). In both cases, enhancing the city's cultural attractiveness was recognised as a key step, while cultural facilities and events were the tools to achieve this aim. Waterstad (Hajer, 1993) and the Museum Triangle (Meyer, 1999), as well as the large-scale redevelopment project for the Kop van Zuid area (Doucet, 2013) are examples of this policy.

After a few pioneering experiences of cultural events, cultural policy became a “spearhead of urban development” in the city (Hitters, 2000, p. 188). In 2000, Rotterdam was the city that hosted the final match of the UEFA European Football Cup, along with other matches in the group and knockout stages. All matches in Rotterdam were played at Feyenoord Stadium, which was refurbished for the event. A metro line connecting Feyenoord district to the city centre was also built. The following year, Rotterdam was also the European Capital of Culture. The European City of Culture (European Capital of Culture since 2001 – ECoC) was proposed in 1985 by the Greek culture minister Melina Mercouri. The first ECoCs, such as Athens 1985, Florence 1986 and Amsterdam 1987 were cultural festival in established cultural city. Glasgow 1990 marked a watershed in the history of the programme (Bianchini *et al.*, 2013) as it was a year-round cultural event focusing on urban regeneration. Since then, ECoCs attempted to use the event as a catalyst for urban regeneration, city branding and tourism development. The ECoC 2001 in Rotterdam was conceived to celebrate the rebuilding of its cultural infrastructure (Hitters, 2000). Although the event had very little physical impact – the transformation of the Las Palmas building on Wilhelminakade (Figure 3, left) into an exhibition space was one of the few examples – the ECoC was more oriented at presenting Rotterdam as a cultural city.

3. The Las Palmas building (left, bottom right), which was refurbished for the ECoC 2001, and view of the Erasmus Bridge and Kop van Zuid (right).

Genoa

Genoa is the sixth largest city in Italy, with a population of 580,000 inhabitants, and one of the country's main ports. It is the perfect example of a historic Mediterranean port city, where the city centre faces the historic port. Demographic growth in the 19th and 20th century was sustained by industrialisation, as Genoa was part in Italy's

Industrial Triangle together with Milan and Turin. Population peaked at more than 800,000 in the early 1970s. Since then, the decline of state-owned heavy industry and of port activity more broadly, together with the effects of the 1973 oil crisis, contributed to a steady structural economic and demographic decline. The inner harbour was also partly abandoned, as it was no longer adequate to the needs of maritime practices.

In this context, Genoa hosted a series of MEs and other large events in the 1990s and 2000s. These included a few matches of the 1990 FIFA World Cup, a Specialist Expo in 1992 in occasion of the 500th anniversary of the discovery of the Americas, the G8 summit in 2001 and the European Capital of Culture in 2004. These events were used as catalysts to trigger and sustain the redevelopment of Porto Antico – the inner harbour – and the city centre. Urban regeneration at the port-city interface can thus be considered as a result of a number of actions, rather than one single project (Gastaldi, 2012). Porto Antico was reconverted into a leisure port and open to residents and visitors for the 1992 Specialist Expo, albeit the event was not necessarily successful in terms of audience numbers. A €900 million investment included flagship facilities such as the Aquarium, Bigo and Piazza delle Feste and the redevelopment of the Magazzini del Cotone, while the Biosfera by Renzo Piano was built for the 2001 G8 summit (Figure 4). The European Capital of Culture 2004 included a €220 million investment in physical interventions, such as the restoration of a number of heritage buildings in the city centre and the construction of the Galata Museo del Mare (Maritime Museum) in a city-owned dock.

4. Flagship cultural facilities on Genoa's waterfront: the Biosfera, the Aquarium, Piazza delle Feste and Bigo; Galata Museo del Mare (Maritime Museum, right).

Valencia

Valencia is the third largest city in Spain, after Madrid and Barcelona, and the second busiest port in the country, after Algeciras. Its population account for more than 800,000 inhabitants. Unlike other Spanish cities like Barcelona, Malaga or Alicante, the city centre is located about 6km inland, while the port faces the Mediterranean Sea and it is surrounded by a few historical maritime urban districts.

However, Valencia was not an industrial port city. Its traditional economy was based on agriculture and horticulture, while the port served as a gateway to export agricultural products (Prytherch & Boira i Maiques, 2009). The deviation of the River Turia to the South – after the severe flood occurred in 1957 – and the 1988 spatial plan set the conditions for the development of contemporary Valencia. Since the mid-1980s, a linear park called Jardín del Turia was built on the dry bed of the river. Flagship cultural facilities were also built, such as the Palau de la Música in 1987, the Palacio de Congresos by Norman Foster in 1998 and the iconic Ciutat de les Arts i les Ciències from 1998-2002. Between the late 1980s and the late 1990s, a huge port expansion took place to the South, with the construction of the logistics zone. This generated considerably port-city tension to the South, where the port engulfed the district of Natzaret and caused the destruction of La Punta.

In this context, Valencia hosted the America's Cup 2007 and 2010. The 2007 edition saw more than €400 million invested in the transformation of the inner harbour, which was redeveloped as a leisure port and separated from the commercial port through the construction of a new exit channel. From 2008-2012, Valencia also hosted the Formula One European Grand Prix in a dedicated street circuit which was realised in and around the port estate (Figure 5).

5. Valencia's inner harbour during the America's Cup 2007 (left); part of the Valencia Street Circuit along the inner harbour (right).

MEs at the port-city interface

This section briefly outlines and discusses the findings in relation to the evolution of port-city relationships in Europe. The first sub-section explores questions of spatial outcomes and permeability of waterfront areas, while the second discusses issues of cultural involvement of port authorities and socio-cultural port-city links.

Socio-spatial port-city relationships

Although contributing to reversing the tendency of physical and functional separation between ports and cities, MEs in the four case-study cities have had rather different outcomes in terms of direct physical impact. Little or no transformation was produced in Hull and Rotterdam. In the former case, key cultural facilities were refurbished and public realm was renovated, while the event had only an indirect impact on the ongoing redevelopment of the Fruit Market. In the latter, the Las Palmas building and Villa Zebra were the only exhibition and museum spaces developed for the ECoC 2001. On the contrary, MEs were used for the reconversion – and reconnection with the city – of historic inner harbours in Genoa and Valencia. In both cases, these areas were partly or fully inaccessible by residents and visitors, albeit no longer used for maritime activities, and were transformed into public spaces through MEs.

In part, this has to do with geographical settings and traditional port-city relationships. However, adopting Evans's (2011) view of MEs as pivotal moments along the cities' trajectories of urban development and regeneration, the position of MEs along these trajectories becomes crucial. In the case of Hull and Rotterdam, MEs did not have significant direct physical impacts also because waterfront redevelopment was already at an advanced stage, since considerable transformation had taken place in the 1970s and 1980s. In these cases, MEs were used more as branding devices, in particular to tackle the negative aspects of the port city image. Nonetheless, MEs produced considerable impacts in other domains of port-city relationships, such as the cultural involvement of port authorities (see next section) or in the intangible cultural links between cities and ports. Conversely, in the case of Genoa and Valencia, MEs were used to overcome the physical and functional separation that still characterised port-city relationships in the early 1990s and 2000s respectively, through a redesign of the port-city interface.

In either case, the concentration of investment and regeneration at the port-city interface through MEs risks producing “spatial dilemmas” (Bianchini, 1993, p. 201). In all four cities, waterfronts have become attractive areas, even for international tourism. However, this transformation has arguably widened the gap with the ‘back city’, which did not benefit from such regeneration processes. Examples are Hull’s housing estates, Feyenoord in Rotterdam, part of Genoa’s city centre and Natzaret in Valencia.

Whether MEs were used to achieve this reconnection or as branding devices, the permeability of the port-city interface represents a crucial issue. In Hull, Genoa and Valencia, waterfront spaces were used to host cultural events or redeveloped more or less directly through MEs. However, waterfront areas in these cities display rather different degrees of permeability. In Genoa, the pedestrianisation of Porto Antico and its reconnection with the nearby city centre was also facilitated by the fact that, back in the 1960s, a flyover was built to improve the accessibility of the port. Conversely, in Hull and Valencia, port ring roads are still used by road traffic. In Hull, Castle Street – part of the A63 road connecting Leeds with the port of Hull – separates the city centre from the Fruit Market and the waterfront (Figure 6, left). In the bid for the UK City of Culture 2017, £170 million were budgeted for road improvement, which were considered “critical to festival venues” (Hull UK City of Culture 2017, 2013, p. 77). However, the iconic footbridge that was designed to overcome this barrier is still under construction in 2019. Although much less busy because of port expansion to the South, the road that borders Valencia’s leisure port still represents a barrier to permeability (Figure 6, right).

6. Castle Street in Hull (left) separates the Old Town (on the right) from the Marina, the Fruit Market and the waterfront (on the left); the port ring road in Valencia (right) also represents a physical barrier.

In this case, if the America’s Cup 2007 was used to convert the inner harbour into a leisure port with the aim of connecting Valencia to the sea, the subsequent Formula One events contributed to retaining this barrier. As pointed out by one informant:

“It’s true that the port-city relationship was not optimised, because Formula 1 prevented that the road that every port city has, or had, between the city and the port... This road ring was kept because it formed part of the [F1] circuit. So, it wasn’t pedestrianised.” (Interview with academic, 2018, author’s translation).

The case of Valencia also shows how the unmanaged legacy of MEs can worsened permeability and accessibility. After 2012, Valencia Street Circuit was abandoned, while part of it was fenced off (Figure 7). This contributed to further isolating Natzaret, which had been engulfed by port expansion and now is cut off from the city centre. A port-city agreement was reached to attempt to reconnect Natzaret to the rest of the city.

7. The impact of the abandoned Valencia Street Circuit on the permeability of the port-city interface.

Socio-cultural port-city relationships

MEs in port cities are also an opportunity to explore the ‘cultural’ role of port authorities. The disruption of traditional port-city relationships based on proximity and mutual dependence, technological developments, automation and securitisation are amongst the factors fuelling the “dehumanisation” of seaports (Van Hooydonk, 2007, p. 42). In addition, port cities still face issues of negative external image in relation to perception of poverty, crime and negative port externalities such as congestion and pollution. In this context, port authorities are increasingly interested to contribute to the city’s development and branding to both legitimise port operations and to increase competitiveness. As noted by Vries (2014), the attitude of port authorities can be mapped between two extremes: port authorities as landlords, where they only manage the port and have little or no contact with the city, and as developers, where they take part in the political and cultural life of the city.
