¹ For example, the Eamau-Ecole Africain des Metiere dell'Architecture e de l'Urbanisme requests is funded by each member state and by the UEMOA for courses. The occasion is the UEMOA-Economic and Monetary Union of West African countries (there are eight) that have an important role given the economic support given to university education, since the states participate with reference to what is required by the Eamau.

The collaboration between the Sapienza and IPP offered valid support to define the specific needs of each territory in order to better share the priorities of an action for sustainability: a) networking and enhancing the experience gained in the various Italian cities; b) accompanying the interaction between the different parts; c) promoting open and inclusive participation processes.

The adopted scheme of SHARING > EXPERIENCING > PRACTISING used among Italian and Senegalese university partners is oriented towards sustainable development objectives through the sharing of experience and reflections on the importance and implications that sustainability effected on the quality of life on an urban scale, strengthening and, by “doing together”, further validating plans and rules for the sustainability and inclusiveness of western African cities. Pursuing sustainable development objectives is indispensable for the survival and development of European as well as African cities. However, we also need to cooperate to fill the culture and knowledge gap as regards sustainable development by exchanging knowledge with African universities and cities, thereby supporting them on the urban planning design issue and experimentation at the local level for strengthening urban governance and contributing to the achievement of SDG 11.

The project is trying to bring together the different experience and knowledge of the Sapienza and IPP by trying to promote directions for long-term sustainable development plans for the sustainability and inclusiveness of western African cities based on a larger network of universities. It is therefore a working hypothesis that converges the pragmatism and skills of those who work on these issues – theoretically as universities and practically as local authorities – in order to intervene on a concrete reality while aiming to deduce directions also useful for those African cities that, due to political and administrative instability, cannot at this moment set themselves the urgent goals of sustainable development.

For the future, more exhaustive experiment objectives should include: - sharing sustainable inclusive development by bringing together Italian urban experience and practices and those of African cities (starting from Dakar), the better to reach jointly the 11 goals through plans and a regulatory framework;

- experiencing sustainable inclusive development by selecting areas for demonstrating at a practical level how urban resilience could be experimented on the urban scale;
- carrying out sustainable inclusive development to strength urban governance by involving the population in the process.

We feel sure this will have positive effects on:

- incentivizing. Technicians and professionals of all local authorities will be better stimulated to do their job. Adequate incentives for local authority technicians and professionals are generally sadly lacking, while playing a very important role in developing new competencies and skills for urban resilience and sustainability, starting from public institutions;
- Best practice. Researchers and academics in the field of urban planning, environmental engineering, and administrative law are considerably interested in comparing practices for defining plans and new and more adequate rules for pursuing sustainable development goals in the different contexts;
- Public involvement of inhabitants, local associations, school and university students of all the cities involved, particularly the citizens themselves.

A collaborative learning approach to promote positive interdependence in a “Planning Sustainable Cities” course

Javier Martinez¹

Abstract: Following the scholarship of teaching and learning, this study is contextualized in a “Planning Sustainable Cities” course. It presents a collaborative learning approach to promote positive interdependence. Under certain conditions, collaborative learning approaches can promote among students each other’s efforts to learn, resulting in positive interdependence (cooperation). However, cooperation is not always facilitated, and it might be challenged when students have diverse backgrounds. This study incorporated elements of mixed-methods and design-based research approaches. Pre and post-intervention surveys were conducted with 23 international students as well as in-depth interviews and focus group discussions on the type and level of collaboration, and student’s view of cooperative learning. Based on the results of the descriptive phase and the literature, we addressed two key issues during the design phase: improving group dynamics and facilitating collaboration in the Learning Management System (LMS). No outside enemy interdependence was observed (negative interdependence with another group). Means interdependence is the most predominant characteristic of positive interdependence present in group work and positively perceived by the students. In the collaborative learning approach that was designed, both a group dynamics workshop (analogue/in class) and group pages in the LMS seem to help in improving means interdependence.

Keywords: scholarship of teaching and learning, design-based research, collaborative learning, positive interdependence

Introduction

Following the Scholarship of Teaching and Learning (Bishop-Clark and Dietz-Uhler, 2012), this paper self-reflects and is grounded on the opening course of the MSc specialization on Urban Planning and Management (UPM) of the Faculty ITC of the University of Twente (the Netherlands). The UPM specialization consists of four interconnected courses of 7 ECTS credits each:

- UPM 1. Planning Sustainable Cities
- UPM 2. Building Inclusive and Competitive Cities
- UPM 3. The Compact City
- UPM 4. Risk-Sensitive Urban Planning Studio

Students of these courses are international and predominately from the Global South. This paper relies on the critical analysis of the “Planning Sustainable Cities” course where group work is one of the main teaching activities. Some of the advantages of group work are that students have the potential to maximize and share their skills with the rest of the group (Brewer and Klein, 2006; Haigh and Gold, 1993). However, during group work, cooperation is not always facilitated and motivated and it might be challenged when students have different cultural backgrounds, disciplines or skills (Hennebry and Fordyce, 2018).

I would argue that in a diverse and unequal world educating (future) planning practitioners requires them to practice empathic and collaborative forms of learning as opposed to competitive ones. Competitive values are clearly differentiated from those of *cooperative efforts*. Cooperative efforts values comprise “commitment to one’s own and others’ success and well-being, commitment to the common good, and the view that facilitating and promoting the success of others is a natural way of life” (Johnson and Johnson, 2009, p. 372). On the contrary, *competitive efforts* teaches the values of “getting more than others, beating and defeating others, seeing winning as important, and believing that opposing and obstructing the success of others is a natural way of life” (Johnson and Johnson, 2009, p. 372). In collaborative efforts group membership per se is not enough to produce higher achievement and cooperation, “knowing that one’s performance affects the success of group mates seems to create responsibility forces that increase one’s efforts to achieve” (Johnson and Johnson, 2009, p. 366).

Under certain conditions, collaborative learning approaches can promote and facilitate among students each other’s efforts to learn, resulting in *positive interdependence* (cooperation) (Brewer and Klein, 2006), critical thinking (Cooper, 1995) and students satisfaction (So and Brush, 2008). A typical structure of collaborative learning is think-pair-share. This study concentrates only on positive interdependence as long-standing evidence shows that it is at the core of collaborative learning (Johnson, Johnson, and Smith, 2007, p. 23; Laal, 2013, p. 1436).

However, there are different views on how to establish positive interdependence (Brewer and Klein, 2006) and new challenges emerge with the incorporation of digital tools (Jaldemark, Hrastinski, Olofsson, and Öberg, 2018). Therefore, the main goal of this research is to develop a (computer-supported) collaborative learning approach that promotes positive interdependence in a group assignment. This collaborative learning approach entails the use of digital tools such as a learning management system (LMS) as well as analogue methods (e.g. group dynamics coaching). The main research question of this research is:

How can certain computer-supported collaborative learning approach facilitate positive interdependence in a group assignment?

Effective cooperation and positive interdependence

Johnson and Johnson (2009) theorized that five variables mediate effective cooperation: positive interdependence, promotive interaction, individual accountability, social skills, and group processing. Furthermore, positive interdependence it is also considered as “the heart of cooperative efforts” (Johnson *et al.*, 2007, p. 23) and a pivotal aspect (Laal, 2013, p. 1436).

Positive interdependence exists when “there is a positive correlation among individuals’ goal attainments; individuals perceive that they can attain their goals if and only if the other individuals with whom they are cooperatively linked attain their goals” (Johnson and Johnson, 2009, p. 366). Positive interdependence encourages students to work together in order “to maximize the learning of all members, sharing their resources, providing mutual support, and celebrating their joint success” (Johnson *et al.*, 2007, p. 23). Johnson and Johnson (2009) also consider that positive interdependence results in *promotive interaction* and they give the example of “individuals encouraging and facilitating each other’s efforts to complete tasks in order to reach the group’s goals” (Johnson and Johnson, 2009, p. 366).

Types of positive interdependence

The literature on cooperative learning describes three main types of positive interdependence: *outcomes*, *means* and *boundaries interdependence*. From a motivational perspective, the goals and rewards that are defined in the project group task will encourage and orient the students to cooperate and work towards a common desired outcome (*outcomes/end state interdependence*). For example, a group could get a joint reward (a bonus) when every member of the team obtains a specified score (Johnson et al., 2007). Slavin (1996, p. 44) indicates that “cooperative incentive structures create a situation in which the only way group members can attain their own personal goals is if the group is successful”. The way that students perceive goals and rewards will influence what means they will choose to achieve the desired end state (Johnson & Johnson, 1992).

Means interdependence -and those proposing a social cohesion perspective- include the (complementary) *roles* that students are assigned within the group and the *tasks* assigned to individuals (tasks which are overlapping and interdependent on each other). Social cohesion theorists, “emphasize the idea that students help their groupmates learn because they care about the group” (Slavin, 1996, p. 46). Teambuilding, group self-evaluation and other cohesiveness-building activities can teach students value their groupmates, their roles will also make them dependent on one another and more likely “to encourage and help one another to succeed” (Slavin, 1996, p. 46). From a cognitive perspective the tasks and interactions that students perform will benefit cooperation and e.g. critical thinking for “reasons which have to do with mental processing of information” (Slavin, 1996, p. 49). Slavin (1996) explains the importance of group interactions and how students learn from each other since “in their discussions of the content, cognitive conflicts will arise, inadequate reasoning will be exposed, disequilibrium will occur, and higher- quality understandings will emerge” (Slavin, 1996, p. 49). *Resources interdependence* is the third subcategory of means interdependency and requires that each member has part of the resources needed to complete the task (Johnson et al., 2007, p. 23).

Boundaries among individuals and groups will also determine positive interdependence as they will determine who is interdependent with whom. Johnson et al. (2007, p. 23) state that *boundaries interdependence* may be determined by the way individuals are segregated into different groups based on “abrupt discontinuities” (e.g. students seat together, wear same shirts or share history). Three subcategories are recognized: *environmental* (related to the specific work area), *identity* (what binds students together), and *outside enemy* (negative interdependence with another group). This last sub-category, in my opinion and based on my teaching practice, may be problematic as it contradicts the values of cooperative learning by establishing an “outside enemy”. My assumption is that inter-group cooperation also generates intra-group cooperation and that groups do not compete against each other.

In this study, I focus on positive interdependence because its three categories: outcomes, means and boundaries interdependence are in direct relation to how a teacher designs the teaching and learning environment. In turn, positive interdependence results in *promotive interaction* and occurs when students encourage and facilitate each other’s efforts to complete tasks and achieve the group’s goals by (a) helping and assisting each other, (b) exchanging needed resources such as information and materials, (c) providing each other with feedback, (d) challenging each other’s conclusions and reasoning, (e) advocating working harder to achieve the group’s goals, (f) influencing each other, and (g) acting in trusting and trustworthy ways (Johnson et al., 2007, p. 24).

Theoretical framework

Figure 1 summarizes the theoretical framework used in this study. It focuses on a collaborative learning approach aiming at effective cooperation as a result of distinct types of positive interdependence. Based on this theoretical framework, the main research goal for design research is to develop a (computer-supported) collaborative learning approach that promotes positive interdependence in a group assignment.

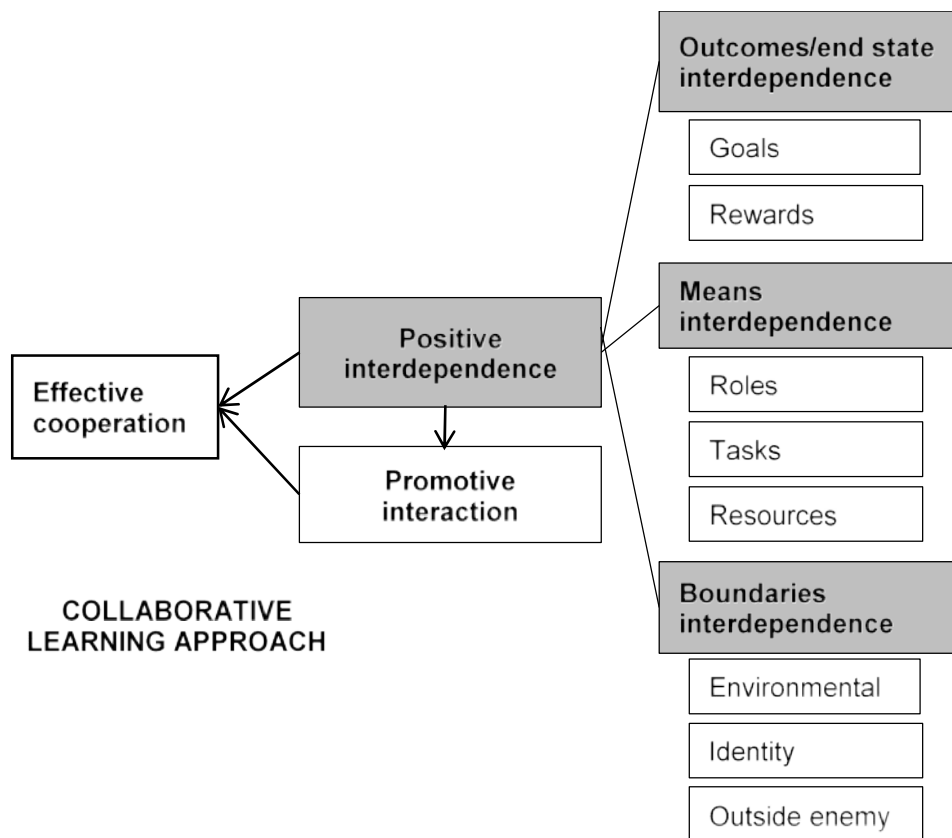

Figure 1 Theoretical framework. Positive interdependence types in collaborative learning.

Methods

This study incorporated elements of a mixed-methods (QUAL-quant) approach (Bryman, 2006; Tashakkori and Teddlie, 2010) and designed-based research approach. A better understanding of the needs, design and evaluation of a (computer-supported) collaborative learning approach required both the use of quantitative methods (e.g. cooperative learning questionnaire survey) as well as in-depth understanding of the type and level of collaboration, what students think about cooperative learning and why. The research participants were 18 students registered in the elective module “Analysis of intra-urban, socio-spatial patterns” (cohort 2017-2018) and 23 students of the UPM specialization course “Planning the Sustainable City” (cohort 2018-2020).

Data collection

Data was collected to 1- improve the understanding of student’s perception of group work, current obstacles and forms of group interaction; 2- to design a computer-supported collaborative learning approach; and 3- to identify what dimensions of positive interdependence emerge through collaborative learning.

During the different phases of this study, data was collected on 1- Students perception of group work assignments, current obstacles in group cooperation, types of positive interdependence and extent of use of Learning Management System tools in those interactions (descriptive phase), 2- types of positive interdependence emerging from computer-supported collaborative approaches (design phase), and 3- recommendations emerging from discussion with colleagues and course evaluation (evaluation phase).

Data was collected between June and December 2018 through: one paper based self-administered survey (Cooperative learning questionnaire –(Fernandez-Rio, Cecchini, Mendez-Gimenez, Mendez-Alonso, and Prieto,

2017)), one in-depth interview with alumna, two focus groups discussions (FGDs) and observations in the use of the LMS CANVAS™. As course coordinator and teacher, I collected the data myself and asked the support of a colleague to conduct the FGDs. The first FGD was conducted as a practical within a research methods class after the students had learned about FGDs. The facilitator was one of the students and we provided her with the conceptual framework. This help reducing the research-participant gap and power bias. The final FGD was moderated by an education specialist and was part of the course evaluation.

The measurement level of the quantitative data from the survey is ordinal (liker scale). The rest of the data is qualitative (text).

Secondary data was compiled and they consisted of formal course evaluations (EVASYS™) and instructions of similar group assignment used in the last 3 years.

Ethical standards and concerns

Participants were informed about the project and gave their consent (in written for survey and verbally for FGD). The FGD was recorded after informed consent. To reduce power bias, I used triangulation (i.e. anonymous students' evaluation of previous years) and final evaluation discussion was conducted by education specialist. Storage and processing of data is done following ITC protocols.

Analysis

The analysis of the data was done in three phases.

1. *Descriptive phase / needs analysis.* It included the definition and construct of positive interdependence (Figure 1) and current collaborative learning. I analysed the in-depth interview with former graduate, FGDs and course evaluation by making use of ATLAS.ti™ (axial coding).

2. *Design phase.* It included the design intervention (evidence-based). I used an existing and validated “cooperative learning questionnaire” (Fernandez-Rio *et al.*, 2017). The results of the survey were processed in SPSS. The variables were grouped into each of the five scales (including positive interdependence) using the median. I analysed pre- group work activity (before intervention) and the types of positive interdependence with descriptive statics of the survey.

3. *Evaluation phase.* It included an evaluation of the approach and recommendations for further design. I analysed and compared pre and post group work activity (after intervention) and the types of positive interdependence with descriptive statics of the survey. The results were compared with the pre- group work activity survey. I used text analysis to study the open questions of the course evaluations and the FGDs to identify which characteristics of positive interdependence where achieved during the group work.

Results and discussion

Descriptive phase

This section presents the results of the descriptive phase and it is structured around the sub-questions, qualitative data, literature review and quantitative data.

Students' perception of group work assignments and types of positive interdependence

Above all students are positive and value group work. As one student stated:

“For me group works is really important for the UPM course and they are the backbone because during those group works students learn a lot. So that’s one thing we cannot do without in UPM class”

In the course evaluation, one student specified that group work is particularly helpful during certain phases of the work such as sharing ideas:

“Group work is good especially in the analysis of data, you can learn some ideas from the other group members and build on your skill” [...] “It allowed sharing of ideas with colleagues”

A recurrent positive issue about group work during the FGD was that students appreciate the learning from different and each other’s backgrounds, skills and discussion. This is in line with studies that emphasize the cognitive perspective in group work (critical thinking) and social cohesion in particular. Slavin (1996) explains the importance of group interactions and how students learn from each other since “higher- quality understandings will emerge” as a result of the discussions (Slavin, 1996, p. 49).

The three types of positive interdependence (Figure 1) emerge from the interview and FGD but with different degrees of prevalence.

1- Outcomes / end state interdependence

For some students the main goal and motivation was to finalize the assignment in time and successfully. As one student put it “you need a common output”.

The importance of group integration in positive interdependence can be recognized in the words of this student: “For within the group I think you need a kind of 100% interaction because if you don’t integrate well the assignment will not come out well”. Therefore, providing a good output of the assignment was the motivation for that group to seek for integration within the group members.

A different type of motivation was present in students that received a scholarship. They were motivated to help each other to obtain a final group mark above the threshold required by the scholarship regulations.

Working together did not prevent that some students recognize individual learning goals as well. As one of the students explains:

“My goal was, regardless of whether we have to finish the assignment; I had to understand all the aspects of the assignments. For instance, if it was about spatial analysis and even if I am not the one doing the spatial analysis I have just to do it and get to know how has this person done the spatial analysis”

Above all, several students perceive the need to bring –as one student put it- “different strengths together to succeed”.

2- Means interdependence

From all the forms of positive interdependence means interdependence was the one that students discussed most about during the FGD.

The tasks and roles are clearly divided within the group and they are interdependent of each other. However, some students complain that they remain in their role and expertise throughout the course:

“So if I am assigned to do the things that I am able to do then I was continuously doing GIS work but I am not learning how to become a planner. So you should assign different people to different works so you can learn something else”.

All the students recognize the existence of a process of negotiation to identify skills and distribute tasks. Before starting the group work, students divide the tasks based on their existent skills and they negotiate who is doing what. One of the interviewees explains this process:

“First of all, when setting the TOR, I mean the division of labour, we tried to pick what you are good at, what you think you can handle comfortably or even with some effort. If you are not very sure about a particular section, it makes no sense to pick it...because then you don’t deliver”.

Another student added that the “most important thing is to coordinate all the work. You need to give...divide the work into several parts and everyone should complete their own part”. This negotiation process seems to be a pre-requisite for the fulfilment of expected outcomes. It requires strong social skills and determines the importance of social cohesion in the group. In some cases, this seems to be challenged by problems of communication among members. Some students complain that some participants were absent during work and did not communicate with the rest of the group.

In terms of resource interdependence, each member of the group has parts of the resources needed to complete the task. This is confirmed by one interviewee, and particularly in relation to resources provided to each of the groups by the teachers:

“One of the best things about assignments in UPM or ITC is that most of the resources such as data you find that is provided or is from case studies, from real life projects. So you find each and every student is able to access that”.

3- Boundaries interdependence

Boundaries among individuals and groups will also determine positive interdependence as they will determine who is interdependent with whom. From the analysis of the interviews, it seems that the environmental interdependency subcategory (*where* students work) plays a role in this but neither the distribution of the furniture nor the LMS had been designed considering that aspect.

The international character of ITC may be the identity that binds together members in a group. From the text analysis no outside enemy interdependence was observed (negative interdependence with another group); on the contrary, several students indicated that the collaboration transcends the boundaries of their own group:

“If we had a group discussion the class was the perfect environment because at the class you were able to know what the other groups are doing, are you also at the right direction and the lecturers were able to pop in and see if you are working well. So the classroom was the perfect place for group discussion”

Another student further elaborated on inter-group cooperation:

“We were able to solve any difficulties that arise among, for instance if it is a group that has a difficulty for instance in analysing flooding, they do not know how to use the tool, they are able to get the way or to get the skill from another member form another group”.

In terms of environment interdependence, students prefer to work in a classroom designated for group work as they can consult each other (within the groups and across the groups), “the classroom was the perfect place for group discussion”. Lecturers also came in to respond questions or support students. In case of extra work required to reach a certain deadline, students use the facilities at the ITC Hotel (the student accommodation provided to international students enrolled in ITC courses).

Current obstacles that hinder cooperation during group work and types of interaction

Most of the obstacles that students mention relate to social cohesion (e.g., group formation) rather than motivation (lack of goals or insufficient rewards). In terms of motivation, some students find that the weight of

the group mark is too low (in the case they mention they suggest that it should be 50%, equally to the individual reflection report). The pressure to achieve a certain group mark above threshold due to sponsor or scholarship regulations was also mentioned as an obstacle.

Several obstacles related to social cohesion and means interdependence were mentioned during the interviews. Some students prefer to choose the members of the group themselves (as they know the skills and capabilities of their potential partners) and even completely refuse to work with others (at least one case was mentioned during the interviews). The later generated conflicts especially when a lecturer allowed those students to work individually and they were exempted to integrate with the other groups. One student also reflected that some short course participants (those that are enrolled only for a particular course and not the full MSc) probably had different motivations to work in groups:

“There are people that come for short courses...their motivation is different from ours. Some of the groups that collapsed had this kind of people who came here for a SC [short course]. Maybe their main motivation was to go to Amsterdam Friday night...this kind of things creates a problem”

Finally, some students feel trapped in the role that was assigned to them in the group work (e.g. “the mapmaker or the GIS expert”) and they must conduct that role throughout the course. Rules on group dynamics are present in the group assignment but they seem not to motivate students to cooperate or to facilitate social cohesion. It is worth noting that none of the students mentioned boundaries interdependence elements hindering cooperation. From this, and the staff meeting discussed in the following section, it was clear that in the design phase social cohesion and means interdependence should receive special attention.

Types of positive interdependence explicitly stated in previous UPM assignment

The UPM group assignment that has been used in the past (The Sustainable City, cohort 2017-2019) only included a separate section with brief indications on groups dynamics to determine roles (e.g. coordinator and reporter). No rewards for group work or clear objectives for the need of group co-operation were reflected in the rubric. During a meeting with teachers involved in group work I also identified current challenges (e.g. lack of specific objectives in the study guide that justify group work). One of the outputs from that meeting for the design phase (also in coincidence with the literature) was to have a cohesiveness building and group dynamics activity.

Types of tools students use in and outside the LMS for group interaction

During the FGD students indicated that they mostly use WhatsApp™ groups to make appointments and Google™ Drive or Dropbox™ to exchange and share data outside the LMS (that cohort had used BlackBoard™). Eventually e-mail is used as “sometimes Google Drive does not work”. From the FGD it came clear that the design of the computer-supported collaborative learning approach could incorporate elements to facilitate means interdependence (e.g. facilitate discussion and sharing of data) but other elements related to social cohesion and group dynamics should be conducted in classroom. The next section discusses the literature review on computer-supported collaborative learning. Some of the studies show comparable results.

Computer-supported collaborative learning

Research on computer-supported collaborative learning shows that learning management systems (LMS) enhance collaboration (Jaldemark et al., 2018). In particular, group interaction usually increases significantly in the phase of project where students need to exchange work (Taylor, 2005, p. 35). Asynchronous interaction can be facilitated by computer-supported environments and offers advantages to collaboration such as reflection. Furthermore, “document sharing communicates project focus and demonstrates progress toward the final deliverable. Autonomously intra-group interactions —discussions, problem solving, sharing, revising,

reviewing, and commenting are all important learning opportunities” (Taylor, 2005, p. 35). Contrariwise, in the University of Twente a report showed that group collaboration is hardly used within the LMS (i.e. BlackBoard™). Students choose to use tools outside the LMS (i.e. Whatsapp, Dropbox and Google-tools). In the faculty ITC the function “groups” in BlackBoard was only used by 9% of the respondents (University of Twente, 2015).

In a project carried out for the Media Studies Seminar at the Katholieke Universiteit Leuven, computer-supported collaboration was used to facilitate positive interdependence (Buelens, Mierlo, Bulck, Elen, and Avermaet, 2005, p. 129). The authors indicate that to favour high positive interdependence they created a fair division of tasks “by partitioning group work into mutually connected sub-tasks, and by advising about role and turn taking within subgroups”. The authors further promote means interdependence, and to enhance individual accountability and responsibility, they subdivide the task in smaller units and students have to peer assess their contribution within the group at four points during the academic year. Some of the tools mentioned by the authors were aimed at facilitating *information delivery and information exchange* between students (e.g. digital drop boxes, group pages, and group calendars). To prepare (and follow up) regular face-to-face meetings, *asynchronous communication tools* (e.g. group email and group discussion forums) were also provided. Some elements of boundaries interdependence are observed in this project as the authors claim that “besides facilitating group work in a direct way, having a virtual group space at one’s disposal was also intended to enhance a feeling of belonging to a group” (Buelens *et al.*, 2005, p. 129).

There are claimed benefits related to the use of social media to facilitate interaction and sense of community within groups. Some authors claim that current students as “digital natives” tend to use social media as their primary source of information (Ahern, Feller, and Nagle, 2016). These authors report that students prefer “unofficial” channels of communication instead of “official” channels (e.g. LMS or e-mail). The choice of using unofficial channels like Facebook seems to be related to the easy to access characteristic of Facebook, which motivates them to interact with each other.

Results of cooperative learning questionnaire before design

Table 1 shows the results of the cooperative learning questionnaire. This was used to measure the level of positive interdependence perceived by the students in the cohort 2017-2018.

Table 1 Cooperative learning survey cohort 2017-2018

		Cooperative learning perceived by students				
		Positive Interdependence	Individual and group accountability	Promotive interaction	Interpersonal skills	Group processing
N	Valid	18	18	18	18	18
	Missing	0	0	0	0	0
Mean		4.3333	4.3333	3.9444	4.1944	4.1389
Median		4.0000	4.5000	4.0000	4.0000	4.0000
Std. Deviation		.56880	.56880	.78382	.59752	.63722
Range		2.00	2.00	2.50	2.00	2.00
Minimum		3.00	3.00	2.50	3.00	3.00
Maximum		5.00	5.00	5.00	5.00	5.00

Note. Likert scale 1-5 (1 strongly disagree, 5 strongly agree)

Promotive interaction is the scale with the lowest value and the highest standard deviation (Table 1) this can also be observed in the percentage of responses in some of the items (Figure 2) such as in questions 19, 14 and 8). The disagreement in the responses on question 8 “we cannot finish an activity without the contribution of our colleagues” could be explained by some specificities in the group related to the type of sponsor or funding rules students have. As some students explained, if they must take over a task from someone else to finish the work and obtain a higher mark, they will do it, in particular if they feel the pressure to obtain a higher mark due to sponsor regulations. In the group dynamics section of the previous UPM assignment there was no indication given to the different expectations students may have while starting a group work.

The literature shows the importance of sharing material in order to facilitate positive interaction (Buelens *et al.*, 2005, p. 129). Yet, 17% of the students disagree that sharing materials is important (question 13 in Figure 2). In the design phase social cohesion, means interdependence and sharing facilitation receives special attention.

Figure 2 Promotive interaction (19, 14, 9, 4) and Positive interdependence (18, 13, 8, 3) responses students (cohort 2017-2018).

Design phase

Based on the results of the descriptive phase and the literature review I addressed two key issues during the design phase: 1- improving social cohesion through group dynamics workshop and 2- facilitating collaboration in CANVAS through asynchronous tools.

To improve social cohesion and group dynamics, I had a meeting with teachers involved in group work and we identified the main obstacles in group dynamics. We incorporated a group dynamics workshop the first day that the group assignment was presented. The other main element of this approach was incorporated in the

formulation of the assignment and in the design of the course material in CANVAS. We paid attention at the following dimensions of positive interdependence.

1- Outcomes / end state interdependence

We included a peer assessed item in the rubric for “active group participation” including these items:

“Rate your group members. Rate yourself at your own name on:

- a- “Active participation in group discussion” (contributing with ideas, discussing, communicating)”, and
- b- “Active working on agreed tasks (according for example the group contract)”.

The possible responses ranged from 1 (contributed scarcely) to 5 (contributed significantly). We intended to incorporate this peer assessment using an LMS extension called WebPA (which had been functional in BlackBoard) but it was not possible in CANVAS. The assessment was conducted in Google forms.

We included in the rubric 5 points (out of 115) to every student that collected green space data and shared it to the rest of the groups.

One of the outputs of the group dynamics workshop was a group contract. Each group had to sign a group contract where they also made explicit their expectations (e.g. if they aim at having a higher mark due to sponsor). Each group uploaded their group contract in CANVAS within the group home page.

2- Means interdependence

In CANVAS we included collaboration tools and instructions to facilitate cooperation and communication. They included group pages, group work discussions page and a group dynamics pages with invitation to the group work dynamics workshop. We included videos (tutorials) on how to use these tools.

Each group received its own group home page where they could upload files, share data, and create group discussions. The structure of the group page was pre-designed to stimulate cooperation –i.e. folders included names such as shared data and shared literature.

The group assignment pages included the instructions for the assignment and hyperlinks to group pages and general discussion section for group work questions.

3- Boundaries interdependence

The classroom was divided in two spaces, one for lectures and group presentations (traditional classroom arrangement) and one for group work (five tables and workshop material were always available in the room). Students were encouraged to appropriate the space and hang posters if needed.

Student created a name for their group to stimulate positive identity interdependence (e.g. “The dreamers”, “Bizck-T”)

In the meeting with teachers involved in the course we decided that it was better that I (course coordinator) assigned members to each of the group. Five groups were preassigned mixing gender, country of origin/continent and course duration (2 years MSc or short course). In total, there were three groups of five members and two groups of four members. One of the students indicated during the FGD that their preference was to choose themselves the members of the group but, on the other hand, they understood that in real life projects, and in particular, in the field of planning, they have to work within a team of people they do not necessarily choose.

Evaluation phase

This section aims to evaluate the design of the LMS. It compares the survey scores of the cooperative learning questionnaire before and after design and tries to find out explanations of possible changes.

The quantitative analysis shows a slight improvement in the perception of positive interdependence after the group work. The mode and mean in positive interdependence increased from 4 to 5 although the standard deviation and strongly disagreement responses increased (Tables 2 and 3). This can be observed in the statement “*we cannot finish an activity without the contribution of others*” with an increase of those who disagree from 13% to 33% (Figure 3). The statement “*It is important to share materials, information to do the tasks*” received responses that are more positive after the intervention. The percentage of students who perceived sharing materials as important increase from 52% to 71% (strongly agreed with the statement). From the qualitative analysis this could be explained by the positive perception that students gave to the group pages in the LMS as a place to share information within the group.

4. Conclusions and recommendations

The quantitative and qualitative analysis show that means interdependence is the most predominant characteristic of positive interdependence present in group work and positively perceived by the students. In the collaborative learning approach that was designed, both the group dynamics workshop (analogue/in class) and the group pages in the LMS seem to help in improving means interdependence.

Outcomes interdependence requires further attention as the objectives of the group work and the instructions uploaded in the LMS are not always clear.

In terms of boundaries interdependence, it seems that working in class in different groups is favoured by the students and even more when there is the possibility of contacting the staff in class (e.g. to receive feedback). No outside enemy interdependence was observed (negative interdependence with another group) but inter-group collaboration. Some students prefer to choose the group members, but they also recognize that in real life projects, and in particular in the field of planning, they have to work within a team of people they do not necessarily choose.

Johnson et al., (2007) summarize the core of positive interdependence by asserting that the precondition for any cooperative learning situation is that students “*must perceive that they are positively interdependent with other members of their learning group, that is, students must believe that they sink or swim together*” (Johnson et al., 2007, p. 23). The way that the LMS and the collaborative learning approach is designed and implemented could help them to “swim together”.

Based on the implementation and the course evaluation these are the main recommendations:

1- Outcomes interdependence

- Add clear learning objective(s) to group work instructions.
- Make more explicit why group work is relevant for the assignment.

- Improve instructions and discuss with students face to face if they have difficulties interpreting the assignment. It should be noticed that the discussion page in the LMS where students could have posted questions on the assignment was not used by the students.
- Reconsider the use of tools embedded in the LMS to peer assess participation, preferably in consultation with students before starting the group work.

2- Means interdependence

- Keep in the LMS group pages as students valued the possibility of storing and sharing data within the LMS.
- Keep group dynamics workshops and evaluate possibility of introducing social skills as part of the core training in the MSc.

3- Boundaries interdependence

- Keep the classroom as the place where students can work in group, physically interact with group members, across groups and staff.
- Invite students to choose a name for the group as it stimulates positive identity interdependence.
- Value and encourage inter-group collaboration.

Despite of the development of a computer-supported collaborative approach, I find that an LMS cannot substitute face-to-face teacher and learner meetings and interactions. Group pages in an LMS are useful but this paper shows that group discussion did not take place in the virtual environment and students prefer to communicate in class. Above all, students clearly appreciate working in class in a diverse and international environment.

The main strength of the scholarship of teaching and learning and the design-based research approach, was that it allowed me to reflect on my own teaching and perform research related to a specific teaching and learning activity in an urban planning course. As I indicated in the introduction, I would argue that in a diverse and unequal world educating (future) planning practitioners requires them to practice empathic and collaborative forms of learning as opposed to competitive ones. Within the UPM specialization and in courses like the “Planning Sustainable Cities” we emphasize, among others, the relevance of a better understanding of unequal quality of life conditions, spatial equity and social justice, and concepts of inclusive city and the just city (Fainstein, 2010, 2014). In this paper I have not discussed in detail the content of the planning course. However, it is not only *how* we teach and learn but also *what* we teach that will determine how empathic future planning practitioners will be.

Acknowledgements

I thank UPM students for their willingness to participate in this research, my colleague Christine Richter for facilitating the focus group discussions and Eduardo Hermesen for facilitating the group dynamics workshop and course evaluation. This paper is the result of a Senior University Teaching Qualification (SUTQ) trajectory of the University of Twente. I would like to thank Chris Rouwenhorst and Kim Schildkamp for their supervision and advisory role during the SUTQ project.

Training Young Planners as Experts in Participatory Processes: Thoughts and Experiences from Palermo, Italy

Marco Picone¹, Filippo Schilleci²

¹*Department of Architecture, University of Palermo (Italy), marco.picone@unipa.it*

²*Department of Architecture, University of Palermo (Italy), filippo.schilleci@unipa.it*

Abstract: The following reflections are based on an innovative planning education model inspired by the cooperation of the Department of Architecture with public and private stakeholders. The model is based on two topics that are widely debated in urban studies, but apparently unconnected: the dissemination of participatory practices and cooperation between public and private actors, and the scientific and professional training to provide for new generations of urban planners. We argue that preparing students engaged in urban studies to the management of participatory practices is an inescapable need in today's Italian and international context. To address the issue of public-private cooperation in Italy, as a new approach to contemporary governance, we must consider that participation is increasingly becoming a subject of discussion. In the educational path we propose, qualitative techniques have been used mainly, but not exclusively. Thanks to the comparison of the points of view of the social actors involved in these processes, planning students have acquired professional skills that are producing significant professionalizing effects, including the birth of some associations of young graduates engaged in cooperation processes with the municipal administration. We therefore believe the experience of Palermo can be significant beyond the unique local context.

Keywords: participation; teaching methods; education; governance

A combination of participation, research and education

The relationship between participation and research has been extensively investigated in recent decades, up to the theoretical elaboration of the Participatory Action Research (PAR): several scholars (see for example Kindon, Pain and Kesby, 2007 for the English-speaking context; in Italy see Sclavi, 2007; Cellamare, 2012; Morisi and Perrone, 2013) have highlighted how the forms of participation are excellent tests for field research. On the other hand, the link between participation and educational practices is also a well consolidated approach that urban scholars have been investigating in the last few decades (Howard, 2010).

However, books and articles that try to connect the three fields mentioned above (participation, research and education) in a single theoretical framework prove to be less widespread and acknowledged. A few essays (McNall, Barnes-Najor, Brown, Doberneck and Fitzgerald, 2015) point in this direction, highlighting the potential for systemic change that the synthesis of those three fields has, but there are likely several steps forward that need to be taken. The effects of such a theoretical advancement could be significant, for example,

in terms of the repercussions on the occupational sphere of young jobseekers, as Stenberg and Fryk (2012) have pointed out.

In the light of these considerations, the present work proposes the task of investigating an experience in Palermo, which has been going on for 6 years and which has involved a large number of various social actors, in order to think precisely about the relationship between participation, research and education. As the conclusions of this paper will show, reasoning simultaneously on these three areas can produce concrete effects that have an impact not just on the territory, but also on the careers of young graduates in urban studies.

Participation as an unavoidable horizon for urban studies

To date, we cannot but recognise that participatory practices have become an indispensable element in tackling the issue of contemporary governance. Even Italy, albeit several years late, is facing the need – or even the legal obligation, as we will soon describe – to increasingly include participatory instruments in its urban policies.

Over the last fifteen years, in fact, we have witnessed a multiplication of studies on participation in Italy, both with the circulation of ‘practical guides’ for users and administrators (see, for example, Bobbio, 2004 and Regione Emilia-Romagna, 2009; also, Arena and Iaione, 2015 discuss a topic which is very close to participatory practices: urban commons and their management), and, sometimes, thanks to theoretical frameworks that can support the use of participatory practices (Ciaffi and Mela, 2006; Bignante, Dansero and Scarpocchi, 2008; Sartori, 2011; Cellamare, 2012; Picone, 2012; Burini, 2013; Morisi and Perrone, 2013; Celata, 2014).

As already mentioned a few lines ago, today in Italy participation is increasingly becoming a legal obligation (Banini and Picone, 2018). Several Regions have enacted laws that provide for the use of participatory processes (Table 1): the presence among these Regions of Emilia-Romagna, Umbria and Tuscany it is not surprising (Vizioli, 2014), considering the facts that these have always been ruled by progressive local governments; however, other Regions are joining the first ones, although they do not have as many previous experiences as those of the three Regions mentioned above. There are also cases of particular importance, such as the very recent case of Apulia: in this context, the national State considers that the Region is advocating to itself, with Regional Law no. 28 July 13, 2017, competences that do not belong to it; see the news ANSA published on http://www.ansa.it/puglia/notizie/2017/09/08/governono-a-legge-partecipazione-puglia_2b42399c-ef76-47a0-ac04-0cbac9ae7dbf.html, date of access: 12/05/2019.

Table 1: Regional Laws on participation in Italy, in chronological order.

At the municipal level, several cities are also increasingly carrying out experiments on the subject of citizen participation. Among these, Turin (Sclavi, 2014) and Bologna (Arena, Iaione, 2015) have a long and well-known history of NGOs and associations that have long been dealing with this issue; less frequent are for the moment the participatory experiences in Southern Italy, although with some notable exceptions, such as the case of Palermo which is described in this paper. Suffice it to say that more or less effective participatory experiences have been carried out in Palermo for years (see Schiavo, 2003; Trapani, 2012; Picone and Lo Piccolo, 2014; Picone and Schilleci, 2016; also see the website <https://www.comune.palermo.it/partecipa.php>, date of access: 12/05/2018).

Despite the mediatic and political interest in the topic of participation, however, many notions are still vague and easily exploitable, probably because participation is not part of the traditional Italian normative and regulatory tradition (Sclavi, 2014; Arena and Iaione, 2015). This shows that it is essential to multiply not only the practical experiences, but also the theoretical reflections on participatory practices, if we want to avoid the risks – or, even worse, the attempts – of manipulation that, among others, Arnstein (1969) and Habermas (1981) have been explaining and describing over the last decades.

The *Panormus* Project

In 2013, the event ‘*Panormus*: The School adopts a monument’ had already reached its twentieth edition in Palermo. During that same year, the University of Palermo, and in particular the Department of Architecture, started a collaboration with the Department of School of the Municipality of Palermo and with several schools ranging, from primary schools to high schools. The Department of Architecture has identified the authors of this paper as the scientific directors of a memorandum of understanding that was signed in 2013. For some years now, in fact, the authors have been coordinating a research group that has initiated specific studies, clearly reflected in the didactics, on the topic of the neighbourhood as a physical element in the design of the city but also as a place of resistance to the crisis of public spaces (Picone and Schilleci, 2012).

The *Panormus* project (Panormus being the ancient Latin name given to the city of Palermo) was structured in such a way that the many actors who, directly or indirectly, act on the transformations of the city could synergistically initiate participatory processes aimed at the knowledge and design of urban space (Picone and Schilleci, 2016).

The motivations that led to seek this collaboration between institutions and citizens find their initial input in the precise will of the authors of this paper to 1) provide the students of planning and urban studies with an educational offer that is not only theoretical but also practical, and 2) to strengthen the planning approach in urban studies, no longer considering it just a technical approach to the analysis and subsequent design of cities, but an approach based on the constant exchange between two disciplinary areas: urban planning and social sciences, which can be considered two sides of the same coin, fruitfully communicating with each other (Phelps and Tewdwr-Jones, 2008).

The students who attended these courses were invited to tear down the mental barriers according to which urban analysis can be either purely technical or purely social, and adopt the neighbourhood itself as the scale of research, within an action-research framework.

The project involves the ‘adoption’ of the neighbourhoods in which the schools are located, and in the first phase of the collaboration it produced – through classroom work, but above all through field experiences – several ‘neighbourhood guides’ that helped the residents (both the younger and the adults) to observe the area in which they live through different lenses, recovering the concept of neighbourhood as commons, beyond the individualism that characterizes today’s society. One of the first goals of the project, therefore, was to create students-citizens aware of the strengths and weaknesses of the territory in which they live, to encourage actions of change from below and participatory planning of neighbourhoods from multiple points of view.

A significant step forward was taken after the second year of collaboration, when the designing aspect was added to the name, transforming the title into ‘The School adopts [and designs] the neighbourhood’ (*La scuola adotta [e progetta] il quartiere*; see Figure 1).

Figure 1: Poster for the fifth edition of the *Panormus* project.

The project is grounded on the idea that no single building (be it a school, a church or any other historic monument, or even any single residential building) is an island, isolated from the context. Therefore, on the one hand the general interest was no longer addressed to a single element but to the complexity of the urban system that hosts it, while on the other hand this approach led to re-design the context itself through a shared methodology.

This evolution will lead to a real and complete process of participation, which will go through both the knowledge and the design phases.

In a process of continuous verification, planning students have coordinated not only the pupils of the schools involved in the work, but also the inhabitants and institutions, approaching the work as real professionals. In

fact, the actual regeneration projects that stemmed from the generic *Panormus* project, besides being shared and therefore certainly more effective, were based on another essential element: that of feasibility. The final dossiers written by the students, therefore, provided not only for the list of all the actors who will have to play a specific role in the process, but also the possible sources of funding that the administration could draw on for the implementation of the project.

The overall evaluation of the work done so far has been very positive, having met with a high degree of satisfaction from schools and citizens and having started a dialogue process, which is still in progress, with the municipal administration. The latter has recognized the value of the method and results, so as to start discussion tables with the Department of Urban Planning of the Municipality of Palermo, which is drafting the new planning tool (a masterplan) for the city (Figure 2).

Figure 2: The urban regeneration project drafted with the help of students and residents from the 6th municipality ('circonscrizione') of Palermo. The authors of the project are four students of the Urban Planning curriculum of the University of Palermo: Vittoria Attardi, Renato Collisani, Uma Damico and Giulia di Fisco.

Methodology and Professional Repercussions

The path that the students of the Urban Planning curriculum have followed, and that in some cases they continue to follow, has led to the acquisition of a greater awareness of the profession they are going to undertake, producing significant professionalizing effects, even if at the moment the process is still ongoing.

Certainly the awareness of the role of the planner as the main actor in the planning process is a great step forward, which has led the students to reflect on the skills and on how to create professional associations that, based on the experience conducted and increasingly deepening the methods of participatory planning, can make us think again of the city project as a shared project which is never imposed as top-down, but rather discussed and enacted in a framework that is focused on governance as collaboration between public and private stakeholders.

Some initial results have already arrived. The launch of some of these associations has already borne fruit, through forms of cooperation with the municipal administration.

Based on these first experiences, today we are working on the creation of an academic spin-off, which can create job opportunities for young professionals, by developing those methodologies that the students have been practicing and by bearing in mind that the city, along with its project, is not a series of lines drawn on a map, but is a bustle of people living together, is the set of multiple heterogeneous spaces but in relation to each other.

The experience of Palermo, if related to others that are starting to grow over different cities all over Europe, can be significant, even beyond the local context, for a relaunch of the project of urban regeneration.

Acknowledgements

The authors would like to thank all those who have made possible, from 2012 to the present, the implementation of the projects for the adoption of the neighborhoods. A special thanks goes to Barbara Evola, Cecilia Villanova and Pasquale D'Andrea of the Municipality of Palermo, as well as to the many schoolteachers who have dedicated energy and enthusiasm to the project. Among the university collaborators, the support of Riccardo Alongi, Lisa Biondo, Bruno Buffa, Giovanna Ceno, Giancarlo Gallitano, Elena Giannola, Maria Luisa Giordano, Chiara Giubilaro and Francesca Lotta was essential.

Although the paper should be considered a result of the common work and reflection of the two authors, Picone took primary responsibility for the first two sections of the paper, while Schilleci took primary responsibility for the last two sections.

Creating shared consciousness through collaborative education: the case of municipal amalgamation in Ukraine

Igor Vlasenko¹, Urs Thomann²

²*CANactions School, uthomann@canactions.com*

Abstract: Since the launch of decentralization reform in Ukraine in 2014, the country has become an arena for a large-scale transformation of territorial governance and planning systems. Currently, 899 amalgamated municipalities have emerged through the voluntary merger procedure, with an overall population of 9.5 mln and total area equivalent to 38.9% of that of Ukraine. Being far more just an enlargement of territorial units, amalgamation is envisioned as a major tool for fiscal decentralization, community empowerment and re-defining the scale of social infrastructure provision. Currently, the planning process in newly created municipalities is constrained by the lack of appropriate legislation and planning tools, a severe shortage of planning professionals and low self-consciousness of municipal management in regards to objectives and potential of spatial planning. This paper discusses experimental pedagogic approaches implemented for enhancing spatial planning capacities of staff of newly formed amalgamated municipalities in the settings of post-socialist Ukrainian countryside and in the context of the ongoing decentralization reform, advocating the relevance of the blended learning formats that produce knowledge along with transformative change.

Keywords: municipal amalgamation; strategic spatial planning; collaborative education; ecological university

Introduction

A so-called *decentralization reform* was launched in Ukraine in 2014 as a means of smoothing regional divisions in the country and strengthening capacity of local communities (Shapovalova, 2014). The political mission of the reform was to fulfil the key demands of the Euromaidan public protests in 2013-14 in terms of accountability of national and regional authorities, as well as to offer decentralization perspective within the existing unitary state (*ibid.*). The package included into the National project 'Decentralization' consists of local government reform and an overall revision of centre-periphery relations, including fiscal and budget decentralization, which leads to structural changes on local, sub-regional (*rayon*) and regional (*oblast*) levels.

The current stage of the reform (2015-19) has been focused on the establishment of a basic level of municipal self-governance through the voluntary amalgamation of territorial communities of cities, towns and villages. The enlarged municipalities, referred to as *amalgamated hromadas*¹, are supposed to be formed before 2020 to become a territorial basis for upcoming local elections (Parliament of Ukraine, 2014). According to the perspective plans proposed by the government and approved on a regional level, the amalgamation of 8906 territorial communities into 1293 AH-s is envisioned, with 70% (899 AH-s) of this plan already completed.

¹ Amalgamated territorial communities – *Ukr.*, further referred to as *AH-s*, or *hromadas*.

The emergence of AH-s should put an end to prevalence of state administrations in terms of local decision-making and distribution of resources, as well as renew possibilities for local communities to govern land resources within the hromada territory (*ibid.*). For that, AH-s receive subsidies from the central government for upgrading local infrastructure in the first five years after amalgamation (State Treasury of Ukraine, 2018). Moreover, since 2018 the government has launched the process of agriculture lands transfer into communal ownership of newly formed municipalities (Decentralization, 2018). With the influx of resources comes a set of additional responsibilities for sustainable land-use and provision of services of general economic interest to the population, including education and healthcare. Enlarged territories and budgets bring an absolutely new level of requirements for AH executive bodies and political leadership and require long-term planning for a new territorial scale. While short-term socio-economic plans are generally available and the strategic planning process is currently ongoing in most of the AH-s, in most cases spatial dimension of such plans remains problematic.

As stated in Rudenko *et al.* (2017), the deficiencies in AH-level planning include the absence of official standards for a new planning scale, inadequate human resources to develop the plans for all AH-s and lack of detailed information on landscape qualities of the AH territories. Moreover, neither of the three planning tools available at a municipal level – general plan, zoning plan and detailed plan – make a good fit to the scale and character of the hromada area. While the introduction of AH-scaled plan is envisioned in the upcoming amendments to the national legislation, currently the only available planning tool is a ‘planning scheme of amalgamated hromada territory’ regulated by the national building norms.

Another complexity constitutes a never complete nature of the AH-s caused by the voluntary character of the municipal amalgamation procedure. The latter leads to the effect of ‘floating borders’ between the perspective plan of the AH and its actual spatial configuration, as presented in Figure 1. The reason for this phenomenon lies in the nature of amalgamation as a politically charged process in which spatial factors and landscape qualities are considered of secondary importance. According to expert estimations up to one-third of the already formed AH-s appears unsustainable in terms of infrastructure provision, managerial capacity and budgetary resources, which might lead to their re-configuration in 2020 (Decentralization, 2019). Such findings suggest that the ‘floating borders’ phenomenon will be persistent at least for a few years to come.

Figure 1. Perspective plan of Barska AH in Vinnytsia region (thick red border) against its current configuration (red dotted border). Image courtesy of Hanna Chernat.

The effect of voluntary municipal amalgamation on territorial governance in general and spatial decisions in particular also remains unclear. According to Swianiewicz (2018), between 2008 and 2017 territorial reforms have been implemented in 15 European countries, with municipal amalgamation becoming a mainstream solution in the decade after the global financial crisis. Meanwhile, a number of studies indicate the negative effect of amalgamations on the local democracy and uncertainty concerning actual savings in costs (*ibid.*). Udovychenko *et al.* (2017) draw parallels between the reform in Ukraine and Latvia, emphasizing the time pressure for shaping legal, fiscal and administrative background of the reform and reliance on voluntary cooperation between the local councils as factors that eventually led to flaws in spatial organisation, such as non-rational location of administrative centre or spatial fragmentation.

On a more general level, the context for local government reform is complicated by rapid ageing and depopulation in rural areas, poor general condition of basic infrastructure, alarming situation with waste management, dependence of some regions on unreliable and costly water supply schemes. Moreover, the history of Ukrainian village in the Soviet times is the history of forced collectivization and prohibition of individual farming, while its present condition is characterized by the prevalence of large mono-crop agricultural holdings and the extended ban on agricultural land sale (Prentice, 2017).

Finally, the institutional setup for spatial planning in AH-s also remains problematic, largely due to the lack of qualified specialists working on a local level. The AH-s where the central settlement is a village mostly lack a separate unit for architecture and planning within their executive bodies. Meanwhile, in hromadas where such units are at place, their activities are often narrowed down to working with a general plan, which focuses on the central settlement, largely ignoring the surroundings. The character of planning imposed by the general plan often bears the tradition of planned economy and thus remains prescriptive and in some cases unrealistic. This is partially explained by the fact that in most cases the planning tasks are outsourced to the state-owned planning institutes, which organisationally and programmatically inherit the practices of centralized planning.

The pressure of budgetary periods and newly transferred assets (lands, buildings, funds) creates a sense of urgency concerning spending without adequate long-term planning to support it. Where the strategic plans exist, they are often poorly connected to spatial dimension and thus unhelpful for decisions regarding precise land plots, buildings or public spaces. Hence, the role of planning in AH-s at an early stage of their development should not only imply regulation and control but also should suggest a long-term, spatially coherent vision for the future for all settlements and territories within a new municipality.

Conceptual framework

Strategic and integrated approaches in spatial planning

The ongoing local government reform in Ukraine puts pressure on management of the newly formed amalgamated municipalities in regards to generating strategic spatial development visions. The use of strategy in planning, as stated in Sartorio (2005), is a highly ambiguous concept, as the strategy has several meanings. For instance, while strategy generally implies pursuing a long-range vision, it also opens opportunities for the presence of different actors that could follow different, or even clashing, objectives (*ibid.*).

The revival of strategic planning in 1990s is generally associated with increased competition between cities (Sartorio, 2005) and rapidly blurring boundaries between municipalities, provinces, regions (Albrechts and Balducci, 2013). Strategic plans are often viewed as instruments of change and action plans, while the traditional plans are designed for stability (*ibid.*). While the possibility of identifying strategy in planning as a separate recognizable subject remains questionable (Sartorio, 2005), it is possible to grasp some of its recurring characteristics, such as the necessity to plan for a longer range, comprehensiveness in terms of wide array of actors involved, interactivity, process orientation and interconnectivity (*ibid.*).

The effect of implication of strategies in planning is described by Healey (1997, as quoted in Albrechts and Balducci, 2013) as ‘self-conscious collective effort to re-imagine a city, urban region or wider territory and to translate the result into priorities for area investment, conservation measures, strategic infrastructure investments and principles of land use regulation’. Albrechts (2004) adds ‘public sector-led’ and ‘socio-spatial’ as characteristics of strategic spatial planning as a process and emphasizes its orientation towards the future (‘what a place is and may become’, *ibid.*). Strategic spatial planning requires the decision-makers to challenge conventional wisdom and is distinguishable from traditional planning by the following characteristics (as discussed in Albrechts and Balducci, 2013):

- Shift from comprehensiveness to selectivity in planning;
- Action and process orientation;
- Ability to cope with uncertainties;
- Focus on co-production by multiple actors;
- Ability to change and reformulate the mindset of actors;
- Ability to grasp the momentum.

Hence, strategic spatial planning best serves in cases with an ambiguous and rapidly changing context for planning and where the existing decision-making perspective ought to be challenged or expanded. While the strategy allows turning planning from a regulatory mechanism into an action plan, coordination between the sectoral, spatial and temporal aspects of territorial policies remains an important factor for the effectiveness of planning overall and efficient spending of public funds in particular.

One of the European policy frameworks for streamlining such coordination is pronounced in the Leipzig Charter for Sustainable European Cities of 2007. Developed during the German presidency of the European Union, the charter is based on findings of the background study focused on integrated urban development as a policy tool and ‘*a prerequisite for urban sustainability in Europe*’ (BBR, 2007). Accordingly, an integrated approach is described as the one involving spatial, sectoral and temporal coordination of various policy areas and resources planning with the use of financial instruments (*ibid.*, p. 14). On the implementation side integrated approaches are embodied into integrated urban development concepts for certain territories that imply:

- Analyzing strengths and weaknesses of a spatial entity and its components;
- Formulating goals for particular areas;
- Increase the effect of public measures through coordination and pooling of public and private funds;
- Integrated planning for particular areas and sectors;
- Empowering citizens and encouraging corporate social responsibility;
- Supporting intermunicipal cooperation and partnership between urban and rural areas.

The vision of integrated urban development voiced in the Charter is being carried out further by the German federal ministries (for instance, see BBSR, 2017) and included into German-funded technical assistance and capacity building projects in the fields of spatial planning and urban development in the third countries. For instance, the project *Integrated Urban Development in Ukraine*, commissioned by the German Federal Ministry for Economic Cooperation and Development (BMZ) and Swiss State Secretariat for Economic Affairs (SECO) is being implemented in six cities of Ukraine since 2015. While the integrated urban development policy framework largely addresses cities, the integrated approach remains relevant for projects focused on different territorial contexts but implemented by the same agent.

Hence, in the context of Ukraine, utilizing strategic planning toolkit for coordination of spatial development appears to be relevant, provided the rapid socio-economic and political change and perceived low effectiveness of the existing planning tools, such as the general plan. An integrated approach to urban development policy still finds limited application, however benefits from a strong agency provided by international technical assistance projects.

Planning education in Ukraine and the new role of a university

Education is an essential prerequisite for developing strategic visions for amalgamated municipalities and embedding new mindsets among the local actors. It is possible to split this broad term into two categories – the one referring to the professional education of planners, and the one that could be generally described as building capacities of local actors to deal with spatial issues. Regarding the former, it is important to mention that currently no separate programs in urban or regional planning are being offered by Ukrainian universities, and planning disciplines are only included into graduate programs in architecture. University programs in urban or regional studies offered by social sciences departments are also a novelty². Hence, a lack of academic tradition that would nourish the interdisciplinarity of planning work is currently observed.

Regarding the latter aspect, it is important to highlight the absence of inter-sectoral encounters in local administrations, as well as the lack of holistic understanding of spatial planning outside its technical domain. Improvement of inter-sectoral coordination and strategic planning and management of resources thus makes one of the focuses of international technical assistance projects that support decentralization reform in Ukraine. One of the examples of such projects is *U-LEAD with Europe*, a multi-donor action supported by several of the EU Member States and implemented by German and Swedish development agencies.

The rapidly changing context for planning under the local government reform requires increased individual and collective capacity to deal with challenges and differences. A great role in such capacity building could be performed by initiatives that have both educational and transformative objectives. One of the examples of such initiatives comes from sustainability science and is conceptualised as ‘real-world lab’, a scientifically designed space of collaborative sustainability research involving intervention’, characterized by transdisciplinarity, transformative approach and inclusion of civil society (Singer-Brodowski *et al.*, 2018). Designed as spaces for learning, real-world labs employ experimental strategies for studying the local context and focus on centrality of the learner in the educational process (*ibid.*).

Along with such models for social experimentations with learning and transformative effects, comes re-thinking of traditional educational establishments and their connectedness to the environment. Barnett (2011) comes up with a list of utopian future views for contemporary universities as an alternative to increased entrepreneurialism, in particular proposing the concepts of ‘ecological university’ and ‘networked university’. Accordingly, the multiple networks that university forms with business and industrial sectors should be put to a use other than securing a better position in the academic market place (*ibid.*, p 4). Rather, the university should act in accordance to ecosystem functioning and adopt the responsibility wellbeing of its environment. Doing so, the university does not just safeguard the wider society, but actively enhances the public realm (Barnett 2009, as quoted in Standaert, 2012). Serving such purpose requires a change in the pillar structure of the university consisting of disciplinary departments into a web-like structure (Standaert, 2012). Such transition launches a set of ‘nomadic’ practices associated with openness, mobility, public character, experientiality of educational activities (*ibid.*).

² The first intakes of such programs offered by Kyiv National University, Kyiv National Economics University, the Karazin University in Kharkiv were announced only in 2018.

The following parts of this paper will outline the case of application of strategic and integrated approaches to spatial planning in amalgamated municipalities, which takes the format of an educational program carried out by CANactions School, a non-formal educational institution based in Kyiv and Amsterdam. The concepts of real-world labs and ecological university will be further applied for evaluating the chosen educational approach and format.

Case study

CANactions School

CANaction School was founded in 2015, in response to the growing social demand for principled reform of relationships between citizens, government authorities and planning and design professionals in Ukraine. The School formulated the two key questions pursued in all of its subsequent activities:

1. Who are those change-makers who could moderate the process of building new types of connections in Ukrainian cities?
2. What tools and approaches do they need to be able to successfully deal with the complexity of the current challenges? (Thomann and Tyminskyi, 2015)

Working on these questions, the School shaped an educational approach based on shifting of professional roles from 'specialists' to 'generalists' and guided by the following principles:

- Interdisciplinary approach;
- Teamwork and experiential learning;
- Project-based learning;
- Strategic approach to urban design and spatial planning;
- Cooperation with a vast net of international experts and institutions.

The pilot educational programs of CANactions School in 2015-2016 were conducted in the format of semester-long full-time Studios, focused on the urban development contexts of various parts of Ukraine, with an aim to propose long-term spatial visions for the case cities that would reflect the outcomes of interdisciplinary research carried out by the students and complement (or oppose) the existing general plan. In the course publications, the School critically reflected on the experience of the pilot year, for instance, sharing concern for the possibility to initiate and carry out the systemic changes in cities and expressing the opinion that the impetus for the development of a city must come from the local community (Thomann and Tyminskyi, 2016).

In the following year, the School launched modular Advanced Studies in Integrated Urban Development (ASIUD) courses with an expanded vision of a study group. Unlike to the first programs targeted at professionals who participate in urban development, the student cohort was expanded by representatives of city administrations. Thematically, the focus shifted towards the concepts of integrated urban development. Such focus had been strengthened by a partnership with the project Integrated Urban Development in Ukraine, which provided links to city administrations and offered implementation prospects for student projects.

Four educational programs (two full-time studios and two ASIUD courses) resulted in a set of spatial visions and strategic urban development project models for seven Ukrainian cities. At the end of educational year 2017-18' CANactions School was characterized by bold experimentations with formats, student profiles and thematic foci, which led to educational methodology that interprets the nature of design and planning as 'continuous oscillation towards a consensual vision of the future of a certain place' (Thomann and Tyminskyi, 2018).

Integrated Spatial Planning for Amalgamated Hromadas

In October 2018 CANactions School announced the launch of a year-long educational program focused on the application of strategic and integrated approaches in spatial planning in the context of decentralization reform in Ukraine. The aim of the program was to enhance the capacity of local stakeholders in amalgamated municipalities to handle spatial aspect of strategic planning. The program emerged from partnership between the School and the *U-LEAD with Europe* Programme, which awarded a grant for its implementation.

It was decided that representatives of 30 amalgamated municipalities will participate in the program. The broad selection was aimed to ensure representation of most regions of Ukraine, various types of AH-s depending on the status of their central settlement (city, town, village), as well as of those both with and without strategic plans. The open call for AH-s resulted in 101 applications, based on which a cohort of 30 was selected (see the regional and typological diversity of the AH-s in Figure 2).

Figure 2. Location and typological overview of 30 AH-s that participate in the program

On a local level, the participating AH was required to form a working group consisting of six members that represent various stakeholder groups (see Figure 3).

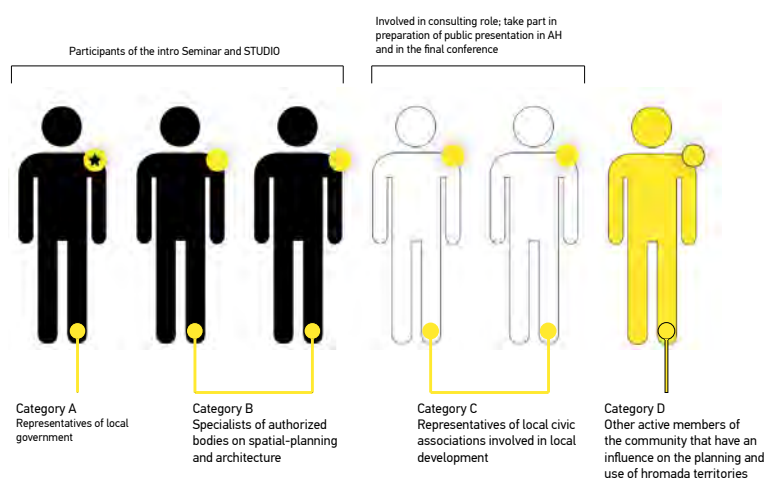

Figure 3. Recommended squad of the AH working group

Despite the observed rotations and incomplete working groups in some of the AH-s, the proposed composition generally favoured knowledge dissemination on the ongoing educational program and also formed a basis for inter-sectoral collaborations within the administration. The AH cohort formation confirmed the hypothesis concerning the lack of planners in amalgamated municipalities (see in Figure 4) and showcased the great diversity of newly formed municipalities in terms of size, population and spatial organisation (see in Figure 5).

Figure 4. Professional background of program participants

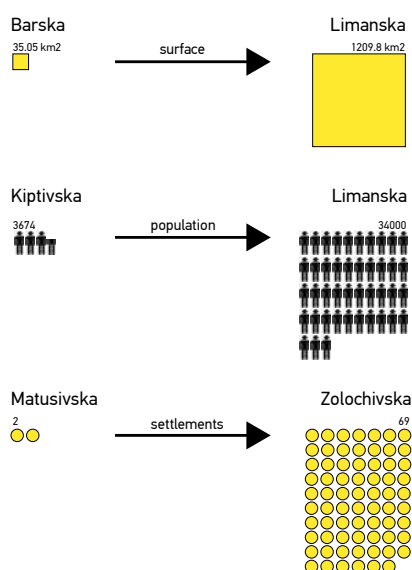

Figure 5. Diversity of 30 AH-s in terms of size, population, number of settlements.

These findings posed a challenge to the School's organisational and methodological setup. One reaction to them was the inclusion of an additional participant cohort into the program, namely 30 'spatial planning practitioners', who were selected separately through an open call procedure. As a result, an interdisciplinary group of thirty 'practitioners' was selected (see in Figure 4) to match the number of AH working groups with the following objectives:

- To provide for the lacking planning, design and social research skills and thus to enable the application of *learning by doing* approach;
- To help the AH working group embed a broader external perspective on local potentials and challenges that arise in the planning process;
- To help to re-create 'the client' and 'the planner' roles in the educational process, build new connections and encourage post-program cooperation.

The educational process was designed as three distinctive blocks visualised in Figure 6, where the preparatory block served to formulate a shared understanding of the strategic spatial planning and principles of integrated urban development frameworks, as well as to introduce the School's learning principles using simulation exercises. The block also included an international fieldtrip to Sweden and Denmark designed with an aim to challenge the established mindsets and present the pressing issues of municipal development, such as addressing decay of peripheral settlements, outside the usual context. The second block (Studio) consisted of practice-oriented workshops. During this block AH working groups were introduced to spatial planning practitioners. The third block envisions delivering two public presentations of the results in May and September 2019 and includes post-production of the Studio results.

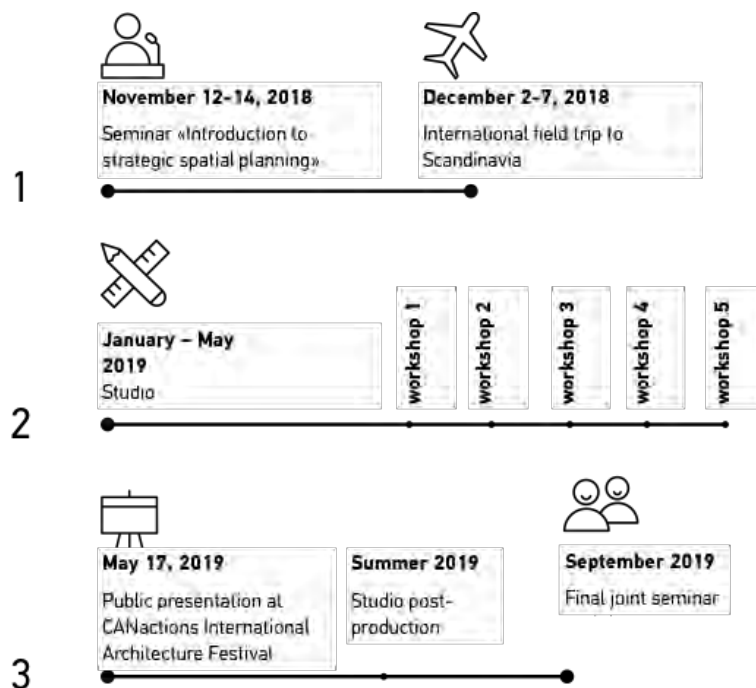

Figure 6. Educational program blocks

To ensure project-based learning each AH working group was presented with the case of their own municipality to work on; hence, 30 cases were reviewed in total. The workshops focused on production of a ‘spatial development concept’ for AH-s, created using the strategic spatial planning methodology. The aim of the concept was to achieve integrated, balanced and sustainable spatial development strategy, as well as to enhance legitimacy and awareness levels of local stakeholders in regards to spatial plans (Thomann and Tyminskyi, 2016). As a planning document, spatial development concept reflects the north-western European approach to spatial planning and has some common features with a number of instruments that are in use on regional and municipal levels of planning in other European countries, e.g. Räumliches Entwicklungskonzept (REK) in Austria, Germany and Switzerland. The key features of the spatial development concept in the context of amalgamated municipalities are outlined in Table 1.

Table 1. Features of spatial development concept in the AH context

Coordination instrument:	<p>communication tool which addresses all spatially relevant actors and provides inter-sectoral coordination among spatially relevant policies;</p> <p>pursues consensus with sub-regional and regional governance levels, as well as within the local community;</p>
Spatial study:	<p>strategic document at a local level that outlines the main spatial development potentials and challengers;</p> <p>describes socio-economic situation in AH-s;</p> <p>proposes a vision for all settlements and areas in AH;</p>
Not a legally binding plan	<p>not a statutory instrument, but must be considered in the preparation ToR of local plans;</p> <p>does not contain land-use regulations that are binding for land owners;</p>

Application of strategic and integrated approaches can be best illustrated on the basis of the Studio. The learning process took a form of a series of five consecutive workshops of five days each that took place once a month in the period between January and May 2019. Due to the size of the cohort the Studio work was split into five regional clusters, with the group size in each cluster under 30 persons. Each Studio workshop was oriented towards completing one of the parts of the spatial development concept, described in Table 2.

Table 2. Expected Studio deliverables.

Part 1. Analysis
Structural analysis of relevant aspects (socio-economic, landscape and environment, physical space etc.) is used to derive objectives and goals for future development. Spatial aspects and correlations should be presented in suitable schemes.
Part 2. Image of the future (Vision)
The Image of the future mirrors the vision and goals underlying the development concept. For communication, not only a «slogan» shall be used, but also a sketch or scheme to illustrate the idea on place together with short text for explanation.
Part 3. Concept
The concept builds the «bridge» between vision and plan. In various thematic schemes (environment and landscape, settlement, transport, economic development and working places, etc.), it shows “what” and “where” is intended. Up to three priority fields of actions are identified, of which at least one is elaborated as a “strategic project” and show-cases strategies and principles which shall be used for implementation.
Part 4. Road map
A road map for implementation shall answer the questions on the “how”, the “who” and the “when” actions are considered for implementation of the concept in plans and for realization of the “strategic project”. Specific “building blocks” of the concept should be identified and interdependencies between them explained.
Part 5. Description of the elaboration process
This part serves to explain the whole working process behind the Studio project, especially which actors and stakeholders were involved and what parent planning documents were used as base for the elaboration of the spatial development concept.

While the framework and deliverables were common for all five regional clusters, the precise methodology was developed by the teaching staff working in each cluster. Each cluster was assigned a team of one senior and two junior mentors. The requirements for senior mentor position were a track record in planning projects, pedagogic and professional experience in Eastern Europe. All senior mentors of the program were international and were supported by local professionals who served as junior mentors. Seven out of ten junior mentors were the alumni of CANactions School, which made possible the transfer of knowledge, toolkit and organisational culture of the former programs. Senior mentors defined the workshop curriculum, while junior mentors facilitated the group work, also occasionally stepping up as reinforcement to spatial planning practitioners. The organizational diagram of the Studio is presented in Figure 7.

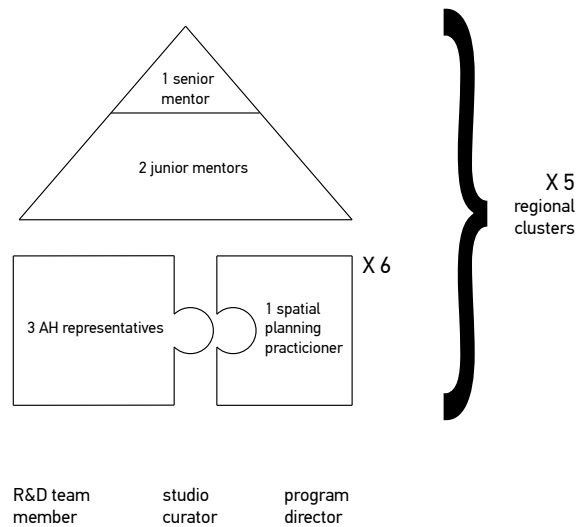

Figure 7. Studio organizational diagram

The learning process was also facilitated by the Studio set-up as a space for inter-disciplinary and also inter-municipal encounters. The group work was framed around the interaction between the AH representatives and the spatial planning practitioner, where the former acted as local informants and decision-makers, while the latter employed multiple roles of interviewers, data analysts, planners and project coordinators. In order to enable productive and evidence-based planning interactions, a dossier with the key socio-spatial data and base maps was prepared by the School for each AH. The character of group work in most cases implied producing sketches on printed base maps, thus cultivating spatial thinking and securing the involvement of all participants into planning exercises, regardless of software skills.

The Studio format largely implied regular interaction with the limited number of local actors divided into five regional clusters, several touchpoints for knowledge-sharing were introduced, including two seminars for spatial planning practitioners and the final workshop in May, which was conducted for all Studio participants in common. On a local level, the AH working groups delegates were responsible for the information flow within the local administration. In March 2019 thirty participatory events in the participating municipalities were organised as part of the third Studio workshop to test the developed spatial scenarios, involving over 1500 attendants overall. The public events were also utilized for needs assessment of the AH periphery and of various social groups.

Discussion

It is possible to interpret this abovementioned case through the ideas of ‘networked’ and ‘ecological’ university proposed by Barnett (2011). The ‘networked’ character here is proved by the complex web of interactions between the School and actors involved into implementation of the territorial reforms. In regards to bearing the responsibility for well-being of its ecosystem, which is an essential characteristic of an ‘ecological’ university, the School engages with the described program into several ongoing debates focused on the following themes:

- Shaping toolkit and strategic framework for spatial planning in amalgamated municipalities;
- Review of spatial planning practices and regulations on a municipal level;
- Generating new connections between the actors involved into the local government reform.

The School's latest program also confirms its nomadic nature, as described by Standaert (2012), which finds manifestation in the highly flexible and adaptable format of the Studio where workshop setup, location and methodology become subjects of free modification (and multiplication) whilst the core educational principles persist.

This paper focuses on the design of a learning framework while providing little information on the programmatic essence and specific results of the course. Yet, the presented evidence can be utilized for supporting the claim regarding the relevance of the blended learning formats that produce knowledge along with a transformative change in the contexts of territorial entities that experience rapid transition. This claim can be elaborated and discussed in three dimensions:

- Creating legitimacy through non-formal planning process;
- Conceptualizing Studio as a lab that fosters interdisciplinary, inter-generational and inter-cultural learning;
- Presenting the Studio deliverables as action plans.

Legitimacy

The legitimacy of planning decisions is particularly important in the context of the municipal amalgamation, as the enlargement implies a revision of centre-periphery relations and bears the risks of uneven development. Utilizing the strategic spatial planning methodology, the program benefits from its action and process orientation, as well as the focus on co-production involving multiple actors, as suggested by Albrechts and Balducci (2013). Due to high level of uncertainty, for instance connected to planning legislation and possible reconfiguration of the AH-s, the program grasps the momentum to influence the mindset of actors involved in spatial planning before such planning occurs.

The utilized methodology also allows reviewing selectively the issues that go beyond the competence of formal planning, helping to create legitimacy and analytical grounding for future political decisions. In the abovementioned case of Barska AH the working group made the decision to create a spatial development concept that stretches beyond the current AH border to use it during negotiations with neighbouring village councils (see Figure 8). On the other hand, the legitimacy of spatial ideas developed during the Studio is constrained by particular AH working group composition, lack of public involvement throughout the Studio and prevalence of the limited AH administration's perspective concerning needs and priority actions.

Figure 8. Sketch of the project map of Barska AH. Image courtesy of Hanna Chernat.

While the Studio's set-up is highly situational and fluid, it is nevertheless possible to claim that its pedagogical and transformative effect stretches beyond the educational program and could be in some instances compared to one of the real-world lab. Organizationally, it replaces the hierarchical structure of AH administration with a flat working group set-up. While the power relations in most cases persist, rotation within the working group, presence of spatial planning practitioners and non-administration representatives enabled bringing upfront the new situational leaders. The variety of participants' and mentors' backgrounds was utilized to produce meaningful inter-disciplinary, inter-generational and intercultural links. The most intense exchange took place between the AH representatives and practitioners, whose role transformed from external consultants to fully assimilated working group members with a strong AH identity. The Studio settings also opened new opportunities for inter-municipal cooperation through on a basis of discovered common challenges and regional similarities.

A communication cascade had been formed within the Studio for translating spatial and strategic planning notions into everyday language. In some cases, the translation was literal due to the foreign background of senior mentors and mixed use of English and Ukrainian during Studio work. The Studio handbook prepared and disseminated by the School included a brief dictionary mostly consisting of project management and planning jargon. Throughout the program, the participants were encouraged to use non-conventional formats for communicating planning ideas, such as preparation of local newspapers and videos that disseminate the Studio findings.

Participatory events trained the participants in essential skills that are required for embedding new approaches to spatial planning in the multi-stakeholder environment and proved the potential of 'hybrid forums' (Callon *et al.*, 2001) for creating a shared consciousness through discussion of raw ideas and concepts. However, the potential of interacting with the general public was not fully utilized due to a very limited amount of fieldwork and concentration of participatory events in central settlement. It was also identified that the design of a participatory event largely determines what it achieves. This is especially the case in a 'thirsty' environment, where people not so often yet had the opportunity for bring themselves into a planning process with a potential of co-production in interventions. In general, friendly and open atmosphere in the conducted events is an optimistic sign for the potential of the applied methodology, but it does not yet proof that it will be successful in conditions outside the lab. It is nevertheless possible to argue that the modelling of the planning process merits at least as much attention as the design of structures during this process.

Content-wise, the Studio encouraged experimentation in terms of studying the effects of territorial enlargement on day-to-day functioning of infrastructure, economic and social ties between the settlements, thus utilizing an opportunity to observe the impact of an independent variable (amalgamation) on the dependent, as suggested by Swianiewicz (2018). In some cases, Studio work led to the discovery of previously unknown data sets and local spatial qualities. For instance, in the case of Zolochiv AH consisting of 69 settlements (see the integrated map in Figure 9), a strategic project had been proposed to foster the internal exploration of local crafts, landscape qualities, development challenges and potentials that are generally unknown for the residents and administration alike. In the case of Storozhynetska AH, a hitherto unrecognized timber construction culture in churches and residential buildings has become a common identity and sustainability potential for economic and cultural development.

From the Studio to action

Utilizing the integrated approach, Studio framework implied inter-sectoral coordination of discovered socio-spatial issues and addressing them in various temporal scale, with scenarios stretching to 2030 or in some cases to 2050. A number of discovered challenges concerned providing the most basic infrastructure, such as fresh water supply, or was related to global challenges, for instance, the effects of climate change on land fertility in Southern Ukraine. In the case of Komysh-Zorya AH, a proposal for introduction of a new waste management system was developed, implying inter-municipal cooperation and reorganisation of underutilized land plots currently functioning as informal dump sites (see Figure 10). Addressing global challenges through municipal perspective would require cooperation on a regional level, which also made the participants label such projects as the ones beyond their authority. In order to address this issue demonstration projects focused on soft measures and local scale along were introduced along with strategic projects.

Figure 10. Proposal for inter-municipal cooperation in waste management project.
Image courtesy of Lidiia Chyzhevska

Despite the ambiguity concerning implementation capacities, observed lack of expertise of Studio mentor team in some of the narrowly defined projects, such as the establishment of dairy farming cooperatives, the action orientation of the Studio helped to localize and specify otherwise abstract ideas presented on the integrated AH-scale plan. Spatial development concepts provide a useful basis for clarifying future expectations and objectives, as well as for defining priorities for action in larger and more open forums.

It is important to stress that for none of the participating municipalities a simple patent solution can be used for the development of the community or even one of their settlements. Utilizing integrated and strategic approaches, all work points to strengths, potentials and opportunities, which now have to be further processed with the necessary perseverance. What will be more important than the mere choice of the tool (spatial development concept) is the collective and thus communicative evaluation of definitions of planning goals.

Conclusion

Based on the presented review of ‘Integrated Spatial Planning for Amalgamated Hromadas’ program, it is possible to suggest that creating shared consciousness of stakeholders regarding spatial development is an essential prerequisite of sustainable use of lands and resources in the context of territorial reforms. The selection of process design dictates the opening up of spatial planning processes for a certain politicization or the closing down of opportunity spaces of the transition phase and their isolation from the realm of public debate.

Strategic spatial planning tools offer a broad overview of strategic development potentials in a dynamic environment, non-constrained by a static framework of comprehensive planning. Learning formats that attempt to moderate the discussion of planning priorities amongst local actors and bear transformative goals in terms of mindset change should be sensitive to the specific context of areas in transition and flexible in terms of setup, location and duration of educational activities.

Practice-oriented nature of the program with both educational and transformative objectives and based on the own cases of participating territorial entities provide incentives for local actors to invest time into the educational process. Inclusion of participants with various backgrounds and professional roles and presenting the work in progress to the general public generally appeared very beneficial for practising new types of

connections and communication channels by AH administrations, while a broad selection of participating municipalities and exposure to international cases created a basis for inter-municipal cooperation.

Studio work has succeeded in putting together a wealth of analyses, ideas and measures for the newly founded AH. Discussion of these results in the various forums (e.g. working group with mentors and experts / working group in communities / working groups with other working groups.) was very fruitful, not least of all testified by elaborated project ideas, which were immediately submitted to grant programs for implementation. Whereas a professional administration can be, of course, supportive but also restrictive, the Studio as a lab showed that a small, lay-controlled community may bring forth a highly motivated individual or team who is able to create a constructive climate for discussion.

Acknowledgements

This paper owes a great deal to the participants, initiators and partners of the educational program 'Integrated Spatial Planning for Amalgamated Hromadas', as well as to the educational and research teams of CANactions School.

Abstract: This study conveys the two-semester studio experience of the Urban Planning Master's Program at Istanbul Technical University in the 2018-19 academic year. The aim is to build on the conducting of this studio considering its teaching strategies, methods, and curriculum, which were designed for an experiential learning and collaboration experience in line with its topic of collaborative planning and governance. Planning studios in Turkey are largely characterized by an ends-driven comprehensive planning paradigm. However, this study argues that in order to address contemporary planning practices and increasingly complex planning problems such as those in Istanbul, today's planning studios must explicitly focus on the means of the planning issue at hand and invite students to take on the role of the actual practitioners and empathize with local stakeholders.

Based on these premises, the first-semester studio allowed the students to choose a case neighborhood in Istanbul in line with their academic interests. Supported with relevant theoretical readings and case-driven literature research, they were involved in a field trip, a formal briefing at the local municipality, thematic data gathering and analysis (including an advanced stakeholder analysis), assessments, and collaborative planning proposals with spatial, financial and participatory aspects. In the following semester, they were expected to fit their refined plans into a collaborative governance model. They discussed various approaches in both a structured studio debate and an on-site focus group study with local actors to test and revise their models.

Through instructor observations, jury assessments, and informal student feedback, the preliminary findings have revealed that an interactive and inclusive studio design which actively involves both students and local actors has greater benefits for graduate students' motivation, comprehension, and solution generation to real-life planning issues. These findings will be further tested towards a refined studio framework by the end of the academic year.

Keywords: planning studio; experiential learning; collaborative planning; governance

Experiential learning in planning studio

A quote that is attributed to Confucius expresses the conviction of effectiveness of experiential learning:

I hear and I forget
I see and I remember
I do and I understand.

Simply put as the process of learning from experience, experiential learning has been termed in various ways throughout its evolution. For instance, John Dewey (Dewey and Dewey, 1915) discussed “learning by doing,” while Wolfe and Byrne (1975) used the term “experience-based learning.” David Kolb (1984), who is extensively cited in the experiential learning literature, defined the term as “the process whereby knowledge is created through the transformation of experience. Knowledge results from the combination of grasping and transforming experience” (p. 41). Here, Kolb reinforces the idea that reflecting on the experience can potentially lead to a transformation as a result of the experience. Kassem (2007) defines experiential learning as “a purposeful process of engaged, active learning in which the student constructs knowledge, skills, or values by means of direct experiences in authentic, real world contexts” (p. 2). Perhaps the most recent definition is suggested by Beard and Wilson, who stresses the inner and outer world of the learner, and of the experience for and of learning:

A sense-making process involving significant experiences that, to varying degrees, act as the source of learning. These experiences actively immerse and reflectively engage the inner world of the learner, as a whole being (including physical-bodily, intellectually, emotionally, psychologically and spiritually) with their intricate ‘outer world’ of the learning environment (including belonging and acting (conative) in places, spaces, within the social, cultural, and political milieu) to create memorable, rich and effective experiences for and of learning. (adapted from Beard and Wilson, 2018, p. 3)

Learning through the “outer world,” more specifically real life experiences, is now synonymous with terms such as fieldwork, applied learning, learning by doing, hands-on learning, problem-based learning and experiential learning. This growing emphasis on experiential learning in higher education is clearly evidenced by a simple keyword search through scholarly literature. He is also credited for the model which challenges relevant past theories and reveals the complex nature of experiential learning (Figure 1).

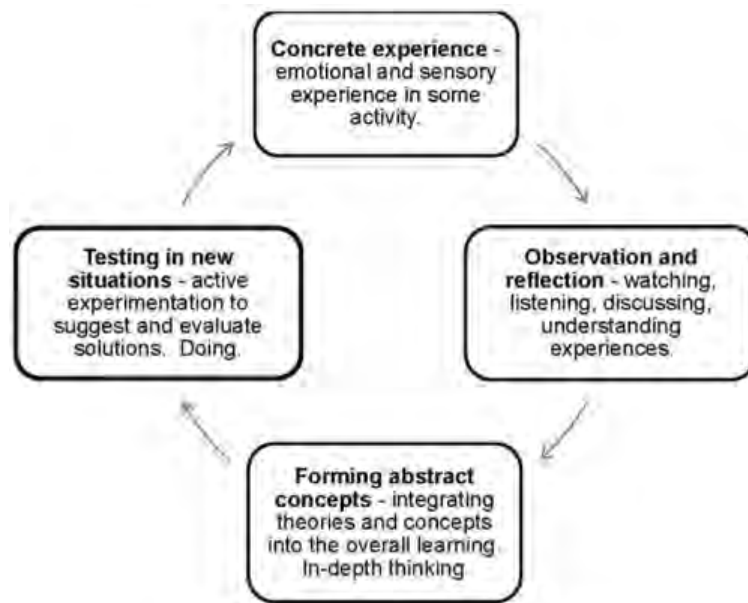

Figure 1. Kolb's experiential learning cycle (adapted from Baldwin and Rosier, 2017, and Kolb, 1984)

Since the 1980s, inspired by Kolb's influential model, experiential learning has attracted more attention in and entered into numerous education fields including planning. Planning literature demonstrates considerable interest in experiential learning, such as the Journal of Planning Education and Research's special issue dedicated to community outreach partnerships (JPER, 1998). Here, the emphasis is on reflecting on fieldwork, learning that takes place via first-hand experience outside the constraints of the four-walled classroom setting, as central to the teaching of planning (Kotval, 2003). For urban planning programs the US Planning Accreditation Board (PAB, 1992) requires accredited graduate planning programs to "train students to be able to work effectively as members and leaders of planning teams and to apply an understanding of interpersonal skills in interacting with community organisations."

Despite this movement, experiential learning is seen as a departure from traditional lecture-based courses and is considered on the fringes of serious teaching and learning (Margetson, 1995). Another common criticism is the lack of faculty experience in structuring such a course. Professional organisations and scholars (Kolb, 1994, Harland, 1998) in liberal arts-based education illustrated best practices and principles in an effort to help design and develop courses that better link theory to practice. Kotval (2003) cites the National Society for Experiential Education (1997) for the development criteria they suggested, such as intention, authenticity, planning, clarity, orientation, training and mentoring, monitoring and assessment, continuous improvement, reflecting, evaluation and acknowledgement. Building on these, she offers insights for teaching courses with experiential learning aspect in planning and allied disciplines as follows:

- Understand and articulate the importance of the Practicum course clearly;
- Structure the course and its relationship to the entire curriculum such that it reflects its unique characteristics;
- Foster good client relationships to ensure good community projects and effective working partnerships;

- Encourage healthy group dynamics and foster transferable skills;
- Encourage greater faculty involvement to seamlessly link theoretical and practical instruction;
- Evaluate students fairly on all aspects of the course experience (Kotval, 2003).

It would be right to argue that while planning studio provides a quasi-real world situation not offered by classroom courses, incorporating experiential learning into planning studio brings it to the real world. Planning studio in general focuses on planning-related tasks or issues that involve creative thinking and critical analysis to produce a practical solution or outcomes (Higgins *et al*, 2009). It offers opportunity for students to acquire skills in managing other people, themselves and their time as well as the project. It promotes learning outcomes that focus on process, involving both individuals and groups, alongside the application of skills (Grant and Manuel, 1995). However, the complexity and uncertainty encountered in real life situations cannot be duplicated in a traditional studio education (Roakes and Norris-Tirrell, 2000). When coupled with experiential learning, planning studio can better delve into the legal, financial and collaborative challenges of real life planning cases. Such experience-based learning can provide “intentionality of design and planning through structured activities such as role plays or games” (Andresen *et al*, 2000), which are practiced in the case study conveyed in this paper.

In line with these discussions, the study aims to improve graduate students’ knowledge and skills to enable them as highly efficient and competent professionals through experiential learning methods. Consequently, the main objectives of the planning studio subject to this study are to train students who can (1) integrate theoretical discussions of reading and the topic of the project and produce knowledge-based planning models; (2) determine how local actors participate in the process of model development, manage attendance meetings in accordance with the broader meaning of the project, and combine and model contributions with theoretical readings; (3) share the models they have developed with the participants, be open to discussion in the belief that feedback strengthens the model, and reconsider and organize rather than merely defend their models; and (4) discuss the developed models in the context of institutional structures and arrangements that determine the scope and capability of the planning action itself.

Studio themes: Collaborative planning and collaborative governance

Traditional planning has been associated with the rational comprehensive model developed at the University of Chicago since the 1970s. This type of planning searches for the best possible combination of means for the given ends. Throughout the evolution of the discourse, planners were told to attend to means and to leave the selection of ends to the interested stakeholders using pluralistic politics (Albrechts, 2003). Eventually, this common understanding introduced collaborative planning into planning literature.

At the end of the last century, Healey’s 1997 book, *Collaborative Planning*, argued that the challenges of urban development in the neoliberal era could no longer be handled effectively by government alone but required the participation of all sectors of society in a form of planning that involved dialogue and negotiation among stakeholders seeking an actionable consensus (also see Friedmann, 2008). Consensus building among people with conflicting interests, however, often required the intervention of mediators, and so mediation became an important new branch not only of planning but of legal

studies as well (LeBaron, 2002). Larry Susskind and John Forester made key contributions to this new specialization, the first in a series of publications culminating in the book by Susskind, McKearnen, and Thomas-Lamar (1999), *The Consensus Building Handbook: A Comprehensive Guide to Reaching Agreement*, the second in *The Deliberative Practitioner: Encouraging Participatory Planning Processes* by Forester (1999). Other contributions regarding collaborative methods and consensus building as a mode of planning and policy making that took place in the last two decades include the works of Sager (2002, 2006), Kolb and Associates (1994), Innes and Booher (1999), Yiftachel and Huxley (2000), Allmendinger and Tewdwr-Jones (2002), and Ansell and Gash (2007). These scholars found that such processes could be creative and effective, offering planners substantial roles. Thus, communicative or collaborative planning became a focus in planning theory.

The resulting paradigm, called the ‘communicative turn,’ has certainly dominated theoretical discourse since the late 1980s, and as Allmendinger and Tewdwr-Jones (2002) put it, it has since undergone a number of mutations, including ‘planning through debate,’ ‘communicative planning,’ ‘argumentative planning,’ ‘collaborative planning’ and ‘deliberative planning.’ It has also developed in different directions as a result of its origins in various intellectual schools of thought that have intertwined with the communicative approach, including neo-pragmatics, critical theory, Foucauldian perspectives, and planning practice. In its general manifestations, the communicative turn has been referred to as ‘collaborative planning’ in UK literature and ‘deliberative planning’ in US literature.

Inherently, the features of collaborative planning imply those of communicative turn. The main components of a communicative rational approach to urban planning have been advanced by Healey (1992). In her perspective, the communicative turn in planning involves the following:

- an interactive and interpretative process;
- a focus on the ‘arenas of struggle’ where public discussions occur and where problems, strategies, tactics and values are identified, discussed, evaluated and where conflicts are mediated;
- implementation among diverse and fluid discourse communities;
- development of a reflective capacity that enables participants to evaluate and re-evaluate; and
- the ability of participants to collaborate to change the existing conditions.

Consequently, collaborative planning is often mentioned as one of the most appropriate planning theories for the network society (Agger and Lofgren, 2008). It engages public and private sector players and other relevant stakeholders representing many different interests while maintaining concern about power distribution and the participation of the public with an aim to reach consensus through deliberation.

Referring to her earlier work, *Collaborative Planning*, Healey (1997) defines planning as “a governance activity occurring in complex and dynamic institutional environments, shaped by wider economic, social and environmental forces that structure, but do not determine, specific interactions” (p. 104). Indeed, planning increasingly moves away from the idea of government as the mobilizer of the public sector, providing solutions to problems, towards an idea of governance for a more desirable future situation through the mobilization of different interests, goals, and strategies (Albrechts, 2003). By

governance, Healey (2003) means the processes by which societies, and social groups, manage their collective affairs. Other scholars highlight the regenerative aspect of governance that reshapes policy ideas and institutional structures through a bottom-up approach (see Innes and Booher (2003); and Phelps and Tewdwr-Jones (2000), among others). There are, of course, many modes in which governance can occur (for a detailed analysis, see Cars *et al*, 2002). Addressing governance instead of government provides the basis not only for more broadly handling issues of power but also ensuring greater participation and inclusion. Also, governance can include institutions that are not normally considered in a narrower ‘government’ approach to planning decisions and processes. This brings up the definition of ‘collaborative governance’ in planning literature.

Most planning literature uses the term collaborative governance to describe a participatory relationship between public institutions and non-state stakeholders. For example, Reilly (2001) describes collaborative efforts as a type of problem solving that involves the ‘shared pursuit of government agencies and concerned citizens.’ Smith (1998) argues that collaboratives involve ‘representation by key interest groups.’ Connick and Innes (2003) define collaborative governance as including ‘representatives of all relevant interests.’ Such definitions set standards for the type of participation of non-state stakeholders which makes collaborative governance never a merely consultative process. Thus, it is no surprise that in their collaborative governance model that they developed by analyzing 137 cases, Ansell and Gash (2007) define the features of their cyclical collaborative governance process as face-to-face dialogue; trust building; commitment to the process; shared understanding; and intermediate outcomes (Figure 2).

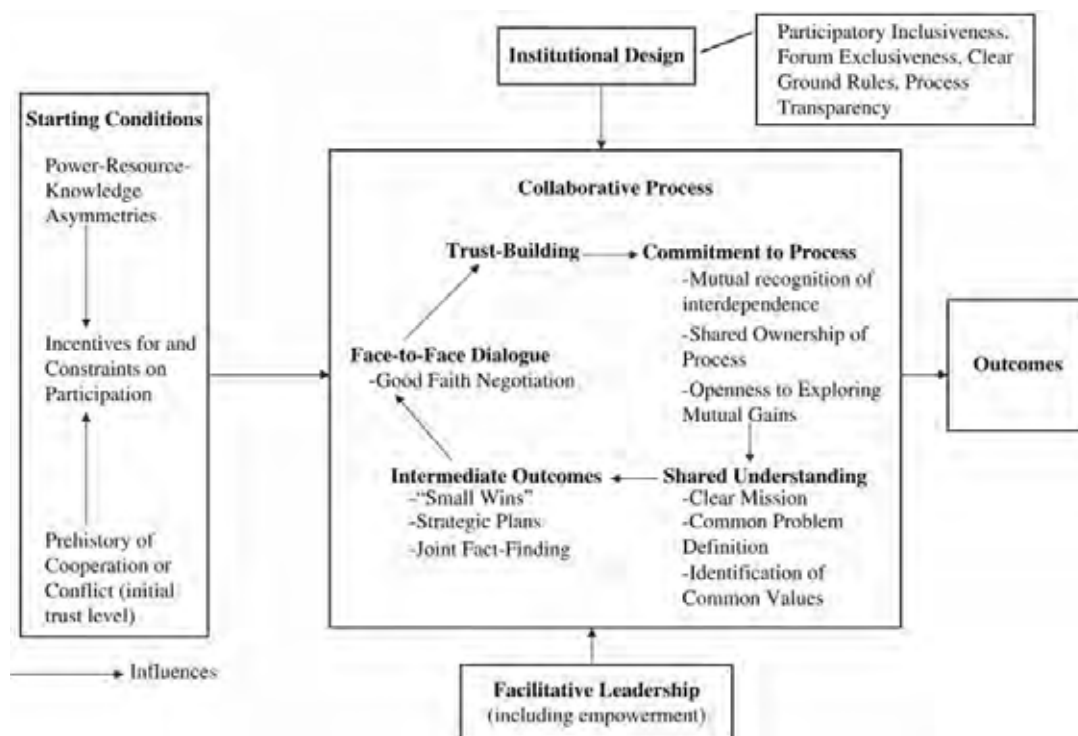

Figure 2. A Model of Collaborative Governance (Ansell and Gash, 2007, p. 550)

Although interest groups and public agencies have predominantly engaged in a conventional two-way flow of influence, the definitions of collaborative governance imply an explicit and public strategy of organizing this influence. There is a clear emphasis here on the power over process and procedures to effect, presumably through the weight of rational thought, reflection, expression, and change for the good of the majority of stakeholders (Phelps and Tewdwr-Jones, 2000).

Project studio description and process

Thus, the consecutive studios, Project 1 in fall semester and Project 2 in spring semester, were designed to demonstrate one holistic curriculum with two incremental themes: collaborative planning and collaborative governance, respectively. The students were asked to propose extensive models that correspond to the studio theme by the end of each semester that consisted of 15 weeks. The weekly program is summarized in Table 1.

Building on the course description and the topic of collaborative planning and governance, Pınar Neighborhood in Sarıyer District, Istanbul, offers an interesting study area regarding tangible and intangible site characteristics, intervention areas, and pluralistic approaches. In particular, Pınar Neighborhood has already proven to be a suitable case area to study such practices due to its eager local government, many engaged local residents and NGOs, and not-yet-solved *gecekondu* (squatter) redevelopment dilemma. Proximity of the neighborhood to the campus was another criterion for site selection so that the students could make frequent visits to the site.

The fall semester studio, Project 1, aimed to make the best of the potentials Pınar Neighborhood offers. It refers to the planning of the neighborhood with a thorough organization of relevant stakeholders and their fair involvement in planning decisions so as to achieve successful and sustainable planning outcomes towards the betterment of the local public's wellbeing. Following the previous semester's studio topic, Project 2 aims to further collaborative planning practices in Pınar Neighborhood. It refers to enhancing redevelopment plans of the neighborhood by using collaborative governance models that require an in-depth analysis and organization of relevant stakeholders, their powers, leadership capacities as well as any conflicts and risks that are embedded in the planning, decision-making and implementation processes. This way, the outcomes of this two-semester studio curriculum aim to take the planning scheme closer to the ideals of social justice and just planning.

The experiential learning method of the curriculum design allowed students to experience on site observations and data gathering, and real life interaction with local community. Supported with relevant theoretical readings and case-driven literature research, they were involved in two structured and several occasional follow-up visits to the site, a formal briefing at the local municipality, thematic data gathering and analysis (including an advanced stakeholder analysis), assessments, and collaborative planning proposals with spatial, financial and participatory aspects. In the following semester, they were expected to fit their refined plans into a collaborative governance model. They discussed various approaches in both a structured studio debate and an on-site focus group study with local actors to test and revise their models. They worked in teams of 4 or 5, to form a total of 5 student groups. These groups are introduced as Groups A through E in the analysis below.

Fall Semester, Project 1: Redevelopment through collaborative planning

Students were expected to closely read, review, and reflect on related literature while determining and solving the planning problems of Pınar Neighborhood and the district it is located in, Sarıyer. They worked in teams during and outside studio meetings to produce said planning study in an inherently collaborative process; they presented their work using written, oral, and graphic expression techniques throughout the semester. Studio meetings served to frame and review weekly topics, further off-studio production, and allow for an inclusive discussion, thus enabling learning from different teams' work. This process were reinforced with two jury meetings.

Based on this scope, the Project 1 studio followed the steps below:

- Gathering and analyzing data on natural and built environments, as well as social and economic conditions, and needs of local stakeholders as a preliminary planning task;
- Assessing sorted data and analyses using various evaluation methods with collaborative planning in mind;
- Proposing alternative intervention scenarios and embedding collaborative approaches in decision-making processes;
- Foreseeing possible conflicts and proposing ways to mediate them;
- Refining analyses, assessments, and scenarios to ensure the ultimate project goal: improving Pınar Neighborhood locals' lives while effectively involving them in planning.

The weekly program below further broaches the fall studio process and lays out expected deliverables at each step.

Week 1: Introduction to the studio & logistics

Weeks 2-3: Field trip & site analyses

Natural, physical and socio-economic characteristics of the project site:

- Location and references in the vicinity;

- Important natural references that reveal the site's topography, geology, ecology, vegetation/soil, climate, and disaster peculiarities;
- Physical identifiers and patterns of transportation network, land use and ownership, urban services, building characteristics, etc.
- Demographic, social and economic conditions of local inhabitants via online and on-site secondary data, and primary data derived from observations and surveys with households, businesses, and local government institutions.

Site analyses included location, historical development, environmental relations and relevant planning decisions regarding the study area. In addition to them, natural environment, land use and accessibility (to hospitals, schools etc.) analyses and Bosphorus Law that have restrictions were critical to understand the area (Figure 3). First developed in the 1950s, the neighborhood is one of the first *gecekondu* areas of Istanbul. In the 2000s, shopping centers and gated communities were built that have had significant physical and social impacts in the neighborhood.

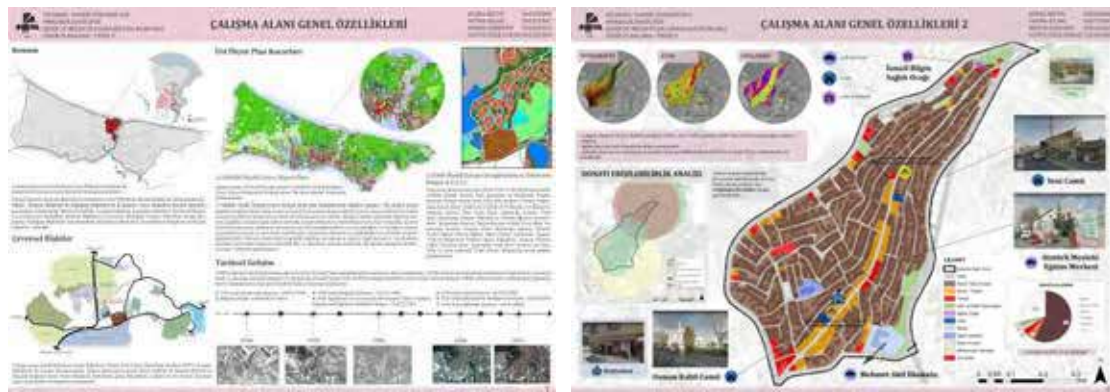

Figure 3. Physical and natural environment analyses (Group C)

Socio-economic structure analyses of neighborhood provided information about population, minimum-maximum and average household income, average age, numbers of housing and workplace, average land value per square meter, and education levels (Figure 4).

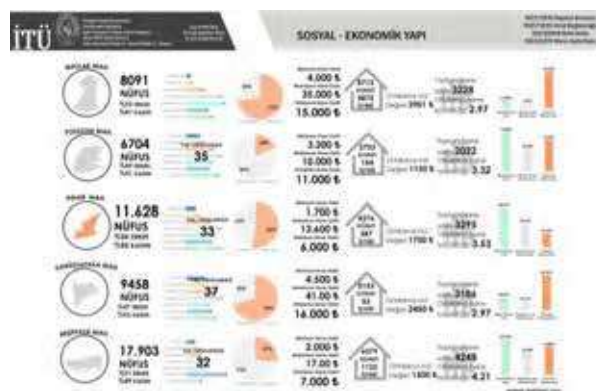

Figure 4. Socio-economic analysis (Group A)

Weeks 4-5: Stakeholder analysis & good practices with collaborative and participatory approaches

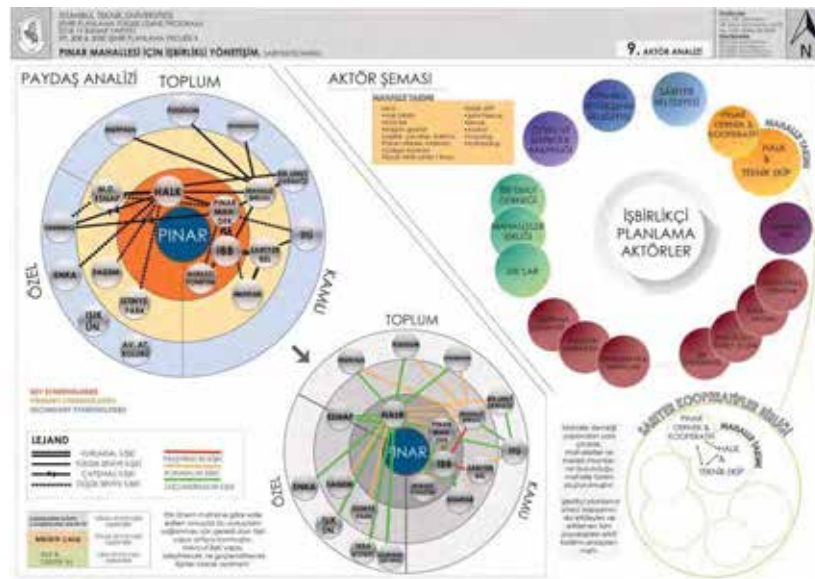

An advanced stakeholder analysis of the project at hand:

- Formal vs. informal stakeholders
 - government, private, non-profit, local public, businesses, etc.
- Interests vs. resources
 - interests— livability, quality of life, money, votes, reputation, etc.
 - resources— laws, politics, money, knowledge, time, liberty, etc.
- The influencer vs. the influenced
 - power relations

Participation and collaboration review of select international cases:

- Short description
 - case area size, population, main natural, physical and socio-economic characteristics
- Planning approach
 - planning problem(s), policies, goals, decisions
- Participatory approach
 - actor structure, participation policy, level, methods, and process
- Impact of collaborative approach on planning decisions and outcomes towards deriving lessons for the studio project

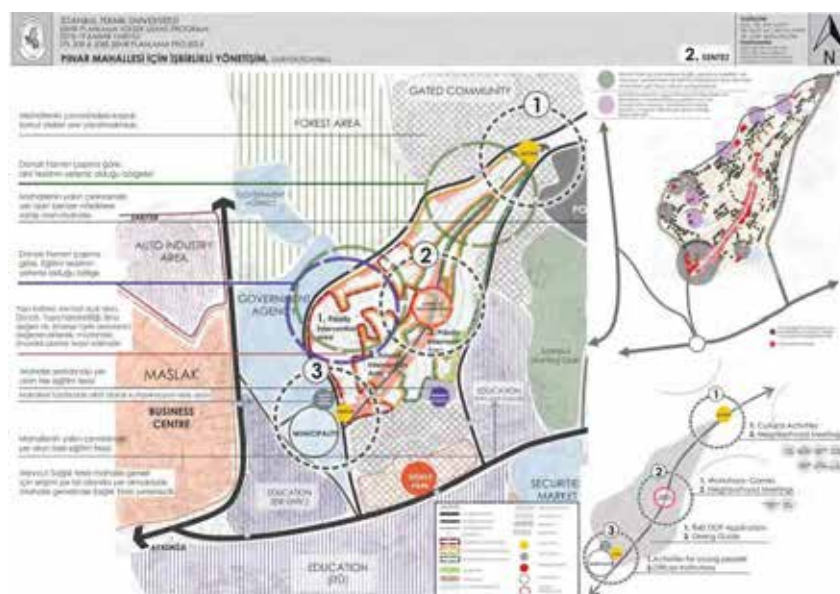

The actor and stakeholder analyses revealed those who potentially influenced and who were influenced by the redevelopment decisions. The students grouped stakeholders into three: local public, private sector (shopping mall, private university in area, entrepreneurs, etc.), and public sector (Istanbul Metropolitan Municipality as the land owner, local municipality, neighborhood associations, etc.). The relationship between actor groups were defined via various approaches (e.g. legal, financial, conflictive, high/low level) in terms of their interests and resources (Figure 5). Moreover, the stakeholders' significance-impact matrices ensured that relationships which are important for the collaborative planning process would be strengthened, improved and/or sustained.

Weeks 6-7: Assessments: Synthesis & problem areas

Refining and superposing analysis findings that are critical to the safety and wellbeing of general and/or a group of local public to reveal planning problems and intervention areas; associating these problems with actor groups' profiles.

As seen in Figure 6, the syntheses included the integration of natural and built environment analyses and the socio-economic characteristics. Examining the relationship of the study area to its vicinity further revealed strengths and weaknesses in term of physical and social characteristics (Figure 6).

Week 8: Fall break

Week 9: 1st Jury assessment

Analyses of the study area, its vicinity and relevant cases review & preliminary assessments

Weeks 10-12: Plan alternatives with a collaboration focus

Planning interventions & collaborative scenarios:

- General approach to the planning problem(s)
 - Solution-based modelling of the project process;
 - Designing a project process with relevant steps
- Conceptual elaboration and discussion of the project model
 - How model steps correspond to the problems and solutions;
 - Actors, their roles and contributions to the solution process

Possible conflicts & their mediation:

- Plausible risks for and conflicts in/between various actor groups that may arise during planning process
 - Interest groups and conflicts of interest (i.e. demands on space, public services, economic gains, etc.);
 - Possible cases of neglect and/or repression of vulnerable groups (i.e. regarding age, gender, disability, ethnicity, knowledge, income, etc.)
- Corresponding conflict resolution process
 - Conflict types and resolution processes in literature (Turkish and international) that engage mediation/participation methods;
 - Current Turkish laws and regulations towards conflict resolution;
 - Selecting and applying resolution tactics, tools and processes that are workable for the project at hand

Policies for public interest and wellbeing:

- Policies and principles derived from the project model
 - Expected outcomes;
 - Collaboration policies;
 - Conflict resolution policies that seek public interest

The students determined prominent parameters in collaborative planning process such as public and private investments, population and employment characteristics, social and physical infrastructure, land ownership, legality and gentrification. One group developed collaborative plan alternatives in the context of relationships based on the levels of investment and consensus (Figure 7). According to

analyses, the best alternative (#1) is achieved through high-level investment and consensus, while the worst (#4) relates to low-level investment and consensus.

Figure 7. Plan alternatives with a collaboration focus (Group C)

Weeks 13-14: Refining and concretizing proposed project model & policies

Making sure plans have achieved:

- Reflecting the project process model to the conceptual project at hand;
- Integrating solution methods and tools with spatial project decisions;
- Translating findings and implications into suitable resolution, participation and consensus building methods and processes that suit the possible conflicts determined in collaborative scenarios

Week 15: 2nd Jury assessment involving the local municipality

Revised analyses and assessments, planning interventions, collaborative approaches, consensus building scenarios, resulting project model and policies

Spring Semester, Project 2: Collaborative governance model

Like in the previous semester, students were expected to closely read, review, and reflect on related literature while determining and solving the planning problems of Pınar Neighborhood. They worked in teams during and outside studio meetings to produce said planning study in an inherently collaborative process; they present their work using written, oral, and graphic expression techniques throughout the semester. Studio meetings served to frame and review weekly topics, further off-studio production, and allow for an inclusive discussion, thus enabling learning from different teams' work.

The project process was reinforced with one structured studio debate, one focus group study with relevant local stakeholders and one final jury meeting.

Based on this scope, the Project 2 studio followed the following steps:

- Gathering and analyzing any additional data regarding natural, physical, socio-cultural and economic characteristics of the study area;
- Enhancing the previous semester's analytical assessments and physical, financial and collaboration plans;
- Enhancing collaborative planning principles, processes and visuals with added perspective from relevant planning cases from around the world;
- Reviewing past and current collaborative governance models and adapting them to the project at hand;
- Testing tailored collaborative governance models by a student-steered focus group activity that involves relevant local stakeholders;
- Revising the models by reflecting on the focus group findings, possible pitfalls, and good governance principles; and
- Drawing implications for collaborative and good governance legislation and practices in Sarıyer, Istanbul and Turkey.

The weekly program below further broaches the spring studio process and lays out expected deliverables at each step.

Week 1: Introduction to the studio & logistics

Weeks 2-3: Site visit & refining analyses and plans

Site visit for further analysis:

- Search for any missing or additional secondary data;
- Field observations, social encounters (in-person and in-depth examination of physical and social conditions & any changes in them)

Refining synthesis & assessments:

- Reflecting on revised primary and secondary data;
- Search for various feedback from previous semester's plans;
- Revision of synthesis, SWOT and problem areas

Refining physical & financial plans:

- Reflecting on any data changes, observations and assessments;
- Revising physical and financial planning decisions, diagrams and maps

Based on the three main groups of actors (i.e. local community, local municipality and entrepreneurs) they defined, one student group further examined various interests and expectations in a financial model (Figure 8). These models were developed to make the redevelopment project self-sufficient thanks to energy saving protocol, taxes and other incentives/means.

Figure 8. Financial model (Group D)

Weeks 4-5: Revisiting good practices & further refining plans

Collective overview of world cases with collaborative and participatory ambitions:

- A short paper (5-7 pages) that:
 - Compares and contrasts all cases reviewed in previous semester regarding physical, collaborative and participatory approaches;
 - Delivers concrete lessons and strategies for the studio project

Refining collaborative plans with input from literature:

- An “actor scheme” using stakeholder analysis
 - Formal v. informal actors (individuals, organized groups, private entities, government agencies);
 - Interests v. resources (overlaps, gaps, contradictions);
 - The influencer v. the influenced (power relations)
- A revised “collaboration scheme” and its adaptation to plans
 - Collaboration process with relevant actors, roles and responsibilities integrated to the physical and financial planning timeline;
 - Community participation process with relevant participation policy, level and methods integrated to the planning timeline

The world samples of collaborative (and participatory) planning experiences were reviewed in terms of problems, participants, organizations, processes and keywords. Some of world cases are Davis Creek, Anfield-Breckfield, Berlin etc. as depicted in Figure 9.

Figure 9. Review of world cases with a participatory and/or collaborative emphasis

(Group C)

Collaborative planning process was detailed into five phases by one group: organization, analysis-synthesis, determination of vision, aim, strategy and principles, finance and implementation (Figure 10). All phases involved different actors and interests.

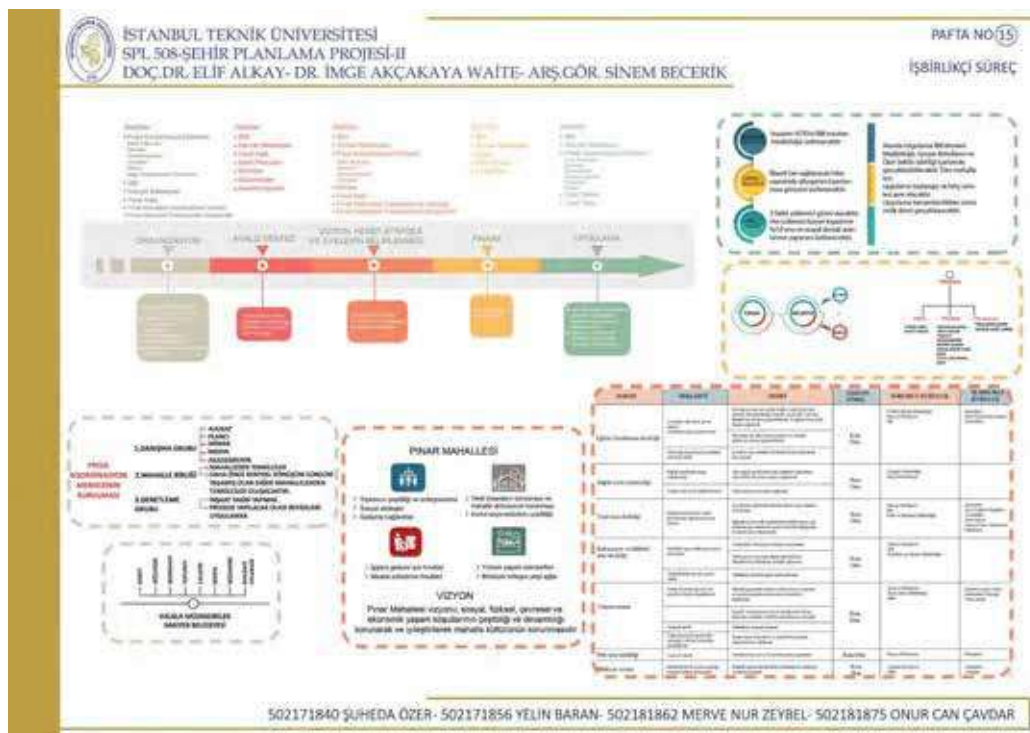

Figure 10. Collaborative planning process (Group E)

Weeks 6-7: Collaborative governance model

- Adapting Ansell and Gash's 2007 model (or another one, of the students' choice) to the Sariyer case based on previous studio studies
- Structured studio debate: Which model, which path of adaptation?
- Revised assessments, plans & adapted collaborative governance model

The collaborative governance models by Ansell and Gash (2007), Lasker and Weiss (2003), and Connick and Innes (2003) were analyzed in detail (Figure 11). The students' assessment of models was mainly related to the models' aim, important inferences, critical points of process, and phases. Then, each group developed a model for collaborative governance for the study area (Figure 12).

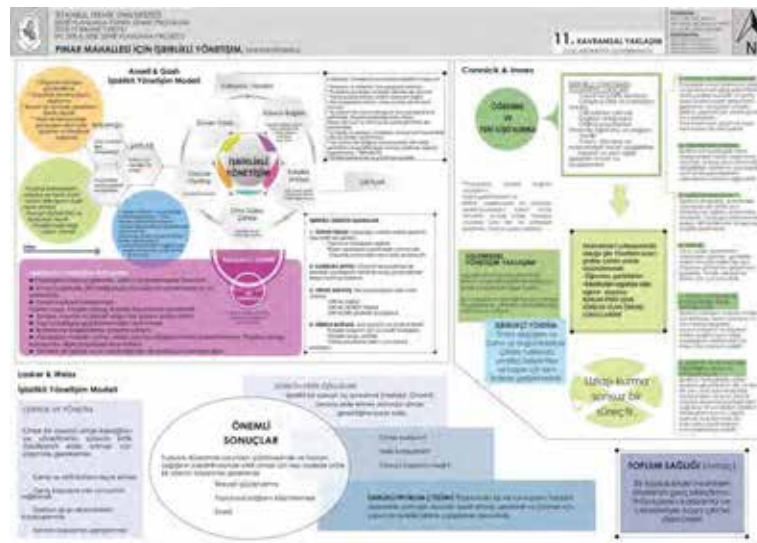

Figure 11. Analysis of Collaborative Governance Models (Group B)

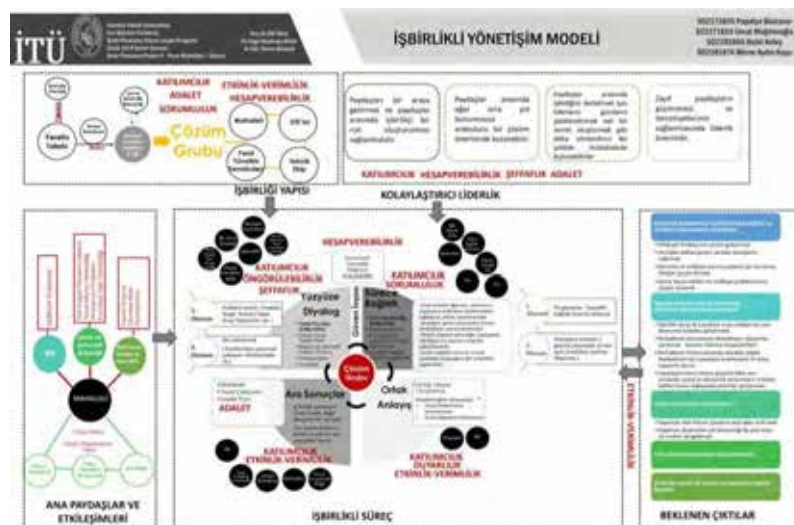

Figure 12. Collaborative Governance Model Proposal (Group A)

Week 8: Spring break

Week 9: Focus group preparation workshop in studio

Facilitation strategies— Facilitative leadership and mediation tactics (by students) that:

- Promote broad and active participation;
- Ensure broad-based influence and control;
- Facilitate productive group dynamics; and
- Extend the scope of the process (based on Lasker and Weiss, 2001)

Assumptions vs. expected outcomes— How to test the model:

- Existing assumptions: power/resource imbalances, incentives to participate, possible cases of antagonism and cooperation
- Collaboration tools: participation methods, face-to-face dialogue, trust building, commitment to the process, shared understanding
- Expected outcomes: planning decisions and their (intermediate) impacts, possible conflicts and their resolution/mediation

Question/discussion guide and logistics— Developing a question/discussion guide to test models and advance them:

- Open-ended questions;
- Students as overt participants;
- Task distribution (facilitating, note-taking, recording, etc.)

Week 10: Focus group study with local stakeholders

With participation of all interested stakeholders; facilitated by students using the question/discussion guide and strategies developed in studio— Focus group study took place in the municipality building with the participation of representatives of local community and NGOs. It started with presentations of student groups about their models. Participants were then asked to choose the one of group for discussion and evaluation of models (Figure 13).

Figure 13. Focus group study at local municipality conducted by students

Weeks 11-12: Focus group data analysis, revision of models & addressing model pitfalls

Analyzing focus group study:

- Organizing participant responses;
- Merging focus group observation notes;
- Coding data (looking for common themes);
- Translating data into findings;
- Supporting findings with outlier responses and notes

Revisiting collaborative governance model:

- Adjusting and detailing the model as necessary based on focus group findings;
- Designing a project process with relevant steps

Possible model pitfalls and responses:

- Plan B's addressing any risks;
- Community and institutional capacity building and (other) empowerment needs

The analysis of focus group was divided into two: first part involved citizens' comments, ideas and demands, the other one reflected on observations and inferences (Figure 14). The data were coded and examined in line with the collaborative governance model components. Models were then revisited to reflect the focus group findings.

Figure 14. Focus group analysis (Group E)

Weeks 13-14: Implications for “good” and collaborative governance

“Good governance” in action:

- Good governance principles in planning literature;
- Integrating good governance principles with the collaborative governance model

Implications for good governance in current Turkish governance legislation:

- Current guidelines, laws and regulations towards (good) governance in Turkey;
- Evaluating the Turkish (and local) planning practice regarding good governance (Figures 15 and 16);
- Generating relevant policies for national/city legislation to improve governance practices in planning

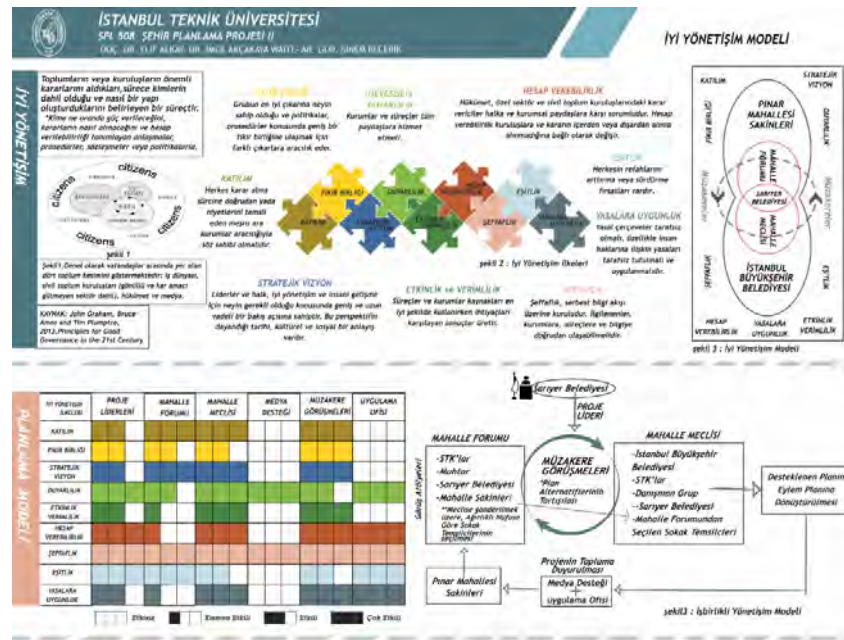

Figure 15. Good governance model

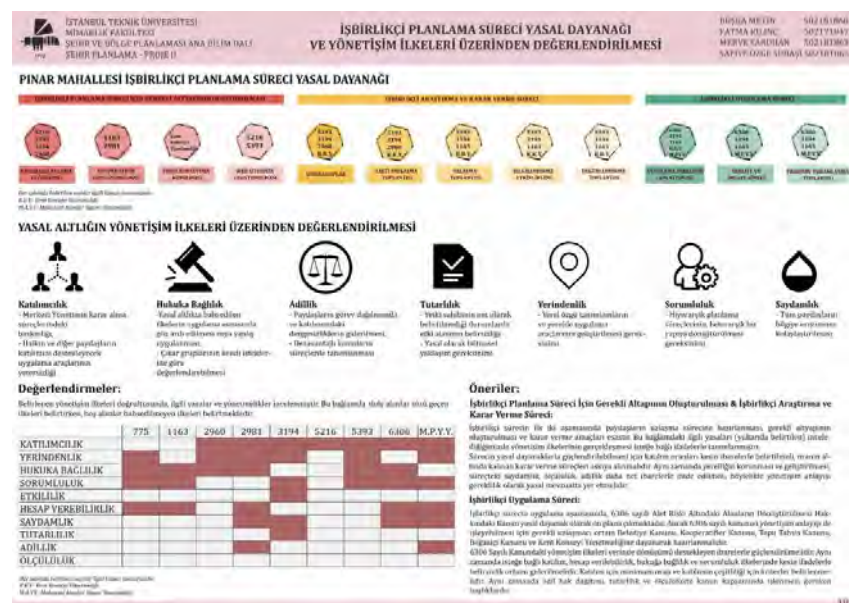

Figure 16. Current Turkish redevelopment laws within good governance perspective

Week 15: Final jury assessment involving local stakeholders

Cohort analysis and reporting of focus group study; revised collaborative governance models with adaptive strategies and good governance inputs; refined policies to improve governance practices in Sarıyer and Istanbul, with implications for Turkey

Preliminary findings and discussion

In the context of course content and development strategies, all five groups based their general framework and models on current conditions of natural, built and socio-economic structures of the study area. Initially, main problems of Pınar Neighborhood were defined in relation to the quality of physical environment, accessibility due to topography and lack of green areas. However, following the structured and semi-structured site visits, a formal briefing at the municipality, and surveys and interviews with local actors, one crucial problem of the area appeared as the land registration issue. All groups defined stakeholders and actors that will take part in the decision-making process of the neighborhood redevelopment in detail. In this perspective, local residents who do not have land titles, the Istanbul Metropolitan Municipality as the major land owner, the district municipality, and local NGOs were defined as important stakeholders for collaborative planning. However, the issue was to remedy all political and economic power relations and the jurisdiction disputes.

All studio groups have developed solution- and network-oriented organizational models and schemes to design neighborhood redevelopment alternatives in terms of spatial, financial, collaborative and legal restructuring. One of the groups described the core project values in keywords “participation — equality — equity — trust — right — clear — desire — need — expectation — empathy — public interest — participatory democracy — reconciliation.” It is observed that all models aimed to achieve successful and sustainable planning outcomes towards the betterment of the local public’s wellbeing. The students developed physical, financial and collaborative plans, with a special emphasis on the public participation aspect. All in all, both course context and collaborative studio environment enabled the graduate students to be more motivated, as they were encouraged to think about collaborative planning and governance processes for the neighborhood’s rooted redevelopment problems by empathizing and consulting with its everyday residents.

It is found that experiential learning based project studio design has been a factor in obtaining the studio deliverables analyzed in detail above. Unlike the more conventional planning studios, the graduate students discussed their findings and models with municipality officials throughout the semester and at studio juries. They also had an opportunity to test their models with a focus group study involving local community representatives. In fact, on-site interviews and the focus group study were main tools for re-examining the models and establishing further connections with locality. As students develop their ideas in their own groups, they can take into account the views of local representatives with different competencies and expectations. They also held intra-group and inter-group discussions concerning common pitfalls, responses and understandings; thus, studio meetings have helped students to observe various approaches to problem-solving and process management, and that they should question their models accordingly. The students have highlighted the importance of such inclusive and interactive processes both in the studio and on site towards building trust between planning practitioners and local actors. They have experienced that face-to-face dialogue goes beyond the developments of a site-based model, and that the model is an inevitable necessity in connecting with real life.

Acknowledgements

The authors would like to thank the cohorts of the two studios of Urban Planning Master Program in the 2018-19 academic year. They would also extend their thanks to the Sariyer Municipality administration and the Urban Design Department and its employees, Fahrunnisa Esentepe and Nazım Özcan in particular. This study would not have been as effective without the eager cooperation of both students and the local municipality associates.

Teaching planning for the transition

Collaborative International Workshops – A joint Brazilian-German Teaching Experience for Planning in Vulnerable Areas

Collective Learning on Planning for Integration and Transition

Almut Wolff¹, Gerônimo Leitão²

¹ University of Applied Sciences, almut.wolff@jade-hs.de

² Universidade Federal Fluminense, geronimo_leitao@uol.com.br

Abstract:

A joint teaching experience involving Brazilian and German students of Architecture, from Universidade Federal Fluminense (Niterói/Brazil) and Jade University of Applied Sciences (Oldenburg/Germany), promoted the development of urban planning proposals. Based on previous teaching experiences in planning for vulnerable urban areas in the participating faculties we developed a workshop series as a collaborative teaching project.

In 2017 we worked in Niterói on a project for a centric favela and fishermen village at the Guanabara Bay. In 2018 we elaborated a project for a centric neighbourhood gathering (social) housing, enterprises, abandoned plots and harbour uses in Bremerhaven. In 2019 we will be back in Rio de Janeiro.

The workshops were accompanied by local actors. Students learnt to understand social implications of planning in a new context, started a critical reflection of own experiences and developed a cooperative project that was dedicated to open the local discussion about the places further development. During the Workshops students acquired knowledge about local conditions of urban development such as in the case of Brazil the challenge to integrate informally grown neighbourhoods and the formal city or as in the case of Germany dealing with the consequences of economic and demographic changes like shrinking populations and drastic changes of uses. Parallel to the development of projects the students participated on lectures and excursions. The concepts aim to integrate the neighbourhoods into the city and to develop ideas for public spaces, community facilities, affordable housing, and local economy.

These teaching experiences are challenges to integrate compact workshop formats and the manifold new experiences for the student into professional approaches within complex working fields. At the same time the experience of an immediate communication to planning agents and local communities create an intense learning process and a critical reflection on given for granted planning knowledge.

Keywords: collaborative teaching; vulnerable urban areas; urban planning; socio-spatial integration

Introduction

This article reflects on a joint teaching experience involving Brazilian and German students, from Universidade Federal Fluminense (Niterói/Brazil) and Jade University of Applied Sciences (Oldenburg/Germany). We developed a series of workshops as a collaborative teaching project to promote the development of urban planning proposals for vulnerable areas.

The School of Architecture and Urbanism (EAU) and the Faculty of Architecture (FBA) developed a format of iterative workshops. The Workshops were organized and taught by the authors, integrated around 30 students for each workshop and were held in English. This workshop series was funded by the International Office of the Jade University and by the German Academic Exchange Service (DAAD). In 2017 we worked in a mixed students group on a project for a Favela in Niterói (Brazil). One year later we elaborated a project for a neighbourhood in Bremerhaven (Germany). In September of 2019 we will continue the programme at Rio das Pedras (Brazil). Throughout the implemented workshops students learnt to understand social contexts of planning in a new context, started a critical reflection of own experiences and developed a cooperative project that was dedicated to promote the local discussion about the places further development. Parallel to the development of projects the students participated in lectures and excursions.

While in the case of Brazil a key issue was to integrate informally grown neighbourhoods and the formal city in the case of Germany it was about to deal with the consequences of economic and demographic changes like shrinking populations and drastic changes of uses.

In Niterói students in mixed teams developed concepts for the local favela Vila dos Pescadores. The goal was to show development alternatives that facilitate the integration of the existent favela into the city without expelling the community of dwellers and fishermen. So there had to be found ideas for public spaces and community facilities within the neighbourhood, for affordable and flexible housing projects and last not least ideas for local economy to develop as a stable base for the community of dwellers. There were developed divergent proposals based on the central approach to reinforce local qualities and to open up opportunities for the local community to use and discuss these proposals as much for self-initiative activities as for negotiations with planning administration.

In Bremerhaven the objective was to develop a proposal for the requalification of a degraded area, near the local harbour, students and teachers involved had the possibility of building a dialogue with different agents - public and private -, in the area under study, seeking for solutions that could create a urban morphology capable to attend social demands for housing, community facilities and also promote the integration into the surrounding neighbourhoods. In addition to these relevant issues addressed in the project development, the focus was on stimulating business activities in the area under study in order to generate income and job opportunities. Another determining point in the development of the urban projects was the creation of different types of housing projects including social housing.

Along the workshop, the students had also the opportunity to establish a rich dialogue between them, discussing references and similar projects of requalification of degraded areas, in different countries of Latin America and Europe.

The final presentation of the studies developed by the student groups, allowed – in addition to the return of the urbanistic proposals to the several agents involved – a first experience (for most of them) of a contact with some of the real "clients" of their projects. Finally, it is expected that the projects elaborated during the workshop will contribute with ideas to the development of future urbanistic solutions for the area object of study.

In both faculties there are courses that focus on integrating teaching into real planning discourses and specific needs of local communities and vulnerable urban areas. They are part of the compulsory programme of either school: At the School of Architecture and Urbanism (EAU) in Niterói it is the course on popular housing project. At the faculty of Architecture (FBA) in Oldenburg it is the course of urban design project. The joint workshops take these teaching experiences as a starting point to explore new didactic approaches by creating an intense learning process and vivid studio atmosphere and by using the different backgrounds of the two student groups as a base for a critical reflection on given for granted planning knowledge. Especially the immediate communication to planning agents and local communities create manifold new experiences for the students and opens up their perception of a complex working fields for them as future professionals.

The Social Housing Project Course at the Escola de Arquitetura e Urbanismo (EAU) at UFF

The Social Housing Project course is taught over six months, in the penultimate period of the Architecture and Urbanism course. Comprising three modules, the discipline addresses each semester one of the three distinct fields of the social housing project in Brazil: the urbanization of consolidated informal settlements; the re-qualification of abandoned properties, aiming to adapt them to the use of housing; and the occupation of empty land in urban areas equipped with sanitation, transportation and services infrastructure, with the construction of multi-family buildings. In addition to the teacher responsible for the discipline, teachers from other areas (sanitation infrastructure, structural calculation, transportation, social work), linked to other units of the Federal Fluminense University, also participate in the orientation process.

Each semester, a community - in the case of urbanization projects of informal settlements - or an area - when it comes to the development of housing projects - is object of study, addressing one of the themes mentioned above, in different municipalities of the Metropolitan Region from Rio de Janeiro. Thus, the students developed several projects in communities located in Niterói, São Gonçalo, Nova Iguaçu, Itaboraí, Duque de Caxias and in the state capital, Rio de Janeiro.

Organized in groups of up to four members, the students act according to a project development methodology, which foresees the development of the following activities: socioeconomic surveys in the areas where the interventions will be carried out, in order to build the social profile of the project. population that will be served; collection of data in different public agencies, in order to subsidize the architectural and urbanistic proposals that will be developed; participation in assemblies with dwellers, to discuss existing problems and identify solutions; and, finally, the development of urban-architectural projects, which will be presented and discussed with community leaders and the local population.

In the development of projects, lectures are also held with the participation of architects and town planners, who work in the State Housing Company of the State of Rio de Janeiro and other Brazilian states, with the objective of knowing different experiences and discussing them. Students are

encouraged to elaborate their work, almost exclusively, in the project studio, in order to share the different project approaches.

At the end of the course, copies of the material produced by the students are submitted, after approval by the dwellers, so that their representative entities can use the studies developed by the students, in their lawsuits and negotiations with the municipal and state governments. The level of resolution of the studies carried out by the students should allow the architectural and urban planning projects to be detailed later, without any significant changes in the proposals developed together with the community.

With regard to informal settlements, the studies developed by the students are focused on favela communities occupying sites with different characteristics. Some of the communities where the interventions were carried out had settled sloping areas with high risks of landslides. Others were located on land situated along riverbanks and lagoons, subject to floods. Finally, there were those that arose from the occupation of public areas, through actions implemented by the organized social movement, which sought to redefine patterns of land use and subsequent land regularization and the implementation of sanitary infrastructure and community equipment. The projects carried out by the student teams would thus contribute to negotiations with municipal and state agencies, aiming at the expropriation of the occupied area, thus giving it a social function - in the words of one of the leaders of this movement: the creation of a popular neighbourhood.

The analysis of the results achieved by the course of popular housing project, in the academic field, points to a positive balance. The students have access to a socioeconomic reality quite different from the one they experience in their daily lives, which undoubtedly contributes to the construction of another concept of citizenship, committed to democratic values and social justice, and, also, another perspective about what a city can be.

As far as their professional training is concerned, they have the possibility of developing architectural-urbanistic projects that question the standardized and poor quality solutions, which, with exceptions, characterize the official production of popular housing.

At the same time, the interaction with teachers from other areas, such as civil engineers and sanitarians, sociologists, social workers, geographers, in turn, makes it possible to anticipate the experience of a multidisciplinary dialogue, which will take place in professional practice of the students, in the future.

Finally, the architects who received this formation, in the bachelor course of the Fluminense Federal University - one of the few Brazilian architecture and urbanism faculties that has a course specifically built for the question of social housing – will have a special role in the labour market for their particular qualification in this field of planning.

However, with regard to the effective contribution of this academic production to the formulation of public policies, or even to meet the demands of the communities with which the projects were developed, the results are not that good, for several reasons.

Initially, it is important to highlight the resistance of a significant portion of government agencies, in their different spheres, to promote greater integration with the University, in the sense of building

partnerships. Whether for reasons of a political nature, or because there is a distrust of academic production, whose deadlines and products are supposed to be incompatible with the dynamics of public administration (some managers even affirm that the University is distanced from the real world) few projects served, in fact, as a reference for interventions in the areas under study. However, even though the projects presented were not implemented - most of the time - the solutions presented by the students contributed to the community leaderships having a study that materialized their aspirations, giving a base to their positions in the negotiations with the public power.

Considering the last 25 years of regular courses of Social Housing Project, at the School of Architecture and Urbanism of the Fluminense Federal University, we find that, despite adversities, we have sought to achieve our goals. One of these objectives is to contribute to the training of qualified architects for the practice, in a project field that has particular characteristics and that require another professional posture and a social conscience. Another is the commitment to contribute to the formulation of social housing solutions committed to popular participation in the planning process, the quality of the built environment and sustainable urban development - the University, joining forces in the construction of the right of Architecture for all.

Joint Workshop at Vila Dos Pescadores in Niterói

The partnership between the Federal University of Fluminense and the Jade University of Applied Sciences was originated by one of the Brazilian students who had studies there at the faculty of Architecture (FBA) due to his participation in the "Science without Borders Program" - an international exchange program promoted by the Brazilian federal government.

For 2017 we agreed on a first workshop in Niterói and in September 15 students from the Faculty of Architecture of Oldenburg came to Brazil to participate in a 2 weeks urban project workshop, involving students of the course popular housing project. The workshop was held by the authors and Ronaldo Brilhante.

The German students had participated in a preliminary seminar about urban development, housing policies and architectural approaches to social housing in Latin America at their home faculty. The Brazilian students prepared the workshop by own research activities that would give a base to the analysis of the site. In the beginning of the workshop several excursions within the Cities of Rio de Janeiro and Niterói were offered. Especially the visits of two Favelas, Rocinha and Parque Royale, allowed German students to acquire first on site experiences of informal city growth and urban interventions to integrate the favelas. After these first experiences the student groups visited and analysed the area that would be studied during the workshop.

The workshop was engaged to develop proposals for the community of Fishermen Village, in Niterói. This informal settlement, located on the shores of Guanabara Bay is home to about 80 families. Located in the central area of the city of Niterói, it was originally a colony of fishermen. Along the years, the community reduced their fishing activities, due to the pollution of the waters of the bay. According to information from local dwellers, some of the former fishermen are currently engaged in the promotion of boat trips for tourists. The place is still used for the anchoring of private boats, whose owners pay a small amount, to leave there their boats. The Fisherman Village presents recurrent problems in the Brazilian favela communities: lack of adequate infrastructure for basic

sanitation; need for improvement of the quality of housing conditions, the precariousness of the urban structure; absence of access to basic community facilities, such as day-care centers.

Regarding fishing activity, the intention was to propose suitable solutions of mooring for the boats in order to support the existing fishing activities and to support to the growing demand for sightseeing activities in the bay - considered the tourism and leisure potential of this area. Nevertheless, this involves a more complex situation that transcends the interventions envisaged for the project. It is not enough to propose a physical structure to support this activity if fishing in the area has been increasingly compromised by agents who deposit material in the sector of the border where the fishing is carried out. In this sense, it is possible to foresee in the project the implementation of infrastructures like sheds with refrigeration structure, for fish storage, to meet the demands of the fishermen's' association. But it has to be stated that this will not change the loss of water quality.

In order to provide adequate treatment for the bay's edge, it would be necessary to promote the resettlement of families who built, in extremely precarious conditions, irregular housing in this area. So the resettlement of housing within the area of the community was proposed, suggesting the demolition of a part of the buildings (with fair compensation of its occupants) and offering new housing within the area. Along the shore of the bay it will be useful to define with physical landmarks a precise boundary of settlement.

All interventions considered the need for improvement of the conditions of living for the local dwellers as for example the implementation of sanitary infrastructures and pavement of the existing streets. To support a positive future development of the area the group planned also community-based equipment that would meet diverse dwellers demands: health, professional training, culture, etc.

The community is adjacent to a state-owned abandoned plot. This area was included to create new opportunities for social housing or for affordable self-help construction with corresponding public spaces and infrastructure.

Needed to say that all proposals developed should consider aspects related to costs, in order to make them feasible.

Regarding the relationship with the community of Fisherman Village, the crisis of community representation, expressed by the absence of an active and combative dwellers association, compromised the perspective of a more active participation of local dwellers. Nevertheless several dwellers were interviewed by the students, accompanied by the teachers involved in the project workshop.

In addition to the above mentioned problems of the favela dwellers there is a project presented by the City Hall of Niterói, which proposed the withdrawal of all families currently living in this area, with the aim of promoting a "gastronomic centre", focusing on the tourist potential of the area. Until now - above all for economic reasons – it was not carried out. For this reason the local community had on one hand formulated their main demands but on the other hand they hesitated to promote them actively.

Within this complex situation the students considered the site analysis and, the community's demands to develop goals for the future development of the area. These results would be handed to the dwellers

association and it would be left upon their decision to consider whether they would use them for further negotiation or not.

Considering all these questions, the teams formed by German and Brazilian students developed urbanistic proposals focusing on site analysis and on the points presented as local demands. The student teams worked together beginning with creating knowledge and understanding of the local needs and going up to develop specific projects. Students' discussions were very concerned about the possibilities to create flexible housing typologies that could be afforded by the local dwellers. By this motivation they discussed private and collective needs, the minimal equipment of a basic house and strategies to amplify the houses by self-construction. The groups also discussed alternative options to facilitate economic and educational activities within the neighbourhood, and the adequate urban spaces for the area that would allow an integration to the city but keep a certain privacy for the community in the fishermen village. So besides presenting relevant possibilities for the development of the favela the students lived an intense process of reflection about human needs on housing, education, work and collective life.

Urban design projects at Faculty of Architecture (FBA) at Jade University

The urban design project Faculty of Architecture (FBA) at Jade University is part of the Bachelor Degree Programme. In the third year the students develop their first urban design project. Students work on the project for the duration of one semester.

The aim is to introduce students to current issues of urban development and the complex links between social, economic, ecologic and morphologic aspects. Projects are developed on base of real planning needs in cities within the region as Bremen, Bremerhaven, Wilhelmshaven and last not least Oldenburg. Bremerhaven and Wilhelmshaven have suffered severe shrinking processes. All cities have planning needs for the redefinition of areas with former uses for industry, harbour, military, railways, etc. The choice for working areas takes into account to form part of a current local planning debate. So the areas chosen are zones that require a transition of use and represent current urban voids not in the sense of being brownfields but having been excluded, being in decay or comprising conflictive uses and morphology within the area. The aim is to develop mixed use areas that allow hybrid functions between housing, commerce, business, leisure activities and social infrastructure.

The specific planning requirements are defined in collaboration with local planning administration, borough council, local citizens' groups or neighbourhood associations. While preparing the course contacts to the involved local actors are made and the main issues are defined in a cooperative way. At the beginning of the course students meet up with some of the actors on site. During the course of the semester the local actors are invited to on the mid-term presentations. The students elaborate their projects in groups of two. So, at the end of the course around twelve alternative project proposals are presented.

The developed project show divergent concepts to structure the areas, to develop a layout for buildings, to insert new uses, to create public spaces and infrastructure that integrates the areas into the surrounding neighbourhoods.

Project are presented in public on site or handed over to the involved local actors. In most of the cases the students' projects serve as a base of debate for local actors in order to define next steps for possible future development. The students explore by their project for the area alternative approaches and planning criteria. By this the developed projects have contributed to develop criteria for future professional processes.

Joint Workshop at Rudloffstraße in Bremerhaven

In September 2018, 15 students from the Escola de Arquitetura e Urbanismo (EAU) came to Germany for 14 days to work together with the students of the Oldenburg Department of Architecture to develop urban planning concepts for the further development of the Bremerhaven district. The workshop was held by the authors.

The topic of the workshop "Abandoned Industrial Areas" and the aim of developing hybrid urban spaces are based on the main questions of the previous workshop. Issues such as the participation of local actors in the development of goals for urban development projects were explored during the project work in the workshop.

The project area is located in Bremerhaven in a former port area close to the city centre. The properties located directly on Rudloffstraße are currently used mainly for commercial purposes or are abandoned. In the west of the area, the Wilhelminian Quarter "Alte Bürger", which in recent years has turned into a lively district with a wide range of cultural attractions. At the north-east there are neighbouring two major historic social housing projects.

The students had prepared themselves in preliminary seminars with overarching topics such as shrinking processes in cities, neighbourhood development and social housing.

At the beginning of the workshop several excursions took place. First of all, it was about introducing the group to current issues of urban development, housing policy and knowing existing settlements of social housing and the recent interventions to adapt them for future needs in Bremen and Bremerhaven.

Besides that in Bremerhaven students visited the neighbouring Goethequartier which is the neighbourhood most affected by relative poverty within Germany. Students learned about problems and social projects. During one afternoon the students played, designed and talked with children and pedagogical staff at a local child care project.

With this background, the students now explored and examined the project area more in detail. All discussions concerning the project area were accompanied by actors from Bremerhaven dealing with the area as the representative of the neighbourhoods' development agency, local planning department and the Bremerhaven Company for investment and urban development.

The local planning administration had initiated a public workshop with dwellers and initiatives in 2017. Citizen developed initial ideas and identified spots of special interest. Of particular importance within the project area are the large warehouses in the north (Marcushallen) and a former municipal construction yard. The still existing allotment gardens and the memory of former allotments in the area inspired to develop new community gardens and to foster urban gardening.

The main challenges for the areas is the contradictory situation in the current uses: The area is stretching parallel to the waterline but blocked from it by a shipyard for cruise liners. That give a fascinating scenery but also a high level of pollution. The area has a mostly commercial use but there are also a lot of abandoned plots. Towards the east side of the plot the predominant use is housing. The challenge is to integrate existing uses in a future mixed-used area, to foster more housing and to stimulate the use of public spaces, and to provide attractive social and cultural infrastructure for neighbours and new inhabitants. For the economic situation of the city there is a low investment rate and the possibilities for public investment are limited. Thus, all proposals have to be stimulating for investment on one hand and ensuring social inclusion on the other hand. Only a minor part of the plot are state owned. These plots have to be used to initiate a change. So besides finding a spatial solution students had to find a strategical approach for the development of the area.

In their urban planning concepts, the students sought solutions for the appropriate mix and zoning of living and working, the possibilities of social mix, the design of public spaces and the development of further ideas for the new use within the new neighbourhood to be developed.

The students elaborated five alternative proposals and presented them at the end of the workshop. The local actors were invited to the presentation after the intensive project work and were able to convince themselves of the developed urban planning concepts and give the students a feedback. For the local actors the workshop result were a relevant impulse to initiate and specify further planning steps.

As a follow up the workshop results were used a base for a further urban design project at the faculty of Architecture. The projects of both courses were shown in an exposition on site where citizens were invited to discuss the results. Meanwhile a planning office was found to develop a plan for the areas. They took part in the exposition and by this planning administration and professional planners can integrate the results of public debate. The students' projects visualized different planning approaches so they gave a visible base to define the criteria for future planning.

For the students of the workshop in particular the specific feedback of local actors reflecting issues discussed during the workshop in the context of the actual development process in Bremerhaven had a big impact. It enabled the students to gain new perspectives on possible positive impacts and constraints of their planning proposals.

Conclusions

The experience of working together allowed, as well for students as for teachers, a rich exchange of project approaches, work methodologies, and contact with distinct socio-economic and cultural realities. The joint project elaboration along the workshop and the experiences gained represent a significant enrichment of students' education for the members of both groups. The students discovered similarities and differences in planning processes and tasks of urban development. The opportunity for the students to get in touch with relevant urban issues of both countries, such as urban interventions in informal settlements (in the Brazilian case) and the rehabilitation of degraded urban areas (in the German case) is a very valuable outcome of this cooperative project. Likewise, the contact with public and private agents involved in the urban structuring processes of the two study areas of the workshops allowed an understanding of the practices of these agents in contexts of countries with very different stages of economic and social development. In the informal city in Brazil the local communities were represented mainly by dwellers associations, especially in the current

situation with an absence of state driven programmes for the integration of favelas into the city. In change in Germany the initiative to local development is far more formalized. Local planning department and an agency for economic development were in charge of the project, and even the neighbourhood representative was employed (by external funding) to gather and advocate the interests of the surrounding neighbourhoods. The experience of this different field of actors and the formal and economic conditions for urban development was an enriching experience for both groups.

For the German students, the experience of working in an informal settlement was something absolutely new and represented a challenge for the formulation of proposals appropriate to the particular characteristics of the area under study. Especially facing the pressure of informal construction on open spaces was a new experience for them. This made the projects for the needed public spaces becoming a challenging task. The Brazilian students were of course more familiar with the challenges of planning within informal settlements. Nevertheless the cooperation gave them the possibility to know another perspective, which allowed them to reflect on aspects of urban informality that, due to the proximity to their daily life, were unnoticed. The students developed due to this active process of mutual learning and reflection a high commitment to find appropriate solutions for the area.

On the experiences in Bremerhaven the ideas of Brazilian students about the visibility of social needs and poverty were questioned. When working on the Bremerhaven project the Brazilian students were confronted with shrinking processes and the consequently low pressure on spatial development and had to think about the stimulation of uses for public spaces, infrastructure and investments (public and private). So they found a completely new situation of involved actors and needed collaborative approaches with these actors. The German students could rely on previous experiences referring to the given situation but learnt a lot in the exchange about the more community oriented approaches of the Brazilian students.

For the teachers involved, it was an opportunity to discuss the methodologies of project teaching practiced in the courses of the two educational institutions, and also of the curricular structures of each course, what allowed a valuable exchange of teaching experiences. Besides this the joint workshop also promoted discussions with others faculty members involved in this partnership.

The cooperation in the joint workshop has been a relevant contribution to promote experimental and intercultural learning within the faculties. Both faculties are interested in continuing the workshop series and to keep on working on the possibilities of its didactic format. Nevertheless, this will depend on the possibilities to access future funding. In the Brazilian case, the desirable continuity of this partnership - with regard to the groups of students and teachers going to Germany - is difficult due to the economic crisis experienced by the country and, above all, by the cuts made in the current federal administration, in the budget of the Public University. But this complex economic and political restrictions also show the divergent embeddedness of learning for future architects and this is another essential part of the learning process for the cooperating students groups. So we remain with the commitment of all the teachers and students involved in this academic partnership program to pursue this valuable international interaction.

⁴*Independent researcher, barbieromassimiliano@gmail.com*

Abstract: The earthquake that involved Central Italy in 2016, in addition to its disruptive effects on people, heritage and social capital, cracking the fragile balance of economic and demographic systems, has greatly amplified the attention paid small municipalities, on the Apennines Mountains. Summing the Small Municipalities Law and the National Strategy for Internal Areas, a sole large-scale project affecting the so-called "earthquake crater" of Central Italy can be outlined and presented as a widespread reconstruction work, in the name of safety and technical, technological, administrative and planning innovation. Despite the magnitude of the objectives, the dislocation of damages, the distribution and over-provision of historical, public and private assets, the particularity of the places involved, characterized by extreme specificity and inhabited by local micro-communities with a strong local identity, are likely to enhance little programmatic tools. Assuming the necessity of a context-based and collaborative approach to producing effective change at the local and regional scale, the question is: how to make possible and support a local pro-active and co-operative environment? By focusing on the collaboration developed in 2017 between the Municipality of Bolognola and the IUAV University, the paper explores the possibility of co-designing an action plan for post-earthquake development.

Keywords: Governance tools, Participatory process, Institutional innovation, Territorial regeneration, Risk planning

Central Italy Small Municipalities. A resourceful context, between criticalities and new strategies.

In 2016 the Central Italy Earthquake involved a large part of the small municipalities attested on the Apennines, between Marche, Umbria, Lazio and Abruzzo. In addition to its disruptive effects on people, heritage and social capital, the earthquake cracked the fragile balance of economic and demographic systems. Those territories showed, since the fifties, a process of disarticulation of the social and economic fabric and abandonment of the land, with the population moving toward less marginal areas of the country, *i.e.* big or medium cities and largely industrialized valleys. Within this already critical situation, the earthquake emerged as an opportunity not only

to describe and discuss the intrinsic values and potentialities of those territories but also to fund a reconstruction process that would have worked as a complex and transversal system of improvements and reforms to flip the marginalization process of the Apennines. Two major national programmes would have allowed the regeneration process of these territories: the so-called Small Municipalities law and the SNAI (National Strategy for Internal Areas). Interestingly the surface areas of the two programmes largely overlap (ANCI 2017).

The driving idea to reimagine the Apennines is a form of *intrinsic sustainability* that these territories show (Fondazione Symbola 2018). They emerge as laboratories where industrial production is organized within local districts based on local communities (Becattini 2002; Sforzi 2008), and the agricultural production is investing in the creation of local supply chains and organic products (Fondazione Symbola 2018); also they were able to save high levels of biodiversity and memories of an ancient past (Calvaresi 2015b). At some degree, those tendencies are an implicit and innate form of sustainability that the inner part of the country displays. They were only possible because of the marginality of those territories from the industrialization and modernization processes that caused, on one side, the previously mentioned abandonment processes but also, on the other side, produced high levels of pollution and bureaucratization in big cities and intensively exploited lands in the rest of the country. In this sense, these territories constitute a resource to be taken into account for public policies.

The relevance and the strategic role that Italian inner areas and small towns play were already shaping the mentioned national programmes. The so-called Small Municipalities Law -officially *"Misure per il sostegno e la valorizzazione dei piccoli comuni nonché disposizioni per la riqualificazione e il recupero dei centri storici dei medesimi comuni"*, law 158/2017- is the output of a long and careful observation of local systems, and its approval was only speeded up by the earthquake. The law included a series of measures to support and develop small Italian municipalities with less than five thousand inhabitants and also contained actions addressing the renewal of their historical centres. This law affected 5.567 towns, approximately covering the 54% of the whole national territory with a population of about eleven thousand inhabitants, and allocated about 100 mil., to be distributed between the 2017 and 2023 (ANCI 2017). The SNAI, on the other side, was already at work since 2013. According to this programme, marginalities, calculated through a series of indicators of the distance from 'centralities' and services, should be at the centre of national policies. The policy design process should use a place-based approach that, working through prototypes and fostering strong local governance by public administration, would have overcome the illusions of purely bottom-up local projects and pretence of state-driven projects (Calvaresi 2015a). In this sense, what should emerge is that both the instruments, the 158/2017 law and the SNAI, even though with lightly different interpretative models, and different implementation protocols, are aimed at making this portion of Italian Territory less marginal, more cohesive and, so, more competitive. The programmes allocated consistent funds in the selected areas to achieve this enormous goal.

Therefore the earthquake should be taken into account not only because of its sudden and tragic nature but also as the accelerator of already existing processes. On one side there where dynamics of progressive social-economic impoverishment and depopulation, despite any small signal of recovery showed before the earthquake (Renzi 2018); on the other side, the earthquake fuelled the approval of programmes and projects aimed at stabilizing qualitative strengths of Central Italy. The whole reconstruction project, then, seems to be the last opportunity to avoid an inevitable decline and a future in which Central Italy Internal Areas, the earthquake crater, could represent a model for sustainable development. Thus the physical (and selective) reconstruction project in the earthquake crater could be considered a part of a larger urban and territorial regeneration project that could benefit from national and European funds (Law 158/2017, SNAI, reconstruction funds plus European funds as, among others, FEASR, FSE). In this sense, this complex project, being the crater the first experimental step, would be the more significant public investment in territorial regeneration in the history of the Italian Republic (Renzi, 2018). It would represent an extensive work of reconstruction, the most extensive building site in Europe, in the name of risk resiliency and innovation in design, technological and bureaucratic protocols.

Despite that, the described instruments, being too programmatic and hardly able to catch, understand and engage the extreme local singularities and the many diverse local communities, were easily unable to reach their objectives. The over-provision of public and private goods, the social capital and the specificity of the context, where micro-communities have strong and conflicting identities would need an approach and a series of instruments able to catch and rearticulate the many different identities and actors. Demonstration of it lays in the long-lasting state of *emergency* and in the awkward start of the reconstruction in a context where local communities have traditionally shown a pro-active tendency. The relation between local, i.e. micro-communities and specific contexts, and territorial, i.e. the Apennines and any institution aimed at addressing their governance, becomes critical.

Summing up, what emerges within the post-earthquake reconstruction – pertinent but also too much pre-determined and constraining- is not the lack of norms or innovative aspects in the administrative orders, yet their substantial inability to radically transform design and planning protocols. The approach to a post-earthquake rebuilding seems unable to include all of the mentioned singularities and adversarial (business) interests that emerge if we look at small municipalities. Here again to look at local governance processes gains a critical perspective, because of the genuine possibility to implement any national policy or programme. The participatory workshop in one small municipality –Bolognola- then emerges as an experiment to develop a place-based approach, that assumes one case study, in between the exceptional and the norm (Thomas 2005), from which we could move back to a general theory and then get back to practice, proposing new territorial settings and collective and collaborative strategies.

The workshop “La ricostruzione del possibile” in Bolognola, between collaboration and co-design.

Bolognola is the smallest municipality of the Marche Region, both in terms of area (25,88 km²) and in terms of inhabitants (137, of which only 108 permanently living in Bolognola); it is also the highest ones (1070 m. a.s.l.). Its territory is included in the National Park of the Monti Sibillini, and its economy is mainly connected with resources typical of mountain areas. Particularly relevant, in local economies, are woods-connected activities and pastoralism, with sheep and bovines, and tourism-related activities. The first group also survive thanks to the enduring of quite extended common lands in the area. The last group has experienced fluctuating success, but, recently, gained relevance thanks to the growing attention toward the naturalistic, historical and cultural value of the mentioned National Park and the revamp of outdoor sports and free-time activities such as trekking, mountain biking, and many others. The 2016 earthquake adds on an already fragile milieu with the disruption of productive infrastructures such as burns and sheds –putting the livestock in danger during the freezing winters- and hotels, housing and lodges for tourists, made not fit to use. The earthquake also meant a reduction in tourism flows, since people were scared by the risk of other tremors.

For what regards the housing stock, in Bolognola only the 30% of it was permanently inhabited by residents, mainly in the main village constituted by the three original medieval villages from which the municipality was born; 70% of the residential buildings were empty for most of the time. The earthquake did not provoke the collapse of any building, but it made non-habitable, more than the 50% of the all housing stock, and, among those, the 80% of the houses inhabited by all-year residents. Right after the earthquake, then, most of the residents moved to the coastal area of the Region, and only about 79 persons stayed in Bolognola. The risk is that those who left during the emergency will never come back: this was the leitmotiv of many public meetings, not only in Bolognola but in all the earthquake-crater. In the case of Bolognola, due to the already low number of inhabitants, it would have meant the disappearance of the local community and the possibility that the municipality would be incorporated to the close ones (already discussed as a possible option before the earthquake and also already happened in other close municipalities).

Because of the critical situation, the resources described in the previous paragraph represent a significant opportunity to let the local community stay, not only as small and utopian pockets of resistance. The earthquake became the opportunity to invest in a regeneration project that could transform hopes and vague ideas into

tangible improvements. To pro-actively use endogenous resources to sustain a *minimum vital flow*, and to foster any small improvement able to attract new users and (economic) activities becomes imperative.

From this urgency, the collaboration between the local administration and the IUAV University started. The driving question was: *how to proactively use endogenous resources to sustain a minimum vital flow, and to foster any small improvement able to attract new users and (economic) activities?* Moreover, the focus was not only about how to practically produce those new economies and futures, but *how to stimulate –and sustain in the long term- local pro-active subjectivities and a learning process between institutions, citizens and new economic stakeholders*, interested in investing their energies in projects in –and for- Bolognola?

The hypothesis that the mentioned workshop wanted to test is that a co-design event, open to the public, in other words with a high degree of *participation*, could represent not only a participatory design tool but a moment of empowerment of the local community, setting the scene for a collaborative approach for future development.

In this sense, collaboration is here not only used to depict a participatory environment that includes, in the planning process, the public institutions/decision makers and also everyday people. Neither collaboration only means conflict resolution through alternative dispute resolutions (ADR) techniques. Collaboration is here intended as an approach, a state of mind that, acknowledging the existence of conflict, tries to overcome the mere confrontation of two different positions fostering understanding, empathy and mutual respect. Collaboration implies a great effort in explaining technical and personal reasons and in carefully listening to other participants to the process. To foster such an approach within participatory events ideally sets the mood to participate in other meetings collaboratively.

On this premises, the workshop “The reconstruction of the possible”, whose title recalls the aim to build on the ruins produced by the earthquake in order to envision possible alternative futures for the territories hit by the catastrophic event, was held. During the design studio -“Laboratorio di Sintesi”- of the Master in City and Environment Planning and policies at IUAV University, thirty students, together with the authors of this paper, were invited for one week in Bolognola to listen to the inhabitants and to facilitate the workshop.

Clearly to be on site for one week is neither enough to set a collaborative environment successfully, or to prepare a charrette –a participatory method aimed at designing a project/plan/programme, and reflecting with the participants about how to practically configure physical spaces to achieve an objective. Also, the programme was so dense that there were only a few moments dedicated to co-design, and also there were not all the expected participants. Despite that, the students were able to pinpoint key-people and fruitfully engaged with them, also through walks and informal chats. The result was the production, by the students, of six reports. A part of them focused on the legal and technical framework in which the reconstruction process was starting (at the time of the workshop and the design studio, the emergency phase had just ended). Others concentrated their attention on local material and non-material resources; other groups carefully identified, through the conversation they had with the inhabitants of Bolognola, visions and hints for local social entrepreneurship.

Bolognola can be considered as an extreme example of criticalities experienced by many surrounding towns in Central Italy Internal Areas. At the same time, the small municipality also exemplifies all the opportunities and the strengths that a careful reconstruction project could put at stake and that were mentioned in the first paragraph of this paper. Within those premises, the guideline for further reflections could be: which kind of *material or virtual infrastructure*, or platform, could enhance collaborative forms of *interaction among the diverse stakeholders* to let local strengths and visions emerge in order to build a local agenda for development? In other words, how to let local social entrepreneurship emerge and survive in the long term? Which tools planners have? The presented workshop suggests that, despite the difficulty to set actually collaborative processes, only moving to a generative form of listening -as the most in-depth way of listening to the others that requires the listener to be out of his system and open to what surrounds him-, we can generate solution as

collective creations (Scharmer 2009, 2018). In other words, only through active forms of listening (Sclavi 2009), we will be able to detect molecules of bottom-up *projectual sensitivities* and connect them with (i) institutional frameworks and founts and (ii) necessary skills and expertise. By doing so, and starting from detailed enquires of local *micro-cosmos*, an articulated and trans-scalar set of plans, programmes, projects and actions, either public or private, could be outlined toward the definition of a coherent group of policies for the regeneration of the territory.

Toward a post-earthquake development agenda.

A preliminary listing phase, formalized in a document called "the collection of ideas and projects" was necessary to reconstruct in detail needs, ideas and project emerged within the design-charrette. For Bolognola, its public administration, the private stakeholders and the citizens, the catalogue represents a shared document and is an attempt to return all the interests at stake, in the most exhaustive manner possible. The collection might both be the base on which pacts between the public administration and the citizens could be build and function as a support on which the institution sustain those pro-active groups that are already developing projects in the area. The reasoned list can also constitute support for those who, thanks to existing funding, decide to start new activities.

The next step in the design of a development agenda would imply to transform the collection into a *constellation*, meaning, with that, the identification of supply chains in which an existing projectuality can be accounted (for its economic feasibility) and for its nexus with other projects (in and out each constellation).

The concept of the supply chain is here used to describe multiple connections and different actors involved in the transformation process of a resource into a good. It implies organizations, public and private deals, regulations and norms. Constellations of projects should be described and grouped in different supply chains, assessing their impacts on *the micro-cosmos project*, which identifies the ensemble of actions and inputs that would guarantee a minimum vital flow –services and micro-economies- in the small municipalities. The micro-cosmos project is only made possible by forms of collaboration and partnerships between the public, the private and the people.

Between East and West. EU and China's competing spatial integration logics for the Western Balkan Region

Erblin Berisha¹, Giancarlo Cotella²

¹ Politecnico di Torino - DIST, erblin.berisha@polito.it

² Politecnico di Torino - DIST, giancarlo.cotella@polito.it

Abstract: The Western Balkan Region (WBR) is currently undergoing a complex process of integration into the European Union (EU) and its countries, although at different paces, are progressively nearing the moment of accession. This has several implications for the spatial integration of the region in the EU territory, with the EU that, since the 1990s, has been supporting the latter with a number of programmes and actions. In the last decade, however, a new, cumbersome actor entered the game: the launch of China's Belt and Road Initiative in 2013 has triggered a growing influx of foreign capitals into the region, potentially limiting the influence of the EU on ongoing transformations and reforms. The contribution aims at shedding light on this matter. It does so by exploring the logics of the Chinese interventions on the WBR, in terms of vision, approach, priorities, sectors and volume of investments and means of implementation, and by comparing it with the logics of the ongoing integration process. Overall, the contribution shows that, whereas the EU remains the most relevant player in the regions, the growing political and economic role played by China may in the slowdown the process of integration.

Keywords: Belt and Road Initiative, Western Balkan Region, European Union, China, conditionality.

1. Introduction

The paper addresses the question of whereas China is a credible alternative to or facilitating the integration of the Western Balkans Region (WBR)¹ into the European Union (EU). This question raises a series of considerations concerning the role of EU and China in the region and, in particular, the economic, political, social and environmental consequences they may bring up. As widely recognized, China is increasing its geopolitical and geo-economic influence globally. At the edge of the new millennium, the Chinese government launched the so-called *going-out strategy*, that had gained further concreteness with the development of the Belt and Road Initiative (BRI) in 2013. The latter represents the first global initiative in terms of economic investments, infrastructure connectivity and territorial development. Geographically speaking, the BRI partially retraces the ancient Silk Road; the corridor connected the European continent with the far East. As Sarker *et al.* (2018, 626) argue, the BRI 'has a great impact on global economy through integration of a large part of the world under an umbrella'. While, throughout the world, some branch of the BRI are already concluded or going through the final stages of their implementation, the consequences of this initiative for Europe has been partly underestimated, at least from the EU institutions. As far as the various countries'

¹ For the purpose of this article, the Western Balkan Region includes Albania, Bosnia and Herzegovina, Kosovo, Montenegro, North-Macedonia and Serbia.

positions on the matter are concerned, the majority of EU Western states are lukewarm at best, while the Eastern states appear more open to engagement. As similar position also is taken by Balkans countries, which watch at Chinese resources as an alternative to the EU financial mechanisms.

Whereas a growing influence of China on the WBR is undeniable (Hake and Radzyner, 2019), no assessment has been attempted yet of the impact of this influence over the EU integration process the region is going through. This contribution builds on evidences collected in the recent literature and policy document, as well as on interviews with selected stakeholders to shed some light on this matter. After this brief introduction, the authors focus on the role of the EU in addressing political, social and economic challenges in the WBR, by acknowledging its strategic position and importance for the future of the EU integration project. It shows where WBR countries stand along the process of EU Integration and introduce the main funding actions put in place by the EU in the region. The third section of the paper illustrates the origin of the BRI's vision, its objectives, geopolitical ambitions as well as all political vicissitude the initiative is bringing along with it. The fourth section focuses on the WBR, exploring the implication of the BRI for the latter: the authors highlight the scheme and volume of investment, the main projects undertaken and foreseen as well as their mechanisms of implementation.. The fifth section then compares the EU and China's roles in the WBR through different lenses of interpretation: (i) the vision - which implies considerations in terms of geopolitical, economic and strategic decisions; (ii) the approach – that focuses on the type of agreements and conditionality (economic, political etc.); (iii) the main priorities – showing what priorities each player has (political, economic, social and environmental); (iv) the sectors of investment – illustrating who invest where in terms of infrastructure, energy and industry sectors as well as; (v) the mechanisms of implementation – exploring similarities and differences between the EU and China in terms of management, financial mechanisms, environmental and social standards. After the comparison, a final section rounds off the contribution, reflecting on the potential impact of the increasing role of China in the WBR for the integration of the latter into the EU, and paving the way for future research on the matter

2. The role of the EU in the Western Balkan Region

After the collapse of the Berlin wall and, in particular with the beginning of the 2000s, the EU has progressively invested in the geopolitical and economic stabilization of the WBR. By stipulating the Stabilisation and Association Agreements (SAA), which characterized the Stabilisation Agreement Process (SAP) launched 1999, the EU promoted a progressive integration process. Overall, the relation between the EU and the Balkans countries has not been linear, due to internal and external contingences. According to Rogelj (2015), there it is possible to distinguish between at least four different phases, that describe this relation (figure 1). Moreover, the integration process differs from one country to another. In fact, since the signature of the SAA, only Croatia had joined the EU in 2013, while the other countries are still dealing with the transposition of the *acquis communautaire* (table 1). At present, Serbia and Montenegro have already started the chapters' negotiation phase, and Albania and North Macedonia have been awarded the candidate status, in 2014 and 2005 respectively, and are now waiting to start negotiating the chapters. On the other hand, Bosnia and Herzegovina and Kosovo that are still going through the early stages of the Integration process, with the former that has only applied for the membership in 2016, while the latter did not apply yet.

Source - authors' own elaboration.

Despite delays along the process of EU integration, in the last three decades it is possible to witness a progressive economic convergence between the EU area and the WBR. According to official data (EEAS 2017) there is a strong economic relationship between EU and Balkans countries: the share trade volume has reached the value of 49,5 billion in 2017 (EEAS, 2017), with the EU countries that represent the WBR best trading partner, with 73 per cent of the total trade volume. The leading role of the EU in the region is also confirmed when taking into account the inward Foreign Direct Investment (FDI) stock (figure 2).

Figure 2 - Inward FDI stock by source country, in % of total, 2016²

Source - wiiw FDI Database. EIB (2018)

These data confirm the EU has a strong influence on the WBR economy, trade and investment system, and this economic interdependency is expected to be consolidated further once the full integration of the region into the EU is achieved (EEAS, 2017). To this purpose, the EU has mobilized a set of funding mechanisms that target different economic sectors. Through a number of tailor-made instruments, these funds have contributed to strategic fields like transport infrastructure, energy production and efficiency, environmental protection and greenfield investment. For instance, during the period 2014-2017, the EU invested more than €330 millions for transport projects, in turn generating €930 millions³ of private investments and overall positive repercussions in terms of job-creation (EEAS, 2017)⁴.

Many of the introduced programmes and initiatives have had an explicit spatial and territorial dimension (Berisha, 2018). More in particular, despite being excluded from the structural funds' programming, Balkan countries are eligible for a series of other funding schemes altogether grouped under the Instrument of Pre-Accession (IPA). At the same time the region countries located in the WBR are involved in two EU macroregional strategies – i.e. the European Strategy for the Adriatic-Ionian Region (EUSAIR) and the European Strategy of Danube Region (EUSDR) – as well as in a number of other EU programmes – for instance Horizon2020, Creative Europe etc.

Since the introduction of the first (2017-2013) and second (2014-2020) generation of IPA, the EU invested more than 23 billion of euro on the WBR⁵ (table 2). Under the umbrella of IPA, numerous projects concerning regional cooperation and connectivity were developed. Importantly, a high share of funds has been dedicated to soften the distance between border communities by facilitating and implementing cross-border projects both among member-states and non member states as well as between two or more extra-EU countries. Beside the impact recorded by the IPA and the other initiatives on the territory, one should highlight that these tools similarly to the pre-accession tools implemented in the countries from central and eastern Europe throughout the 1990s and early 2000s, progressively contributed to channel in the region a number of EU priorities in terms of sustainable regional development, tourism, environmental protection and measure against social exclusion of minority and mitigation of climate change effects (Cotella, 2007, 2014; Cotella et al. 2012, Adams et al. 2011). This occurred through incremental logics of economic conditionality, with the EU that has developed an articulated set of conditions for the attribution and use of the established economic incentives.

² Acronyms stand for: EU – European Union; Ch – China; Ru – Russia and; Tr-Turkey

³ For more info see: <https://www.consilium.europa.eu/en/infographics/western-balkans-connectivity/>

⁴ A similar attention has been dedicated to greenfield investments, a sector in which the EU has contributed to create more than two hundred thousands jobs since 2003.

⁵ According to the European Commission, IPA I had funded with 11,5 billion while IPA II with 11,7 billion.

Whereas the landing into the region of a growing number of Chinese investments had progressively slow down these logic, and with it the integration of the region into the EU, is not clear yet, and will be reflected upon in the following sections.

3. The Belt and Road Initiative: objective and geopolitical ambitions

Since the edge of the new millennium, China has been attempting at expanding its geopolitical, economic and strategic influence (Pu, 2016). One of the ways pursued to achieve this end consisted in a revitalization of the ancient Silk Road, which for centuries constituted the only corridor connecting the Western and the Easter side of the Eurasian continent. The first step of relocating China in this modern corridor has been undertaken in 2013, when Xi Jinping launched the proposal for developing the so-called Belt and Road Initiative (BRI), that is a combination of the Silk Road Economic Belt and 21st-century Maritime Silk Road (figure 3). Whereas the Silk Road Economic Belt aims at connecting China with its international partners by investing in roads, motorway and railway, the 21st-century Maritime Silk Road, focuses more on maritime investments such as docks, logistic infrastructure etc. Both aim to promote the connectivity and the economic cooperation between China and the countries included by the initiative⁶. In this sense, the BRI is certainly one of the most ambitions and economically relevant initiative ever experienced, comparable only with the Marshal Plan⁷ launched by the United State after WWII and to the activities of the Council for Mutual Economic Assistance instituted by the Soviet Union shortly after.

⁶ The BRI includes 68 countries over the world and, in particular, countries located in the Eurasia region. In so doing, it concerns the 65% of the world's population and over 40% of the GDP produced in the world.

⁷ To allow a comparison, whereas the Marshall Plan envisioned an investment of \$130 billion (in 2015 value) dedicated to the post-war reconstruction of Europe., the BRI strategy is expected to mobilize more than \$4 trillion.

Figure 3 – The geographical scope of the BRI.

Source: Xinhua (Silk Road routes); U.S. Department of Defence

What the future economic and geopolitical consequences of the BRI, and more in general, of China's trans-continental ambitions, is however still subject of debate. As it is widely recognized in the literature (Liu, 2015, Griger 2016, Djankov, 2016, Tonchev, 2017, Cai, 2017) the reasons beyond the launching of the BRI can be divided into three main, intertwined spheres domestic-driven, external-driven and diplomatic.

The first group of reasons focuses on China's domestic and contextual needs and priorities. According to various authors, China seems to have reached its internal market expansion limits while overcapacity is becoming a serious problem (Pu, 2016). This is confirmed also by Grieger (2016), which states that the fast economic growth model implemented in the last decades is losing its impetuosity, by causing an economic slowdown, which could derail into social instability and rising unemployment rate. To avoid that, China is constrained to find new open markets for its goods, services, investments and labour forces. Secondly, one of the BRI's objective is to rebalance regional development between the more advanced coastal regions and the under-developed western Chinese's regions (Pu, 2016, Cai, 2017). In this perspective, BRI will be an instrument of Chinese territorial and social cohesion helping those provinces to fill the development gap with the most advanced East coast.

On the other side, externally, China is taking advantages from a set of positive global geopolitical contingencies, among which the recent EU economic, political and social crises. Adopting a *divide et impera* approach, the influence of China is growing over the world and in particular on the Europe continent. In this respect, Chinese investments in the EU area have been increasing exponentially since 2008⁸. At the same time, the progressive retreatment of USA from an increasing number of multilateral agreement, and the consequent decreasing of its international investments package contributed to leave free room to China's international initiatives. It is under this geopolitical condition that, China's going-out strategy has developed and

⁸ China's annual foreign direct investment in Europe grew from \$840 millions in 2008, to \$42 billions in 2017..

consolidated, aiming at reducing the transport cost of goods, to diminish the economy dependence of internal infrastructure development and to secure China's energy supply⁹.

Finally, yet importantly, China seeks to build a new geopolitical order, as explicitly argued by Xi Jinping during the Peripheral Diplomacy Work Conference in 2013. The objective is to turn China into the pivotal center of the world economy, by connecting the existing markets in the Eurasia continent and consolidating an increasing number of economic interdependency between the main economies in the World beside the United States. In the European continent, the Chinese investment capacity is positively seen by those countries that are struggling to recover from the recent global economic crises and/or presents level of development that lags behind the EU average. As it will be further detailed in the following section, this is the case of Eastern and South Eastern European countries (CEECs) and, in particular, of the countries located in the WBR.

4. The role of Chinese initiatives in the Western Balkan region

After having briefly delineated the geo-economic and geopolitical characteristics of the BRI, this section retraces the main historical and diplomatic relations developed between China and the countries of the WBR during the last decade. According to Liu (2015), the attitude of the Balkan countries towards the BRI has been rather positive since the beginning, if compared to the suspicious approach that characterized most Western European countries. Indeed, the first summit between China and Central and Eastern European Countries (CEECs) was took place in Warsaw in 2012, aiming at improving cooperation among countries and giving birth to a number of bilateral agreements. Heavily impacted by the global economic crises that manifested in 2008, CEECs and Balkan countries chose to *look to the east*, in so doing further legitimating the role of China in the international, and in particular in the European geopolitical framework. On the other side, China considers the CEECs as an opportunity to get access to the EU market, which remains the biggest in the world. The mutual interests were confirmed a year later, in 2013, during the Bucharest Summit, where the new cooperation between China and CEECs was seen as opportunity to bring China and the EU closer and to facilitate the EU integration process. This established the bases of the so-called "16+1 initiative", a cooperation platform between China, CEECs and South Eastern EU countries¹⁰. A year later, during the Belgrade Summit, the BRI was presented as a new economic driving force for both China and the mentioned countries (Liu, 2015). In this sense, President Xi Jinping recognized the importance of creating strategic and economic synergies between BRI and the 16+1 platform. The idea is to facilitate investments for increasing infrastructure connectivity within those regions and simultaneously helping the implementation of the BRI economic and spatial visions.

Differently from the BRI, the 16+1 cooperation is restricted to countries located in CEE and in the WBR. One of its priorities is to increase the inflow of China's foreign direct investment to the region by financing projects dealing with: construction of transport infrastructure (motorways), development of railway network, development of logistics such as airports and seaports, renewable sources of energy and the food production sector (Jakóbowski, 2015). In this sense, the 16+1 cooperation is more focused on economic and infrastructural objectives, if compared to the broader geopolitical perspective brought forward by the BRI. The objective of the 16+1 cooperation is to facilitate trade investments and acquisition ability of Chinese companies (both public and private). In this sense, the strategy of those companies is clear: diversification of investments. In less developed countries as those located in the WBR, transactions involves the mining industry, the wood processing industry and the production of foodstuffs. At the same time, in the more developed economies that characterise CEECs, that sectors interested by Chinese investments are those related to advanced technologies, ICT, automotive industry, electronics, biotechnology, nanotechnology, precision industry, R&D (Jakóbowski, 2015). Having a strategic geographical position between Western Europe and the East, Western Balkans are attracting the majority of the Chinese financed project within the framework of the 16+1 cooperation. In this sense, numerous projects are being implemented in several sectors like infrastructure, energy, electricity and logistic (Liu, 2015). Another particularity of the 16+1 is the proliferation of coordination platforms among

⁹ For example, 85% of China's imports and between 70-85% of its energy supplies passing mainly through the Strait of Malacca in Southeast Asia.

¹⁰ The European countries participating to the 16+1 initiative are: Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Montenegro, Czech Republic, Estonia, Lithuania, Latvia, Macedonia, Romania, Serbia, Slovakia, Slovenia and Hungary, Poland.

participating countries in very different sectors like tourism, agriculture, infrastructure, logistic, energy etc., aiming at facilitating cooperation among institutional and non-institutional actors.

Coming back to the BRI, its spatial configuration presents two Europe has two different paths: the north and the south line. Whereas the former refers to the Silk Road Economic Belt and mainly involves CEECs, the latter focuses on the China-Europe Land-Sea Express Passage located in South Eastern Europe, with particular attention to those countries in the Balkan Peninsula. According to experts and policy-makers, the synergic relation between these two paths will increase the cooperation and trade exchange, not only in the region, but also between the two major economies in the Eurasia continent: China and the (Western) EU¹¹. This is the main reason for China to invest time, resources and diplomatic efforts in ensuring cooperation (multilateral and/or bilateral) with the countries involved. Chinese policy-makers consider the implementation of these two paths as strategic for the enactment of the entire BRI strategy. In this light, they dedicate a high volume of economic and political efforts to investment in infrastructure development (ports, roads, railway, etc.), aiming at guaranteeing a good connection network within the region and outside of it. Connectivity (material and immaterial) is indeed implicitly or explicitly at the center of the BRI, as it has been confirmed by multiple Chinese authorities and in particular by President XI Jinping¹².

Differently from the EU approach to infrastructural development - which aims at regional balance and cohesion - China seems to be not interested to evaluate the social and environmental impacts. As recognized by Liu (2015), the implementation of the BRI may potentially rise a number of domestic and international challenges. By considering its transnational nature, indeed, the BRI is exposed to, thus weakened by, international contingencies. In the Balkan region, in particular, the initiative is dealing with path-dependent regional economic and political instability, as for instance the Greek crises, the Macedonia political impasse, the potential risk of terrorism. Despite that, the importance of the Balkan segment of the BRI has been unanimously recognized.

When it comes to the financial means adopted by China to support the implementation of the BRI in the WBR, it is interesting noticing the introduction of several financial institutions developed to this very purpose, such as the Silk Road Fund and Asian Infrastructure Investment Bank, or of targeted funds like the China CEE Investment Co-operation Fund. The way of how these institutions operate are very different. The recent literature on the matter identifies at least three line of investments:

- (i) direct investments - through which Chinese private or state owned companies invest in acquisition of local companies;
- (ii) open credit line and loans - used for the development of strategic infrastructure and,
- (iii) acquisition of national debt shares.

Each of these credit line has been set according to a number of different objectives and together constitute the financial machine that is supporting the implementation of the BRI. Various authors (e.g. Stumvoll and Flessenkemper, 2018) are sceptic on the introduced measures and, in particular, concerning the acquisition of national debt shares by China State funds. According to the authors, this way of financing has negative effects in terms of states' debt accumulation and debt interests. The *debt-trap nightmare*, as experts call it, is one of the alarm launched by several global observers (among those Hurley *et al.*, 2018) which suggest to have a clear understanding of the potential consequences of Chinese acquisition of domestic debt and its real political implications (EIB, 2018). When looking Foreign Direct Investments (FDI) of China in the WBR, the period 2007-2014 show an increase of value almost everywhere, and in particular in Serbia and, to a lesser extent, in Croatia (see figure 4).

¹¹ In this sense, Liu (2015) affirms that more than 80% of Chinese products are exported to Europe through shipment while land transportation is still in its initial stage.

¹² In 2014, President Xi Jinping had the occasion to re-affirm the importance of the BRI and, in particular, of the Silk Road Economic Belt. He then repeated the message one year later during his visit to the headquarter of the EU.

Figure 4 - China's accumulated foreign direct investments in WBR

Source - Authors' own elaboration on data of MOFCOM, SAFE, NBS, 2015

According to Jakóbowski (2015), During the period 2011-2014, a credit line of 10 billion euro has been dedicated to the development of infrastructure and, in particular, for the construction of the Bar-Boljare motorway in Montenegro, the Mihajlo Pupin Bridge in Belgrade and of the Stanari thermal power plant in Bosnia and Herzegovina (Table 3). Whilst the last publication of the European Investment Bank affirms that, since 2013, China invested almost 7.8 billion in the region and in particular for the development of several initiatives in the field of transport, energy and technology projects. According to the report prepared by Bastian (2017) for the European Bank of Reconstruction and Development (EBRD), China dedicated to the development of the only Balkan Silk Road (from Piraeus to Budapest) almost 8 billion investing in four countries: Greece, North-Macedonia, Bosnia and Herzegovina and Serbia. Despite divergences regarding the total volume of investments, what is interesting to note is that, the majority of funds are loans which means that sooner or later countries should refund them.

When analysing China volume of investments in the WBR, it is also interesting to explore what sector do they target. According to Stumvoll and Flessenkemper (2018), the main Chinese investments are dedicated to the implementation of projects and programmes in sectors like transport, energy and industrial production (i.e. mainly by acquisition of local enterprises). This responds to the traditional delay in terms of infrastructure development suffered by the WBR, as a consequence of almost forty-five years of socialist and communist regimes, that have contributed to the spatial and economic isolation of the region¹³. Compared to the western countries, the level of infrastructure services scores among the lowest in Europe. This also concerns the energy production and distribution capacity, where Balkan countries score lower than their Western and CEE peers (EIB, 2018). Table 3 shows how pervasive the investments of China are becoming considering few aspects. In particular, it is interesting to note that awarded contractors of the projects are always Chinese companies, and so are the credit providers. This demonstrates that direct benefits from the realization of the projects mostly remain in the hands of Chinese companies, in so doing producing scarce spillover effects. This *only China-win scheme* is applied in all countries in the region, largely limiting the domestic economic and territorial impact of Chinese financial resources¹⁴.

¹³ Even after the downfall of the Berlin wall, the economic, political and social instability that followed did not facilitate the convergence of the region to the main western economic market. At present, Western Balkan countries have typically low or average levels of motorway density as well as railway infrastructure capacity (EIB, 2018).

¹⁴ Kosovo constitutes an exception as China did not recognize the declaration of independence of Kosovo. Due to this reason, no Chinese investment targets the country.

Table 3 –Main projects financed by China in the Western Balkan Region¹⁵

¹⁵ The table does not take into account those projects that are currently under evaluation in the framework of the recent China-EU Connectivity platform, such as (i) the Rijeka-Zagreb-Budapest project; (ii) projects in the Orient/East-Med Corridor in the Western Balkans Region and (iii) the Corridor 5c Highway Project in Croatia and Bosnia and Herzegovina.

¹⁶ Data and volume of the investments builds on available secondary data.

5. Comparing of EU Initiatives and China's "going out" vision

According to the BRI spatial and territorial vision the WBR has a great opportunity to become the *trait d'union* between China and the EU. This why there is a growing attention on the region both by EU institutions and by China government. For that reason, it is worth to compare their approach to the region, in search for potential convergences and divergences between, in turn aiming at raising the attention of potential synergies as well as clashes. In this light, this section compares how the EU and China approach the WBR, respectively through the EU integration process and the implementation of the BRI. The results of this preliminary comparison are reported in table 4, and grouped around five main categories (each presenting a number of subcategories): vision, approach, priorities, investment sectors, implementation. For each of them, the approach of the EU and of China is proposed, and their convergence or divergence highlighted. Moreover, a preliminary inquiry of the risks and opportunities for the WBR is proposed.

The first category concerns the strategic vision and how the WBR is seen in term of geopolitical, geo-economic and geostrategic viewpoint. From this perspective, there is a substantial divergence between the EU and China approach in dealing with the future perspective of the Balkans. As emerged, the BRI, but also the entire China *going out strategy*, is profoundly characterised by a *top-down* approach where China establishes the main objectives as well as the rules of the game, while partners are rarely included in the process of vision making. In contrast to this China-centric global vision, the EU is promoting a more continental EU-centric perspective, putting at the centre a more open market system and the full integration of the WBR. For the latter, however, being at the centre of this international dispute can influence negatively the regional economic performance, turning it into a *transit region* for good and resources, with the risk to step away of the EU integration path.

The second category of analyses refers to the approach adopted and the types of influence and involved in the process. In this respect, the approach adopted by EU and China seems to be very different in terms of adopted agreements (multilateral vs bilateral), economic conditionality (co-financing vs loans), political conditionality (political stability vs *divide et impera*). In this respect, China pragmatism in international relation suggests to combine multilateral and (preferable) bilateral agreements in order to facilitate the implementation of the BRI. On the contrary, the EU institutions promotes multilateral approach to establish agreements between EU and other countries. In this sense, the main risk for the Balkans is to remain stuck within a number of international disputes that can slower the integration process.

The third category refers to the priorities of the players in the game (political, economic, social and environmental priorities), when it comes to the implementation of project and strategies in the region. Here China and EU show very different concerns in terms of political, economic, social and environmental consequences of projects. While the EU promotes a particular attention to environmental sustainability, due to the conditions and regulations specified in its Treaties, China has no particular attention on the preservation of the environmental quality and it does not award any priority to projects' impacts on local communities and/or on their social consequences. On the contrary, both players agree on the importance of the economic growth of the region and of its capacity of convey goods and resources towards EU richer regions.

The forth category focuses on understanding the differences in sectors investments in terms of infrastructure, energy as well as industry. Both players agree on the importance of infrastructure development in the Balkans. As table 5 shows, the Orient-East/Med corridor planned by the EU's TEN-T perfectly coincides with the BRI's Balkan Silk Road segment¹⁷. Indeed, there is no explicit conflict to what concerns the general ideal of the spatial transformation nor about the main develop trajectories of the main corridors in the region. In this sense, the recently signed "Memorandum of understanding on establishing a Connectivity Platform between EU and China" (2015) gives the opportunity to strengthen the synergies between BRI and TEN policy. Its action plan foresees a series of cooperation in terms of corridor

¹⁷ The TEN-T Corridor X presents the same path of the China-Europe Land-Sea Express Passage, running from Serbia to Greece via Macedonia

infrastructure development to improve the quality of infrastructure and services as well as developing green transport infrastructure.

Table 4 - Comparing TEN-T and BRI spatial strategy

EU Infrastructure Network (TEN-T)	Balkan Silk Road Corridor
	

Source – authors’ own elaboration

Divergences emerged, instead, concerning the energy development and industrial policies approach. While the EU is promoting a more eco-friendly and sustainable use of resources by financing renewable energy provisions, China is still funding coal-fired power plant, as with the Kakanj plant in Bosnia and Herzegovina. While the EU supports the development of innovation all over the region by contributing to research and capacity building, China focuses on the aquisition of the best and innovative industries. In terms of regional consequences, the Balkans can benefit of course by the volume of funds dedicate to the infrastructure network but on the other side, there is the risk to underestimate the social and environmental impacts of the investments. Similarly, le acquisition of companies by Chinese enterprises may have unintended consequences in terms of desertification of the domestic industrial environment.

Finally, the last category explores the implementation mechanisms. Here divergences can be distinguished concerning, management, financial mechanisms, environmental and social standards. A number of critiques concerned the implementation of the interventions, and in particular the fact that the majority of tenders have been entitled to Chinese companies (public or private), because of rather untransparent selection processes. For example, the lack of transparency in the selection process led to the momentary stop of the works for the completion of the Belgrade-Budapest railway. On the contrary, the EU procurement package clearly establishes how tenders should be conducted by respecting transparency and open-access principles, in so doing constituting a guarantee in this concern.

In sum, while the EU seeks a complete and systematic integration of social, economic, political and environmental components, China seems exclusively interested to guarantee infrastructure continuity along the BRI scheme. There is no ambition, indeed, to create a more proactive and inclusive economic development of the region, as it is instead among the aim of the process of EU integration. In this sense, the EU’ spatial development strategies promote a more coherent territorial and social cohesion, polycentric development and regional competitiveness. On the other side, China conversely uses the BRI to achieve exclusively its own regional development interests, as many experts confirmed. Differences emerged also regarding the modality and economic mechanism adopted in the process of plans implementation. In particular, China privileges loans instead of grants or other kind of investments while the EU promote a more coordinate funding system that guarantee a combination of EU and domestic funds (co-financing mechanisms). In the Balkans, the coexistence of such kind of different approaches can produce negative externalities in terms of countries credibility, increasing of national debt share and political and economic instability, among others.

Table 5 – Similarities and differences of EU and China interventions in the Western Balkan Region

Factors	Convergent, Divergent or Neutral	European Union	China	Opportunities and risks for the WBR
Vision				
Geo-political	Divergent	Complete the EU Integration Process	Implementation of the “Going out strategy”	This geo-political dispute may slow down the EU integration process for the WBR
Geo-economic	Divergent	Pro open-market	State oriented market	Risk of increasing negative economic trade balance
Geo-strategic	Divergent	EU-centric Continental vision	China-centric Global vision	The risk for the WBR is to become the “land of transit” of resources
Approach				
Nature of agreements	Divergent	Preferable multilateral	Combination of unilateral/multilateral	Political ambiguity where emerged personal interests and corruption
Economic conditionality	Divergent	By promoting market continuity and EU investments	Loans and investments	Balkans countries may benefit from those external investments (attention of the debt trap)
Political conditionality	Divergent	The EU aims at guaranteeing political stability	“Divide et impera” strategy	Political representatives are being attracted by the China pragmatism in the field of investment by losing sight its political implications
Priorities				
Political	Neutral	Integration of the Balkans to the EU	To guarantee the BRI implementation	The Balkans may benefit from the opportunity offered by the BRI only if its implementation can facilitate the EU Integration process
Economic	Convergent	Improvement of market economy indicators in the region	China agrees on the development of WBR	Positive effects on the regional economic performance
Social	Neutral	Increasing of social well-being	No specific indication	The risk is to underestimated the social effects of China investments
Environmental	Divergent	Protection of natural resources	Overexploitation of natural resources	Serious environmental risks
Investment sectors				
Infrastructure	Convergent	Increasing connectivity in the WBR	Balkans Silk Road	WBR can benefit from the potential synergy of TEN-T and BRI
Investment sectors				
Energy	Divergent	Renewal energy	Carbon based energy	Increasing risk of overexploitation of natural resources and air pollution
Implementation				
Industry	Divergent	Creating positive innovation based industrial policies	Acquisition of the best innovative industries	Desertification of innovative industrial environment
Management	Divergent	Transparency and public procurement	Not transparency mechanism	Lack of market competition, limit spill over effects. Increasing corruption etc.
Financial Mechanism	Divergent	Co-financing mechanisms	Top-down financial instruments	Risk of increasing of state debt
Environmental Standards	Divergent	Stringent regulations and standards	Scarce attention to environmental issues	Risk of over exploration of natural resources
Social Standards	Divergent	Social cohesion	No particular importance has been given to this issue	Underestimate of the social potential impacts of project implementation due to the top-down approach adopted

Source - authors' own elaboration

6. Conclusive remarks and future research perspectives

Since the beginning of the 2000, all Balkans countries have been involved along in the EU Integration process. Despite the important progresses made, only Croatia managed to access the EU, with the other countries (i.e. Albania, Bosnia and Herzegovina, Kosovo, Montenegro, North-Macedonia and Serbia) that are still struggling with the EU requirements and the transposition of the *acquis communautaire*. At present, there seems to be no chance for those countries to join the EU before 2025-2030, as indicated in the Enlargement strategy (European Commission, 2018). Despite the univocally recognised importance to join the EU, the countries of the WBR are progressively looking for alternative political alliances and economic opportunities, also as a consequence of a number of concomitant factors emerged in recent years, among which the growing instability that characterise the overall European project.

Doubtless, the increasing geopolitical action of China is attracting more and more interest all over the world as well as in the Balkans. In particular, the BRI place the WBR in high consideration, due to its location between Western EU and China. This ensures to the region important economic incentives and unprecedented infrastructure development, in so doing representing a tempting alternative to the EU sirens.

However, the EU and the WBR will also face with important regional challenges that should be addressed. As illustrated, China is demonstrating more and more interests for the Balkans Peninsula and in particular for the Western Balkans. Aside from unprecedented increasing of Chinese foreign direct investments in the region, Chinese private and state own companies are orienting their major efforts by investing in several sectors. The presence of China is not only an economic issue but is rather a political one. As recognized by Stumvoll and Flessenkemper (2018) China is moving into a structural development gap and is meeting real investment needs in the region, a dynamic the EU has been slow to acknowledge. Despite that, one should note there is no explicit intention of China to interfere with the process of EU Integration but conversely, China seems to be interested on a regional stability of Western Balkans as well. According to the authors, China will not be a game-changer in that respect, but it is expected to be a motivating factor for the EU to step up its engagement in the Western Balkans and embrace a constructive partnership with China. There is no explicit evidence showing interferences of China (whatever kind positive or negative as well) along the process of Balkans' EU Integration. As the provided evidence illustrates, the EU remains the biggest investor in the region despite the growing role of China as well as Chinese investments.

Overall, the answer of the question whereas China is facilitating or inhibiting the WBR's EU integration process seems to be negative. Based on this contribution, there are four elements that let us conclude that China is not facilitating, at least directly, the EU integration of the Balkans. First, the EU Integration process is not a priority for China, hence there is no explicit initiatives in this direction. Secondly, from a political point of view, no common EU-China agenda for the WBR has been developed, and China is seen as an alternative partner to the EU. Thirdly, from an economic perspective, China's investments are mostly oriented to the benefit of Chinese players, rather than facilitating the EU Integration process as the majority of the EU investments do. Finally, yet importantly, there is considerable distance between Chinese and European approaches in dealing with the development of the region (vision, approaches, priorities, investments and implementation mechanism).

On the contrary, it may be true the opposite since several divergences emerged. The highlighted ambiguity faces the countries of the WBR with some important choices. Should domestic authorities privilege the EU Integration path or let themselves be fascinated by China? Should they respect the requirement imposed by EU laws, norms and regulation in terms of transparency, standards and public procurement or follow the more pragmatic mechanisms attached to Chinese investments? At present and based on our analyses, the presence of China it seems to be a *slowdown factor* of the EU Integration process instead of facilitating it. In this view, China may potentially trigger *de-europeanisation* processes in the regions.

Building resilience through collective learning in project-oriented organizations in infrastructure planning

Bert de Groot^{1,2}, Wim Leendertse^{1,2}, Jos Arts¹

¹ *University of Groningen, Faculty of Spatial Sciences, Department of Planning*

² *Ministry of Infrastructure and Water Management, Rijkswaterstaat, The Netherlands*

Abstract: The performance of existing main transport infrastructure networks in The Netherlands is currently being challenged by for example climate change, new mobility technologies, ageing infrastructure and energy transition. These challenges call for an adaptive approach towards existing and new infrastructure. One way is to make physical infrastructure itself more resilient, another way is to create organizational resilience. Literature describes learning as a key element in organizational resilience. Most infrastructure network agencies are organized in a project-oriented way and consist of multiple projects and a parent organization. However, how do projects learn from each other and how does the whole organization learn from projects? This paper aims to enhance the understanding of collective learning and resilience of project-oriented organizations within the domain of infrastructure planning at three distinctive levels: within a single project, between multiple projects, and between projects and their parent organization. Findings are based on an in-depth case study at Rijkswaterstaat - the executive agency of the Ministry of Infrastructure and Water Management in The Netherlands. The study uses Social Network Analysis to analyse the observed network. Based on this study, it seems that collective learning in project-oriented organizations still remains limited despite the urgency of it.

Keywords: organizational resilience; collective learning; project-oriented organization; infrastructure planning

1. Introduction

The performance of existing main transport infrastructure networks in The Netherlands is currently being challenged by for example climate change, new mobility technologies, ageing infrastructure and energy transition. Infrastructure network agencies need to build resilience to be able to adapt to these continuously changing circumstances. These agencies fulfil societal functions through a combination of social and technical aspects and therefore can be considered to be socio-technical systems (Geels, 2004). By focussing on technical aspects, an infrastructure network agency can make the physical infrastructure itself more resilient. However, it is also important for infrastructure network agencies to act resiliently as an organization (Brown *et al.*, 2017).

In order to efficiently build, change and improve infrastructure facilities, infrastructure network agencies often manage by projects (Gareis, 1991). They organize themselves as project-oriented organizations (Gemünden *et al.*, 2018). Project-oriented organizations consist of multiple project organizations – projects – and a parent organization. Organizational resilience has been subject of

research in various types of organizations. However, previous studies have dealt little with project-oriented organizations. It is still largely unknown how the resilience of projects and their parent organization relate to each other. Research on this relationship is relevant because parent organizations expect projects to contribute to the organization's goals. If there is need for a project-oriented organization as a whole to adapt to changes in the environment, projects should support this change in interaction with their parent organization. However, projects are initiated to realize specific goals within a fixed budget and a fixed amount of time. These limitations may put constraints on the absorptive and adaptive capacity of projects and consequently on the project-oriented organization.

People in organizations interact with each other and create social networks that can cover projects and their parent organization. Barasa *et al.* (2018) and Lee *et al.* (2013) argue that information and knowledge, that flows through these networks, contributes to the resilience of organizations. In addition, de Kraker (2017, p. 101) states that “in resilience thinking, learning is given a central role in the adaptive cycle”. Despite these insights into information, knowledge and the relevance of networks that facilitate knowledge sharing and knowledge creation in organizations, little is known about how collective learning contributes to organizational resilience. How do projects learn from each other and how does the organization as a whole learn from projects? This paper intends to enhance the understanding of how collective learning takes place in project-oriented organizations in the domain of infrastructure planning at three distinctive levels: within a single project, between multiple projects, and between projects and their parent organization. The findings are based on an in-depth case study at Rijkswaterstaat – the executive agency of the Ministry of Infrastructure and Water Management in The Netherlands. Rijkswaterstaat is a major project-oriented infrastructure network agency that is faced with challenges, the need to become more resilient, and enhancing collective learning. Social Network Analysis is used as a method to analyse the observed network. Based on this study, it seems that collective learning in project-oriented organizations still remains limited despite the urgency of it.

2. Background

2.1. Organizational resilience

Organizational resilience can be defined as “a system's ability to continue to perform and meet its objectives in the face of challenges” (Barasa *et al.*, 2018, p. 496). Some researchers would define resilience as a process or an outcome, but increasingly authors, such as (Barasa *et al.*, 2018), define resilience as an ability or a property. This retains to the definition of resilience by Holling (1973, p. 17): “In this definition resilience is the property of the system and persistence or probability of extinction is the result.” In this research, resilience is viewed as an ability or property of a project-oriented organization.

Various authors distinguish two perspectives regarding organizational resilience (Lee *et al.*, 2013; Lengnick-Hall *et al.*, 2011): first, *absorptive capacity* of an organization that insures an organization to bounce back to business as usual in the case of unwanted events; second, *adaptive capacity* of an organization that enables an organization to respond to emergent situations and thrive amidst changes in the environment. Absorptive capacities are linked with short-term interventions and adaptive capacities are linked with longer-term interventions (Berman *et al.*, 2012). It is a combination of absorbing the challenges faced, and adapting and transforming so as to continue to thrive in the face of challenges that makes it possible to achieve organizational resilience (Burnard & Bhamra, 2011).

Research in the past twenty years has brought much insight into organizational resilience. Two studies that summarize the essentials of organizational resilience are especially worth noticing. First, Barasa *et al.* (2018) identified factors that influence the resilience of organizations, like leadership practices, information management, and preparedness and planning. Second, Lee *et al.* (2013) have made an explicit distinction between indicators for *planning capacity* – which we call absorptive capacity – and *adaptive capacity* – as shown in Table 1.

Indicators for absorptive capacity	Indicators for adaptive capacity
Planning strategies	Minimization of silos
Participation in exercises	Internal resources
Proactive posture	Staff engagement and involvement
External resources	Information and knowledge
Recovery priorities	Leadership
	Innovation and creativity
	Decision making
	Situation monitoring and reporting

Table 1 Indicators for absorptive and adaptive capacity (Lee *et al.*, 2013)

2.2. Project-oriented organizations in infrastructure planning

In order to efficiently build, change and improve infrastructure facilities, infrastructure network agencies often manage by projects (Gareis, 1991). Infrastructure network agencies often organize themselves as project-oriented organizations (Gemünden *et al.*, 2018). They have a responsibility to provide and maintain adequate infrastructure facilities. As such, they use projects to realize necessary changes in the existing infrastructure facilities. Therefore, realizing projects is not the main activity in a project-oriented organization, but it is a way to fulfil responsibilities.

Projects operate within set conditions to deliver a predefined result. This causes projects to operate relatively autonomous from the parent organization. While an efficient management of resources calls for structure, “adaptive responses resist the pull to order and capitalize on the collective intelligence of groups and networks” (Uhl-Bien & Arena, 2017, p. 10). Furthermore, Weichhart and Stary (2017) argue that for the evolution and improvement of the organization it would be beneficial to learn across multiple projects. Learning across projects and organizational levels enables organizations to deal with challenges more appropriately by increasing the diversity of response options (Folke *et al.*, 2005). Projects and their parent organization are part of a network, through which knowledge flows and learning can take place.

2.3. Collective learning

Learning is described as a key type of adaptation (Armitage *et al.*, 2011) and is therefore a key element when it comes to building organizational resilience. Organizations need to learn as fast as the environment changes in order to survive. They can learn by both formal and informal learning practices. According to Marsick and Watkins (2001, p. 25), “formal learning is typically institutionally sponsored, classroom-based, and highly structured”, whereas control of informal learning primarily rests in the hands of the learner and may occur anywhere and at any time in institutions. The interesting thing about informal learning is that it can be deliberately encouraged, but it can also take place even if an organization takes no deliberate action to encourage learning (Marsick & Watkins, 2001). This means that informal learning can take place under any circumstance. What makes collective learning interesting in the context of our study is the fact that it is concerned with learning as an accumulation of individuals rather than learning by a single individual. Backström (2004, p. 471)

defines collective learning as “... rather enduring changes in a collective as a result of interaction between the collective and its context. In simpler terms, it is the ability of the collective to learn from experiences drawn by members of the collective while working.” This can take place in both formal and informal ways.

The predominant resource regarding learning is knowledge. Knowledge differs from data and information. Although there are various definitions of these concepts, we interpret *data* as symbols that represent properties of objects or events, *information* as data that is processed to make it useful (know-what), and *knowledge* as what is needed for the application of information and data (know-how) (Rowley, 2007). In general, there is a distinction made between tacit and explicit knowledge. Tacit knowledge is based on personal experience and embedded in individuals, whereas explicit knowledge is articulated in formal language, stored in documents, databases, et cetera. In literature, four modes of knowledge conversion are distinguished (Nonaka, 1994): *socialization*, from tacit to tacit knowledge through interaction between individuals or shared experience, *combination*, from explicit to explicit knowledge through the sorting, adding, recategorizing and recontextualizing of explicit knowledge, *externalization*, from tacit to explicit knowledge through articulating into metaphors, analogies, models, hypotheses and theories, and *internalization*, from explicit to tacit knowledge through action, practice and reflection. Collective learning in project-oriented organizations might predominantly involve combination, because people from various projects and departments directly interact to transfer knowledge between each other. However, knowledge can also be transferred between individuals through documents. Knowledge is then externalized by one individual and subsequently internalized by another individual. The possibility to interact is gone and a part of the richness of the knowledge is lost, but this is still a useful way to transfer knowledge from one project to another across time and space.

3. Methods

3.1. Multiple-case study

One of the major infrastructure network agencies in The Netherlands is Rijkswaterstaat – the executive agency of the Ministry of Infrastructure and Water Management. Rijkswaterstaat initiates projects in order to fulfil its responsibility for the design, construction, management and maintenance of the main infrastructure facilities in the Netherlands, including the main road network, waterway network and water systems (Rijkswaterstaat, 2018). Changes in the external environment put challenging demands on Rijkswaterstaat as an organization and on its infrastructure facilities. For this reason, Rijkswaterstaat was selected for an in-depth case study. To collect data on collective learning within a single project, between multiple projects and between projects and their parent organization, a multiple-case study has been conducted within Rijkswaterstaat.

A set of criteria was established to select relevant cases. The cases should support the possibility to draw general conclusions so homogeneity is necessary. The selection criteria were type of contract (DBFM: Design, Build, Finance, Maintain), challenging environment, project phase (realization), type of infrastructure (highways), and realization in different periods in time.

In selecting the cases, first, the cases should support the possibility to draw general conclusions so homogeneity is necessary. Second, the selection criteria included: type of contract (DBFM: Design, Build, Finance, Maintain), challenging environment, project phase (realization), type of infrastructure

(highways), and realization in different periods in time. For collective learning in relation to organizational resilience, cases that contain an above average amount of uncertainty, surprises and changes are particularly interesting. DBFM, as a type of contract, was selected because this is a relatively new and complicated type of contract, introducing uncertainty for both client and contractor with respect to their collaboration and changes in responsibilities from what they were used to. Next, cases were selected based on a challenging environment, with many stakeholders close by. The realization phase was selected, because of the large amount of different activities and time pressure.

In relation to multiple case studies, Eisenhardt (1989) recommends to four to ten cases. Projects with DBFM contracts in challenging environments are numerous in The Netherlands, especially regarding highways. In this study, six cases were selected clustered in two metropolitan regions: Amsterdam and Rotterdam. Infrastructure projects in these regions are challenging and appeal to the resilience of organizations that realize these projects. With a relatively new type of contract and complex context, one would expect projects to learn from other projects that are realized at the same time or earlier. To be able to analyse whether this happened or not, the realization phase of the selected cases started in the period between 2010 and 2018 with an interval of one to two years.

Since collective learning involves people interacting with each other, in-depth semi-structured interviews (Mann, 2016) are considered an appropriate way to study this phenomenon. The key questions for the interviews focused on learning and interaction. The indicators of Table 1 were used in the analysis of the interviews to identify which ones seemed to be relevant for learning. In order to strengthen construct validity and to corroborate findings based on the interviews, also documents were analysed (Yin, 2003), such as the project management plans, which describes the way a project is organized and carried out, and reports of peer consultancy or evaluation trajectories.

3.2. Social Network Analysis (SNA)

Considering the importance of social networks to collective learning (see Section 2.3), subsequently a Social Network Analysis (SNA) has been carried out to understand more about learning through a network. Scott (2017, p. 2) states that SNA “comprises a broad approach to sociological analysis and a set of methodological techniques that aim to describe and explore patterns apparent in the social relationships that individuals and groups form with each other”. A social network consists of *nodes*, representing actors such as individuals, departments, and projects, and *ties* (Robins, 2015), which are relationships between the nodes that represent the flow of knowledge or other resources, either material or nonmaterial (Wasserman & Faust, 1994).

This research concerns collective learning in a social network as a whole. Therefore, a whole network view (Scott, 2017) is adopted. There are two ways to set the boundaries of a network: the *normalist* and *realist* approach (Pryke, 2012). In the *normalist approach*, the researcher defines the boundaries beforehand, whereas in the *realist approach*, the actors in the network define the boundaries themselves. The *realist approach* begins with some relevant actors. By asking these actors with whom they link up, the network starts to unfold. This way of letting the network unfold is also called snowball sampling (Robins, 2015). This research used the *realist approach* as: it is impossible to determine beforehand who interacts with whom; by setting the boundaries beforehand, possible relevant actors might be excluded from the research; besides the departments in the functional organization, there might be other hallways (Dixon, 1999), or events (Robins, 2015), where actors form a link between projects and the parent organization. Since this qualitative research seeks to understand how processes of collective learning unfold, snowball sampling is considered an adequate

approach. Snowball sampling began in the projects by interviewing two key actors for each project: the project manager and the stakeholder manager. Together, they have an overview of most of the relationships within a project and between a project and its environment. In the next phase of our research, we will expand to other parts of Rijkswaterstaat based on the references that were made by the participants.

In SNA, various centrality measures are relevant, particularly to collective learning. First, *degree centrality*, which is about the popularity or activity of a node (Robins, 2015). Directed networks, like in this research, comprise in- and out-degree centralities. *In-degree centrality* is the number of ties directed towards a node and, therefore, indicates the popularity of a node. *Out-degree centrality* is the number of ties directed away from the node and, therefore, indicates the activity of a node. In- and out-degree centrality indicate the available channels for knowledge flow to and from nodes. Second, *betweenness centrality*, which is a measure of the importance of a node in connecting other nodes through short paths (Robins, 2015). Nodes with a high betweenness centrality serve as bridges between parts of the network. Last, *eigenvector centrality*, which indicates the centrality of a node's network partners. Nodes with high eigenvector may have low degree centrality or betweenness centrality, but have relatively easy access to much knowledge, because they are connected to well-connected nodes. The data was processed with Gephi (Gephi, 2019).

4. Results

4.1. Network visualization

Figure 1 provides the main results of our study. The nodes in this visualization represent the projects from the multiple-case study (navy blue nodes with a capital letter A to F), the projects that were mentioned by participants (lavender nodes with small letters), the departments that were mentioned by participants (light blue nodes with a capital D and a number), other relevant platforms like communities of practice (yellow nodes with a capital O and a number), and relevant entities external to Rijkswaterstaat (green nodes with a capital E and a number). The size of the nodes represents the degree centrality of that node.

The arrows, or *edges* as called in SNA, in this visualization represent knowledge transfer. The direction of the edges shows in which direction knowledge was transferred. The weight (thickness) of the edges represents the strength of the relationship between a pair of nodes based on how many participants mentioned this relationship for each type of knowledge conversion. The colour of the edge represents the type of knowledge conversion:

- combination (green edges);
- externalization (orange edges);
- internalization (blue edges);
- individuals moving and taking their own knowledge from one project to another (black edges).

Figure 1 Network visualization of interactions in the cases studied

4.2. Learning within a single project

As Figure 1 shows, projects have their own collection of past projects (see the lavender coloured nodes with small letters) from which project members bring their knowledge and experience. When they are brought together in a new team to realize a new project, project members use their own knowledge and experience to give meaning to events. Changes or unexpected events and their effects on individual project members were often considered deliberately to collectively make sense of what was happening and how to proceed with the project. Participants indicated that it was important to do so to prevent miscommunication and to be able to proceed as a team.

The project management teams generally consisted of five members who represented various specialisms in a project: project manager, stakeholder manager, technical manager, contract manager, and manager project control (Rijkswaterstaat, 2019). They met each other regularly and discussed issues that they could not solve within their own specialism. Other than that, most of the interaction between project members took place within the boundaries of their own specialism. Although

participants indicated that this worked well for them, some participants indicated that problems arose at a later stage because their specialism was not considered at an earlier stage. A stakeholder manager interviewed said: *“Driving piles during the night is no cause for concern for a technical manager, as long as it happens safely and in accordance with rules and regulations. It becomes an issue once we have to inform the neighbourhood. For them it obviously is a problem.”*

Interviewees suggested that as a project proceeds, uncertainty reduces. They indicated that the frequency of interaction and knowledge transfer decreased during the realization of a project. There were less issues that needed to be solved, which allowed for less interaction. However, interviewees indicated that they were sometimes surprised by issues resulting from project members not being as well informed as others assumed. Furthermore, participants addressed knowledge loss due to project members leaving without transferring their knowledge to a successor as an issue. In contrast, knowledge transfer to future successors, i.e. apprentices, through socialization was mentioned by a few interviewees.

4.3. Learning between multiple projects

Like the frequency of interaction within a single project changes over time, also the interaction between multiple projects changes over time. The realization phase starts with preparing a contract and finding a contractor that realizes the physical infrastructure. Participants indicated that much knowledge was transferred from other projects during this phase. Projects want to learn how contracts from other projects worked out and they want to prevent themselves from making the same mistakes as other projects. Once this has been taken care of and the contractor has started, a project seems to go to a primarily internal focus. Often, many issues arise and project members need all of their time and attention to solve these issues. As the end of the realization phase approaches and issues are solved, projects start to open up and become willing to share their knowledge and experiences more proactively.

Nevertheless, participants indicated that they did also transfer knowledge during busy periods. Urgency seems to be dominant for engaging in knowledge exchange with other projects or experts. Participants mentioned three aspects that made knowledge exchange urgent:

1. infrastructure interfaces (e.g. projects having a physical interface due to parts of the infrastructure network directly connecting to each other, and projects having to align project activities in order to minimize effects on infrastructure availability on a regional level);
2. connections with the same stakeholders (e.g. clients, local governments, authorities, companies, and citizens);
3. similar issues (e.g. the same type of contract, the same project phase, the same period in time, and a similar project environment).

The aforementioned urgency aspects are recognizable in the network visualization. Projects A, B, and C were realized in the same region (Amsterdam), shared many stakeholders and had to deal with similar issues. Furthermore, these project teams were located in the same building. This physical proximity urged, and was beneficial to, knowledge transfer between the projects according to the participants. These aspects also hold true for projects E and F, although these projects were realized in another region (Rotterdam) than projects A, B, and C. Project D was realized also in the Rotterdam region like projects E and F, but was realized a few years earlier.

Projects A, B, and C were realized in a programme structure. This might explain why these nodes are closer to each other than the other nodes in the network visualization. Participants mentioned frequent knowledge transfer and learning activities between these projects. Apart from sharing documents and having frequent meetings, project members also switched between these projects. The programme board actively encouraged learning activities and tried to keep project members within the programme in order to retain a high knowledge level.

The interviewees indicated that project members engage in different networks depending on their specialism. These networks are predominantly communities of practice and functional networks in the parent organization. In projects, various specialisms interact, but the interaction between projects primarily takes place within a certain specialism. Furthermore, knowledge transfer is primarily initiated based on questions that need to be answered or problems that need to be solved. For all projects in this study, the weighted in-degree was higher than the weighted out-degree. This implies more knowledge transfer from another project than knowledge transfer to another project.

Participants mentioned the importance of considering the specific characteristics of each project, especially when experiences are externalized, e.g. in best practices and evaluation reports. When experiences are conversed through socialization or combination, it is possible to interact and, for example, talk about differences in project characteristics that may cause certain measures to be less effective or even counterproductive. Another way to transfer knowledge from one project to another and ensure that it is applied in a way that fits with the specific characteristics of a project is to move individuals with their knowledge from one project to another. This happens often as participants indicated. However, this can become problematic for individuals, especially when they have to serve multiple projects. An interviewee (stakeholder manager) said: *“... when the problem is big enough, they create facilities that allow me to get involved in the three biggest projects in my region, although this is somewhat difficult for me, because I have to continuously switch between the projects and also between the various roles that I have.”* This interviewee adds to this that the knowledge remains personal knowledge. In other words, collective learning is absent: *“So, they do create facilities, but there is a lot to gain when it comes to how you actually transfer knowledge to people who are the future of our organization.”*

4.4. Learning between projects and their parent organization

The network visualization in Figure 1 shows that learning platforms, such as communities of practice, are more centrally positioned than departments. Participants mention the relevance of these learning platforms for their work in projects. For example, node O5 represents a learning platform for stakeholder managers within Rijkswaterstaat. People from all over the country meet each other monthly to discuss issues in their field. This also lowers the threshold to interact with colleagues in the same field elsewhere in the parent organization at other times. In contrast, nodes O3 and O4, which represent similar learning platforms for project managers, are separated from each other based on organizational departments. Strikingly, the most central learning platform (node E3) is an external learning platform, namely Neerlands Diep. Nearly all participants mentioned this specific learning platform and its importance for learning within their project and between their project and other projects. This node also ranks highest for betweenness centrality, weighted degree centrality, and eigenvector centrality, behind the nodes that represent the investigated projects. This supports the interviewees' perceived importance of this external learning platform to learning between projects.

Interviewees mentioned a lack of interaction with the parent organization. Half of the participants mentioned that there was little or no knowledge transfer to departments at all. Some participants felt no need to interact with their department, because of the physical proximity of colleagues from other project teams who have a similar specialism. Others experienced a distance to their departments, rather physical, psychological or social, which prevented them from transferring knowledge. When knowledge is transferred, it is important for the richness of the transferred knowledge that project members experience social safety and trust. This holds true especially when people have to show their vulnerability as they tell others which mistakes they have made. As an interviewee said: *“To share that knowledge is very difficult, because it gets close to you as an individual. ... you actually do that once you have a lot of trust in each other.”*

Interviewees mentioned that a programme functions as buffer. Relatively small changes, both positive and negative, are absorbed at programme level. However beneficial this might be for the projects within such a programme structure, a programme structure was also considered to be disadvantageous for learning between projects and the parent organization. Interviewees experienced isolation from their parent organization. For example, an interviewee mentioned managers in the parent organization explicitly stating that the programme stood apart from the parent organization, as if those projects were not realized by Rijkswaterstaat, and experiencing a form of competition between the programme board and management from the parent organization.

5. Discussion

5.1. Collective learning in project-oriented organizations

The *network structure* resulting from this study (Figure 1) can be considered as decentralized. There are many ties, often weak, which allow for knowledge transfer from various directions and varying in content. This network structure makes sense for project-oriented organizations, because projects come across many and varying issues. To solve these issues, they depend on knowledge from outside the project. However, as Hansen (1999) argues, the transfer of complex knowledge through these weak ties may be problematic. This is why in practice people engage in combination, for example by intensifying interaction through frequent phone calls or face-to-face meetings. Furthermore, this retains the social safety and trust that people need to feel when they engage in the transfer of complex knowledge.

Figure 2 Network between projects

In Figure 2, the network between the projects in the case study is retrieved from the entire network and has a more distributed structure. A distributed network is beneficial to sharing tacit knowledge in an environment where people need to experience trust and safety (Smedlund, 2008). Not only the network structure, but also the weight of the ties shows generally strong connections between projects.

Figure 1 shows that each project has its own *satellites*. These satellites are knowledge sources. Some ties with satellites represent individuals moving from one project to another and, thus, the displacement of knowledge. Other ties with satellites represent the transfer of knowledge, mainly through combination. The knowledge from these satellites and the various specialisms within a project result in a multiplicity of perspectives. Dixon (1999) argues that the occurrence of multiple perspectives is one of the critical elements that fosters collective learning. Differences in knowledge enable learning. Therefore, projects need satellites, various specialisms and a decentralized network to reach and exploit as much knowledge as necessary to maximize response options in case of changes or unexpected events.

When we examine the relationships in Figure 1 more closely, we can see that many relationships are “homophilous”, which means that people have relationships with people who are socially similar or physically close (Rogers, 2003). This makes sense, because social similarity makes it easy for individuals to understand each other and physical proximity makes these relationships less time consuming. Furthermore, it is easier to assess if someone similar to you is able to help with an issue than someone you do not know. The research of Borgatti and Cross (2003) shows that it is important to know what another individual knows and to have access to that knowledge. It is a challenge for project-oriented organizations to stimulate heterophilous relationships to enable a higher level of collective learning.

Rijkswaterstaat regularly combines similar projects in multi-project *programmes*. Figure 1 clearly shows that projects A, B, and C, which are part of a programme, are closer to each other than the other nodes in the network. However, the only difference seems to be the frequency of interaction between the projects. This raises the question how collective learning within programme structures actually differs from other collective learning between separate projects. Furthermore, since participants experienced isolation from the parent organization due to the presence of a programme structure, one might wonder whether the advantages of a programme structure for the projects outweigh the disadvantages in the relationships between these projects and the parent organization. This needs further research.

Next to direct interaction between projects, learning between projects takes place through *learning platforms*, such as the so-called *communities of practice*. Figure 1 shows that such learning platforms have a central position in the network within a project-oriented organization like Rijkswaterstaat. These communities are somewhere in between the projects and their parent organization, but what is their actual function? Nonaka (1994) describes the importance of this kind of communities of practice for socialization and its contribution to the overall organizational knowledge creation process. However, based on the indications from interviewees about explicit knowledge, combination seems to be supported through these communities as well. Furthermore, the external learning platforms offer the benefits of multiple perspectives (Dixon, 1999) due to the participation of other organizations, but the knowledge that is transferred or created through these platforms only remains within the projects that were already engaged. There seems to be no diffusion to other organizational units.

Strikingly, the interviewees indicated an absence of relationships with *departments of the parent organization*. Departments are considered to be relevant for human resources management. In other words, according to projects, departments have to make sure that there are enough employees for each specialism and that they are equipped to perform at the right level. Considering that collective learning, also within specialisms, prominently takes place through learning platforms, raises the question whether departments should have more central positions in the network of a project-oriented organization or not.

5.2. Absorptive and adaptive capacity of project-oriented organizations

Many interviewees indicated that they proactively interacted with the environment. Projects interact with their environment to understand the context in which they operate and to identify changes to which they have to adapt. Doing so prevented them from surprises or crises and allowed them to adapt to changes in a controlled manner. This means that the indicator *proactive posture* (Table 1 in section 2.1) was clearly present. Other indicators for absorptive capacity were not clearly present. This might be because projects exist temporarily and have a specific objective to accomplish. If the business case of a project is no longer justified, for example due to changes in the context or a crisis that occurred, then that project simply ends.

Regarding adaptive capacity, interviewees indicated that the indicators *minimization of silos*, *internal resources*, *information and knowledge*, and *situation monitoring and reporting* received the most attention. A large project-oriented organization like Rijkswaterstaat consists of numerous departments, projects and specialisms, each making up a silo. Although people experience these silos and indicate that there is room for improvement, the aforementioned learning platforms do noticeably contribute to *minimization of silos*.

As Burch (2010) argues, it can be concluded that it is not a lack of capacity or *resources* that limits the building of organizational adaptive capacity, rather it is often a lack of facilitating the effective use of existing resources. This study shows that lack of time is a major issue in project-oriented organizations. Although all participants view learning as important, they often consider investing time in activities that might have benefits on the long term and are more abstract less urgent than spending time to solve concrete problems in short term. However, some participants indicated that they planned events or participated in externally organized learning trajectories to ensure that they kept investing time in preventive learning instead of only spending time on corrective learning.

With respect to *information and knowledge* we have observed fluctuations in learning between projects. Whereas adaptive capacity has a longer-term focus (Berman *et al.*, 2012), the aforementioned urgency in projects shows that learning is merely an adaptive response to find an instant solution for unexpected events. Furthermore, learning between projects occurs prominently at specific transition stages, i.e. right before writing a contract specification – knowledge transfer from other projects – and at the end of the realization phase – knowledge transfer to other projects. In the intermediate period, projects primarily maintain an internal focus. This makes the organizational knowledge-base (Nonaka, 1994) out-dated, fragmented and inaccessible to the entire organization. Further research is needed about what the implications are for the adaptivity of project-oriented organizations.

One of the prominent aspects of organizational resilience is to maintain an external orientation (Weick & Sutcliffe, 2007). How should a project adapt to changes in the environment? This external orientation is covered by the indicator *situation monitoring and reporting* and is mentioned by many participants. Projects depend on stakeholders in the environment for the acceptance of the project and, thus, the project success. How do the external orientation of projects and their parent organization differ from or complement each other? This needs further research.

6. Conclusions

This paper discussed the way collective learning takes place at three distinctive levels: within a single project, between multiple projects, and between projects and their parent organization. The findings indicate the following:

- A project-oriented organization like Rijkswaterstaat seems to consist of decentralized networks, which enable much knowledge transfer due to the presence of many weak ties. Projects interacting with each other do so in a more distributed network, which allows for sharing tacit knowledge in an environment where people need to experience trust and safety, and mainly through direct interaction with combination as the predominant mode of knowledge conversion.
- Learning within projects and through external learning platforms benefits from multiple perspectives in contrast to learning between projects and through internal learning platforms, where individuals generally engage in homophilous relationships.
- Programme structures and learning platforms enable learning between projects. However, they seem to hinder learning between projects and their parent organization.
- Learning between projects and between projects and their parent organization is hindered by a lack of time (internal resources). Next to solving acute problems, learning is urgent when projects share (1) infrastructure interfaces, (2) stakeholders, and (3) similar issues.
- Learning between projects occurs prominently at specific transition stages, i.e. right before writing a contract specification – knowledge transfer from other projects – and at the end of the realization phase – knowledge transfer to other projects.

7. Further research

This study is the first part of a research project on the contribution of collective learning to the resilience of project-oriented organizations. In subsequent stages, the research will expand from projects to the parent organization's perspective. The observations that were made so far will be further examined. Among others, further research is needed to identify (1) the advantages and disadvantages of programme structures for collective learning between projects and between projects and their parent organization, (2) the implications of an outdated and fragmented organizational knowledge-base for the adaptivity of project-oriented organizations, (3) the position of departments as opposed to learning platforms in project-oriented organizations, and (4) how the external orientation of projects and their parent organization differ from or complement each other.

In-between dynamics

Towards a reconceptualization of soft spaces in regional planning

Abstract

Collaboration across organizations is generally seen as a prerequisite for dealing with complex regional problems. This has led to a proliferation of new, informal and improvisational collaborative approaches, next to the more classical, formally institutionalized realities. From a geographic perspective the emergence of these different types of approaches has been captured in terms of 'soft spaces' and 'hard spaces' of regional planning. Despite the proliferation, soft space scholars observe a limited impact of these approaches. Drawing on a case study on urban regeneration strategies in the Dutch Randstad conurbation, we suggest that the limitation is caused by dynamics in the interaction with other spaces. In this paper we argue that, considered from a dynamic perspective, the emergence of soft spaces next to hard spaces, invokes an in-between space which is not geographic, but rather performative. We coin the term 'in-betweening' as the activity to switch and bridge between multiple harder and softer spaces by focusing on what regional planners 'actually do' when they are confronted with an accumulation of spaces. We argue that combining softer and harder spaces increase the problem-solving potential, that tensions between different spaces are structural and vital and that practitioners acting 'in-between' are crucial to deal with these tensions.

Key words: regional planning, soft space, problem-orientation, tension, practices of in-betweening

1. Introduction

In 2014 administrators and policymakers from a ministry and a province in the Netherlands invited participants from several municipalities, housing corporations, research institutions, real estate investors and developers to work together to revamp the urban regeneration strategy for the Southern part of the Dutch Randstad conurbation. This invitation came at a moment that organizations realized that they could not find solutions via the well-established approaches. This was particularly true now the consensus was that cities should increase their density and safeguard the remaining green spaces in the crowded Randstad as much as possible. Yet building in inner-cities stagnated and generated complex issues regarding transportation, parking, energy efficiency, building costs and dispersed ownership of land and real estate. Consequently, the actors agreed to embark on an experiment to use novel ways to collaborate and find innovative solutions. Facilitators were named to guide the informal collaborative process, meetings were organized and many ideas and initiatives were born. However, the governmental organizations involved had a long history in (formal) collaboration on infrastructural projects already. They developed extensive procedures, rules and routines and continued to operate in their own separate setting. Although the new, experimental and informal approach produced meaningful outcomes according to the participants, the governmental officials of the formal second approach did not recognize these as solutions for their regional problem. Yet

accelerating urban housing became more urgent and several actors worked on an Urban Agenda executed through ‘city deals’ with new playing rules and responsibilities. With this, a third approach was born. The three collaborative approaches consequently and simultaneously co-existed, but struggled in their interaction.

The regional level is often conceived a central scale in solving complex social problems (Albrechts, 2010). For these problems organizations need to mobilize the problem-solving potential of other actors involved (Healey, 2006; Cropper et al., 2008). “In the Netherlands (but also elsewhere) this primarily occurs at the level of urban regions, where the most intense forms of deliberation and negotiation on issues of policy integration take place” (Zonneveld and Spaans, 2014, p544). As a result the field of regional planning, formerly dominated by public organizations, is now increasingly influenced by business, social and civic actors (Boelens, 2010). This growing occupancy of organizations has led to a growing fragmentation (Hajer, 2009). Haughton et al. (2013) observed that “over the last two decades the nature of spatial governance has changed dramatically, both quantitatively [...] and qualitatively in the ways in which multiple networks of actors are continuously made and remade to carry forward particular strategies” (p217). In this growing variety of collaborative approaches, many observe an increasing emergence of informal and experimental arrangements (Lemke, 2002; Van der Steen et al., 2015; Powell and Soppe, 2015; Almendinger et al., 2015). Haughton et al. (2013) presume that “whilst planners have always worked informally and sought to coordinate activities arranged across multiple forms of administrative geographies [...], what we are seeing is in fact distinctive, new and still evolving” (p.221). It therefore comes as no surprise that when studying the strategic plans of public organizations, they aspire to collaborate in new informal ways, stimulating partnerships, networks, labs and communities (Ministry of Infrastructure and Environment, 2014; Ministry of Internal Affairs, 2016). Nonetheless, in practice actors experience disincentives as interorganizational collaboration is seen as an inherently difficult activity due to dynamics caused by divergent interests, opposing approaches and conflicting perspectives (Gray, 2008; Huxham, 2003; Human and Provan, 2000; Ospina and Saz-Carranza, 2010). The above described empirical context is therefore no exception to the present-day increase in quantity and diversity of collaborating actors and collaborative approaches that co-exist around a regional problem. And no exception to the struggle of creating accepted and embedded results across organizations and approaches.

However, studies that focus on the variety in collaborative approaches around the same problem, the interaction between these and the way this influences the collective problem-solving potential are limited. The leading question of this paper is therefore: *How to understand the collaboration across organizations in dealing with complex regional problems?* To answer this question we draw on the concept of ‘soft spaces’ as introduced and elaborated by Almendinger and Haughton (2007; 2009; 2010). They consider soft spaces as new informal forms of territorial governance with blurred boundaries that arise as a response to hard spaces; existing, statutory and formal spaces of government. Analyzing regional planning processes through the lens of this concept is powerful. Yet we argue that we can enhance our understanding of present-day regional planning by taking the conceptualizing of soft spaces further. Especially, because soft space scholars observe a proliferation of soft spaces, but also observe a limited impact of contemporary soft space approaches (Almendinger et al., 2015). We argue more attention is needed for the interactive dynamics in regional planning, within which both ‘hard’ formal spaces and ‘soft’ informal spaces are implicated. As described in the above empirical situation, different ‘spaces’ were involved in tackling the same problem, but there was only little interaction between them which limited their impact in effectively dealing with the regional problem. We adopt a dynamic perspective to investigate the way practitioners are dealing with the interaction between overlapping and concurrent ‘harder’ and ‘softer’ spaces. Not to eliminate, resolve or minimize these dynamics, although this is a regular reflex of practitioners and scholars (Hajer and Laws, 2006), but to work with and exploit the dynamics.

With the focus on interactive dynamics a different kind of space comes in view. We call this a performative space where the tensions between the different collaborative approaches are experienced and dealt with and where new practices of governance get enacted. A performance perspective puts the analytical lens on the ‘work’ that is being done in concrete situations in which understandings of dynamics are performed or enacted (Hajer & Pelzer 2018; Hajer, 2009). To investigate the way in which planning practices are enacted in the in-between space we apply insights from ‘practice theory’ as an approach that emphasizes the interactive, context-bound character of activities (Hajer 1995, 2009; Wagenaar and Cook, 2003; Shove et al., 2012). In practice theory, dynamics are understood through acting (Rein, 1983) and practitioners develop professional standards and repertoires while working (Lynch, 2004; MacIntyre, 1985). Practice scholars focus therefore on the practical activities, judgements and interpretations of the day to day struggle of practitioners in dynamic contexts (Lipsky, 2010). We use the conflict-sensitive orientation to practice theory as defined by Nicolini (2017). This allows us to investigate the co-evolution, conflict and interference of contrasting harder and softer spaces. Nicolini observes that a focus on conflict is used infrequently, yet paradoxically, this focus on tensions and contradictions often trigger new insights in dealing with the actual dynamics. Empirically this requires access to the detailed accounts of practitioners. This article draws on the privileged access of the first author who, as consultant, conducted 25 interviews to evaluate the experiences in planning with hard and soft spaces in the Randstad South region. She has been active as reflective practitioner for many years in a variety of collaborative approaches at different levels. She has experienced the conflict-ridden context herself, but she has also coached practitioners and guided organizational change trajectories to better deal with collaborative dynamics. As Dewey (1910) and later Schön (1983) formulated, reflection is the practitioner’s unique encounter and conversation with a situation through which “he shapes it and makes himself part of it” (Schön 1983, p. 163). And as Johns (2017, p. 13) puts it “knowing in action is intuitive drawing on tacit knowledge”. This approach follows up on the suggestion of Allmendinger et al. (2014), which has not yet been executed by soft space scholars themselves, that for further empirical testing an in-vivo perspective would be valuable (p. 2714).

In this paper we first explore the prevailing conceptualization of soft spaces. In the section that follows we reconceptualize this by investigating in the problem-solving potential of combining multiple spaces, the structural and vital role of tensions between different spaces and the personal impact of dealing with these tensions. In the fourth section we illustrate our theoretical positionings with the case of urban regeneration as briefly introduced at the start of this paper. This case provides a good opportunity to explore the in-between dynamics, because a new informal space emerged, that did not replace the more familiar space and evoked in turn another space, allowing us insights in (un)productive practices of in-betweening. This reflection leads, finally, to the suggestion for orderings and a proposed research agenda that more thoroughly investigates in the in-between dynamics.

2. The concept of soft space

The concept of ‘soft space’ was introduced by Haughton and Allmendinger (2007) to capture the phenomenon of new informal government arrangements in the British and Irish context under the New Labour government (see also Allmendinger and Haughton, 2009). Since then the concept has been wider applied in comparative work in spatial planning and territorial management in Europe (Allmendinger et al., 2014, 2015; Haughton et al., 2010, 2013; Metzger and Schmitt, 2012; Stead, 2014). Soft space became framed in a context of metagovernance (Jessop, 2004; Haughton et al., 2010), neoliberal spatial and state restructuring (Cochrane, 2012; Haughton et al., 2013) and policy integration in the European Union (Chilla, et al., 2012; Faludi, 2013). Important themes were administrative reform, decentralization, competitive localism and territorial governance. It is well

recognized that the emergence of soft spaces relates to the loss of steering capacity of forms of networked territorial governance that are organized around fixed scales and boundaries in this more complex relational world (Zonneveld and Spaans, 2014; Allmendinger and Haughton, 2009). Purkarthofer (2018) similarly states that regional planning today is increasingly dealing with new scales that emerge outside the formalized planning system. Against the background of the limits of statutory planning, soft spaces are seen as a result of “[...] a policy impetus to break away from the shackles of pre-existing working patterns which might be variously held to be slow, bureaucratic or not reflecting the real geographies of problems and opportunities” (Allmendinger and Haughton, 2009, p. 619).

Despite the substantial resonance of the concept, definitions and manifestations of soft space vary. Examples given by Allmendinger et al. (2015) are the Hamburg Metropolitan Region, the Sillon Lorrain, the Fehrman Belt or the Upper Rhine. Despite the different manifestations some key characteristics can be derived from the work of soft space scholars. Soft spaces are mainly regional spatial concepts or regional entities (which regularly coincide) for mostly urbanized areas between the local and national scale (sometimes across national boundaries). Soft spaces, thus conceived, can emerge by coincidence or evolve in a strategic and intentional way, either initiated from the national or European level (top-down) or from the local level (bottom-up). They involve diverse mixes of actors, including government, civil society and the private sector. They are, according to Allmendinger et al. (2015), by nature experimental, intended to provide testing grounds for new policy interventions. Soft spaces are therefore “often counterposed against what might be termed the ‘hard’, statutory spaces of government; formal territorial units of government typically with legally defined and definite territorial boundaries linked to administrative structure of subnational government, and to democratic electoral processes” (Haughton et al., 2013, p. 218). Soft spaces “[...] exist alongside but separate to the spaces and scales of elected government bodies such as local, regional and national government. Whilst some governance spaces can be coterminous with the territorial boundaries of elected government, soft spaces by contrast involve the creation of new geographies that transcend existing political administrative boundaries” (Allmendinger et al., 2015, p.4). Considering these characteristics we here briefly define soft spaces as ‘informal collaborative arrangements governed by a horizontal logic of improvisation’ (see figure 1 for a geographic visualization of the differences between soft and hard space).

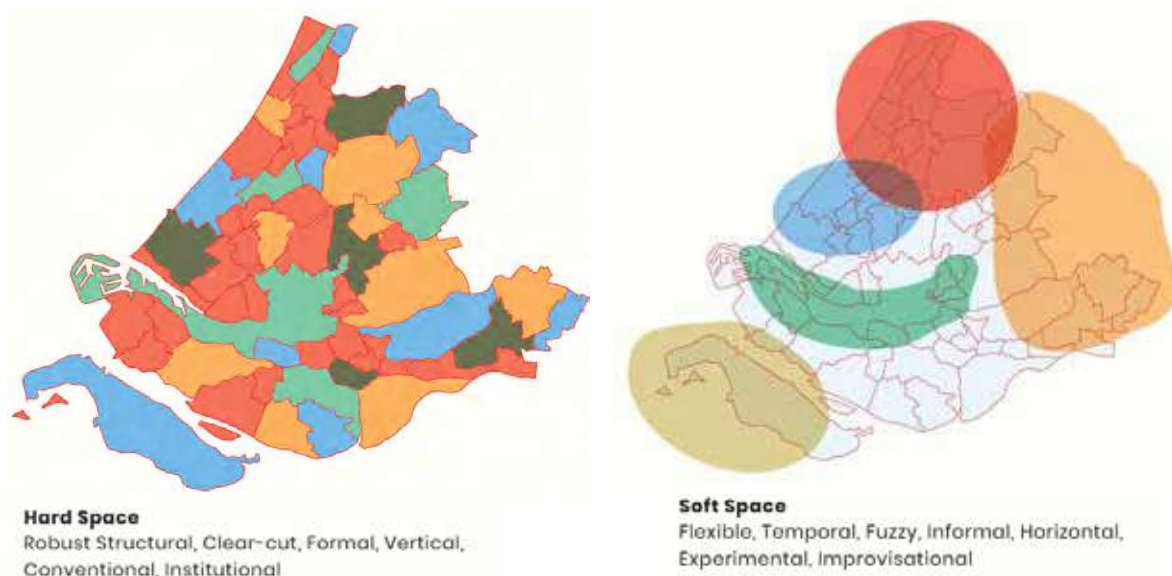

Figure 1. Geographic visualization of differences soft space and hard space (source: authors' own illustration).

Soft space scholars note several aspects on the positive value and impact of soft spaces for regional planning, in the context of the limitations of politics conducted in (pre-)existing hard spaces. Soft spaces are frequently set up to either address the mismatch between administrative and functional areas or to promote the identity of a chosen geography with new imaginaries that change and influence existing perspectives. Through this, soft spaces can help set geographical, institutional and financial conditions, for example to compete with other regions for national and European funds or to establish informal knowledge networks among policy-makers and practitioners (Allmendinger et al., 2015). The often temporary nature of soft spaces allows for a new momentum. Longer term effects of soft spaces are in the prevailing conceptualization captured speaking of ‘hardening’ and ‘softening’ stages, suggesting they can become more structural in their presence when cooperation processes, partnerships and governance arrangements that started with soft spaces may continue to exist over time (Metzger and Schmitt, 2012; Allmendinger et al., 2014). Haughton et al. (2013) state that “Soft spaces have played an important role in mediating and translating neoliberalism, providing flexible and ephemeral experimental spaces and alternatives to costly and disruptive reorganization of hard, statutory spaces” (p.227). Soft spaces are mostly low cost approaches and offer flexibility which implies room to manoeuvre, creating “a space for experimentation that local, regional or national authorities with official planning competencies do not possess. They also allow deniability if such politically sensitive solutions do not work” (Allmendinger et al., 2015, p.225). The authors conclude that successful soft spaces accept and include the heterogeneity of actors on a pragmatic basis and consciously avoid a formal geography. They promote flexible or blurred boundaries instead.

Linked to the positive evaluations the authors also raise serious concerns. They describe the democratic deficit of soft spaces, as democratic structures and processes might be circumvented, accountability outsourced to those running the new bodies and that less glamorous areas of policy might become marginalized (Allmendinger et al., 2015). Haughton et al. (2013) observe that soft spaces are used as a sidestep for existing political, legal or administrative spaces, and are often literally used to evade difficult issues. They also observe that “soft spaces have been the vehicle for a series of narrowly conceived experiments in promoting different forms of high economic growth, albeit in rather disconnected fashion, such that different soft spaces might have contradictory and rather loose aims” (p.231). Allmendinger et al. (2015) add to this by describing “[...] even if they appear to have achieved some measure of success, sometimes a soft space organization’s very existence could have stymied alternative forms of change that might have been even more successful” (p.224). “[...] there is little or no evidence from any of our case studies that soft spaces are somehow more effective, producing speedier or better-quality outcomes. This is in part because they necessarily still rely on using the statutory planning systems to get most large-scale development projects approved [...]” (p.233). Olesen (2012) even observes that soft spaces were not able to fill in the gaps between formal scales of planning and increase pressures on hard spaces. In their final conclusions Allmendinger et al. (2015) state that soft spaces work best when they try to find solutions for particular boundary effects with hard spaces instead of ducking “[...] awkward issues around who is in and who is out of particular arrangements, what is being negotiated over and what is being excluded from consideration, and the patterns of winners and losers that necessarily stem from such selectivities” (p.234).

3. In-between multiple harder and softer spaces

We concur that the realities of regional planning can be meaningfully analyzed in terms of ‘hard’ and ‘soft’ spaces. However, we are intrigued by the finding that authors observe a limited impact of soft spaces in actual planning processes. We suggest that this limitation may be caused by dynamics in the interaction with other spaces. Harder and softer spaces appear to constrain and compete with each other instead of reinforcing and completing each other. Considering the prevailing conceptualization

relatively little is known about the relationship between hard and soft space, how they can work in tandem and how practitioners deal with a multiplicity of spaces and hybridized forms of softer and harder spaces (Allmendinger et al., 2015). In the light of the growing emergence of softer spaces and the remaining presence of harder spaces, we argue that dealing with the interaction between multiple overlapping and concurrent spaces will only become more imperative. Starting from an appreciation of the complexities of regional planning (De Roo and Boelens, 2016) and following a practice approach (Shove et al., 2012) we suggest we may have to interpret the interaction between softer and harder spaces from a dynamic perspective, focusing on the fabric or space in-between. We foreground three theoretical positionings that help deepen our understanding of the interactive dynamics: (1) the problem-solving potential of multiple spaces; (2) the structural and vital tensions between different spaces; and (3) the impact of individual practitioners in dealing with tensions.

The problem-solving potential of multiple spaces

Empirical research illustrates the difficulty for organizations and especially public organizations to respond effectively to complex problems (Kettl, 2009; Head and Alford, 2015; Boelens, 2010). Complex problems are hard to define, contested by different actors, interrelated to other problems and identified by uncertainty (Termeer et al., 2015; Ney and Verweij, 2015). Multi-actor, multi-sector and multi-level collaboration is increasingly highlighted as a key driver for creating innovative solutions for these kind of problems (Davy, 2012; Hartmann, 2011; Ney, 2009; Verweij, 2011; Innes, 2016; Sørensen and Torfing, 2014; Buijs et al. 2018, Termeer et al., 2015). The multiplicity of cross-over interactions is particularly important, because the added value of collaborating becomes greater when actors think and work differently (Schrujjer and Vansina, 2008). In this respect, the (variety in) involved actors and the collaborative approach chosen for should follow the degree of complexity of the problem (Gray, 1989; De Roo, 2001). This contrasts the often employed way of working with predefined tasks and structures. When problem solving is central in the work that needs to be done, organizational structures and arrangements are not set; collaborative formats differ per situation (Teisman et al., 2018). Furthermore, different actors will have different interpretations of what is the problem and will have different preferences that influence the choice of approach (Lubell, 2003; Van der Steen et al., 2015).

Accordingly, multiple approaches are consequently and simultaneously possible for a specific regional problem. However, we observe a shift towards new, informal and improvisational spatial planning approaches as the appropriate way to deal with complex problems and a move away from more classical, formal and institutional approaches (Boonstra and Boelens, 2011; Termeer, 2009; Arts and Van Tatenhove, 2005). Soft space scholars tend to also highlight these new constellations of actors coming together (Allmendinger et al., 2015). Following Zuidema (2011) we argue that complexity is a reason for an increased plurality of collaborative approaches and that classical, formal approaches can act as a crucial foundation for new informal approaches. Thus, solving complex regional problems does not only raise the need for informal collaborative approaches, but merely the combination of and interaction between different approaches. Whereas soft space scholars consider soft spaces as the outcome of a thoroughgoing critique of hard spaces and its failure to deliver (Allmendinger et al., 2015), we rather focus on the strengths and values of harder spaces complementary to softer spaces, because considering 'the new' as a disqualification of 'the old', would stimulate unproductive and defensive reactions (Termeer, 2009). With respect to this, Lawrence et al. (2002) disclosed that collaborations that are highly embedded, which is the degree to which a collaboration is enmeshed in other interorganizational relationships (Dacin et al., 1999; Granovetter, 1985), are more likely to diffuse innovations beyond the boundaries of the collaboration. According to Lawrence et al. (2002) organizations that focus solely on their partners, at the expense of the connection with the broader interorganizational network, may secure competitive advantages, but forego the opportunity to effect more fundamental change: A common concern amongst soft space scholars (Allmendinger et al., 2015; Olesen, 2012).

When carrying forward this line of reasoning, it is fruitful for effective problem-solving to focus on *multiple spaces that emerge around the same problem*. However, the prevailing conceptualization of soft spaces puts the focus on the *hard and soft spaces that exist in one region concerning multiple problems*. Putting problems central allows us to appreciate how actors dance through the scales and when and how actors from different levels are involved (Teisman et al., 2018). More importantly still, it allows us to better focus on the interactive dynamics between spaces. With this focus a more performative, in-between space comes into view in which the actual interaction between spaces takes place and where the combination of these interactions together has certain effects. It shows resemblance to the work of Soja (1996) on the concept of ‘third space’ where different qualities add up to a new, unknown, third quality. The in-between space that arises out of the interaction between softer and harder spaces cannot be marked on a geographical map, but rather on a mental map. The in-between space is a performative space, but on certain interactive moments it can reveal itself when meetings are organized between the different harder and softer spaces. Allmendinger et al. (2015), however, raise concerns for overlapping spaces with different competencies that might lead to inefficiency, mistrust and tensions. Our hypothesis is that multiple collaborative spaces around the same regional problem can enhance the problem-solving capacity and that it are exactly the tensions between the divergent collaborative approaches that enable this to happen.

The structural and vital tensions between different spaces

In the prevailing conceptualization soft spaces exist next to, but outside hard spaces as separate realities (Allmendinger and Haughton, 2009). In practice soft spaces are often deployed as workarounds and sidesteps to avoid conflicts with hard spaces (Allmendinger et al., 2015). From a complexity perspective the dynamics of a system are exactly characterized by its relationships and interactions and these can only be understood by taking into account the parts, the whole and the context (Cilliers, 1998: 4; Prigogine & Stengers, 1984; Teisman et al, 2009). Using a dynamic perspective we therefore reveal both conflicting types of spaces as part of one reality. Lewis and Smith (2014) likewise suggest that in conflict-ridden situations we need to move from ‘either/or’-debates to ‘both/and’-perspectives that engage opposing approaches simultaneously. They herewith stress the value of a paradox lens and define a paradox as contradictory yet interrelated elements that exist continuously and simultaneously. The opposing elements of a paradox are therefore in a permanent state of tension, for example, between formal and informal cultures, institutional and improvisational approaches or mechanistic and organic structures. Lewis and Smith describe that researchers have long responded to these tensions by identifying conditions under which organizations or practitioners should attend to the one side or to the other side. However, nowadays different authors describe the reflexive character and ineffectiveness of this strategy to repress or avoid paradoxes in satisfying our need for consistency and uncertainty reduction (Derksen, 2016; Jay, 2012; Lewis, 2000; Smith and Tushman, 2005). In contrast, paradox scholars consider paradoxes as persistent unsolvable puzzles fostering the existence of the tension and fueling the interplay between the two poles to achieve long term success (Derksen, 2016).

Next to the fact that tensions between new, informal and improvisational approaches and classical, formal and institutional approaches are structural, they are also vital (Miron-Spektor et al., 2011; Smith & Lewis, 2011; Rauws and De Jong, 2019). While tensions often complicate collaboration, the coexistence of opposing values contributes to a system’s capacity for change (De Roo, 2017). Seo and Creed (2002) likewise state that inconsistencies, contradictions and tensions are enablers of change. Shove and Walker (2007) and Van Meerkerk (2014) both show that change takes place through processes of co-evolution and mutual adaptation within and between arrangements. Powell and Soppé (2015, p.770) confirm this: “Organizational forms can be conceived of as assemblages of elements

and practices. For newness to occur, existing templates and ideas must flow together and be recombined in novel ways, and integrated into the social world. [...] Such generative dynamics frequently occur when otherwise distant social arenas are brought together. Structural spaces between multiple networks have a high potential for foreign material and elements to flow together and become repurposed and rearranged to form a fresh constellation.” In this view tensions are seen as an opportunity and invitation for creativity and unconventional lines of thought (Miron-Spektor et al., 2011). Also Cameron (1986) describes that if there are no tensions, an unproductive and schizophrenic situation may arise. In contrast to soft space scholars we thus perceive tensions between spaces not as something negative and something to avoid or resolve (Allmendinger et al., 2014), but as something positive and something to exploit. By bringing harder and softer spaces around the same problem into the same reality, tensions are not unexpected, uncontrollable external intruders, but expected and manageable parts of the process.

However, this does not imply that dealing with tensions between new, informal and improvisational approaches and classical, formal and institutional approaches is easy. The embeddedness of soft spaces also complicates innovation (Termeer, 2009). Alter and Hage (1993) show that not only individual organizations institutionalize, interorganizational activity is affected in a similar fashion. Particular collaborative approaches may become the widely accepted and understood default approach for how actors work together around a specific problem. In the in-between space where harder and softer approaches assemble, the tension between new and classical scripts of working is preeminently experienced. Here, the impact of soft spaces on hard spaces resembles the transformative process of niche dynamics on existing regimes to change (Kemp et al, 1998; Raven, 2006). Hosking (2004) describes that once a particular pattern becomes stabilized, the other possibilities may be harder to have them validated as relevant and good. Van der Steen et al., (2015) call this a distortion of the process of choice, because current (institutionalized) ways of working might prevent actors from choosing new ways. Termeer (2009) illustrates that as a result many public managers talk the talk of new informal and improvisational approaches but in practice get entangled in all kinds of barriers and revert to more familiar, traditional strategies. As stressed by different authors dealing with these and related tensions asks for specific personal skills to “[...] create a whole new system of meaning that ties the functioning of disparate sets of institutions together [...]” and “[...] bridge what have come to be called the ‘old’ and ‘new’ [...]” (Garud et al., 2007, p. 957).

The impact of individual practitioners in dealing with tensions

Williams (2002) observes that the discourse about collective complex problem solving is positioned at an institutional and organizational level and comparatively little attention is accorded to the pivotal role of individual actors. The same applies for the soft space literature in which scholars have a strong focus on the emergence of the phenomenon and have largely neglected the impact of individual practitioners. However, they do suggest that tensions in how relationships are aligned and managed will arise and that it depends on individual actors whether they try to survive by competing or by developing complementing roles (Allmendinger et al., 2015). In different ways *interorganizational* collaboration studies have paid regard to the role of individual actors. By referring to for example ‘brokers’ (Gray, 2008) or ‘mediators’ (Susskind, 2008) the connecting role of individuals across organizational boundaries is explored. The term ‘boundary spanners’ was originally focused on the connecting role within an organization (Tushman and Scanlan, 1998), but was later oriented to the interactions between the organization and its environment in order to realize a better ‘fit’ (Van Meerkerk, 2014; Baker, 2008). Considering the above described context of multiple spaces around a regional problem, we share the crucial role of individual actors in *intraorganizational* and *interorganizational* collaboration. Yet, we argue that their role between multiple harder and softer spaces (on the *intercollaborational* level) is little exposed and understudied. While, practitioners in-between multiple spaces have to deal with all these interactions separately and simultaneously. Ospina and Saz-Carranze (2010) also describe that in successful collaborations the inward work (between

organizations) and outward work (between the collaboration and external actors) is done concurrently rather than sequentially.

We here consider the inward and outward activity, as ‘in-betweening’ and the individuals performing this activity as ‘in-betweeners’ (see table 1 for an overview of the concepts of in-betweenness). To be able to specify different practices of in-betweening we here define a practice as a coherent setting in time and place with actors performing an organized set of doings and sayings (Schatzki, 2002; Nicolini, 2017). These can be both a productive or unproductive practice. According to Cooper action does not take place inside or outside boundaries, but in the midst of things (Burrell and Parker, 2016). In this in-between setting the impact of the repertoire and behavior of individual actors increases: they are themselves instruments to switch and bridge between spaces (Vermeulen, 2012). Furthermore, Kivimaa et al. (2019) describe that intermediary actors can be key catalysts that speed up change and transition. However, when a situation is ambiguous professionals experience unease when they cannot ‘read’ a situation and choose readily among alternatives (Bauman, 1991). Also Argyris (1996) showed that we have developed defensive mechanisms and routines when contradictions threaten to undermine the harmony and consistency. Darling and Walker (2001) describe that backup behavioral styles come into focus as responses to high level of stress and conflict: “An individual’s primary backup style is a predictable yet unconscious shift to more extreme, rigid and non-negotiable behaviors” (p.237). According to Darling and Walker backup behaviors seem to relieve tensions, but are usually counterproductive for the individuals using them. A more reflective way of acting requires the ability to deal with contrasting viewpoints, actions, and intentions (Le Grand, 2007; Noordegraaf, 2007), to create optimal conflict levels (De Dreu, 2006) and in the words of Miron-Spektor et al. (2011) to adopt a paradoxical frame to identify contradictory elements, to explore their linkages and to find and test alternative solutions. Akkerman et al. (2006) also state that it requires people to have dialogues with actors of different spaces or organizations, but also to have inner dialogues between different perspectives they are able to take on.

According to Darling and Walker (2001) style flexibility is a key to interacting more effectively in conflict situations. In-betweeners therefore have to be conscious about their own style, the style of others and have to be able to broaden their own style or repertoire of actions to adapt to the different settings (Grant, 2016). In our perspective switching and bridging softer and harder spaces requires switching and bridging between ‘harder’ (formal and institutional) and ‘softer’ (informal and improvisational) styles or repertoires. Walker and Nocon (2007) define this as ‘boundary-crossing competences’, which is the “ability to manage and integrate multiple, divergent discourses and practices across social boundaries” (Walker and Nocon, p.181). The in-beweenner can be considered as a special type of boundary worker (Metze, 2010; Akkerman and Bakker, 2011). Professionals at boundaries “enter onto territory in which we are unfamiliar and, to some significant extent therefore unqualified” (Suchman 1994, p25). They “face the challenge of negotiating and combining ingredients from different contexts to achieve hybrid situations” (Engelström et al. 1995, p319). This resonates with the later work of Lawrence et al. (2011) on ‘institutional work’ in which they describe “myriad, day-to-day equivocal instances of agency that, although aimed at affecting the institutional order, represent a complex mélange of forms of agency - successful and not, simultaneously radical and conservative, strategic and emotional, full of compromises, and rife with unintended consequences” (p. 52-53). Switching and bridging between spaces therefore requires continuous reflection on what in-betweeners do and who they are (Johns, 2017): The signs to read a situation “[...] are often subtle, requiring perception, imagination and intuition. There are no prescriptive solutions” (p.13). Appreciating this difficult position and stressing the need for skills of adaptivity and switching capacity could in our perspective be crucial for stimulating the interaction between spaces and the impact and embeddedness of soft spaces.

Table 1. Concepts of in-betweenness

In-betweenness highlights the interconnections between multiple softer and harder spaces		
Term		Definition
In-between space	Playing field	The performative space in which the interactions and tensions between multiple harder and softer spaces around a regional problem becomes manifest
In-betweener	Player	The individual practitioner that switches and bridges between different spaces and works on the intra-organizational, interorganizational and intercollaborational level
In-betweening	Interplay	The outward and inward activity of switching and bridging within and between different spaces while constantly adapting one's style
In-between dynamics	Dramaturgy	The inward, outward and intermediate dynamics that cause ambiguity and tensions

4. In-betweening in the case of urban regeneration

The case of defining strategies for urban regeneration in the Randstad South region constitutes an interesting case to study the interaction between multiple spaces. We studied the interactive dynamics between a new soft space and several other harder and softer spaces in the period 2014 (when the housing market was in a crisis situation) to 2016 (when the housing market was overheated). The first author was involved in the soft space as an evaluator of and reflector on the collaborative process allowing for an in-depth case-study. To enhance our understanding of the interactive dynamics we conducted qualitative research: events were attended to observe the interaction, regular meetings were held with the facilitators of the soft space to stimulate reflection and feedback, a document analysis of official letters, reports and newsletters produced by the different spaces were conducted, stories of 25 different participants of the multiple spaces were collected through interviews to produce 'thick descriptions' on practical judgements and interpretations made, and finally a focus group was organized to combine and test our initial findings. In this section we first describe the context of the multiple harder and softer spaces and highlight three collaborative spaces that acted as 'stages' for practices of in-betweening around the same regional problem.

Multiple harder and softer spaces

The 'Randstad' refers to the most urbanized western part of the country where 8.1 million people live and work and where a gross regional product of 367 billion is produced, which is more than half of the Dutch economic activity and which makes it the fourth-largest metropolitan region in Europe (Randstad Region, 2017). While interactions transgress municipal borders, the Dutch system does not foresee in regional planning authorities (House of representatives, 2012). So planning issues in the Randstad require collaboration among many municipalities, three provinces and several national ministries. Based on regional economic analysis the northern Randstad (focused around Amsterdam and Utrecht) is now often approached separately from the southern Randstad (focused around Rotterdam and The Hague). A major problem in the southern region is the stagnation of building houses in inner-city areas. Research shows that about 80% of the inhabitants of the southern Randstad would like to live in urban areas (MIRT-onderzoek, 2014). This results in an expected need to house 230.000 households in the region by 2030 and a need to build 200.000 houses by that time. Despite the massive need for new urban units, only few initiatives for inner-city housing projects are taken. The constraining factors are not clear-cut and extent to many different (policy) fields. Amongst others, there is a search for new business models to overcome the investment gap, for understanding the specific housing needs of target groups, for adjusted national and local regulations, for new parking and mobility solutions and for new sustainable and energy efficient concepts. If nothing

changes the estimated shortage in the urban segment amounts to 85.000 households by 2025 (MIRT-onderzoek, 2014). This situation can rightfully be perceived as a complex regional problem.

In 2014 the Dutch Ministry of Internal Affairs and the province of South-Holland agreed that the building of new housing stock in the urban areas was stagnant and that change would require action from a range of interdependent actors. Acting on this awareness they started a bottom-up collaborative process inviting over a hundred actors, ranging from municipalities, housing corporations and research institutions to real estate investors and developers (MIRT-onderzoek, 2014). This new soft space is the starting point for our research. Up until then they did not share knowledge and experiences. Yet the call for collaboration was clear. The aim was to come to a collective understanding of the problem and devise strategies to overcome the blockages for urban densification. However, the default approach of the national, regional and local governmental actors involved, was to formally regulate regional collaboration with extensive procedures, rules and routines, often directed by the Ministry for Infrastructure and Environment. The newly introduced space did not replace this more familiar space and evoked in turn another space. While acting most participants were not always aware of the different embedded spaces. Yet, when evaluating the collaboration process, they started to unravel the three spaces that had the most impact on their work and vice versa (some participants were involved in more spaces like for example the ‘watertorenberaad’, but these three were most often named and seen as interconnected). Figure 2 represents these multiple harder and softer spaces. The spaces were present in broadly the same period and involved similar organizations, but often in different roles and with different practitioners. When we would use the general definition of soft spaces set up by Allmendinger et al. (2015) not only the first space, but all three spaces could be defined as a soft space whereas they all have fuzzy boundaries and are a way to collaborate with multiple actors on the regional level of the southern Randstad. Yet in these three different spaces very different approaches were enacted representing a spectrum of harder and softer approaches.

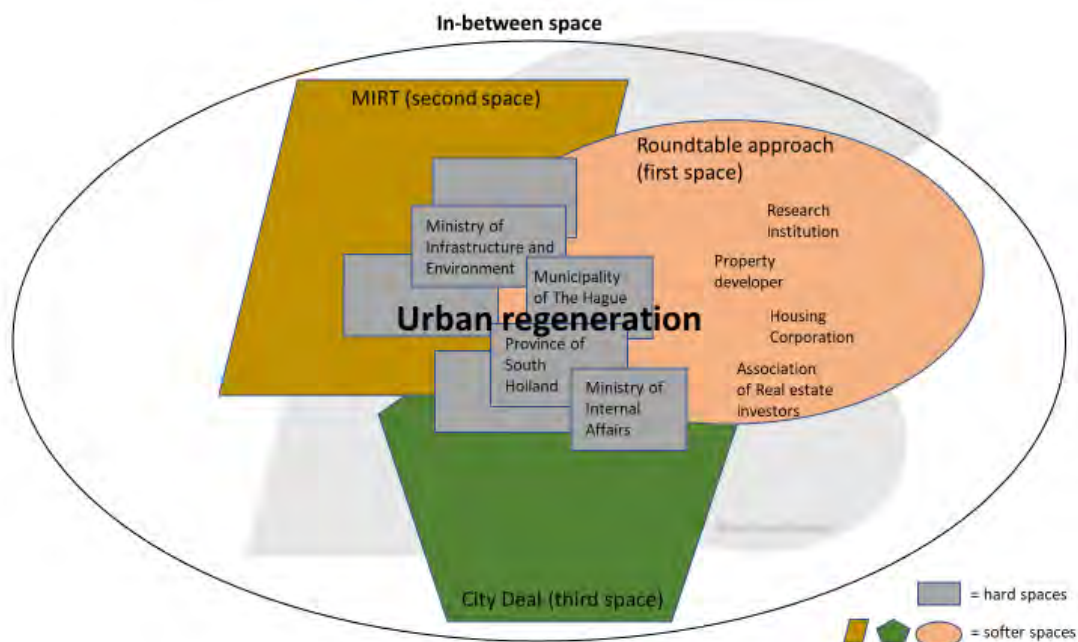

Figure 2. Visualization of the multiple harder and softer spaces for the case of Urban regeneration (source: authors' own illustration).

Roundtable approach (first space)

The Ministry of Internal Affairs and the province of South Holland offered each a facilitator to guide the collaborative process. They selected five themes for pilots employing a so called ‘table-approach’.

The tables were asked to illustrate the obstacles they experienced and were encouraged to suggest creative solutions for their theme. For each table an independent chairperson with a private, social or academic background was appointed. A civil servant from one of the involved public organizations was assigned to support him or her. The chairperson got a list of possible participants with diverse backgrounds but was also stimulated to invite participants from his or her own network. Next to this, people were able to invite themselves to the table. The process was open to everyone who wanted to join, as long as they (1) had something to contribute in solving the problem, (2) were able to organize themselves and (3) were open to reflect on their own agenda and interests. With this the conditions for a new soft space were born. At first mainly associations and platform organizations joined, but during the process more individual member organizations and entrepreneurs started to join as well. From September till December 2014 four big general meetings were organized by the facilitators for all five tables to exchange knowledge, get inspired and discuss the theme at hand. The facilitators hired reporters to make notes. People not involved in or committed to the pilots could sit in on these general meetings. In 2015 the approach was organized more loosely and informally and twelve tables became active on a diversity of themes. Each table was expected to deliver a concrete advice, without the format being specified beforehand. Consequently, each table had its own style and pace of working. Sometimes the ‘official’ informal process was overtaken by initiatives from people not committed to one of the tables. An example of such an initiative was ‘p-matching’ set up by three diverse participants that organized local sessions to match possible housing locations and possible investors and developers.

MIRT (second space)

The second space can be considered as the formal collaboration between the governmental organizations that have a history of about twenty-five years in the long-term national government investment program for infrastructural, spatial and transport projects called MIRT (Meerjarenprogramma Infrastructuur, Ruimte en Transport). It started in the beginning of the 90s under the name MIT as appendix to the Infrastructure fund in the national budgetary framework for only infrastructural and transport projects. To stimulate integrated policies and coherence in regional investments in 2008 it was broadened to MIRT by adding also spatial projects. Through the years MIRT became an institutionalized way of collaborating. The content of the program is described in an annual MIRT project book, which is presented to the parliament on the third Tuesday of September each year. These projects are based on regional strategic agenda’s and have a fixed sequence of steps in their development: MIRT-research, MIRT-exploration and MIRT-plan. The way of working is described in the MIRT playing rules. Decisions about the course and finance of the projects are made once or twice a year in an administrative gathering per region (BO MIRT), like the Southern part of the Randstad, where all involved ministers, deputies and aldermen come together. These gatherings are carefully prepared by civil servants from the involved public organizations and are directed by the Ministry of Infrastructure and Environment. Because of the institutional approach this collaborative space is highly influenced by hard space characteristics. In 2014 the ministry accepted the downsides of their ‘harder’ approach, which was considered to be too rigid, time-consuming and bureaucratic for tackling the increasingly complex regional problems and the growing amount of involved actors (MIRT, 2016). A program to renew or ‘soften’ the approach of collaboration was launched with a broader view on problems, involved parties and possible solutions (MIRT, 2016). This was supposed to pave the way for the soft space approach in the first space.

City deal (third space)

At the same time in 2015, three ministries presented an Urban Agenda to strengthen the economic growth, innovation and livability in Dutch cities as catalysts of the national economy (Ministry of Internal Affairs, Ministry of Economic Affairs and Ministry of Infrastructure and Environment, 2015). This Urban Agenda is executed through ‘City Deals’ on important themes for transition. These deals are concrete agreements between public, private and social organizations on solving urban problems,

but also on learning from new ways of collaborating. Originally the private and social sector was supposed to be leading and the public sector was supposed to be facilitating (PBL, 2017). In practice, however, all sectors took their equal responsibilities. One of the deals made was the ‘City Deal Building and Transforming Inner-cities’ (Binnenstedelijk bouwen en transformatie). In the beginning of 2016 the City Deal was signed by seventeen organizations in the Southern part of the Randstad and a third collaborative space was born (City deal, 2016). The organizations committed to the common goals specified and for each organization their contribution to the goals was made explicit. Important in this City Deal were the seven municipalities that selected a pilot area and had to be open on the real-estate interests and investments. These pilots were partly based on the results of the first space. This third space was characterized by many soft space elements, however some elements were slightly ‘harder’ when the governmental organizations involved were called on their constitutional tasks.

The experienced value of the first soft space approach

The recognition of the complexity of the problem made that the initiators explicitly chose for a new, informal and improvisational soft approach in the first space. The respondents were very well aware of the fact that they needed different actors across usual and unusual sectors and levels to find solutions. The initiator from the Ministry of Internal Affairs stated about this:

“We wanted the collaborative process to become a festivity which is fun to contribute to, but we decided that it could not be a governmental party, like it mostly is on themes like infrastructure and water management. In the housing sector it are organizations outside the government that develop and create. We invited the private sector at the first meeting already. I remember the meeting still very well. The whole venue was packed. We were nervous whether private parties wanted to join, but we had no doubt that this was the right approach for dealing with our housing problem” [Respondent 20]

A right-hand man of a chairperson from the housing field emphasized the importance of the diverse disciplines and actors in this approach to solve the complex problem:

“Actually, I didn’t want to speak to people from ‘housing’. If you want to change something, you need other actors. That is why this was such a good process. With our group we combined accessibility, mobility and housing and translated an international guideline for transit-oriented development” [Respondent 8]

During the meetings many surprising and spontaneous encounters happened that would otherwise not have taken place:

“At a certain point I walked around on a very vague meeting and I bumped into someone that is the exact opposite of me. A very entrepreneurial type. We started talking and before we knew, we were making exciting plans. I would have never met a person like him, if these meetings were not organized” [Respondent 17]

However, participants did have to get used to the soft approach as a respondent from the institutional investors association for real estate illustrates:

“At a certain moment we were asked by a director of a housing corporation to join. He knew that we are a very active organization. I hesitated but said yes. And then I arrived in a chaotic setting with all sorts of enthusiasts. At first it gave me an awkward feeling. I wondered who was participating in what role. It seemed to be mainly people that put themselves forward. Sometimes voluntary and sometimes paid for. This is not how we are used to work. It was a mix of discussions, working groups and cross connections. And in the midst of this multiplicity I thought: we are going to do our own thing and we made a ‘reversed bid book’ to show what institutional investors do and want” [Respondent 2]

Since it was an experimental approach some tables delivered the expected advice, some came with unexpected outcomes and some did not come to results at all. Yet, the respondents at large signaled to be satisfied with the results of the soft space approach. Compared to classical approaches this approach was less expensive and produced a greater variety in results. However only few respondents

oversaw the variety and upon reflection some suggested that the more fluid or indirect outcomes were most impactful. A participant of the housing corporation explained:

“This process generated a lot of ‘side-effects. Usually we don’t have the time to explain the way our world and our systems work to each other, but in this collaborative format we had. The setting made it possible to talk about everything and we knew that it would not out on the streets the next day. This helped adjusting the traditional images of each other. It was probably not aimed for beforehand, but it created the relationships among the organizations we can now draw upon in subsequent engagements. I find participating in these processes much more effective than attending conferences. I experienced it as a gift and learned a lot” [Respondent 18]

The experienced value of in-betweening

The aim of all three presented spaces was to try and create a breakthrough in the complex regional problem of the stagnation of building new dwellings in inner-city areas. Yet, most participants were unaware of the multiple spaces active around the same problem:

“It was only after quite some sessions that I understood there is MIRT [second space]. I had the impression that it was mainly a search for money, but I had no idea what was going on there” [Respondent 2]

During the interviews and focus group the respondents expressed a strong need for an overview of spaces, their interrelationships and their link to the problem. The few respondents that did oversee and exploit the interactions between the different spaces experienced a deeper and more sustainable impact:

“To prevent fragmentation we [first space] have to be part of MIRT [second space] and we have a strong relationship with the City Deals [third space]. We use each other’s products. That gives my effort an added value and functions as a multiplier of my work. I have no doubt that my dedication was worth it” [Respondent 17]

One of the initiators of the ministry of Internal Affairs also described that the first space made the start of the third space easier:

“The signing [of the deal in the third space] was in my last working week at the end of march in 2016. With the help of the ‘Watertorenberaad’ as an intermediary organization we called everyone with the question whether they would sign. They could sign up with commitment or as a sympathizer. They all chose for the first. That was the result of the initial collaboration [of the first space]” [Respondent 10]

And one of the chairpersons used the relation between the first and second space:

“The connection with MIRT [second space] made it a lot easier for me to informally contact administrators and civil servants from the national level” [Respondent 1]

Several participants of the first soft space actively searched for legitimization in hard spaces by involving representatives of harder spaces at milestone moments or by referring to formal documents:

“Sometimes I use a line from the coalition agreement, not because of that line, but because I need a connection to legitimate our efforts and investments” [Respondent 20]

Some were surprised by the impact the connection with hard spaces had:

“It is actually a gigantic success that the Provincial Council decided to largely adopt our guideline for transit oriented development as a starting point for all conversations with the municipalities about inner city plans. And next to this the examples that we collected lead to an accepted motion in the council of the municipality of The Hague to evaluate their parking policy and start a pilot to build in higher density with less parking places” [Respondent 8]

And a participant from the housing corporation described the relevance of job rotation between the facilitator of the province of South Holland and a colleague from the housing corporation to better understand the institutional context. She also observed the softening of the province as a hard space stimulated by their role in the first soft space:

“Before I participated I had strong doubts about the province as a valuable administrative body. That image totally changed. They performed a beautiful role in-between the municipalities almost without using power or politics. I think they can profile themselves much more as an intermediary organization. This role was harder to play when the two bigger cities of Rotterdam and The Hague were involved, but next elections I am going to emphatically vote” [Respondent 18]

And finally the respondents experienced that being transparent on their own interests and role helped in making realistic connections between spaces:

“My face is associated with the national government. As if I can represent all these interests and worlds. Now, I am much more precise in what people can expect from me and it works” [Respondent 22]

In these positive experiences we can unravel some productive practices of in-betweening (see figure 3 for a visualization) like stimulating informal and verbal contact, stimulating spontaneous encounters at meetings concerning the regional problem at hand, involving representatives of hard spaces at milestone moments in soft spaces, adjusting historic images of the different organizations by taking time to really get to know each other’s world and systems (for example through job rotation), being explicit about the own role, using intermediary organizations like the province and the Watertorenberaad to connect different spaces, using the products and outcomes of the one space as a starting point for the other and embedding ideas through guidelines that can be politically adopted in hard spaces. These practices of in-betweening could be perceived as ‘micro practices’ responsible for ‘macro breaks’.

The experienced struggle of in-betweening

However, the respondents also expressed frustrations about the lack of interaction between the multiple harder and softer spaces. There was no explicit strategy for connecting the different spaces. As a chairperson noted:

“In my opinion we were finally doing something really valuable, but from June 2015 everything was focused on the City Deals [third space] instead of our tables and experiments [first space]. I didn’t get feedback from the administrative gathering of MIRT [second space] and we were not involved in the selection of the cases for the City Deal [third space]. The different parts seemed to work at cross purposes.” [Respondent 13]

Her righthand man explained why they were struggling themselves as well to make connections with the traditional hard spaces:

“The products that we delivered at our table [first space] had to be useful for the city councils [hard space], but we found it hard to act strategic, to use the appropriate language and to legitimate our results” [Respondent 8]

A participant from the ministry of Infrastructure and Environment was disappointed about the way the results of the first space were presented in the second space and therefore had less impact on the administrative level:

“In my opinion we didn’t fully exploit the label of MIRT [second space]. We didn’t succeed in having a true conversation on urban densification. It was presented under the heading of ‘international competitiveness’, but it drowned under that heading” [Respondent 22]

The initiator from the Ministry of Internal Affairs complained:

“Everyone is responsible for its own delegation, but the fact that the departments of spatial planning and mobility were involved in MIRT [second space] and the departments of housing in our process [first space] didn’t help” [Respondent 20]

One of the chairpersons was dissatisfied by the level of integration:

“Because of the separations between the spaces and the fact that we didn’t develop an integral perspective on urban regeneration. There were no moments of integration. You have to have the guts to let the chairpersons [of the first space] sit down at the table of MIRT [second

space] to present the red lines. I would have taken responsibility for that. Now there was very few interaction. We certainly would have lost energy if we had to comply with the structure and formats of MIRT, but there are other ways to connect” [Respondent 1]

During most interviews the respondents expressed concerns about the embeddedness of the soft space approach, which turned out to be not self-evident:

“I am worried about the follow-up and embeddedness of ideas [of the first space]. We tried to incorporate the innovative instruments in the city deal [third space], but they were not open to experiment. We had to start the discussion all over again” [Respondent 22]

In almost every interview it was stated that the success of the first soft space relied on the ‘people’ and the continuity of their involvement. They also noted that the different spaces needed different personal styles and repertoires as the initiator from the province put it:

“The MIRT process [second space] and the process around the initiatives [first space] are completely different settings and thus we needed different people. The way of working has to suit your personal style. I have really thought this through when I asked possible participants to join” [Respondent 21]

During the conversation in the focus group, the participants concluded that not every style and repertoire was valued and exploited in every space and that stimulating a mixture of styles and repertoires would have helped in better connecting the spaces. For example, styles attracted and activated in the second space could have helped to increase the administrative relevance of the first space. Styles attracted and activated in the first space could have helped to shake up the routines and playing rules in the second space. A participant from the private sector said:

“I wouldn’t be afraid of the presence of the people from MIRT [second space]. Of course, it are fixed-role persons. It would easily feel like you draw outside the box, but that is the point of mixing these styles.” [Respondent 17]

Some practitioners explicitly functioned as in-betweeners and were seen as crucial to the success of the soft space:

“A private and social participant said to me: ‘you have to be in between, then we feel safer. It helps when someone can be a neutral mediator and moderator. Someone that builds bridges, guides the conversation and formulates issues’. No one wanted to be in this position, but I learned a lot and increased my network, gained more understanding and got a stronger profile” [Respondent 7]

The in-between position was not easy to fulfill and the respondents raised the need for more specific individuals explicitly fulfilling that position:

“The facilitator of the Ministry of Internal Affairs was a strong connector. He has an enormous network and is an innovator, but even he had to drag and push to make things happen. The national governmental role was in my opinion too much depending on him alone. I think we should have made that line stronger and organize backing for him” [Respondent 22]

As a consequence of the struggles of in-betweening, the soft space approach of the first space that was largely considered a success from within the space itself, was less recognized across the spaces and therefore less embedded. However, in these frustrations and regrets possible practices of in-betweening can be derived. For example: Developing an integral perspective on the regional problem with input from all spaces, stimulating overlap in participants and key agents across spaces, naming explicit in-betweeners that take care of the connection between spaces, combining participants with different styles and repertoires in one space that have affinity with repertoires in other spaces, investing in a common language to discuss in-between topics, communicating about the successes of the different spaces, knowing and using the right headings that are important in another space and involving participants from other spaces in decision-making.

The conditions for in-betweening

Why did they not perform these practices? The respondents explained that the co-existence of the multiple harder and softer spaces made regional planning more difficult. It resulted in role diffusion and uncertainty about the own position and approach. The respondents felt discomfort, unease or awkwardness when switching between spaces. Although they were mostly unaware of the underlying fields of tension that caused this feeling, in reflective conversations several tensions were defined. For initiators and directors the most pressing tension was ‘protecting a space to be able to be innovative’ versus ‘connecting it to other spaces to be able to spread innovation’. The fields of tension experienced in the differences of approach between the spaces were for example ‘monitoring results according to agreements (central in the second space)’ versus ‘creating energy for a movement and unforeseen results (central in the first space)’. Or ‘stimulating big gestures and decisions to solve this urgent problem (second space)’ versus ‘taking small steps as part of a new approach to unravel the complexity (first space)’. A tension experienced in the different roles performed in spaces was ‘fulfilling a directing role in the hard(er) space of the province and MIRT’ versus ‘fulfilling a facilitating role in a soft space. Fields of tension experienced in the timing between spaces were ‘following the pace and planning of the own space’ versus ‘adjusting the pace and planning to important moments in other spaces’. Or ‘stopping a soft space that is followed up by another space’ versus ‘letting a soft space run parallel to another space to keep on stimulating innovation’.

There were many more fields of tension tangible in the fabric between spaces and the respondents had their own ways in dealing with them. The regional initiator choose to protect the first space against the hardness of the second space:

“I didn’t want to bother an energetic arrangement with the rules and regulations of the other”
[Respondent 21]

The director of the Ministry of Infrastructure and Environment involved in the second space choose to not become involved in the first, but felt the downsides:

“If I would have intervened [in the first space], then I would have done it in a traditional way, but the consequence of not intervening is that I now have no control on the next steps”
[Respondent 19]

The initiator of the Ministry of Internal Affairs made futile efforts to connect the first space to the second space:

“I really had to push to bring this beautiful example [first space] to the attention of the administrative table [of the second space], but it didn’t last” [Respondent 10]

Judgements about both sides of the tension and corresponding spaces made it harder to equally value both sides and stimulate a ‘both/and’-approach. Most participants assessed the second space by its characteristics as a hard(er) space and also criticized it like that:

“MIRT truly is horrible. Sometimes there are even thirty civil servants around one table to prepare the administrative gathering. All the speeches are ratified beforehand. My minister experienced it as a puppet-show” [Respondent 20]

“MIRT to me is comprehensive and complicated. They work with complex instruments and cost-benefit-analyses, but hardly raise ‘why-questions’ to talk about the heart of the problem”
[Respondent 15]

Participants also illustrated that the way of working in this second harder space, being the most historical and dominant space, made people fall back in their traditional reflexes and choose the one side of a tension over the other. The director of the Ministry of Infrastructure and Environment explained the difficulty to soften this space and stimulate spillover effects:

“I wanted to break through the culture of routine and formality in MIRT [second space]. But it sometimes felt useless to try. Our measure stick is still too much focused on the professional preparation of meetings, which is constraining personal involvement. All our ambitions to work differently are prohibited by the fact that we have money and then our traditional

accounting lines become dominant again, what makes it harder to be an equal partner in collaborations” [Respondent 19]

In the above some less productive in-betweening practices can be recognized when neglecting the tensions or explicitly choosing one side or space over the other: focusing on the rationale of one’s existence instead of the rationale of the regional problem, postponing involvement until things get more concrete for decision-making, defending the value of a soft space by explaining instead of experiencing, bypassing hard(er) spaces, applying the playing rules of the one space to the other, opposing to another space, not following up on earlier connections or even continuously separating the different spaces out of fear for slowing down innovation or decision-making. Making practices of in-betweening productive made a strong appeal to the competences of the respondents. The initiator from the Ministry of Internal Affairs deliberated:

“I wondered what could I have done differently? The label of MIRT and the renewal of MIRT was not recognized in my own organization. It was ‘not invented here’” [Respondent 10]

Having difficult conversations to address tensions was part of these competences that some tried to avoid and some found challenging:

“I feel challenged to guide tense conversations and find it fun to do. You have to feel the tension in order to be able to move” [Respondent 15]

One participant explicitly tried to increase the tension to break through stalemates and experienced resistance:

“On the basis of accessibility we explored new locations for housing. Until then no one dared to discuss sacred cows. The province got pretty nervous about this and people reacted with ‘What were you thinking to name specific locations and numbers?’ It was difficult to talk about, but conflict can help to innovate” [Respondent 5]

The secretary of the first space explained that dealing with tensions required opposing competences:

“You have to be able to deal with chaos and structure, you have to be able to move along and to set directions and to wait and speed up the pace” [Respondent 23]

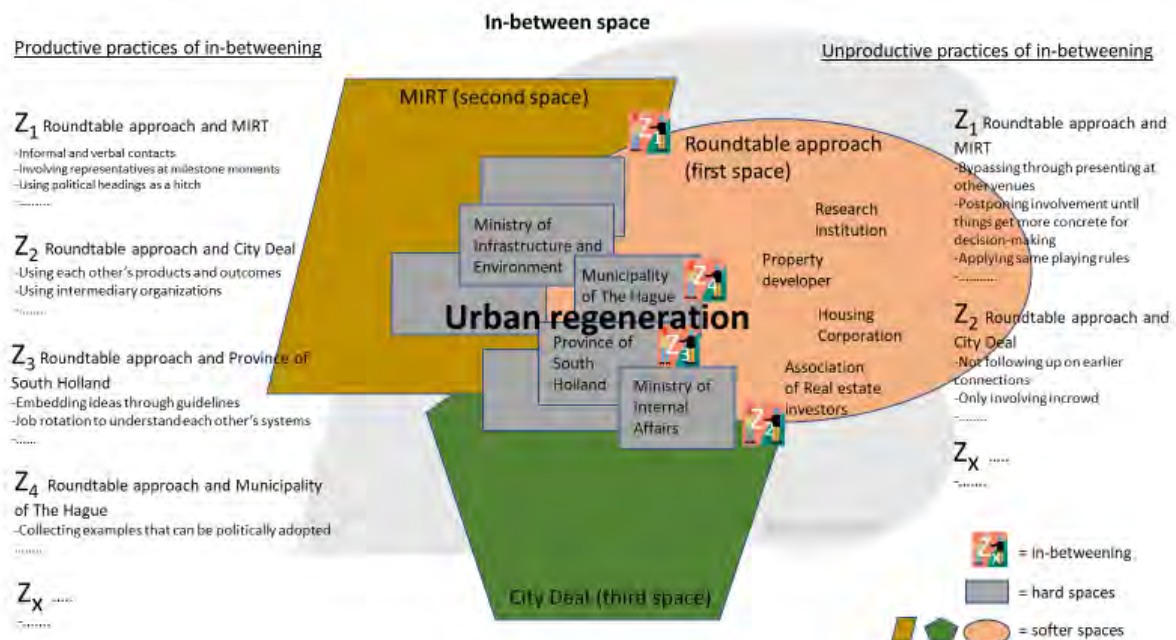

Figure 3. Practices of in-betweening for the case of urban regeneration (source: authors' own illustration).

Considering the above, four conditions for in-betweening can be distinguished. Firstly, participants have to have an overview of the different spaces related to the regional problem at hand and have to

consider these multiple spaces as part of one reality. If participants are not aware of the interconnections they cannot build bridges. Secondly, the different spaces have to be understood and appreciated for their positive strengths as equally valuable and complementing approaches. If participants do not value a space they are not motivated to connect with that space. Thirdly, also the different personal styles that are performed in different spaces have to be considered as equally valuable. If participants are not valuing different styles they will not be able to use each other's strengths and talents. And fourthly, as a consequence, participants have to be able to deal with differences and inherent tensions. If they are not able to, they will easily fall back on unproductive in-betweening practices limiting the impact of soft spaces.

5. Conclusion and further research

We used the concept of soft and hard space to study the collaboration across organizations in dealing with complex regional problems. We argued that soft and hard spaces are not opposed to each other in separate realities. We observed an accumulation and variation of harder and softer spaces around the same regional problem. The case of urban regeneration showed that hardness or softness was not so much defined by the geographical boundaries (administrative or functional) and statutory responsibilities, but mainly by the (in)formality of the collaborative approach. It also illustrated that new, informal approaches and facilitating roles by the public sector do not replace more familiar directing roles and formal approaches: softer and harder spaces consequently and simultaneously co-exist. Explanations for the contemporary limited impact of soft spaces were found in the dynamics between the multiple and divergent spaces. We showed there is merit in focusing on the specific characteristics of the in-betweenness and that more attention is needed for the 'institutional work' in-between harder and softer spaces. We illuminated many 'micro practices' of in-betweening that practitioners draw upon. Considering these micro practices helps to better understand the effects of the whole of spaces. We could bring these fine-grained practices out because of our in-vivo involvement and tacit knowledge. Considering the work in-between, the micro practices may lead to macro breaks in impact. However, the tensions between the different spaces complicate the work in-between and can also lead to unproductive practices. The tensions that arise from the in-between dynamics are hard to manage, but at the same time offer potential for change and innovation.

Further research is necessary to investigate how to act upon these in-between dynamics. General and familiar intervention tools and methods are often not useful, because they are not set up for the specific context and practitioner using them. Hajer and Laws (2006) use the term ordering device to explain how practitioners structure their reality to get a grip on their daily work and deal with the dynamics. They write that the analytic task for studying practices, is to develop concepts that can mediate between actors and structure. Orderings can help doing this. Also, Halffman (2003) explains that ordering stimulates interaction and according to Moor (2012) we need to disintegrate to be able to survive in complex in-between settings. This resonates with a performance perspective that focusses on the 'work' that is being done to create order and stability in inherently unstable situations (Hajer & Pelzer 2018; Hajer, 2009). We suggest that further research is needed to find orderings in the multiplicity of harder and softer spaces, orderings in the different styles and repertoires for in-betweeners and orderings in practices of in-betweening that allow dealing with inherent tensions between spaces and styles. We suggest to involve reflective practitioners to stimulate a deeper understanding of the work in-between on the one hand and to help practitioners reflect on their work in-between on the other hand.

Metropolitan Governance in Mexico: The Institutions

Juan Angel Demerutis-Arenas¹

¹*University of Guadalajara. Planning Department.*

juan.demerutis@cuaad.udg.mx

Abstract: Metropolitan Areas in Mexico are the result of the process that has led world population in general and of Mexico in particular to settle in urban areas. However, citizen participation in metro planning processes has been uneven through time, particularly for vulnerable groups. Therefore, this article analyses the relationships between local governments and the actors of civil organized society using as categories for the analysis, modes of governance considering: key decision makers, public-private relationships, and the key instruments that govern the processes of planning the metropolis. A three-step analysis is conducted: 1) Descriptions of context and background; 2) Revisions of adopted laws; and 3) Participation of organized groups of society in the decision-making process for metropolitan planning. This "chain of evidence" is used to explain two case studies in a narrative sequence: Guadalajara and Monterrey metropolitan areas. The research structure also allows characterizing some common stages of planning processes in both cities ranging from State Governments led planning, to the appearance of the federal Government in urban planning arena, to the fragmented planning by municipal governments of the metropolitan areas, to the emergence of coordination and municipal association, to the reappearance of the federal government in the metropolitan planning arena.

Keywords: Metropolitan governance; metropolitan planning; Mexico

The Process of Urbanization and Metropolization in Mexico

While the 20th century witnessed the development of urban Mexico, with the concentration of the country's population in settlements larger than 15,000 inhabitants (Table 1), the 21st century is characterized by a process in which these concentrations are articulated, and consolidated into large metropolitan areas (Table 2).

Population growth and rural-urban migration have led to urban sprawl and irregular development, which often exceeds the capacity of municipal institutions to adequately manage metropolitan territories; consequently, the metropolises risk becoming chaotic and out of control centers. In addition, urban growth has damaged the environment, as the invasion of cities into lands with high agricultural value, as well as the pollution they generate, both in the air and in the water, are evidence of the negative environmental impact on the process that has led the world population to concentrate in cities. This lack of capacity to manage metropolitan areas requires better governance modes and better institutions for citizen consultation and participation.

The urbanization process in Mexico has gone through several phases (Unikel, et al., 1976). The process was relatively slow in the period between 1900 and 1940, particularly in the first two decades due to the Mexican Revolution. This period of slow but steady growth, both in the countryside and in the cities,

generated a regional polarization of the country, with Mexico City, Guadalajara and Monterrey as the main poles. In the period between 1940 and 1970, the growth rate increased significantly due to a decrease in the mortality rate combined with an increasing migration, particularly of young people from the countryside to the city. The population growth in the country decreased at rates below 2% in the 1980s, with a consequent stabilization in the percentage of young people with the general population, which has placed great pressure on the government, since it must provide more jobs, facilities and services in urban areas. In the seventies, more than half of the population was already concentrated in urban agglomerations of more than fifteen thousand inhabitants, with the rest of the population settled in small settlements scattered throughout the national territory (Table 1).

Year	Population	Annual Growth Rate (%)	Urban population > 15,000	%	Non-urban Population < 15,000	%
1900	13,607,259		1,434,423	10.54	12,172,836	89.46
1910	15,160,269	1.09	1,782,911	11.76	13,377,358	88.24
1921	14,334,096	-0.56	2,085,117	14.55	12,248,979	85.45
1930	16,552,644	1.45	2,891,410	17.47	13,661,234	82.53
1940	19,649,162	1.73	3,927,694	19.99	15,721,468	80.01
1950	25,779,254	2.75	7,198,360	27.92	18,580,894	72.08
1960	34,923,129	3.08	12,746,685	36.50	22,176,444	63.50
1970	48,381,547	3.31	21,556,568	44.56	26,824,979	55.44
1980	66,846,833	3.29	36,135,767	54.06	30,711,066	45.94
1990	80,840,622	1.92	46,343,352	57.33	34,497,270	42.67
2000	95,753,396	1.71	58,311,557	60.90	37,441,839	39.10
2010	110,991,953	1.49	69,049,369	62.21	41,942,584	37.79

Table 1. Population in Mexico (Urban and Rural) Source INEGI.

Despite the decline in the rate of growth, during the 1980s the population growth would be enough to generate a city of 1.4 million each year; and in the next 2 decades a city of 1.5 million per year. The demographic data also show a pattern in the distribution, since there is a trend towards concentration in urban settlements, that is, those greater than 15,000 inhabitants (Unikel et al., 1976 and CONAPO, 2012). But there is another trend: the physical articulation of localities that originally worked independently, but which are now integrated into a single unit, in such a way that they add up to a population of 50,000 inhabitants, whether it is formed by a locality of a municipality or by localities that are located in two or more municipalities that show a high degree of physical and functional integration (SEDATU-CONAPO-INEGI, 2018). Considering the previous criterion, by the year 2000, more than half of the Mexican population resided in a metropolitan area, and by the year 2010 it was already 56.80% in 59 metropolitan areas (Table 2).

Of these metropolitan areas, there are three which in 2010 concentrated a quarter of the country's population; one of them, Mexico City, reached one million inhabitants in the 1920s, and the other two, Guadalajara and Monterrey also did in the 1960s. These three monopolized - even before reaching a million inhabitants, not only the attention of the municipal authorities that composed them, but also that of their states and of the federal government; the first for being the capital of the country, and the other two for being the capitals of their respective states. For this reason, subnational governments focused

on their development since the beginning of the 20th century, and hardly considered areas outside of them at the time of making decisions for the introduction of facilities and infrastructure, because at the same time that this trend was taking place, there was a great dispersion that included more than 5,000 settlements under 15,000 inhabitants in the national territory even before the 1960s (INEGI). However, local or municipal governments are embedded in a federal system, and metropolitan areas must be addressed in that context.

Category	1980	1990	2000	2010	2015
Metropolitan Areas	26	37	55	59	74

Metropolitan population (% of Total)	39.1	38.8	52.8	56.8	62.8

Table 2. Metropolitan indicators. Source: SEDATU (2018).

The federal system that structures intergovernmental relations in Mexico comprises 32 federal entities, including the recently created Ciudad de México (CDMX). These sovereign units are the foundations of the federal pact; the Mexican Constitution establishes three orders of government: federal, state and municipal, without the possibility of an intermediate level between them, that is, a regional or metropolitan government. The Constitution establishes two orders of sovereignty: the federation and the states. The municipalities are free and autonomous but not sovereign, leaving the municipality as the basic cell of a political, administrative and territorial structure. Municipal governments can collect taxes, charge for subdivision rights of land and infrastructure, receive share of taxes charged by the states and the federation, and charge as consideration for water services, drainage, garbage collection, cemeteries, parks and maintenance of green areas. In the analysis developed in this study, the sovereignty of states and their capacity to formulate and implement policies are fundamental for understanding the structural framework in which metropolitan planning is carried out.

Study Analysis Criteria

Urban and territorial planning has been implemented through time in different ways in public policies throughout the Mexican territory. However, not all states have experienced and implemented it with the same resolve; some states have a relevant history in planning issues, while others simply had not dealt with it until the enactment of the General Law of Human Settlements in 1976. The most experienced states have achieved success stories but also failures, which should serve as a reference to inform those who are just following federal guidelines in this issues, about the pros and cons of planning policies and instruments. That is why it is important to describe and frame the contexts that have led to the development of planning at subnational level.

This study focuses on a recent trend in urban and territorial planning in Mexico, which is the coordination of state and municipal areas in the decision-making processes in metropolitan areas of the country, from a governance framework.

Governance is a term widely used today, which originated in the discipline of political science. It considers the participation of various social groups in conjunction with government action as a fundamental component, and emphasis is placed on the greater capacity for decision-making and on the

growing influence of non-governmental actors in matters previously reserved for the government (Becerra Mercado & Reyes Rodríguez, 2014). The term can be found in association with diverse planning issues, such as: environmental governance, water governance, good governance, or urban governance, to name a few. Urban governance is the most meaningful in the development of cities, and the concept has been an initiative of the UN-Habitat program as a campaign to empower citizens, to facilitate "good governance" and social inclusion (UN-Habitat, 2002). In large cities, urban governance has recently spread in coverage, to even consider "metropolitan governance", a very relevant concept, given the need for inter-municipal coordination, but above all, because of the urgency for participation of the groups of the organized civil society.

In the available literature, a wide range of debates about governance can be found; the vast majority grants three essential variants to the concept: 1) governance as opposed to the term government; 2) governance as a set of norms; and 3) governance as an integrated category of analysis in the regulation of issues of public interest, that is to say, as an interface between government, market and civil society (Henning & Heinrichs, 2011). The latter is the definition considered for the preparation of this study.

Governance includes two fundamental elements: normative and analytical. Governance as a normative concept can provide guidelines and norms for good planning, and as an analytical concept, it can facilitate the reflection and categorization of the reality of planning, particularly the mode of governance.

Henning and Heinrichs (2011) propose, based on Motte (1996), four categories for the analysis of governance: actors, relationships, institutional framework; and the decision-making process itself. With regard to the actors, it is essential to define who participates in the planning process, whether they are individual or collective actors, but above all, their roles, interests, resources and means of financing must be recognized. The relations are associated with the formation of coalitions or opposition fronts that can either become convergent interests or trigger a conflict between the different actors. The institutional framework provides rules of conduct, and enables the identification of institutions that prevail in both social and political contexts. Finally, the decision-making process is fundamental in the analysis, including: the effectiveness of the different actors to balance their interests (the state, the private sector and civil society); the identification of the mechanisms of social interaction that regulate the activities of the actors (both horizontally and vertically); and even the connection with those actors who are not directly involved in the process.

Urban and territorial planning has been influenced by the processes of law and policy making, particularly in the way in which diverse actors participate. Therefore, considering the approach of the modes of governance determined by Henning and Heinrichs (2011) as described before, a three-step analysis is proposed to be applied to two case studies: 1) descriptions of the context and background; 2) the revision of the approved laws; and 3) the membership of the consultation bodies involved in planning processes in the states in general, and in the metropolitan areas in particular, so as to describe the real possibilities of participation from the constitution of these participation/ citizen consultation bodies, and the guidelines of the approved laws. In order to organize this analysis, it was considered as a script for the development of the narrative the proposal of phases of Urban and Territorial Planning established by Demerutis (2005), which is based on the intergovernmental relations of the federation, the states and the state municipalities. The phases are listed below:

Phase 1. State experiences in urban planning: The planning of capital cities and the abandonment of small municipalities (1970-1975).

Phase 2. Federal revolution in urban and territorial planning (1976-1982).

Phase 3. Resistance by state governments to municipal planning by federal decree (1983-1992).

Phase 4. Municipal governments responsible for planning and fragmentation in decision-making in metropolitan areas (1993-2007).

Phase 5. Metropolitan coordination: municipal governments in conjunction with state government and governance (2008-2015).

Phase 6: The reappearance of the federal government in the arena of urban and territorial planning (2016- present).

Two case studies are comparatively approached using the proposed method of analysis, given that by their nature they can be paradigmatic to understand the situation of coordination between municipalities in a metropolitan area in Mexico; these cases are the Metropolitan Areas of Guadalajara and Monterrey.

Urban and Territorial Planning in the Metropolitan Areas of Guadalajara, Jalisco and Monterrey, Nuevo Leon

The States of Jalisco and Nuevo Leon have a long tradition of urban legislation dating back decades before the enactment of the General Law of Human Settlements (*Ley General de Asentamientos Humanos, LGAH* or GHLS in English) in 1976, which marked the beginning of the Federal Government into the scope of urban development. Both States are free and sovereign, like the rest of the states of the Mexican Republic. Their government is composed of three powers: Executive, Legislative and Judicial. Their Constitutions grant powers to enact laws to the Legislative Power, which is required to follow clearly defined procedures, in accordance with the Organic Law of the Legislative Power.

There are three metropolitan areas in the state of Jalisco: Guadalajara, Ocotlan and Puerto Vallarta. Of the 7.35 million inhabitants who lived in the state of Jalisco in 2010, more than four million lived in the Guadalajara Metropolitan Area, whose official name in Spanish is *Área Metropolitana de Guadalajara*, which currently consists of nine municipalities: Guadalajara, Zapopan, Tlaquepaque, Tonalá, Tlajomulco de Zúñiga, El Salto, Juanacatlán, Ixtlahuacán de los Membrillos and Zapotlanejo. In the Metropolitan Area of Ocotlán, which includes 3 municipalities (Ocotlan, Jamay and Poncitlan), the population in 2010 stood at 164,256 inhabitants. In the Metropolitan Area of Puerto Vallarta, an inter-state metropolis, 379,886 inhabitants lived in 2010 in two municipalities: Puerto Vallarta in Jalisco, and Bahía de Banderas in Nayarit.

In Jalisco, the issue of urban development was included in the public agenda since 1933. Among the principal initiatives, it stands out the requirement that any municipality of the state that included a city with more than three thousand inhabitants, should have a Commission of Planning and Public Works, in order to assist the Municipal Governments with the improvement of urban areas, as well as in the formulation of policies for their development. These commissions would be composed of the municipal president, the councilor in charge of public works, one representative of the merchants (Chamber of Commerce), a representative appointed by the municipal owners of the municipal seat, and an engineer

or expert from the same capital. The members of the Commission occupied honorary positions, for which they received no remuneration. The governor reserved the right to preside over any of these commissions at his own request. The main function of the Commissions was to elaborate and adopt a "master plan" for the physical development of the city.

These collegiate bodies adopted different forms over time but consistently their main function was to provide urban infrastructure for the municipalities, which was effectively performed; however, the issues related to planning and setting development controls were neglected. These oversights would later hinder the implementation of projects for the resolution of large-scale urban problems. It would also represent difficulties in developing master plans for the communities. For example, some of the issues related to transportation planning of Guadalajara are a proof of this lack of care in the planning of the city (Wario Hernández, 1998).

Up until that point, the mode of governance could be considered of the corporatist / administrative type, since the key decision-makers were predominantly businessmen and professionals - both with origins linked to the state government, together with public officials, and whose main objectives were economic growth and the regional redistribution of development with a very pragmatic style of policy-making.

In the State of Nuevo León there is a single metropolitan area, Monterrey; however, this federal entity also has extensive experience in politics for urban and territorial planning.

Valadez Fernandez (1995) categorized the history of planning in Monterrey in five periods, based on actors, planning techniques and legislation: 1) The private sector and planning: 1931-1950; 2) Advisory master planning: 1951-1960; 3) The institutionalization of the master plans: 1961-1970; 4) Consolidation of the legal framework: 1971-1980; and 5) Institutionalization of metropolitan planning: 1981-1990. In short, in the first years of planning in Nuevo León, from the 1930s to the 1970s, the private sector played a leading role, and later became an advisor to the state government, promoting the development of master plans for the city of Monterrey.

In the case of the state of Nuevo León, urban and territorial planning appeared on the agenda of the state government in 1927. By that time the goal was to to implement basic physical changes to the city, such as the widening of pre-existing roads and the construction of new roads, of which the state government was responsible in conjunction with the private sector.

Phase 1: State experiences in urban planning: Planning of capital cities and the abandonment of small municipalities (1970-1975)

This phase corresponds to policies adopted during the period prior to the publication of the General Law of Human Settlements (GLHS). Although the two states studied displayed a strong interest in urban and territorial planning for human settlements development controls in the period from the 1930s to 1970, this section emphasizes what happened in the immediate years before 1976, just when the capitals of both Jalisco and Nuevo León exceeded one million inhabitants and showed the features of a metropolitan area.

In both cases the planning of the capital city had been the main objective of the policies of the state governments. That is why this phase could be understood as the policy of "Plan the capital, forget the small municipalities".

In both states there was a strong participation of the private sector in conjunction with the state government, so that a type of corporatist governance existed, in which public-private partnership projects predominated for the growth of cities, mainly in the state capital. However, the governors' very strong link with the private sector, rested in the fact that their funding was necessary to implement planning actions. This strong bond, along with the centralist style of governing in the country, resulted in that the laws of planning and urbanization and their reforms were solely initiatives of the governors; in fact, there is no evidence that any local congressman or woman or specific interest groups proposed any amends during this period.

The private sector played an important role in promoting the city development. In Jalisco, merchants and industrialists were part of the commissions for public works and planning, and as members of them, they prompted the municipal government for the development of a master plan. Meanwhile in Monterrey, the industrialists supported the decision to develop a master plan for the state capital that defined the necessary infrastructure works for the metropolis.

In conclusion, planning was practically dictated by the State Executives and their associated businessmen, who with their resources established the guidelines of planning in the capitals. Governance was lead in a corporatist manner, because it aimed at growth, with a public-private agreement in which their partnership projects were carried out through cooperative works.

Phase 2: Federal revolution in urban and territorial planning (1976-1982)

This phase refers to the period between the appearance of the GLHS, published in the official periodical on May 26, 1976, and the following six years. The federal government amended three articles of the Constitution (27, 73 and 115) to provide a legal framework for the new law. During the first year after the GLHS, most states passed new laws on urban development controls. This general law established the basis for planning in the states and for the standardization of a national structure of urban and territorial planning. Following the establishment of this legal framework, each state modified its laws in accordance with its guidelines. Paradoxically with the GLHS, the federal government granted powers -which it didn't have before, on urban and territorial planning of the states, and simultaneously empowered the municipalities as key actors for the development of the cities and the territory. The participation of the three levels of government in urban and territorial planning through the GLHS attends to a principle of concurrence stipulated in the Mexican legislation. Although the federal government interceded for the municipalities, this was greeted with certain reservations by the state governments, resulting in contradictory state legislation sometimes.

The GLHS also included the concept of "conurbation" for the first time, which referred to an urban agglomeration where two or more cities became a homogenous geographical, economic and social unit. As a unit composed of several municipalities, the State executive was responsible for coordinating efforts among the municipalities involved, since in Mexico there are no regional governments. The state plan, as well as the plans for Conurbation Zones, became the first instruments of metropolitan planning in the Mexican states.

Guadalajara was declared a conurbation in September 1978 and Monterrey in 1984, although as explained earlier their size and functions were metropolitan since the 1970s when its population grew exponentially, which made it exceed one million inhabitants.

The GLHS included a requirement of citizen participation in the legislation. The plans of any level had to be presented to public consultation before being published; however, there was no mechanism to guarantee that the observations resulting from the consultation process were included in the Plan, that is to say that public participation was actually symbolic.

In Jalisco, the promulgation of the GLHS prompted the publication of a new Law which had the purpose of adapting to the provisions of the recently promulgated GLHS. However, the bases of the new law were mainly set in past experiences and scarcely in the guidelines of the general law. In reality, municipalities were not entitled to plan, since most of the responsibilities to authorize and plan the cities were left to the State executive.

During this phase the legislative changes generated discrepancies about its contents among the private sector leaders. In fact, they considered these changes a "socialist content of the law", in particular they mentioned that zoning threatened private property. These interest groups also expressed rejection for the granting of powers to local governments and favored a status quo and particularly supported the role of the state government.

This unprecedented situation in the state, represented a kind of startle between the corporatist relations that had prevailed in the state, which rarely questioned the decisions made by the authorities, to a more critical -although cautious- relationship of the various state interest groups.

Unlike other states that adjusted their legislation almost immediately to the promulgation of the GLHS, Nuevo León waited four years to do so. The purpose of the law was to determine the procedures and rules for zoning. It was also responsible for laying the foundations of a framework of attributions for the state executive and the municipal governments in the administration of the plans, but above all, for harmonizing the policy of urban and territorial planning in the state with the GLHS.

The Governor maintained the responsibility of authorizing the state and municipal plans of urban development, including zoning. He also was responsible for planning the metropolitan area, playing the role of coordinator of local governments, the same role he already had as coordinator of the actions proposed by the national plan for urban development. He ultimately acted as a mediator in conflicts between the government authorities and the public over the issues covered by the law and its application.

In this period, although the federal government had set guidelines to follow in the states, in Nuevo Leon, the state government *de facto* retained the attributions of the municipalities, Monterrey included.

In sum, both in Jalisco and in Nuevo León, the coordination of the municipalities of the metropolitan areas was still guaranteed by the state governments, whose interest in what happened in the territory, meant that in practice they were involved in all the planning processes in the municipalities. As for the mode of governance, this had the characteristics of the Corporatist and Administrative modes, because they aimed at growth and redistribution as well as efficiency; they had a pragmatic style and the nature of the public-private relationship was concerted, but at the same time in a competitive environment, mainly due to the emergence of the federal government.

Phase 3: Resistance by state governments to municipal planning by federal decree (1983-1992)

In 1983, the Mexican federal Constitution was amended to establish that municipal governments had the right to formulate, approve and administer urban development as zoning (Article 15). Despite this reform to the Constitution, the elaboration and implementation of the plan were still carried out by the states' governments. In Nuevo Leon, the authorizations of residential subdivisions were made directly in state agencies; something similar happened in Jalisco because although municipal approval was necessary for any development, there had to be a review or "technical advice" from the state executive.

In the municipal reform of 1983, reactions were generated from municipalities claiming their rights to autonomously manage municipal life in general, and the administration of the growth of cities in particular. However, only a few municipal governments were in shape to claim their independence; most of these municipalities were large and rich and were commonly part of the metropolitan areas. This was the case of the municipalities in the metropolitan areas of Guadalajara and Monterrey.

During this period, urban development plans for metropolitan areas were promulgated in both States - although the name referred to conurbations from Guadalajara (1982) and Monterrey (1988). This stage marked the entry of the state government into territorial/ regional planning implementation, but also the lack of resources and capacity of the municipal agencies became evident. At the time of the municipal reforms in the states of Jalisco and Nuevo Leon, only the metropolitan areas were decentralized, and only the municipalities that formed them were granted the responsibilities of urban and territorial planning.

In the state of Nuevo Leon, a new law, granted additional planning responsibilities to the municipalities, but still it reserved most of the planning powers for the state government. Due to this legislation, Municipal planning was strongly debated in Congress; a recurrent concern of the congressmen was the lack of capacity of the municipal governments that were not part of the Metropolitan Area of Monterrey. The congressmen highlighted the existence of a huge gap in urban planning of the time: on the one hand, a relatively new state plan was published as an instrument of planning policy, but on the other, the municipal plans were not executed due to the lack of resources in the municipalities.

In this phase, the coordination was carried out by the state government, which was responsible for the preparation and publication of urban development plans of the metropolitan areas, with the approval of the municipal governments. Regarding the mode of governance, it still had the characteristics of Corporatist/Administrative, since the membership of the consultation bodies was practically the same, as it relied on public-private partnerships through councils in which decisions were shared among organized entrepreneurs and officials of the state government to a greater extent, and municipal to a minor. Although in both states the consultation and citizen participation bodies had the same responsibilities and almost the same membership, it is important to highlight the incorporation, in the case of the Urban Planning Commission of Nuevo Leon, of two Universities of the state, while in Jalisco this still did not happen.

Phase 4: Municipal governments responsible for planning and fragmentation in decision-making in metropolitan areas (1993-2007)

In 1993, the federal Congress approved a substantial reform to the General Law of Human Settlements (GLHS). This law attempted to clarify the need of the municipalities to have the autonomy to decide on

planning and zoning within their jurisdictions. Although municipal governments were assigned to make plans, the necessary resources were not channeled to implement them through the elaboration of specific instruments. This situation resulted in an imbalance between rich and poor municipalities. In most cases, large capital cities -already converted into metropolitan areas, claimed their right to elaborate their own plans and determine zoning; meanwhile, the rest of the urban areas could not plan with autonomy, as provided by state law.

In addition to granting powers to local governments, there is an interesting fact worth noting in this phase: the initiatives for the new legislation were, for the first time in the history of the states of Jalisco and Nuevo Leon, proposals by an actor that was not the governor. In this phase, a new generation of urban and territorial planning policy was proposed, which included a sophisticated set of tools in which the experiences of the states as well as federal guidelines were merged. It included a complete list of zones, the limits of urban growth and the incorporation of strategic planning for city plans. In both cases, the initiatives were presented by congressmen, which broke with the tradition of direct proposals from the governors. This action can be interpreted as a change in the making of policies in the states because it was not only an imposition, but there was a consensus among congressmen and interest groups represented in Congress. There was also a notable concern about regional disparities within the state, which was not so evident in the previous phases and which had also been the product of the rapid growth of cities.

Organized groups of the society took part in the formulation stage of the law, as forums were convened to allow citizens to participate. These forums were organized by the official development committees in both state congresses. It was also the first time that stakeholders expressed their opinion on legislation for urban and territorial planning in a formal document.

The legislation of 1993 allowed municipal governments to finally have the possibility of implementing an official planning process, with which they became responsible for planning within their jurisdiction. The state governments promoted the elaboration of urban development plans in the municipal capitals during 1993 and 1994, but they left the local governments with decision making responsibilities on zoning. While this was an example of power devolution previously granted by the GLHS to the municipal government, the fragmented decision-making in land use became a serious planning problem. The municipal governments had the right to plan and to administer zoning as long as the content of their plans had been consistent with the guidelines established in the state plans, but interestingly, the state governments abandoned their responsibility as regional planners, leaving the full burden of planning to the municipalities.

In this phase, the municipal governments were characterized for exercising their responsibilities independently of the state government; as the state executive forcedly released some responsibilities to locals, as a result, metropolitan coordination was practically minimized. As for the mode of governance, it still had the characteristics of Corporatist/Administrative, since it relied on public-private partnerships, but at the same time a tendency was generated towards the populist mode, since the municipal governments sought to legitimize themselves with their citizens and voters so as to demonstrate its ability to help organized groups with interests in the municipal territory, and municipal-level politicians became key decision-makers.

It is worth noting again the participation of the academy in the consultation bodies in the state of Nuevo León, while in the state of Jalisco this sector continued to be relegated.

During this period, the municipalities took the lead in urban and territorial planning, and although they had a requirement of congruence with higher plans (regional/ metropolitan) these were never published. In the absence of these reference documents, each municipality opted -based on GLHS itself, for generating its own planning policies, generating an atomization of the decisions in this matter.

Phase 5: Metropolitan coordination: municipal governments in conjunction with the state government and governance (2008-2016)

In this phase, the problem of fragmented decisions by the municipalities is recognized, and a metropolitan coordination agenda is proposed in both states. This agenda includes the publication, in the case of the state of Jalisco, of a Metropolitan Coordination Law (2011).

The concept of Metropolitan Coordination appears for the first time in the legislation for planning in the Urban Code for the State of Jalisco. To reinforce the above, in February 2011, the Metropolitan Coordination Law of the State of Jalisco was published, and simultaneously, several articles of the Urban Code were amended and repealed, with which the metropolitan coordination was supported by a specific legislation that at the same time laid the foundations for the future of coordination in the Metropolitan Area of Guadalajara. This law, unique in the country, aimed to regulate the procedure for the constitution of metropolitan areas and regions, as well as to establish the bases for the organization and functioning of the metropolitan coordination bodies from the declaration of metropolitan area or region, the conclusion of coordination agreements and the constitution of coordination instances.

It is important to highlight that the Metropolitan Coordination Law of the State of Jalisco considers three instances of coordination: the Metropolitan Coordination Board (MCB), the Metropolitan Planning Institute (IMEPLAN), and the Metropolitan Citizen Council (MCC).

In Nuevo Leon, the State Congress the lack of inter-sectoral and inter-governmental coordination was acknowledged, as well as the need to respond to the challenges posed by metropolitan areas. Therefore, a new law was passed including guidelines for conurbations, as well as metropolitan and regional areas. According to this law, the municipalities that are part of a conurbation, had to conclude an agreement for the integration of a commission, in addition to the powers and obligations of the municipalities and the state.

The development of the metropolitan coordination institutions analyzed in this phase indicated an unprecedented trend towards the public participation in some decisions, which lead to conclude with two important points: firstly, there is already a process of coordination between the municipal authorities and the state government involved in a metropolitan area that previously did not exist; and secondly, that there is an important tendency towards the opening of spaces to organized citizenship in metropolitan planning processes.

Another key player in the process is the Metropolitan Fund: a national purse for construction of strategic infrastructure and facilities in metropolitan areas, since the year of its creation coincides precisely with the development of legislation regarding this in both states (2008). The amounts provided by the Fund cannot be underestimated; since its creation, in other words, a lapse of 10 years, more than four billion

dollars have been allocated to the metropolitan areas of the country, of which, more than four hundred and fifty million corresponded to the Metropolitan Area of Guadalajara, and more than three hundred to the Metropolitan Area of Monterrey.

In consequence, during this phase the mode of governance moved towards a Pluralist mode, although it still retains its roots in the Administrative/Corporatist mode. If this path follows, it will eventually be possible to make use of instruments such as disputes, mediation and elections or referendums on decisions regarding urban and territorial planning, although the balance of interests and the interactive relationship between the public sector and the organized civil society is still not so clear.

Phase 6: The reappearance of the federal government in the arena of urban and territorial planning (2017-present).

Recently, in November 2016 it was published in the Official Gazette of the Federation the new General Law of Human Settlements, Territorial Planning and Urban Development (*Ley General de Asentamientos Humanos, Ordenamiento Territorial y Desarrollo Urbano*, LGAHOTDU or LHSTPUD) which came to confirm the interest of the federal government in urban and territorial planning issues, and after 40 years, it redefined urban policy, which promotes, among other things, the constitution of deliberative bodies whose objectives are metropolitan coordination and governance. The new policy foresees and reiterates the role of coordinator and supervisor that the state governments should have, unlike the emphasis that the previous legislation had on granting powers to the municipal governments.

In matters of intergovernmental coordination, the new law establishes the need to address issues such as: the right to the city, equity and inclusion, the right to urban property, coherence and rationality, democratic participation and transparency, productivity and efficiency, public space, resilience, urban security and risks, environmental sustainability, universal accessibility and mobility.

The LHSTPUD includes a new definition of the metropolitan area that takes into account the conurbation, but which considers as the fundamental criteria for its conformation its complexity, and its social and economic relevance manifested in a territorial unit. This law also devotes a chapter to the Metropolitan and Conurbated Areas Plans in which the need for intergovernmental coordination is confirmed, but above all, it is important to highlight the metropolitan governance chapter that obliges governments to create two main instances for its management: the metropolitan ordinance commission that must coordinate the formulation and approval of the metropolitan plans, which is a technical instance with the participation of government officials; and also the Metropolitan Development Advisory Council, a body responsible for following up the public consultation and where representatives of the three levels of government participate, along with representatives of legally constituted social groups, schools of professionals, academic institutions and experts in the field, who should represent a majority on the council.

As a result, coordination processes, together with a consolidated governance, allow a new order to be foreseen in metropolitan areas, where intergovernmental coordination (both horizontal and vertical) should prevail, in addition to the increasing participation of representatives of the organized civil society, including the academy, since never before in the phases previously analyzed there was such diversity in the composition of the organs of citizen participation and consultation in urban and

territorial planning processes; time will tell whether this new order depicts better metropolitan scenarios.

Abstract: The non-linear complexities of urban development processes exceed the understanding of any individual. Consequently, more actors are entering planning processes for enabling the synergy of multiple knowledges, simultaneously increasing their internal complexities. These complex dynamics contest the everyday planning practice from within, requiring increased awareness of their possible consequences. Planning research has acknowledged that the actor-relational aspects of planning processes are not yet adequately understood, calling for methods to reveal the often invisible dynamics and their possible effects over time. This research aims at revealing the social complexities of integrated planning processes and recentering the understanding on the actor-relational level by focusing on the aspects of knowledge co-creation and process memory development. A practice-based example of the actual actor-relational dynamics is explored with mixed methods and detailed longitudinal data of an actual four-year strategic spatial planning process in the Nordic context. The findings indicate that a range of actor-relational dynamics affects the level of sectoral and scalar integration over time, and social complexities carry an essential role for enabling knowledge co-creation and process memory development within integrated planning practice. Unveiling the actor-relational dynamics is a promising research direction, requiring new methods for bridging research and practice.

Keywords: planning practice; organizational learning; strategic spatial planning; integrated planning

Introduction

The growing complexity of cities is a widely discussed theme (Batty, 2005, de Roo and Silva, 2010, Portugali, 2012, Boonstra, 2015, Sengupta *et al.*, 2016). The nonlinear complexities of urban development are claimed to be incomprehensible to any one individual with regard to the often invisible interrelations (Innes and Booher, 2010). For responding to the growing complexities, and the need of more holistic planning, integrated planning has been discussed (Bertolini, 2017). Even though the exact definition of integration is not fixed sectoral and scalar integration are typically included in all frames (Healey, 2006, Vigar, 2009, te Brömmelstroet and Bertolini, 2010, Holden, 2012), complemented with organizational integration (Kidd, 2007). In the context of this paper, integrated planning is understood as the communicative practices over time, which enable the crossing of thematic and scalar boundaries for reaching systemic and holistic planning solutions. Consequently, for supporting the understanding of the nonlinear complexities, more actors enter into the planning processes to share their knowledges, simultaneously increasing the complexities from within due to their values and views, which contradict in the institutional settings. Thus, complexity is not only a feature of the environment, but also

of the collaborative processes themselves. For understanding the actor-relational complexities, the relational level needs to be explored, as the social interactions produce properties that are not present in the individuals. Moreover, a procedural focus supports the temporal understanding of their dynamics over time (Pettigrew, 1997, Langley, 1999). Discussion of planning processes is critical for understanding how our urban futures are developed in these collaborative and value-laden processes, as there is a relation between processes and substance (Innes and Booher, 2015). Planning research has acknowledged that the actor-relational aspects of planning processes are not yet adequately understood, calling for methods to reveal their often invisible dynamics and effects over time. Thus, methodological contributions are needed to understand the nonlinear and emergent nature of the actual social realities, and their impacts on knowledge co-creation and process memory development in the integrated planning processes. However, there has been a lack of established methods for systematic longitudinal analysis of the collaborative realities of planning processes, mainly due to the challenges in acquiring applicable data.

The aim of the research is to develop methodological contributions for understanding knowledge co-creation and process memory development in these collaborative processes over time. To illustrate the actual relational dynamics, the paper presents an example of the actual social dynamics over a four-year statutory strategic spatial planning process in the Nordic context. Social network analysis is used for identifying the networked dynamics over time, and the possible reasons and impacts of the networked structures are explored through interviews with practicing planners. Moreover, the applicability and relevance of the findings for planning practice are discussed with practitioners. The Finnish planning system works in the context of a Nordic democracy, where planning is a central element of the urban development system (Puustinen *et al.*, 2017). Municipalities hold a planning monopoly, even though the processes involve various private and public actors (Mäntysalo *et al.*, 2011). Planning is mostly regulated by the Land Use and Building Act (132/1999), which is currently re-evaluated. Consequently, the selected case serves as a relevant example for exploring the dynamics that emerge due to the collaborative nature of processes. In the next section, background on organizational learning and process memory development are discussed in the context of planning. Thereafter, the utilized data and methods are presented, followed by the findings concerning the networked structures, and their possible reasons and impacts. Finally, the answers to the research questions are discussed, and the paper is concluded.

Process memory development as a prerequisite for organizational learning

The significance of knowledge and learning in the context of public administration and planning organizations has been widely discussed (Rydin, 2007, Campbell, 2012, Tennøy *et al.*, 2016), and public sector organizations have been criticized due to their inefficiency of learning (Moynihan and Landuyt, 2009). Organizational learning capacity is essential for an organization's development, influencing its capacity to adapt to the changing societal needs (Senge, 1990, Prahalad and Hamel, 2000). Knowledge influences the learning capacity of organizations (Argote, 2013), and learning is not possible without memory (Lehner and Maier, 2000). Various concepts regarding memory in organizations have been suggested, including organizational memory, network memory, systems memory, and transactional memory (e.g., Wegner, 1987, Walsh and Ungson, 1991, Spender, 1996, Olivera, 2000, Soda *et al.*, 2004, Innes and Booher, 2010). Despite of the various descriptive concepts, it is widely agreed that through the iterative utilization of memory, organizations may consciously unlearn and forget, as the original memories develop further (Holan and Phillips, 2004, Fernandez and Sune, 2009, Easterby-Smith and Lyles, 2011, Martin de Holan, 2011). This kind of intentional unlearning has been considered important for developing organizational processes (Martin de Holan, 2011). However, unconscious forgetting may have surprising impacts when valuable knowledge is unintendedly lost (Holan and Phillips, 2004). Hence, knowledge, learning, and memory are interdependent parts of organizational processes (Spender, 1996). Previous research has suggested that learning in public sector organizations occurs in structural settings, which encourage interaction (Moynihan and Landuyt, 2009, Siciliano, 2016).

Planning processes are an example of knowledge-intensive settings, in which a variety of specialized knowledges is applied. As new knowledge in planning is typically generated in interaction rather than through value neutrality (Healey, 1992, Rydin, 2007, Rydin *et al.*, 2007), discussion of social processes in planning has emerged (Davoudi, 2015). In the social constructionist view, knowledge evolves in social processes, and is continuously purposefully and unconsciously filtered, selected, and post-rationalized on the way. There has been considerable discussion about whether organizational learning and memory resides on the individual or organizational level (Senge, 1990, Walsh and Ungson, 1991, Nonaka and Takeuchi, 1995, Lehner and Maier, 2000). According to Senge (1990), individual actors learn, but learning itself happens through interpersonal dialogue as a relational activity. However, part of the knowledge may be integrated into organizational structures, routines and traditions (Fiol and Lyles, 1985, Argyris and Schön, 1996). Memory in organizations resides on the level of individuals and their relations (Argyris and Schön, 1978), and is distributional in nature (Walsh and Ungson, 1991). What is not encoded in information systems, resides in the individuals, and transfers through their interaction.

Knowledge co-creation is specifically important for integrated planning, in which multiple perspectives should be adjusted with each other. Integration is challenged by differences in values, ideologies, epistemologies, and policies, which may stem from conflicts between actors (Waddell, 2011, Holden, 2012). Integration may be understood as a hierarchy from co-operation (functional relationships to avoid duplicating work) through coordination (adjusting functions not to leave gaps) to integration (joining efforts for creating a policy owned by multiple actors) (Stead and Meijers, 2009), which may be thought to have different networked structures (Curtis and James, 2004). Coordination refers to a single-core structure, whereas integration entails a more equally connected structure with actors linked to each other.

Coughlan and Coughlan (2011) have referred to the importance of network action in inter-organizational learning. According to them, learning is both a capacity and a process, requiring also conscious and intentional actions to be achieved. In order to enable learning and process memory development, an organization has to be aware of its structures, which affect the learning capabilities. Thus, the analysis of organizational learning should deal with the dynamic processes of organizing (Argyris and Schön, 1996) in social settings. Hence, social network perspective is important for the relational understanding of organizational knowledge, learning and memory as it makes the social processes more explicit (Borgatti and Cross, 2003, Oh *et al.*, 2004, Cummings and Higgins, 2006). Through the identification of their social networks, planning organizations may become more capable of answering to the challenges they face. Thus, understanding of the relational dynamics in planning processes are an important element for enabling organizational learning and memory development. In the understanding of this research, organizational learning is enabled through the knowledge flows and memory development in various social networks. In order to enable the understanding of planning as socially constructed and knowledge-intensive process, this research focuses on the actor-relational process structures, which enable knowledge transfer, and affect process memory development over time. Based on the current research of organizational memory, the characteristics of process memory development in networked planning processes are not yet well understood. Consequently, building on the current understanding, this research approaches the organizational learning processes by moving the unit of analysis to the relational level and longitudinal view of the complex adaptive systems (Innes, 2005, Innes and Booher, 2010) that reproduce the knowledge over time.

Methodology

The lack of process memory poses a critical challenge for learning in planning organizations. In order to understand the development of process memory during planning processes, this paper focuses on an example of social dynamics in actual practice-related planning context. The aim here is to develop methodological contributions for understanding knowledge co-creation and process memory development in the collaborative processes over time. The topic is approached through answering to more detailed questions: How the social

network structures unfolded during the process, when measured with betweenness centrality? Why the dynamic patterns of interaction emerged over time, and what were their impacts on knowledge co-creation and process memory development? And what is the relevance of the findings for planning practice?

Utilizing mixed methods and detailed longitudinal data of organized actor interactions during a four-year statutory strategic spatial planning process in one of the cities in the Helsinki Capital Region, Finland. The raw data included the documented process data, which was available still after the process was finished, including over 10,500 pieces of process documentation (see Eräranta, 2019 for a more detailed description of the data). The raw data was processed into a standardized time series of approximately 400 organized actor interactions during the process. The analyzed process was classified into four periods of time: goal phase (G), draft phase (D), proposal phase (P), and ratification phase (R), which were further divided into intervals of two months, for increasing the resolution analysis. Resident information was not individualized during the process, and was limited out of the analyses.

With the data, social network analysis (SNA) was used for identifying the everyday reality of the networked dynamics over time. Instead of focusing on the individual actor characteristics, SNA considers the relational attributes for exploring the dynamics of nodes (actors) and their ties (interactions) over time (Wasserman and Faust, 1994). As an established methodology, SNA includes a variety of network- and node-level measures for understanding the relational structures of interactive processes. In this paper, analyses of the socio-temporal network structures were elaborated through the measure of betweenness centrality, which was selected for understanding the potential information flows in-between the social actors in the process. Betweenness centrality can be interpreted as an indicator of an actor's ability to control the other actors' access to all parts of the network, measuring how often a node is positioned on the shortest path between two other nodes with the ability to manipulate the information (Freeman, 1978). For example, central actors may be considered as gatekeepers, by being able to manipulate or bias communication in the network due to their relationally strong position (Rowley, 1997). Borgatti (2005) has suggested an equation for the betweenness centrality (Equation 1) to measure the number of times that the information reaches a specific node. In the equation b_k is the betweenness of node k , g_{ij} is the number of geodesic paths from i to j , and g_{ikj} is the number of shortest paths from i to j , passing through node k .

$$b_k = \sum_{i,j} \frac{g_{ikj}}{g_{ij}} \quad (1)$$

As SNA has not been applied before for understanding the dynamics and process memory development over time in planning processes, the findings were validated through individual interviews (Symon and Cassell, 2013) with participants of the analyzed process. The applicability and relevance of the findings for planning practice were analyzed through focus group interviews (Morgan, 1996) with practicing planners. All research data was anonymized to avoid harm to the research subjects.

Findings

Overall dynamics of the network structures

The social network was in constant change during the process. In Figure 1, the network graphs have been illustrated by measuring the betweenness centrality of the individuals, describing their relational positions for influencing the information flows between other actors. In most of the graphs, the structure is strongly centralized with a clear core actor or a team of actors, suggesting that the relational power was highly centralized. The fewer central actors there are in the network, the greater their relational power may be, giving them a possibly stronger relational position considering the information transfer.

Figure 1: The networked dynamics of a four-year process were continuously changing. Over time, there were usually one or two actors having considerably high betweenness centrality in the network. Consequently, the information flows were strongly centralized.

Factors behind the dynamic patterns of interaction

The emergence of the networked structures was nonlinear. The structures were not tied to specific phases, but were influenced by a variety of factors on multiple levels (e.g., individual, actor-relational, institutional) over time. Some of the network dynamics were explained through institutional rules and routines, such as decision-making procedures, but also by emergent actor-relational factors, such as escalated arguments between some actors. Alongside the institutional framing of collaboration, emergent social dynamics affected the interaction over time. According to the interviews of the process participants, the social dynamics had effects on their intensity of involvement in the process. These actor-relational dynamics were typically not bound to the specific process, but originated in or had consequences also on other processes.

Based on the findings, the institutional framework did not support the longevity of network ties between processes. Planning processes are traditionally separated into different sub-projects led by different individuals, challenging learning between the processes. As the processes are dependent on the same scarce organizational resources, the situation is vulnerable to disturbances. The administrative division of the processes is typically due to a large number of simultaneous processes, and may challenge the actors' ability of focusing on individual processes. According to the interviews, when the participants see only disconnected snapshots in time, their commitment in the individual processes may decrease. Some process participants did not have enough time for

active participation, thorough consideration, information acquisition or collaboration in the analyzed process. As the participants visited the process only rarely, and only related to their own sectoral expertise, their overall understanding of the process remained unclear. Moreover, their awareness of how their own input affected the plan solution, or the subsequent parts of the urban development process, remained low.

Based on the interviews, centrality tempted more centrality, leading into strongly centralized network structures. According to the interviews, when the central actors were well-known by other actors, they were used for information acquisition in the process, leading them into an even more centralized position. For example, all actors referred to one specific actor as focal for information transfer in the process. The polarized positions between the few central actors and the others was intensified by intentional information withholding. The decision to not inform of changes in the process was aimed to protect the actors from information overflow by giving them an opportunity to focus on their own responsibilities. However, some participants explained that this decision decreased their ability to form an overall understanding of the process, challenging their ability to develop understanding of the interrelations between various scales and sectoral themes. Additionally, the sectoral themes were kept separate from each other, and were mainly handled among the few central actors, and the assigned sectoral experts. In case an actor had a tight sectoral responsibility in the process, a holistic view of the plan solution was typically decreased. Moreover, the adhocracy of communication challenged the generation of an overall understanding over time.

In addition to the aspects above, the emergent structures were influenced by the actors' own activity, as well as the actual subnetworks in which the actors participated. In the interviews, support from other actors with similar backgrounds was named as an important reason for forming subnetworks during planning processes in general. The support structures were explained to be dependent on personal relations, which take time to establish. Some of the participants described that their collaboration patterns were influenced by arguments, which led to their lack of input in the process. The participants explained that sometimes the plan solutions could have been different, if they had not quit collaboration due to the actor-relational reasons. The confrontations were intensified by the strongly centralized structures, which caused distrust between actors, as the actors were not aware of each other's opinions. Due to previous experiences, some actors tried to avoid confrontations, which reduced the information transfer and knowledge co-creation even more. The emotional side of the collaborative dynamics may have long-lasting impacts on the processes and plans. Furthermore, some participants described that due to the challenges in the overall awareness, the process seemed occasionally irrational. In addition, the emergent factors affected the process strongly, when some participants left the process and their tacit knowledge was lost, and ways of working were changed. Changes on the individual level affected also the collaboration patterns, as actors holding the same administrative position had different ego-network structures.

Impacts of the network structures on knowledge co-creation and process memory development

The network structures during the process can be classified into four main categories: single-core structures (e.g., phase G₇ in Figure 1), dual-core structures (e.g., phase P₂ in Figure 1), multi-core structures (e.g., phase G₆ in Figure 1), and complete structures (e.g., phase G₁ in Figure 1). In addition, disconnected structures (e.g., phase G₈ in Figure 1) may be formed through combinations of two or more simultaneous networks without a direct connection with each other, leading into challenges when the networks do not communicate. Here, the four basic structures are explored (Figure 2), focusing on their possible advantages and challenges for information transfer and process memory development. The possible advantages and challenges were discussed in focus group interviews with practitioners, who work in and around strategic planning processes.

Figure 2: The four main categories of network structures (from left: single-core, dual-core, multi-core, complete) had different impacts on knowledge co-creation and process memory development during the process.

Single-core networks had one central actor. According to the interviews, a single-core structure can be effective for information transfer with one clear coordinator, but has few possibilities for wider discourse and integration due to the scarce connections between actors. Integration of the various views is done by one central actor, and the underlying reasoning remains unclear to the other participants. Moreover, the central actor can dominate the information flows, as was suggested by some interviewees. Considering process memory and knowledge co-creation, the single-core structure is risky, as it is focused on one key actor. The structure may lower the quality of the substance, as was suggested by some of the interviewees, because it is not possible for any actor to consider the variety of interrelations thoroughly alone. If the central actor leaves, the rest of the network may be severely disturbed. According to the interviewees, too centralized responsibility is not beneficial for the individual, for the organization nor for the substance of the process.

Dual-core networks had a pair of central actors. As was suggested in the interviews, a dual-core structure allows either of the central actors to be replaced without a total process memory loss. If one of the central actors leaves, the other still remains, and a new one can be trained by the remaining actor. According to the interviewees, dual-core structure is similar to single-core, as it does not enable diverse enough discussion and ideas to emerge, and does not allow holistic consideration of the various sectors and scales. The process may end up having highly personalized views of the central actors, as was suggested by the interviewees. The benefit of the dual-core is that the actors can support each other, and discuss the issues at least with each other. Some interviewees pointed out that for this structure to be efficient, both of the central actors should build their own subnetworks.

Multi-core networks are built around multiple cores, which are connected with each other. In particular, the core team can be formed by various experts, supported by their own subnetworks as mentoring structures. They central actors can integrate the knowledge of the subnetworks in the core team, bringing added value into the process. According to the interviews, a multi-core structure allows all of the actors to proceed quite independently. When the central actors are strongly linked, and their subnetworks are known, they can be also replaced with a lower risk. A multi-core structure enables easily the utilization of shared expertise, as was suggested by some interviewees.

In complete networks, all actors are connected with each other. When actors represent different expertise or scales, the structure supports the testing and integration of various views. According to the interviews, a complete structure has low risk of changes, as all actors hold similar meeting-based knowledge. From process memory perspective (not considering the differences in expertise), any actor can be replaced without a risk for process memory loss. Thus, when everyone is equally informed of everything, the risk of memory loss in case of personnel turnover is low. According to the interviews, a complete structure has good possibilities for effective information transfer within the network. However, the structure can also be considered ineffective and resource-consuming.

Relevance of the process analysis to planning practice

In relation to process memory development, the interviewees stated that statutory strategic spatial planning processes typically occur rarely in planning organizations. When the process experiences are not documented and actors change, much of the memory is lost, and subsequent processes have to start from zero. Thus, processes can become inefficient, when time is utilized on testing through trial and error, and on re-establishing networks. Process memory supports organizations in situations when personnel turnover is high, as was suggested in the interviews. Much of the memory and knowledge is attached to the actors, which is a risk in case of personnel turnover or voluntary withholding of information. However, some interviewees pointed out that personnel turnover and unintended forgetting are not always a challenge. It was suggested that organizations can also learn through personnel turnover by adapting new practices from outside. Moreover, when people change, process memory is dispersed to other organizations, and is not situated only in the originating organization. According to the interviews, process memory supports also organizational learning between processes.

Based on the interviews, network and process thinking in municipal planning organizations is diverse, and changing the established practices is difficult. Many interviewees stated that planning processes are not understood well enough due to their nonlinear and complex nature. Consequently, generating more understanding of the process structures is important to understand the reasons behind the actors' involvement in the processes. According to the interviews, discussion of planning processes is strongly focused on digital methods instead of the collaboration structures. Thus, it was suggested that improving awareness of the actual networked structures and their possible impacts on knowledge co-creation and process memory development is important. Moreover, the interviewees pointed out that SNA, as a method, is usable for analyzing the processes by making them visually understandable. In the interviews, the analyses were considered important for learning new ways of thinking about process development in planning practice, and for visualizing process development needs. Improved process awareness may enable better utilization of shared expertise, as actors become more aware of the phases in which they could share their expertise.

Discussion

Based on the findings, knowledge and memory in the analyzed process were strongly concentrated on few central actors, who were trusted as information sources, acting as knowledge brokers in a way described by Rydin *et al.* (2007). Previously established networks were primarily utilized for information acquisition and the actors turned more easily to someone whose expertise they already knew in advance. Previous research has identified that core networks represent ties, which provide support over time, whereas the peripheral network assists at specific moments in time (Cummings and Higgins, 2006). This seems to be the case also in the analyzed process. The more central actors, and their ties, endured over time, whereas the more peripheral actors typically changed from one phase to another. Combined with the views of social capital (Oh *et al.*, 2004), two types of ties can be suggested to exist. The core ones offer more homogeneous social capital and constant support due to the strength of ties. The more peripheral ones provide ad hoc support through access to diverse social capital, offering access to other ongoing processes and transferring process memory between processes. Although the exact memories of the process were generally scarce, multiple participants visited the process for varying periods, carrying parts of the process knowledge forward to their own organizations. Consequently, memory in the process was not only located in the specific responsible unit, but was dispersed widely through the network.

The findings indicate that social dynamics carry an essential role for enabling knowledge co-creation and process memory development within integrated planning practice, affected by the actors' ability and willingness to collaborate. The findings suggest that memories of planning processes are vulnerable to accidental and intended forgetting, affected by the social dynamics of the processes. The findings imply that process memories are typically saved as patterns of activities, which are detached from time. Thus, memories are affected by post-

rationalization, decreasing the possibilities of tracing process dynamics with traditional methods. Moreover, the intensity of involvement in the process influenced the randomness of the memories. The memories were strongly related to the actual networked structures, and their information transfer capabilities in the process. Differences in the process memory were considerable, and typically related to the actor's thematic responsibilities and position in the network. The more an actor attended in the process, the more exact the memories, and the wider the overall awareness of the process, tended to be. The interview findings suggest that this was partly because information transfer for supporting holistic understanding of planning processes was insufficient, and the interdependencies between the various themes are typically handled by few. The centralized structures affected the possibilities of aiming for integrated solutions.

In addition, findings imply that different networked structures can have various impacts on the possibilities for integrated planning, and on the vulnerability to process memory loss (Figure 3). In the structures which allow the simultaneous integration of a multiplicity of views the vulnerability to process memory loss is decreased, as many actors know the rationalization behind the plan solution, and the made decisions during the process. However, the collaboration and reflection of various views simultaneously takes time, and the structure may be resource-intensive. As the number of central actors decreases, also the possibilities for integrating multiple views simultaneously declines, and the integration is done by the few central actors, who coordinate the discussion between various separate thematic groups. Simultaneously, vulnerability to process memory loss increases. Based on the findings, there is no one optimal solution for all processes, but various structures may serve various phases and purposes during planning processes. In case of high personnel turnover, holistic memory held only by one or two individuals is not a resilient strategy, as it is vulnerable to actor-level changes.

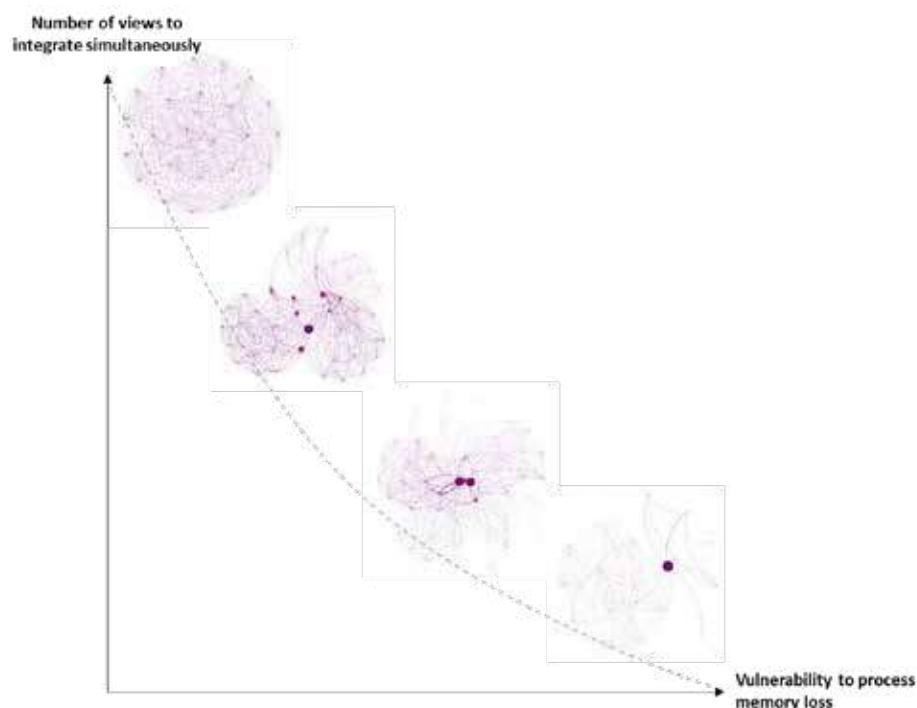

Figure 3: The different networked structures have various impacts on the possibilities for integrated planning, and on the vulnerability to process memory loss. The more views there are to integrate (complete), the less vulnerable the structure is for process memory loss, but the more resource-intensive the structure is, as well. The less views there are to integrate through collaborative

dialogue (single-core), the more vulnerable the process is to memory loss, and the less resources are required.

Based on the findings, utilization of longitudinal time-series data allows the analysis and evaluation of evolving phenomena, such as process memory. SNA may support the identification of structures, which may cause sectoral siloing or process memory loss in the processes. SNA supports the exploration of process memory development, which is influenced by different relational dynamics, which enable or restrict information transfer during the processes. Currently the related factors, such as organizational memory or experience (e.g., Wegner, 1987, Walsh and Ungson, 1991, Spender, 1996, Olivera, 2000, Soda *et al.*, 2004, Innes and Booher, 2010), are mainly utilized in a descriptive manner without methods for analyzing their relation with various process structures. The findings show that SNA has capacity for generating visual and statistical criteria for analyzing such concepts, suggesting a methodological contribution for studying integrated planning processes.

Conclusions

Based on the findings, we can conclude that planning processes are dynamic and continuously changing social systems. Memories of such a system serve as a basis for learning, and consequently, for process development practices in planning organizations. At least two types of memories develop during planning processes: content-related and procedural. Content-related memories are more context-dependent, spatially bound, deal with the rationalization and justification of the plan solution. They are primarily applicable on various scales in a certain spatial context, giving answers to questions like what and why. Procedural memories are more structural, and serve various processes on various scales and contexts, assisting in process development aims, and answering to questions like how, why, who, and when. Especially the procedural memories are an essential factor for organizational learning and process development. Thus, planning processes can have generalizable and repetitive structures that go beyond the unique nature of processes. Learning from the past experiences may consequently support the organizations in developing their everyday practices. In conclusion, unveiling the social dynamics of planning processes, and their relations with process memory development and organizational learning, is a promising research direction. This research stream may be supported with longitudinal and relational methods, which enable the visual-analytical understanding and evaluation of the various networked process structures and their impacts.

4_Institutional change and regional transition

Regional innovation and the new territorial governance. French and Spanish cases

Cristina García Nicolás

Universidad de Castilla-La Mancha (Spain), cristina.garcia@uclm.es

Abstract: The European territories, especially in the southern and eastern peripheries, face various challenges linked not only to socio-economic globalization, but also to population aging and climate change. The regional innovation policy offers the possibility of facing these challenges and contributing to the cohesion - economic, social and territorial - provided that the specific characteristics of each territory are taken into account. Decentralization is a fundamental factor in the design of policies that clearly respond to the principle of subsidiarity of the European Union. In our work, we deal with the cases of Spain with a degree of quasi-federal decentralization with broad competences designed in the 1978 Constitution, and that of France that has progressively decentralized in the last decades until reaching the 2015 reform in which they reduced the regions from 22 to 13 in order to create functional territories that would help reduce regional divergences. Although in both cases there are marked differences between the territories, innovation rates are higher in the French case, while in Spain only the Basque Country is included in the group of strong innovators. The objective of this work is, therefore, to analyse the policies developed - design, objectives and financing- and the governance model -characteristics of the subcentral levels of government- in order to highlight their strengths and weaknesses.

Keywords: cohesion, territory, innovation, governance

Introduction

The turn of the century was a new scenario for the European Union both outside and within its borders. The great enlargement towards the East, the definitive economic and political globalization, the intense migratory flows, the aging of the population and the economic-financial crisis forced the European institutions to modify the objectives of their policies. Among these changes is the foreground given to the objective of competitiveness and innovation policy, complemented by new regional strategies and the so-called smart growth.

There does not seem to be any doubt that regional innovation policies can become the ideal instrument to face the multiple challenges and socio-economic transformations. For this, they will have to combine

a broad vision of change inserted in the common European policies with the territorial perspective considering the specific characteristics of the space in which they will be applied. That is, to make the principle of subsidiarity effective without losing sight of the objectives set by the Europe 2020 Strategy. This implies creating a strong synergy between cohesion, competitiveness and innovation with a markedly territorial character. It should not be forgotten that, as Bevilacqua *et al.* (2017) claim, there is a link between the regional innovation strategy (RIS3) and the principle of territorial cohesion, because the territorial approximation of this is based on its character of development policy (Regulation 1303/2013). Therefore, the initial concept of "smart specialization" that emerges as a response to the deficiencies identified in the EU in terms of competitive weakness in research and development is left behind. The objective of filling these differences will be the four-helix model -based on development and endogenous resources, cooperation with other territories, innovation and application of the creative process- that appears as essential in the definition of new regional innovation strategies.

However, innovation policies and regional strategies have highlighted the diversity and divergences that exist between the Member States and within each one of them. The Barca report (2009: 129) included an innovation index (2002-2003) that highlighted regional disparities in terms of innovation. Among the possible causes the author highlighted the fragmentation of the national research system, while among its consequences he cited the following: not taking advantage of the effects of scale; leakage of human resources and very limited relationships between research centres and the private sector; excessive diversity, positive in many cases, but negative in the dispersion and in the appearance of externalities that are not taken advantage of; and research overproduction in the same line.

This is one of the main challenges of innovation, since the differences in the application of territorial policies and their design have to do with the different quality of their governments, their ability to absorb funds, and their institutional capacities. According to Morisson and Doussineau (2019), it is based on the fact that there is no single regional innovation policy framework that can be applied to all territories. In this sense, Tödtling and Trippel (2005) affirm that the differences are related to the concrete innovation priorities according to the capacities, the industrial base and the institutional context. However, Fritsch and Graf (2011) conclude that the analysis of a RIS should take into account not only (sub) national conditions, but also the position of the region within the socio-economic framework of the surrounding space. That is, it is not enough to study only the region to design the regional innovation policy. In addition to these factors, the governance model and the degree of decentralization are fundamental, as affirmed by Hassink and Marques (2015), who are committed to strong regional institutions without forgetting that the state level continues not only to contribute decisive factors for innovation, but also explaining the different rates of economic growth, as well as the problems at the regional or local levels.

Regional planning following the principle of territorial cohesion is key to the development of innovation policies is truly efficient and effective. In this sense, the state framework continues to be fundamental even when processes of a bottom-up nature are favoured. All of them must be part of a state strategy that facilitates synergies between all territories in line with European policies. Especially if we take into account that innovation has a marked preference for urban areas, especially for larger ones, contrary to what happens in rural areas, and to a lesser extent in intermediate urban areas (Dijkstra, Garcilazo and MacCann, 2013).

Taking into account the different elements linked to regional innovation policies and that the objective of this paper is to analyse the management, design and financing of these policies in the French and Spanish regions, the structure of the article is as follows: first after this introduction the second section will address the regional position of Spain and France with respect to competitiveness and innovation indices; In a third section we will analyse the situation of innovation policies, that is, the application of decentralized governance, using the data and references offered by the Regional Innovator Monitor Plus (institutions, regulatory framework and financing). Finally, the work closes with some reflections.

The cohesion-innovation relationship

The 2014-2020 programming period definitely puts the accent - and the budget - on the objective of competitiveness. Its objectives are those of the Europe 2020 Strategy, approved in 2010, which is developed around three priorities: intelligent, sustainable and inclusive knowledge. The first of these priorities is based fundamentally on innovation - and on knowledge - to achieve the above-mentioned objective of competitiveness. Therefore the concept of intelligent specialization is currently part of both the Innovation Union program and the cohesion policy reforms (MacCann, Ortega-Argilés, 2015).

In our analysis we started from the regional competitiveness index, since the third group of factors are related to innovation¹, based on the link established by Sabatino and Talamo (2017). The 2016 edition, like the previous ones, shows elements linked to cohesion, which would indicate the need to maintain the structural aid of both the ERDF and the ESF. To maintain the cohesion-competitiveness-innovation link, we have organized the analysis following the typologies of regional policy aids for the 2014-2020 period (less developed regions and more developed regions) in combination with the regional innovation index. For our study we will leave the Canary Islands for being considered an outermost region and the autonomous cities of Ceuta and Melilla for having very peculiar socio-economic and geographic characteristics. In the French case, our analysis will focus on metropolitan France.

Table 1 shows the positions occupied by the Spanish regions with respect to all 263 regions analysed, both attending to each of the groups of factors and the global competitiveness index. The best placed region is the Community of Madrid, both in the RCI and in the pillar of efficiency and especially in innovation. The second position is occupied by the Basque Country, but in a much more remote position, although it is the best placed with respect to the efficiency pillar. As far as the pillar of basic factors is concerned, there is no Spanish region among the top 100. The last position is occupied by Extremadura, which receives Community Funds as a less developed region during the 2014-2020 programming period.

¹ The three pillars on which the Regional Competitiveness Index is based are, in turn, formed by a series of factors that contribute to a greater or lesser extent to determine the degree of competitiveness of a territory. Thus, the basic pillar includes institutions, infrastructures, macroeconomic stability, health, and basic education. The efficiency pillar covers the factors of higher education and lifelong learning, labour market efficiency and market size. Finally, the innovation pillar refers to technological readiness, business sophistication and innovation.

Table 1. Global position of the Spanish regions in the EU

	Basic Pillar	Efficiency Pillar	Innovation Pillar	Regional Competitiveness Index (RCI)
Galicia	181	191	179	181
Principado de Asturias	173	188	172	174
Cantabria	161	167	171	164
País Vasco	153	78	134	119
Comunidad Foral de Navarra	151	130	160	148
La Rioja	154	196	185	184

Table 2 shows the positions of the French regions prior to the modification of their limits, although we have grouped them to better observe their characteristics. Île-de-France is the best region in terms of competitiveness, standing out in the efficiency pillar and ranking among the top ten regions of the European Union. Midi-Pyrénées and Rhône-Alpes are the next best-placed regions, both also standing out in the efficiency pillar. The worst index corresponds to Corsica and is similar to that of Spanish regions such as Galicia, La Rioja or the Valencian Community.

Regarding the Regional Innovation Scoreboard, the measurement system distinguishes four main types of indicators and ten dimensions of innovation, resulting in a total of twenty-seven different indicators. *Framework conditions* measure the main drivers of innovation performance external to the company and encompass three dimensions of innovation: human resources, attractive research systems and an environment favourable to innovation. The *investments* indicator measures public and private

investment in research and innovation and covers two dimensions: financing and support and investments of companies. The *innovation activities* take into account the innovation efforts of the company grouped into three dimensions of innovation: innovators, links and intellectual assets. The *impacts* indicator covers the effects of the company's innovative activities in two dimensions of innovation: impacts on employment and impacts on sales (European Innovation Scoreboard 2018 - Executive summary).

If we apply all these indicators to the map of the European Union, we will see how four groups of countries are established: leader in innovation and three degrees of innovators: strong, moderate and modest. The inclusion in each of these groups and their position within them has varied since 2010, the reference date of the first innovation index and coincides with the signature of the Europe 2020 Strategy. Graph 1 shows both the four groups of countries such as the evolution of the innovation index. In line are Romania and Bulgaria, whose situation has worsened since 2010, more sharply in the first case. The group of moderate innovators includes both countries in Central-Eastern Europe and the Mediterranean, corresponding to a periphery that still needs cohesion policy for its development, and which was very affected by the economic crisis of 2008. In this case, the situation of Croatia, Cyprus, Estonia and the Czech Republic has worsened with respect to the 2010 index, and that of Portugal, Greece and Hungary has stagnated. The group of strong innovators includes Slovenia, France, Austria, Ireland, Belgium and Germany. The latter has somewhat reduced the situation compared to 2010. And finally, the leading group, the leaders in innovation are Luxembourg, the United Kingdom, the Netherlands and the Nordic States (Finland, Denmark and Sweden).

Graph 1. Performance of EU Member States' innovation systems, 2010-2017

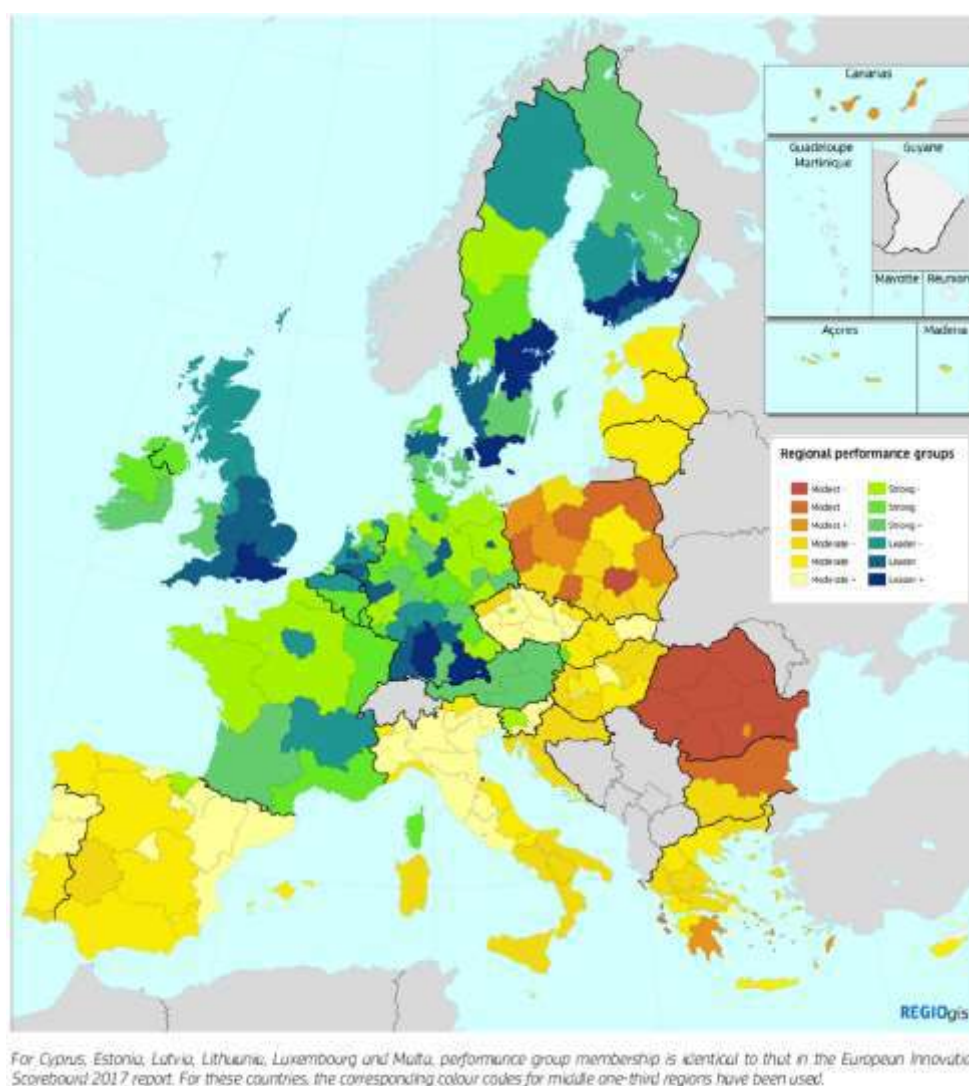

Source: European Commission (2018a: 7).

As with the Competitiveness Index, the analysis at the regional scale shows a heterogeneous panorama, as it appears in Figure 1. In the case of Spain, characterized as a moderate innovator, several levels of innovation are observed, ranging from the lowest in Extremadura, an intermediate level in the case of Galicia, the Principality of Asturias, Castilla y León, Castilla-La Mancha, Andalusia, Murcia and the Balearic Islands, to a greater degree in Cantabria, La Rioja, Comunidad Foral de Navarra, Aragón, Cataluña and Comunidad de Madrid. The Basque Country is an exception to be part of the group of

strong innovators. As for France, the whole of the country is characterized as a strong innovator, although Île-de-France and the Centre-Est region are leaders in innovation.

Figure 1. Regional performance groups

Source: Regional innovation scoreboard

In addition to territorial diversity, the innovation index shows a different evolution in the Spanish regions (Table 3) and in the French regions (Table 4). In the first case it is easy to observe the effects derived from the economic crisis with a reduction of public and private investment. On the contrary, the French regions show a more constant evolution, although the Est region and the Méditerranée region have experienced a setback in 2017.

Decentralized governance of innovation

In the last two decades, the decentralization process has accelerated in practically all European States. A process with multiple variants (Ismeri Europe, 2010) has the practicality factor contributed by the Europeanization of national policies and the principle of subsidiarity. The latter has favoured a new and complex distribution of skills, which, following Tödtling and Trippel (2005: 1207), has three levels: regional, national and European. This is a change in governance, as indicated Borràs (2003), which links competitiveness, development and innovation, relating sustainable economic growth - advocated by the Europe 2020 Strategy - with the ability of regional economies to change and innovate. In this relationship, it is necessary to consider not only the current characteristics of the territory, but also the previous (historical) circumstances that have led to this situation (Boschma, 2008).

The first point to take into account is the degree of *political-economic decentralization* with which innovation policies will be addressed. Thus, France concluded with the Law Notre (2015)² a process of decentralization that had been carried out over more than three decades, beginning in 1982 with the recognition of the region as a territorial community. The law passed in 2015 does not imply a radical change in regional policies, but a redefinition of the competences assumed by the new regions. These have been reinforced and classified, incorporating the following: economic development, tourism, territorial planning, transport (assumed from January 1, 2017), education and teaching, vocational training and employment, environment and energy, housing and habitat, culture, sports, and health-social. According to the Commissariat Général à l'Égalité des Territoires (CGET), the new territorial organization seeks, rather than establishing a model, to provide all regions with the indispensable

² Law n° 2015-991 of August 7, 2015 on the new organization of the Republic. It constitutes the complement of the Law of territorial public action and of consolidation of the metropolis (Maptam) of January 27, 2014, and the Law relative to the delimitation of the regions of January 16, 2015. The three form what has been called Act III of decentralization.

instruments for economic development. Its objective will be to find the modality that best adapts to the socioeconomic characteristics of its territory, applying the principle of subsidiarity, which is proper to decentralization, and seeking, equally, a place in the globalized economy. On the contrary, Spain is a decentralized state, as indicated in Article 137 of the Constitution of 1978. Its territories are organized into Autonomous Communities, whose powers are included in Article 148 - expanded by the total transfer of competences in health and education -, while article 156 refers to "financial autonomy for the development and execution of their competences".

These differences translate into the fact that in the Spanish case the main agent in charge of designing, developing and managing innovation policies is the corresponding regional government, given that the corresponding development agencies and / or agencies will depend on it to a large extent. innovation such as subsidies and financial aid; while in the French regions they intervene with the regional council, the French investment bank and in some cases the chambers of commerce.

The second point is the **regional innovation systems**, which, according to Asheim et al. (2015), can be of three types: a) endogenous: very linked to the characteristics of the territory; b) regional network systems: multilevel governance models; and c) "RIS directed", which are regionalized national innovation models. In our case, perhaps the second model predominates, although the French regions have less autonomy. To develop the objectives set by the CGET, including innovation, the French regions apply two types of programs³, whose guidelines complement those made at the national level: 1) the Regional Scheme of Economic Development, Innovation and Internationalization (SRDEII - Schéma Régional de Développement Économique, d'Innovation et d'Internationalisation), which defines the guidelines on business aid, support for internationalization, and aid for real estate investment and business innovation; 2) the Regional Higher Education, Research and Innovation Scheme, 2017-2021 (SRESRI - Schéma Régional de l'Enseignement Supérieur, de la Recherche et de l'Innovation).

In the case of Spain, regional governments establish their own development and innovation plans without a pre-established model by the national government. There is a great variety not only in the approach, since the economic characteristics of each territory are taken into account, but also in the temporal extension of the plans (Table 5). In some cases, such as the innovation strategy of Cantabria or the industrial plan of the Balearic Islands, the horizon of the objectives extends beyond the current programming period of European funds. In other cases, such as in the Community of Castilla y León, the plans show a broad previous route, that is, they are territories in which the objective of innovation was established in the 90s of the last century.

Table 1. Plans of development and innovation of the Autonomous Communities

REGION	POLICY DOCUMENT

³ Although not directly linked to innovation policies, the Regional Scheme for the Organization of Sustainable Development and Equality of Territories (SRADDET – Schéma Régional d'Aménagement, Développement Durable et d'Égalité des Territoires), incorporated in the Law Notre, has as an added value its transversal character and its contribution to the territorial coherence of the great regional groups. It allows taking into account the interdependence of the thematic areas of intervention, that is, mobility, ecological coherence, climatic and energy challenges, and the prevention of waste

With regard to higher education, except the Basque Country, Navarra, Madrid, Andalusia and Murcia, public universities are presented as direct agents in innovation policies, emphasizing the fundamental factor of higher education and research. In the case of the Basque Country, the innovation agency (Orkestra - Basque Institute of Competitiveness) is managed by the University of Deusto, which has a private nature. Madrid, Andalusia and Murcia have organizations that incorporate universities into an exchange network together with other economic agents. They would be the Foundation for RDI Knowledge Madrid, which addresses aspects such as universities, entrepreneurs, Europe, scientific culture, and science and technology; the Andalusian Agency of Knowledge (AAC), linked to the Ministry of Economy, knowledge, companies and universities; and the Seneca Foundation, which is the Science and Technology Agency of the Region of Murcia.

Following the line of multi-level governance Tödtling and Trippl (2005) distinguish three levels, regional, national and European, according to the competences assumed. Levels that are interrelated, since the same authors affirm that regional innovation systems are not self-sufficient units but depend on both internal and external networks.

Regarding internal networks, we will refer both to the regional development and / or innovation agencies, as well as to the foundations and organizations destined to put in contact the different actors that intervene in innovation policies, that is, those that link universities, research centres and companies. It is not a static relationship, but by its very nature is called to change and evolution, depending on the degree of interdependencies with global innovation networks (Asheim et al., 2015: 2). With respect to the agencies, Prota, et al. (2012) distinguish between regional development agencies and regional innovation agencies, stating that the latter are closely linked to the regional government. They add that the decision to implement them is the last step of a process of raising awareness about the importance of innovation in the development of a territory: "It begins with the recognition of the importance of innovation for the economic development of a territory, continues with stronger regional commitment to RTDI, until there is the formulation of a specific innovation strategy and the creation of a specific body to realize it" (56-57). If we consider this argument, the regional innovation agencies are not predominant in the countries analysed. In Spain we would have the Galician Innovation Agency (GAIN), a public autonomous agency with its own legal personality, and attached to the Ministry of Economy, Economy and Industry; INNOBASQUE. Basque Innovation Agency, created in 2007 as a public-private foundation; and the Valencian Agència de la Innovació (AVI), which is a public autonomous agency. For its part, in France we find Grand Innove - Agence d'Innovation which is the

agency of the Grand Est region created in 2017; Transferts - Agence Régionale d'Innovation, which was created in 2005 as the Languedoc-Rousillon regional innovation agency and currently covers the entire Occitan region; and L'Agence régional Pays de la Loire - Territoires d'Innovation. This has changed its name to Solutions' & Co, and has been transformed into an economic development agency, which offers integral solutions to facilitate the development of companies and territories. This last example is the most numerous, agencies that incorporate an integrated vision of competitiveness, development and innovation. In France, the following would form part of this group: Dev'Up Center-Val de Loire - Innovation and economic development agency, Hauts-de-France Innovation Development (HDFID), Bretagne Development Innovation, Regional development and innovation agency - Nouvelle-Aquitaine, Madeeli, Regional Agency for economic development, exportation and innovation and Regional Development Agency (both in the Occitan region), Corsica Economic Development Agency (ADEC).

As for the Spanish regions, something similar happens, although in this case it is necessary to distinguish between public, private and mixed agencies, as shown in Table 6. We found private equity agencies in the case of Asturias, a Basque Country, Extremadura, Catalonia and Andalusia. Those that have both public and private financing are in Asturias, Basque Country, Aragón and Madrid.

Table 2. Development and innovation agencies in the Autonomous Communities

As far as external networks are concerned, some regions of both countries participate in projects with other Member States. Thus, Castilla y León, the Basque Country, Hauts-de-France and Provence-Alpes-Côte d'Azur are part of the Know-Hub Project⁴, while Catalonia, the Basque Country, the Principality of Asturias, Cantabria, Galicia, Navarra, the Pays de la Loire and Auvergne-Rhône-Alpes are integrated into the Vanguard Initiative⁵. Galicia is the only territory of our analysis that has an RIS3 that, integrated with the border region of Portugal, overlaps the existing Euroregion [Cross-Border Smart Specialization Strategy of Galicia - Northern Portugal (RIS3T)]. It is a space in which there is cultural and socioeconomic continuity beyond political and administrative borders.

The third point of our analysis is *the financing of innovation policies*. In the case of France, in addition to investments from Bpifrance, whose mission is to provide financial and technical support to companies in areas such as innovation, internationalization, creation and transfer of companies, the regions have so-called program-contracts State-Region (2015-2020). The Contracts include six essential axes (multimodal mobility, higher education, research and innovation, ecological and energy transformation, innovation and business, digital agenda, and territories) and a transversal priority (employment) linked to the objectives of the Europe 2020 Strategy. This investment translates into around 15.2 billion euros from the regions and a state contribution of about 14.3 billion. The amounts have been modified since the signatures of the contracts in 2015, due to the regional restructuring, since they included a revision clause expected from the autumn of 2016.

With regard to the Spanish regions, they have greater financial autonomy although they receive transfers from the State following the principle of solidarity that governs the Constitution. It must also be borne in mind that currently two models of regional financing coexist: on the one hand, the so-called common with own funds and the State, and the regional model (Basque Country and Navarre) with a collection of 100% of taxes and, therefore, greater spending autonomy. Although there are national frameworks in areas such as science and technology, the different economic capacity of the regions makes coherence between the different territories difficult⁶.

Funding from the Structural Funds of the European Union constitutes an important part of the total. We have considered that innovation policies would include funds for research and innovation, information and communication technologies, and competitiveness of small and medium-sized enterprises, which correspond to the first three thematic objectives established in the community regulations. Graph 2 shows the total amounts per country approved for the 2014-2020 programming period, with the highest percentage corresponding to the European Regional Development Fund, followed by the European Agricultural Fund for Rural Development and the European Maritime and Fisheries Fund.

Conclusions

After the revision of the indexes, and the development and management of innovation policies in the different regions, we can draw some general conclusions. In the first place, innovation policies could not only provide positive elements of territorial development and articulation, but also some negative effects that would have to be corrected in the design of these. They could favour territorial disparity, especially in the most disadvantaged regions that have less capacity to absorb the funds allocated to innovation, consolidating the so-called innovation paradox. On the other hand, if there is no strategy that takes into account the neighbouring regions, the development of innovation in a specific territory could cause negative externalities in neighbouring regions, such as the abandonment of rural areas, the brain drain, the loss of business fabric, among others. However, we must not forget that the innovation policy could contribute positively in the consolidation of the territorial aspect of cohesion, favouring the relationship between the different spaces -or new functional territories- and articulating the territory. In its incorporation to the reform of the cohesion policy, the policy of innovation and the intelligent specialization of the territories are just one more element. It is necessary to consider the whole and take into account other aspects and problems linked to institutions, governance, cross-border cooperation and limitations in the capacity to absorb investments (MacCann and Ortega-Argilés, 2015: 1300).

Secondly, the analysis of the French and Spanish regions shows common features defined by European regulations, but also important differences derived from their political and socio-economic trajectory (past and present), as well as geographic and spatial characteristics. In the position of the Autonomous Communities regarding innovation, several factors seem to contribute, although it is not always possible to apply a common guideline. Thus, for example, the case of the Basque Country -the most outstanding territory in innovation- has a financing model (regional) that favours the full management of income and expenses. However, Navarre - which shares a border and financing model - is characterized as a moderate innovator. The defining elements seem to be precise in the historical and socioeconomic trajectory. This reaffirms the theory that regional innovation policies cannot be unique but must be defined based on the characteristics of each territory. The way of designing and applying the development and innovation plans has a lot to do with the trajectory related to the regional cohesion policy since the accession of Spain in 1986. In the French case we would highlight the close link between innovation, economic development and territorial planning through the two schemes designed at the national level but adjusted to the specific characteristics through regional governments. The regional transformation culminated with the Notre Law has established a model that starts with a

vocation of balance between the spaces that make up the new regions, applying the principle of subsidiarity to the management of policies.

Finally, it could be asked whether overcoming the aforementioned differences and the diverse capacity to face the challenge of innovation requires the creation of functional territories that overcome the administrative barriers of regional boundaries. The coordination of efforts not to duplicate them and achieve more beneficial results for all actors goes through a multilevel governance in which regional plans and national and European guidelines are articulated.

Track 4/ Institutional change and regional transitions

Regional Transition, Territorial Differentiation, Composition for sustainable trajectory

Gilles VERPRAET

Sophiapol, University Paris Nanterre

GVerp2015@gmail.com

Abstract: Abstract. The art to compose social transactions, environmental transactions have progressed with the explicit method of negotiation and mediation on the common project (Forester, 1999). Social knowledge and policy planning could progress when they specify how the different transactions can be combined so to reinforce the requirements of sustainability on a territory.

The construction of public policies have made possible to integrate these contradictory pressures inside a public policy who may stabilize the space of negotiation. The case of Venice Marghera demonstrated in the 1990 the social capability to articulate two levels of negotiation, between city council and polluting enterprises, between Unions, enterprise and National government on the stages a of depollution and new technic of refinery. The main analytical question intends to integrate the local public actions inside an articulated public policy (Crosta,1999)

The current process of sustainable transition is involved after 2015 in a new period with a diversity of local actions for sustainability. They have to be composed with parallel actions and policies, researching some convergence. In the french case of Loire Atlantic, we may identify three type of transitional territories, each one develop his own conception of ecological transitions.

Urban metropolis transition demonstrates his capacity of coordination on the economy of energy and management of risks inside a coordinate model of sustainable urban development. Municipal and institutional coordination are supporting the extension of urban environmental transactions

Countryside territories support the land protection but they require extended mobility, and are also reluctant to the economy of energy facing the gasoline struggle. Peripheral territory are struggling between precarious life styles, urban consumption and constraint of mobility.

At the regional level the coordination of action by explicit public politics, require more flexibility in a *federative combination* between differentiated territorial actions. Some conflicts emerge between urban and rural population, between stable and precarious population v workforce are developing at regional level. The institutional innovation have to be combined with their planning capacity so to support purposive trajectories of development.

Keywords: Sustainable pathways, Institutional Coordination, Community of Risks,

Introduction

§ I / Social cohesion and environmental policies

***Social cohesion has different meanings. The basic meaning details how to make groups and to cooperate on some basic tasks (so the group dynamic of Festinger. Social cohesion means that the functional interdependencies and solidarities are stronger than social and cultural cleavages (Coser). In State politics, social cohesion takes some normative and political meanings, claiming for a social order between social groups. In progressive area, social cohesion can be a resource and a goal so to initiate and frame a social welfare on consensual basis. In Europe, the politics of social cohesion means a list of transfers and funds for the declining region (zone 6 as Sicily, as Greece) facing the convergence of the European market. The key questions come on the interactions between national Welfare cohesion and European market cohesion.**

***Environmental politics address the response inside a community of risks (in group/ out group/ type de connections). How to protect together, how to define the first short term solidarity before the institutions take the relay. Agenda 21 in Nantes case Social cohesion could prepare some new institutional arrangements, including the risks management, based on a common pool of resources (Ostrom, 1991). Some other sociological questions address the process where the social groups are included in the cohesive social order, in the mobilization for economic growth, the way they are concerned by the environmental politics (protection return, politics of cultural diversity). Social cohesion address different facets on the relations between social community and State organization. This notion requires more analytical development.**

The criteria of social cohesion in the politics of urban renewal (France and Europe)

The notion of social cohesion appears as *a sociological category* with institutional, social and functional dimensions. We may recall and specify its relevance for the analysis of urban politics and the analysis of urban (Astengo). This category of social cohesion is currently developed on different repertoires : in - Economic restructuring as: market exchange, as logic of access and connexion. - in Welfare State constituency : as social solidarity, as logic of access and public support; - in Urban politics as social composition and urban solidarity. The redefinition of the Welfare State inside the economic restructuring (fordist, flexible) concerns the housing politics, the social politics, the urban politics; so result multiple definitions of urban politics. The city politics can be envisioned as a simultaneous arrangement of urban politics and social politics. The notion of social cohesion appears simultaneously as a criteria and as a political frame to evaluate and limit these political constituencies.

Governance and social cohesion : the institutional arrangements

Urban theories tend to connect directly the construction of governance with the arguments of social cohesion, by combining enlarged networking and flexible coordination. The diagnosis of social cohesion has to be experienced within the social differentiation inside the city and the metropolis. M Parkinson develops a more subtle argumentation, how the *competitiveness between cities* can be counterbalanced by

some social cohesion *“Employment is clearly a critical link between competitiveness and cohesion... However the overriding conclusion is that governance can make a significant if relatively marginal impact “..(Broddy, Parkinson, 2004). ”The main argument considers the urban system as a whole, as well as the broad patterns of urban change”*. But the enlargement of resources for the competitive sectors and professional do not conduct directly to the reduction of inequalities in housing market. So we have to consider the urban politics and the social politics who are counterbalancing: regulating the competitive sector.

Metropolitan governance, between competition and inequalities

During the 1990's, the trend to global cities is counterbalanced by some political constructions to contextualized the urban politics (Jessop, 2006, Crosta, 1999). So was elaborated a new analytical frames between urban societies, urban politics and system of governance. The theory of metropolitan exchange is connected with the requirements of market efficiency (Marin,). The rational choice preferences are supporting the differentiated development of urban services, the differentiation of middle classes (Dunleavy, Butler). The theory of coordination is connected with the contractualist approach of public action, but also with the paradoxes of contractualism connecting local joined actions and financial centralization. It induces different political and institutional solutions between the institutional fix (Jessop; 1999); the quango organization, the design of new democratic structure (Maggio). These dilemmas can be distributed between the levels of government.

The double structuration of government is sustained by his capacity to manage two levels of problems, the daily management and the global orientations. The first opposition between the direction setting and the steering government indicate the double requirement of problems inside metropolitan government (Thornley, Newman, 1997). It could be enlarged between the objective of modernization and the difficulty of social cohesion (Parkinson). But it has to deal with the cultural dimension of the steering government (materialist / post materialist) and the resources of economic modernization (high/ low) (Savitch, 1999). In addition, the differentiation of the urban systems (industrial, suburb, post industrial) restrain the unification of the urban economy and metropolitan cohesion inside the competitive governance. The community of risk facing climate could enhance the mutualisation of risks sustain new institutional arrangements.

*Models for social cohesion, and public choices framing

- The social cohesion at the metropolitan level concerns other requirements such as the access to employment (depending from the urban economy), the access to public service, the access to city centre. It is not limited to the management of the Welfare State.
- the social cohesion at regional level between agro farming and ecology, between urban area, rural area and natural protection is enlarged by the conflicts of yellow jackets questioning the relation between transportation non policy and distribution of populations

These levels of social cohesion, correspond to the double enrolment of the social groups between a residential community and a metropolitan economy. The entry of urban analyzis, only by the area of excluded people tend to limit the frame. Other dimensions of social cohesion have to be taken in account such as the institutional dimension, the redistributive dimension, the European dimension. They introduced some other large debates

*Urban regimes; type of social cohesion and sustainable development trajectories

Urban regime theory has been framed so to analyse the supports of local government and the construction of local politics (Stone, 1995). *The New state spaces* are involved in the politics of sustainable development. The politics of local state can be described as a specific arrangement of politics and institutions, on urban development, on sustainable development (Boyer, Brenner). This intermediary level of analysis contribute to analyse the urban regimes (Cl Stone) developed on specific issues as the urban sustainable development. It contributes also to frame the different social supports of an urban regime such as the network supports, the institutional clientelism, the elite coalition of interest. The working class areas are the objects of an addition of politics (economic restructuring, urban requalification, social cohesion, sustainable development).

Such an institutional regime analysis has been applied to describe and to characterize the trajectories of sustainable development in two french metropolis, such as Nantes metropolis and St Denis Plaine commune, not only as urban development, as urban social requalification but also as a combination of social requalification and sustainable development. In this view, the dichotomy between maintenance regime and growth regime need a new articulation. The stabilization of the economic regime as support and resources of political urban regimes requires also a clarification. The politics of sustainable development are questioning the standards of production in post fordist productions, and the combination of politics in urban development. The key question of urban regime is to combine economic interest, urban interest, political interest.

Different approaches of the urban regimes

Urban regime connotes the informal arrangements that surround and complement the formal modes / choices of government authorities between public and private orders. A regime involves a relatively stable group which accounts for the institutional resources that enable sustainable actors in making government democracy. Clarence Stone has defined *four different regimes* : *maintenance or caretakers regimes*, *development regimes concerned with changing land use*, *middle classes progressive regimes* which includes aims such as environmental protection, *lower middle classes opportunity expansion regimes* that emphasize human investment policy and widened access to employment and ownership.

Kathy Mossberger questions *the role of selective incentives* :_The three types of urban regimes (growth, maintenance, progressive) incorporate local dependence, selective incentives and purposive incentives. In this way the civic capacities can be extended to the Urban educational projects (Stone, 2003)._She recognizes two qualities of the theory of urban regimes : -To connect and interrelate the relations between actors and structure (as a structuration theory applied on urban affairs), to extend the formal and informal resources, civic and financial who shape the urban and metropolitan coalitions. But such an extension of urban networks of interest requires a formalization on the criteria explicating” the construction of power, the construction of politics. She concluded by the political assessment : “*The appeal of the regime frameworks has been its ability in use a political economy approach to synthesize structure and agency*” (Mossberger ‘(2001)

Transformative regulations

In contrast with the regime theories of the 1990’s, B Jessop develops a post regulation approach. His vision of integral economy such as Gramsci tends to envision the global determination by market, such as the American fordism of the 1930’s. His analysis underlines the effects of the social representation on the mediation inside the institutional analysis. This framework is supported by a specific analysis on the

dynamics inside the asian economies, such as state entrepreneurship in Singapour, as expert led economy in Japan, so to envision the change in the regulation systems; to connect more deeply the state development with the economic conditions. He criticises a static approach of regulation so to develop a transformative approach of regulation leading on accumulation regimes: He makes explicit the different dimensions of this reappraisal for transformative regulations inside accumulation regime : The Jessop's programme is leading on multiple and tense dimensions, the ideological and cultural basis of regulation, the cultural basis inside the historical compromise, the dynamic transformation inside regulative regime.

Social changes between industrial space, local state and sustainable development

The Large Urban Research Area (LUDA) questions the politics of sustainable requalification by focusing upon the working class territory with a special consideration on the industrial conversion by sustainable requalification. We describe how the policies of sustainable development are supported by the urban politics; as politic of district requalification (ie "politique de la ville"), with their social consequences. In this view, sustainable development is concerned by the issues of urban segregation and urban injustice (Harvey, 1996). We observe the progressive construction of the politics of sustainable development that incorporate the production process of goods and services. New models of industrial development have been suggested. These models imply new process in coordination and deliberation, promoting more integrated industrial space (for economy of scales, for risk management). So we can question the new relations between industrial politics and the politics of sustainable development.

We can formulate an hypothesis on the respective contribution of the state and local government in re-composing the industrial state:

* The state may actively support the politics of transportation, the politics of energy. A liberal state may accentuate the politics of industrial delocalisation and eventually support a regulation policy between social cohesion and industrial requalification¹ (such as the EEC policy).

* Local government may actively open the area of industrial requalification (restructuring, modernizing, complementing). It supports a key role in local arrangement and coordination between different politics (e.g. energy, transportation, industrial requalification, maintenance of industrial activity). It can supervise different actions (social requalification, sustainable development as inequalities containment).

The discourses and implementation policy of sustainable development have been examined at the level of metropolis guided by the definition of the public actions for sustainable development (community groups, city hall, expert groups, city hall administrations). A socio historical approach of each locality set the different sequences of the local definition of sustainable development (as path dependency), the degree of convergence and coalitions between these actors and stakeholders (Sabatier, 1999), but also the institutional arrangements mobilizing different actors and coordinating different actors. Historical sequences of each metropolis can be described by a trajectory of urban development and sustainable development. The practices of social deliberation for sustainable development are developing on different place and different scales of decision. Community and district deliberation are supporting the issues of housing requalification, with economy of energy and consequences on household affordability. The environmental deliberation is envisioned as a response to the ecological mobilization (on space and water preservation, on risks assessment / and alert (Hajer, 2009).

Construction of sustainable policies and mobilization of institutions

The political construction of sustainable development (e.g. the Agenda 21, sustainable planning, risk management, ecological activism, and civic environmentalism) requires to articulate different interventions and implementations. So it involves a wide-ranging mobilization covering different institutions, actors and stakeholders. The global dimensions of climate change (International Group for Climate and Environment, Giec^j) involve the local actions of associations: NGOs and community groups of city and municipal administration (for practising the Agenda 21).

The role of metropolitan government (by common institutions) involves shaping different functions: a role of communication between associations, community groups, elected members and professionals. A policy of coordination by: networks, professionals, agencies and policy setup and implementation process. So results a new redefinition of the urban sustainability by the level of anticipation and social support. In this policy framework, we can question the mediatory role of metropolitan agencies that frame new mediations inside global /local relations.

The methodology for local observations proceeds by extensive questioning of the process including multi-actors (community groups, policy definition, and deliberation process). By initial approach, we can find out the typical organizational inquiry connecting the administration and the professional. By enlarging the inquiry to the phases of implementation process with the place of community group and deliberation process, we can formalize the social relations on the issues (such as urban politics coalition, sustainable definition) and overcoming the institutional cleavages and visions (Latour, 2006).

Metropolitan changes and institutional arrangements for sustainable development

The social and industrial territory of Plaine community located in the north of Paris (120.000 being employed out of 250.000 habitants) and Nantes Metropolis (500.000 habitants) have been transformed significantly since the late 1980s:, This area study shows much larger presence of working class composing of 30 to 40 per cent, a lot more younger population, and much larger immigrants. In this framework of industrial, urban and sustainable trajectories, we can specify the role of pluri-communal

institutions and the city *enhancement of structural actions* (requalification, public health, and environment). The social outcomes (territorial, institutional, politics, technical) of these political constructions can be clarified.

***In Nantes the implementation process of sustainable development is sustained by metropolitan reorganization (Communauté urbaine in 2001). The implementation of sustainable development policies (e.g. the Agenda 21, risk management, and energy politics) governs the elaboration of planning politics (scot). The Agenda 21 provides a framework for procedural actions in addition to other document of housing politics (PLH) of transportation. Therefore comes up some strong and continuous innovation (Agence Nationale pour les Economies d'énergie, such as ADEME), such as eco-quarters, requalification of Ile of Nantes) can be developed. The community of risk can be a base for mutual and collaborative actions supported by institutional arrangements.**

Urban and political options: Metropolitan Coordination and Deliberation

St Denis and Plaine Commune have made the choice of cities with high population density, politics of urban requalification, eco-requalification with more urban intensities (population density, transport, eco-cycle). The industrial territory of la Plaine combines services (such as logistic, research and residential areas in a middle class territory). The urban territory of Nantes Metropolis and the schema for Territorial Coordination (SCOT) have to control and to regulate the urban sprawl – the extension to the periphery where single home units are available– with the cost of transportation and energy consumption. In this reason, city with a higher population density and the redefinition of metropolis and regional function in a new urban centre (Ile de Nantes) are promoted. The debate over the Agenda 21 elaboration raises the issue of mobility and transportation, and the combination of temporalities.

Institutional combinations inside the metropolitan trajectories

Within the territorial and metropolitan transversal dimensions, a large thematic of sustainability (environment, risks management, energy) emerges. This gives rise to a thematic reorganization and new institutional arrangements for the institutional supports of public policy (Table 1). They promote the politic of “transversality” (the Agenda 21, SCOT) and they require some administrative and political coordination. The metropolis of Nantes presents public policy for sustainable development, combining the City Politics (“politique de la ville”), the Agenda 21, management of risks, and planning politics. But the conception on the socio-spatial development model is supported by the Agenda 21 before the planning document (SCOTⁱⁱ). An open debate on the peripheral model of development (urban sprawl, compact area, mode of public transportation) is raised. The mutual and interdependent combinations between urban metropolis and environmental transversal dimensions in the model of development require some new institutional arrangements in the definition of metropolis development.

Table 1: Metropolitan Urban Sustainable Politics as a combination of public politics

The Metropolis of Nantes (2007) combines the “politique de la ville + agenda 21 + Management of Risks.

Politics	Politic of environment	Management of Risks	Politic of energy	Politic of Transportation	Politic of Housing
Public “Service” Board	Office of Environment	Office Of Risks	Office for Energies and Sust Dev	Public Transportation Company	Mayor and Metropolitan Agency
Document of Reference	Athénée Programme Eco quartiers	SIG System Craoil	Energy Programme (PPAE)	Transportation Plan	Housing Local Programme
Specific Territory Of Actions	River bank of Loire Great Area Project (GPV)	Integrated Industrial Areas	Energy Networks (Housing council)	Metropolis Area	Housing District And Village
Political Elected Reference	Vice Mayor For Environment And DD	Mayor	Vice Mayor For Environment And DD	Vice Mayor For transportation	Vice Mayor for Urban Development

In this framework of urban exchange, coordination and institutional arrangements develop multiple processes of social deliberation (The Agenda 21, council of development, community council). However we have to distinguish the collective of deliberation as community issue and the collective of decision as coalition legitimating a public policy. This is only at the level of decisional community (Dahl) that can be stabilized with certain referential matrix (Sabatier, 1989). The referential of sustainable development is fixed on the shaping and the organization of urban sustainable transversality.

Redistribution of competences and instruments

Within the large institutional changes, the instruments and dispositives settled for the risk management contribute to the stabilization of a pluri-communal “reference” frameworks with their effects on municipal frames, with their outcomes on private actors (citizens, residents, enterprises). The official discourses and narratives insist on the continuity between private values and public values (partnership, development, mixed economy). But a policy viewpoint has to specify the adjustments cost, inside the redefinition of the urban structure (local planning and land values, politic of requalification, conversion of brownfield). They promote new economy of scales, some new external economy (Baumol, 1994). Therefore the types of conflict emerge in the management of risks (environmental conflicts, political conflict, conflict of coordination).

In the current conditions, we may recognize *two regimes of the management of risks*: A middle range vigilance focuses on the envisioned risks of the global warming, inside the documents of urban planning (water, urban sprawl and energy costs). The local surveillance by municipal institutions focuses on specific risks (industrial areas, flooding) and the responsive capacity of each municipal administration.

New formulas of coordination

The new metropolitan authorities are not only some conventional agencies, but also new institutions with territories and competencies. They can support collaborative networks between representatives and associations. So result multiple forms of coordination, not only administrative and functional coordinations, but also civic coordinations with joined elaboration. Sustainable development is mobilizing community groups, representative and institutions in an “ascendant” mobilization. It groups institutions and local actors by top / down programme. The links between pedagogy and mobilization give a specificity to the implementation of sustainable development.

Path dependency approach suggests that each step of sustainable development, requires some specific coordination of actions, and some social support by deliberation on the norms and the orientation (Pierson, 2001). The legitimization of the public action on sustainable development is in processes (Sabatier, 2004). So results some functional interpretation of deliberation, so to promote pedagogy. We have already quote how conventional institutions are sustaining lateral mobilization by networks, by pragmatic linking of particular interest (Beaumont and Nichols). This analytical scheme can be extended on metropolis institutions.

Table 2. Institutional Levels and Social Responsibilities on Risks : Multilevel State and Sustainability

Cities / Municipality	Hygienic and Safety	Vulnerable Area / Vulnerable Population	Reference of Mayor
New Urban Communities/ Metropolis Agencies	Communality Management of Risks SCOT = Metropolitan Orientation Scheme Agenda 21, Climate Energy Plan (PCE)	Transversal Coordination Urban Project Territories Transformations	Communalities Cultures Deliberation
Department / Province	Agenda 21 for public services Environmental Pedagogy, in school, with association, Communication, Animation Climate Energy Plan (PCE)	Communication Social Links Social Care	Segmentation Specific Population
Region	Great Risks, Seveso Risks Agro farming and Pollution Natural park protection Transportation modalities and distribution of population (SDAU)	Territorial Changes Prospective	Regional Politics and Sustainability conflicts

The social dimensions of sustainable development

The classical approach of sustainable development points to the fact that social inequality “are setting large constraints on the arrangement and on the policies of sustainable development (Harvey, 1996). Therefore, the territory of high risks is likely to be that of vulnerable population like flooding areas (observed in the 2004 flood of New Orleans in the USA) and industrial areas (Bullard). The activist approach of sustainable development pay attention to the appropriation of the thematic of sustainable development by local actors. Social issues can be mediated through by different social channels such as local associations, community groups and their environmental claims – e.g. territorial politics of each municipal administration.

Our analysis of path dependency process (Pierson, 2004) insists on the necessary social conditions for implementing, the actions and the politics of sustainable development, such as the social actors supporting initiative and animation for sustainable development. The behavioural changes concern the economy of energy, education and consumption, the changes of institutional norms (policies of energy and transportation). The ecological modernization of Metropolitan institutions (law SRU of 1998ⁱⁱⁱ) seems to precede the social and ecological adjustments, which depend on the territorial choices of municipal politics and the management of territorial change. Some new relations between the economy of scale and adjustment costs as the rescaling and the downscaling of public politics are created (Brenner, 2004).

III / Two-levels of negotiation in Venice : Industrial policy and Sustainability policy

These results on the sustainable conversion of industrial sites in France can be compared, evaluated by the Italian process of requalification of industrial sites based on a dual process of political exchange and territorial coordination. This clarification of the urban regime at the metropolitan level (model of metropolitan governance) make explicit the political coordination between the urban model of development and the policy making in the industrial areas. These industrial changes implicate some new metropolitan reorganization (technopolis, quasi integration of industrial spaces, transportation logistics, training and flexibility of the industrial work force). The referential of sustainable development emerges inside the discourses of territorial change and the new requirement of sustainability.

The reconversion of the chemical activities of the port of Marghera, involves several collectives: (trade union, municipal, ecologist) and several levels of industrial relations (ecologist / elected officials, union / chemical industry). The dispersion of ecological activity groups fighting against industrial pollution (chemical) and for the preservation of the lagoon (natural environment, historical), is placed before the centrality of conflictual negotiations between contractors and employees on the modernization and preservation of jobs. The municipality of Venice Mestre provides a frame of reference for negotiations on environmental issues and the modernization of the port. Marghera's new plan in 1998 establishes a framework of reference and compromise between the diversification of the port's activities (tertiary tecnopolis tourism) and the continuity of certain chemical activities. Social demand passes through the unions. The environmental demand moves through the municipalities inside double level of negotiation

But the second stage of bargaining has moved up to a national level of negotiation so to establish a framework agreement between unions, companies and the central government. This February 1999 agreement links the maintenance of chemical activities with the preservation of certain environmental criteria on chemical discharges (discharges and water temperature). This addition of contractual agreements shows an example of an industrial and environmental partnership between municipalities and entrepreneurs seeking to promote a "common good", as a common asset between residents and employees of the industry. In Italy the partnership is conceived as a relay of territorial policies. It involves convening public and private actors to implement urban policy objectives. But the implementation of this policy remains problematic given the weakness of investment and coordination of public administrations (Perruli,). The 1998 framework agreement comes after the downsizing of the mechanical industry and oil. Large groups decentralize their production to other sites (Down Chimica, ENI) The actual result is a decline in the number of employees from 33 000 in 1998 to 13000 in 2005 with a diversification of activity on small businesses (Trifiro, 2008)

IV / Environmental conflicts in Nantes Region and shift in social cohesion

The current process of sustainable transition is involved after 2015 in a new period with a diversity of local actions for sustainability. They have to be composed with parallel actions and policies, researching some convergence. In the french case of Loire Atlantic, we may identify *three type of transitional territories*, each one develop his own conception of ecological transitions. Urban metropolis transition demonstrates his capacity of coordination on the economy of energy and management of risks inside a coordinate model of sustainable urban development. Municipal and institutional coordination are supporting the extension of urban environmental transactions (§ 2) *Countryside territories support the land protection but they require extended mobility*, and are also reluctant to the economy of energy facing the benzine struggle. Peripheral territory are struggling between precarious life styles, urban consumption and constraint of mobility.

1 / The refusal of eco tax in 2015

The ecological transition plan prepared by Minister of the Environment 2016 was based on the development of the eco-tax. This tax policy of road transport has met with strong resistance in 2014 2015. The organizer of roadblocks were based on truck drivers, self-employed, farmers Breton. The socio-economic issue concerns the final price of the goods, the free movement on the Brittany radial and the level of export of industrial agriculture. The rallies on the logo "red cap" which was based on Breton regionalism, associating a strong cultural identity as Breton regionalism and the intensive development of industrial agriculture. Hence the retreat of the government, as a deferred measure, canceled, not acceptable in July 2015. There remains the feeling of distrust facing the state and its ecological policies

2/ Contestation de Great Airport in ND Landes

The ND Landes airport project between Rennes and Nantes associates, the regional elected representatives of Angers Loire, Rennes and Nantes, The decision comes from an interregional conference with a scheme distributing the attractiveness, the accessibilities, the mobility. The challenge of the airport is the attractiveness of Nantes to new activities (airbus framework), the recovery of agricultural lands when Nantes Bouguenais airport face the pressure of urbanization. Ecological resistance is interpreted according to the theme of No growth, on the defense of bio diversity (Guerande,

Briere), on the defense of agriculture. The actions combine mass demonstrations of 10,000 people with a media dimension and land occupations (130 students, precarious housings), resulting in a heterogeneous coalition versus an explosive mix anti-government, anarchist for other forms of life (authoritarian)

The elected representative ecologists plays both the defense of nature and peri urban housing, the collaboration with sustainable development in Nantes metropolis the defense of the urban period against the intensive urban development, In January 2018, Macron Gvt Philippe, cancels the decision of the airport for budget savings (report) sustaining an alliance with environmentalists Ministers (Rugy, Hulot). Alliance between alternative ecologist and independent peasant are emerging. 60 precarious can cultivate agricultural land in a transitory way, under the argument of an agricultural laboratory of biodiversity. The new ecology focus on the defense of bio diversity, a new compromise between farming and organic agriculture. The pathways of transition could be very diverse between generations, with some blockages and large uncertainty of the strategy of sustainable urban/ rural development.

3/ Contestation of eco taxes in the periphery The conflict of yellow jackets between November 2018 and June 2019

The mobilization of the movement of the yellow jacket starts from a clear protest, even if it assume several causes. The mobilization refuses the increase of the eco tax (50 euros per ton) and its negative consequences on a high fuel prices. The high cost of peripheral mobility affects the monthly budget of precarious households. Media images expose the feeling of blocked lifestyles, a deep questioning on the constraints of the peripheral lifestyle (in dispersed rural area, especially in the central massif) and also lifestyle suburban, very far from the big cities (Meuse, South of France.) The analytical approach will be linking lifestyles and planning styles (Genestier 2019).

The process analysis of the mobilizations set up the aggregation of different audiences around the roundabouts, heterogeneous social recruitments between truck drivers, nurses and low-paid employees, retired peoples,, middle managers in the public service. Beside the independent professions resulting from the first mobilizations of the red cap are added the public of precariousness. After two months of explosive demonstration in the urban centers, the social demand, on the low wages on the precariousness tends to take precedence over the territorial claim of the peripheral way of life, the peri-urban autonomy, on the ecological claim. The government responds in December 2018 by measures concerning the precariousness of pension and very low wages (a year bonus)

The initiative of the great debate on the four themes (taxation environment mobility democracy) aims to curb the movement in the social and fiscal consensus. I intends to explore the deep reasons for this explosion of anger between rich city centers and poor areas, and possibly move the coding of the movement. Beside the aspiration of poor retired residents and precarious employees, there is a limitation of the ecological aspiration on the daily (eco gestures). The movement of yellow vests remains fixed on the wealth tax and the referendum of popular initiative (R.I.C.), on a direct political expression on the financial choices.

The viewpoint of planning notices the increased differentiation of the territories of lifestyles (suburban, peri urban, rural center). It can be diagnosed three territories of lifestyles and project. The current process of sustainable transition is involved after 2015 in a new period with a diversity of local actions for sustainability. They are composed with parallel actions and policies, researching some convergence. In the case of Loire Atlantic, we may identify three type of transitional territories, three community of issues, each one develops his own conception of ecological transitions.

V / Disjunctions and Conjunction framing / Regional Politics

Regional policies in France are based on several arbitrations, territorial conflicts and potential conflicts. The rural / urban conflict focus on densities and land pressure with regard to agricultural land (Hamman, 2012). They moves today on the conflict between rural agriculture / organic farming, on the protection of water resources.

a/ The regional policy of the Region des pays de Loire (3, 7 million inhabitants, 117 inhabitants KM² 2 surface, 32000 KM²) is a selective policy oriented territories and agricultural enterprises. It assumes its orientation on a policy of agro diversity, on the defense facing coastal risks. The budget for biodiversity 2018/2012 amounts to 192 million euros over 5 years: 71 million from Europe. The regional policy of Region Pays de Loire proceeds on the continuity of the industrial agriculture (Mayenne with refusal of the eco tax) The State is engaged with 2.5 million euros and the Region up to 6.5 millions of euros in a joined State Region contract. Its goal is to restore confidence in the territory. -Environmental policy manages coastal risks raised after flooding incidents in the Charente Sea

b / Regional policy is less assured on the energy transition, on the renovation of buildings, on an indicative construction of rural mobility. The search for new renewable energies remains experimental (St Nazaire wind energy project, electrical car as experimental). Renewable energy production is expected to triple the rate of energy consumed in the territory of renewable origin by 2021 (today this rate is 8%) (€ 33 million - European funds € 9.5 million). The energy saving dispoitives is referred to the cities Nantes against Angers. The coordination of energy cycles is delegated to department with Plan Climat Energy (P. C. E). The energy building plan (€ 39 million with -€ 22 million European funds) to support the energy renovation of private housing The challenge is to renovate 100,000 housing units by 2021. Sustainable mobility covers 3 commitments (Region € 10m - European Funds € 25m)

c/ This uncertain policy has consequences in the heterogeneous mobilization of cities (Nantes, Angers St Nazaire, Laval). Regional mobility is contrasted between city policy and regional policy. It assumes a policy of privileged territories (agro) and territories at risk (forest and parks) without link between territories and development objectives. The mobilizations of yellow jacket highlight the weakness of regional policies on peripheral mobility, on energy savings to develop, (see regional consultation). it combines a peri-urban crisis and crisis of the regional development model . Regional politics mobilize differently the three identified territories of issues. Countryside territories support the land protection but they require extended mobility, and are also reluctant to the economy of energy facing the agsoline struggle. Peripheral territory are struggling between agro protection and Metropolis mobilization on sustainable development (§ 2). At this time they do not present autonomous politics of sustainability and development

At the regional level the coordination of action by explicit public politics, require more flexibility in a *federative combination* between differentiated territorial actions. Some conflicts emerge between urban and rural population, between stable and precarious population v workforce are developing at regional level. *The regional policy presents itself as a federation of causes, territories without clear objectives* Parallel paths of sustainable development could amplify the areas of conflict such as eco tax or a disjunctive synthesis with predations. The tension odevelops between the advanced energy transition in the cities like Nantes and Angers and the policy of bio diversity on the agricultural and peri-urban grounds (regional politic). The new compromise would come from the regulation of conflicts, promoting a sustainable regional welfare state.

* How to organize urban coordination and environmental coordination in transition plans and regional coordination ? The urban region is fractalized in diversity of trajectories (rural region °) The

stabilization of the policies of sustainable development requires a sustainable welfare state, protecting the populations, supporting the social solidarity on the eco taxes. We notice the crisis of financial incentives facing the social differentiation and spatial dispersion. We may evaluate this crisis of financial incentives in regard with the possibility of coordination of action and federalization of risks

VI / Conclusion * :Multiscale governance between local State and national state

This paper has focus on the *new institutional arrangements set up at the regional and metropolitan levels on the rescaling of urban politics*; the development of the politics of social cohesion by requalification and gentrification; the new combination between urban politics and the policy of sustainable development. The local institutions and the local government play a specific role, so to adapt the actions of sustainable development by urban context and by social relevance. Metropolitan government has the specificity to coordinate the local actions, the public policies to modify the model of urban development in a more sustainable process. They develop a large influence by implementing some differentiated capabilities of actions.

The central State may keep a central role to impulse a rhythm and an agenda of modernization between sustainable development and industrial models. It may sustain or frame the role of metropolitan institution. The key issues concerns compromises between public norms, local mobilization and modernization of the eco-industrial models. In the current situation redefining the State authorities, experimenting the sustainable development policy, is not assumed the convergence of norms and rules between central state (by norms) and local state, with flexible coordination and autonomous institution. Different trajectories can be developed by coordination and deliberation.

Within this approach, we may compare the social outcomes in the production of the urban sustainabilities between national policies of the nation state and the policies of the local state:

- The politics of the nation state focuses upon the debates on the politics of energy, on transportation priority and economy of energy. Besides the media corporate debates, new eco technologies are envisioned.
- The politics of local state on sustainable development may articulate citizenship mobilizations on concrete issues, with open construction of these politics between public deliberation and social changes, the framing of alternative way of life (compact district, soft mobility). We may notice different urban solutions, different urban assemblages between contexts, between nature, social territories and institutional coordination.
- The regional area is leading the issues stakes on biodiversity, on agricultural land, on mobility politics

Table 3 Dual politics inside Climate Transition (Energy Transition, Biodiversity Politics)

	Energy Transition	Bio Diversity Politics
Dispostives	Energy system, autonomy and distribution	Territories and Eco systems
Behaviour	Information and autonomy of behaviour	Territorial attachment
Metropolis	New energy system Geothermy Public transport Multi modalités	Environmental politics Biotechnopolis
Periurban	Wind energy, solar energy Car consumption	Conflict rural land urbanization Bio farming and peri urban
Region	Innovation on new energy Pb/ extension, distribution	Agro ecology Coastal protection Park protection
Nations State	Coordination, Concentration Balance of energy system	Biodiversity mapping and rules of protection

*** New spaces of the state and sustainable development**

The local state (metropolitan agencies, regional state) may federate the local actions for sustainable development by networking and flexible coordination. It can give place to local communities and groups. The local coalition of power have to make their choices between the territorial based bureaucracy and the postmodern bureaucracy, with the social networks for environment (association, risk management).

Central State may keep a normative role in the construction and the protection of markets, such as the housing market, economy of energy, carbon balance and fiscal policy, eco technological innovation. We have framed how the normative dimension of a State keep a sense of responsibility in the risk management in a neo liberal State. This question concerns the relation between central state coalitions and the diverse plural local coalitions. This is the heuristic to analyse the urban and metropolitan trajectories and their institutional arrangement. How they change the local coordination and the norms of reference. The sociological analysis of urban sustainable trajectories may specify the purpose of social compromises and the place of deliberation inside these compromises".

In a first approach, we notice some stability in the analysis of social compromises bounded around the urban politics and the environmental politics.. The participation on the urban politics and the politics of sustainability, is more sustaining some arrangements between urban middle classes and central elites (Beaumont and Nichols, 2007, Hajer, 2005). Environmental compromises are destabilized by the new sustainable development policy. Energy transition and biodiversity are two pathways of sustainable development, two types of institutional arrangements. The classic tools of land use and property planning must be combined with incentive policies that support energy policies (market, finance, taxes). These questions concern the new future stages of sustainable regional development.

Institutional change and regional transition

Setting up the new planning system in Kosovo - evolution and influences in the development

Ilir Gjinolli

Abstract: This paper analyses the evolution of the Kosovo Planning System and the influences in the planning practice and development. It looks back in the period of socialism when planning was established and the overall context after the wars in the Western Balkans by identifying similarities and differences of the planning system in the former Yugoslavia and the shift from a centralized administrative to a democratic system after the war in Kosovo in 1999.

The author investigates the role of the international actors, in particular UN Habitat, in setting up the planning system, institutional development, capacity building as well as exercising planning tasks in the practice from 2000-2013. The paper analyzes also the impacts of the shifts in 2013 influenced by the World Bank towards a more liberal planning system and development.

The paper explores roles of main local actors in planning, including Kosovo government and the municipalities, international as well as local agencies and civil society organizations in promoting the relevance of planned development and necessary changes in the spatial planning policies.

Through the evidence based research the paper intends to measure the outcomes of the plans at central and local planning level throughout the territory of Kosovo.

Keywords: Spatial planning system, Department of Spatial Planning, Institute for Spatial Planning, UN-Habitat, Kosovo Spatial Plan,

Introduction

In this paper, I intend to present the planning system in Kosovo and how it changed after the war in 1999 to date. In order to trace back the emergence of the system, it was considered that it is necessary to mention some of the historical moments that marks the shifts in the development of planning as a profession since 1945 when Kosovo was set up as an autonomous province in the Former Yugoslavia. After the war in 1999, there are two phases that marks the establishment and development of the planning system of the new Kosovo as an independent country. The first period is under UN Administration 1999-2008 when the new planning system established the path to plan future developments. The second is the period from 2008 when Kosovo became independent. Although substantial changes took place in 2013, the planning system, structurally as a government sector, decentralised levels of planning and planning institutions, still remains as it was designed in 2002.

History

The roots of Kosovo planning system date back from 1945, when Kosovo emerged as a province within Republic of Serbia as one of the federal units of Federative Republic of Yugoslavia. According to Rudolf Bicanic¹ in the former Yugoslavia, during the period between 1945 and 1990 there were three models of planning:

- The centralized model of planning - 1947-1951
- The decentralized model - 1952-64

¹ Bicanic R. (1973) Economic Policy in Socialist Yugoslavia, Cambridge University Press, Cambridge, 1973.

- Polycentric model - from 1965

Some economists consider, in theory, the centralized planning model as the most rational planning pattern, although some of its supporters do not agree with its political presuppositions. The decentralized model had a certain level of rationality, although limited. The polycentric method seems to have been less homogenous than the centralised system.

The evolution of the Planning System in Kosovo could be considered a generative one. It emerged in 1974 with the changes in the constitutional Law of the Socialist Federative Republic of Yugoslavia (SFRY) and Republic of Serbia, when Kosovo was granted with the status of Autonomous Province within Socialist Federative Republic of Yugoslavia. The Parliament and the Government of the new Province were established and Constitution was adopted. This constitution delegated the power of spatial planning from the Federal Government and the Government of the Republic of Serbia to Kosovo government, so the first Law on Spatial Planning in Kosovo was drafted in 1975. In 1977 the first Kosovo Spatial Plan was adopted in the Kosovo Assembly.

The planning system in Kosovo before 1990 could be summarized in the table² below:

PERIOD	TYPE OF PLANNING ACTIVITIES	TYPE OF PLANNING DOCUMENT
1947 - 1965	Central command planning (Controlled development, urban growth and city limits/ public interest over the private / focused on technical solutions)	<ul style="list-style-type: none"> • Regulation and detailed plans
1965 - 1987	New system of voluntary planning, “social self-management planning”/ Communication and coordination of different bodies at all levels through agreements and commitments, with no hierarchical approval system	<ul style="list-style-type: none"> • Top down master plans as goal formulations from - (land use) • Regulatory and detailed plans as solution bottom-up driven (5 years plans)
1974 - 1990	Decentralized - Provincial level and local planning Spatial planning at the Provincial government level Municipal and urban planning, Regulatory and detailed urban planning	<ul style="list-style-type: none"> • Spatial Plan of Kosovo • Regional spatial plans • General urban plans • Regulatory Plans • Detailed Urban Plans

Table 1. Planning system in Kosovo from 1945-1990

2. After the War 1999

Although the theory of transition considers that it is a primarily political process, in Kosovo the transition process should be seen in a more complex context including liberation from Serbian apartheid system.

After the end of the war, Kosovo was administered by the UN Mission - UNMIK. It was a complex international organization involving also European Union and OSCE and other international Agencies specialised in particular sectors. The basic duties that UNMIK was responsible include:

- Performing basic civilian administrative functions;
- Promoting the establishment of substantial autonomy and self-government in Kosovo;
- Facilitating a political process to determine Kosovo's future status;
- Coordinating humanitarian and disaster relief of all international agencies;
- Supporting the reconstruction of key infrastructure;
- Maintaining civil law and order;

² Hoxha, E. (2006) PRISHTINA ESCAPE-Challenges for Urban Development-MSc Thesis, Catholic University of Leuven, 2006.

- Promoting human rights; and
- Ensuring the safe and unimpeded return of all refugees and displaced persons to their homes in Kosovo.

These tasks were implemented through four pillars:

Pillar I: Police and justice (UN-led)

Pillar II: Civil Administration (UN-led)

Pillar III: Democratization and institution building (led by OSCE)

Pillar IV: Reconstruction and economic development (EU-led)

The period of nine years of international rule had a large impact in Kosovo society in terms of law and governance, economy, social development. In the beginning all discriminatory laws approved after 1989 were abrogated and the laws of the former SFRY were considered applicable. In 2000 UNMIK organized first elections for the local governments. In 2001, a Constitutional Framework was approved as a supreme legal act based on which a set of laws were designed and approved in next seven years. This was the base to organize the first election for the first Kosovo government - so called Provisional Institutions of Self Government of Kosovo, composed of three bodies - Kosovo Assembly, Kosovo Government and the President. The administrative system was divided in two levels - central and local government. Most of the competences concerning local development issues were transferred to the municipal assembly, including spatial planning.

2.1 Transition

The process of transition in Kosovo include political, economic, social and transformations of urban morphology of the cities after the war under UNMIK administration and the extensive presence of international organizations that turned the reconstruction process and status negotiations into a global agenda for more than 10 years.

According to Harloe, transition, is not a unilinear process in terms of contents, sequence or timescale. It depends on system of local governance, legal and institutional framework, the way in which privatized public assets are distributed and policy choices³. In the case of Kosovo cities, this was even a more complex process. While before 1999 it was an apartheid-like situation, after the war the international administration changed the situation to democratic governance that gave the shape to future Kosovo development. In terms of time, due to the war it took more than in the other countries of the region, especially compare to countries of former SFRY. Due to the long period of conflicts situation, Serbia and Bosnia suffered from delay in transformation from unitary to democratic state.

In Kosovo, the period of discontinuity lasted 10 years, from 1989 to 1999. After the end of the war, UN took the role to establish the Provisional Institutions of Self Government in Kosovo. Through process of privatization a new liberal economic order was set up, and a new legal and constitutional order created the path to the new statute for Kosovo in 2008. New rules of social integration came to place by establishing the civil society, supported by the international community, which supported the reconstruction and development in the fields where government was not able to act due to limited capacities.

During this transition period, institutional and organizational structures of the cities were under reconstruction led by UNMIK, and other international organizations such as EU, OSCE, and different international development agencies. Decentralization was one of the goals of this transition process. This was reflected also in the planning and construction matters. Although in the former socialist system the power were decentralised, considering that it was a single party rule, the decentralisation was more or less controlled by the communist party committee.

Due to changes in the city institutions and organization of the governance, changes of property rights, urban development was disturbed by the needs for reconstruction of housing and the long period of very limited construction activities. Beside these facts, unmaintained public spaces and buildings suffered damages that were

³ Tsenkova, S, Budovic-Nedic, Z., (2006) The Urban Mosaic of Post-Socialist Europe introduction to 'The Urban Mosaic of Post-Socialist Europe: Space, Institutions and Policy' Edited by Tsenkova, S, Budovic-Nedic, Z., Physica-Verlag, Heidelberg

necessary to improve. But the existing planning instruments were too rigid to provide planned construction. In the other side, UNMIK Administration didn't want to strictly control development due to the needs for housing.

2.2 The Liberal Economy

Dostal (1998) concludes that a successful early post-communist transformation means (1) a quick resumption of macroeconomic balance and economic growth resting on (2) genuine democratization and economic liberalization, and (3) higher level of modernization'⁴

Liberal economy or so-called market economy came as a logical result of transition. After a long economic decline during 1990's, after the war, there was a big amount of donor support in reconstruction process, which generated an economic revival in the first years of 21st century.

UNMIK Administration introduced free market economic development policies. The abandoned industry in the beginning started to operate under international administration, but in 2002, the privatization process started and gradually most of the, industries stopped production due to old technologies. Privatized industries in most cases were transformed in services or changed the production technology or sometimes even demolished to leave the sites for construction such as in the inner part of city of Prishtina.

Flea markets and improvised bazaars were a rapid respond to growing demand for different kind of goods - clothing, everyday articles, and different kind of tools. The abandoned sites were given at a very low rent to allow people set up their businesses. For example a flea market operated in the city centre of Prishtina and was a very vital area until it has been displaced in the industrial area in 2007.

Due to the very high price of the land and big pressure for housing, industry and service economy - retail the municipalities begin to plan for the periphery. Beside planned areas, a lot of illegal construction occurred along the main infrastructure corridors. It was obvious that investors wanted to bypass procedures and decrease the investment due to the taxes. New spaces for private small and medium-sized production were constructed sometime of a very poor quality. But there were also very serious investments that followed the regulations in terms of space standards and construction materials. Privatization provided the opportunity for the investors with clear programme to bypass construction process and they used existing premises very efficiently, sometime even combining the production with renting the unused facilities.

As investment begin to grow, the service sector grew as well. When the Government of Kosovo was established it became also an important employer, although with very modest salaries. Other services such as education, health and culture also provided a considerable number of jobs.

There were also informal economic activities. Amongst them, illegal construction, which will cause big problems in the years to come. About illegal construction there will be some thoughts in the next pages of this research.

But, the investments and new jobs were not sufficient to provide jobs for growing number of unemployed population. Although there were a lot of informal economy, unemployment rate in 2002 was at the rate of 50-55%, down from a high of 74% in the second half of 1999.⁵ According to RIINVEST, an institute for economic development in Prishtina, the unemployment in 2003, was at the rate of 49%.⁶

The table below shows the unemployment rate between 2004 and 2008

Table 2. Key labour market indicators according to Kosovo Statistics Agency in the period 2004 - 2008

2.3 Growing international competition

As from 2000, Kosovo became a region with a high interest for the international investors and suppliers. Since there was very limited production, the supplies came primarily from import - the region and EU countries.

Import remains even today very high, because production is still at a very low level. Low production is caused by low investment potential of the local population, limited incentives from the government and growing international competition. As an example, after the highway that links Prishtina and Tirana, the import of agricultural products from Albania had roused. Kosovo has signed CEFTA- a regional free trade agreement, which adds more difficulties in regard to this competition. It will become even more difficult after Kosovo starts the Stabilisation Association Process with EU.

2.4 Privatisation process

Privatization of land and housing is the most radical aspect of the transition from state socialist systems to democratic and market system.⁷ Property rights lie at the heart of that process (Marcuse1996). According to Webster and Lai (2003), "institutions that protect private property are essential for market activity and economic growth"(p3)."

The public housing stock has been privatised during the Serbian regime in 1992. At that time, Serbian government had two goals, to provide social peace within raising economic problems and unemployment. In the other side the acquired fund was used to finance the war in Croatia and Bosnia.

Immediately after the war, the property market boomed. Prices of properties owned by Serbs were sold quickly due to migration from Kosovo to Serbia, while many of these properties were soon transformed or sold out in higher price. During the years to come the property prices has grown tremendously, especially in Prishtina as a capital of Kosovo.

Beside achievements in setting the bases for a new independent state of Kosovo, UNMIK administration in Kosovo faced severe difficulties in terms of sustainable economic development. Privatization of the social owned properties to private ownership had as a goal economic development. But the way in which privatization was conducted, posed a lot of question starting from the source of investments, corruption and the future development of the industrial premises, agriculture land or other privatised assets. The former workers in these socially owned enterprises were supposed to be legal owners. From the total value of sold premises, the workers shared only 20%.

PLANNING FOR THE NEW LIBERAL CITY

The latest planning activities in Kosovo took place during 1980's, when most of the cities drafted city master plans - so called General Urban Plans, comprehensive long-term planning documents for at least 10-15 years. Some planning activities were exercised during 1990's by the Serbian government in Prishtina and Prizren in 1996/97. But they were carried out away from public, and in particular excluding Albanians. As a teacher in a

⁷ Tsenkova, S, Budovic-Nedic, Z., (2006) The Urban Mosaic of Post-Socialist Europe introduction to 'The Urban Mosaic of Post-Socialist Europe: Space, Institutions and Policy' Edited by Tsenkova, S, Budovic-Nedic, Z. Physica-Verlag, Heidelberg

parallel education system, the author of this research has found out about these document only in 2004.

Until 2002, limited planning activities took place in the local level based on the applicable law on spatial planning from 1974. Few plans were drafted but with very limited impact in the ground. For example, the General Urban Plan for Prizren was drafted from 2001-2002. Although it took some 8 years to redraft it according to the law, beside limited impacts in infrastructure, was not implemented according to decisions. The shifts in the planning system are shown in the table below:

PERIOD	TYPE OF PLANNING ACTIVITIES	TYPE OF PLANNING DOCUMENT
1990 -1999	Central imposed planning from above – Serbian government (top-down control) Exclusion of Albanians from planning process (Planning activities oriented towards the goals of sustainability / not linked with the real context - superficial	Land use Scenarios for development Regulative plans
1999-2002	Reconstruction and emergency activities “shelter programs “ Some limited regulatory planning activities	Applicable planning law of Kosovo from 1987
2002-2013	Decentralized- central and local planning Strategic planning at the central level Municipal and urban planning, regulatory planning	Central level: Spatial Plan of Kosovo, Spatial plans for special areas Local level: Municipal Development Plan, Urban Development Plan and Regulatory Plan
2013	Decentralized planning process, centrally approved plans, Strategic planning at the central level Municipal planning, zoning - land use plans, regulatory planning	Central level: Spatial Plan of Kosovo, Kosovo Zoning Map, Spatial plans for special areas Local level: Municipal Development Plan, Zoning Map, and detailed Regulatory Plan

Table 3 - Kosovo Planning System from 1990 - 2013

In 2001, before the first election, UN administration defined the main sectors that new elected government have to manage. Amongst main sectors, such as finance, economy, health, education, welfare, culture and youth, environment and spatial planning were chosen as on of the sector. The Ministry of Environment was established in the beginning of 2002 and immediately, the Minister signed a cooperation agreement with UN Habitat to support the Ministry in developing the planning system, including legal framework and setting up the sector institutions in the central and local level.

The new Law on spatial planning approved in 2003 defined the way the spatial planning will be carried out in Kosovo. The law defined two modes of planning:

- Spatial planning, carried out at the central level with two types of plans: Spatial Plan of Kosovo and Spatial Plans for Special Areas for which central government will be responsible, and Municipal Development Plan

(MDP) at the local level, for which municipalities will be responsible.

- Urban Planning, carried out at the local level with two types of plans - Urban Development Plan (UDP) and Urban Regulatory Plan (URP).

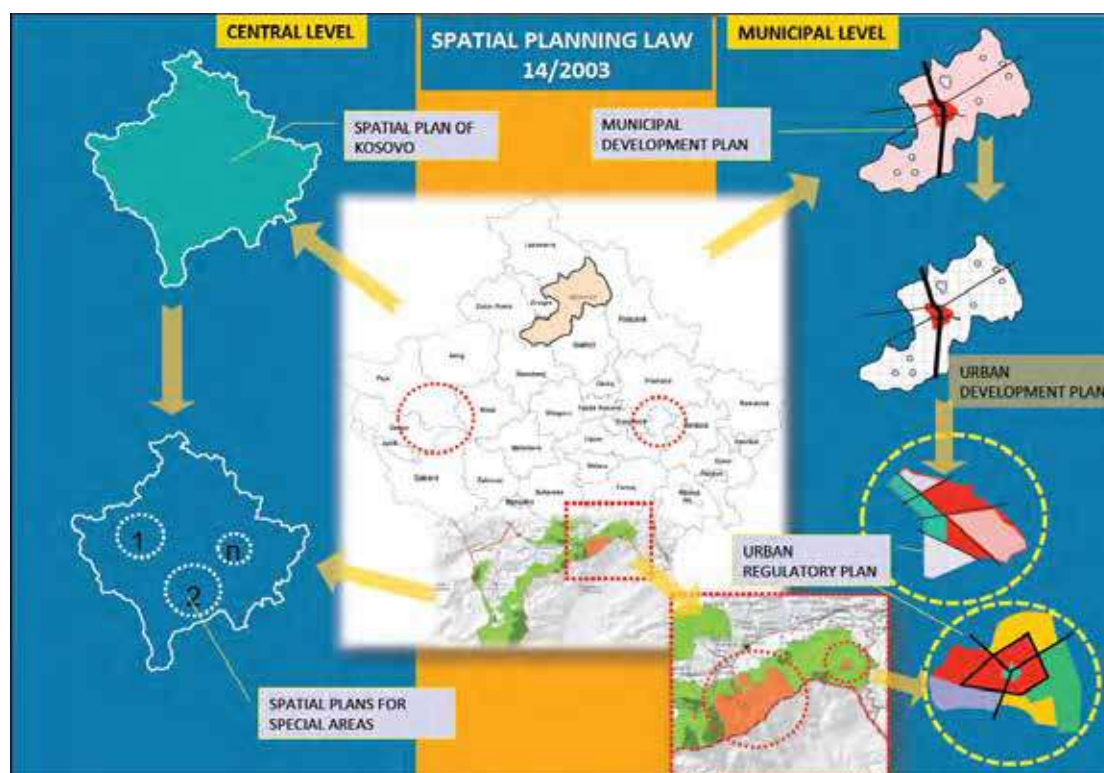

Figure 1. Planning System in Kosovo according to the Law on Spatial Planning 2003/14⁸

In the Figure 2, a summary of the planning policy instruments graphically illustrates the scale of the plans from central to local, through types of plans related to territory they serve and the character that they have

Policy Institutions

Spatial Planning in Kosovo is implemented at the central level - Ministry of Environment and Spatial Planning. Other ministries such as Ministry of Transport and Telecommunication, Ministry of Agriculture, Forestry and Rural Development, Ministry of Energy and other government bodies, have a role in the process of plan preparation. The relations between the policy institutions and instruments are presented in Table 1 below.

Content of the Plan and Planning Process

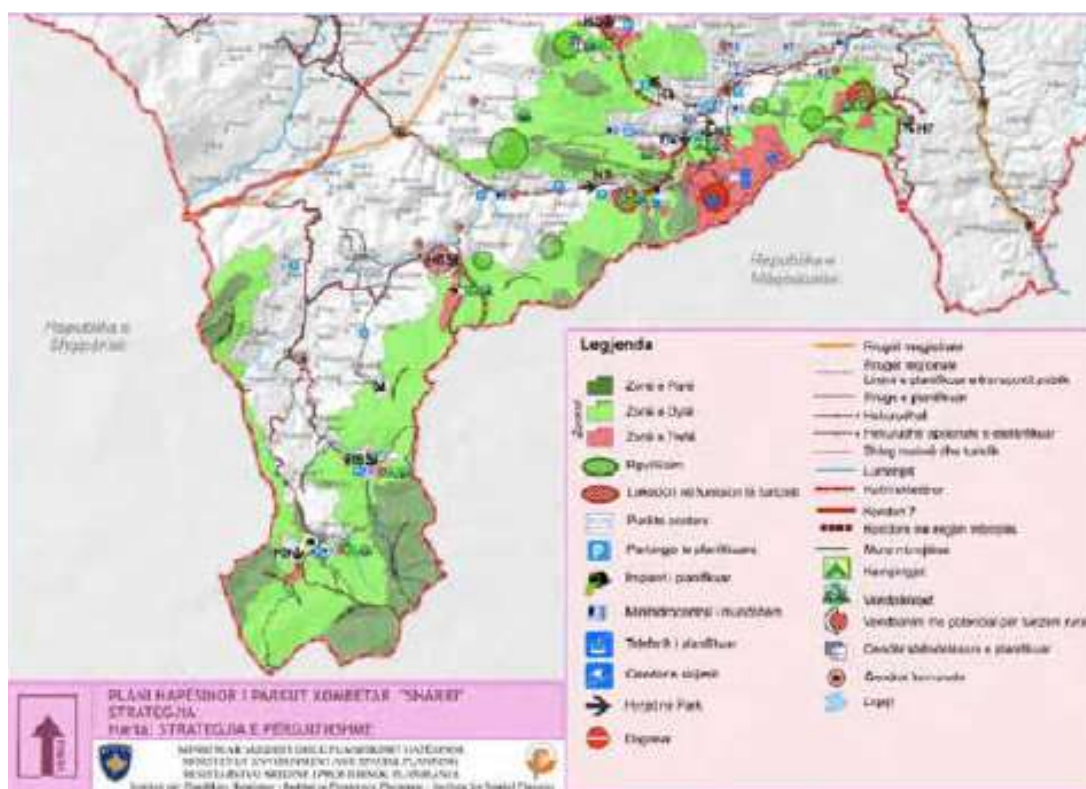

The main elements of the spatial plans at the central and local level which are framework or strategic plans contain graphical part (maps) and textual part: Urban Development Profile, Vision and Goals, Spatial Development Framework, Implementation Strategies and Actions, and Implementation Provisions. The differences are mainly at the scale of territorial coverage and at the competences that they have within the level of decision making authorities. They also differ in terms of stakeholder groups and the level of participation accordingly.

From 2003 until 2015, most of the municipalities in Kosovo drafted their MDP and UDP, and covered with urban regulatory plans partly or fully, the whole territory of the town/city, except Prishtina and Prizren, that used already completed the plans and drafted them later- Prizren 2009-2012 and Prishtina 2012-2013.

Public participation

By the Law, Spatial Planning in Kosovo is all inclusive and respects principles of good governance and public participation. Public participation is regulated by an administrative guidance. The process differs according to the planning level taking into consideration competencies in the decision making process. Spatial plans prepared in accordance with this Law are subject to public review. Further more, it is mandatory to include public consultations during the process of plan preparation. The consultations may be an extensive process, which depend on the level of the plan and needs for involving appropriate stakeholders.

The public review of any plan shall include a report on the review with complains, comments and proposals on the plan and justification of approval or rejection of the proposals.

Figure 3 illustrates stakeholder involvement and participation in the process of drafting the Spatial Plan of Kosovo which took place between 2003-2006.

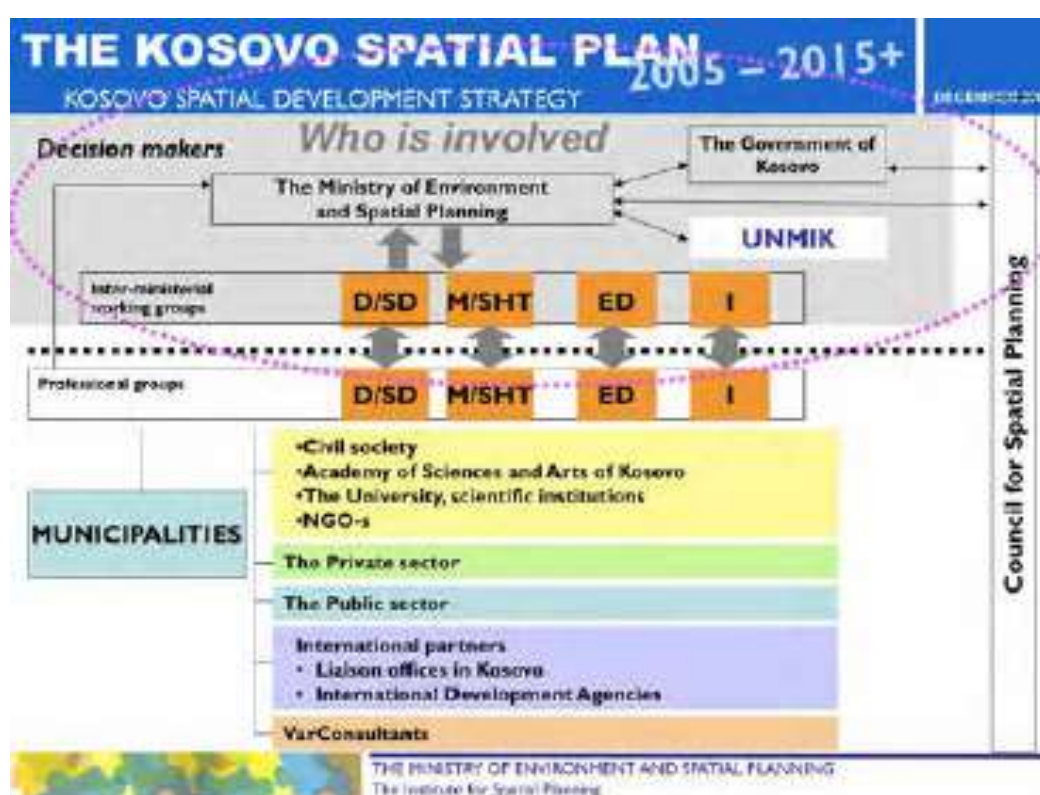

Figure 5 - Stakeholders involvement diagram in the process of drafting the Spatial Plan of Kosovo¹⁰

The Contribution of International Organisation

In 2000, UN Habitat established the office for Housing and Property Rights in Kosovo, a project that aimed to establish the property return to the owners, especially property claims linked to the war. In 2001 UN Habitat organised first training in community planning, a very important shift from master planning that used to be practiced in the former Yugoslavia. When the Ministry of Environment and Spatial Planning was established in 2002, UN Habitat became the main partner of the Ministry.

The contribution of UN Habitat was crucial for establishing the planning sector in Kosovo. Beside the direct support to the Ministry, their substantial contribution was in capacity building of planning professionals, mainly trained at the architectural schools.

¹⁰ Source: Kosovo Institute for Spatial Planning, Ministry of Environment and Spatial Planning

The Urban Planning and Management Programme, UPMP (2002-2003) funded by the Government of the Netherlands. It worked closely with the Ministry of Environment and Spatial Planning. It played a key role in development of the new planning law for Kosovo and also supported the first steps of establishing a the Institute for spatial planning. Another significant component of the Programme was its engagement with all 30 municipalities of Kosovo both from the planning perspective, and from the development of tools for gender mainstreaming in Kosovo municipal management. The Programme imparted comprehensive training to urban planners in the application of the strategic planning approach, through the Urban Planning and Management Framework (UPMF).¹¹ Within this programme, the new planning curricula for the Masters in Urban Planning and Management at the Department of Architecture, University of Prishtina was developed, involving Royal Danish School of Architecture and Aalborg University.

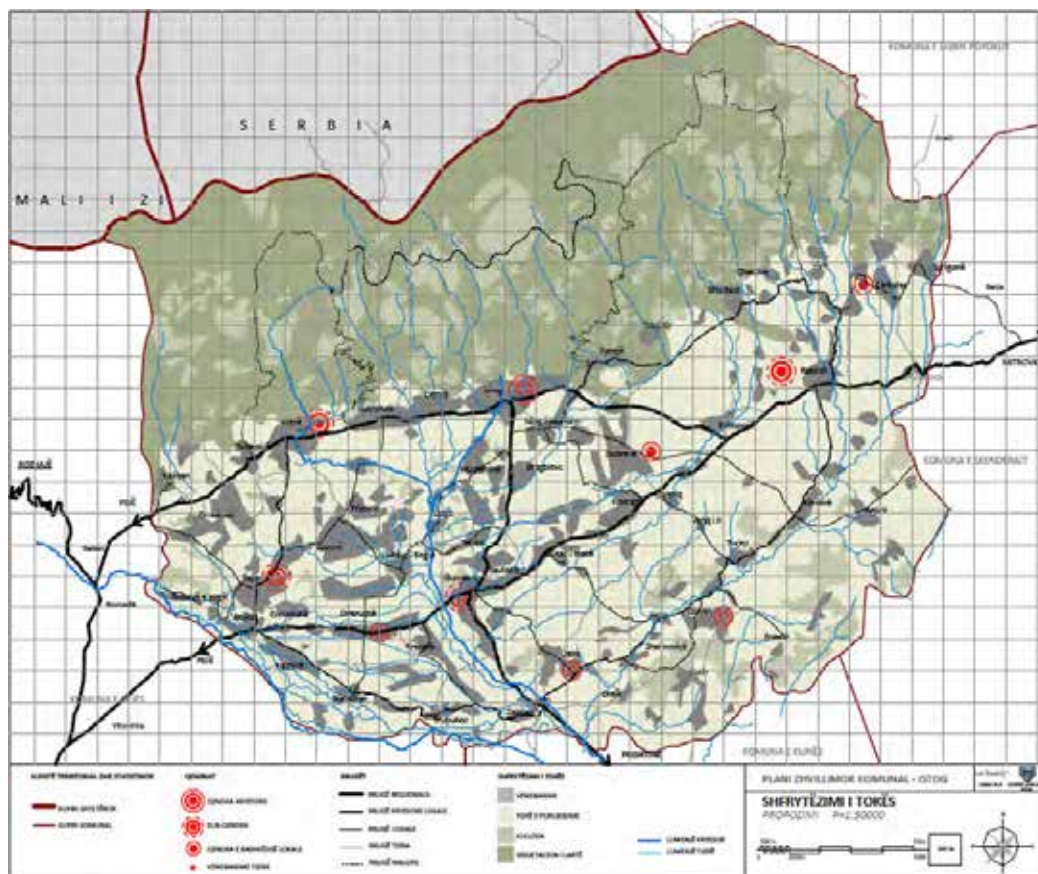

Figure 6 - Municipal Development Plan Istog - Land use plan - (Local Level)¹²

The Governance and Development Planning Programme, GDPP was funded by Dutch Government and started in 2003 and was completed in 2005. Its objectives were focused on continuing the assistance to further strengthen all three levels of spatial planning in Kosovo reflecting the linkages as required by the Law on Spatial Planning. It included more intensive capacity building at municipal and central levels to deal with spatial planning in an inclusive manner. The aim was to consolidate the new planning approaches, policies and legislation by making them more inclusive and compatible with countries in the region and in other parts of Europe.¹³ During this period of support, UN Habitat supported the establishment of the Spatial Planning Institute, responsible for drafting the spatial plans at the central level. The training of the staff of the institute was implemented with the Institute for Housing and Urban Development Studies from Rotterdam (IHS). The on job training continued for three years and was aimed to support the staf in drafting of the Spatial Plan of Kosovo.

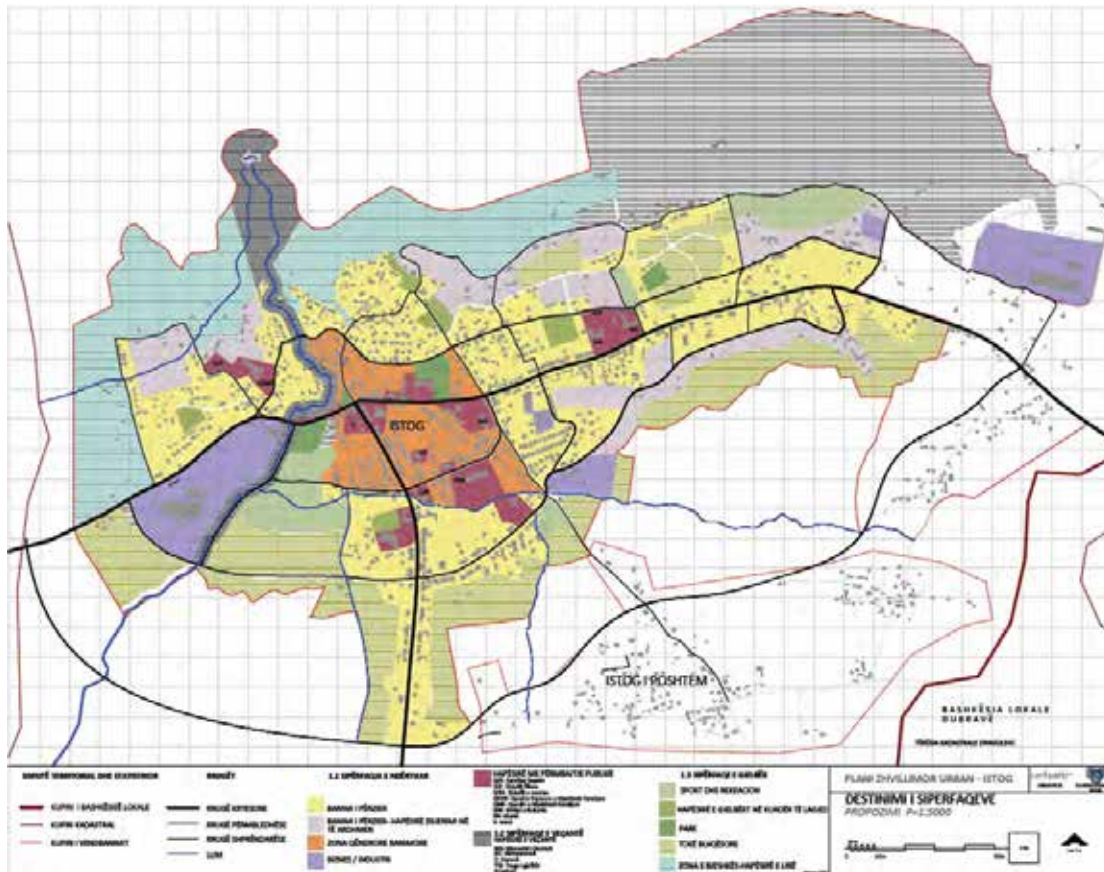

Figure 7 - Urban Development Plan Istog - Land use plan - (Local Level)¹⁴

The Municipal Spatial Planning Support Programme (MuSPP) funded by the Government of Sweden through the Swedish International ¹⁵ Development and Cooperation Agency (SIDA), was supporting 6 secondary municipalities through daily, intensive on-job advice and guidance in the preparation of spatial planning documents. It also assisted the Ministry of Environment and Spatial Planning and civil society organisations to support and actively participate in this process.

The Ministry of Environment and Spatial Planning was the key central level counterpart of the Programme. Close cooperation was maintained also with the Association of Kosovo Municipalities and the Ministry of Local Government and Administration. The Programme was carried out under the motto “Making Better Cities Together” which meant that by planning and working all together Kosovo cities can be a better place for living to all its citizens. The programme assisted partner municipalities in developing and implementing small demo-projects aimed at upgrading public spaces in urban areas.¹⁶ The MuSPP had two more phases from 2008-2011 and 2011-2014.

PART II - INDEPENDENT KOSOVO

The Constitutional Law of independent Kosovo 2008

Kosovo declared independence on February 17, 2008. Soon after the independence is declared, in April 2008, a new Constitutional Law¹⁸ was adopted. Although no direct provisions on planning are included in the constitution, some of the basic provision related to planning may be found below:

Constitution defines Kosovo as democratic state of its citizens. Kosovo is a multi-ethnic society based on principal of equality. The Republic of Kosovo ensures the preservation and protection of its cultural and religious heritage. The Republic of Kosovo protects and guarantees human rights and fundamental freedoms. Human rights and fundamental freedoms guaranteed by the international agreements and instruments.

The right to property is guaranteed by the Constitution. No one shall be arbitrarily deprived of property. The Republic of Kosovo or a public authority of the Republic of Kosovo may expropriate property if such expropriation is authorized by law, is necessary or appropriate to the achievement of a public purpose or the promotion of the public interest, and is followed by the provision of immediate and adequate compensation to the person or persons whose property has been expropriated.

New spatial planning context

The context for planning did not change much until 2013. In the new constitution, sectors which are governed by the Government are not mentioned at all. Environment and Spatial Planning neither, so by the constitution, there is no explicit order to establish Spatial Planning as a sector and its institutions.

After the constitutional law was adopted, necessary changes in the Law on Spatial planning in regard to protective areas, defined by the Ahtisari Plan¹⁹ had to be amended. These are cultural heritage areas of particular for the Serbian community.

Article 4 Protective Zones

4.1 A selected number of Serbian Orthodox Church monasteries, churches, other religious sites, as well as historical and cultural sites of special significance for the Kosovo Serb Community, shall be provided special protection through the establishment of Protective Zones. The objectives of the Protective Zones are: to provide for the peaceful existence and functioning of the sites to be protected; preserve their historical, cultural and natural environment, including the monastic way of life of the clergy; and prevent adverse development around them, while ensuring the best possible conditions for harmonious and sustainable development of the communities inhabiting the areas surrounding such sites.

Box 1 - Ahtisari Plan, Article 4

Spatial regulations in terms of buffer zones and restricted uses for these areas were given in the Ahtisari Plan which were also included in the Law on Culture Heritage Protection. These areas then had to be treated accordingly in the Spatial plan of Kosovo and Municipal Development Plans.

The New Law on Spatial Planning 2013²⁰

In 2012, the Ministry of Environment, under the influence of World Bank report on 'Doing Business' decided to start the procedures for drafting a new law because The Law on Spatial Planning 2003/30 was causing problems to development and the procedures for acquiring the planning permit, were 'highly' bureaucratic. This fact was based on a very narrow and limited survey, which World Bank carried out with individuals and businesses in Kosovo. The planning turned from a public sector interest to a planning based on the market economy, leaving public interest in the margins.

What happened for example in terms of institutional organisation is that the Spatial Planning Council at the central level and Committee of Spatial Planning at the local level were abolished. In the meantime, Ministry of

¹⁸ Constitution of the Republic of Kosovo

¹⁹ Comprehensive Proposal for the Kosovo Status Settlement-Ahtisari Plan

²⁰ Law on Spatial Planning - No. 04/L-174

Environment and Spatial Planning integrated Planning, Housing and Construction into a single department covering three sectors. In 2012, the Ministry of Environment, under the influence of World Bank report on ‘Doing Business’ decided to change the law because according to the afore mentioned report, Kosovo the procedures for acquiring the building permit, according to the law, were ‘highly’ bureaucratic. This fact was based on the limited survey, which World Bank carried out with individuals and businesses in Kosovo. What was interesting in the process of drafting the law, Department of Spatial Planning of the Ministry, had limited engagement, while the main actors were professionals involved from USAID, representing a pure American way of planning based on the market economy, living public interest in the margins.

The New Law introduced new spatial planning instruments. Zoning maps, an imported concept from the US, required at both central and local planning. These are regulatory instruments: Zoning Map of Kosovo in the whole territory of Kosovo for all developments which are government responsibilities and Municipal Zoning Map at the municipal territory for all other developments regulated by the municipality. Detailed regulatory plans are regulatory instruments which are not mandatory. They define the conditions for spatial regulation for urban or rural areas as defined in the Municipal Development Plan and Municipal Zoning Map. The relations between the policy institutions and instruments according to the new Law, are presented in Table 2 below.

Policy institutions			Policy instruments		
Level	Planning authority	Average number of inhabitants	Types of Plans	Description	Legal effect
Central	Ministry of Environment and Spatial Planning	2,000.000	Spatial Plan of Kosovo	Include vision goals and objectives and strategies Maps, implementation provisions and policy guidance	Guiding developments, protection of environment and national resources Binding for the national and local authorities
			Kosovo Zoning Map	A multi-sectorial document- defines type of land use and action measures Include maps and land use regulations for developments at the central level	Defines land use and regulates developments at the central level Binding for the national and local authorities

			Spatial Plans for Special Areas	<p>Include vision goals and objectives and strategies</p> <p>Maps, implementation provisions and policy guidance</p>	<p>Guiding developments, protection of environment and national resources</p> <p>Binding for the national and local authorities</p>
Local	Municipalities - (36)	from smallest 20,000-200.000 - Capital Prishtina	Municipal Development Plan	<p>Include vision goals and objectives and strategies for municipality</p> <p>Maps, implementation provisions and policy guidance</p>	<p>Guiding developments, protection of environment and national resources, may include regulatory provisions</p> <p>Binding for the local authorities</p>

			Detailed Urban Regulatory Plans	<p>Include maps and land use regulations, regulatory framework for buildings and infrastructure development</p>	<p>Detailed development plans including site plans</p> <p>Binding for the local authorities and landowners</p>

Table 5 - The Framework of Planning System in Kosovo -No.04//L-174-2013

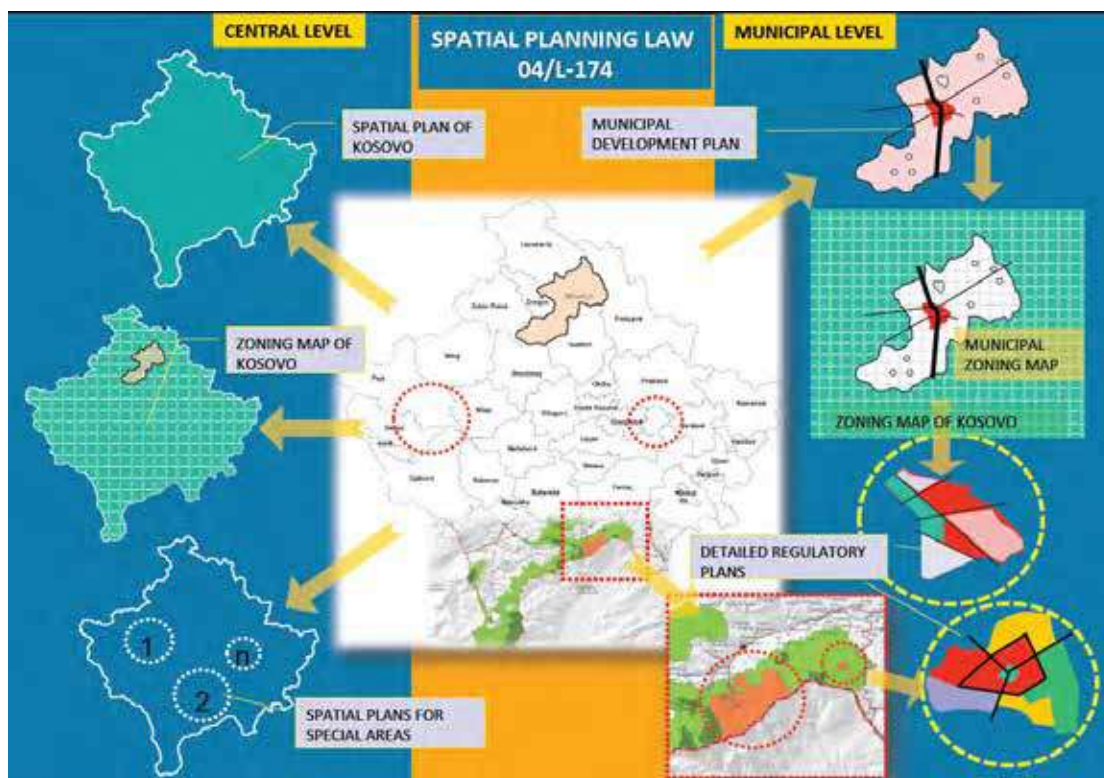

Figure 8- Planning System in Kosovo according to the Law on Spatial Planning 04//L-174²¹

The new planning instruments are more comprehensive so they take much longer to draft them. For the municipalities the process is longer and harder. A certain degree of centralisation is now on place and does not comply with the European planning practices. The fact is that municipalities are still acting according to planning instruments drafted based on the Law on Spatial Planning 2003/30, due to missing administrative guidance's that supports plan-making.

Protected Areas²²

Protected areas is a new provision of the Law on Spatial Planning. When approved, protected areas define the long-term protection and preservation of a geographical area with special features of natural resources, flora and fauna, cultural heritage and cultural landscapes, with a potential of social and economic development for the country.

Protected area consists of site perimeter designated under protection and the buffer zone of fifty (50) or one hundred (100) meters from the perimeter, or as it is determined by the competent institution. The aim of the protected area is to restrict constructions or other activities that could damage the natural and cultural heritage features. Depending on the features a protected area will be approved by the Government as a Special protected area through the Zoning Map of Kosovo.

AGENCIES AND MECHANISMS FOR DEVELOPMENT AND CONSERVATION

Approach to development

A mixed approach development involving public and private sector is in place in Kosovo. The role of public sector is usually to enable and promotional role as well as resource coordinating role in terms of land acquisition in implementing spatial plans, such as in big infrastructure projects implemented with public private partnerships (recent projects of highways, airport, new power plant, etc).

²¹ Source: Kosovo Institute for Spatial Planning

²² Law on Special Protective Zones No. 03/L-039

There is also strong involvement of private sector with limited development control from the government. Often this is not within a strong plan-led framework and very often plans record actual development, in particular investments in business and production facilities in particular alongside the main infrastructure.

Land policy mechanisms

In Kosovo, the only land mechanism for plan implementation is the Law on expropriation²³ which deals with land acquisition for the public interest. The constitutional law defines that everybody has the right to his/her property. However, the land may be subject of expropriation for the public interest. A process of expropriation and compensation based on the market values is lead by the Ministry of Finance. Acquisition of the land is possible only for the public interest and for non discriminatory purposes. The expropriation authority at the local level, is the Mayor of a city/ town, or a public body authorised by the municipal assembly. Expropriation is carried out for:

- Implementation of urban and spatial plans adopted by the Municipality.
- Construction of new and improvement of existing technical and social infrastructure
- Licences for exploitation of mineral resources that has been granted to the Municipality

At the central level the government is responsible authority for expropriation of the land for the developments with particular importance for the whole country. Expropriation deals exclusively with the properties within the municipal territory for the following purposes:

- Implementation of spatial plans adopted by the Ministry of Environment and Spatial Planning,
- Implementation of government responsible public social and technical infrastructure projects.
- Natural and Cultural heritage sites
- Areas of storing and disposal of dangerous materials and products
- Energy production and mining areas and mineral extraction, dams

DEVELOPMENT

In Kosovo there are many agencies and organizations dealing with development. They are usually linked to government sector authorities or with different international development agencies. International Development Agencies present a very important chain of development actors such as EU Office, UNDP, USAID, GIZ, DFID, SDC, ADA, SIDA World Bank, EBRD etc. Since after the war, these agencies have played a crucial role for Kosovo reconstruction and development. They are still very important partners in implementation of government development policies. Some of the local agencies are listed below:

Association of Regional Development Agencies

The Association of Regional Development Agencies (ARDA) is a network for the implementation of Kosovo and EU policies and is an independent, non-governmental organization established in January 2013 by the five Regional Development Agencies (North, East, West, South and Centre) in Kosovo.

Kosovo Cadastral Agency

Established by UN-Habitat in 2000, Kosovo Cadastral Agency is the central authority for the maintenance of cadastral database, property registers, mapping and GIS. It is also the central authority for geospatial data infrastructure. The rights, responsibilities and overall mandate of the KCA is regulated by the Law on cadastre and other legal acts, all accessible through the Kosovo Geoportal, the cadastre information database.

²³ Law on Expropriation of Immovable Property - No. 03/L-139

Kosovo Forestry Agency

The KFA is responsible for issues related to the regulation of forests and forest lands, and management of publicly owned forests and forests in Kosovo national parks in, except those issues that the law specifically assigns to any other government authority.

Kosovo Agency of Statistics

Kosovo Agency of Statistics is a professional institution which deals with collection, processing and publication of official statistical data since 1948.

The Agency provides qualitative statistical data in time and space so that users have reliable base to conduct regular analysis in the interest of planning and project development at the municipal and country level. ASK support government institutions, scientific institutes, research academies, businesses in order to provide proper information for decision-makers and other users in Kosovo.

PROTECTION OF THE ENVIRONMENT

Environmental Protection Agency

Kosovo Agency for Environment Protection (KEPA) is a government institution that engages, through integrated environmental monitoring, efficient system of environmental information and continuous reporting on the environmental situation, to maintain quality of air, water, soil and biodiversity, promote use of renewable energy sources and sustainable use of natural resources in order to ensure a healthy environment for generations present and future in harmony with the progress of economic and social developments.

Institutes, within KEPA are: Kosovo Institute for Nature Protection, Kosovo Hydro-meteorological Institute, and Kosovo Institute for Spatial Planning. Whereas, Directorates within KEPA are: Directorate of Environmental Monitoring, Assessment, and Reporting; and Directorate of National Parks.

The Institute for Cultural Heritage Protection

The Institute for protection of the cultural heritage deals with the issues of protection, reconstruction and revitalization of the cultural heritage sites and monuments mainly concerned with the central level issues in cultural heritage protection. It operates as a central government body linked to the Ministry of Culture, Youth and Sports. At the local level, there are regional centers for culture heritage protection which are subordinated to the institute at the central level.

Archeological Institute,

Archaeological Institute also part of the Ministry of Culture, Youth and Sports, deal with archeological sites - research, archaeological diggings, reconstruction and management.

POLICIES

A system of well developed and integrated policies is very important for a development country such as Kosovo, in particular as a newly established country. From 1999, efforts to develop sector policies have contributed to improve governance system in providing better quality of life, although it is still necessary to align cross sectorial cooperation for necessary synergies to accelerate economic and social development.

Through the 10 years of independence, there was an extraordinary commitment to draft the sectorial policies linked to spatial development. In particular housing, environment, industry, tourism, energy, transport, cultural heritage, agricultural land and mineral resources are well covered with the legal framework and policy strategies. These policies are now guiding planning process at the central and local level.

Most of the policies tend to be aligned with the European policies although a lot has to be done yet, due to very difficult political context in the region and difficulties caused by the unrecognised position of the Republic of Kosovo from five EU countries.

Conclusions

Measuring the outcomes of the period of 18 years would not be an easy task for those who are outsiders. For those who were actors in several tasks such as legal framework, capacity building, planning at the central and local level, the achievements may be seen subjectively, as they put a lot of efforts to bring profession to the state in which we could talk about planning that leads the development and not planning that is serves for recording developments.

At the central level, the Ministry, beside the work on legal framework, the Institute for Spatial Planning is responsible for drafting of the Spatial Plan for Kosovo, already under the review process. and plans for special areas such as two National Parks- Bjeshket e Nemuna (Coursed Mountains) and Sharr Mountains, Mirusha plan which is a Natural Park and coal mining area close to Prishtina capital. Recently the Institute has developed sectorial national policies linked to the spatial planning.

Most of the cities and towns have already drafted plans or are currently reviewing plans according to the requirements of the new Law on Spatial Planning. The plan implementation may vary from city to city and is mostly politics that affects changes that violates the planed development. Within the municipal administration, there are established planning departments, combined with housing and environmental protection, responsible for organising and leading the planning process. Although most of the plans are drafted through the consultancy, there is a significant role of municipal planning officers in the plan preparation and decision making process.

Public participation as a way od democratisation, during the years shifted from information and active listening, the public consultation and direct involvement of the public and civil society has been improved. And there is a growing interest to be involved in planning process from the civil society organisations. A process of capacity building for participatory planning has been developed for more than five years now. People are more aware of planning activities as municipalities publishes all planning documents in the Municipal online platforms. These platforms helps citizens to get information, to make online applications for what ever they might be interested in regard to planning and construction.

From 2002 to date there was a continuing process of capacity building led by UN Habitat programmes, from plan making, public participation, policies and decision making, always trough the on job training of the planning officers. These programmes were tailored for both planning officers at the central and local level, including civil society and university. At the university the planning is taught at the Department of Architecture and is based on the planning system so students are able to understand their role in a planning process. The problem based learning pedagogical model is applied so student can actually experience a real planning context.

Although from an initially decentralised planning system, with the new law, the planning process at the local level is not only monitored by the central level, but it is also controlled in terms of decisions taken. This is a step back if we compare to decentralised planning systems in Europe. The new Law on Spatial Planning has given the right to the Ministry to examine thoroughly all municipal plans before they are approved at the municipal assembly, which is an almost impossible task to preform due to limited number of staff.

In 2006, while participating in World Urban Forum in Vancouver, Forbs Davidson introduced myself and Mr Luan Nushi to some colleagues from RTPI as responsible for establishing the Kosovo planning system in a period of four years. The President of RTPI replied "... In four years?! That's really an achievement!" Of course, setting a planning system is not possible in such a short time, but Mr Davidson wanted to say that the commitment to make things happened were extraordinary.

Acknowledgements

I would like to thank the Presidency of Kosovo for the full financial support of participation in this Congress. Without the Presidents generous support, presentation of this paper would not be possible. .

Responsibilisation in fish habitat rehabilitation and stewardship

Kieran Gregory¹, Dr Deanna Grant-Smith²

¹Queensland University of Technology, kieran.gregory@qut.edu.au

²Queensland University of Technology, deanna.grantsmith@qut.edu.au

Abstract: Neoliberal thought has influenced how government policy is crafted, resulting in a stepping away by government in the implementation of policy solutions, and an ever-growing list of non-state actors enlisted to advance environmental policy agendas. The actions of these non-state actors are positioned as integral to solving environmental policy challenges such as habitat rehabilitation. Drawing on the theory of responsibilisation as a technique of governance this research explores the ways fisheries stewardship policy seeks to mobilise non-state actors to accept responsibility for addressing environmental problems which have previously been the responsibility of the State. Dvora Yanow's approach to interpretive policy analysis is used to analysis key policy artefacts to identify the discursive strategies used to attribute blame for fish habitat degradation and responsibility for rehabilitation actions in an Australian state. This research uncovers a tension between the attribution of blame for the degradation of fish habitats and attempts to mobilise recreational fishers to take responsibility for remediation action through engaging in voluntary rehabilitation actions. An analysis of the selected texts highlights how recreational fishers are constituted as moral, political and authoritative actors, and by extension responsibilised to ameliorate degraded fish habitats.

Keywords: responsibilisation, stewardship, interpretive policy analysis, recreational fishing.

Introduction

One of the more profound challenges in environmental governance lies in responding to the myriad diffuse threats to ecosystems to ensure their ongoing social and economic utility and ecological sustainability. The core challenge for government lies in determining how best to deploy increasingly limited public resources in the most effective manner to respond to these policy challenges (Howes *et al.*, 2015). An ever-growing list of non-state actors—individual citizens, community groups, as well as other non-government and business entities—have been enlisted to advance environmental agendas (Shamir, 2008, Jansssen and Estevez, 2013). This positioning of the actions of non-state actors as panacea to solving environmental policy challenges is a sufficiently significant shift of responsibility from the state to be worthy of academic and policy attention.

One of the hallmarks of neoliberalism has been a move by state actors to rely on non-state actors to perform tasks traditionally carried out by the state (Shamir, 2008). This move has extended to the realm of natural resource management and has manifested through the actions of fisheries managers seeking to integrate recreational fishers into solutions to some of the most pressing environmental challenges. A desire by policymakers to mobilise recreational fishers and increase their involvement

in participatory stewardship activities can be analysed through the concept of responsabilisation. Responsibilisation refers to the expectation and assumption of the reflexive moral capacities of social actors (Shamir, 2008). The remote and indirect actions of the state are enabled by the establishment of a form of self-hood, whereby the agent (here, recreational fishers) produces the ends of government themselves, allowing the state to govern at a distance (Pyysiäinen *et al.*, 2017). Authority and rule are exercised by individuals acting upon themselves, rather than giving way to some externally enforced agent, such as the state (Pyysiäinen *et al.*, 2017).

This paper explores the movement towards public stewardship of natural capital, and the trend towards devolving responsibility for the management of fisheries habitat to non-state actors. A case based study of fisheries policy in the Australian state of New South Wales (NSW) is used to explore the ways that recreational fishers have been responsabilised to shoulder a disproportionate stewardship burden in ameliorating environmental problems. Whilst this burden is framed in terms of civic responsibility, it is ultimately a manifestation of responsabilisation.

The public stewardship of natural capital

Stewardship can be understood as ‘the responsible use (including conservation) of natural resources in a way that takes a full and balanced account of the interests of society, future generations, and other species, as well as of private needs, and accepts significant answerability to society’ (Worrell and Appleby, 2000: 263). Central to the concept of stewardship is the idea of looking after something ‘in trust’ for someone else, be that nature, society or future generations (Worrell and Appleby, 2000). Engendering high levels of stewardship amongst users of natural resources is viewed as an important policy outcome because it fosters support for rehabilitation and conservation measures, even when these place restrictions on the use of or access to these resources (Granek *et al.*, 2008). Statutes and regulations prescribing unconditional environmental standards, with punitive consequences are considered to be key components of the traditional regulatory toolbox, and can form part of the regulatory mix deployed by policymakers (Preston, 2012). The trend thus far, however, has been for policymakers to adopt an approach which actively constructs and deploys notions of stewardship in an effort to generate public good conservation outcomes, rather than solely relying on statutory obligations (Cooke and Moon, 2015). This trend can be partly explained by a reconfiguration of the societal role played by both state and non-state actors.

There is a significant body of political theory advocating for an increasingly participatory style of government – one in which the citizenry has the opportunity to have meaningful input into decisions that will impact them (Cameron and Grant-Smith, 2014). This has coincided with a shift in perceptions of the public as being a homogenous group to being perceived as diverse and heterogeneous (Cameron and Grant-Smith, 2005). A more participatory approach has also been linked to a growing acceptance that many of the key challenges facing society today – particularly complex social and environmental issues – may be best resolved by sharing responsibility with, and with the input of the stakeholders who are directly impacted by them (Head, 2007, Grant-Smith and Edwards, 2011, Serrao-Neumann *et al.*, 2015).

The mere presence of policy instruments, legal frameworks, and support programs does not in and of its own result in better public participation or policy outcomes. Arguably, genuine public participation strategies (particularly those that vest power in the hands of the community) could significantly

improve engagement by the community with planning and environmental management decisions, encourage collective debate and reinforce the legitimacy of final decisions, if executed correctly (Serrao-Neumann *et al.*, 2015). Whether such involvement necessarily flows on to deliver high quality outcomes is contested (Brody, 2003, Serrao-Neumann *et al.*, 2015). There are clear barriers to effective participation, with the obvious one being the reluctance of policymakers to devolve power and control of decisions, in conjunction with the responsibility of carrying out participatory activities, to targeted actors (Head, 2007, Serrao-Neumann *et al.*, 2015). By necessity, this also raises the question of whether this power and control should be devolved, or indeed whether the citizenry should accept such a devolution. In an environmental context, concerns have also been voiced regarding the lack of measurable conservation outcomes achieved, combined with those criticising participatory governance as a manifestation of neoliberal thought (Fletcher, 2010). Faced with trying to solve complex environmental problems, governments tend to rely on solutions driven by technocrats, who construct participatory processes which reinforce the beliefs of policymakers (Fletcher, 2010)

Critical social science engagement with natural resource management has increasingly engaged with the concept of neoliberalism, due to its predominance in shaping contemporary policy and discourse (Fletcher, 2010). The relationship between the environment and neoliberalism, with its calls for allowing ‘the market’ to address environmental governance issues, is one that is complex and inexplicable (Mansfield, 2004). The impacts of this restructuring of economic and social life, as well as on the management of natural capital, have been immense (Meynen and Doornbos, 2004). These impacts include: the privatisation of functions previously performed by the state through putatively market-based schema, the rescaling of governance and devolution of regulatory responsibilities to local government (often without proportional transfers of power), and a shift from relying solely on binding laws to achieve compliance to increasingly voluntary, neocorporatist regulatory frameworks premised on non-binding standards and self-regulation, public-private cooperation and greater participation from the citizenry (McCarthy and Prudham, 2004, Fletcher, 2010). This shift is evident in the policy instruments that are being deployed by governments across jurisdictions in an endeavour to deliver sustainable ecological outcomes.

The move towards neoliberal modes of governing has seen an increasing emphasis on the role that private actors can play in the delivery of services that historically have been seen to be the responsibility of government (Gray, 2009, Soneryd and Ugglä, 2015, Mitlin and Bartlett, 2018). An important assumption underpinning contemporary Western capitalism, and neoliberal governance in particular, is that processes of governing and responsibility-taking are interlinked (Pyysiäinen, *et al.*, 2017). Whilst interpretations around the tasks which should fall within the purview of the public and private sectors have swung over time (Reinecke and Ansari, 2016), there has been a clear trend in recent years to shifting responsibility to non-state actors, and to encouraging civil society actors to accept additional responsibilities, without a commensurate transfer of power (Gray, 2009, Thörn and Svenberg, 2016). State policy actors have mobilised individuals, private enterprise, and communities, while divesting themselves of the responsibility of meeting the social, environmental and economic needs and aspirations of the citizenry (Ilcan and Basok, 2004). This process is known as responsibilisation, a concept which serves as the practical link connecting ideal-typical schemes of governance to the practices of policymakers on the ground (Shamir, 2008).

Responsibilisation operates at the level of the individual, reconfiguring roles and identities in order to mobilise designated actors to undertake and perform self-governing tasks (Shamir, 2008, Summerville and Adkins, 2008). As a technique of governance, it is squarely premised on the construction of moral agency as a necessary precondition for ensuring an entrepreneurial, self-sufficient disposition in the citizenry, and socio-moral authority in institutions (McCarthy and Prudham, 2004, Shamir, 2008). A unifying theme across neoliberal policy programs is the desire to create congruence between economic rationality and moral responsibility (Shamir, 2008). In the neoliberal paradigm, networks consisting of government agencies, businesses, environmental advocacy groups and other stakeholders are established to either self-regulate (based on discourses of moral responsibility) or to establish standards and codes which are meant to function as either an alternative to, or complement to, traditional regulations (Thörn and Svenberg, 2016).

A case study of responsibilisation in fisheries habitat rehabilitation

Through a process of cyclical corpus building (Mautner, 2008) forty key policy artifacts deemed to be significant carriers of meaning were collated and analysed. These included policy documents, legislative and regulative texts, government reports, brochures, social media posts and other materials explicitly or implicitly authored by the NSW Department of Primary Industries (DPI), which at the time of the study was the relevant department with carriage of fisheries in NSW. Texts were selected where the primary focus was on the construction of the problem of fish habitat degradation in the NSW fishery, or on the framing of solutions to respond to the stated constructed problem. A purposive method of text selection was utilised, which attempted to capture the important texts – ‘those which are widely distributed, that are associated with changes in practices, or that were produced in reaction to a particular event’ (Phillips and Hardy, 2002: 73). The selected texts were authored during the period 2009 – 2018. Taken together, the collated corpus of naturally occurring data (Silverman, 2011) provides a useful insight into the NSW DPI’s strategic aims.

Yanow’s (2000) approach to interpretive policy analysis informed the methodological decisions made in the course of this study. Interpretive policy research encompasses a range of analytical approaches which are primarily aimed at studying language through narratives and discourses, objects via symbols and programs, and actions via rituals and observations (Yanow, 2000; Wagenaar, 2006; Hendricks, 2007). Interpretive policy analysis has been used in a number of environmental governance contexts, and has provided new ways of thinking about contemporary environmental policy challenges (Grant-Smith, 2015, Aukes *et al.*, Behagal *et al.*, 2017, Osborne and Grant-Smith, 2017). The texts were analysed through a process which involved: identifying policy artefacts that were significant carriers of meanings and the communities for whom this meaning was shared, identifying the meanings being communicated through these artefacts and their entailments, key points of conflict and conceptual sources, and finally exploring the implications of different ways of understanding and ways of bridging these differences (Yanow, 2000). Through the interrogation of language, representations, and absences, interpretive policy analysis can be used as a mechanism to understand and uncover implicit and explicit policy intentions (Osborne and Grant-Smith, 2017). Specifically the analysis identified how the NSW DPI frames fisheries habitat degradation, how solutions to the degradation are constructed, and which stakeholders groups are attributed with responsibility for enacting the articulated policy solutions.

Findings

The term recreational fishing captures non-commercial fishing activities which are not the fisher's primary resource for meeting their essential nutritional requirements (Granek *et al.*, 2008). As an activity, recreational fishing is extremely popular, with approximately ten per cent of the global population participating in it in any given year (Granek *et al.*, 2008). Participation rates in Australia are slightly above the global average, with around three million Australians participating in the activity each year (Copeland, 2012, Barwick *et al.*, 2015). The most recent figures for NSW suggest that around 12% of the population participate in recreational fishing each year (Department of Agriculture and Water Services, 2018). The recreational fishing industry makes a significant contribution to social and economic life in Australia, with the activity contributing an estimated \$1.8 billion per annum to the national economy and sustaining around 90,000 jobs (Department of Agriculture and Water Services, 2018). Recreational fishers themselves have become powerful stakeholders in fisheries management, as is evidenced by their influence over the policy processes governing recreational fishing activities in NSW.

The case study which forms the basis of in this research project meets Flyvbjerg's (2006) definition of a critical case, as it provides a valuable opportunity to understand how the degradation of NSW fish habitats is framed in stewardship policy, how the solutions to the degradation of NSW fish habitats are constructed, and which stakeholders are attributed blame for enacting the constructed solutions. Within the Australian context, policymakers in NSW have been at the forefront of policy enactments whose primary aims are to mobilise stakeholders to volunteer to ameliorate degraded fish habitats and to increase involvement in participatory stewardship activities. Through the NSW DPI, the NSW Government has been a key driver in establishing networks such as the Fish Habitat Network and the Fishers for Fish Habitat program, both of which are focused on mobilising recreational fishers to increase their involvement in participatory stewardship activities (Fish Habitat Network, n.d, NSW DPI, n.d.). The focus of the NSW DPI on increasing participation in stewardship activities, and the availability of artifacts authored by the NSW DPI which are evidence of pursuit of this aim, provides an excellent context through which to explore the concepts central to this research

Changing stewardship responsibilities in fisheries habitat management

Climate change, overexploitation of resources, habitat destruction and pollution have contributed to the degradation of the world's fisheries (Granek *et al.*, 2008, Al Mamum, 2015). NSW has a diversity of fish habitats, including the presence of cooler high country, warm interior freshwater systems, a narrow continental shelf, and coastline interspersed with beaches, estuaries and rocky headlands (NSW Parliament, 2010). There have been numerous studies conducted which suggest there has been significant loss and degradation of fish habitats in NSW since European settlement (Balcombe *et al.*, 2011, Rogers *et al.*, 2016). For example, the extent of fish habitat in coastal NSW that is either degraded or completely lost since European settlement has been calculated at 62, 258 ha, which equates to over 70% of the total area at the time of European settlement (Rogers *et al.*, 2016). In an assessment of fish species, hydrology and macro-invertebrates, Davies *et al.* (2010) found twenty out of twenty four river basins to be in poor or very poor condition. Up to 97 per cent of assessed river length in NSW has been modified, and fish passage in many rivers and creeks has been blocked by floodgates, weirs, causeways, and impoundments, the combined impact of which has a negative influence on levels of production of fish species (NSW Parliament, 2010).

When articulating the threats to fish habitat, the NSW DPI names the destruction of fish habitat as the primary threat to the ‘health, abundance and diversity of fish in NSW’ (NSW DPI, n.d.-a: para 1). The NSW DPI names diffuse activities including agriculture, urban and industrial development, and land use as activities which have impacted on marine environments. This can be seen in statements such as ‘urban development associated with heavily populated areas has altered marine environments’ (NSW DPI, n.d.-i: para 2) and ‘agriculture, urban and industrial development has impacted... through land clearance, agriculture, dredging, reclamation and water development’ (NSW DPI, n.d.-a: para 2). In this series of texts, the NSW DPI names eleven threats to fish habitat: acid sulfate soils, barriers to fish passage, climate change, cold water pollution, degradation of riparian vegetation, fish kills, impacts of urban and rural development, pests and diseases, removal of large woody debris, water flow and block and chain in sensitive habitats (NSW DPI, n.d.-a).

Throughout the analysed policy artifacts, causality is attributed in broad, diffuse terms to a range of human-induced activities. These activities include (amongst others) urban and rural development, the introduction of species and pathogens, construction of structures which amend water flow, and clearing of riparian vegetation. The absence of attribution of blame for the problem of fish habitat degradation to actors who are having the greatest impact on these habitats is consistent across the corpus of texts analysed. As the NSW DPI (2016: 2) states ‘rivers, creeks and wetlands through NSW have undergone extensive changes due to urban, industrial and agricultural development.’ In these texts, however, there is an apparent reluctance to attribute causality for any of the key identified threats to specific stakeholders or users of fish habitats. Although there is some evidence that recreational fishing is as negatively impactful as commercial fishing, there is significant disagreement relating to this among key stakeholders, and regardless the damage through these activities pales in comparison to other sources (NSW Parliament, 2010, Young *et al.*, 2016). Instead, for the most part, the attributed causes are able to be linked back to developers, agricultural interests and farmers, commercial interests, and government action (or inaction, as the case may be).

In order to prevent further degradation, and ameliorate the damage already done, policymakers have sought to rely on a range of regulatory measures in order to ensure the ongoing social and economic utility of fisheries, and to balance the competing priorities of resource use and preservation (Al Mamun, 2015, Young *et al.*, 2016). Examples include legislation that limits the number and size of fish that fishers are able to catch, when and where fishers are able to access particular environments, and the technology and gear that fishers are able to use (Cooke *et al.*, 2013). However, governments are increasingly moving away from wholly relying on compliance with legislative and regulatory mechanisms in order to achieve environmental policy aims. Instead, there is a trend towards deploying policy instruments to foster participatory behaviours amongst key stakeholder groups in order to deliver environmental governance solutions. In the fisheries arena, this includes targeting recreational fishers (Copeland, 2012).

Fisheries management has historically tended to rely on ad-hoc, reactive approaches to policy development and enactment. On occasion, these approaches have sometimes failed to produce desired behavioural changes, which may be attributed to the objectives, possible actions and resulting outcomes being treated as simple and known (Irwin *et al.*, 2011). Whilst the traditional regulatory toolbox used to manage recreational fisheries is diverse, it is apparent that policymakers see an opportunity to deploy new mechanisms in order to achieve compliance and environmental objectives, relying heavily on voluntarism (Cooke *et al.*, 2013). With this in mind, this research identified that

there is a lack of discursive connection between which actors are framed as the causal agents of the degradation of fish habitat in NSW and which users are ascribed responsibility for implementing the constructed solutions. This is a clear point of conflict within the analysed texts. By keeping the blame for fish habitat degradation diffuse, the collated corpus of texts, whose audience is primarily recreational fishers, do not provide the full story. There is a significant disconnect between causal attribution, and the attempts to responsabilise recreational fishers to take ownership of the problem of degraded fish habitats. The mobilisation of recreational fishers occurs in a seemingly decontextualised, depoliticised mode, and from the analysed texts it is unclear whether this is recognised by policymakers.

Shifting responsibility for fisheries habitat management

If actors are understood in terms of the consequences that flow from their actions as rights and duty bearing units, then a shift in the rights and duties assigned to actors will change the social consequences of their actions and simultaneously the discursive nature of their agency (DeWinter, 2001, Shamir, 2008). This position has previously been articulated in the context of corporations assuming socio-moral obligations that were once considered solely the role of the state. Although focussing on recreational fishers, the implications of this can be extended to citizens more broadly. Through the prism of responsabilisation, one can see a discursive shift underway, with social actors taking on additional responsibilities for tasks previously within the purview of the state. Abrahamsen (2004) frames citizens as agents who are conscripted – active creators of their own future rather than objects of external statist benevolence. This research suggests that ideally, this is how policymakers would like to position non-state actors such as recreational fishers – rather than people passively benefiting from the NSW DPI remedying degraded fish habitat themselves, instead recreational fishers are being positioned to take charge of their destinies and that of the environments of which their leisure activity depends. In such a paradigm, responsibility can be understood as one of obligation to those individuals care about the most – their family, neighbours, colleagues, and ultimately the community (Summerville and Adkins, 2008). Whilst in the corpus of analysed texts a broad array of stakeholders are ascribed responsibility for certain solutions, recreational fishers are the primarily attributed with carrying out their implementation. This is arguably as a result of both the sheer number of people engaging in recreational fishing as an activity, as well as a result of the vested interest that recreational fishers have in quality fish habitat.

Responsibilised actors, be they individuals or those acting as part of a club, are constructed as virtuous, particularly when they accept responsibility for maintaining the property of the state. For example: ‘... Bass Sydney took matters into their own hands and applied to Council for co-management of the reserve. With approvals granted, the Club applied for a habitat action grant to initiate rehabilitation of the site’ (NSW DPI 2016: 6). In this case example, the NSW DPI state that the Club are ‘aware that their hard efforts need to be preserved’ and that they have committed to maintaining the site (which is an asset owned by the State) for five to ten years (NSW DPI 2016: 6). The case example further notes that the Club has reached the ‘considerable milestone’ of 1000 hours of volunteer labour allocated to maintaining and restoring this site (NSW DPI 2016: 6). The actions of the Club are lauded and celebrated by the NSW DPI as a positive example that other clubs can follow. Although the efforts of the Bass Sydney Club were considerable, non-state actors are often encouraged to start small - ‘We all just need to start somewhere, even in our own backyard’ (NSW DPI 2016: 12). Within this context, the term ‘our own backyard’ is used to refer to state assets.

The responsibilisation of recreational fishers

The analysis of the selected texts provides evidence of a desire to shift how governmental authority is deployed, with an emphasis on voluntary mechanisms operating in concurrence with regulatory mechanisms that have the coercive backing of the state. Recreational fishing remains a highly regulated activity. The NSW DPI has used a number of rhetorical devices to shape perceptions, and encourage collaboration between recreational fishers and relevant government authorities at the state and local level. The former Executive Director Fisheries NSW, Dr Geoff Allan stated ‘Fish habitats underpin the productivity of our State’s fisheries resources. It is therefore vital that the government and community work together to protect and restore them, in order to sustain our fisheries in the long-term’ (NSW DPI, 2013: iii). The use of the word community here is contextual, with the implication being recreational fishers and users of fish habitats are the key stakeholders who need to work with government to protect and restore fish habitat.

The NSW DPI encourages collaboration between recreational fishers and local, state and federal government, in order to rehabilitate degraded fish habitat. This is achieved through praising actors who ‘took matters into their own hands’ (NSW DPI 2016: 6) as well as through celebrating outcomes which ‘significantly demonstrated that small community groups can collaborate with government to achieve positive outcomes for native fish’ (NSW DPI: 2016: 10). The NSW DPI uses phrases like ‘strategic partnerships’ when advocating for collaborative efforts, and links the projects delivered through these partnerships back to the improved utility of fish habitat targeted by recreational fishers (NSW DPI, 2016: 7). Increasing the participation of non-state actors, particularly those who are perceived to a stake in the issue at hand, provides an opportunity for the state to govern through regulated choice by strategically creating moral, autonomous actors with ethical commitments to those around them (Summerville and Adkins, 2008).

What is apparent here is that the NSW DPI is advocating disjunctive ideologies and goals through the message of ‘more habitat equals more fish’, and the use of case studies to highlight what volunteers can achieve in conjunction with the state. The analysed texts construct recreational fishers as empowered volunteer citizens who are meaningfully able to improve the quality of natural capital for the benefit of themselves, their communities, and for future generations. This construction of recreational fishers may be conceptualised through two frames. The first is one that is individualised, focusing on the benefit to the recreational fisher herself through increased fishing opportunities that arise as a result of the improvements to habitat. The second is collectivised, emphasising a goal of giving back to the community and to future generations. These two frames are mutually reinforcing, however they exist in a relationship of uneasy tension, particularly given that much of the damage to fish habitats is caused by sources which recreational fishers have no control over.

Discussion

Whilst the traditional regulatory toolbox used to manage recreational fisheries is diverse, it is apparent that policymakers see an opportunity to deploy new mechanisms in order to achieve compliance and environmental objectives, relying heavily on voluntary behaviours by key stakeholders. With this in mind, this research identified that there is a lack of discursive connection between which actors are framed as the causal agents of the degradation of fish habitat in NSW and which users are ascribed responsibility for implementing the constructed solutions. This is a clear point of conflict within the

analysed texts. By keeping the blame for fish habitat degradation diffuse, the collated corpus of texts, whose audience is primarily recreational fishers, do not provide the full story. There is a significant disconnect between causal attribution, and the attempts to responsabilise recreational fishers to take ownership of the problem of degraded fish habitats. The mobilisation of recreational fishers occurs in a seemingly decontextualised, depoliticised mode, and from the analysed texts it is unclear whether this is recognised by policymakers.

The participation of non-state actors in delivering policy solutions is often framed as positive - public participation tools, including IAP2 (2014) can be viewed as participatory buffets from which appropriate strategies can be selected based on levels of risk and the complexity of the issues at hand. An analysis of the selected texts highlights however how non-state actors – and particularly recreational fishers – are being constituted as moral, political and authoritative actors by the NSW DPI, and by extension are being responsabilised to ameliorate degraded fish habitats. While the resourcing pressures which policymakers are dealing with need to be recognised, it could be suggested that recreational fishers are being expected to shoulder a disproportionate stewardship burden. Whilst this burden is framed in terms of civic responsibility, it is ultimately a manifestation of responsabilisation.

There is a clear tension underpinning how government resources are deployed in order to ensure the ongoing social, environmental and economic utility of natural resources. What is self-evident is that, in the contemporary neoliberal paradigm, governments do not have the resources or the capacity to solely shoulder the responsibility for ameliorating degraded fish habitat. The core contemporary challenge for government lies in determining how to best deploy limited resources in order to achieve policy aims. Australian policymakers have looked to the international experience in mobilising recreational fishers and may be attempting to replicate that success. What does not appear to have been acknowledged is that recreational fishers are being disproportionately ascribed the responsibility for remedying the degraded state of fish habitats. There is a clear disconnect between the agents which are framed as causal agents of the degradation, and the actors which are framed and named as being key to delivering the solution. The NSW DPI is not seeking to remunerate recreational fishers for their involvement in participatory stewardship activities, and it is worth noting the time and resource commitment being sought from recreational fishers and fishing groups is not insignificant.

Conclusion

Although an interdisciplinary body of scholarship has explored the neoliberalisation of nature (Bridge, 2004, Mansfield, 2004), whereby environmental problems are solved through market mechanisms and public-private partnerships (Ciplet and Roberts, 2017), the associated rescaling of environmental responsibility to the individual has received less attention. This research highlights the discursive strategies used to mobilise stakeholders to become involved in stewardship activities. As a subset of environmental governance, fisheries management provides an empirical site through which to study these issues. Further, although increasing academic attention is being paid to the role recreational fishers may play in delivering on solutions to the degradation of fish habitats, little has considered the discursive strategies used by policymakers to responsabilise recreational fishers.

Future research opportunities may consider whether the identified dissonance in the selected corpus of texts extends to other artifacts which are produced by the NSW DPI. Further, conducting semi-

structured interviews with recreational fishers would be useful to gain a deeper understanding of how they respond to the responsabilisation agenda. Future research opportunities also lie in testing whether the discursive strategies utilised by the NSW DPI are deployed by state actors in other national and international jurisdictions. This research is potentially relevant to all neoliberal states, and while the content of responsabilisation may vary, it is likely to manifest itself across a range of public policy initiatives, including those within the environmental governance, health and education spaces.

Spatial Evolution Characteristics and the Planning Coordination Mechanism of Cross-border Regions in Rescaling

Yinbo Huang¹

¹ TONGJI UNIVERSITY COLLEGE OF ARCHITECTURE & URBAN PLANNING, yinbo.huang@foxmail.com

Abstract: Since 1980s, the transformation of industry production and migration in the process of globalization has triggered the reorganization of “scales”. Furthermore, the space rescaling has spawned the phenomenon of “cross-border area”, which has been a “softer” and flexible functional region. Space and governance are two important attributes to analyze cross-border area. This paper try to sort out the cross-border regional evolution of Hong Kong, Macau and the Pearl River Delta Region. The development of this area could be divided into spontaneous period(1978-1997), transition period(1997-2003) and official period (2003-2019). Research shows that: Firstly, in terms of spatial change, the industrial space were the forerunner, traffic links were followed almost at the same time. The ecology space was not valued until the official period. The social spatial connection, however, has not yet been established. Secondly, the governance has been developed from informal to the formal one. Planning and coordination mechanisms have been adjusted for many times. Formal contacts have been established through inter-governmental relations adjustment and multiple regional planning controls. In conclude, the empirical research proves that the “space-governance” model is efficient. The model might be effective in governing the rescaling region and ensuring coordination between multiple policy levels and administrative units.

Keywords: Rescaling; Regional Coordination; Cross-Border Area

Introduction

“Guangdong-Hong Kong-Macau Greater Bay Area”(GD-HK-MO GBA) is a hot spot in China in recent years. The Central Economic Work Conference and the 19th National Congress of the Communist Party of China regard it as an important strategy to promote coordination between the mainland and Hong Kong and Macau.

For this "cross-border area" formed by space rescaling, this paper attempts to explore two issues: Why does Guangdong, Hong Kong and Macau cross the border and reorganize the spatial scale? Between the three places, what mechanism is used to achieve cross-border restructuring and cooperation.

1 Literature Review: transition in the regional planning

1.1 Rescaling

Since the 1980s, with the deepening of economic globalization, the factors of production have accelerated, and the production mode has shifted from the original Ford system to the post-Ford elastic accumulation model. In this process, there has been a shift in scale and system (Wei et al., 2011). Many countries and regions have established new spatial platforms through rescaling, adapting to new production methods and promoting capital accumulation (Brenner, 2000).

Re-scaling includes two categories, the rescaling of countries and cities (Brenner, 1999). On the one hand, the state has formed a super-national organization such as the EU, the NAFTA through the upward movement of power, and the power has moved down to form a sub-national organization. On the other hand, cities form a world urban system through the capital flows of multinational corporations; new spatial systems such as super metropolitan areas and multi-center urban areas are formed between cities with geographical proximity.

1.2 Cross-Border Area

In the rescaling of countries and cities, a special spatial phenomenon occurs: a transborder region, that is, a spatial unit composed of two or more neighboring countries or subnational regions (Perkmann, SUM.NL, 2002).). In different contexts of discussion, it needs to be interpreted from different political and economic perspectives.

1.2.1 Interpretation from a global perspective

In the process of globalization, different transnational capitals, countries and local societies generate complex games. In the 1990s, cross-border areas emerging in the European Union and North America were super-national or national (Perkmann, 2003). After the Asian financial crisis in 1997, regionalization in East Asia increased, and the integration paradigm shifted (Liu, Regnier, 2015), cross-border integration in sub-national regions (Hall, 2002), and more objects and activities in cross-border areas emerged.

1.2.2 Interpretation in the context of Chinese

With the reform and opening up and accession to the WTO, China's entry into the global capital system has also undergone scale reorganizing and cross-border areas emerging.

China's traditional urban development takes place within a relatively closed administrative district. Due to the intensification of the flow of production factors, the region has developed and transformed its demands, and the phenomenon of integration between urban areas has emerged (Peng Zhenwei, Qu Niu, 2011). Under the promotion of cross-border industrial cooperation and transfer, cross-border collaboration, reconstructed cross-border areas such as the Hong Kong-Shenzhen area (Yang Chun, 2008) and even the Guangdong-Hong Kong-Macau Greater Bay Area, and the cross-border areas such as the Nanchong Economic Belt. Economic corridor (Wang Lei et al., 2012).

1.3 Regional Coordination

The transformation of the system and the reorganization of spatial scales have brought new problems to regional development: how can cities that are closed to open, how to coordinate various contradictions in industries, transportation, and ecology? Especially for cross-border areas with different systems, such contradictions are more acute.

In this context, regional coordination (especially urban space coordination coordinated by the government) has become an important means to promote the scale restructuring region from conflict competition to orderly competition and cooperation and win-win. Different from the Western “new regionalism” through the horizontal cooperation of the department and the comprehensive administrative and market role, China has adopted more forms of regional planning to promote regional coordination (Fang Wei, Zhao Min, 2013).

It can be argued that in China's rescaling, “*space conflict and coordination*” and “*government governance and planning*” are a core set of regional coordination, which have an important impact on the development of cross-border areas and are also the focus of this study.

2 Research framework: “space-governance” model

2.1 Basic inference: two characteristics of cross-border regional coordination

2.1.1 Spatial characteristics: reconstruct regional spatial organization, release factor flow

“Space” refers to spatial changes and conflicts in cross-border areas due to rescaling. This feature can be divided into regional spatial organization patterns and changes in spatial linkages and elements between cities.

- Regional space: The cross-border area in the rescaling will reshape the urban agglomeration relationship and rank of the region, break the original administrative district economy, and promote the relatively closed region from a single central structure to a multi-core and networked development.
- Urban space: The linkages between cross-border areas usually begin with economic and trade flows and ultimately establish cultural identity (Brunet-Jailly, 2005). This promotes the establishment of inter-city linkages between industry, transportation, and ecology, and the release of information, technology, capital, and talent.

2.1.2 Governance characteristics: multi-level governance, promote the coordinated development of space

“Governance” is the means of coordination adopted by the government when the development of the region changes. By adjusting inter-governmental relations, organizing multi-departments consultations, and issuing regional plans, the government implements multi-level governance to ensure coordinated regional development. Governance research includes two aspects.

- The inter-governmental relationship. This includes the vertical inter-governmental relationship between the lower and upper levels of government and the inter-governmental relationship between local governments (Xie Qingkui, 2000);
- The regional planning as the specific means of governance . It is an important medium and means adopted by the government, combining economic, administrative and legal aspects.

2.2 Research framework design

Based on the above inference, a research framework is established from the two aspects of “space” and “governance”. Firstly, through historical research, we sort out the development process of cross-border areas, and study the regional spatial organization of each period and the evolution of urban industrial space, transportation space and ecological space. Second, analyze the changes in governance methods from inter-

governmental relations and regional planning. As is shown in Figure 1, a “space-governance” analysis model for cross-border areas is established.

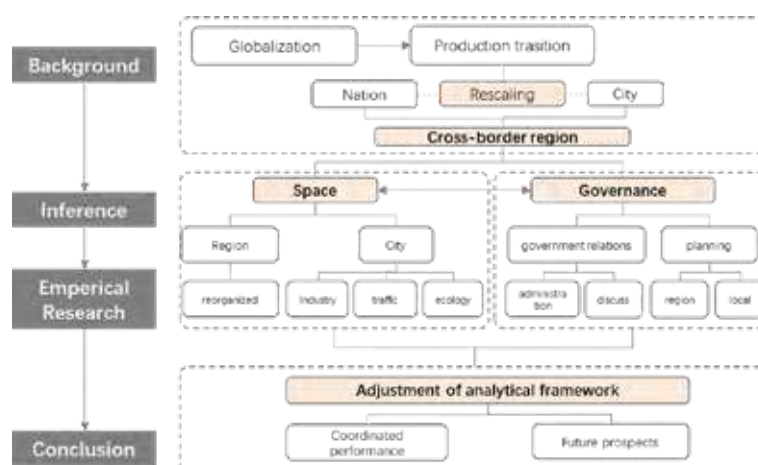

Figure 1 Research framework

2.3 Time and space range

The space includes Hong Kong (HK), Macau(MO) and the nine cities in the Pearl River Delta (PRD) region.

The time ranges from 1978 to 2019. It is roughly divided into three historical stages. From 1978 to 1996, it was a bottom-up, informal spontaneous communication period (spontaneous period). 1997-2002 was the transitional period (transition period) after Hong Kong and Macau returned. CEPA was signed in 2003, which marks the beginning of formal regional collaborative development period (official period) (Luo, Shen, 2012).

3 Spatial Evolution Characteristics of the Cross-border Areas of Hong Kong-Macau-Pearl River Delta

The border between Hong Kong and Macau and the Pearl River Delta includes both land and sea boundaries, and border inspection is required at the port through the border. Some of the Hong Kong-Shenzhen borders are still "forbidden zones" - although they have been reduced from 2,800 hectares to 400 hectares.

Since the reform and opening up, border space has been indirectly crossed – including cross-border industries and cross-border transportation. This has led to the reorganization of regional relations and the strengthening of urban spatial links. Some of the border space will even be directly crossed, and the restricted area will become a cooperation area.

3.1 Regional space: spatial organization relationship is reconstructed

1. In the spontaneous period, Hong Kong and Macau are relatively free from the Pearl River Delta region, and the interior of the Pearl River Delta is centered on Guangzhou.
2. With the tortuous fluctuations in the Hong Kong-Shenzhen relationship during the transition period, the central structure became loose. Hong Kong and Shenzhen formed a new economic core. The economic and transportation links between cities strengthened, driving the development of regional networks.
3. In the official period, Hong Kong and Macau integrated into the Pearl River Delta. Guangdong-Hong Kong-Macau Greater Bay Area initially presented a networked regional spatial structure.(Figure 2)

Figure 2 Regional spatial organization relationship in cross-border areas

3.2 Urban space: urban linkages strengthen and promote the flow of factors

3.2.1 Industrial space

1. Spontaneous period: “Before and after the factory” is the main feature of the cross-border industrial space. This model is the result of changes in the internal and external environment: on the one hand, the production costs of ASEAN countries are reduced, the trade protectionism tends to be in the West, and the development of Hong Kong's manufacturing industry is constrained. On the other hand, the reform and opening up policy has pushed the closed Pearl River Delta to cross economic isolation. Therefore, Hong Kong businessmen and foreign investors cross the border to use the cheap labor and land resources of the Pearl River Delta to reduce product costs (Xu Jiang, 2008). The main undertakings of Hong Kong capital are Dongguan, Huizhou and Shenzhen in the eastern part of the Pearl River Delta, and most of them are concentrated along the Guangzhou-Shenzhen Expressway. Hong Kong capital will accelerate the expansion of the space in the Pearl River Delta cities and promote the rapid development of professional towns, laying the foundation for cross-border links.
2. Transition period: The category and value chain of industrial transfer began to upgrade. The economic pressure brought about by the Asian financial crisis has forced some service industries in Hong Kong to transfer their operating bases. Secondly, the manufacturing transfer was upgraded from the toys and clothing industries in the 1980s to electronic components and electronic appliances and smart toys with high added value. However, it is still based on OEM production and assembly, and lacks its own brand (Chen En, Li Jiahong, 2011).
3. Official period: The connection of industrial space is strengthened and new trends appear. In the transfer and acceptance of global capital, Hong Kong and Macau are not the only “portal” and trade intermediaries. Guangzhou and Shenzhen can undertake foreign investment relatively independently. The global financial crisis in 2008 further promoted the manufacturing industry and industrial transformation of the Pearl River Delta. (Figure 3)

At present, the Pearl River Delta is no longer a “post-factory” for the passive development of Hong Kong and Macau's transfer industries. The regional production relations and spatial pattern are developing in a flat manner. The industrial space of each city has both cross-border cooperation areas and considerable autonomy, from relative subordinates to equal cooperation. In space, there is a tendency to gather in the Bay Area.

Figure 3 Evolution of the main agglomeration space of cross-border industries (from left to right: spontaneous period, transition period, official period)

3.2.2 Traffic Space

1. Spontaneous period: There are few cross-border traffic spaces, but industrial demand drives Hong Kong companies to invest in the Pearl River Delta infrastructure. For example, Hong Kong's Hehe Industrial Subsidiary will build the Guang-Shen Expressway and Huo Yingdong to build the Humen Bridge with the private construction and operation transfer mode to eliminate the space barrier of capital circulation and attract more investment. Cross-border transportation investment during this period was concentrated on the east coast of the Pearl River Delta.
2. Transition period: The government incorporates cross-border transportation into its planning strategy. Hong Kong proposes a regional express route scheme for Lok Ma Chau and Lo Wu. It will lead directly to the Kowloon Southern Link and the Island Line. The Pearl River Delta has built roads such as the Guangzhou-Macau Expressway, and the regional traffic has been further improved.
3. Official period: The cross-border communication has really arisen, the east-west connection has been strengthened, and the transportation mode has been diversified. In 2007, the Hong Kong-Shenzhen Western Corridor was completed and docked on Highway 9 in Hong Kong. In 2017, the Hong Kong-Zhuhai-Macau Bridge cross-border road was opened. In addition, the northern section of Guang-Macau and the second line of Guangzhu West Line, which were completed during 2005-2013, were linked to the east and west coasts. More closely. In addition, it also includes different modes of transportation such as intercity railways and port transportation.(Figure 4)

Figure 4 Cross-border traffic space evolution (from left to right: spontaneous period, transition period, official period)

3.2.3 Ecology Space

The cross-border cooperation in the ecological space appeared late, and there was no clear guidance until the official period.

In 2008, the "Plan of the Pearl River Delta Reform and Development Plan" encouraged the establishment of a pollution prevention and prevention joint prevention mechanism, the implementation of environmental pollution control, the construction of cross-border ecological protection zones, and the protection of reservoir catchment areas, thereby promoting the establishment of a cross-border quality life in Guangdong, Hong Kong and Macau. ring. (Figure 5)

In 2012, in the “Livable Bay Area around the Pearl River Estuary”, based on the overall layout of the Pearl River Delta Green Island Network, the “Green Network” and “Blue Net” of the Pearl River Estuary Bay Area will be further proposed to protect the cross-border ecological space. Encourage the integration of cross-border leisure life.

Figure 5 Cross-border ecological space cooperation planning (from left to right: ecosystem, green network action, blue network action) (Adapted from official planning file)

3.3 Cross-border node

After formal and comprehensive cooperation, Hong Kong and Macau and the Pearl River Delta have carried out research on several cross-border cooperation nodes, which can be divided into two types: the adjacent type geographically adjacent to the border, and the non-geographically adjacent "enclave" type. The construction of cross-border nodes is a new round of comprehensive space cooperation after the close connection between industry, transportation and ecological space. This marks a new phase of cooperation between the three places.

3.3.1 Adjacent type

There are three adjacent types: the Zhuhai-Macau Cross-border Cooperation Zone, the Shenzhen-Hong Kong Lok Ma Chau Loop and the Zhuhai Hengqin New District.

The Zhuhai-Macau Cross-border Cooperation Zone is the country's first cross-border industrial park. It develops functions such as high-end logistics, exhibition and sales, and transit trade. The purpose is to support the diversified development of Macau's economy and is also an important modern logistics business park on the west bank of the Pearl River. In addition to economic cooperation, the cooperation zone reflects the ecological governance of cross-border cooperation. The ecological management of the Yayong River is carried out in Zhuhai and Macau, including controlling pollution discharge and improving greening in the waterfront.

3.3.2 "enclave" type

There are four types of enclaves: Guangzhou Nansha New District, Shenzhen Qianhai New District, ShenZhen-DongGuan Harbor New City, and ZhuHai-ZhongShan Binhai New City, which are concentrated near the Pearl River Estuary.

Among them, Nansha New District, as a new national district, assumes the function of “one district across three cities”. The construction of the enclave once triggered concerns among Hong Kong people, fearing that the further transfer of the industry would trigger the hollowing out of Hong Kong's local industry. Therefore, in addition to economic, people's livelihood, transportation, social innovation and other functions, the most important thing in Nansha New District is to explore a new mode of cooperation between the three places – how to establish a new mechanism of cooperation and diversified cooperation channels to achieve a win-win situation.

4 Multi-level governance and regional planning

4.1 Adjustment of inter-governmental relations

At present, Hong Kong and Macau are special administrative regions. The administrative structure of the Pearl River Delta includes sub-provincial cities, prefecture-level cities, county-level cities, counties, and municipal districts. It is a cross-border area with multiple administrative structures. In different economic stages, it has also undergone several adjustments such as the withdrawal of the county to set up the city and the withdrawal of the county.

In the evolution of cross-border areas, the inter-governmental relations have undergone several adjustments, including two sets of relations: the relationship between Hong Kong and Macau and the Pearl River Delta, and the administrative adjustment within the Pearl River Delta.

After the reform and opening up, Hong Kong, Macau and the Pearl River Delta changed from the "three-country division" diplomatic relationship to the "market-led" economic cooperation relationship, driving the cross-border evolution of industry and transportation space.

However, since the three are divided into interest groups of different political entities, cross-border cooperation pays less attention to areas outside the economy, such as social security and environmental protection. During this period, in the Pearl River Delta, in order to promote capital accumulation, the government implemented a series of decentralization measures, including the withdrawal of townships in 1985 and the establishment of cities in 1993 (Guo Yan et al., 2017).

After the return of Hong Kong and Macau, the attitude of the Hong Kong and Macau government's "cross-border protectionism" hindered regional cooperation to a certain extent. It was only in 2001 that the attitude was changed and the areas of cooperation were initially expanded, including improving cross-border traffic and calling for the establishment of a free trade zone (Shen Jianfa, 2002). At the same time, the Pearl River Delta region, which is restricted by the economics of the administrative region, has adopted the district (county-level city) to integrate the inter-governmental relations, forming a pattern for the development of the surrounding areas.

After the signing of CEPA in 2003, the local governments of Guangdong, Hong Kong and Macau entered a period of comprehensive cooperation. Although administratively divided into one province and two districts, in recent years, regional concepts such as “Guangdong-Hong Kong-Macau Greater Bay Area” and “Guangdong-Hong Kong-Macau Greater Bay Area” have received increasing attention, and collaborative development has become the mainstream.

The multiple adjustments of the relationship between the two groups have promoted the cross-border relationship between Hong Kong and Macau and the Pearl River Delta and established a networked inter-governmental cooperation relationship.

4.2 Changes in regional planning

With the adjustment of inter-governmental relations, the spatial scope and planning content of regional planning in the Pearl River Delta region are also changing, which is shown in Figure 6.

During the spontaneous period, Deng Xiaoping's southern tour strengthened the influence of Hong Kong-owned overseas Chinese capital on the economic development of the Pearl River Delta. In 1994, Guangdong Province promulgated the "Pearl River Delta Economic Zone Urban Group Planning", which covers 9 cities in the Pearl River Delta (excluding Zhaoqing's peripheral number).

There is no regional planning during the transition period. The official period is to improve the content of regional planning with the expansion of the cooperation level between the three places.

In 2004, a more comprehensive Plan for the Coordinated Development of the Pearl River Delta Urban Agglomeration was promulgated. In 2008, the Outline of the Pearl River Delta Reform and Development Plan was first added to the coordination with Hong Kong and Macau. In 2012, the scope of the "Livable Bay Area around the Pearl River Estuary" was planned. Formally adding Hong Kong and Macau, it is a construction plan jointly prepared by the three governments. It is also a planning open to consult the public.

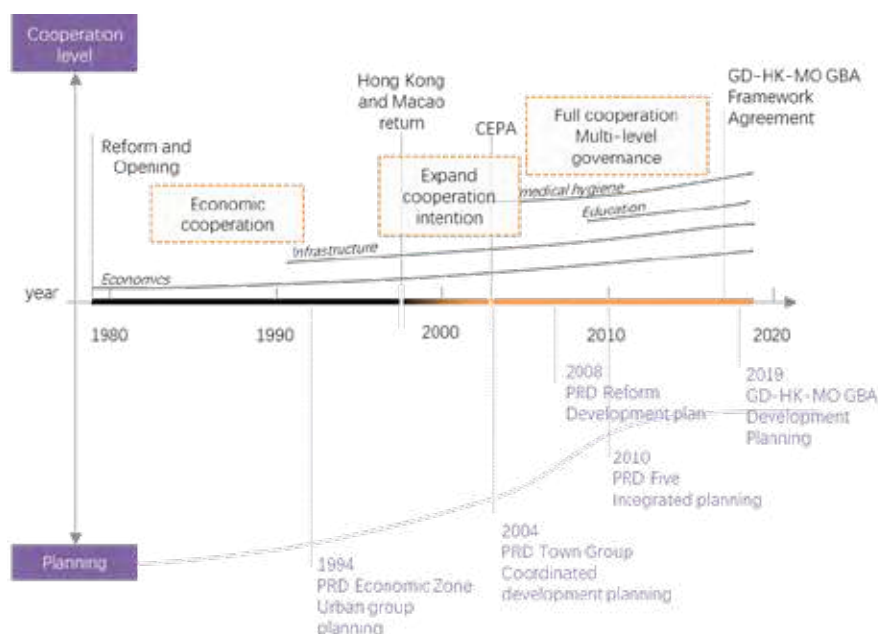

Figure 6. Evolution of cross-border cooperation levels and regional planning

The level of cooperation between the three places has been deepened. In 2017, the Guangdong-Hong Kong-Macau Greater Bay Area framework agreement was established. In February of 2019, the development plan for the Guangdong-Hong Kong-Macau Greater Bay Area was issued. This indicates that cooperation between Hong Kong, Macau and the Pearl River Delta will truly cross the border and formally become a multi-level cooperation area.

5 Conclusion and Discussion

5.1 Conclusion: The relationship between Hong Kong, Macau and the Pearl River Delta from the perspective of "space-governance"

In the past, the study of cross-border areas adopted a relatively single perspective of space or governance research. This study analyzes the characteristics and mechanisms of cross-border areas through the dual perspective of "space-governance". Studies have shown that spatial evolution and governance mechanisms are interrelated (Table 1), and the "space-governance" analysis model is effective.

1. In the spontaneous period, the capital of Hong Kong and Macau entered the Pearl River Delta across borders, triggering the reorganization of regional and urban space. The inter-governmental relations between the three places are led by economic cooperation. The series of administrative measures taken by the Pearl River Delta to adapt to the entry of foreign capital has led to the fragmentation of inter-governmental relations. In terms of regional planning and regulation, there is no formal cross-border planning, and only the urban agglomeration planning based on the economy within the Pearl River Delta.
2. During the transition period, with the return of Hong Kong and Macau, the three countries were fluctuating due to the shackles of "cross-border protectionism". Under the leadership of market capital, the cross-border relationship between industrial space and transportation space is still strengthening. The relatively developed economy of the Pearl River Delta began to integrate inter-governmental relations, enhance the status of cities such as Guangzhou, and lay the foundation for network cooperation in the next period. During this period, no plans were issued within the Pearl River Delta, but in the early analysis of regional planning, the awareness of cross-border cooperation has sprouted.
3. In the official period, the signing of CEPA marks the formalization of the partnership. Under the government's promotion, cross-border space has broken through the market economy, and carried out ecological governance and construction of integrated cross-border nodes. The inter-governmental relations between the three places have entered the multi-level governance stage, and through a series of initiatives such as joint meetings, the level of cooperation has been continuously deepened. In terms of regional planning, the content is more comprehensive, and the scope of space and participants are more diverse. Cross-border areas try to break through the shackles of borders and institutions, and truly build a new platform for multi-level and equal cooperation in economy, transportation, ecology and society.

Table 1 Evolution of the relationship between Hong Kong, Macau and the Pearl River Delta from the perspective of "space-governance"

	Space research		Governance research	
	Region space	City space	Adjustment of inter-governmental relationship	Changes in Regional planning
Spontaneous period	The PRD is a single center. HK and MO are relatively independent.	The industry first appeared in contact, and HK businessmen invested in the PRD traffic.	Divided governance and market-led cooperation. The PRD has broken down due to the establishment of the city in the county.	1989 Planning of the urban system 1994 PRD Economic Zone Urban group planning
Transition period	HK and SZ reconstructed into a core, breaking the structure of "central geography".	The industry shifts and the government considers cross-border traffic engineering.	The return of HK and MO, "cross-border protectionism" has hindered cooperation. The Pearl River Delta integrates inter-governmental relations.	2003 CEPA
Official period	GZ-FS and HK-SZ are the main cores. ZH-MO is the secondary core. The region is moving towards networking.	The industry has moved from subordinate to cooperation, and there has been an enclave/adjacent cooperation area. Cross-border traffic is increasing. Carry out ecological and environmental cooperation.	Comprehensive cooperation, under the premise of one country, two systems, carry out multi-level networked collaboration. Establish a joint meeting.	2004 PRD Coordinated development planning 2008 PRD Reform Development plan 2010 PRD Five Integrated planning 2014 PRD Planning 2016 PRD Space Planning
Future	Mature networked structure, Extend to the Pan-PRD.	From the physical space to the cultural space with a sense of belonging.	A new model of multi-faceted, cooperative and efficient.	2019 GD-HK-MO GBA Development Planning

5.2 Discussion: Future trends

According to the analysis model of "space-governance", Hong Kong, Macau and the Pearl River Delta have entered a relatively mature stage of cross-border regional evolution. According to Brunet-Jailly's hypothesis, cross-border areas will eventually establish cultural identity and ownership.

Although citizens in the Mainland and Hong Kong and Macau now have relatively consistent recognition of economic and trade cooperation, there is still a certain distance in cultural identity and attribution (Shen, 2014). With the deepening of the Guangdong-Hong Kong-Macau Greater Bay Area, the three governments should invest more in social and cultural exchanges and public service sharing to promote cross-border areas to a deeper level.

Abstract: Based on the cases from central China, this study discusses the relation between regional governance and regional challenges in the suburban areas surrounding the metropolitan areas in China since the 1990s. Under the trends of globalization and metropolitanization, the spatial-temporal features, and governances are changing toward a different direction. The territorial governance arrangement is shaped by the regional competition and the goals of economic development, which is pushed by the central city through the interaction of powers from different levels of government and stakeholders, under the China's administrative hierarchy, especially the "city-leading-counties" system. One of the prominent examples is the governance arrangement of the industrial parks located in metropolitan fringe areas, which shows both changes and continuity over time. To be more specific, this study starts with analyzing the features and changes of the governance on the county regions in the special periods. Further, the study focuses on the cases studies of a type of specific spatial unit – industrial park. By analyzing the cases of three time-sequential but spatial-separated industrial parks, the researcher examines specific mechanism of the impact of external regional challenges and policy changes of governance arrangement. Central city's attempt to join the fringe area for the development of industrial parks into county territory has to comprise with the suburb county's government. Eventually, a typical region government arrangement at the metropolitan fringe area came into being. The "softer" governance at the fringe area could be divided into three phases: the separation of city and county, the collaboration of city and county, and the dominance of the central city.

Keywords: Governance arrangement, Metropolitan fringe area, Suburban counties

Introduction

Since the 1990s, a series of market reforming conditions in China has led to corporatist thrust and promoted competition among cities, aiming to gain regional central status in competition with other cities. The central city has expanded rapidly and the area has expanded to the entire administrative region. The central city is tightly connected with the peripheral areas and suburban counties, forming a greater metropolitan area. In the context of globalization and metropolitanization, the geographical uniqueness, spatial governance characteristics and governance structure of the county present unprecedented transformations and new features under the influences of societal development.

On one hand, the „city-leading-counties“ system with Chinese characteristics has significantly consolidated the power of the central city, vigorously realizing the infrastructural integration and spatial integration that promoted under the administrative force. Therefore, the regional reconstruction shares the same characteristics in the cases across Europe and the United States, such as administrative division adjustment, a certain degree of decentralization, various public-private partnerships, cross-border cooperation, etc. On the other hand, there are also the inherent characteristics of the internal system and culture, especially the complex property rights and institutions between the central, provincial, cities, counties and special administrative regions under the Chinese transformation system.

However, most of the existing researches are pure theoretical debates in macro scope. There are few fine empirical studies on specific regions as cases, and particularly on spatial governance in the suburban counties surrounding metropolitans. This paper aims to study the regional governance changes in Feixi County, a suburb of Hefei City, Anhui Province in the central region in China, and showcase a relatively complete representation of the historical section of the extent of development in this area, with particular attention to the following issues:

How have the characteristics of county spatial governance arrangements changed? What role municipal and county governments play in the transformation of urban areas? What specific mechanism should be applied during the change of county spatial governance? What specific mechanisms are mandatory under the impact of external regional challenges and policy changes on governance?

1. Research design

The geographical scope of this study is the central region, where generally considered an economically underdeveloped region largely consisting of Anhui, Hubei, Henan, Hunan, and Shanxi, and is directly radiated and affected by the developed regions in the east. After 2000, due to the influence of globalization and industrial transfer in the eastern region, the central cities have achieved rapid development, especially the provincial capitals have successively entered the developing stage of metropolitanization.

The time window of study was selected between 1990 and 2015, starting from the establishment of a cross-border economic development zone in the central cities, ending at a new round of planning compilation aimed at promoting regional integration, and the history will be traced according to the purpose of each project. There are three cases selected, they are TaoHua Industrial Park (completed), the Xingang Cooperative Park (completed) and

South China City Project (later stage), which represent the main features of the county space governance change in the previous period.

During 2017-2018, with respect to relevant personnel in policy-making in the case studies, we conducted a series of in-depth interviews with government officials, planners, academics, and directors of operations companies on specific projects. Among them, we focus on external environment, land and planning policies and the variables during project construction. We hoped that the analysis of these changes will be used to track the changes in the power structure between acting subjects, and to study the clues of county space governance changes. The research mainly adopts analytical methods on event analysis and literature analysis.

2. Changes in characteristics of regional governance -- The development of city and county integration

Feixi is located to the west of old Hefei county historically. With reference to administrative, economic or cultural aspects, it has a close relationship and integration tendency with Hefei, which is in the center of the region.

After the founding of the People's Republic of China, a series of administrative division adjustments (1952, 1958, 1961, 1983, 1997, 2006, 2011) led to a final configuration in the development of integration of Hefei City and Feixi County. From the official point of view, this integration has gone through three stages: Separation of City and County Industrial Parks --Construction Phase of Cooperative Parks -- Main City of Hefei Southwest. Efforts were made on the economy, industry, facilities and other factors, and gradually the city and county disintegrated the unfavorable factors of the district administrative economy under the separation of cities and counties established in the 1980s.

With a typical metropolitan suburban county model in the central region, the central city is anticipated to obtain more space and reduce conflicts between districts and counties. As shown in Table 2, within the context of the development of integration of the whole city and county, in the early stage, district adjustment of the county was mainly carried based on the problematic administrative division. In the latter stage, compromise and negotiation among cities and counties were the main focus. The government and related functional departments always made substantial progress. It can be seen that the integration of cities and counties is a typical urban area reconstruction led by the government. However, the government is not a completely homogenized whole, but a hierarchical system of vertical management. The coordination and conflict of internal power operations can be manifested through the space carrier peripheral development zone that is regarded as the substantial promotion of integration. Its propulsion timeline is shown in Table 1.

Table 1 , City and county integration development stage and its content

	Separation(1991-2004)	cooperation (2005-2010)	Integration(2011-2015)
main problem	Urban development direction, Administrative division adjustment, County industrialization	Unified planning of edge development zone, Partition implementation management, City and county cooperation	The development of peripheral development zones to the urbanization of diversified formats
Way of promotion	set up development zones separately on the edge of the city and county	Benefit distribution, cooperation establishment	Integrated development
Substantial progress	Discussion stage	Agreement phase	Entering the operation phase
Major events and administrative division adjustments in the development zone	In August 1991, the Hefei Municipal People's Government approved the establishment of Hefei TaoHua industrial park in Feixi County. In 1997, the administrative division of Hefei Economic and Technological Development Area(HETA) was adjusted, 16 administrative villages in Feixi county and Hefei suburban district were placed under the jurisdiction of HETA. The land use scale is 39 square kilometers, covering one county (Feixi county), one district (former suburb district), and three townships (Changqing town, Feixi county Taohua town and Yandun town).	In 2006, district-county cooperative Xingang industrial park between Feixi county and HETA, In 2005, district-county cooperative Baiyan science park between Feixi county and Hefei Hi-Tech development zone	The municipal government put forward “county breakthrough” strategy and promoted urban infrastructure, and urban public services extend to the suburban areas.. In 2012, mega-project China south city located in Feixi county ,city-county collaboration dominated by central city came into being

In the construction of the peripheral development zone, we pay attention to the following node changes: The first is a policy gap between the constructions of peripheral development zones and obtaining national policies, in another word, the development zone policies broke through the restrictions of land and urban regulations. The second is the cooperation model: how to distribute the land quota? What is the functional division of investment and management between district and county? How is the relationship changed between the province, Hefei City and Feixi County during this process? And what is the specificity of the Feixi case for the governance in the central region? Through answering these, we can gain insight into the original power framework and its changes between city and county governments.

2.1 Geospatial characteristics of peripheral suburb counties: development and construction of peripheral development zones

Because of the location and development conditions near the main urban area, peripheral suburban counties, especially the cross-border areas, have huge potential development space and less demolition required. In the upsurge period of the establishment of development zones, they are often the ideal location for central cities. At the same time, the development of the cross-border areas in suburban counties is not only a unilateral action of the city, but also a location advantage and basis for attracting urban resource spillovers and constructing urban infrastructure. The disparity and imbalance in the development of cities and counties also prompted the county to shift its focus of development from the traditional county-level town development to the peripheral development. Especially around or towards the main city development or enclave development zones established by the central city, county-owned industrial parks will often be formed and developed at opposite and peripheral location; and the county-level development shows the spatial configuration in growth around the metropolitan areas.

Such peripheral development zones refer to the development zones set up in the fringe area in the light of their own interests by the municipal and county governments. Firstly, the cities' locations are selected relatively far away from the central city, the county's are adjacent to the cities' in the opposite direction. By attracting investment, it accommodate the enterprises that withdrawn from the central city due to urban renewal, and the enterprises that industrial transferred from developed areas.

Since the 1990s, Feixi County has developed a series of peripheral development zones to the southwest of Hefei's main city. Through nearly 30 years of development, it has formed 60 square kilometers Great Taohua industry plate, with an economic volume of 100 billion China Yuan. In a word, for the main body of cities and counties, the industrial plates of cities and counties in peripheral areas are the key bearing areas of industrial economy, and the center of economic growth in the past 30 years of reform and development. These regions also reflect the change of spatial governance of counties.

2.2 characteristics of county space governance

The essence of the problems of space governance in the suburban counties originated from counties' geographical adjacency and administrative divisions, leading to the conflict and coordination on urban planning, construction, management and development. All problems were embedded in the geographical relationship between the two administrative units and rooted in this particular space. The characteristics of space became the origin of regional governance, and space was used as a means to achieve governance goals. The evidence was shown in the progress of the regional integration in Table 2 that since the integration operation (2003-2009), almost all government cooperation projects involve spatial cross-border coordination, and spatial coordination is the most important content of regional governance.

Since the establishment of HETA and the Hefei High-tech Zone at the city-county border in southwest Hefei, peripheral area like Feixi County had already been included in the their

planning. Due to various conflicts from cross-administrative regions, the municipal government promoted the simple regional integration model of administrative division of the county. Relations between city and county development zones were not cooperative, but separate competitive. In this context, the regional space was characterized by the separation between two major municipal development zones and several county industrial parks. There are also many problems in the coordination within cross-regional areas.

The single way of administrative-division adjustment is difficult to integrate the county-founded industrial parks. The development of county industrial parks faces the shortage of funds and resources, and the challenges of cross-regional coordination. Under the "city-leading-counties" system, city mastered the administrative right on resources distribution, especially land. As a result, a cooperative park model that county bargain away its space in exchange of resources was created. In the cross-regional cooperation of district-county co-governance, the district led planning of the cooperative park, from which cross-regional planning and infrastructure coordination between cities and counties would be favored.

Since 2003, with the expansion of industrial transfer in the eastern region, lack of resources that once restricted county development zones in peripheral area was no longer development constraint, and the co-governance model of district-county cooperation lost the foundation of existence. In this context, Hefei City proposed a strategy on county-breakthrough. In the investment of large-scale municipal projects, the county area was considered as the main site, with support from municipal administrative resources. At the same time, the municipal financial investment on cross-regional infrastructure construction will realize the road connection between central city and counties. In the planning, the south western region will be included in the main urban area of south western Hefei, and unit division planning will be compiled. The spatial governance of the cross-regional area has entered the governance stage of the municipal-led cooperation between cities and counties under task division. During this stage, the spatial governance was characterized by the municipal-led spatial integration model and large industrial parks model within county space. The county has become the main entity of implementation in the scope of regional governance of metropolitan integration.

2.3 Characteristics of governance structure: from separation to municipal-led cooperation between cities and counties

Corresponding to spatial governance, in the stage of separation between cities and counties, districts and counties led separately the planning and construction of development zones, and cross-regional coordination was severely inadequate. The governance structure corresponds to the city-district and county. The county industrial park was not the municipal focus, instead it was regarded as occupying the advantageous space of the peripheral area. The industrial park of the district was the embodiment of the interests of the central city.

In the stage of cooperation-park, the cooperation between districts and counties was under the municipal coordination. The central city no longer obtains the incremental development space

for the district through benefit compensation, but provides with a relatively fair partnership through the distribution and integration of resources for districts and counties.

In the stage of the city-led integration mode, it was reflected in the direct division of work and cooperation of city-county. The county gained equal importance to district due to its geographical advantages.

3. Case and mechanism analysis

Due to the complexity of each case, the paper select a few concerns in each cases (Table 2)。

Table2 The cases and a few concerns in each cases

The cases	Key factors of concern	Change in governance structure	Mechanism: the concern of factors on the change of regional governance structure
TaoHua Industrial Park	Special development zone policy The game of provinces, cities and counties in the adjustment of administrative divisions	Development zone is an important space in the administrative adjustment	
XinGang Industrial Park	Changes in urban planning and land policy Changes in investment and financing methods and improvement in integration	District-county collaboration led by the municipal government	
China South City Project (New Industrial Park)	County breakthrough strategy	City-country collaboration led by central city	

3.1 Taohua Industrial Park

Since the Reform and Opening-up, the central region followed the experience of the eastern region and advocated the development of township enterprises. But after the 1990s, in general it faced the crisis of aging in production capacity, small scale and poor efficiency, which led to a great crisis to the township economy. Concentrated industrial parks, which were set up in the mode of industrial agglomeration and investment attraction, it became a tendency to promote county economy with industrial development. In this context, Taohua Industrial Park was the first one established by Feixi County in Southwest Hefei.

Before the 1990s, constrained by regional transportation, investment environment and policies, the central region did not have the practical conditions to attract large-scale industrial transfer. With the transition from Planned Economy to Market Economy and the diversification of ownership structure, after Deng Xiaoping's South Tour Speech in 1992, the Opening Policy was carried into act in the central region. With the advantage of low-cost

labour resources, the industrial transfer to the central and western regions started, and promoted the booming of industrial parks construction. Gaining the affirmation of Anhui Province and follow-up policy, the county industrial parks undertook small and medium-sized enterprises from the spill over of the main urban area, as well as a small number of low-end manufacturing industries transferred from developed areas. However, with the establishment of HETA in central city, relying on better policy levels and infrastructure allocation, the investment of county industrial parks has been reduced.

In the process of regional governance, as industrial parks became an important land use arrangement in peripheral suburban counties, it was not only an important support for county economy, as well as an important means to prevent administrative division adjustment from municipal government.

3.1.1 changes of planning and land policy

At the early stage of the Reform and Opening-up, the characteristics of national legal system were “try-and-trial” with the priority on economic development, leading to the incompleteness of laws and regulations on the development zones. The incompleteness provided opportunities for the establishment of County development zones.

According the local government documents of Anhui Province, “the counties and towns have rights to establish industrial parks. The important towns and industrial parks have rights to occupy the lands before the development plan being approved. The development zone administration commission will have the power to manage the finance, local tax, national assets, lands, industries, economy, commodity prices, labours, personnels, environmental protection, social security and other related works. The authorization of independent power and land use autonomy rights to the administration commission actually contributed to the disordered expansion of development zones in all levels of development zones..

3.1.2 Provincial, municipal, and county games in the administrative division adjustment

The government is not just a non-homogeneous system, but also has vertical hierarchy. Provincial, municipal, and county governments have a close relationship with the urban fringe development areas, and their opinions on the administrative divisions adjustments sometimes are inconsistent. For example, the administrative division adjustment in 1997 promoted by Hefei City, intends to add the Taohua Industrial Park into the Hefei Economic Technology Area through the executive order under the „city-leading-counties” system. However, the boycott from the county and the support from the provincial government on the county’s policies eventually forced Hefei to modify the administrative division adjustment documents and kept Taohua Industrial Park in Feixi, which also laid a foreshadowing for the subsequent series of fringe development zones growth along the main city and the establishment of a development zone. Finally it forced the central city to abandon the simple promoting administrative division adjustments through executive orders.

3.1.3 Development space as a target for administrative adjustment

The „city-leading-counties“ system gave cities the power to deprive the resources of counties, but counties“ institutional independence also gave themselves the autonomy and the power to build industrial parks. The city-level implementations were „mainly simple regional integrations, having not entered a period of regional co-governance yet, which was more diverse, more complex, and more focused on consultation.

3.2 Xingang Industrial Park

Under the background that HETA was limited by space which belong to municipality and the adjustment of administrative divisions was difficult to implement after 2003, the municipal government advocates to build the District-County Cooperative Xingang Industrial Park, according to the division of labor between city and county, which is dominated by HETA and supplemented by the Feixi county government, the Xingang Cooperation Park gradually integrated the roads and municipal facilities with urban areas“, and integrated into the urban planning area of Hefei city center, providing administrative resources such as land quota from the provincial and municipal levels. The Xingang cooperation park used the city-level platform to attract investments. Under the scope of county-level power allocation, Feixi adjusted land use planning, integrated land resources, and solved specific problems such as land and farmers' demolition and resettlement under the constraints of new land policies.

3.2.1 Changes in urban planning and land policy

In 2003, to solve the disorders in the economic development zone developments at the county level after the 1990s, the central government started working to control the land market with the focus on rectifying the economic development zone. However, Anhui Province, as the key province for supervision, passed the original local documents that are inconsistent with the relevant national land management regulations and standardized land management practices according to the opinion. At the same time, the Anhui Province also cancelled the land management authority authorized by the Development Zone Administration commission. The changes specifically included two aspects: firstly, all levels of government except the State Council and provincial governments have no right to approve the establishment of economic development zones, regulate the part of the economic development zone administration commission's authority and land rights that is inconsistent with the relevant provisions of the state, nor collect the right into the local government. Secondly, the overall planning of the economic development zone should be organized by the people's government of the host economic development zone according to the master plan. The adjustment of the land use approval system after 2004 mainly includes the right of examination and approval for the adjustment, and the revision of township land use planning back to provincial government. The adjustment of basic farmland needs to be approved by the State Council. It also included the implementation of the ombudsman system for land and resources enforcement, strengthening accountability for land violations, and strengthening the role of the land sector in land use policies.

With the cleanup of the development zone and the adjustment of policy documents in 2003, the plan of the peripheral suburban counties development zone is included in the county master plan. The disorders in the master plan for development zone have been standardized. The system of urban planning work in Feixi county has been also further clarified, and the standardization and regularization have been greatly improved. Urban planning approval and licensing systems are becoming increasingly strict. The municipal government officially obtained the power of planning approval and the allocation of land quotas, becoming the main administration of reviewing and approving the county's master plans. The interests of the city also penetrated into the regional governance of the counties through urban planning.

3.2.2 District-county collaboration led by the municipal government

The significant difference from the previous stage is that Hefei no longer seeks administrative division adjustment to obtain incremental space for HETA, instead of encourages the collaboration of districts and counties. Within the newly established Xingang Industrial Park, there are 10.4 square kilometers, of construction land and general farmland and 3.6 square kilometers of the basic farmland. The agreement stipulates that the basic farmland part will be adjusted by the Feixi County Government when the land use planning is revised. Feixi County used the land new policy issued by Anhui Province in 2006 to focus on the main quotas used in the cooperative park, through the method of replace construction land between city and country. Hefei provides land for large projects through mega-project specific supply and municipal-level land elasticity quotas. Under the constraints of land policies, districts and counties cooperate with each other and develop through the exchange of space resources and administrative resources.

To establish a coordination organization for city and county cooperation, the HETA commission set up the Xingang Industrial Park Office, which is responsible for the planning and construction, economic and social affairs management, and the Feixi County sent staff to participate.

3.2.3 Changes in investment and financing methods and improvement in integration

In the investment and financing mode of county-led development zone, the municipal finance did not support the Taohua Industrial Park. The investment and financing of the industrial park had to rely on the fragile county-level government financial support to gradually improve the infrastructure construction. Due to the shortage of external capital and policy resources, the county only can afford low-level infrastructure construction, and it is difficult to compete with HETA. As a result, small enterprises with small scale and low output value are in the development zone. The land use function is mixed and highly fragmented. The overall performance is lower than the adjacent HETA. In the cooperative park model, the new investment and financing plan is led by the district investment company to build infrastructure and park development, and more reliance on the district's local finance and social capital.

Under the background of the city and county integration strategy, Integration with the HETA has realized in the plan and Xingang Industrial Park has become part of the spatial structure of the HETA and is integrated in transportation, space and land. Xingang Industrial Park can

be regarded as the expansion and extension of the general planning of the HETA in Feixi County.

3.3 China South City project

After 2009, the development of industrial park depends on the attraction of small and medium-sized industrial project was restricted by higher investment threshold and less allocation of land quota. . However, with the continuous progress of the integration of city region, the development path dominated by industrial parks gradually turns to large-scale space production of industrialization and urbanization. In 2012, new industrial park founded by Feixi county in 2019 was chosen to develop China South City's mega e-commerce logistics center in the three sites recommended by Hefei government. According to project requirements, the former plan was adjusted and satisfied the demand of land size of 17 square kilometers.

The Mega-project represented by China South China has strong supportive role in county industrialization and urbanization, which has become a typical model of county development and arouse social attention widely in this period. The development of industrial parks was dominated by one or several Mega-projects that account for the majority of city incremental development space, which affects both county's spatial form and future development direction, besides the government's fiscal balance.

3.3.1 The proposal of county breakthrough strategy with counties' increased importance in municipal administrative area

After 2009, the city government participating in the fierce regional competition was challenged by the increasingly scarcity of incremental land in the central city, the development has focus on suburban county for broader space and more convenient land supply under China's characteristic land supply policy. In this context, the municipal government attaches importance to industrial and spatial layout of the county, positively introduce projects for county industrial parks and puts forward the development strategy of county breakthrough.

The specific strategies for county breakthrough mainly include the integration of metropolitan fringe area county administrative division into the southwest central district in the newly formulated Hefei strategic plan and the promotion of interregional infrastructure construction. The TaoHua area has in fact been integrated with the Hefei central district from urban planning, construction management and economy development.

Another implication of county breakthrough is that Municipal government promoted urban infrastructure, and urban public services extend to the suburban areas. After 2006, the integration of planning and infrastructure between cities and counties was rapidly promoted, the three counties leading by Hefei were required to construct infrastructure by the same standard of central city, the public service including water supply, public transportation, gas and traffic facilities etc. were constructed to integrate urban and rural area. The significant

example is the interregional roads extension to three counties. The country road used to be built as required were upgraded to regional expressway network, the investment of expressway construction is for the municipal government while the land expropriation cost is for the counties. With the elimination of traffic barriers, the integration of cities and counties contribute to attract Mega-projects located in the suburban counties of metropolitan areas.

3.3.2 City-county collaboration dominated by central city

Constrained by central government's tighter control of land, land quota distributed by upper government besides sufficient development space is the key factor for development and possible revenue growth. Only through mega-project's additional land quota at the expense of transfer part of its administrative power can Feixi county enjoy the fruits of mega-projects development and take the lead in the political tournament with neighboring districts and counties. The representative mega-project development pattern of city-county collaboration and consultation mechanism at this stage reflects the direct intervention of municipal government upon the county administrative area.

In mega-project's special insolvency procedures, the county urban planning was revised and different departments, lower levels government and social forces would be mobilized in implementation, for example, simplified procedure and one-stop service, the privilege land and taxes policy for mega-projects and the acceleration of land expropriation, house removal and infrastructure construction.

3.4 Mechanism analysis on Regional Governance changes

Changes in county governance arrangements, especially the regional governance of the suburban counties of metropolitan areas, can be regarded as results of interaction between city and county under external factors such as external regional challenges and policy changes etc.. In the first phrase, Hefei municipal government established development zone located in metropolitan fringe areas to participate in regional competition and obtain development space through administrative adjustment on county while the incompleteness of laws and regulations on the development zones provided opportunities for the establishment of county development zones to prevent administrative division adjustment, which also brings problems such as space fragmentation and insufficient spatial integration. With the central government's cleanup of the development zones, the adjustment of policy documents and difficulties to continue administrative adjustment, marked by the establishment of the cooperative park led by the municipal government, administrative, economic resources were cooperated and exchanged between city and county, which contribute the initial development of regional integration. In the third phrase, the increasingly scarcity of incremental land in the central city while suburban counties' broader space and more convenient land supply policy drive the municipal government reconsider the development of municipal region and promoted the interregional infrastructure construction to integrate urban and rural area and the integration of metropolitan fringe area county administrative division into the southwest central district in the newly formulated Hefei strategic plan. In the representative mega-project development

pattern, regional government of City-county collaboration dominated by central city came into being through Feixi county transfer part of its administrative power to city government after evaluation of external conditions and interior resource.

In general, the territorial governance arrangement in the suburban counties of metropolitan fringe area is shaped by the regional competition and the goals of economic development, which is pushed by the central city through the interaction of powers from different levels of government and stakeholders, under China's administrative hierarchy, especially the "city-leading-counties" system.

4. Conclusion

4.1 Regional governance changes in the suburban counties surrounding metropolitans under the influence of external factors

Driven by entrepreneurialism, central city's attempt to join the fringe area for the development of industrial parks into county territory has to comprise with the suburb county's government. Influenced by the external factors such as external environment, macro-policy, land and planning policies of central China at different development stages, through continuous game among multiple subjects especially the city and county governments, a typical region government arrangement at the metropolitan fringe area came into being.

4.2 Reconstruction of Region Governance in suburban counties surrounding Metropolitans is a government-led project

In all cases of regional governance, administrative power was the most obvious driving force. The mass political and economic capital possessed by the government can effectively promote or hinder the implementation of regional governance measures, which has transformed the urban-regional reconstruction in suburban counties surrounding metropolitans into a huge government project. Influenced by totalitarianism with Chinese characteristics, county government continuously resists administrative adjustment or seeks support or permission from above on its own interests, even if only some acquiescence to local reforms, in order to obtain the legitimacy and enhance the effectiveness of governance.

4.3 Reterritorialization of different levels of government

Under the circulation tendency of capital and the penetrating force of market, the horizontal administrative boundaries between cities and counties has been gradually broken. The city-county cooperation replaced previous competition and resistance. Although it takes time to form a mature cooperation framework and consensus, the most direct, fastest and simplest regional governance of administrative division adjustment have been abandoned. In governance represented by specific projects, participation and participants vary from time to time, the degree to which participants want to co-operate depends on their understanding of the interests of the city and their judgment of the gains and losses of power (Jingxiang Zhang, 2002).

⁴ Politecnico di Torino - DIST, alys.solly@polito.it

Abstract: Although the functions of spatial governance and planning systems are generalizable, 30 years of comparative studies, especially in Europe, have shown the heterogeneity characterising these “institutional technologies”. Particularly, they differ in the capacity for public control of spatial development, a crucial aspect for the life of entire cities, regions and countries. The proposed contribution builds on the materials of the recently concluded ESPON COMPASS research project to propose a European typology on this issue. Based on the opinions expressed by respective national experts, the systems of 39 countries (28 EU and 11 non-EU) are compared in relation to the mechanisms to allocate land use and spatial development rights as well as to the prevalence of public vs. private interests in guiding the development decisions. As a result, the European systems are placed on an X-Y diagram, which makes it possible to cluster them in consistent types that raise new comparative observations and general findings. In summary, the capacity for public control of spatial development looks variegated in Europe, and is conditioned by a mixture of factors. In this scenario, the different models adopted for allocating spatial development rights need to be understood in the context of actual state-market relations.

Keywords: spatial governance; spatial planning; spatial development; systems.

Introduction

The political and technical practices used to order space date back to very ancient times, and the establishment of modern states has led to the creation of their respective “systems” of spatial governance and planning (usually known as “planning systems”), which allow the public authority to guide and control spatial development in respect of property rights. Ultimately, these “institutional technologies” (Janin Rivolin, 2012) allocate the rights to use and transform the physical space through the concurrence of constitutional and legal devices, administrative provisions and tools, and the activity of technical cultures. It is needless to add that, since any social and economic activity requires a space to take place, the spatial governance and planning systems (SGPSs from now on) are determinant for the economic and social life of entire cities, regions and countries, contributing also to shape the “citizenship” affected by their action (Mazza, 2015).

The SGPSs have been subject of comparative analysis especially in Europe in the last 30 years, also for the need of mutual knowledge in the context of Community integration (for a compendium, see: Nadin and Stead, 2008, 2013). The first “comparative study” labelled as such was commissioned by the British government in order to understand the various effectiveness of public control over spatial development in few major countries of Western Europe (Davies et al, 1989). This study clarified that the “legal basis” on which the systems are pivoted constitutes a crucial element for determining the degree of certainty/flexibility in the state-market relations that concur to the spatial development. It showed in practice that, while most Western European systems are based on binding plans, which provide complete and detailed sets of rules created in advance of each punctual decision of spatial development, the British system – inspired by the principles of Common law

– is mostly based on non-binding plans, which allow the planning authority more flexibility (and discretion) in deciding case-by-case.

Without prejudicing this fundamental distinction, the first comprehensive comparative study commissioned by the institutions of the European Union (EU) highlighted that the functioning of SGPSs is characterised by various other factors, such as the scope of the system, the extent and type of planning at national and regional levels, the locus of power, the relative roles of public and private sectors (CEC, 1997). These factors contribute, together with the constitutional provisions and administrative traditions, to determine the maturity and completeness of the system and, ultimately, the distance between expressed objectives and achieved outcomes in each of them. More recent studies have also emphasized the role of “planning cultures” (Sanyal, 2005, Knieling and Othengrafen, 2009) in shaping the concrete practices through which the SGPSs make their purposes operational (Reimer et al, 2014).

However, whatever the various possible analytical distinctions among the systems, it seems clear that their effectiveness in the public control of spatial development (with the related socio-economic consequences) depends to a large extent on the specific methods of assigning the rights to use and transform the physical space (Janin Rivolin, 2008, 2017, Muñoz Gielen and Tasan-Kok, 2010). In other words, the process of operating these institutional technologies is certainly very complex but, ultimately, ‘the final output of such a process is the act of physical development (or, in some cases, the decision not to develop, but to leave the land as it is)’ (Hall, 2002, 3). The most recent comparative study on European SGPSs is the ESPON COMPASS research project, addressed ‘to provide an authoritative comparative report on changes in territorial governance and spatial planning systems in Europe from 2000 to 2016’ (ESPON, 2018a, vii). Although the goals of this research project were multiple, the raw material with which the project was developed makes it possible for the first time to compare how the rights to use and transform the physical space are specifically allocated in 39 European (EU and non-EU) countries, as well as whether the public or private interests prevail in guiding the development decisions.

Having taken part in the research, the authors of this paper have elaborated some meaningful information derived from the questionnaires compiled by the national experts, enabling them to propose a typology of European SGPSs in terms of capacity for public control of spatial development. After this introduction, the paper continues with an illustration of the research context and of the methodology adopted in the study. A following section presents the results of the analysis. The emerging European typology of SGPSs is then proposed and commented. Finally, a concluding section completes the contribution by reflecting on the findings both for the purpose of future research and for the policy implications on spatial governance and planning in Europe.

The COMPASS project and what it can say about the public control of spatial development

The ESPON COMPASS research project – launched in 2016 for a “Comparative Analysis of Territorial Governance and Spatial Planning Systems in Europe”, and concluded in October 2018 – provides a structured overview of investigations, on the one hand, to compare the state of SGPSs in the 39 countries¹ and, on the other, to understand how the EU policies contribute to the change of these systems, with particular attention to the years of the new millennium. Based on a survey that has involved national experts of the respective countries through detailed questionnaires, providing quantitative degrees of perception supported by qualitative evidence and observations, the research project concluded, amongst other things, that (*ibid.*, 28)

The overall formal structure of planning systems and territorial governance is consistent across Europe with governments managing rights to develop through a hierarchy of planning instruments and development regulation. Governments use spatial planning to manage spatial or territorial development and to engage stakeholders and citizens in that process. There is considerable variation in the precise arrangements of instruments and procedures which tends to reflect the legal and administrative structure of government. There are no other significant patterns in the variation of systems. There is strong consistency in the way that countries are reforming planning, particularly to

¹ In addition to the 28 EU Member States, the research was extended to Albania, Bosnia Herzegovina, Iceland, Kosovo, Liechtenstein, Macedonia, Montenegro, Norway, Serbia, Switzerland and Turkey.

reduce the administrative burden of decision making by simplifying plan and regulation procedures; and to provide more speedy decisions and certainty in the system.

Moreover (*ibid.*, 40),

The analyses have shown that the level of policy integration is generally increasing in spatial planning and territorial governance; that spatial planning now engages citizens and stakeholders more strongly than it did in 2000; and that in most countries, spatial planning instruments were more robust and able to adapt to changing circumstances in 2016 than they were in 2000.

In the framework of this research, ten questions addressed to national experts were considered of particular meaningfulness for the purposes of the present work (Table 1).

Table 1 – ESPON COMPASS questions used for the analysis of SGPSs (based on: ESPON, 2018b).

1.	Describe the constitutional framework for spatial planning in your country by indicating what rights exist, who holds such rights and how they are regulated and supervised (I.19*).
2.	Provide a simple diagram explaining the main steps in the process of making a plan that allocates development rights, or provides a policy framework for the allocation of development rights, as at the end of 2016 (I.20).
3.	Provide a simple diagram explaining the main steps in the process of applying for and granting of development rights (permit or permission) (I.21).
4.	Provide a diagram depicting the main planning instruments in the spatial planning system at the end of 2016 (I.5).
5.	Name the local level 1** spatial planning instruments, if any, that are part of the formal planning system in 2016. In the case of local variations choose one or two typical examples of type of instrument (I.15).
6.	For each local level 1 spatial planning instrument, describe briefly what are the main changes since 2000, and any expected changes in the near future, specifically in regard to form or character, scope and content, and procedure within (I.16).
7.	Name the local level 2 spatial planning instruments, if any, that are part of the formal planning system in 2016. In the case of local variations choose one or two typical examples of type of instrument (I.17).
8.	For each local level 2 spatial planning instrument, describe briefly what are the main changes since 2000, and any expected changes in the near future, specifically in regard to form or character, scope and content, and procedure within (I.18).
9.	Explain the extent to which each instrument was actually produced in 2016 – complete coverage, partial, patchy, or none. Are the plans produced still ‘up-to-date’, timely or relevant according to local expectations? Has the production of planning instruments improved, worsened or varied since 2000 (are more or less plans produced now according to national expectations)? What reasons explain performance in the production of planning instruments? (II.1).
10.	Explain what is the degree of influence of each planning instrument (or group of instruments) in guiding or controlling spatial development in 2016. Does the distribution and form of spatial development follow the policies, proposals and regulations set out in those instruments? What reasons explain the degree of influence of planning instruments? Has the influence of planning instruments improved, worsened or varied since 2000? (II.2).
* This number refer to the Questionnaire in which the question was listed, as well as to the number of the question within the latter (e.g. I.19 refers to question 19 from Questionnaire I).	
** The questionnaires asked to define local “level 1” and “level 2” in terms of Local Administrative Units (LAUs).	

In particular, the answers provided by the national experts to questions 1-8 have been carefully analysed, and subsequently compared in order to attribute to each SGPS an X score according to Table 2 below. Here the minimum (0) and maximum (5) scores correspond, without any attribution of value, to the extreme ideal-types of the conformative and performative models of spatial governance and planning (i.e. on the local level, general binding plans decide any detailed transformation vs. plans are non-binding and transformations are decided case-by-case; see: Janin Rivolin, 2008). On the basis of the answers analysed, the SGPSs could therefore be grouped and scored according to four progressive degrees of relevance between the ideal conformative and performative planning models. The first group includes those SGPSs in which, more closely inspired by a conformative model of planning, the public authority tends to allocate land use and development rights through general and rigid binding plans (1). A second group includes SGPSs still inspired by a conformative planning model in which, however, the common use of binding general plans is somehow attenuated by the recurrence of specific variants or other devices that allow the plans to be modified (2). A third group concerns the SGPSs in which land use rights are established in general plans but, in the apparent attempt to pursue the logic of the performative model, the binding plans that assign spatial development rights are negotiated, detailed and very

specific (3). A last group regards the SGPSs in which, more closely inspired by a performative model of planning, the public authority tends to allocate the land use and development rights on a case-by-case basis, against a background of non-binding plans (4).

Table 2 – Scores attributed to SGPSs according to respective positions between conformative / performative models of planning (authors' own elaboration).

X Score	Description
0	<i>Ideal conformative model (general binding plans decide any detailed transformation)</i>
1	The public authority tends to allocate land use and development rights through general binding plans
2	The public authority allocates land use and development rights through binding general plans, but devices that allow to modify plans (e.g. variants) are recurring
3	The public authority allocates land use rights through general plans, and spatial development rights through detailed binding plans
4	The public authority tends to allocate land use and development rights case-by-case
5	<i>Ideal performative model (plans are non-binding and transformations are decided case-by-case)</i>

Furthermore, the answers provided by the national experts to questions 5-10 have been analysed and compared in order to attribute to each SGPS a Y score according to Table 3. Here the actual model of spatial development resulting from each system is at stake, centred around three ideal benchmarks that, without any attribution of value, are: the ideal state-led model of spatial development, where the public interest dominates (3); the ideal market-led model of spatial development, where the dominance of the private interest is absolute (-3); and the ideal balance between public and private interests (0). The SGPSs could therefore be potentially grouped and scored according to four progressive degrees of relevance around those ideal benchmarks, namely: on the one hand, the SGPSs in which the spatial development is mainly driven by public interest (2) and those in which it is driven by a mix of public and private interests, with a prevalence of the former (1); on the other hand, the SGPSs in which the spatial development is mainly driven by private interest (-2) and those in which it is driven by a mix of public and private interests, with a prevalence of the latter (-1). However, due to the extreme variety of answers analysed and to some difficulty to score them the same way, the possibility of intermediate scores (0,5 etc.) was also envisaged.

Table 3 – Scores attributed to SGPSs according to respective positions between state-led / market-led models of spatial development (authors' own elaboration).

Y Score	Description
3	<i>Ideal state-led spatial development (absolute dominance of the public interest)</i>
2,5	
2	Spatial development is mainly driven by public interest
1,5	
1	Spatial development is driven by a mix of public and private interests, with a prevalence of the former
0,5	
0	<i>Ideal balance between public and private interests</i>
-0,5	
-1	Spatial development is driven by a mix of public and private interests, with a prevalence of the latter
-1,5	
-2	Spatial development is mainly driven by private interest
-2,5	
-3	<i>Ideal market-led spatial development (absolute dominance of the private interest)</i>

How European systems are positioned with respect to the models of planning and of spatial development

In accordance with the methodology illustrated above, the 39 systems analysed are positioned in the X-Y diagram as shown in Figure 1.

Figure 1 – Positions of European SGPSs with respect to the models (X) of spatial planning and (Y) of spatial development (authors' own elaboration)

Following the X axis of the diagram, 6 SGPSs all belonging to non-EU countries in the Western Balkan region look more closely inspired by a conformative model of planning, since the public authority tends to allocate land use and development rights through general and rigid binding plans. These systems have in general a very hierarchical character and the allocation of spatial development rights is commonly issued by the approval of local binding plans, general for their administrative extension but very detailed in their form and rigid for their duration, although in some cases (e.g. Albania, Kosovo) the national authorities can directly provide building permissions through plans of national importance (Berisha, 2018, Berisha et al, 2018).

A further 13 SGPSs, which in general belong to Mediterranean countries (France, Greece, Italy, Portugal, Spain, Turkey) but also to some Eastern (Bulgaria, Croatia, Hungary, Romania) and Western (Belgium, Liechtenstein, Luxembourg) European countries, are still inspired by a conformative planning model, although the prevalence of binding urban plans is here compensated by the recurrent use of specific variants and other devices that allow the plans to be modified over time. To give just one example of how the system operates in these cases, the 1995 Turin city plan in Italy has so far been subject to around 400 variants. Furthermore, in many Italian municipalities the “variation request” is now commonplace, so that every citizen or person who has an interest in it can present projects that differ from the plan. While in Mediterranean and Eastern European countries the proximity to a conformative planning model seems to be mainly due to a path-dependence on respective administrative traditions and technical cultures (Muñoz Gielen and Tasan-Kok, 2010, Benedek, 2013, Janin Rivolin, 2017), the Western SGPSs in Liechtenstein and Luxembourg look somehow conditioned by the limited geographical dimension of countries and, in Belgium, by the actual operation of three systems of regional extension in Brussels, Flanders and Walloon (Hanocq, 2011). In Turkey, spatial planning has been subject to centralisation mechanisms since 2000. Here, the political authority attempts to centralize urban politics, to eliminate mechanisms of participation in decision making and to impose an authoritarian and top-down decision-making style as the dominant mode of decision (Lovering and Turkmen, 2011, Tansel 2018).

Almost half of the SGPSs (16), mostly located in Western Europe and in the Baltic region but also in some Eastern European countries (Czech Republic, Slovakia, Slovenia, Poland), seems to be aimed at pursuing the logic of the model of performative planning, since land use rights are generally established by general urban plans, but the binding plans that assign spatial development rights are specific for small areas (therefore subject to verification on a case-by-case basis). Furthermore, as is clear for example in Denmark, the Netherlands, Germany and Sweden, ‘binding land-use rules (whether this concerns a new land-use plan or a modification of one to create new building possibilities) are only approved once negotiations with developers/land-owners have taken place or, at least, when there is enough certainty about their successful conclusion’ (Muñoz Gielen and Tasan-Kok, 2010, 1100). Ultimately, the emergence of “development-led practices” has been recognised in the vast majority of Western and Nordic countries as an opportunity to reform the respective systems in order to achieve, albeit with mixed success, more felicitous public control over spatial development (Buitelaar et al, 2011, Kule and Røsnes, 2011, Gerber, 2016, Valtonen et al, 2017, Humer, 2018, Zakhour and Metzger, 2018). The same transition occurred in those Eastern European countries that saw the exit from the Soviet regime in the late 1980s as an opportunity to re-launch their economies through more flexible spatial development (Cotella, 2007, 2014, OECD, 2018).

Finally, 4 SGPSs that, by possible coincidence, belong to “islands” surrounding the European continent (i.e. the United Kingdom and Ireland to the north, and Cyprus and Malta to the south) are more closely inspired by a performative model of planning, because the public authority tends here to allocate the land use and development rights on a case-by-case basis, against a background of non-binding plans. As is well known, the system was radically changed in the U.K. with the 1947 Town and Country Planning Act, which attributed the right to build to the Crown (the State) and established that ‘the development plan did not of itself imply that permission would be granted for particular developments simply because they appeared to be in conformity with the plan’; rather, ‘in granting permission to develop, local authorities could impose “such conditions as they think fit”’ (Cullingworth and Nadin, 2002, 93). Then the 1968 Town and Country Planning Act assigned to structure plans the provision of strategic orientations for development and to local plans (non-mandatory and concerning only specific areas) the provision of detailed guidance on land use, establishing, despite various reforms under Thatcherism, New-Labour and recent governments, the current features of the British (especially English) system (Nadin and Stead, 2014). Very close to the British administrative and technical culture, the Republic of Ireland has adopted a similar system. The same is true for Cyprus and Malta as former British colonies (Gauci, 2002).

Looking at the Y axis of the diagram, it is worth noting, first of all, that no European SGPS appears nowadays, in the opinion of the respective national experts, mainly driven by the public interest. The system that comes closest to this definition is the French one, in which even the tendency to move from a redistributive planning idea to a more market-oriented notion has not particularly weakened the power of public control of spatial transformations (Waterhout et al, 2013). In another 5 SGPSs, that characterise the Nordic countries, spatial development seems to be driven by a mix of public and private interests, with a prevalence of the former. In Denmark, for instance, a shift from welfare strategies towards more growth-oriented policies, ‘which can be understood as a necessary change of governmental style in order to complete a shift from a demand- to a supply-led economy, has not been accepted by provincial politicians in general, and in particular those from the peripheral regions’ (Andersen, 2008, 12). In Sweden, the 1990s recession led to an oversupply of the housing and construction market, as well as to a massive privatisation process, but the municipal “planning monopoly” remains traditionally very strong, as well as the social policies and democratic welfare state (Caesar, 2016, Zakhour and Metzger, 2018). More generally, the neo-liberal turn that has also affected the Nordic countries and Iceland has given rise to new soft urban planning instruments, non-statutory planning methods and public-private partnerships which, however, have weakened the public authority’s capacity to promote the public interest only to a limited extent (Ilmavirta, 2018). The same has occurred, although to a lesser degree, in the 2 SGPSs belonging to the UK and Ireland where, despite the major effectiveness of systems in terms of public control, recent national governments have explicitly pursued neo-liberal policy agendas and market-oriented policy-making (Kitchin et al, 2012, Waterhout et al, 2013).

Contrastingly, in 12 SGPSs across Western Europe (Austria, Germany, the Netherlands and Switzerland), Central and Eastern Europe (Czech Republic, Estonia, Latvia, Lithuania, Slovakia and Slovenia) and Mediterranean Europe (Greece and Italy) Europe, spatial development seems to be driven by a mix of public

and private interests, but with a prevalence of the latter to varying degrees. The results of spatial planning in Italy are seen as a permanent mediation between public and private needs, in which ‘Patronage and familism are often associated with the establishment of urban coalitions including politicians, developers, landowners, professionals, etc. seeking to maximize urban rent through benevolent land-use planning’ (Vettoretto, 2009, 196). In Austria, Germany and the Netherlands, ‘some impacts of a more neo-liberal (political) agenda have been cushioned by national spatial policies’ (Waterhout et al, 2013, 151), although more recently the financial crisis and economic recession have put the planning culture under pressure (Buitelaar and Bregman, 2016). The major crisis that has struck Greece has also affected its SGPS, the subject of a series of direct and indirect changes with a greater effect on the promotion of private investments (Papageorgiou, 2017, Karadimitriou and Pagonis, 2019). The “managerial turn” that has occurred in the Swiss public administrations has been leading to a more market-oriented approach to face public problems, and a growing influence of flexible private-law or incentive-based instruments in land-use planning practices has highlighted a shift towards a market driven land use planning approach (Gerber, 2016). In the Central and Eastern countries that show similar tendencies, the transition from the socialist economic system to the market one has taken place in parallel with a series of structural reforms (privatization, liberalization, decentralisation etc.) which, in the field of spatial governance, tend to accelerate the release of building permits to attract and facilitate private investment (Ruoppila, 2007, Brade et al, 2009, Notermans, 2015, Liepa-Zemeša and Hess, 2016).

Another 11 SGPSs distributed across Western Europe (Belgium, Liechtenstein and Luxemburg), Balkan and Eastern Europe (Albania, Croatia, Montenegro, Romania, Serbia) and Mediterranean Europe (Cyprus, Spain and Portugal) show, albeit to different degrees, that spatial development is mainly driven by private interests. This trend appears to be more moderate in the Western countries, where however actors, operating in self-interest, frequently bypass, undermine, and reconfigure governance arrangements through informal circuits of decision-making and networked exchanges (Affolderbach and Carr, 2016). Here the setting of building permits has been oriented to the protection of private property, which hinders the government’s ability to implement a coherent spatial policy (Van den Broeck and Verachtert, 2015). In Cyprus, the increased interest of the international real estate market immediately before and after joining the EU has led to the explosion of the phenomenon of second homes (Potsiou et al, 2009). A prevalence of private interests in the spatial development is even more evident in Spain and Portugal, where the development of the urban space is often seen as a sum of private development projects, leading to frequent real estate bubbles (Mantiñán, 2010, Mirò, 2011). This is also the case in the Balkan region, where a high level of corruption, the limited capacity of the public authority to withstand the pressures and logic of the market, and a low level of administrative know-how in spatial planning have led to the privileging of private rather than public interests, even in spite of what the law establishes (Berisha et al, 2018).

However, spatial development seems to be driven by private interests especially in another 8 SGPSs located in the Balkans and Eastern Europe (Bosnia and Herzegovina, Bulgaria, Hungary, Kosovo, Macedonia and Poland), as well as in Malta and Turkey. Although in these Balkan countries spatial planning is often considered a technical device that aims to limit the free initiative of private individuals, corruption, informality, illegal development, poor public control over spatial development – in a social contest characterized by a high level of fragmentation based on ethnic, political and economic reasons – are widespread (Boussauw, 2011, Stefanovska and Kozelje, 2012, Djurasovic, A., 2016). In Bulgaria, the power relation between state and market in spatial governance has changed drastically since the 1990s, and it seems currently that market-led development has definitively taken over from the state-led development (Slaev and Nikiforov, 2013, Kovachev et al, 2017). In Poland, about 80% of spatial transformations are legitimised through the so-called “decisions on development conditions” (*edecyzja o warunkach zabudowy*) which, on the basis of the investors’ proposals, are approved on a case-by-case basis even if in contrast with the local plan (Cotella, 2014). A prevalence of market-led development, particularly for the tourist economy, over state-led development is also evident in Malta (Gauci, 2002). Finally, a sort of “authoritarian neoliberalism” would seem to push public authorities to act as market actors in dealing with land use and spatial development in Turkey (Tansel, 2018).

A (new) European typology of spatial governance and planning systems

The analyses summarised in the previous section have led to the identification of five types of SGPSs which, with reference to the capacity for public control of spatial development, can currently be found in Europe. Without neglecting the margins of uncertainty that such complex interpretations inevitably imply, this

typology can be represented in Figure 2 in the form of SGPS clusters with close characteristics in terms of capacity for public control of spatial development, understood as the final product of the respective models of spatial planning and development. Figure 3 shows how the various types of SGPSs are mapped on the European continent.

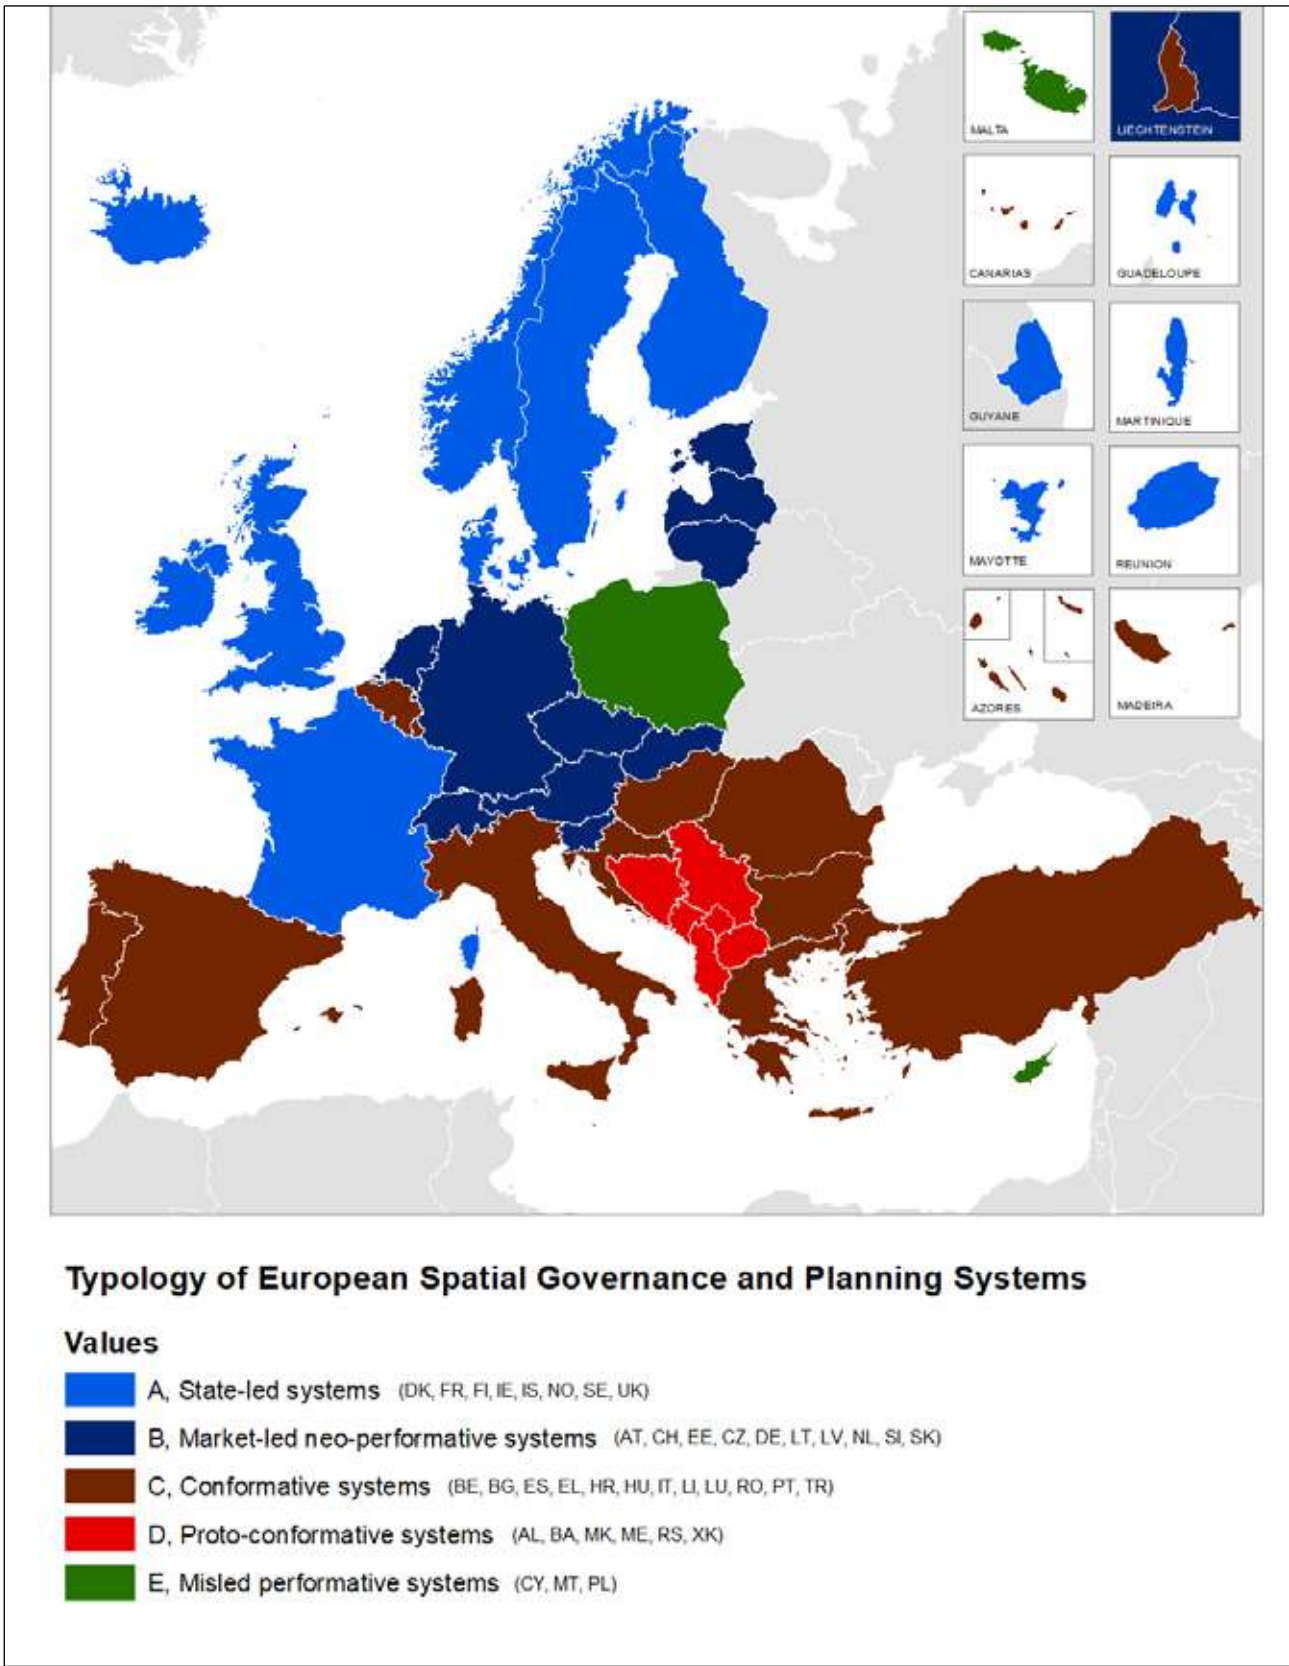

Figure 2 – Typology of European SGPSs with respect to the capacity for public control of spatial development (authors' own elaboration)

Type A in the figures, which includes 8 SGPSs that are mainly found in Northern and Western Europe, can be defined as that of the *state-led systems* because, despite the different models adopted for the allocation of spatial development rights, spatial development is here mainly driven by public interests, even if to different degrees with respect to the influence of private ones. It should be noted that most of these systems (5 out of 8, all located in the Nordic countries) are “neo-performative” in terms of allocating spatial development rights, in the sense that they generally avoid a “blind” pre-allocation through the use of general plans, preferring to postpone it until after specific negotiations with landowners and developers within detailed plans (Janin Rivolin, 2017, 1004-1006). In this framework, the minor capacity of the performative systems of UK and Ireland to guarantee the public interest seems to be due to the explicit political orientation of the respective governments, rather than to the planning model adopted. On the other hand, France seems an exception as it is characterised by a tendentially conformative system that is able to better guarantee the public interest in spatial development, due to the traditional strong role maintained by the central government in orienting the overall process of spatial governance (CEC, 2000).

Type B, which includes 10 SGPSs across Baltic, Central-Eastern and Western Europe, corresponds to *market-led neo-performative systems*, since the model adopted for the allocation of spatial development rights has the characteristics described above (i.e. the rights are assigned through detailed plans previously negotiated with the private actors) so that spatial development is driven by a mix of public and private interests, but with some prevalence of the latter. This prevalence is minimal in the case of Austria, Germany and the Netherlands, and in any case due to the more or less recent neo-liberal tendencies in the orientation of governments. It seems to be increasing in Switzerland for similar reasons (Solly, 2018). In the Baltic Republics and in the concerned countries of Central and Eastern Europe, a greater prevalence of private interests is probably due to the more difficult application of this planning model in the face of the socio-economic and political changes occurred since the fall of the Soviet bloc (Cotella, 2007).

Figure 3 – Map of European SGPSs with respect to the capacity for public control of spatial development (authors' own elaboration)

Type C, which concerns 12 other SGPSs adopted mainly in the countries of Southern and Eastern Europe, but with a few exceptions also in Western Europe, is that of *conformative systems*. Here the public authority

assigns the rights to use and develop the land through the more traditional method of binding general plans, but with the recurrent use of variants that can subsequently modify them. With the sole exception of France, discussed above, with this model spatial development is generally driven by private interests, although by very different degrees in terms of the simultaneous influence of public ones. The general tendency in this regard is that the capacity of public control is relatively less weak in the countries of Southern and Western Europe, where the systems have been established for longer periods, and shows more difficulties in the Eastern countries which, after the fall of the Soviet regime, have embraced this model of planning.

Type D, which includes 6 SGPSs belonging to non-EU countries in the Balkan region, can be defined as that of *proto-conformative systems*, since the method of assigning land use and development rights through binding general plans is based on the original and most authentic ideals of hierarchy (top-down relations between the levels of planning) and of dirigisme (state-led implementation of the plans). However, spatial development proves to be mainly driven by private interest in all these countries, which have embraced this model of development rights allocation after the fall of the Soviet regime. This type of SGPSs, even more than the previous one, seems to confirm that, in current times, ‘when municipalities fix development possibilities early in the development process, this might stimulate land price increases and might also lead to the loss of a valuable negotiation tool’ (Muñoz Gielen and Tasan-Kok, 2010, 1126).

Finally, type E concerns the 3 SGPSs in force in Cyprus, Malta and Poland and can be indicated as that of *misled performative systems*. As we saw in the previous descriptions, the public authority tends to assign land use and development rights on a case-by-case basis or through the use of detailed negotiated plans, but the overall result is that territorial development is driven primarily by private interests, with some moderate attention to the public interest only in Cyprus. In these cases, the “treasure” of public authorities that a performative model of assigning rights can generally guarantee – ‘that of being the only institution entitled to decide, with certain discretionary powers, if, when and what is allowed to be built’ (*ivi*) – is somehow given away to market forces, which have enough power to direct public decisions towards their own interests.

Conclusions

Spatial governance and planning systems (SGPSs) are institutional technologies by which, in every state of the world, the public authority guides and controls spatial development in respect of property rights (Janin Rivolin, 2012). Elaborating the materials of the ESPON COMPASS research project, concluded in 2018, this paper has compared the current capacity for public control over spatial development in 39 European countries. The compiled evidence led to developing a European typology of SGPSs focused on their main functions which, taking into due consideration some necessary warnings, opens a series of final reflections.

The warnings are especially related to the high degree of interpretation that any comparative study on such a complex issue as spatial governance and planning fatally implies. In particular, as explained above, the analysis carried out in this contribution was based on information and opinions provided by individual national experts in the framework of the COMPASS research project. Furthermore, an attempt at simplification was required to reduce the complexity of the data and ratings to a single score, with respect to the land use and spatial development rights allocation model and the public/private interest model that drives spatial development. However, the attribution of each individual score was explained in the previous sections, and the overall typology that emerges from their combinations seems to present a certain degree of coherence with respect to the current debate on the subject.

If so, one general conclusion of the comparison carried out is that spatial development is currently driven more by private interests than by public ones in the vast majority of European countries (31 SGPSs out of 39). This is not surprising and reference can be made to the discussions on the alleged “neo-liberal turn” affecting spatial governance and planning (Brenner et al, 2010), as well as on the correlated effects of the recent global crisis (Ponzini, 2016). In this context, the model of allocation of land use and spatial development rights is not in itself a guarantee of the promotion of the public interest, since the prevalence of private interest in the orientation of spatial development is found in combination with all the models analysed, although in different degrees. After all, as institutional technologies at the service of public authority, the SGPSs – whatever the model of allocating rights – can certainly be used to promote spatial development driven by the market, if this is the declared political direction of governments. But since the political orientation of national governments

in Europe is varied and fluctuating, especially in current times (Hancock et al, 2014), from a technical point of view it is perhaps more interesting to note the trend performances of spatial rights allocation models with respect to the possibility for public control of the spatial development.

In this regard, it cannot be overlooked that the so-called “neo-performative” model (which avoids a blind pre-allocation of rights by general plans, and assigns them through previously negotiated detailed plans) is the most widespread within the few *state-led systems* (type A) and that which characterizes SGPSs in which a prevalence of private interest is contained to a minimum extent (type B). On the contrary, the more traditional conformative model for the allocation of spatial development rights (i.e. their pre-allocation through general plans) is generally unable to guarantee the containment of private interest in driving spatial development (type C) and, as it seems, can work in favour of the public interest only in the very specific institutional, administrative and cultural conditions that are present in Europe only in the French *aménagement du territoire*. Furthermore, the situation worsens in those Balkan countries that have rigidly embraced the conformative model (type D) with ambiguous spatial development consequences and illegal practices. In any case, these countries, like those that have adopted the opposite performative model (i.e. allocation of land use and development rights case-by-case) in the absence of sufficient institutional guarantees of public control (type E), show above all that highly unbalanced state-market relations can end up undermining the very nature of the institutional technology for spatial governance.

Overall, the comparative analysis carried out shows that the capacity for public control of spatial development is highly differentiated in Europe, as a consequence of multiple factors ranging from the political direction of governments to the actual relations between state and market that affect each institutional context. As institutional technologies created to obtain public control of spatial development, the variable characters of the SGPSs existing in Europe are arguably the main reason for this differentiation. The different ways in which systems allocate land use and spatial development rights explain to a large extent the capacity for public control, but each model adopted must be understood in relation to the respective political and socio-economic context. It should be emphasized that these considerations remain valid also in reference to only the current 28 EU countries, which are distributed across the entire typology elaborated here, with the sole exception of *proto-conformative systems* (type D). From a research perspective, this can offer new insights in the field of governance and spatial planning, especially in the context of comparative studies increasingly oriented to assess the performance of systems. From a policy perspective, the coexistence of such diverse SGPSs in Europe also draws attention to issues of coherence as regards the EU economic, social and territorial cohesion policy, whose implementation is ultimately filtered by these systems.

Acknowledgements

The authors are grateful to all the partners of the ESPON COMPASS research project, and particularly to the Delft University of Technology as the lead partner. The authors would also like to thank Donato Casavola for his contribution to the analysis of the questionnaires during his Master thesis work.

Aspern explained: How the Discursive Institutionalization of Infrastructure Planning shaped North-Eastern Vienna's Urban Transformation

Astrid Krisch¹, Johannes Suitner²

¹*TU Wien, astrid.krisch@tuwien.ac.at*

²*TU Wien, johannes.suitner@tuwien.ac.at*

Abstract: Public perception of infrastructure planning is oftentimes simplistic: experts instruct adaptations to the physical environment in consequence of contextual structural influences. Such structure-agency imaginaries imply an argumentative bypass though that neglects discursive institutionalizations of (1) the ideal structure of society, (2) the envisioned ideal-type city, and (3) the disciplinary self-conception of “good planning” as key intermediary instances of development and change. Focusing such discursive institutionalizations thus could aid understanding and explaining the origins of the material transformation of the city. We exemplify this notion with an analysis of Aspern in northeastern Vienna and its urban transformation since 1954. We claim that its conversion from cropland to smart and sustainable development area is not just the often-cited logical result of a re-urbanization trend manifesting in a zeitgeisty form, but the path-dependent materialization of past discursive institutionalizations of infrastructure planning. Employing an ASID and discursive institutionalist perspective, we point to critical strategic action and discursive complexity reduction, the institutionalization of networked infrastructure in the planning system, and its consequential materialization in a distinct form of infrastructure development. Our analysis uncovers institutionally stable phases of infrastructure planning as well as critical transitions in the planning system – all shaping Aspern's subsequent development. Retracing this process serves as an explanation to the multi-layered path-dependency of the entailing realization of a large-scale urban development project. Herewith, the research contributes to a better understanding of the discursive institutionalization of infrastructure planning and the planning-development nexus at large.

Keywords: Networked Infrastructures, Discursive Institutionalism, ASID, Vienna

Introduction

“Study a city and neglect its sewers and power supplies (as many have), and you miss essential aspects of distributional justice and planning power.” (Star, 1999, p. 379)

Public perception of urban change is oftentimes biased by a simplistic conception of how the planning-development relation works. Planning experts with comprehensive knowledge of current and future contextual structural influences instruct physical changes to the cityscape to solve urging urban problems and adapt the city’s built environment and functional pattern to the challenges ahead. Taking an institutionalist stance, however, the practice of regulating city-building must be viewed as the result of path-dependent institutionalizations (Sorensen, 2015, 2018). These institutionalized practices and discourses that constitute a territorial planning system can hardly be bypassed (*ibid.*). Planning-development conceptions as the one described above must thus be discarded as simplistic imaginaries of structure-agency interactions (cf. Jessop and Sum, 2006, Jessop, 2008). Instead, the act of planning must be understood as a practice that is embedded in a specific functional subsystem, characterized by a historically specific institutional order (Servillo and Van den Broeck, 2012, Moulaert *et al.*, 2016). Throughout the history of modern planning, neither has the planner’s expertise, comprehensive knowledge, or his general role within this act been uncontested, nor can we consider ‘context’ an empirically sufficient explanation for urban change. On the contrary, the solidification of certain time- and place-specific ways of doing planning, the goals, norms and rules of the game, as well as the structural constraints and opportunities for material transformations are important path-shaping variables to consider in this regard (Servillo and Van den Broeck, 2012, Moulaert *et al.*, 2016).

Moving away from a container thinking of space, it becomes clear that space is a historical product, organized through a combination of economic, infrastructural and institutional-regulatory practices (Swyngedouw, 1993). Hence, space as a historical product is connected to its social organization and therefore also those power relations involved in creating space. Taking infrastructure networks as the starting point of the investigation of urban change thus sheds light on those social structures as well as path-dependent power relations. “Transformations in the orientation and structuring of urban infrastructure must simultaneously involve reshaping the social organization of power relations in both time and space and the heterogeneity of the networks” (Graham and Marvin, 2001, p. 215). Understanding infrastructure planning therefore is crucial to grasp the interrelations between how a planning system envisions itself, the organization of society and the ideal type city with the actual physical transformation of space.

Infrastructure in this paper refers to more or less stable networks, which determine the mobility and interaction of people, goods and ideas (cf. van Laak, 2018). We refer to technical networked infrastructures as material constructs, such as roads, railways or pipelines, which influence and are influenced by economic, political and social practices. As Steele and Legacy (2017) argue, infrastructure can be understood “as relational; ecological; as everyday practice; as inherently political; as embedded in questions of human and non-human justice and equity, fiscal transparency, institutional accountability; and with a particular emphasis on the critical role of infrastructure as part of a public urban commons.” (p. 2) Also Star (1999) emphasizes the relational aspects of infrastructure. For him infrastructure only becomes real in relation to organized practices, i.e. its institutionalization (Star, 1999, p. 380). This relational understanding of infrastructure networks corresponds with Graham and

Marvin (2001), who regard urban infrastructures as “heterogeneous assemblies of materials, technologies, social institutions, cultural values and geographical practices. Cities are held together by intimately linked social and technical assemblages that mutually construct one another in increasingly seamless ways.” (p. 214) In this sense, infrastructure networks are, contrary to common belief, only temporarily stabilized and only stable through their institutionalization within the planning system. They are determined by institutional relations and formations of power, control and access and can therefore be understood as a socio-political agenda themselves (Steel and Legacy, 2017). Dourish and Bell (2007) emphasize two perspectives on infrastructure: (1) infrastructure development for organizing space and society, and (2) infrastructure development as part of the collective construction of cultural meaning (p. 415).

Previous research has often focused on infrastructure networks in connection to their effects on national economies, analyzing demand and supply of infrastructure provision and understanding infrastructure as the underlying structure of economic processes and economic growth (Frischmann, 2011). Urban studies and related disciplines have in the past largely failed to treat infrastructure networks as an important field of study. For many years, the deterministic view of infrastructure networks as technocratic constructs shaping space dominated academic debates (Graham and Marvin, 2001). Especially studies on large technical systems (LTS) have tackled infrastructure networks in the most comprehensive manner until recently (i.a. Bijker *et al.*, 1987, Coutard, 2002, Hughes, 1993, Mayntz and Hughes, 1988). However, the complex issues of interlinked infrastructure networks and the way in which they “are involved in the social production and reconfiguration of urban space [...] tend to be ignored.” (Graham and Marvin, 2001, p. 30) In the last few years though, research on infrastructure networks increasingly moved towards a poststructuralist analytical viewpoint, regarding infrastructure as embedded in different complex sociotechnical, political and cultural systems, having contingent effects in different places at different times (see also Graham and Marvin, 2001, Graham and McFarlane, 2015, Easterling, 2016, van Laak, 2018). Infrastructure networks are increasingly recognized as systems, which are not only interlinked within different infrastructural systems, but also function as “sociotechnical hybrids”, where the relation to urban development plays a crucial role (Graham and Marvin, 2001). Hence, we also consider infrastructures an important variable for better understanding the path-dependent process of urban development and small-scale urban transformation in particular.

There are three important determinants for the discursive institutionalization of infrastructure development: the ideal structure of society, which makes an ideal type city necessary, which is based on the envisioned understanding of the functioning of planning. Infrastructure networks often serve as a legitimation strategy for a certain philosophy of planning, to legitimize political arguments, from economic progress and growth, economic and cultural competition between cities to technological and technocratic feasibility visions. For urban planning, infrastructure development is often legitimized as an adaptation strategy for urban growth and related urban pressures (van Laak, 2018). This is especially useful as infrastructure and cities are persistently intertwined, making the investigation of spatial transformations through infrastructure development at city level a useful starting point. Just like infrastructures are socially constructed, cities are infrastructural constructions (Graham and Marvin, 2001). Cities therefore function as sociotechnical processes, where “economic, social geographical, environmental and cultural change [...] is closely bound up with changing practices and potentials for mediating exchange over distance through the construction and use of networked infrastructures” (ibid.,

p. 10). Infrastructure networks thus are materialized social relations. Hence, employing the concept of infrastructure networks signals a pivotal responsibility or at least a universal public interest. Infrastructure in this sense is the collective subconscious of society and once established, easily transformed into daily routines and often taken for granted. Thus, infrastructure networks create technical and habitual path-dependencies, which materialize social relations in urban space. They become the very “organisation principle to everyday life”, sustaining “ever-accelerating geographies of production, exchange, and consumption” (Kirsch, 1995, p. 541). This organization system through infrastructure networks consolidates a lasting vision of the ideal-type city on different levels. Different scales interplay within arguments surrounding infrastructure networks, where changing dynamics of global political economies and societies are displayed (Graham and Marvin, 2001). “This ensures a wide variety of particular ways in which the political action of city agencies and politics intersects with that of nation states and international governance bodies, to shape the reconfiguration of infrastructure networks” (ibid., p. 114).

Infrastructure networks also often serve as a legitimization strategy for technologized planning visions. The process of infrastructure development is often obscured through the entanglement within highly technical and technocratic institutions, “driven by supposedly depoliticised, instrumental rationalities of engineering cultures” (ibid., p. 20). Processes of infrastructure development are as a consequence increasingly opaque. Infrastructure networks often pose as neutral and objective, however they are often instrumentalized to keep and enforce political, economic, social, cultural or technocratic interests (van Laak, 2018). Massey (1993) refers in this regard to “sociotechnical geometries of power”, where the combination of infrastructural, economic and institutional-regulatory practices is a historical product for the production and organization of space (Swyngedouw, 1993, p. 310). Especially the history of infrastructure became a significant object of investigation because it “becomes visible as a reformulation that feeds back specific ideas about the future into an urban imaginary” (Vyjayanthi, 2015, p. 40). Infrastructure in this sense can be understood as the outcome of processes of negotiations between different institutions, defining specific compromises for specific times. It is therefore an urgent issue concerning many disciplines beyond urban and planning studies (van Laak, 2018).

This paper therefore investigates the discursive institutionalization of infrastructure development for the specific case of the north-eastern part of Vienna. After introducing the theoretical framework of institutionalist perspectives on planning and in particular the concept of discursive institutionalism, we employ this concept to the specific case of Aspern’s urban transformation process since the 1950s. We retrace the different phases of important points in history, where shifts and continuities can be observed in the development of infrastructure networks and lastly draw conclusions on the planning-development nexus.

Discursive Institutionalism as a Strategic-Relational-Institutionalist Perspective on Infrastructure Planning and Urban Change

Studies tackling the complex relationship between the institutional subfield of planning, the process of infrastructure development and urban change demand a robust theoretical framework that enables categorization and detailed analysis of dimensions and their interrelations. Aiming at a historical explanation of small-scale urban transformation as the result of discursive institutionalizations of infrastructure, we employ an institutionalist perspective that allows us to uncover how the solidification of ideas in the planning system influences urban change (cf. Schmidt, 2012). This makes particular

sense considering the variety of arguments suggesting a close vicinity between infrastructure development and institutionalization processes (cf. Star, 1999, Graham and Marvin, 2001, Steel and Legacy, 2017).

We thus base our concept on the ASID heuristic by Moulaert *et al.* (2016), a meta-theoretical model for analyses of socio-economic development. Incorporating a wide array of theories from development-, regulation- and state theory to evolutionary economics and new institutionalism, ASID puts an emphasis on how institutional dynamics and spatialized regulation influence development (*ibid.*). The model thus also provides a fruitful perspective on the planning-development relation. ASID takes the role of strategic action, the power of discourse, the influence of institutional formations and the constraining and facilitating force of structure into account as mutually related factors of urban development. As the authors explain:

“For an adequate account of socio-economic development, one must refer to the actions that steer or interfere with the development processes, the structures that both constrain and enable action, the institutions that guide or hamper action and mediate the relation between structures and action, and the discourses and discursive practices that are part of these interactions.” (Moulaert *et al.*, 2016, p. 168-169).

Building on a Critical Realist ontology, the model’s emphasis is on the constraining and facilitating forces of structure that help explain time- and place-specific development paths and potential path-dependencies (Moulaert *et al.*, 2016). ASID thus provides a valuable basis when it comes to “making sense” of locally specific urban transformation processes and the local “planning conditions” that inform it. The four dimensions of agency, structure, institutions and discourse provide useful categories for systematically reviewing the layers that constitute the institutional subfield of planning at a certain time in a certain place, while the analysis of particular strategic-relational formations at the intersection of the four dimensions can aid explanations of how and why change occurred. The archetype process as conceptualized within ASID assumes that individual or collective agents strategically employ discourse to maintain or transform institutions and ultimately influence structure, while at the same time structural forces, institutional settings and hegemonic discourse regulate the strategic action of those actors (*ibid.*).

However, being a meta-methodology, its application in empirical analyses demands ASID to be blended with middle-range theories (*ibid.*). Since the multi-faceted definition of networked infrastructures that we developed in the introduction particularly points to the social construction of infrastructure, its relational and institutional character, we consider the Strategic-Relational-Institutionalist research approach (henceforth SRI) (Servillo and Van den Broeck, 2012) a fitting perspective when it comes to detailing our understanding of what dimensions actually constitute planning systems.

Servillo and Van den Broeck (2012) conceptualize planning systems as “a technical device embedded in an institutional frame and produced by groups of actors” (*ibid.*, p. 46). Within this model, the actual technical process of involved actors who selectively structure strategies constitutes the planning system. The planning rules and instruments, ideal-type planning approaches, the discursively constructed aims and keywords, as well as the overarching socio-political structures constitute the envioning institutional frame. The SRI herewith enriches established institutionalist planning theory that draws from sociological and historical/political institutionalism with Jessop’s Strategic-Relational Approach

(cf. particularly Jessop, 2008), stressing the social construction of planning. In doing so, the authors put an emphasis on how institutional formations of planning privilege certain actors and social groups over others. Moreover, they focus the role of strategic agency in the reproduction and reorganization of planning institutions (Servillo and Van den Broeck, 2012). Thus, it is a suitable approach to expand on with regard to the tripartite relationship of planning system, infrastructure development and urban change.

The understanding of development and change as proposed by ASID and the SRI implies three important points for the conception of infrastructure: (1) The planning and materialization of infrastructure is a deeply political process characterized by power, negotiation and strategy. Its instigation thus depends on the strategic agency of certain individual or collective actors, actor networks or social groups. (2) Infrastructure development is historically contingent. It is dependent from and influenced by an existing institutional landscape in the subfield of urban infrastructure planning and the structure of existing infrastructure networks that it is meant to complement or replace. Path-dependence thus is key to urban transformation if we look at it from an infrastructure perspective. (3) Infrastructure development is related to, inspired and influenced by multiple layers and scales of action. Phases of stability as well as incremental or radical change to the institutional landscape of urban infrastructure planning and the actual materialization of infrastructures thus must be considered the result of interrelated and interdependent activities and events embedded in certain social and institutional formations. The notion is that infrastructure is always relational, i.e. linked to other facilitating or constraining forces and events (cf. Moulaert *et al.*, 2016, Sorensen, 2015, 2018).

To make the institutional formations of infrastructure planning and development as conceptualized within ASID and the SRI approach applicable, we use the concept of discursive institutionalism, thus deploying a middle range theory to capture how planning ideas become institutionally fixed and, in consequence, influence urban development. Discursive institutionalism serves as a discourse-based explanation of how and when ideas prevail through historically determined constellations of agency within specific institutional relations, influencing urban development and change. We therefore blend Public Policy Analysis – understood as the study of how actors, ideas and institutions in planning relate (cf. Dunn, 2012) – with Critical Discourse Analysis (cf. Fairclough, 2010) of infrastructure planning policies to uncover the discursive formation of social, urban and planning ideals and their transmission into material urban infrastructures.

The concept of discursive institutionalism emerged as a critique of other forms of new institutionalism, which often overemphasize institutions while underrepresenting agency, ideas and discourses (Davoudi, 2018). This aspect is dealt with in discursive institutionalism by taking discourses and their consequences seriously and putting them in an institutional context (Schmidt, 2008). Discursive institutionalism can be regarded as the fourth and newest analytical viewpoint next to other forms of new institutionalism – rational choice institutionalism, historical institutionalism, and sociological institutionalism (Schmidt, 2012).

The analytical approach of discursive institutionalism allows to understand political processes for organizing space and the cultural construction of meaning by taking both ideas and institutional settings into account. Whereas the other forms of the planning theory strand of new institutionalism leave us with “unthinking” actors, subordinating agency to structure, discursive institutionalists have recently stressed the importance of ideas and discourses (Schmidt, 2008, 2012). Vivien Schmidt as an important

representative of this new analytical approach, investigates not only what the nature of the relationship between structure and agency contains, but also how actors change or maintain institutional practices (Davoudi, 2018). Discursive institutionalism “helps to overcome the structure-agency divide and, thereby, to explain the dynamics of change by lending insight into how actors in different institutional contexts with new ideas may overcome entrenched interests, institutional obstacles and cultural impediments to change” (Schmidt and Radaelli, 2004, p. 207). Discursive institutionalism therefore serves as an analytical approach in political science to trace how ideas are tied to action.

The main argument of discursive institutionalists is, that ideas are carried through agents, which form the basis for collective actions through discursive argumentations and interactions (Figure 1). Ideas, agents, discursive interactions and collective action all function through their institutional context, which acts as the setting, in which ideas have meaning, discourses have communicative force and actions make a difference (Schmidt, 2012).

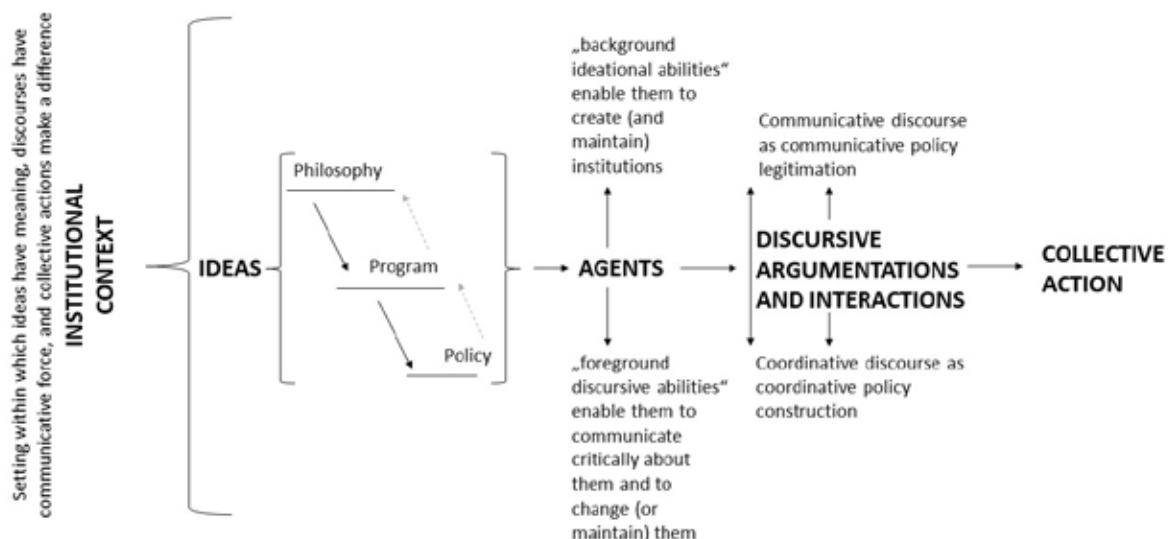

Figure 1: Building blocks of discursive institutionalism; Source: own adaptation following Schmidt (2012)

For Schmidt (2012), the institutional context is the pivotal juncture, where ideas as representations (how agents say what they are thinking of doing) are generated by actors and communicated through discursive interactions (to whom the actors say what they are thinking of doing). Thus, the institutional context determines where and when actors say what they are thinking of doing.

Ideas, discourse or discursive interactions and institutional context are the main building blocks of discursive institutionalism. Schmidt (2008) differentiates between different levels, types and forms of ideas, which are the substantive contents of discourses. Bringing discourse to the centre of analysis aligns with a constructivist perspective, where the focus is on social processes and power relations (Davoudi, 2018). Ideas form the basis, which can either appear on the first level as policies, on the

second level as programs or on the third level as philosophies, worldviews or norms. Furthermore, these levels of generality of ideas can either be primarily cognitive or normative, providing guidelines for political action and justification of policies and programs through interest-based logic or attaching values to political action and justification of policies and programs through appropriateness, respectively (Schmidt, 2008). Lastly, ideas can appear in different forms, as narratives, frames, collective memories, stories, scripts, scenarios or images.

Agents act as carriers of ideas, which form different constellations and communicate their ideas in their specific institutional context. They therefore construct institutions through their “background ideational abilities”, which enable them to create (and maintain) institutions, and their “foreground discursive abilities”, which enable them to communicate critically about the constructed institutions and to change (or maintain) them (Schmidt, 2012).

However, institutions are not only constructed by agents but also structured by discourse. “Institutions [...] are simultaneously structures and constructs internal to the agents themselves” (Schmidt, 2008, p. 314). This internal structure can also be understood with discourses, which Schmidt not only understands as the content of what is said, but also as its context of where, when, how and why it was said. Structure of what, where and how something is said is equally important to agency of who said what to whom (Schmidt, 2008). Using the term discourse indicates the ideas represented in the discourse and the interactive processes by which ideas are conveyed. Thus, discourse functions as an institutionalized structure of meaning and forms an interactive social process. Schmidt (2012) distinguishes between communicative and coordinative discourse. Coordinative discourse mainly happens among actors involved in the policy process, including “policy makers”, government officials, lobbyists, policy consultants, experts or business and union leaders, leading to the coordinative construction of policies. Communicative discourse takes place between political actors, which are engaged in presenting, deliberating, arguing, contesting and legitimating policy ideas to the public, which also includes media, interest groups, public intellectuals, social movements etc. with the goal to legitimate policies through communicative practices. How coordinated ideas of political actors are communicated depends on the institutional context (Schmidt, 2008, 2012).

For planning research and particularly for investigating infrastructure planning, ideas and discourses in their specific institutional contexts are essential to understanding their influence on stability and change and how they shape political behaviour and outcomes and thus, urban space. Davoudi (2018) argues, that especially in the context of the rich history of planning ideas, “discursive institutional analyses of change and stability in planning policies, practices and institutions can be particularly insightful” (p. 72). Moreover, Sorensen (2015) argues, that especially for infrastructure planning, where path-dependencies are a crucial dynamic, the analysis of institutions helps to understand stable phases and critical transitions within the planning system. Discursive institutionalism hence provides a fruitful method in this paper, to investigate infrastructure planning within the single case study of urban change in north-eastern Vienna. We thereby contribute to the not yet extensively empirically researched conceptual framework of discursive institutionalism and provide empirical evidence for its application. Following arguments of Schmidt (2008, 2012), where ideas act on different levels, the section below focuses on the process of how the envisioned structure of a “good” society, the philosophy or worldview, makes a “good” structure of urban space necessary as a programmatic idea, which is based on “good” planning as a policy solution, such as a strategic plan or instrument as an expression of the specific self-conception of the planning profession. How these ideas came to life and persisted or

changed through time sheds light on institutionally stable phases of infrastructure planning and critical transitions in the planning system, which shaped Aspern's subsequent development.

Discursive Institutionalization of Infrastructure Planning: The Case of North-Eastern Vienna

This paper redraws the historic development of infrastructure networks as the result of decisions at the intersection of technology, economy, politics and society (van Laak, 2018). It therefore focuses on planning institutions devoted to infrastructure development, since planning institutions “can be seen as embodiments of ideas that are in turn inspired by interests, aspirations, ideologies or practices” (Davoudi, 2018, p. 65). Our analysis builds on the collective action within the discursive institutionalization of infrastructure planning, which we regard as the materialization of infrastructure development and urban change in Aspern and its surroundings. We connect collective action to the underlying ideas and discourses mediated through agents of infrastructure planning which form specific institutional relations through their discursive interactions, thereby uncovering the institutional context through path-dependent development processes and radical changes in infrastructure planning.

Since the body of literature on the development of infrastructure networks suggests an increase in fragmentation of previously mostly integrated and standardized infrastructure systems (cf. Graham and Marvin, 2001, Marshall, 2013, Easterling, 2014, van Laak, 2018), the analysis of Vienna's North-East allows uncovering similarities and differences of the city's infrastructure development in comparison to global dynamics. In the following section we thus show how infrastructure development ideals and moments of change in Vienna's urban development path shaped the time- and place-specific phases of Aspern's transformation into its current form. We show that each phase is characterized by a distinct formation of ideas, agents, and discursive interactions, all leading to collective action to influence Vienna's north-eastern infrastructure development and, consequently, its overall urban transformation.

The institutional precondition for today's urban development in Aspern is the administrative incorporation of the 22nd district Donaustadt in 1954 after an uncertain time during and after the Second World War. The focus of urban planning was inner development due to stagnating population. Urban growth gravitated mostly to the north and south, not the north-east (Eigner and Resch, 2001, Klusacek *et al.*, 2008). However, the incorporation of Donaustadt as the 22nd district of Vienna represents a critical point in Aspern's history as it formed the basis for its future urban development.

In the 1950s and 1960s, the social welfare state was the predominant philosophy, which was underpinned by social urban planning as the programmatic idea of how to realize the ideal urban structure of Vienna (Pirhofer and Stimmer, 2007). However, this period created hardly any actual urban change in the eastern part of Transdanubia – as the 21st and 22nd district are colloquially called – as planning at that time was predominantly concerned with reconstructing residential housing and the city's population was stagnant. Although many visions from technocratic planning experts emerged, they were mostly incompatible with the social welfare ideas and thus were not incorporated into any policies. Thus, the agents of the strong local state pushed through their ideas of social urban planning

and reconstruction, while technocratic experts¹ visions were left behind. At large, post-war modernist ideas had hardly any influence on Aspern's development, since envisioned projects were implemented in other parts of the city at that time (f.e. Großfeldsiedlung in Floridsdorf) (Suitner *et al.*, 2018).

Thus, the transformation of the eastern part of Donaustadt took until the 1970s, where the airfield Aspern was closed in 1977 and flight operations stopped due to the opening of the second runway at the airport in Schwechat (Wien Geschichte Wiki, 2019a). Moreover, the General Motors factory was built at the former Aspern airfield, opened in 1982 and initially employed 1.500 people (Wien Geschichte Wiki, 2019b). However, the factory was far away from residential housing, which is why the city actively pursued transport development to connect the workers to the inner parts of the city. Moreover, in 1975 the largest shopping mall in Vienna was opened in Kagran, not far away from Aspern, which changed the functional structure of the district (Wien Geschichte Wiki, 2019c).

The underlying philosophy of the 1970s and 1980s was influenced by the shift from Fordism to Post-Fordism, which led to consumerism, the retail sector's wide-ranging makeover, and increasing inequalities – also in Vienna. However, the local state's passed on ideal of promoting equal living conditions was reflected in a new programmatic idea for the ideal city. To compensate Vienna's monocentricity, which put increasing pressure on the inner city, a hierarchical functional model including axes and centres was implemented (MA 18, 1985). One of the axes ran through Aspern, connecting it to 22nd district's established urban centre and a neighbouring municipality. These programmatic ideas were communicated through comprehensive plans, like the masterplan for transport in 1970 (MA 18, 1970) and the first urban development plan in 1984 (MA 18, 1985), and were complemented with small-scale development plans, e.g. the development plan for the 22nd district in 1972 (MA 18, 1993).

However, the ambitious ideas of connecting Aspern to Vienna's public transport system initially failed due to infrastructure costs and the increasingly complex actor structures. Although the 1970s and 1980s represented a new form of planning through comprehensive and communicative modes of development, the increasing complexity of projects and involved actors thwarted the success for the most part. Hence, insufficient job supply combined with a lack of efficient transport routes are recurrent debates in Aspern's development path.

In 1992 the city of Vienna acquired the properties of the Aspern airfield, creating the basis for on-site developments (Wien Geschichte Wiki, 2019a). At the same time, population in Vienna was growing again, thus making active acquisition of land for urban development necessary.

With the fall of the Iron Curtain in 1989, the new underlying philosophy was to promote Europeanization, integration and growth. Competition between cities and states was the driving force for development, strengthened by the programmatic idea of the European city model combined with the concept of "New Urbanity" for urban expansion (Hatz, 2009). Planning's self-conception gradually

¹ see for instance the satellite towns of Brunner (1952) or the comprehensive vision for Vienna's future development of Rainer (1962)

shifted towards planning as an entrepreneurial task with “valuable” projects of urban development (Novy *et al.*, 2001). As such, Aspern as a new urban quarter in the north-east of Vienna became the flagship project for the city with the alleged possibility to function as a bridge to the new Europe (Suitner, 2015).

Urban expansion projects were supported by new agents of urban management, routed in institutionalization processes of the 1970s and 1980s: the Wien Holding, founded in 1974 as an umbrella organization for mostly infrastructure companies, which reflected future intersections between state and market within the governance system for urban development; the WWFF (Vienna business development fund) founded in 1981, which acquired properties for companies in search for suitable development sites and was supported by public subsidies; the WBSF (Vienna land provision and urban renewal fund) founded in 1984, which acted relatively flexible under private law but was financed by the city government; and the urban development commission founded in 1985 to represent all departments and political parties to discuss urban development policy issues (Pirhofer and Stimmer, 2007). These complex constellations of actors represented the consensual planning model in Vienna. The acquisition of the airfield in Aspern is an expression of these intersections between different agents and reflects an institutionalized form of planning, where the philosophy of a provident state for future development is expressed in the programmatic idea of buying land itself in order to be able to develop a new urban quarter under its own conditions.

Shortly after the acquisition of the airfield, the City of Vienna, together with the WWFF and with the participation of the urban development commission, carried out an urban planning procedure for the development of the airfield. The resulting master plan by Rüdiger Lainer covered about half the area of the expansion plans of today’s Seestadt Aspern. 10.000-12.000 residents and 6.000 jobs were to be accommodated in the new district (City of Vienna, 2019a). However, the plan was not put into practice due to its incompatibility with the lacking infrastructural linkage of Aspern to the rest of the city.

Hence, in the 1990s, construction of transport routes was the main focus to prepare urban development in Aspern. The railway S80 and highways such as the A23 or the A22 were expanded to the north-east of Vienna to connect the area to the rest of the city (MA 18, 1994). The construction of traffic infrastructure accumulated at that time to construct high-ranking transport links to connect and upgrade the area between Danube and north-east of Vienna and thus prepare for future urban development. With Europeanization, integration and growth being the dominant drivers at that time, efficient traffic connections became mandatory prerequisites for urban expansion. The policy to reach this programmatic idea of the consensual planning model, which was an institutionalized practice since the first urban development plan was issued in 1984 (MA 18, 1985), continued in the urban development plan of 1994 (MA 18, 1994) and small-scale policies for Donaustadt (MA 18, 1998a, 1998b). The latter pled for closing the gap of infrastructure provision in the north-east and criticized Transdanubia’s lack of functional integration.

Although the vision for urban development in Aspern existed since the 1970s, it took 20 years to finally initiate the according transport links as prerequisites for the subsequent transformation process. The complex constellation of agents and ideas, which manifested in the 1980s through different organizations relevant for development processes and the lacking infrastructure provision thwarted the success of various development ideas like the first master plan for Aspern. Only the decision for the

development of the underground line U2 as a necessary precondition for infrastructure development and future urban development at the airfield led to the subsequent urban change in the 2000s.

However, the complex division of competences, especially in transport infrastructure, led to the construction of transport links mostly for road traffic, whereas public transport was caught up in difficult negotiation processes between national and municipal competencies (f.e. the City of Vienna and the ÖBB – Austrian railways). Thus, the foundation of Wiener Linien, Vienna's own public transport company in 1992 was no surprise (Wien Geschichte Wiki, 2019d).

However, it took until 2010 for the construction of today's Seestadt Aspern to begin (Wien Geschichte Wiki, 2019a). An important prerequisite was the expansion of the canal network to the eastern part of the 22nd district from 2009-2013 and the construction of a collection sewer with a pumping station in Aspern in 2013 to make the settlement in the rather flat land of Donaustadt possible (City of Vienna, 2019b). In 2010, the underground line U2 was expanded to Aspernstraße and in 2013 finally to Seestadt, thus connecting the new urban quarter to the centre of Vienna via high-ranking public transport (Wien Geschichte Wiki, 2019e). Moreover, the small-scale functional integration of the two districts north of the Danube was further intensified through the newly expanded tram line 25, which connects the 22nd to the 21st district since 2012 and the tram line 26 between the centre of the 22nd district and the eastern part of Donaustadt in 2013 (Tramwayforum, 2019).

Seestadt Aspern reflects a new planning philosophy, which incorporates place-making and management-oriented planning strategies to cope with increasing uncertainty and complexity. This zeitgeist of planning as an attempt to steer urban development by discursively preparing the direction and design of structural transformations through place-making is consolidated by the programmatic idea of the city's structure as a polycentric agglomeration, where the construction of the underground serves as a successful model and legitimation for urban development. Currently, it legitimizes a more than optimistic vision of the development of eight potential centres in addition to the six existing ones in the strategic planning for the eastern part of the 22nd district (MA 21, 2013). For Seestadt Aspern, the master plan was created as the guiding policy. However, it not only reflects the underlying planning philosophy and programmatic idea of the future city, but simultaneously influences planning orientation and future visions for Vienna, since Seestadt Aspern has turned into a prestige planning project that is "too big to fail".

Moreover, the development of Seestadt Aspern also reflects the shift from government to governance as the complex interactions between diverse groups of actors show (f.e. national infrastructure agency, municipal infrastructure agency, political ministries, regional authorities, urban development commission etc.). These agents are involved in forming different policies concerning the development in Aspern: the urban development plans STEP 05 in 2005 (MA 18, 2005) and STEP 2025 in 2014 (MA 18, 2014), the Smart City Strategy in 2014 (Magistrat der Stadt Wien, 2014) and most importantly for Seestadt Aspern, the master plan in 2006, which promoted Aspern as an independent sub-centre within the city (City of Vienna, 2019a). In 2012, the master plan for the Seestadt was refined, a detailed plan for the development of the northern section and a separate plan for the public spaces at Seestadt were developed (Wien 3420 aspern development AG, 2019a). In 2017, the latest update of the masterplan was published (Wien 3420 aspern development AG, 2019b).

Seestadt Aspern is a reflection of planning between state and market, which manifests in an almost textbook spectrum of “good planning practices”: artistic displays, assemblies, subsidized housing, district management, participation processes, passive energy offices, timber high-rise construction, and much more. Moreover, the functional integration through local infrastructure networks is the mandatory prerequisite for urban expansion in Aspern. However, the original characteristics of the old town centres and structures are ignored. Instead of population growth and housing needs strengthening the existing Aspern town centre, the development of a new district is pushed to meet the needs. As a result, the area around the former airfield is clearly different from the newly constructed Seestadt.

Since 2017, a quarter of the project Seestadt Aspern is already completed (ibid.; see Figure 2). By 2028, the project shall accommodate more than 20.000 people and almost as many jobs (City of Vienna, 2019a), making Vienna’s north-east one of the most promising development areas of the city. However, resentment and resistance towards the increasing traffic load despite of upgraded public transport options is on the rise. Thus, the recent transfer of federal road competencies allows the City of Vienna to construct part of the federal highway B3d in its own sphere of influence. This will be followed by the Aspern urban road in 2021, which will necessitate the full development of the Seestadt area (City of Vienna, 2019c).

Discussion & Conclusion

As Aspern's urban transformation has shown, different phases of stable development and critical ruptures can be identified, which either facilitate or decelerate change (see Table 1). By employing the concept of discursive institutionalism we were able to explain how Aspern developed from agricultural land and former airfield to one of the biggest urban development projects in Europe.

While the 1950s and 1960s facilitated rarely any physical transformation as planning at that time was mostly concerned with post-war reconstruction, the 1970s have seen quite radical changes that first established in the centre of the 22nd district to slowly radiate to its eastern parts thereafter. The provident understanding of urban planning from the 1960s until the 1980s was however delayed in Aspern's development, as the acquisition of the airfield by the city in the 1990s was the prerequisite for today's urbanization of Aspern. However, the institutions created in the 1970s and 1980s prepared this change and provided the basis for Aspern's physical transformation. While urban planning in Vienna is traditionally paternalistic and, thus, top-down, the project of Seestadt Aspern itself influenced the underlying philosophy of planning's self-conception by its mere size. The project's master planning approach, its public-private financing structure and the well-orchestrated image- and place-making campaign all reflect the emergence of management-oriented urban politics and flexible governance in Vienna at the turn of the century..

The concept of discursive institutionalism thus enables us to retrace how projects, which are manifest realities today, are based on different levels of ideas from past times, which resulted from very different motives. Hence, the provident understanding of urban planning in Vienna from the 1960s until the 1980s created the basis for today's development, whereas today's urban transformations emerge from the planning ideas of the 1990s and 2000s, which were much more focused on supply-oriented approaches and strategic competition.

This paper hence has provided empirical evidence for the applicability of the concept of discursive institutionalism as an explanatory tool in urban development and planning research. Particular temporal decelerations and accelerations of infrastructure development are put in their respective institutional context, allowing a broader perspective that goes beyond reiterations of the simplistic planning-development nexus.

Observing governance from the ‘street level’

An investigation on First Access services in Bologna, Emilia Romagna, Italy.

Benedetta Marani¹

¹*DASStU (Department of Architecture and Urban Studies),
Politecnico di Milano – benedetta.marani@polimi.it*

Abstract: This contribution aims at addressing how institutional changes might affect the spatial configurations of services in cities. Grounding on the territorial and multilevel features of governance in urban planning and social policy fields, the analysis focuses on the provision of specific services in a selected Italian context. Starting from the assumption that space is a product of policy decisions and instruments, the paper would consider three spatial dimensions of social assistance services: the localization (where services are located in the city), the container (in which building they are located and which functions are coexisting), the content (how spaces influence the services provision). Underrepresented in the academic debate, poorly financed among the social protection measures, rarely considered from a spatial perspective, social assistance services will be analysed for their fundamental role in local welfare provision. In particular, the contribution will focus on first access services, representative of the street-level meeting between citizens and welfare policies. Starting from an empirical research led in the Social Counters (i.e. Sportelli Sociali) of the city of Bologna - Emilia Romagna, the paper will furtherly address space-related issues of social services provision, that might reshape the contact between citizens and institutions and reorient policy decisions.

Keywords: welfare; spaces; social services; first access services.

Local welfare: a planning issue?

The panorama of the welfare services provision in Europe is consistently reshaped and challenged by major social, economic and demographic changes. The combined effect of economic reorganization processes, the increasing precariousness of the job market and the shrinking of the national welfare systems, have progressively eroded the traditional social protection measures and increased traits of fragilities in many European cities (Bricocoli, *et al.* 2017). These trends should be read together with a policy rescaling toward the local level, that finds origin and definition in the territorialisation policies of the 80s (Kazepov and Carbone, 2007, Vitale, 2009), which decentralized the decisional and regulative powers in many European countries to face post-industrial societal changes and new demands of social services (Ferrera, 2008). The withdrawal of the national states as direct suppliers of social protection measures, together with a significant reduction of the public resources dedicated to welfare services, led the basis for the involvement of third sector and private actors in the services' provision, in order to maintain an adequate supply with a reduced public investment

(Ascoli and Ranci, 2003). The variety of actors involved in these welfare systems and the consequent redefinition of the role of the states in regulating their activities has been defined as welfare mix (*ibidem*). This new policy framework, that developed with specific features according to policy traditions and resources of different EU countries (*idem*), implied new patterns of governance and stimulated a renovated attention to the territorial scale as a reference to experiment policies and interventions (Bifulco, 2015, Kazepov, 2009).

In Italy these processes seem to be grounded in the normative reforms of the 90s, that were conceived to decentralize the policy decision at the local level, supported by emerging debates on vertical and horizontal subsidiarity. As in other European countries, new private and third sector enterprises started to be involved in the welfare services provision and, since their official acknowledgement in the Italian juridical system, they became part of a new territorial governance (Bifulco, 2015). This new regulative framework led the basis for the introduction of two major reforms that reshaped, and still regulate, the whole national welfare system (Ferrario, 2015, Vitale, 2009). Firstly, the reform L.328/00, that recomposed in a unitary framework all the interventions and the economic measures that have been formerly developed in a fragmented and categorized way, and established the roles, the responsibilities and the criteria of access to social services (Kazepov, 2009). This norm entailed the State obligation of guaranteeing a uniform provision of services at the national level (LIVEAS) and created a specific National Fund for the implementation of Social Policies (*Fondo Nazionale per le Politiche Sociali*). The law also introduced the so called Piano di Zona, a planning instrument for social services to be developed at the Municipal level following the guidelines of the Regional laws. Moreover, it established the criteria for the participation of the third sector and no profit organizations to the welfare services provision, acknowledging their official role in the public decision (Ascoli, 2001). A second relevant normative change has been the reform of the Title V of the national constitution (L.3/2001), that attributed autonomous decisional and regulative powers to the Region, the Metropolitan Cities and the Municipalities in all the subjects that were not framed under the direct intervention of the State, including social and urban planning policies. Since the introduction of this reform, the responsibilities of local administrations increased, as well as their economic involvement in financing policies and services at the local scale, often without appropriate transfers of resources from the central government or the necessary know-how to manage the new delegated subjects (Kazepov, Carbone, 2007, Bifulco, 2005, Sabatinelli, 2009). Many authors agree on the mismatch between the two considered reforms, with particular concerns on the regulative and decisional roles of the Regions and the Municipalities in providing and financing social services, that should have been financed by a dedicated national fund (Bifulco, 2015, Kazepov and Carbone 2007, Vitale, 2009).

Moreover, the impact of these reformistic attempts have been strongly limited by the economic crisis of 2008, that furtherly reduced the resources allocated to public administrations as well as the spending capacity of the families. The stagnation, where not recession, of the national economy, together with the introduction of austerity policies, have worsened the families conditions and drastically reduced public expenditure dedicated to welfare services provision. The consequences have been even more evident for the local administrations, challenged with the urgency of more adequate policies, with reduced resources. Furthermore, the increasing job insecurity, the ageing of the population, the new migration flows, the more frequent mobility, the more articulated life paths and the impoverishment of many families, have generated new heterogeneous needs, challenging the traditional sector-based welfare systems. In these sense, the actors of the above mentioned welfare mix have been constantly defied in finding resources and solutions beyond the traditional ones (Bricocoli and Sabatinelli, 2018).

Planning social services: where does ‘space’ fit in?

Within this changing scenario, this contribution aims at addressing how spatial configuration of social services provision is/has been shaped by different decisional levels of urban planning and social policy fields. To understand the goal of this analysis, a terminological clarification needs to be addressed. The term ‘space’ is hereby approached as the tangible result of policy decisions and instruments (Lascoumes and Le Galès, 2007)

that often belong to different policy fields. In particular, this research focuses on the spaces of social assistance services from an urban planning perspective. Underrepresented by the academic literature and poorly financed by the national social protection measures, these services are fundamental for the implementation of local welfare policies, currently more and more relying on citizens' involvement and capacitation (Bifulco, 2015). Among the complex panorama of social services, each of which involving a wide variety of actors, instruments and policy levels, the contribution focuses on First Access Social Services (from now on: FASS), defined by law 328/2000 as *the door* of welfare provision. These are the spaces where people meet the system of welfare for the first time and, by extension, where they experience contents and rationales of welfare policies through bureaucracies and bureaucrats (Lipsky, 2010). In these spaces citizens can express needs for social help and/or economic contributions, appreciating the promptness of social work or experiencing the delay of public services. Most of all, these *doors* are both the metaphorical and physical entrance to the local welfare system, where people get to know the organization and its limits.

Within a “controversial and anomalous” role of the current national urban planning discipline, nowadays welcoming as many different perspectives as are the dimensions of the urban realm (Gabellini, 2018: 9), this contribution aims at reorienting the attention of decision makers of both urban planning and social policy fields on the relevance of space in services' provision. In particular, the analysis argues the necessity for urban planning policies to focus on social services as those primarily and institutionally devoted to answer citizens' needs, and at the same time suggests a need for social policies to consider the role of the spatial dimension in welfare services provision. Focusing on FASS, the spatial configuration is here tackled in three dimensions, each of those concerning various levels of governance and scales of observation, and influencing the users' experience in different ways:

- The localization: in terms of accessibility and distance to other meaningful centres;
- The container: the physical features of the buildings in which these services are provided and the coexistence with other different functions;
- The content: the influence that interior spatial settings exert on service experiences and on user-provider relationships.

Climbing back the ladder of multilevel governance in social services provision

Against the considered territory-based policy framework, the paper focuses on FASS provision in the city of Bologna, Emilia Romagna Region, where welfare and urban planning policies have traditionally been implemented with far sighted instruments and within an extraordinary political continuity. Introduced by the Law 328/2000 to homogeneously accomplish the access to social services throughout the country, FASS have been implemented over time according to different regional laws and have been financed by the National Fund for Social Policies together with other local resources. FASS were conceived by the National Social Plan (*Piano Sociale Nazionale*, Dpr. 3/5/2001) with four main purposes: to inform, to provide help and counselling, to gather data about social needs and existing services, to promote citizens participation and community development (Pesaresi, 2008). Emilia Romagna introduced FASS with the regional law n. 2/2003, naming them ‘Social Counters’ (*Sportelli Sociali*). Following the regional guidelines, social services have been planned dividing the regional territory in districts, each of those hosting at least one Social Counter. The Municipality of Bologna introduced Social Counters in 2008, within the second edition of the Local Welfare Plan (*Piano di Zona*). Together with the new national territorialised policies, a huge process of decentralization reshaped the organization of public administration and the services provision in the city. In fact, from 2008 to 2016 welfare policies in Bologna have been managed at the neighbourhood level, where small local councils had the political and economic power to organize and provide social assistance services. The city was divided in 9 neighbourhoods and counted 10 Social Counters, one per each neighbourhood with the exception of Navile, the most populated area of the city, that had two. (Annichiarico *et al.*, 2009). Within this configuration, Social Counters were usually located in multifunctional buildings known as *Quartieri* (neighbourhoods) and worked in

strict contact with Neighbourhood councils, on which they depended. These structures hosted local administration and social services offices, school-related services and general register counters. Moreover, spaces dedicated to the activities of local associations could be found, together with multipurpose rooms for public events or collective meetings.

This configuration changed in 2016, when two intertwining reforms reshaped the entire local welfare system as well as the neighbourhood-based division of the city. The National restraints on public expenditure, together with the necessity to tackle different social and demographic challenges, led the Municipality of Bologna to rethink the structure of public administration and to reform the decentralized system of services provision (Tomesani, 2018; 2019, Evangelisti, 2018, Orioli, 2019). The neighbourhoods were reduced from 9 to 6, each of them counting around 60.000 inhabitants (see Figure 1). This implied both a significant reduction of public employees and a reconfiguration of the former decentralised administrative headquarters. The number of *Quartieri* buildings shifted from 9 to 6 and the offices of Social Counters from 10 to 6.

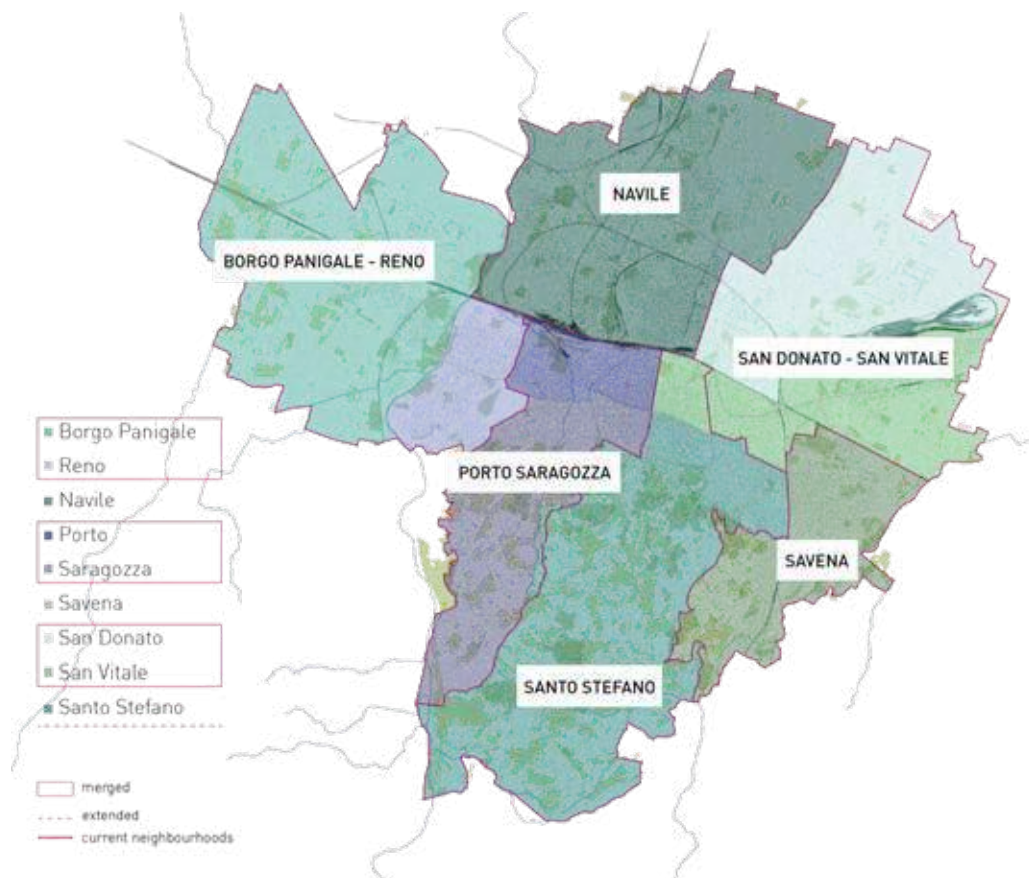

Figure 1: The neighbourhood reform of 2016. Elaboration of the author from the Open Data Comune di Bologna, 2016.

In parallel, due to the local welfare reform enacted in 2017, social services provision has been recentralized from the neighbourhood councils to a dedicated area of the Municipality named Area Welfare and Promotion of Community Wellbeing (*Area Welfare e Promozione del Benessere della Comunità*, from now on: Area Welfare). In practice, the decisional and economic powers of Neighbourhood councils have been drastically reduced, while welfare services, still relying on a territorial subdivision, became directly dependent on the public administration through the Area's chiefs. If on the one hand this new configuration in some neighbourhoods entailed a physical separation of social services offices from the *Quartieri* buildings and their services, with which significant collaborations have been consolidated over the years, on the other it was an occasion to rethink social services headquarters as independent monofunctional structures. This has to be read

together with the shift from a category-based system, that provided access to social services in different offices according to specific categories of need (elderly, disabled, adults, minors.), to a transversal one, guaranteeing a universal access in specific informative points, from which people could be reoriented to more specialized services (Tomesani, 2017). This orienteering task was assigned to local Social Counters (Regional Deliberation 1012/2014). Moreover, this reform also entailed a new Community-based welfare system (*Welfare di Comunità*), enhancing the interactions between different public actors, third sector bodies and active citizens. The idea was to promote local resources to develop a networked system of self-help, in the light of a possible ‘community taking over’¹ (Piano di Zona 2018-2020; Foschi, 2018). In this sense, social operators have been challenged to reinterpret their role as mediators between citizens’ needs and available local resources.

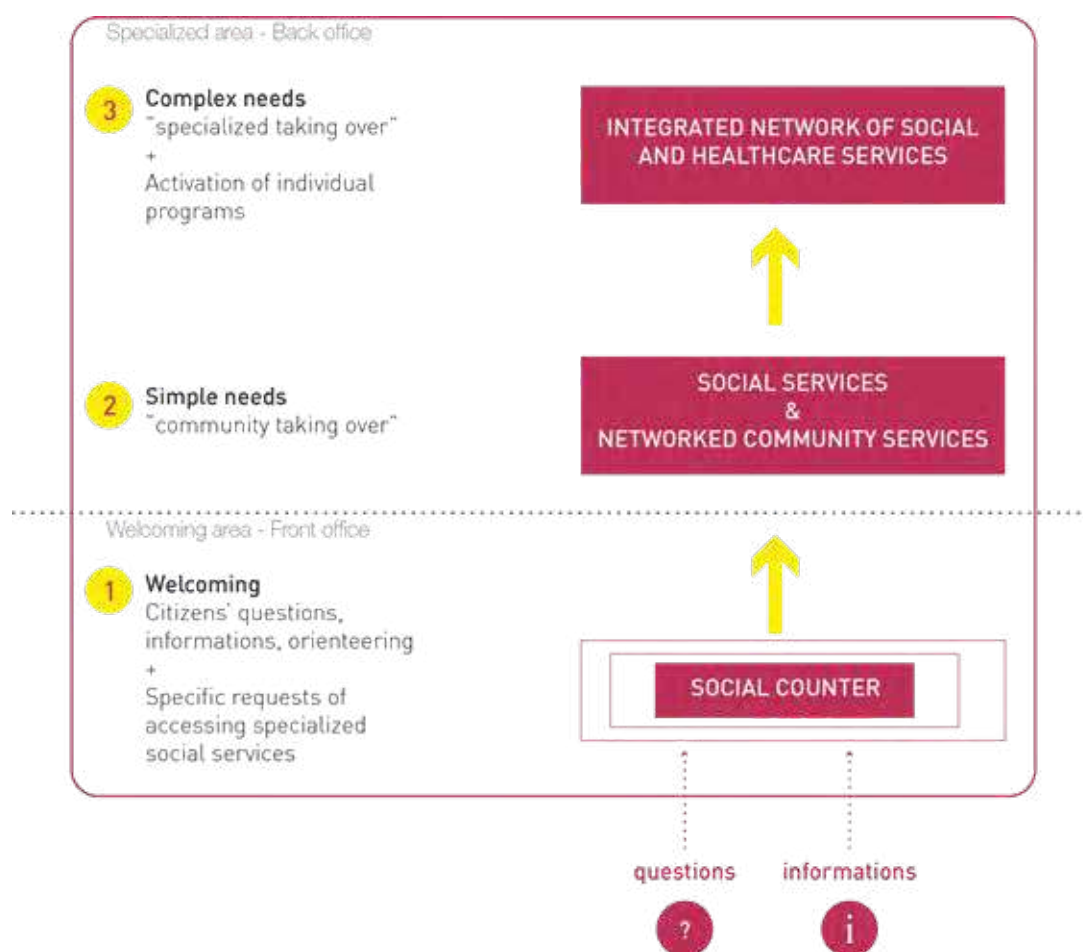

Figure 2: the pathway through the social services in Bologna. Schematic elaboration of the author from Forni, Regazzini, Paltrinieri, 2009, Tomesani, 2017.

¹ ‘Taking over’ translates the Italian *presa in carico*, i.e. the official process in which social assistants develop personalized projects for families or individuals and activate a series of ad hoc social and healthcare services.

The image represents the role of Social Counters as a *door* to access the overall local system of social services. In these spaces citizens can be reoriented to other services according to the complexity of their needs. In case of ‘complex’ needs they are taken over by the specialized social or healthcare services provided by the Municipality or other private bodies (e.g. ASP, Azienda Servizi alla Persona). In case of ‘simple’ needs, they are reoriented to a networked system made up by the Municipality, Third Sector Bodies, local formal/informal groups, etc. This ‘light’ networked taking-over is a major point of the renovated local welfare system and calls for the collaboration of different administrative levels and professional skills. In fact, the reform promotes a strong cooperation between the Area Welfare and the Area New Citizenships, Social Inclusion and Neighbourhoods (*Area Nuove Cittadinanze, Inclusione Sociale e Quartieri*), on which the reformed Neighbourhoods currently depend. The two areas collaborate through the Network Offices (*Uffici Reti*) with which the Representatives of local social services are in close contact. Born to monitor the initiatives and activities spread on the neighbourhood territory, these offices have the task to develop social inclusion through community capacitation and networking and depend on the central new-born Civic Imagination Office (*Ufficio Immaginazione Civica*). Their role is strictly related to the activities of the Urban Innovation Foundation (*Fondazione Innovazione Urbana*, FIU). This body, half participated by the Municipality of Bologna and half by the University of Bologna, organizes the majority of participatory projects in the city² and is entitled to monitor citizens needs in strict collaboration with the Network Offices, through the organization of periodic workshops named *Laboratori di Quartiere* (Tomesani, 2018). All the interactions and the interdependencies among different actors are represented in the scheme below (see Figure 3).

² The FIU’s collection of citizens requests in different areas of the city will constitute the basis for the next Urban Plan, that will be presented by the Urban Planning Department of the Municipality in 2020 (Evangelisti, 2019, Orioli, 2019, Ginocchini, 2019). This information is currently reported in the Urban Innovation Plan (see references).

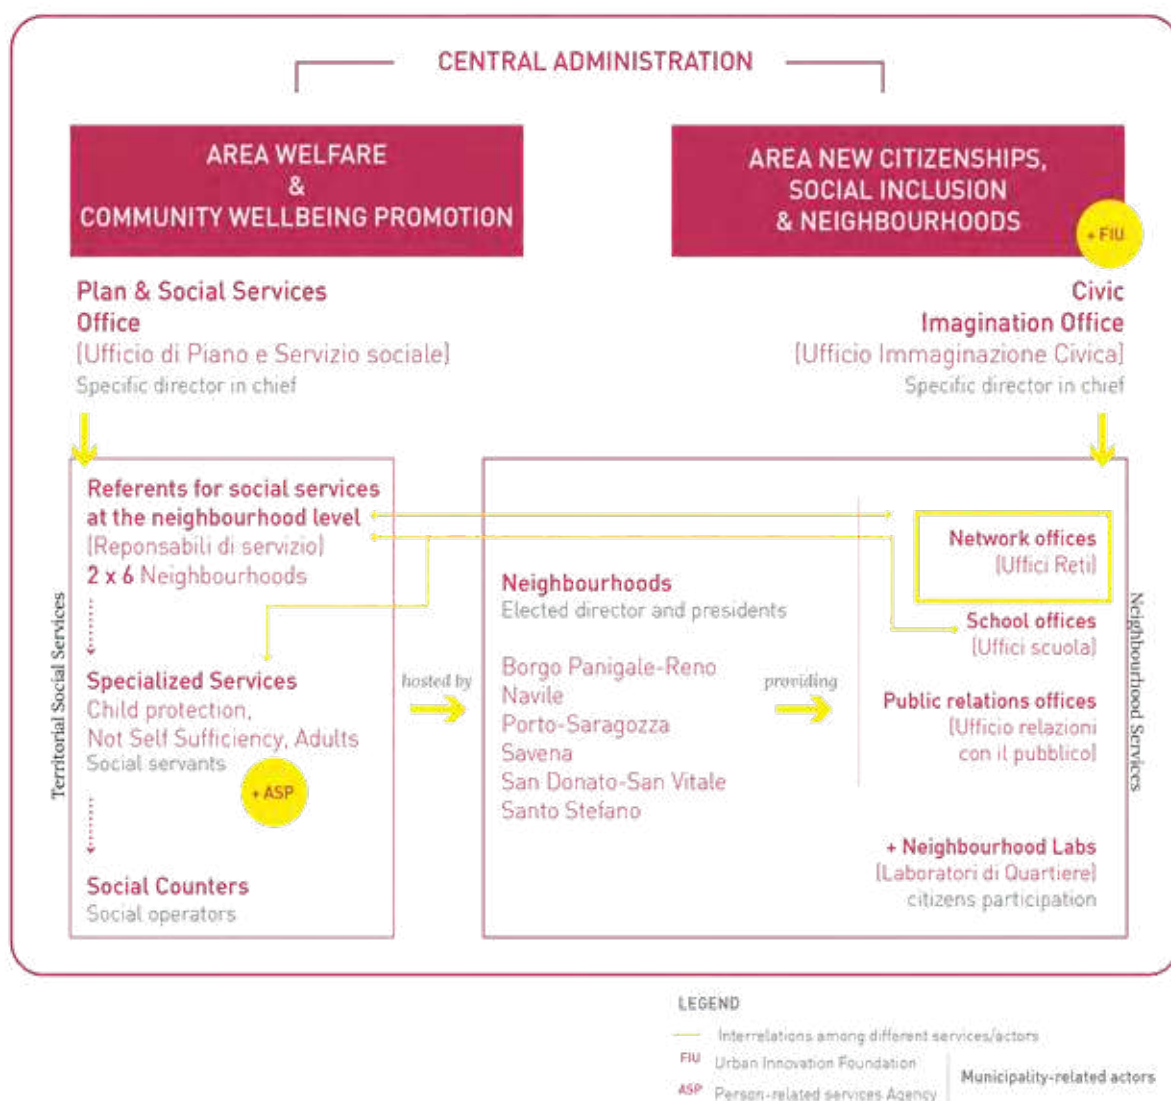

Figure 3: scheme of the governance of social services provision in Bologna. Interrelations among administrative levels and actors. Elaboration of the author from the fieldwork interviews (see references).

Against this background, Social Counters represent citizens' first access to a wide and complex system of welfare, of which they experience multiple features. The following paragraphs will be dedicated to the analysis of their spatial configuration in a specific neighbourhood of the city, chosen for its representativeness of the ongoing transformations. The aim is to show the influence of these institutional reforms on first access services through a spatial perspective (§2) The analysis relies on direct personal observations³ of the Social Counters and semi-structured interviews to key actors of the services provisions.

³ The author spent two months in the Social Counters in Bologna (February and March 2019). The direct observations have been transcribed in a logbook and are accompanied by drawings and photographs that would be presented during the conference.

Localization, containers, contents: the case of San Donato-San Vitale

The two mentioned reforms had major impacts on the spatial configuration of social services provision in Bologna. A process of redistribution of both neighbourhood councils buildings and social services headquarters started in 2017, under the coordination of the central Office for Logistics of the Municipality and the Department for Public Works, together with other involved Areas (§3). As far as concerns the spaces of Social Counters, the result of this collective consultation was a plan of the forecasted transformations and the financial measures devoted to their implementation (Bruni, 2019). Its contents were agreed by the involved central administration offices and the local Representatives for the social services (Tomesani, 2019).

Among the transformations forecasted for the 6 Neighbourhoods, the following paragraphs would focus on San Donato-San Vitale, the most representative of the ongoing changes and one of the most complex for its territorial, social and demographic features. Created in 2016 with the unification of San Donato and part of San Vitale (see Figure 1), the neighbourhood counts 65.892 residents, the majority of which are adults (45-64 years old) and young adults. Among the 35.068 resident families, 10,1% are single parents, whose 85% are single mothers with children. The social services take over 4,2% of the population, in particular families with minors (Piano di Zona del Comune di Bologna, 2018-2020). The neighbourhood is renowned for its public housing estates, hosting many low income residents since the 60s and attracting numerous foreign families. Even if they already underwent a series of regeneration programmes concerning both the physical and the social dimensions, these areas are still in the spotlight of public debates and require a prior attention in local welfare policies and services provision.

As the result of two neighbourhoods' unification, the Neighbourhood San Donato-San Vitale presents different social services' headquarters, inherited by the former decentralized organization. Before the 2016 reform, San Vitale hosted in a single structure both the local social services and the *Quartiere* council offices, not far from the city centre and well-connected by public transports (Via Rimesse,13). San Donato counted three different buildings for social services, each one addressing different categories of need, respectively located in: Via Zanolini 2, just outside the historical city walls, Via Pirandello 8, in one of the mentioned public housing estates, Piazza Spadolini 7, at the underground floor of the *Quartiere* building. Social Counters, one per each neighbourhood, were located both in the structure of Via Rimesse 13 and in Piazza Spadolini 7. This localization was the result of former political choices, strictly dependent on the pre-existent real estate asset of the Municipality. The new configuration didn't entail a drastic change, but significantly relocated services in the different existing structures as shown in Figure 4.

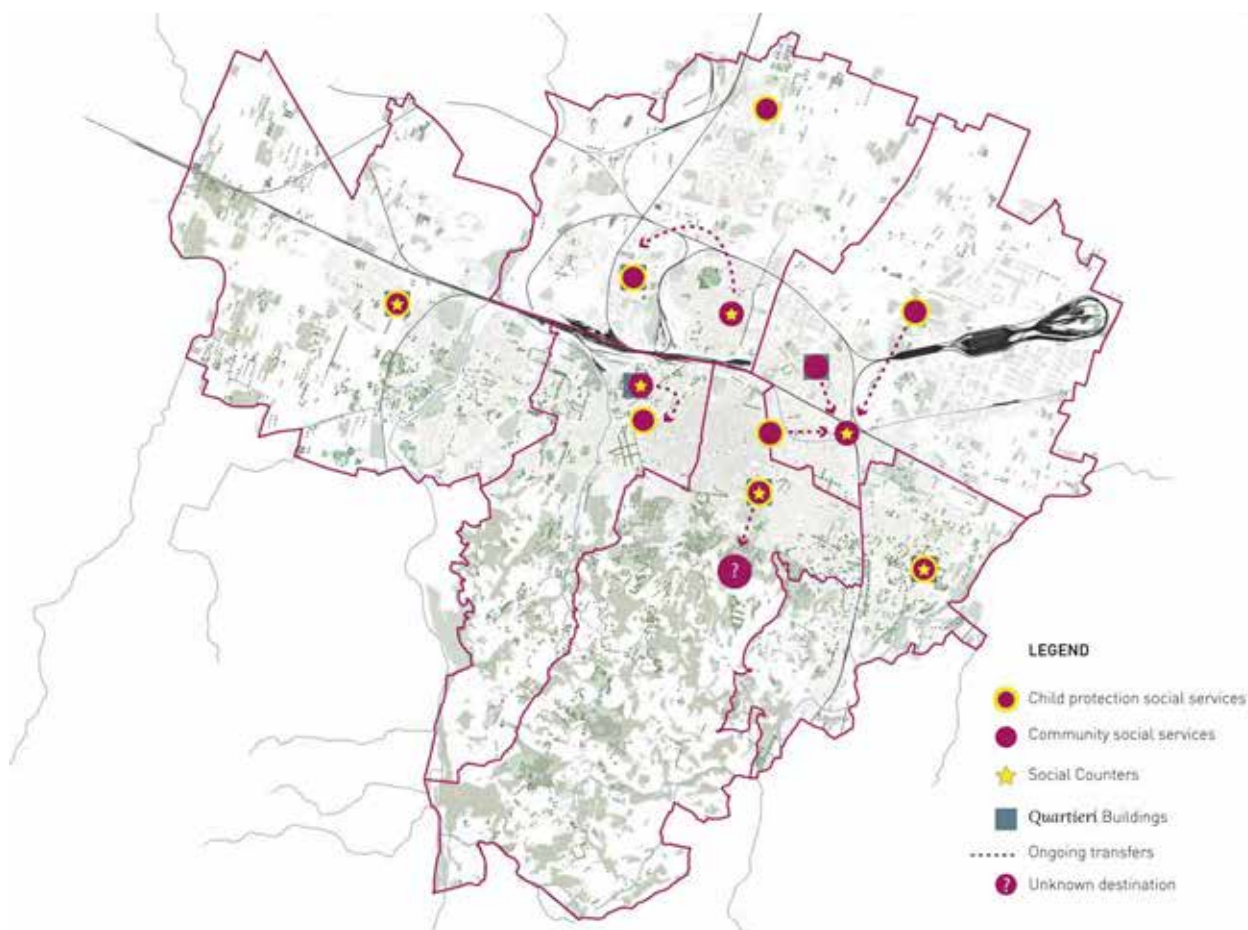

Figure 4: Localization and forecasted transfers of Social Services and Neighbourhood headquarters in Bologna. Elaboration of the author from the fieldwork, 2019.

For what concerns the spaces of FASS, the reform caused the reduction of Social Counters from two to one, due to the unification of the former neighbourhoods. Moreover, the Representatives of local social services, together with the chief of Area Welfare, the Office for Logistics and the Department of Public works, decided to aggregate all the decentralized social services – including Social Counters - in the building of via Rimesse 13, with the exception of the offices in Via Zanolini 2 and in Via Pirandello 8⁴. Originally designed as a school, this building was turned into San Vitale neighbourhood's headquarter in 2008 and also hosted a daily elderly centre and the offices of social services, located in a small portion of the ground floor. When the elderly centre moved to another dedicated structure and the Neighbourhood offices were relocated, the Municipality took the chance to plan a possible extension of the social services to the whole structure (Figure 7,8). Today, the ground floor

⁴ As the Representatives of local social services have underlined, the combination of healthcare and social services located in via Zanolini 2 and in Via Pirandello 8 is fundamental to keep the long-standing service interactions and to maintain an already consolidated political consensus which rely on the presence of social services at the local level (Representative 1, 2019; Representative 2, 2019). As a possible compromise, the Area Welfare has suggested to maintain in Via Pirandello 8 a set of scheduled social orienteering and counselling activities in place of a stable office (Tomesani, 2019).

hosts social assistants and social counters offices, while the first is almost empty, except from two offices occupied by two social assistants of ASP (Azienda Servizi alla Persona), that would be relocated during the renovation works. This project has been approved by the different Areas of the administration in 2019 and would be implemented in the next years (Representative 1, 2019). The decision relied on the semi-central position of the building, but also on the idea that aggregating all the social services in a single space would have guaranteed the continuity of contacts among the social operators, improved the users experience through the complex local welfare system and contained real estate-related public expenditure (Tomesani, 2019).

At the 'street level' – Observations from the Social Counters

The spatial configuration of Social Counters is organized in the whole city following general service guidelines provided by the Area Welfare and is generally arranged in three main spaces: the waiting room, where people are welcomed; the counters, where people are received by social operators and can express their needs; the backoffice, where social operators work when they are not at the counters and where they share doubts and information with colleagues. Then, every Social Counter in the city develops its own features according to the structure in which it is hosted. The following sections would focus on the direct observation of the spaces in via Rimesse 13, whose activities are framed in the theoretical stream of *Street Level Bureaucracies* as introduced by Lipsky in 2010. Within this framework, this paragraph aims at addressing the effects of spatial configurations on services provision, in particular during the first meeting point between citizens and institutions. The reported description and quotations are based on the authors' logbook, written in February 2019 during the site-based research. More spatial details about the user-provider relations in spatial terms are shown in Figure 5 and 6.

The main building entrance, that still brings the sign of the old Neighbourhood services, is equipped with stairs and ramps for disabled people. A glass door illuminates the reception desk from which citizens can be reoriented to different offices, and a small *waiting room* is dedicated to those users who already have an appointment with a social servant. On the left, a dark small corridor leads to a wider *waiting room* dedicated to Social Counters' wait. From this narrow space is already possible to see part of the future expansion of the services: a hole in the wall was made to test its consistency and is still open. Second-hand furniture and childish paintings representing the characters of 'Snow White' decorate this area. There's no room to swing a wheel chair or a pram, mothers should wait in the corridor standing against the walls. At the bottom of the room, a young woman sitting behind a desk welcomes people and invites them to take a number from a ticket machine. Her task is to ask them what they need and if they have prepared the correct documents to access the services. This welcoming figure is known as 'Open⁵' and has been introduced in January 2018 by the central administration to ease the working loads of social operators at the counters, saving both citizens' and employees' time in case of misleading information or incomplete documents. It is easy to understand why: in a single morning more than 60 people might come to the counter asking for economic support, social assistance, the activation of home-based services, or just to chat with someone willing to listen to them. Not everyone who

⁵ The Open preliminary filter to Social Counters is provided by a joint venture among the Municipality of Bologna, Cidas, Arci and Antoniano social enterprises. Around 20 people among 25 and 35 years old, already graduated or about to finish their studies, have been selected through a public call to welcome citizens in the waiting room, working 9 hours a week in shifts. A graduation in social sciences was not a specific requirement of the call but could constitute a preference for the selection. Before entering in contact with citizens they have followed a 4 hours training course to understand the activities of the Social Counters and few skills to manage the interactions with the public.

accesses Social Counters has experience of social services provision or is comfortable with the environment and its features or languages. *“Someone told me to go to the so called Social Counters, but I don’t know where to go...”* – asks a woman around 50 years old to the receptionist. *“I remember I went to the Social Counters many years ago, but they were in Piazza Spadolini: why did you move them? They were way more accessible over there! The Municipality never does something right”* – complains another user with the Open. People accessing the structure are generally disoriented and tend to ask for help to those they meet first. They don’t know where to go neither who is entitled to listen to their needs. A red and yellow totem with the logo of the Social Counter is located at the entrance of the small corridor, it is barely visible. This sign was thought by the central administration to homogenize the graphic identity of Social Counters, helping citizens to find this service within multifunctional structures. If they don’t find the totem or any other indications, people have to ask to, or are asked by, those they met as they step in. The first contact might be misleading: both the Open and the receptionist are not professionals of the welcoming interaction neither apprised of the overall social services provision or informed about service-related news. This might cause the unpleasant redirection of users who are struggling to find their way through welfare provision: *“Where else are you addressing me now? I have been here twice, you have always reoriented me to other services and they told me to come back here. Now I sit and wait. Full stop!”* – states an annoyed man to the Open. Despite these situations, people tend to rely on the information given at the welcoming desks, the nearest and the quickest they can find.

From the waiting room citizens are called to enter the *Social Counters*, the actual meeting points between citizens and public institutions. These spaces are enacted in small offices equipped with a desk, a printer, a computer and a board with information on the ongoing economic or social support measures. The offices are very impersonal, with standard furniture and few objects on the desk. This is mostly due to security measures introduced by the central office of logistics, concerned about social operators safety after several assault episodes. Even the position of the desk is thought to ease a possible escape of services providers, often to the detriment of users comfort. Considering the high numbers of people accessing the counters, some element of discomfort are (consciously or not) introduced to speed the meetings and receive the highest possible number of users. However, when a recipient with complex requests comes to the counter, social operators are entitled to understand his multifaceted need, to organize his/her future steps inside the social services. *“Is there an additional chair? I think it would take long and I don’t want my son to stand all the time”* – says an eighty year old man, accompanied by his son. These meetings could take from 20 minutes up to an hour, with evident drawbacks for those who stand in the tiny waiting room. On the contrary, economic supports are provided in 10/15 minutes, with a little interaction between citizens and social operators. This user-provider separation, emphasised by the presence of the desk, helps the social operator to prevent an excessive level of intimacy and personal involvement (Dubois, 2018) and to consolidate their institutional role. This attitude belongs to ‘an ambivalent identity’ of the street level bureaucrats (*ibidem*, 179), whose struggle is to balance their personal system of values, on which might rely a more or less extensive use of discretion (Brodikin, 2008; Dubois, 2018; Lipsky, 2010), and the tasks of the institution they are representing. This level of discretion not only belongs to the services provision, e.g. when bureaucrats decide which recipients deserve a support or have to be reoriented, but is also reproduced in spatial terms, when providers welcome certain users (typically mothers with children or elderly women) or protect themselves from others (typically adult men). On this purpose, street level bureaucrats tend to organize the space according to specific situations, even if it entails a violation of rules or suggestions given from the central administration. A shift in furniture’s position might facilitate the communication or impede undesired interaction according to the situation. *“You never know which is the mood of who’s crossing that threshold and how he/she would react to your statements”* – says a social operator pointing the door – *“but after years of experience you immediately understand whether is the case to take precautions or not”*. In this perspective, a very common trend among street level bureaucrats is to keep counters doors open to let people in the waiting room notice a possible difficult situation. This goes to the detriment of recipients privacy, to be universally guaranteed by right and particularly assured in services provision, but at the same time represents a fundamental strategy for bureaucrats safety.

Along the corridor, a small room dedicated to the *Backoffice* activities is shared by 4 social operators, two of them sharing the same desk. They work in shifts with their colleagues at the counters. Even if designed for other purposes, this space is frequently used for the provision of particular economic supports. At the same time, the Backoffice is also a sort of ‘outburst room’, where all social services’ employees come to take a break and chat with their colleagues. The result is an overcrowded space, where social operators have difficulties in concentrating and managing phone calls and where there is little room to accommodate recipients. Provider-users interactions are constantly limited by the presence of other social operators chatting, speaking at the phone, and entering the room. Moreover, here social operators express doubts or complaints that shouldn’t been listened by recipients in respect of the institutional image. Accustomed to uneven treatments and uncomfortable situations, users don’t usually complain about inappropriate spaces, even when they obstacle the expression of their need or undermine their privacy. Some of them try to capture other providers’ attention when social operators don’t respond to their need; others are visibly embarrassed. On the other turf, social operators take advantage of their colleagues presence to collectively solve uncertain or difficult procedures and/or to strengthen their institutional position in front of users grievances. Sharing the same space, user-recipient relationships tend to become collective, to the detriment of recipients privacy and their personal will to share his/her own needs.

As the observations show, spatial configurations affect user-provider relations and services supply in different ways. The analysed ‘moments’ of the Social Counter’s activities (welcoming and waiting, expression of the needs, backoffice activities and consultation with colleagues) are organized in specific spaces (welcoming desks and waiting rooms, counters, backoffice), each of them presenting a series of strengths and criticalities (Figure 5, 6). This rigid separation, designed following the guidelines of the Office of Logistics and the Area Welfare, is often overcome both by users and providers to adjust the service environment to different situations. Therefore, different professionals arrange the available spaces depending on users’ needs and/or services circumstances according to a certain degree of discretion. In this sense, the spaces of the first meeting between citizens and public institutions can be understood both as *site-specific*, i.e. enacted in different spaces according to the available resources, and *case-specific*, i.e. reframed according to different users’ features and demands. While encouraging new design strategies towards a more flexible spatial setting, these practices are firmly grounded in Regional and Municipal laws and guidelines that call for standardisation as a mean to guarantee a more homogeneous, universal and safer system of service provision.

To conclude: Fine-grain analysis for wider policy orientations

The analysis developed in the previous paragraphs aims at addressing the different possible spatial drawbacks of institutional changes in social services provision from different policy perspectives. Among the FASS as traced by the national norms, the research focused on Social Counters in the city of Bologna, selected as a virtuous context of organizational and policy transformations. Grounding on two substantial local reforms that reshaped the local welfare provision, the research analyses the spatial effects of governance's changes focusing on three different dimensions: the distribution of services in the city (localization); the building in which services are provided (container); the spatial features of service provision and the user experience (the content). The analysis considers these dimensions simultaneously, basing on interviews with local administrators and social operators and grounding on personal site-specific observations.

Such a 'fine-grain' investigation is embedded in the idea that micro-scale observations could encourage further learnings on the links between different actors and policy levels and show how they are interconnected with wider systems. (Healey, 2015, 121). From this perspective, the research investigates how different levels of governance and policy instruments (Lascoumes and Le Galès, 2007) are intertwined in spatial configurations of Social Counters. Moreover, climbing back the ladder of multilevel governance, this contribution showed how different policy levels are/have intertwined in the creation and the modification of Social Counters spaces. For what concerns the National level, a major focus has been dedicated to the processes of policy territorialisation and decentralisation of the first 2000 and their partial *about turn* with the beginning of the economic crisis, that entailed a significant reduction of resources at the local level but also a drastic shrinkage of the public employees. In Bologna these phenomena led the basis for a reorganization of the neighbourhood subdivision and the local welfare reforms, implemented between 2016 and 2017. To investigate the effects of these reforms on the Social Counters, this contribution has focused on the case of San Donato – San Vitale neighbourhood. The main consequences of these normative changes can be summarized in three aspects. First, in those neighbourhoods that have been merged such as San Donato-San Vitale, the number of users have drastically increased, while social counters and social operators have shrunked, with significant drawbacks on social servants' workloads, on service localization and accessibility and on the consolidated interactions with other existing meaningful services. Second, these changes influenced Social Counters spaces, whose renovated organization led to a partial obsolescence of the existent structures and required different spatial settings that are still to be implemented. Third, social operators have been challenged to interpret increasingly different social demands with few dedicated instruments and to orient them to a variety of existing actors and services of whom they were not aware before.

Against this framework, the spatial configuration of services might be considered as both the results and the driver of institutional changes and policy choices. In particular, through spatial analysis it is possible to observe how different levels of governance are intertwined in services provision at the local level, and frame the main criticalities or advantages of such a complex system. Moreover, looking to governance changes through street-level observations of spaces and practices might lead to a deeper understanding of policy experiences and raise relevant aspects to reorient decision making processes and to develop more equal strategies of services provision.

Institutional patterns for metropolitan governance in LAC countries

The differentiated evidence from Bolivia and Brazil

Maurizio Pioletti¹, Luciana de Oliveira Royer², Patricia Urquieta Crespo³

³ CIDES, Universidad Mayor de San Andrés, La Paz, Bolivia. patricia.urquieta@gmail.com

Abstract: Within the framework of regional urbanization and post-metropolization (Soja, 2011, 2005, 2003) and global cities (Sassen 2016, 2008), Latin American and Caribbean (LAC) metropolitan areas, often grown throughout the aggregation of adjacent municipalities, under the pressure of urbanization and urban growth (Balbo, 2014) have not been properly governed (Maricato, 2011). Nevertheless, numerous cases in LAC countries show that horizontal cooperation among municipalities and vertical cooperation among the municipal level and other government levels are essential to promote shared and effective governance and territorial coordination (Souza, 2017). To do so, a multi-scalar approach (Brenner, 2016) in territorial policies should be used, implying simultaneous horizontal and vertical cooperation among government levels and actors, under a supposed direction for development.

In this light, the paper discusses empirical pieces of evidence from the observation and analysis of a range of the metropolitan configurations, where interinstitutional cooperation has played a key role in setting a metropolitan governance pattern, in improving urban management, especially in basic services.

The selected case studies are the inter-federative cooperation in the State of São Paulo (Metropolitan Regions of São Paulo and Baixada Santista), in the State of Minas Gerais (Metropolitan Region of Belo Horizonte) and some metropolitan experiences in Bolivia (de facto region of La Paz-El Alto, and de facto and de iure region of Cochabamba).

Keywords: metropolitan governance, institutional configurations, Bolivia, Brazil

Introduction

This study focuses on the multi-level metropolitan governance configurations in LAC countries, specifically in institutional and planning terms, with the awareness that metropolitan governance implies also statistical, social and economic factors and dynamics, not considered in this work. In order to clarify the scientific field of this discussion, this paper focuses on governance in spatial and political terms, and so, considers governance as a political process oriented to the allocation of rights for spatial uses and transformations, implying the actions and interactions of local actors dealing with the technical knowledge of planning practice (Mazza, 2015).

The joint analysis of these configurations is framed within the respective national planning systems in order to understand the relationship between each metropolitan governance and the respective planning systems and the main features, strengths, weaknesses, threats and opportunities of the LAC metropolitan governance. More in detail, this paper analyses different institutional metropolitan governance patterns from a range of metropolitan regions in Bolivia and Brazil, considered as a significant qualitative sample, at least because the metropolitan development in these countries was based on different relationship state-market. According to the field research carried out by the authors from January 2018 to September 2018 (data and information presented in this paper are verified up to September 2018), it emerged that Bolivia is a liberal centralized state, with a low level of decentralization and a very low institutional capacity, but a strongly mobilized population with an impact on territorial management, while Brazil is a liberal federal state, with a low level of decentralization, high institutional capacity, suffering from strong real estate sector's speculative initiatives.

In Bolivian metropolitan regions, urbanization has been mostly informal and driven by rural-urban migrations of indigenous farmer communities and results from the mix of the indigenous and post-colonial culture. In Brazilian metropolitan regions, hard urbanization has been driven by industrialization and tertiarization, resulting in a rise and strengthening of the urban middle class.

In LAC countries, the population was in 168,918 million in 1950, 645,593 million in 2017 (UNDESA, 2017), and so, in less than 70 years, the population has almost quadrupled. Considering in the same period (1950 – 2017) Brazil has shown almost the same trend (53,975 to 209,288 million) and Bolivia has shown a little lower trend (3,090 – 11,052 million). In 2018, in LAC area, that together with Northern America has the minor rural population proportion with respect to the other continents (less than 20% of the total), almost half of the total population lived in cities with more than 500.000 inhabitants and especially in cities from 1 to 5 million inhabitants and with more than 10 million inhabitants. In Brazil, approximately half of the urban population lives in the city with more than 1 million inhabitants, and approximately half of the metropolitan inhabitants live in cities with 1 to 5 million inhabitants (this paper is considering Baixada Santista: 1,853 million; Belo Horizonte: 5,972 million; São Paulo 21,650 million). In Bolivia, more than half of the population live in one of the three cities with over 1 million inhabitants (La Paz-El Alto, 1.814 million; Cochabamba, 1,237 million; Santa Cruz de la Sierra 1,641 million). (UNDESA, 2018)¹

A metropolitan region in territorial terms is a large (or mega, being this the case of Brazil, and other LAC countries such as Buenos Aires in Argentina and Mexico City in Mexico, etc.) urban agglomeration coinciding with the sum of adjacent mostly urban municipalities. In both the studied countries, this condition is verified. Both in Bolivia and in Brazil there is an official definition of the metropolitan region thanks to the formal recognition of the existence of the metropolitan regions as well as a central metropolitan policy.

Bolivia

In the Plurinational State of Bolivia, that is a centralized state, the art. 280 of the State Political Constitution (2009) affirms that a region is composed of various municipalities or provinces with geographical continuity, not crossing the departmental borders. These groups of territories share culture, languages, history, economy and ecosystems and represent a planning and management space. In case of an agglomeration having more than 500.000 inhabitants, metropolitan regions can be legally established, as planning units, i.e. they would not be levels of government.

In addition to that, the Frame Law of Autonomies and Decentralization (031/2010), in the art. 26, states that a Metropolitan Council will be established in each metropolitan region, as the higher body of metropolitan coordination. It will include members from the departmental government, every municipal government and the central State. The departmental statutes and the organic charts of the respective municipalities will have to articulate planning based on the metropolitan region and participation in the Metropolitan Council.

Within the wide framework of the State Integral Planning System (Sistema de Planificación Integral del Estado, Ley 777/2016), as briefly shown in Figure 1, planning is organized into three main levels: national, departmental and municipal, community, and into two main phases: the strategic definition, based on the Integral Development Strategy, that also defines regions, including the metropolitan ones, according to the above-mentioned legal statements.

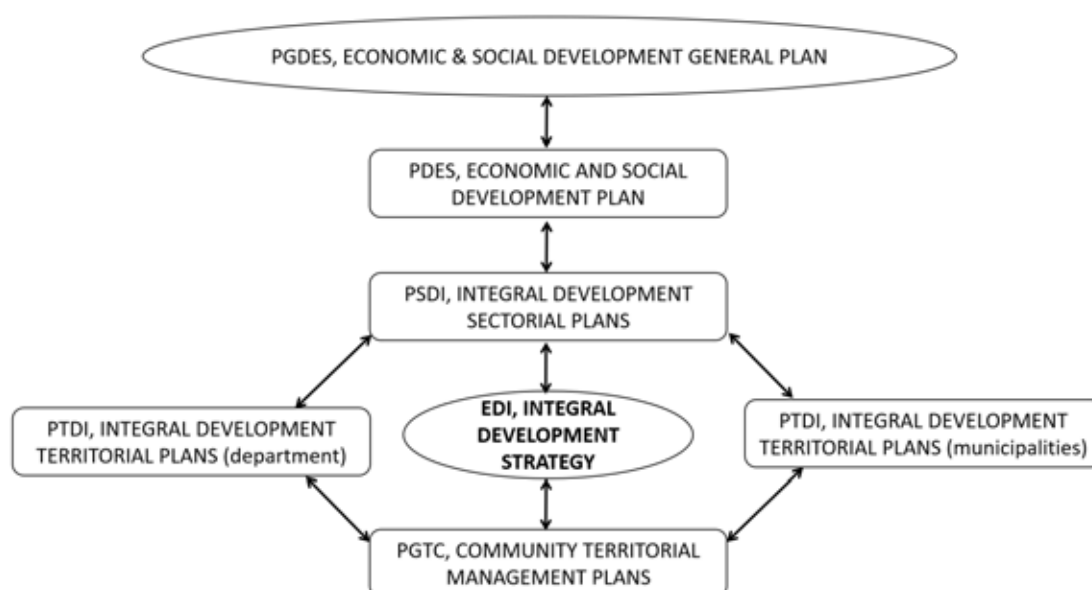

Figure 1: conceptualization of the Bolivian planning system highlighting the combination of strategy and planning

Only the metropolitan region² in the Department of Cochabamba (officially called Kanata) was legally recognized. The institutionalization of the metropolitan region occurred at the national level and was accepted by the departmental and municipal levels in a context of political affinity. Regarding the other regions, in this paper, only the case of La Paz (also called La Paz-El Alto) in the Department of La Paz is taken into consideration because of the current attempt of metropolitan institutionalization from the departmental level.

In 2014, the national Government approved the law 5332 of the Creation of the Metropolitan Region “Kanata” (2/6/2014). That legally defined the first metropolitan region in Bolivia and established a Metropolitan Council and a Metropolitan Secretary. In 2008, 2009 and 2010, three forums and two metropolitan meetings took place, and in 2010, the statutes were developed and a Steering Committee of the metropolitan community was established. Since 2012, the Committee has pursued an integral urban and rural development; a planned urban growth with regulation of land use, agriculture protection, preservation and water and recharge lands; an integral management of the basins of the metropolitan region, water integral management; and an articulated and coordinated management of economic productive and regional development.

In 2015, the Metropolitan Council approved its regulation and since its establishment up to 2017, it realized approximately 15 sessions and worked on the approval of the Metropolitan Action Plan based on a study financed by the IDB and elaborated in 2013 – 2014. According to Cabrera (Interviewed in July 2018), it was a sort of guide for the departmental government, promoting densification, reduction of land consumption, resilience, and institutional function, and overall, socially legitimated (Cabrera, Juan, interviewed in July 2018).

Although this plan was composed of near 28 projects including such fields as water and basic sanitation, urban mobility and transportation, citizenship security, adequate production and employment, social protection of the vulnerable sectors, very little has been implemented to date. One of the causes is that financing of these projects depends on the central government on the basis of agreements before the constitution of this metropolitan region. Despite the Metropolitan Council is a national planning provision and has 12 functions indicated in the regulation, the Council did not directly elaborate the plan nor it really accomplishes its functions.

In brief, Kanata is composed of 7 municipalities and was institutionalized with the national Law 533(27/05/2014). The metropolitan region was defined as a planning space, in order to promote the urban and rural integral development, the planned territorial management, including the land use and a rational and responsible territorial occupation, ensuring a planned urban growth, protecting the

² According to INE (Instituto Nacional de Estadística, Censo Nacional de Población y Vivienda, 2012), the population of this metropolitan region is 1.164.643 inhabitants (64.6% of the department), in 2.598,8 km², and is composed by the municipalities of Cochabamba (that represents more than half of the population), Colcapirhua, Quillacollo, Sacaba, Sipe, Tiquipaya and Vinto.

agricultural land productive potential, preservation and water recharge areas, and contributing to solve other challenges, shared with the Metropolitan Council.

The metropolitan agenda was originated from the Action Plan for the Cochabamba Metropolitan area (2013) financed by the IDB and composed of 19 projects distributed in 5 strategic axes (economic, social, environmental, political – institutional – science and technology). In 2014 the Kanata Metropolitan Council approved the Kanata Metropolitan Agenda (2015–2019), a document leading the actions to be coordinated at regional level and a sort of guide for the departmental government, promoting densification, reduction of land consumption, resilience, and institutional function, and overall socially legitimated (Cabrera, Juan, interviewed un July 2018). Very little of the projects have been implemented to date, one of the causes can be that the financing of these projects depends on the central government on the basis of agreements before the constitution of this metropolitan region. Despite the Metropolitan Council is a national planning provision and has 12 functions indicated in the regulation, the Council did not directly elaborate the plan of action. According to Blanco Cazas (2017, pp. 273-276), although this region was created as a planning and management space, the metropolitan financial instruments were not defined immediately, and even today some of them are lacking.

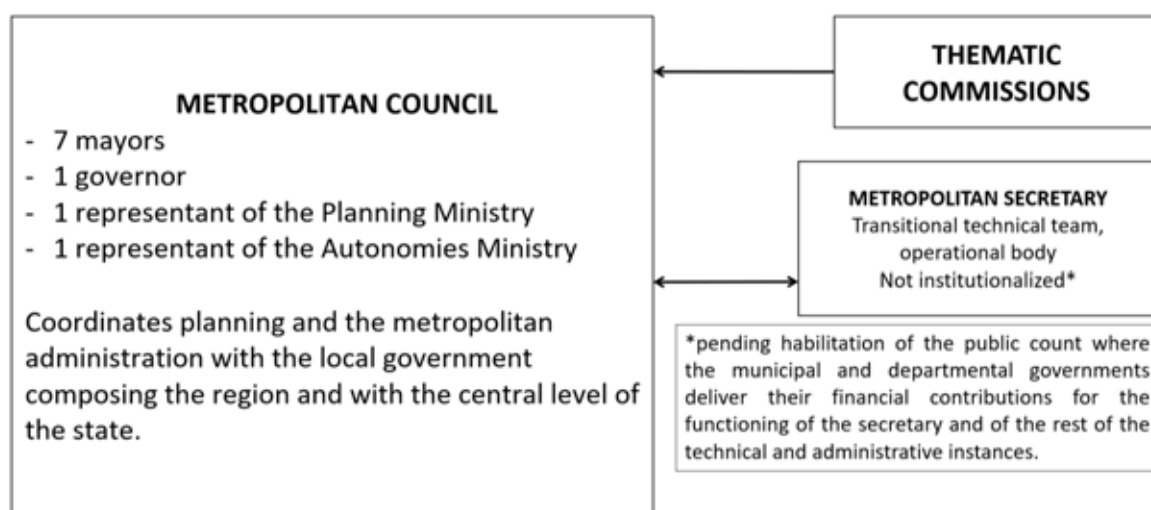

Figure 2: institutional pattern of the Kanata Metropolitan Region

The process of metropolitan institutionalization is still on-going. As shown in figure 2, the metropolitan council is composed of the 7 mayors, the departmental governor, one representant of the Planning Ministry, one representant of the Autonomies Ministry. It coordinates planning and the metropolitan administration with the municipal governments and the central State. It is supported by the activity of thematic commissions, and cooperate with the Metropolitan Secretary, that is a transitory technical and operation body, not yet institutionalized because it has not yet been habilitated to have a public count where the municipal and departmental governments deliver their financial contributions for the functioning of the secretary and of the rest of the technical and administrative instances. The art. 12 introduces the Metropolitan Companies, among the autonomous territorial entities and the central level of the State, for the performance of the metropolitan public services established in metropolitan planning and defined by the Metropolitan Council. However, after the metropolitan institutionalization in Cochabamba, the metropolitan action plan was formalized within

the Metropolitan Development Strategy, but the Metropolitan Secretary was not effectively working because it was not yet legally recognized.

To conclude, various not solved problems related to procedures have emerged. No definitive and effective metropolitan institutional governance has been consolidated so far. The change of political government from 2015, when MAS lost the elections in some municipalities, made even more difficult the metropolitan policy implementation. It seems that the metropolitan governance is not a priority, and any inter-scalar relationship between the municipality and the whole metropolitan region is not recognized. No priority has a metropolitan scale and the Metropolitan Council work is unknown. The marginalization of the metropolitan issue in the urban debate is even stronger among social actors. In general, the metropolis is perceived as a “news” diffused by media only dealing with eventual large metropolitan projects. Further, according to Blanco Cazas (2017, pp. 276-278), in 2015, the Katana metropolitan region constitution created conflicts for the municipal autonomy and gave excessive power to the departmental and national governments. According to Juan Cabrera (interviewed in July 2018), it is positive the fact that the Cochabamba metropolitanisation law is national, because in Bolivia the national laws are more influent than the departmental ones, since departments are weak, having no financial autonomy. In Cochabamba, the creation of a metropolitan fund shared between municipalities and the departmental government would not be feasible. It is the state out of the fund financing the large metropolitan projects. It would be better if the State financed the fund, and not directly the projects, i.e. not holding decision capacity on its own and impeding the action plan implementation.

The metropolitan region in the Department of La Paz³ is not legally defined nor recognized. However, it is composed of the Municipality of El Alto (860.062 inhabitants, 2.482 inhabitants/km²), the Municipality of La Paz (779.728 inhabitants, 395 inhabitants/km²), and the other six municipalities (191.560 inhabitants, 56 inhabitants/km²). According to Blanes (2006), in this area, the growth of El Alto has represented the basis for the growth of the other close urban centres. A centripetal densification process has occurred towards La Paz and El Alto, where most of the urban functions are concentrated. On the one side, urban centres are reinforced, on the other, other small centralities developed their role with specific functions such as residential, recreation, industrial districts. At the metropolitan level, there are such challenges as the mobility which cannot be tackled at the municipal level. Only between El Alto and La Paz more than 300.000 people daily commute. Both municipalities created public transportation companies and the State government created the cable car company. No common transportation management has been implemented so far and the three companies have been working separately. As one of the consequences of the absence of metropolitan transportation policies, private vehicles' mobility is the cause of strong congestion and air pollution.

³ It is located between 3.200 and 4.000 metres, and is composed of Achocalla, El Alto, Mecapaca, Palca and La Paz (Provincia Pedro Domingo Murillo), Pucarani and Laja (Provincia Los Andes), Viacha (Provincia Ingavi). 17,6% of the Bolivian population (i.e. 1.831.350 million people) live in the region.

The municipality of La Paz and the municipality of El Alto, together with the departmental government, worked on the drafting of a Metropolisation Framework Agreement. The first step was the recognition that metropolisation is a voluntary and aware adhesion and not just a legal issue. Signing this agreement in March 2016, 5 municipalities and the departmental government composed the technical committee to define shared priorities: drinkable water and sanitation, climate change and environment; mobility, human development, economic development and citizens' security.

According to Blanco Cazas (2017, pp. 276-278), in La Paz, the political change after the election in 2015 had important implications. The departmental government moved to the opposition. At the municipal level, despite most of the electors from La Paz continued supporting alternatives to the Movement for Socialism, which lost also in El Alto, the other municipalities continued supporting the Movement for Socialism. Two years after this political reconfiguration, the institutionalization process was strongly promoted by the departmental government, headed by Félix Patzi, supported by the La Paz municipal government which produced the Municipal Delegation for the Metropolisation. The Municipality of EL Alto, led by the mayoress Soledad Chapetón, despite she did not open a specific organic instance of the Municipal Executive power, was aligned with the departmental initiative. She signed the "Altopaz" agreement valid for 10 years, promoted by the Municipality of La Paz to handle common issues such as mobility and drinkable water. However, it was not possible to sign the Intergovernmental Agreement for the creation of an Economic Productive Development Metropolitan Agency (March 2016). The Departmental Legislative Assembly approved in September 2016 a departmental law which declared as a departmental priority and necessity the conformation of the La Paz metropolitan region. It also stated criteria for functioning, principles, definitions and implicitly created the metropolitan council, without mentioning the Economic Productive Development.

The departmental government is currently discussing the metropolitan governance configuration, with the other involved actors and authorities. The metropolitan forum has already been organized twice, in 2016 and 2018. This configuration is illustrated in Figure 3.

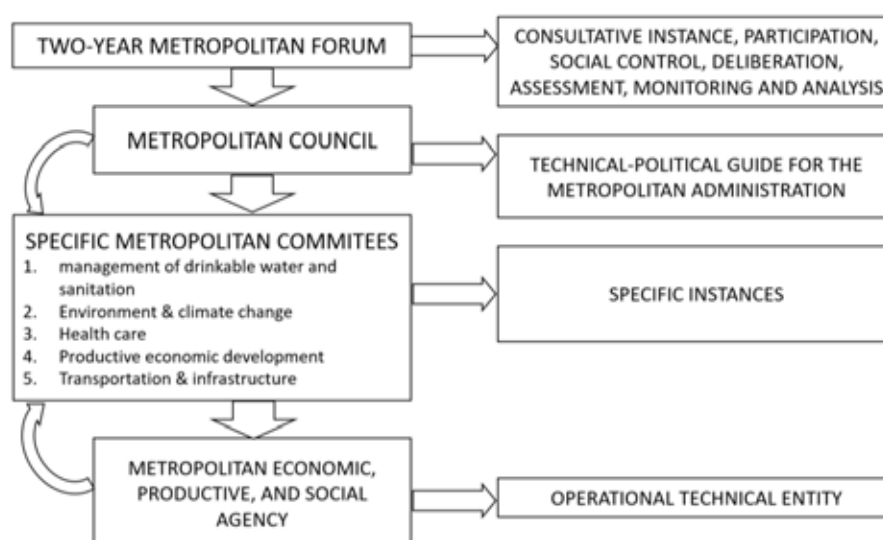

Figure 3: draft of the institutional pattern of the La Paz Metropolitan Region

In the illustrated configuration, the metropolitan forum takes place every second year. It plays a consultative and participatory role, involving the civil society, as well as monitoring and assessing the process. It dialogues with the metropolitan council, which includes the political representation of the Department, the State and the Municipalities, and is supported by specific metropolitan thematic committees. These committees have a technical and scientific role and cooperate with the executive agency, set in the department's structure.

To conclude, in terms of metropolitan coordination, this region is characterized by “soft governance”. The legislative absence of the state and the exclusion of the hypothesis of constructing metropolitan political governments determine the prevalence of soft governance scenarios, therefore situations based on the concept of inter-municipal cooperation (facultative and voluntary) to share a common vision on the problems and priorities for the territorial development and the urban projects at metropolitan scale. In fact, a first facultative and voluntary agreement between all the municipalities in the region was attempted. Among the potentially involved municipalities, only five of them signed the first version of the agreement, in March 2016. Unluckily, the concertation was further reduced to the two major municipalities, La Paz and El Alto, which continue to have no constraining agreement, that could represent the basis to build future projects and initiatives of metropolitan cooperation. Further, a relevant problem is the competitiveness and subsidiarity among municipalities within the metropolitan area. The small municipalities are afraid to lose authority in case the metropolitan region is officially established because La Paz and El Alto would play a hegemonic role. On the other side, La Paz and El Alto could financially support the other municipalities to compensate disparities.

However, although the municipalities of La Paz and El Alto dominate the scene, they are strongly dependent on the other municipalities, given historical problems of municipal boundaries that have heavily limited the action. On the other hand, permanent tension is present due to the correlation of political forces between politically official and opposition municipalities. Thus, although the cities of La Paz and El Alto are continuous in territorial terms and operate with a *de facto* metropolitan approach, and agreements and even certain tools dealing with metropolisation are in force, it seems that their feasibility can be resolved just in the political arena.

Brazil

The Federative Republic of Brazil recognizes as federative levels of government: Federation, States and Municipalities. Each federative entity has federative autonomy, and according to the Federal Constitution (1988) and the federal Metropolitan Statue (2015), each state has to legally create, define and organize the metropolitan regions, in order to improve the management of the public functions of common interest, at the basis of planning. It is worth to remark that within the federative autonomy Brazilian framework, in any case, metropolitan regions are not federative entities, their governments are not elected by people, i.e. they are not levels of government.

In the 70s the federal military dictatorial government invested in national industrialization in large urban areas and created between 1964 and 1985, the following metro-regions which are still the most important ones: Belo Horizonte (5.916.189 inhabitants), Salvador (3.899.533), Rio de Janeiro (12.377.505), São Paulo 21.391.624), Recife (4.044.948), Porto Alegre (4.318.000). Since 1988, when

the democratic Constitution was approved, regions created by the state governments were Goiânia (2.447.874), São Luiz (1.621.102), Florianópolis (1.172.076); Natal (1.587.055), Vitória (1.960.213), Baixada Santista (1.828.212), the only one not being State capital.⁴

In 2004, the State of Minas Gerais, whose capital is Belo Horizonte (BH) defined a metropolitan region as the sum of the adjacent municipalities characterized by a continuous urban fabric and the complementarity of urban functions, where the State capital is the centre and requiring integrated planning and permanent shared management by the public bodies. The metropolitan governance has to identify the public functions of common interest (activity or service whose realization by a unique municipality is infeasible or that impacts on other metropolitan municipalities). They represent the basis for the metropolitan planning, and so, issues, services, infrastructures which have to be realized by the metropolitan cooperation, and not by the individual municipality (IPEA, 2018). Inspired by the BH experience, in 2015 the Dilma's federal government approved the Metropolitan Statue, making the metropolitan planning compulsory.

As shown in Figure 4, at inter-federative level, and at an intermediate scale between Municipalities and State, the metropolitan plan concentrates the planning effort for the public functions of common interest within the metropolitan territory. According to the Metropolitan Statue, the existing municipal masterplans, held by municipalities, should adapt to the metropolitan plan. However, as already said in 2018 the obligation of elaborating the metropolitan plans was deleted by the Temer's Federal government, on the one side, arresting to the metropolitan policy process, on the other leaving the municipalities to carry on their own municipal plan, as usual.

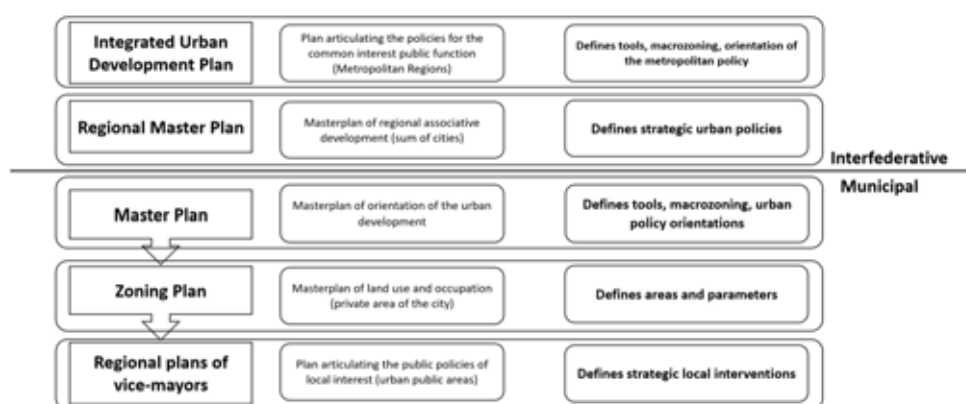

Figure 4: Interfederative and municipal planning levels⁵

The analysed case-studies are Belo Horizonte (BH) metropolitan region (MR)⁶, the capital of the State of Minas Gerais; São Paulo metropolitan region (SP), the capital of the State of São Paulo and Baixada Santista (BS), also in the State of São Paulo.

In BH, even before the metropolitan institutionalization by the State Complementary Law n. 14 (08/06/73), in 1971, a research and planning group was created, coordinated by the João Pinheiro Foundation. The Development Authority was created to promote the integrated urban and regional planning in the state of Minas Gerais. This created analyses and plans with a high technical level. However, its implementation was criticized for an excess of centralism and authoritarianism, not having effective participation of the municipalities, neither the civil society in the planning process. Despite the first configuration from the 70s, the crisis in the 80s weakened the metropolitan management system. A municipalism-based approach, as well as the interruption of the federal investments, resulted in the decline of the bodies responsible for territorial planning and management. As a consequence, in 1996, the Authority was extinguished.

Since 2004, a new institutional configuration has been debated as well as solutions for the economic impacts generated by the absence of metropolitan planning after the extinction of the authority. In 2006, the State Complementary Law n. 89 (12/01/06) in art. 88, 89 and 90 established a new model for planning and managing the region. The institutional innovations included the creation of the necessary arrangements for planning and developing the regions according to the common interest public functions.

At the beginning, the Metropolitan Conferences ensured the discussion and develop the creation of the Metropolitan Assembly (superior decisional body, including representatives of the state, mayors and municipal legislative presidents) and the Metropolitan Development Deliberative Council which is a body for the general coordination of the actions related to the metropolitan planning, with representatives of state, municipalities and civil society. These two bodies are assisted by the Metropolitan Development Agency created in 2009. This technical and executive agency carries on planning, assessing, urban regulation and support the implementation of the public functions. Finally, it was created also the Metropolitan Development Fund, in order to support the activities scheduled by the Deliberative Council, on the basis of the Integrated Development Master Plan, prepared between 2009 and 2011⁷. A shared management was established among the Metropolitan Assembly, the Deliberative Council and the Agency, implying a decisional capacity distribution among state, municipalities and civil society. The configuration of the metropolitan management created in 2006 introduced an innovative model in procedures, which foresaw the decentralization and participation of municipalities and civil society's representatives in the planning and management process.

In 2007, integrated management of the common interest public functions was promoted to make the region more competitive and increase the quality of life of the metropolitan citizens. In order to reach these objectives, between 2007 and 2009 it was defined the necessity of approving the metropolitan

⁶ It is composed of Belo Horizonte and other 33 municipalities.

master plan as a planning tool, involving municipalities, the Minas Gerais State, the federal bodies and the civil society in social movements, entrepreneurship and people associations. The plan's priorities were urban space, accessibility, security, and sustainability. In particular, the plan created and strengthened the urban centralities in network, planned the expansion of the land occupation, intensified the use of the existing urban space, reduced the pressure of the peripheral urban expansion on the green areas, the rural areas and environmentally protected areas, expanded the porous urban areas, restored and revitalized the rivers, consolidated the regulatory framework for the land use and occupation.

Regarding implementation, the inexistence of an investment plan linked to the metropolitan development plan and micro-zoning weakened the legitimacy of the on-going planning and management process. Despite a state of planning more advanced than the other Brazilian metropolis, the metropolitan development plan and macro-zoning elaboration were reduced to land use, planning and management principles, without detailed content.

Further, Minas Gerais was the first State which created the concept of the “metropolitan citizen”, and so, a high level of citizens' participation. The civil society takes part in the biannual Forum and elects 2 representatives of the metropolitan citizens for the Deliberative Council. The Art. 8 of the State Complementary Law n. 89 (12/01/06) defines the functions of metropolitan common interest: transportation and road network, citizens' security, basic sanitation, land use, house gas, cartography and basic information, environmental protection, housing, health care system, social and economic development.

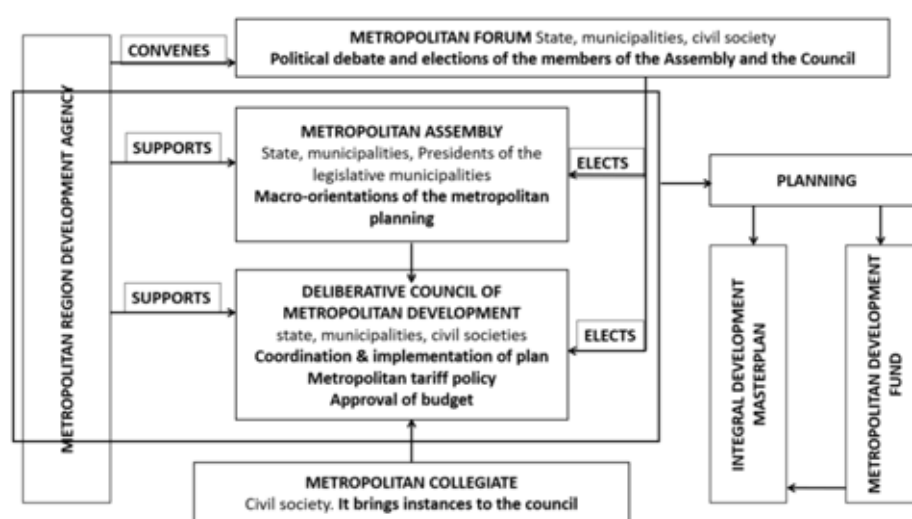

Figure 5: institutional pattern of the metropolitan governance in BH

As shown in Figure 5, the metropolitan region development agency held by the State convenes the metropolitan Forum that includes state, municipalities, civil society, carries on the political debate and elects the members of the Assembly and the Deliberative Council. Assembly and Council are supported by the Agency. The Assembly includes the political representation of the state, municipalities, Presidents of the legislative municipalities and provides macro-orientations of the metropolitan planning. The Deliberative Council includes the representation of the State, municipalities and civil societies, and carries out planning coordination and implementation of planning, the metropolitan tariff policy, the approval of the budget. The Council also receives the

contributions of the Metropolitan Collegiate of the civil society. The efforts of the agency, the assembly and the council determine the planning activity, and so elaborating the integral masterplan and setting the metropolitan development fund.

More in detail, the development agency has a technical and executive role, for planning, assessing, urban regularization, with administrative and financial autonomy. It makes viable integral development tools and the execution of the public functions of common interest, it promotes the plan implementation, it elaborates and promotes technical studies and diagnostics, it endorses and monitors plans and programmes, collects resources for the integral development, promotes the integration of the federative bodies. The Metropolitan Development Fund is composed of various representants, included the Deliberative Council of Metropolitan Development. It finances the structural projects; investments related to the public functions of common interest, defined by the plan. Finally, the metropolitan plan is elaborated and proposed by the Metropolitan Development Agency, supported by the Metropolitan Development Deliberative Council and by the Agency. It expresses the trajectories of the economic and social development integral planning based on common interest public functions.

The metropolitan region of São Paulo (SP) is composed of 39 municipalities, divided into 6 sub-regions: North, East, South-East, South-West, West, Centre. Each sub-region counts on an inter-federative public consortium, voluntarily established. In the 60s, the institutionalization process of the metropolitan region, called Grande São Paulo, was supported by the Institute of Architects of Brazil and in 1967 the Federal Constitution introduced for the first time the “metropolitan region”. In 1970 the Integrated Development Metropolitan Plan of the Greater São Paulo was defined.

At State level, in 1975, a metropolitan planning public company (EMPLASA, Empresa Paulista de Planejamento Metropolitano) was created with a technical and executive role, in order to elaborate metropolitan plans and projects. Regarding the recent period, in 2011, on the basis of the studies realized by EEMPLASA, the reorganization of the metropolitan region was defined by the State Complementary Law n. 1.139/16/06/2011 (IPEA, 2015).

That law created the Metropolitan Development Council, the main body in the metropolitan governance, with a regulatory and deliberative character, overall related to plans, projects, programmes, services and works to be realized with financial resources of the Development Fund. The Council is composed by the representatives of the state government and of every municipality. The indications of councillors have to ensure the parity between municipalities and state, accounting 50% respectively.

It is supported by Thematic and Special Thematic Committees for the promotion of studies, investigations, projects and activities related to the public function of common interest; and special thematic commissions, caring of programmes, projects and specific activities. In 2015, An Executive Committee⁸ was set to promote the metropolitan plan elaboration and go along with its development

⁸ It is composed of 18 members, being 4 representatives of the State government, 4 representatives of the Municipality of São Paulo and 10 representatives of the subregions.

up to its approval, respecting the federal Metropolitan Statue, throughout the organization of a Technical Commission and an Executive Secretary, carried out by EMPLASA and managing working groups.

The Decree n. 57.349/2011 temporarily asked EMPLASA to assume the role of Development Council Executive Secretary because of the absence of a territorial body able to integrate the organization, planning and execution of the public functions of common interest as required by the State Complementary Law 1.139/2011. Throughout State Decree 59.094/2013, the Development Fund was established, but no actions have been funded so far.

In 2015, under the Council responsibility, the plan elaboration process began. Nevertheless, since 2019, changes in the configuration have made unstable the institutional and regulatory framework of the metropolitan region. The current governor has been leading an aggressive privatisation programme and closed EMPLASA. Its functions are transferred to other governmental bodies. Simultaneously, the metropolitan plan (Integrated Urban Development Plan) was approved by the State Legislative Assembly. Unfortunately, this plan contains just the orientations for future interventions and does not set a definitive and effective interfederative governance solution for the region. Therefore, the governance in SP is in transition, making even more difficult the execution of the public functions of common interest. For the closure of EMPLASA, the region loses its main planning body for the metropolitan issues.

The Deliberative Assembly Authority with the civil society representation was established with the attribution of sharing the sphere of decision of the executive authority together with the civil society, by means of the elected representatives for the plan deliberation. It is composed of representatives of each sub-region, indicating entrepreneurs, workers, labour organizations, universities and professional categories, social movements, and NGOs. The metropolitan plan elaboration was based on a participatory approach, as in the case of the municipal master plans.

In brief, as shown in Figure 6, at the political and administrative level, there was the Civil House and Sub-secretary of Metropolitan issue of the State Government, that controlled EMPLASA, which cooperated with the Development Council. The council has a regulatory and deliberative role and contains the representatives of state and municipalities. It focuses on project, services and Works of common interest. Meetings are public, and the Development Council receives contributions from both the civil society's Consultative Council (arts. 14 and followings, LCE 1.139/2011)⁹ and Thematic and special thematic committees. The metropolitan development fund was managed by EMPLASA. But in January the Sub-secretary of Metropolitan issue was closed and in May, EMPLASA was closed too. The governor stated that EMPLASA functions will be embodied by Secretary of Regional Development.

⁹ The Consultative Council is composed of members of the civil society, state and municipal legislative powers, state and municipal executive power.

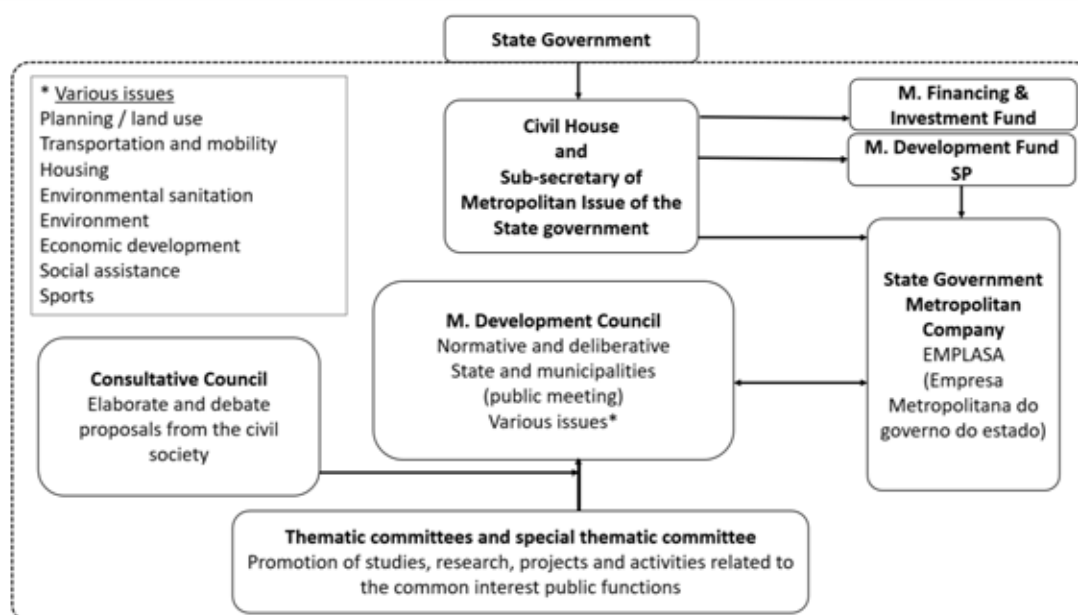

Figure 6: institutional pattern of the metropolitan governance in SP up to December 2018

Baixada Santista (BS)¹⁰ is characterized by a historical strong development determined by the intensification of the land use and occupation in the centre of the region. This was deeply marked by the scarce effectiveness of the regional planning, national structural problems and low salary urbanization process (Maricato, 1996).

The complexity of this regional solution impacted on the basic sanitation, housing, mobility, environmental and technological risk, among other aspects, and since the 60s, it has generated the rise of a movement promoting the metropolisation. Indeed, according to the Federal Constitution, the new institutional organization could contribute to facing all these challenges and impacts. This movement led to the creation of the Commission for the Metropolisation, starting from a Santos municipal legal initiative. This initiative arrived at the Municipal Council and the Legislative Assembly, involving councillors and congressmen.

In the 80s, the State Administration Councils and the Municipal Administration, in each regional government, as a State government initiative, originated the institutionalization of the regional organization. (Viana, 2010)

Since the crisis in the 90s, the political leadership has been concentrated in the Metropolisation Regional Council, a municipal initiative supporting the creation of the metropolitan region, throughout state law.

Further, the above mentioned EMPLASA was used to produce territorial data on the area. Since 1992, the priority issues have been discussed in the municipalities, resulting in the creation of a specific

¹⁰ The Baixada Santista metropolitan region is composed of 9 municipalities: Santos, São Vicente, Cubatão, Guarujá, Praia Grande, Bertioga, Mongaguá, Itanhaém and Peruíbe. Santos is the main centre; whose urban area divides the São Vicente island. In Santos, there is the most important harbour in Latin America. In its agglomeration, Guarujá and Cubatão are also included.

technical council. In 1993, the municipality of Santos created a specific secretary of metropolitan issues, orienting the regional political influence on the creation of the Baixada Santista. In 1996, as a result of the strong political pressure, the SP State formalized the Baixada Santista MR by means of the State Complementary Law 815 (30/06/1996).

However, the initial metropolitan institutional organization was not effective, having the state government an excessive influence on the other municipalities, that resulted in a governance system, partially open to civil society's participation.

The governance structure is composed of a Council with political functions, a technical agency and a fund, to finance the development and the policies related to the public functions of common interest.

The art. 3 (law 815/1996) authorized the institution of the Development Council, which should have a regulatory and deliberative character and be composed of representatives of state and municipalities in the functional field of common interest. Later, law 853 (23/12/1998) set the creation of the BS Metropolitan Agency (AGEM).

Since the creation of the Development Council in 2007, the thematic committees were activated. In 2014, the council approved the restructuration and the distribution of the thematic councils in 4 work-groups: mobility, environment, public policies and economic development, implementing a trajectory of the Strategic Development Metropolitan Plan. The reorganization foresaw the formation of a Regional Planning Group, in order to manage the new model, composed of representatives of the Council, AGEM, actors responsible for the working groups, mayors and members of the Committee of Hydrographic Basin and of the Coastal Management.

In 2002, responding to one council's request, EMPLASA prepared the Integrated Development Metropolitan Plan with a participatory process. It proposed objectives and trajectories but did not indicate actors and actions. Thus, in 2014, a plan promoted by the Council was defined. It represented an innovative regional plan in the SP state. It is composed of 26 sectoral objectives and 179 actions, as the result of the simultaneous participation of municipalities and civil society, throughout public meetings and consultation. The process began with a series of meetings with municipal actors, then with state, federal and private actors. The objective of the plan was the definition of a metropolitan scenario, based on macro-strategies for the metropolitan sustainable development in 2030.

Thus, the institutional structure has been reorganized, as well as the thematic committee, in accordance with the regional planning groups, trying to respect the metropolitan plan. By the same way, the metropolitan governance is influenced by a deliberative participatory authority having the representation of the civil society, who could ensure the democratic character of its management. The Development Council is composed of representatives of the municipalities and of the state government secretaries, indicated by the governor (art. 10 of the Complementary Law 760/1994).

More in detail regarding the agency, according to law 853/1998, AGEM is the executive body of the governance system, aimed to integration, organization, planning and the execution of the public functions, collecting its own tax revenue, or the ones which are delegated or transferred, including fees and prices for the services; monitoring the execution of the laws related to metropolitan regions, applying the respective fines, in the exercise of the police power; establishing objectives, plans, programmes and projects of common interest, as well as monitoring and assessing execution; promoting the misappropriation of public utility goods, when it is necessary to realize common interest activities; keeping updated and diffusing the statistical data and other information, necessary for the metropolitan planning; exercising other attributions which are legally transferred.

Among the thematic committees, the one on planning and economic development is responsible for the elaboration of the metropolitan plan from 2016. It is composed of representatives of the state and

municipalities. Currently, a group composed of members of the civil society enlarges the participation in the process.

From 2013, the first step was the technical assessment of the existing plan and projections, the final definitions of scenarios and the metropolitan plan consolidation. The metropolitan plan introduces the state strategic planning structure, even based on the macro-metropolitan action plan. In a future vision, 2 macro-objectives were established: consolidation of the urban development (i.e. housing, mobility, sanitation) and support to the economic development. With the Metropolitan Statue, AGEM presented to the Economic Development and Planning Thematic Commission, the document entitled Inter-federative Challenges of the Metropolitan Management. In this document, the body stated that the metropolitan region already had an orientation to Integrated Urban Planning; a macro-zoning arising from the Ecological and Economic Zoning, regulated by the State Decree 58.996 (25/03/2013); regional sectoral plans; monitoring system of actions in bidding phase; Public Metropolitan Fund, created and regulated in 1998; cooperation agreements, signed with regional deliberative authority of the Committee of the Hydrographic Basin and Coastal Management.

Thus, AGEM promotes objectives, results and strategies proposed in the plan, using the micro-zoning tool, regional sectorial plans and the municipal master and sectoral plans of the municipalities. Doing so, the agency suggests improvements in the Inter-federative Governance Structure and adjustment regulations and civil society participation. Thus, the AGEM needed to improve participation in the plan's elaboration and deliberation. The plan was presented in April 2016. In 2017-2018, the existing metropolitan plan was converted into the format required by the Metropolitan Statue, using a participatory approach.

Regarding financing the metropolitan actions, the fund, created by the Law n. 815/1996, and regulated by the State Decree 42.833/1988 and 56.635/2011, aims to finance the integrated planning and the related actions, referring to the public functions of common interest between the state and involved municipalities. It is participated by AGEM, Bank of Brazil (BB), and the beneficiaries. However, most of the financed projects are proposed by the municipalities integrating the MR and are addressed to investments in strategic sectors. The resources stem from the state (50%) and the sum of municipalities (50%).

In brief, The executive power is given the competence to establish the Development Council and the Metropolitan Development Fund. The Development Council approved in 2017 the law project that converted the existing plan into the new format, foreseen by the Metropolitan Statue.

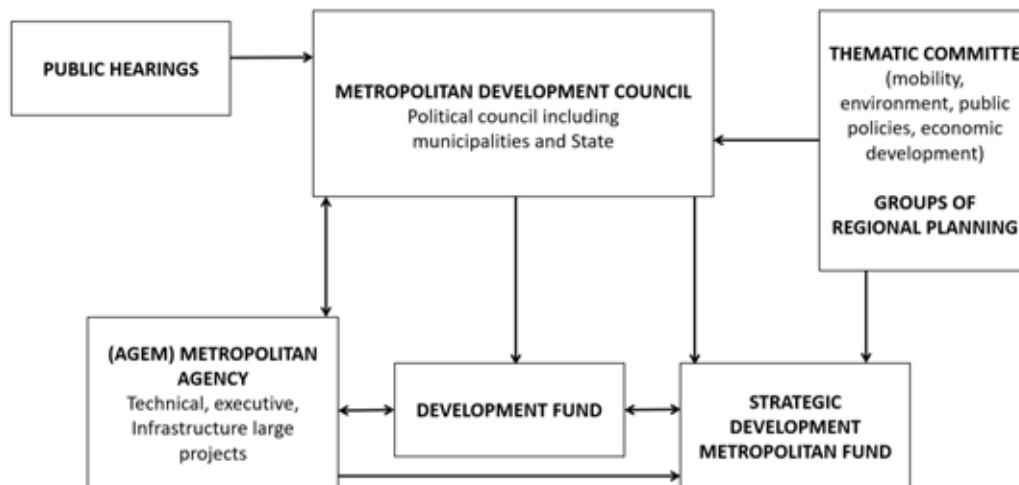

Figure 7: institutional pattern of the metropolitan governance in BS

As shown in Figure 7, the metropolitan agency has a technical and executive role and focuses on infrastructural large projects. The agency cooperates with the Metropolitan Development Council that has a political role and includes the representation of municipalities and state. The Council receives contributions from the public hearings and thematic committees and the groups of regional planning. This cooperation permits to manage the development fund and the strategic development fund.

Conclusion

The cases show some pieces of evidence, important to understand institutional, political, administrative and planning aspects of metropolitan governance.

- Metropolitan institutionalization is defined by an over-local legal provision, so the role of the intermediate bodies (departments in Bolivia and States in Brazil) is essential and implies to decide if the legal recognition and definition of metropolitan regions have to occur at the national or intermediate level. In any case, it seems that an institutional bottom-up approach based on inter-municipal cooperation is not sufficient to activate the metropolisation process, except for Baixada Santista.
- Consequently, basic features of metropolitan regions and their institutional organizations are defined by an over-local legal provision, determining possible conflicts of competences with municipalities, especially if they are autonomous and are given a strong planning capacity.
- A political representation takes part in all the institutional patterns, so metropolitan governance is never considered just as a technical issue. On the contrary, a political value is recognized, even if it has not always implied a strong strategic approach in metropolitan planning so far.
- However, metropolitan institutionalization is considered a strategic initiative and implies the definition of strategic projects, but in many cases, the bodies which should lead the metropolitan governance have no sufficient financial capacity and autonomy and these projects are often financed by over-local levels which follow other logics and priorities.

- An operational agency, having a technical and executive role, is used to carry out the metropolisation process, with a more pragmatic approach to balance the institutional inertia in front of important institutional reorganization and ways of thinking.
- That being said, at the territorial level, metropolisation grows independently on the legal metropolitan recognition, so institutionalization of metropolitan regions is more a regularization and organization of existing territorial processes than a planning activity, even because in many cases the public decision-making is not as fast as territorial social and economic processes.
- In this perspective, the intermediate levels such as departments or federative states have a key role in leading and facilitating the process, especially in case of different political positions of municipalities on common issues.
- Metropolisation deals with the shared definition and implementation of the public functions of common interest. This is an issue, strongly debated in Brazil, but it is the basis of metropolitan management, that unavoidably starts from sharing a vision of the present and future metropolitan space.
- Regarding sharing, pro-active participation of all the municipalities is fundamental also to avoid or limit regulatory conflicts between municipal and metropolitan inputs and plans. At the same time, metropolisation implies a scaling up in local policies, so deals also with a scaling up of citizenship rights. In many cases, rights - and the Right to the City - could not be any more ensured by one single municipality, but by their aggregation.
- Finally, looking at implementation, when planning is weak or uncertain, single large urban projects are more often financed. They could bring immediate benefits to local communities but they also contribute to the spatial disarticulation of these ungoverned metropolitan regions.

Those being observed, regarding metropolisation, these cases highlight a strong relationship between the national and the local level, i.e. all the analysed metropolitan institutional patterns are framed within the respective national planning system. In the same measure as ordinary planning is not effective whenever it is not accompanied by a coherent financial budget for planning activities and implementation, also metropolitan policy needs to be directly financially supported. This point also deals with the fact that implementation is complicated whenever the body having decisional capacity on planning does not coincide or is not coordinate with the body managing the public budget. It is even worst if these bodies are located at different levels.

To conclude, the paper focuses on the problem of governing metropolitan regions which have often grown ungoverned. The weakness of the institutional implementation autonomous power of municipalities in these countries makes weak (or absent) also the horizontal cooperation at the metropolitan scale, and often the capacity to activate bottom-up institution initiatives. It implies that there is a predominance of vertical relationships and of top-down initiatives because even when local

authorities are formally autonomous, the financial resources could be managed at the over-local level. Thus, the legal institutionalization cannot ensure effective metropolitan governance, whether no financing is ensured for metropolitan planning definition and implementation, and metropolitan cooperation is more effective when it starts from the bottom up initiatives.

Abstract: The role of urban areas for sustainability transitions is crucial. Urban unsustainability problems seem to be persistent and a sense of urgency about how to speed up purposive urban transformation is growing. Accordingly, the research community is paying increasing attention to place-based approaches to identify the essential factors for accelerating urban sustainability transitions. This work-in-progress is based on Wolfram's urban transformative capacity conceptual framework (2016) for the analysis of the transition processes in the particular case of Valencia, Spain. The aim is to apply the framework as an analytical tool and to develop an exploratory assessment based on in-depth stakeholder interviews which identifies strategic implications for policy making and urban planning in order to accelerate transitions. In particular, the role of spatial planning (and planners) at metropolitan level have been examined in relation to its capacity of translating and incorporating innovative practices to accelerate urban sustainability transitions. At this level, implications in terms of rationalities, governance, instruments and techniques are shown in the conclusions. Although the research is circumscribed to the city of Valencia, its implications may be valuable for other contexts to enable comparative research.

Keywords: spatial planning; urban planning; sustainability transitions; Valencia

Introduction

Cities and territories require new forms of planning to face global sustainability challenges. Climate change is already a well-known problem. Significant impacts on human and natural systems have been related to climate change (Intergovernmental Panel on Climate Change [IPCC], 2014). Between 1990 and 2015 anthropogenic green-house gas emissions due to energy production increased by 45 % (International Energy Agency [IEA], 2018). Furthermore, cities are responsible for more than 70 % of

global carbon emissions (United Nations Human Settlements Programme [UN HABITAT], 2016). According to the United Nations, 55 % of the world's population live in urban areas (United Nations, Department of Economic and Social Affairs [UN DESA], 2018). Consequently, the role of cities for sustainability transitions is crucial. In addition, urban unsustainability problems seem to be persistent and a sense of urgency about how to speed up purposive urban transformation is growing. The academic community is paying increasing attention to place-based approaches to sustainability in order to address its spatial dimension and to identify the essential factors for accelerating sustainability transitions at urban level. Also all these challenges require territorial governance actors and institutions who deal correctly with uncertainty and complexity.

The city of Valencia seems particularly suitable to analyze urban transformation capacities through spatial planning in Spain. Valencia is the third largest city, just behind Madrid and Barcelona. The whole metropolitan area includes 1.5 million people. According to the first Dobris Assessment report (European Environment Agency [EEA], 1995), the *Valencian Huerta* is recognized as a very singular landscape in the Mediterranean region. This historical vegetable market garden, which surrounds the city, is crucial in terms of the urban transition singularities of Valencia (Figure 1 and Figure 2). The Huerta is also a cultural landscape of interaction between humans and nature throughout the centuries. The Historical Waterscape of the Huerta of Valencia is said to be one of the Globally Important Agricultural Heritage Systems (GIAHS) by The Food and Agriculture Organization of the United Nations (FAO) in 2019¹. It has a medieval design irrigation system and it connects the three water ecosystems of the metropolitan area of Valencia: the Turia River, the Albufera Lake Natural Park and the Mediterranean Sea (Melo, 2018). However, this landscape has not been a government priority since the river flood of Valencia in 1957. After this catastrophe, urban planning was focused on urban and infrastructure development in place of the Huerta (Miralles, 2018). Furthermore, this landscape has been pressurized by recent expansions of the city. Artificial surface of the Metropolitan Area of Valencia increased by 8000 ha during the period 1984-2011 (Fernandez and Lopez, 2015). The urban sprawl was accelerated by the Spanish property boom from 1998-2008 and its consequences motivated new social movements to protect the Huerta (Palau-Salvador *et al.* 2019). In 2000, a *popular legislative initiative* collected 118,000 signatures in favour of a law and a specific spatial plan to protect the Huerta. Both were not finally approved until 2018 (Miralles, 2018). Throughout all these years until the Territorial Action Plan of Huerta de Valencia (PAT HUERTA) was approved in 2018, disruptive initiatives to protect the Huerta have emerged; and the city presents a balanced leadership among public institutions, stakeholders, civil society and private sector initiatives (Palau-Salvador *et al.* 2019).

The purpose of this paper is to inquire into the potentialities of Wolfram's urban transformative capacity conceptual framework (Wolfram, 2016) for the analysis of the transition processes with regard to the city of Valencia in Spain. Urban planning policy field is recognized as having a key role in developing transformative capacities (Wolfram *et al.* 2019). For first time, we discuss the current transformative capacity of Valencia through the articulation of the different components of Wolfram's conceptual framework in relation to the Huerta spatial plan processes. The aim is to reflect on the methodological implications of applying the conceptual framework as an analytical tool and to develop an exploratory assessment to identify strategic implications for spatial planning and policy-making. In particular, the role of spatial planning, institutions and territorial actors has been examined in relation to its capacity to translate and incorporate innovative practices to accelerate urban sustainability transitions.

The next section describes the theoretical framework of this research and lays out Wolfram's conceptual framework. Subsequently, the methodology is described for data collection, assessment and interpretation. After that, the findings of this research are shown and discussed. Finally, highlights and main conclusions about key implications for research and policy are presented.

Theoretical framework

Sociological and institutional theory definitions emphasize transitions as radical transformations, their structural character, multiple causality and co-evolution and a shift in the dominant rules of the game. For Grin *et al.* (2010:1) transitions are a "radical transformation towards a sustainable society as a response to a number of persistent problems confronting contemporary modern societies". Rotmans *et al.* (2001:16) defined transition as "a set of connected changes which reinforce each other but take place in several different areas such as technology, the economy, institutions, behaviour, culture, ecology and belief systems. A transition can be seen as a spiral that reinforces itself; there is multiple causality and co-evolution caused by independent developments".

Transition and transformation have often been used with similar meanings because both words refer to radical and large-scale changes in complex societal systems but they have a differentiated focus and not exactly the same implications (Hölscher *et al.* 2018). In the field of urban studies, while transformation embraces both the process and the outcome of systemic change, transition would only refer to the former. In consequence, 'urban transformation' seems to be more adequate to achieve sustainable development as a normative goal and an open-ended process (Wolfram *et al.* 2016). In fact, sustainable urban transformation has been used to emphasize the structural level of transformation processes involving radical and multi-dimensional change to reorient urban development towards sustainability (McCormick *et al.* 2013). That way, sustainable urban transformation would encompass "both sustainable urban structures and environments and (radical) economic, social, cultural, organizational, governmental and physical change processes" (Ernst *et al.* 2016:2988).

At a theoretical level, different transition schools have different approaches to address this issue (Frantzeskaki *et al.* 2018): (1) Technical innovation systems focused on the emergence of new technologies and the related institutional and organizational changes. (2) Strategic niche management approaches focus on niche creation, proliferation and replication to enable transitions through strategies such as shielding, nurturing, empowering... (Hoogma *et al.* 2002). (3) A socio-technical

systems approach to explain technological transitions as the result of dynamics at three levels (niche, regime, landscape) (Rip and Kemp, 1998, Geels 2002, Geels and Schot, 2007). (4) Transition management approaches are based on governance framework to influence transitions in a more sustainable direction. Including an overall process approach and methodologies to setting the scene, envisioning, backcasting, building arenas... (Rotmans *et al.* 2001, Loorbach, 2007, Wittmayer *et al.* 2018).

On the one hand a multi-level perspective from the socio-technical systems approach (landscape, regime and niches), emphasizes the tension between emerging niches and stabilized regimes as the specific dynamic with the potential to bring about sustainable change (Geels, 2004 and 2011). From this perspective, a transition implies fundamental change of a regime's culture, structure, and practices (Loorbach, 2007) as a consequence of the tensions between the functioning of the regime and the landscape, the stress of internal mismatches in the functioning of the regime and the pressure of alternative innovative options (Frantzeskaki and De Haan, 2009). On the other hand, a multi-actor perspective (agency, networks and governance) gives importance to governance and the role of actors in sustainable urban transitions which have been receiving growing attention while recognizing its importance in influencing systemic change processes (Frantzeskaki *et al.* 2018). Following Grin *et al.* (2010), societies are made of interconnected networks of actors that interact in many ways, at different levels and within diverse social realms. In that way, Fischer and Newig (2016) explore the role of actors in transitions to sustainability and identify different ways to categorize them: as niche, regime or landscape incumbent actors, as belonging to different societal realms or governance levels; or as being intermediaries. While trying to classify them as supporting or opposing urban transition, they find that in fact “actor roles in transitions are erratic, since their roles can change over the course of time, and that actors can belong to different categories” (Fischer and Newig, 2016:1).

Despite all of this, a claim for the lack of attention to agency, power and politics has been made as subjects of contestation, conflict, power and vested interests have often been overlooked (Frantzeskaki *et al.* 2018). On one side, Gillard *et al.* (2016) claim that in order to be transformative, transition approaches have to incorporate social theories where power, politics and social relations are central to account for the institutionalized values, worldviews and discourses that are involved in social change. On the other, Avelino *et al.* (2016) develop a multi-actor perspective to understand politics in transformative change and who is involved in the decision-making process. They conceptualize the shifting power relations amongst actors with an emphasis on the empowering and disempowering processes. Recognizing the important role of governance, power and agency implies the assumption that the urban transformation processes are shaped and modulated precisely by the interactions amongst actors within the framework of societal structures. In this way, understanding actor's worldviews and strategies to influence sustainability transition and assessing who are the different actors exercising power and what are the shifting power relations amongst them becomes a crucial question.

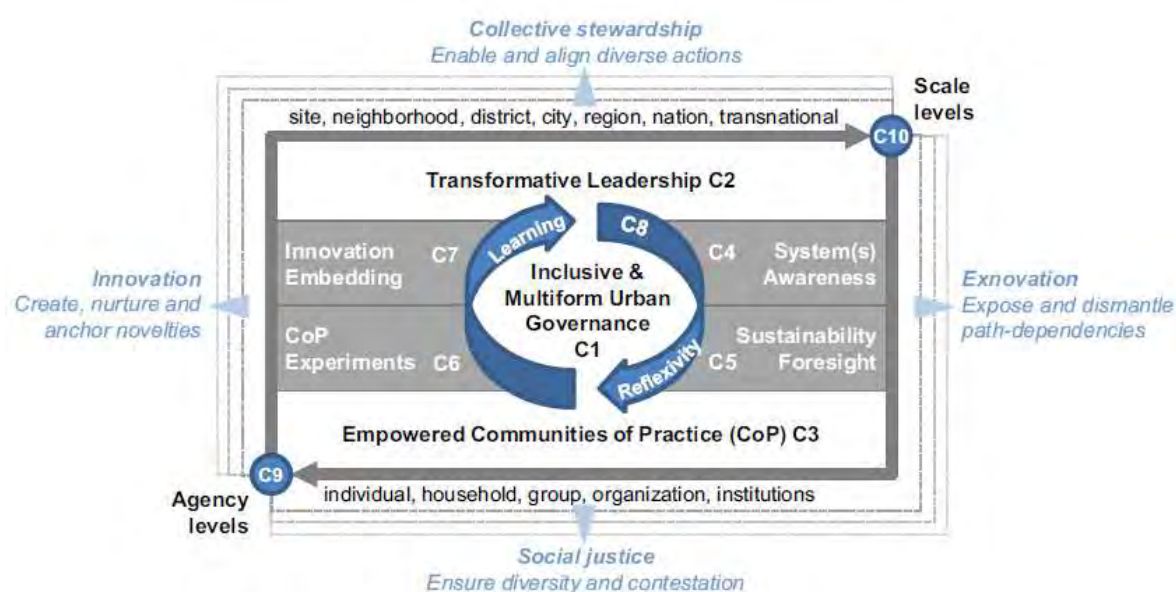

Considering all these perspectives, urban sustainability transitions are empirically and conceptually distinct from sector-specific transitions. Previous contributions on sustainability transitions have largely taken a domain-oriented approach (energy, water, food, etc.). Urban sustainability transitions involve the alignment of resources and actor constellations across domains within a given geographical setting. Therefore cities are the places and scales where the multiplicity of different dimensions concerning sustainability transitions come together, including the role of civil society

(Frantzeskaki *et al.* 2017). After that, urban planning and transition management complementarities have been highlighted (Wolfram *et al.* 2019). Furthermore, the urban planning policy field is recognized as having a key role in developing transformative capacities. In fact, Wolfram *et al.* (2019) suggest challenging and reinventing urban planning as a key arena for developing urban transformative capacities in relation to its potential cross-sector, multi-scale, multi-actor, place-based and comprehensive approach.

By inquiring into urban sustainability transition through spatial planning, this paper draws on Wolfram's holistic conception of urban transformative capacity "as the collective ability of the stakeholders involved in urban development to conceive of, prepare for, initiate and perform path-deviant change towards sustainability within and across multiple complex systems that constitute the cities they relate to" (Wolfram, 2016: 126).

As shown in Figure 3, the framework is composed of 10 interdependent components. The first three are related to agency-core analysis and interrelation forms (C1-C3). C1- 'inclusive and multiform urban governance' assess stakeholder involvement in urban planning, diversity of formal and informal interactions among territorial actors and quality of intermediaries. C2- 'transformative leadership' asks who are the individual or collective leaders in the public, civil society or private sector. And C3- 'empowered communities of practice' identifies the autonomy of the communities to achieve their needs. Five components (C4-C7) are linked to critical capacity development processes. C4- 'system awareness' checks systems analyse and path-dependencies understandings. C5- 'sustainability foresight' gives importance to participatory visioning and alternative scenario designs. Component C6- 'practical experimentation of communities' evaluates new innovative solutions. C7- 'innovation embedding' identifies access to resources and regulation flexibility for innovation. According to Wolfram (2016), C8- 'reflexivity and social learning' is a vital component required to feed outcomes of all four processes through monitoring system change and collective reflexivity. The last components show up capacity development needs occurring at different C9- 'agency levels' and C10- 'scale levels' as relational dimensions needed for change (Wolfram, 2016).

Figure 3: Components of urban transformative capacity. Source: Wolfram *et al.*, 2019: 439.

Methodology

Research methodology is based on qualitative methods including semi-structured interviews and analysis of research papers, spatial planning documents and regulation. This preliminary piece of work follows successful applications of Wolfram's conceptual framework in sectoral-oriented research. It mainly takes references from urban regeneration (Wolfram, 2018) and energy governance systems (Wolfram, 2019). Primary data was collected through semi-structured interviews with 9 selected stakeholders (Table 1) who were involved in current spatial planning processes with regard to the PAT HUERTA of Valencia approval in December 2018. Complementary primary data was also gathered through local events and meeting attendance (3 in total). In order to receive first impressions of the spatial planning process, the interviews were realized between January 2019 and May 2019 through a systematic coverage and balanced representation of critical stakeholders: government agencies (regional and local), civil society and Non-governmental organizations (NGO), academia and intermediaries.

Table 1: List of stakeholders selected for personal interviews

ID	Affiliation	Stakeholder group
V1	Director. Spatial Planning Division (<i>Generalitat Valenciana</i>)	Regional government
V2	Secretary. Spatial Planning Division (<i>Generalitat Valenciana</i>)	Regional government
V3	Planning Service (Valencia-Municipality)	Local government
V4	Per l'Horta	NGO
V5	CERAI	NGO
V6	Cercle (Coop.)	Intermediary (private)
V7	The Water Tribunal of Valencia (since 960)	Intermediary (public)
V8	Urbanism department (<i>Universitat Politècnica de València</i>)	Academia
V9	Geography department (University of Valencia)	Academia

In each case the interviews were recorded and one-hour long. The questionnaire was composed by the 10 components of the urban transformative capacity framework which were already subdivided in 18 subcomponents by Wolfram (2018 and 2019):

- C1.1 actor diversity
- C1.2 inclusion support
- C1.3 intermediaries
- C2 transformative leadership
- C3.1 social needs focus
- C3.2 community empowerment
- C4.1 system analysis
- C4.2 path-dependency
- C5.1 knowledge production
- C5.2 sustainability vision
- C5.3 alternative scenarios
- C6 disruptive experimentations
- C7.1 resource availability
- C7.2 organization adjustment
- C7.3 reflexive regulation
- C8 social learning and reflexivity
- C9 working across agency levels
- C10 working across scales/tiers

In addition, interviewees were also asked to assess the 18 sub-components of the framework on a 5-level Likert scale. The interviewees' assessment scores were aggregated by subcomponents in order to display the stakeholder's overall vision.

Secondary data from spatial planning documents, research papers and the media were analysed to contextualize information from the interviews. All collected data allowed our research team to judge the 18 subcomponents and factors within a researchers' Likert-scale. Since these individual stakeholder assessments drew exclusively on their perceptions of reality, whereas the researchers' assessments show overall insight. This differential assessment between stakeholders and researchers was also useful to enrich discussion and conclusions.

Urban transformative capacities through spatial planning in Valencia

At the beginning of the 21st Century, all the research papers and media showed Valencian spatial planning as an inconsistent policy field. This tradition of comprehensive planning absence has been further developed in previous investigations (Segura-Calero, 2017). In this way, Valencian territorial developments were led by urbanization like a 'tsunami', especially in coastal areas where the residential impact of mass tourism reached its height. In particular, in the city of Valencia urban sprawl was also accelerated by the Spanish property boom, increasing soil selling on the outskirts of the city and the Huerta (Fenandez and Lopez, 2015), which also augmented not only environmental but also administration costs in the Metropolitan Area (Gielen, 2015). The lack of urban planning at metropolitan scale (45 municipalities) seems to have been persistent until the Huerta Law and the PAT HUERTA were approved in 2018. There was a 50 year-long local community claiming process to protect the Huerta of Valencia until the *popular legislative initiative* was proposed in 2000, which collected 118,000 signatures (Miralles, 2018). Now we can recognize a current political change and new community potentials towards sustainability transformation through challenging and reorienting spatial planning in Valencia.

On the word of stakeholders (from V1 to V9), the PAT HUERTA urban planning participation processes were the most resourceful, diverse, extended and inclusive that they have attended. The PAT HUERTA participation tasks were started in 2006 as a serious administrative effort to achieve knowledge through formal processes but also informal meetings (V1, V4, V5). It was recognized especially relevant in terms of diverse governance and network forms (V9). In spite of the obsolescence top-down governance system and stakeholders' interest (V3, V6, V8), those new participation experiences have been considered as having a great success. Nevertheless, there still remains a lack of confidence and cohesion among territorial actors (V6, V7).

The roles of intermediaries are always crucial in relation to governance and stakeholders' interactions in spatial planning. But usually those intermediation tasks are derived to the private sector during spatial plan's elaboration processes in Valencia (V9). Despite this, the *Huerta Council* was recognized by the PAT HUERTA and the Huerta Law, which is under constitution at the moment (V1, V2, V6). It was set up as an official intermediary and management entity that represents all the Huerta stakeholders. The expectations are great but there is only another one-year-old metropolitan entity as reference: the Transport Metropolitan Authority, which coordinates mobility issues among Valencia metropolitan actors (V1).

On the one hand a new political will was particularly essential to achieve the PAT HUERTA approval. Also this leadership was articulated by singular regional administration planners who introduced and articulated the *green infrastructure* concept and open strategic spatial planning processes in Valencia (V1, V2, V9). Furthermore, the municipality of Valencia and the mayor played an important role in favour of Huerta protection (V2, V3). On the other hand, social movement leaderships strengthened community visions towards sustainability and fed them into the local and regional arenas (V2, V4, V9). For example, there are emergent disruptive communities to protect the Huerta and its own way of life. *Per L'Horta*, who are the heirs of the *popular legislative initiative*, or *Salvem movements* are involved in every metropolitan territorial conflict of Valencia (V2, V4, V5, V9). Non-governmental environmental organizations at national level were not so relevant in these local matters (V4). Nevertheless, agro-food collectives such as CERAI in favour of Food sovereignty are emerging as communities of practice (V2, V4, V5). Farmers' associations such as *La Unió de L'auradors i Ramaders*, also contributed to spatial planning processes as stakeholders in the Huerta of Valencia. The academics' role was also relevant in terms of co-production of knowledge and highlighting the Huerta through research. The *Cátedra Tierra Ciudadana* is one important institution from the *Universitat Politècnica de València*, where the Historical Waterscape of the Huerta-GIAHS proposal emerged. It is a space for research, critical reflection, exchange, training and dissemination around the agronomic and social sciences (V9). However, there is a general lack of critical resources and broad mass of people to achieve all those communities' aims (V6, V8).

As indicated by all stakeholders there is not shared vision but a partial one which provides orientation. Also they recognize that alternative scenarios and future pathways are not correctly developed in the PAT Huerta (V1, V2, V4, V8). Furthermore, there are not clear and shared baselines indicating the way to go in terms of sustainability. In absence of administration systematic awareness, there is an important know-how in managing conflicts (V1, V2). The main conflicts in the Huerta have been related to property rights and the dilemma *production vs. protection*. Meanwhile, there are informal dedicated analyses of governance structures and systemic relations in the Huerta by different collectives. In this way, the co-production of knowledge reaches its height in the Huerta and especially in the diagnosis of the PAT HUERTA (V4, V5, V8, V9). Although unsystematically, stakeholders are able to recognize institutional path-dependencies, barriers and drivers for change. Meanwhile, innovation practices to solve these barriers are possible but the comprehensive character of spatial planning implies complex sectoral regulation and coordination issues. Non-governmental stakeholders consider the regulation flexible but institutional administrative structures are still slow to support innovative practices towards sustainability.

In general, there are an absence of accountability practices and monitoring tasks. According to interviewees, a new sensation of institutional transparency improvement has been noticed within this PAT Huerta elaboration process but it still remains reduced. The Huerta Council would be in charge of those management issues (V1, V2, V6). Throughout all these years, this planning experience has involved formal and informal reflexivity and social learning processes but without systematic and continuous management.

Discussion and conclusions

The urban transformative capacities of Valencia are now further deepened by juxtaposing stakeholder and researcher views on all 18 subcomponents of the framework (Figure 4). The current section discusses and compares the principal findings and identifies emerging lessons.

Figure 4: Differential assessment of urban transformative capacity through spatial planning in Valencia. Author's note: (scale: 1=very weak, 2=weak, 3=average, 4=strong, 5=very strong).

Agency and interaction forms (C1-C3)

As stated by stakeholders, PAT HUERTA participation processes have been inclusive and further developed than ever before but governance system and networks seem still to be in development. We can recognize important underestimations in stakeholders' marks for actor diversity because they don't have an overall picture of governance networks. There are a good number of social collectives sharing and supporting a vision towards sustainability but there still remains a lack of space for them due to the administration conservative development pathways. Furthermore, stakeholders' intermediary scores tend to be much higher than those attributed by the research team. This overestimation reproduces government interviewees' predictions on the Huerta Council which is not constituted yet. In fact, there are no official networking or stakeholder discussion spaces beyond the plan elaboration process for the moment.

In spite of all of these factors, there are diverse and strong leaderships but the old and well-known barrier between urban and rural thinking emerges. Generally there is no cohesion between these actors but both collectives have a clear focus on social needs and sustainability.

Core development processes (C4-C8)

In general, stakeholders' capacity development process scores are overestimated. This reflects the perception of PAT HUERTA processes as a positive and even radical change compared to urban planning of the past. However, the researchers' point of view is quite critical due the lack of administration transformative structures and the insufficient access to resources, which avoids disruptive initiatives and experiments. In turn, flexible regulation to support these innovative initiatives has been detected but there is a sense of excessive bureaucracy by stakeholders. Otherwise, stakeholders and researchers share knowledge production component scores but not for the same reason. While stakeholders have a positive point of view due the bad experiences in the past, researchers' perceive a lack of coordination and systematization. In fact, reflexivity and social learning (C8) is considered in the average score for the same reason. In spite of reflexivity and social learning being complete and extensive during all the spatial plan elaboration process; these spaces to reflect on were not developed systematically but through informal pathways. According to researchers, monitoring tasks should be further implemented to guarantee the feedback quality and future reorientation of urban spatial planning.

Relational dimensions (C9-C10)

According to the differential assessment graph (Figure 4), general researchers' critical point of view towards sustainability has been noticed but not in working with relational dimensions. While working across agency levels and political structures is never easy, urban planning emphasizes and involves these issues by definition. Multi-actor, multi-scale, multiple political levels and cross-domain issues have been considered throughout entire planning processes. However, horizontal and vertical integrations still remains a key weakness. In this way, there is recognized a traditional Spanish spatial planning lack of integration, coordination and cooperation among public administrations at different levels is recognised which suggest that much more effort is needed.

In conclusion, this preliminary piece of work shows insights in applying Wolfram's framework through spatial planning. The overall findings highlight that assessing transformative capacity towards sustainability helps to design approaches for unlearning the urban planning conservative paradigm and pathways. In this way, this research paper is also claiming for a greater shift to enhance envisioning, sustainable foresight, working with alternative scenarios, reflexivity and social learning in planning. Such a shift implies redesigning current structures and processes. Furthermore, community resources, networking, collective visioning and intermediation mechanisms have been considered underdevelopment drivers towards sustainability in Valencia. Finally, this research work offers significant potential to enable reflexivity among stakeholders regarding key transformative capacity strengths and weaknesses.

Acknowledgements

The authors wish to thank all institutions and interviewees for their kind cooperation. This piece of work was founded by the Ministry of Science, Innovation and Universities (Spain) with a *Juan de la Cierva* contract (State Programme for the Promotion of Talent and its Employability in R&D&I).

URBAN RENEWAL MECHANISM IN MINORITY NATIONALITY AREAS OF CHINA IN THE NEW ERA

SHEN CHENG¹, ZHANG XINYI²

¹ *Tongji University, China, 1064974373@qq.com*

² *Tongji University, China, 15221373783@163.com*

Abstract: With the development of society and economy in China, old cities need to transform to adapt to the modernization so that urban renewal is carried out in many cities. But China has something special that many urban areas are inhabited by minority nationalities. How to define the public interest in the process of urban renewal is complicated, the institutional problems are difficult and general theories and practices of urban renewal cannot be applied in such areas so there are few good practice in China now. A complete mechanism for this is essential. This article studies on renewal mechanism in the aspect of protecting public interests in minority nationalities areas. Firstly, a social research on different interest groups of minority areas in Changji is carried out to figure out what they are concerned about in urban renewal process; then a study on current cases of urban renewal in the existing minority areas is done to probe into the results and problems and combine with some theoretical analysis a complete summary can be made ; finally according to all the results mentioned above specific mechanism , implementation strategies and policies for the urban renewal process in these areas can be summarized.

Keywords: Minority Nationality Areas, Urban Renewal, Regional Transition, Mechanism

1.Introduction

China is a multi-ethnic country. The large-scale of mixed living and small-scale of centralized residence is a major feature of minority nationalities in China. The renewal of regions and cities with rich ethnic elements, faced with difficulties in the wave of urban renewal, has gradually become a factor that cannot be ignored. Compared with the development of ordinary cities , scholars in China have gradually realized that these cities need some special renewal models to move toward a better future.

Minority nationalities areas are defined as contact areas functioning as a whole in minority city & region. Having become an important part of these city & region after thousands of years of evolution, they inherit the indispensable urban cultural context. For the minorities living here, this is not only the physical space that carries their daily work and life, but also the destination of their inner heart. Their self-esteem and security should be preserved in the mainstream of Han culture in these areas. .

As these city & region change with modern theories and forms, minority nationalities areas have no choice but to be adjusted accordingly at recent atmosphere. Moreover, the current wave of urban renewal has begun to sweep across a large number of minority regions in China, especially in the western part of the motherland. The way of renewal is still a traditional frame, which is undoubtedly a disaster for them. We need a new mechanism

to guide the urban renewal of such cities, and we must not let their features disappear in the wave of urban renewal. This article are based on this background and work for it and is formulated by the following framework shown in Figure 1:

Fig. 1. Research framework

2. Social research for the different interest groups in minority nationality areas

Since there are at least five interest groups (government, estate developer, citizen, minority nationalities and religious organization) in minority nationality areas, what they want and what they think is most important in the urban renewal process are something essential to this study. We carried out some questionnaires of them and make a summary:

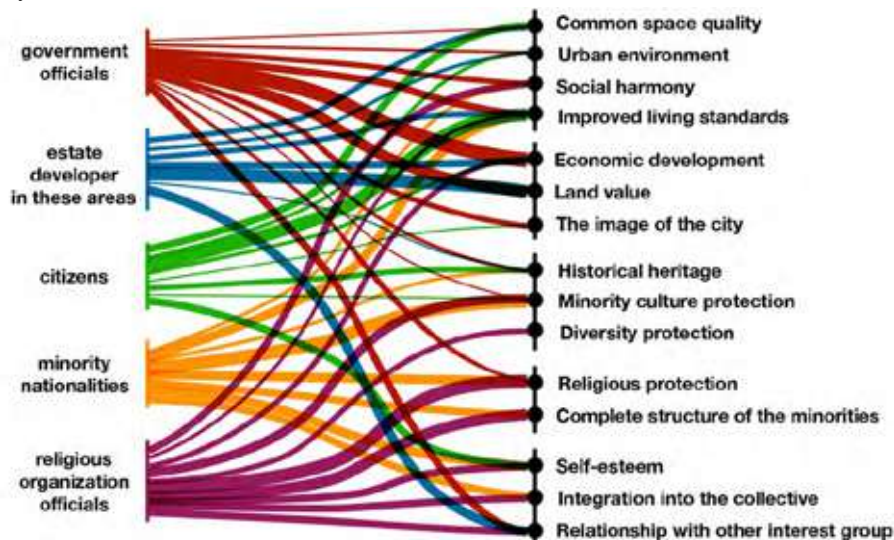

Fig. 2. Social research result

As is seen in Figure 2, what they are concerned mainly focus on five aspect: living condition and social environment, city economy and development, history and culture, religious and minorities, relationships and self-condition. For instance, government officials mainly focus on improving living standard, economic development and making full use of land value; minority nationalities concentrate on protecting historical heritage, minority culture, religious elements and complete structure of their community; religious organization officials think that relationship with other interest group is important, and they focus on religious protection and minority structure protection, and both minority nationalities and their organization officials consider self-esteem a priority and they want to integrate into the collective. These results are references for what we lack in current renewal process of minority nationality areas and can be a support for the withdrawal of the mechanism.

3. Study on current cases

Since there already have been many minority nationality areas in China on which modern urban renewal processes are carried out, this part will analysis some typical examples and point out their implementation effects and problems. These (mostly end up with failures) will provide reminders for our next actions and are beneficial to the withdrawal of the mechanism.

Case name: Beijing Niujie

Strategies: Niujie is one of the earliest ethnic minority areas to start urban renewal. The update mainly adopts a development mode that favors high intensity, and only retains the mosque (also just the formal demand), but completely replaces the original spatial structure with the modern update method of the minority cultural shell.

The program is centered on the Niujie Mosque and builds a gradually increasing building around the radio. The planned height at the north end is 60 to 65 meters. The large public buildings on the east and west sides of Linniu Street are 50 to 55 meters, and the south is 50. Meter. A commercial street with ethnic characteristics was built: a commercial street with ethnic characteristics was formed on both sides of the street.

(Fig. 3 : Comparison chart before and after the update of Beijing Niujie, source: Yang He. *Jamaat: Sub-social research in the city* [D]. Tsinghua University, 2004.)

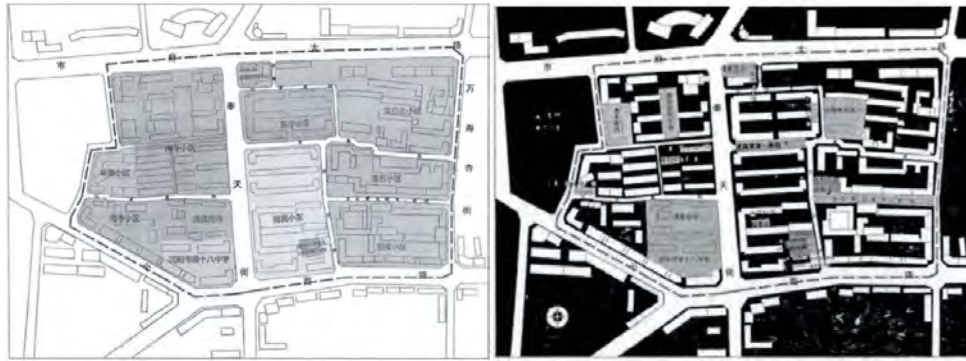

Implementation effects & problems: This update has many obstacles in actual operation: there are 45 multi-storey buildings in the core area of Xinniu Street. The original bungalows will be demolished. Among the 42 towers, 18 commercial houses and 24 relocated residential buildings, this development has caused population density. The sharp increase and the proportion of the Hui population have fallen sharply, and the demographic structure has changed dramatically.

At the same time, the policy of housing reform lacked continuity. The amount of mortgages returned was high, and many residents were unable to move back. At the same time, the traditional living structure and social structure were broken, and the original Hui residents were artificially dispersed. The multi-ethnic mixed population increased and became weaker. The function of the temple system, the number of ethnic issues increased

Case name: Shenyang huihui campus

Strategies: This update is biased towards high-intensity development, trying to adapt ethnic minorities to our modern lifestyle, the so-called modern Islamic ethnic style, and building an Islamic style city that integrates cultural education, business office, business and business, sightseeing and tourism;

According to the overall goal of the plan, the transformation of the area will highlight the characteristics of Islamic architectural style in the appearance of the building, showing the rich Islamic national characteristics and the characteristics of the times.

(Fig. 4 : Land-use and texture, source: Li He. *Research on the renewal planning of urban minority traditional settlements* [D]. Northeastern University, 2011)

Implementation effects & problems: The update evaded many issues, such as the wishes of ethnic minorities, how traditional buildings and neighborhoods are handled, how development is carried out, and how local residents are placed. Muslims have the habit of living in a concentrated way, and they have a living need to live around the temple. Therefore, the Muslim people are reluctant to stay away from the temple and the problem of relocation is very high; Because the living habits of the Muslim people require the simultaneous construction of the custom of the Muslim people and the special design of the house, these increase the speciality of development and construction, investment costs, etc.

Case name: Beijing Jintaili

Strategies: This program is a medium-to-high-intensity update mode that is slightly biased towards development. The Jintaili ethnic community is located on the side of the political center of Beijing. After the implementation of the demolition and relocation policy, some surrounding communities are retained as historical heritage, and the other part is included in the process of urban renewal. The Jintaili ethnic community has experienced the process of urban renewal without exception, from the layout of the Hutong complex to the depth of space compression.

Implementation effects & problems: While not considering the opinions of local residents, due to the special geographical location of the Jintaili community, the Jintaili community cannot build a variety of social public facilities. Residents in the Jintai area must re-adapt to the modern lifestyle. The diversified development of the city has caused residents to lose their sense of belonging and direction. The medium and high intensity development model completely lost the historical and cultural significance of the colony.

Case name: Yunnan Chuxiong

Strategies: This update is actually a low-intensity development. Mainly through the implantation of industries in the inhabited areas, the development of culture, tourism and commercial, etc., while supporting the development of special breeding, ethnic handicrafts and ethnic tourism in minority areas. In this way, we try to promote the development of surrounding plots and increase fiscal revenue to facilitate the subsequent update process.

Implementation effects & problems: From the perspective of the overall level of economic development of the whole city, the development of tourism industry is slightly insufficient compared with real estate business. The proportion of tourism revenue to the GDP of the city is still at a low level, and its contribution to the urban economy is still insufficient.

Case name: Lanzhou Xiyuan

Strategies: This update is essentially a large-scale, medium-strength development that is similar to Niujie but has lower strength. The purpose is to maintain the core position of the mosque, give priority to the accessibility of

the mosque, design the road network structure with the mosque as the core of transportation, appropriately widen the main roads and branches within the area, and form a complete homogeneous road network.

More attention is paid to the shaping of diverse communication spaces. The mosque square makes the most important communication space inside; the living square should also be appropriately added in the settlement area; consider the traffic connection between these open spaces. Reasonably controlling the height of the building around the mosque effectively highlights the dominant position of the mosque in the skyline.

(Fig. 5 : Urban Renewal Program of Xiyuan Hui Community in Lanzhou, Wang Zhiyuan. *Research on Space Renewal of Lanzhou Xiyuan Hui Community in Urban Design Dimension [D]*. 2016)

Implementation effects & problems: It is more like the destruction of a protective coat. Only the mosque is considered. The surrounding development is only based on the premise of highlighting the status of the mosque. It essentially destroys the population structure and life mode of the ethnic minority areas. Nor did it follow the opinions of the local residents. It is likely that only a mosque shell was preserved in the end, and other national cultures no longer existed.

Case name: *Shenyang Xita*

Strategies: This update is primarily a low-development model for micro-implantation. It mainly includes the transformation of the two functions of business and residence: the commercial side is to solve the imbalance of time and space in the format through the participation of Hunchun Walking Commercial Street.

At the spatial level, there are three main levels: the spatial structure of the block, including the control of the "axis", the control of the "nuclear" and the control of the "slice". The axis is the two commercial landscape axis streets, and the core is the control of several spatial nodes. The area is the seven communities in the Xita area; the spatial texture of the continuation block should be repaired as much as possible in accordance with the original texture of the historical block.

(Fig. 6 : Urban renewal texture map of Xita, Zhao Bao. Urban renewal research in Xita area of Shenyang [D]. Shenyang Jianzhu University, 2012.)

Implementation effects & problems: Too idealistic, although the interventional approach of the two pedestrian streets seems to protect the history of the region, in fact, this form of intervention has closed the neighborhood, actually running through the interior but not making it truly open and The surrounding area is integrated. Moreover, the full text is judged from the top down, and the opinions of the aborigines are not investigated. An economically inefficient development model cannot allow the economy to revitalize.

Case name: Huhehaote

Strategies: Adopting a traditional medium-strength development model that is slightly biased to the reserved part, the area is divided into five areas, namely, the key style protection area with the halal temple as the core, the traditional style residential area, the Niujie Huimin modern residential area, the Huimin area and the municipal level. Commercial area. The traditional festivals of the Hui people are combined with the business, and the tourism industry is driven by the tourism industry. The update model combines a “top-down” planning control with a “bottom-up” small-scale update. Both protection and development, including the protection of the space texture with the mosque as the core and the protection of the traditional residence style of the Hui people, also include the protection of the non-physical environment such as the social structure and lifestyle of the Hui people's settlement.

Implementation effects & problems: This plan is a relatively rational and feasible solution. It is necessary to test whether the retained residential and traditional areas can be well integrated with the municipal commercial facilities. Whether modern residential areas and traditional residential areas will occur will occur. Differences in residents' psychology, etc.

Case name: Guangxi Gongcheng

Strategies: It mainly adopts low-intensity protection development and provides certain financial support for the self-renewal of the ancient town through the development of tourism, culture and commerce. At the same time, the original government single protection subject is transformed into a multi-subject with the participation of the government, developers and local residents. Construct a cultural display system, maintain the integrity of the old city pattern, and connect a new and old twin city through traffic and green corridors to build a new and old characteristic city. Reasonable organization of the surrounding traffic flow, setting up appropriate parking lots in each import and export, rationally arranging surrounding bus lines and temporary parking stops for taxis; restricting transit traffic crossing in historical blocks.

Implementation effects & problems: Because of the lack of funds, and the illusion of simply making money through tourism and cultural propaganda to fill the city's renewal of funds, in fact, low-quality tourism cannot lead to the accumulation of funds, the interior of the old city is basically no vitality.

4. Overview of case study and summary of the problems

Table 1. The mode and feature summary of case study

Mode	Content	Advantages	Disadvantages	Cases
Low-intensity protection development	Through industry-driven, market-oriented, policy support, etc., through tourism planning, implanting industry, cultural propaganda and less space interventions as intervention methods	Completely retaining the life style and social structure of core buildings, traditional streets and ethnic minorities, and having certain significance for areas that wish to be completely preserved as historical and cultural heritage.	The spatial pattern of decline is likely to be difficult to adapt to modern needs. It is difficult to truly develop these industries, and the financial benefits are very low. At the same time, ethnic minorities are not truly integrated into the process of urban development.	Guangxi Gongcheng; Yunnan Chuxiong; Xinjiang Kashi
Development mode of medium and low intensity through streets	It is based on the implantation of a pedestrian street and the passage of the transportation system. By creating a minority-style street, the originally closed settlements will be opened up, and the development of the original local block will be promoted.	Relatively small intensity, retaining certain traditional elements, and introducing external flow of people, seems to change the situation of spatial occlusion in most minority areas.	Most of them forced the settlements to open with several large roads, but the relationship between pedestrian streets and neighborhoods was not well demonstrated. The scale of pedestrian streets was rarely the original traditional street scale. At the same time, the surrounding traditional neighborhoods will be gradually eroded.	Shenyang Xita;
Retain core building, medium strength full development model	Retain the core building, complete the medium-strength commercial/residential development, and highlight the status of the core building from the overall space image, and build some small-scale streets and pedestrian streets.	The overall height of the space is not high, it can really highlight the spatial status of the core building. If it is made into a boutique space, it can become a more pleasant business and tourism environment.	In order to emphasize the prominent position of the religious core building in space, it has actually destroyed its central position from all aspects of the residents' hearts and social functions. Conservative development of medium intensity, in the long run, the economic development of the city is also relatively low.	Lanzhou Xiyuan; Beijing Jintaili; Henan Guancheng
Medium and high intensity hybrid development mode	Partition the colony and develop and mix different modes. High-intensity commercial development, modern housing development, traditional building protection mode, tourism development around the core building, etc.	The more mature and effective methods in the current case can make the characteristics of each space come into play. At present, it seems that it can also bear the heavy responsibility of the core area of the city and protect the cultural heritage to a certain extent.	Whether local residents accept this approach and the integration between old and new	Huhehaote
Retain only core buildings, high-intensity full development model	Retain only the core building perimeter for completely modern high-intensity development, residential, commercial, etc.	Fully modern high-intensity development, this kind of comparison can stimulate the economic development of the city, and the value of the land is also fully utilized.	What is caused is more social impact, destroying the structure of ethnic minority groups, causing dissatisfaction among indigenous peoples, etc., so the government should be cautious in this way.	Beijing Niujie; Shenyang "Huihuiying"

For the ethnic minorities, the normal activities of their religious activities, the completeness of the people and the spatial structure of the neighborhoods in their settlements, the respect and protection of their living customs and dependent spaces, the guarantee of their core architectural functions and status are the interests they pursue.

For the public, the original form of settlement will inevitably cause the space to be inward and occluded, the space cannot be enjoyed by the public, and it will become an area that blocks the overall public space structure of the city. At the same time, the general public needs for minority culture and business. There is a certain discrepancy between the business required for the living activities of the ethnic minorities themselves. For the government, the residential and neighborhood forms of the settlements can no longer carry the value of the land, and the settlements are mostly located in the center of the old city, with the city. Development, the importance of these plots is increasing, and the existing forms are difficult to adapt to the needs of urban development.

The specific update means/implementation difficulties, first of all, are mostly top-down judgments, and the decision-makers of ethnic minorities are not included in the development process. Therefore, the voices of a large number of oppositions are often updated. Secondly, only the implementation is considered. The ethnic minorities within the renewal scope basically do not consider the division of labor of their complete social structure system in the whole city, so most of them will lead to the destruction of ethnic minority ecosystems in the city; in addition, the subject of renewal is too single, and there are few multi-subjects. There is no unified agency for the linkage; in the end, the treatment of the core building is too formalistic, and the settlement itself should be a complete ecosystem. It is impossible to achieve a truly effective urban renewal without grasping the characteristics of the areas inhabited by ethnic minorities.

5. Conclusion: Mechanism and support methods of the urban renewal process

Based on all analysis and studies carried out above, a contact mechanism of renewal of minority nationalities areas is put forward:

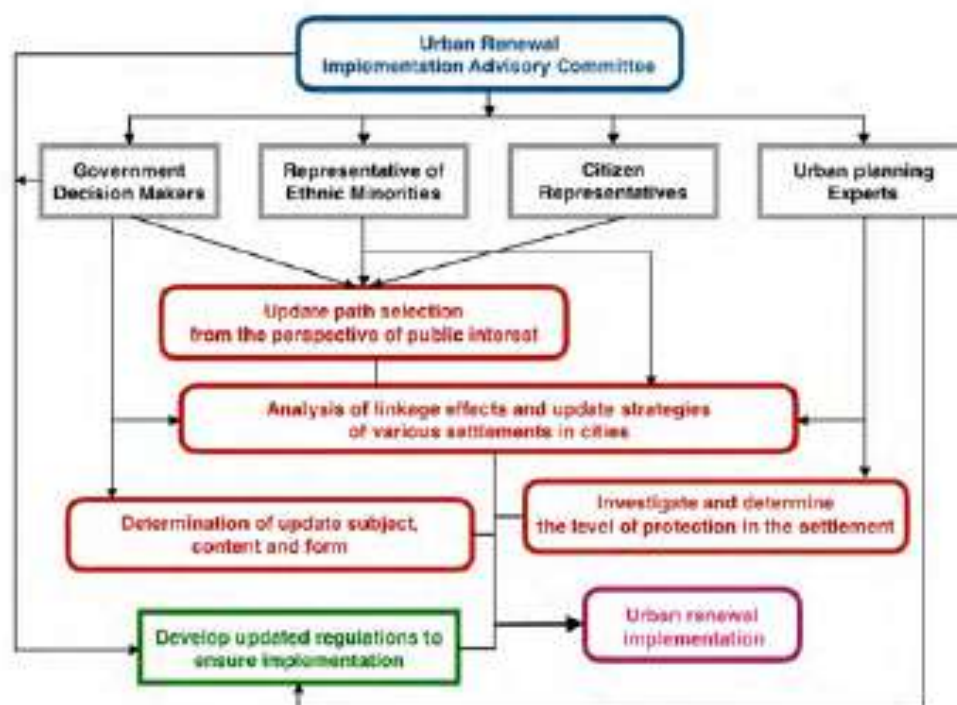

Fig. 7. Urban renewal mechanism of minority nationality areas

Based on all analysis and studies carried out above, a contact mechanism of renewal of minority nationalities areas is put forward:

5.1 The government should first ask professionals to investigate and determine the level of protection in the minority nationalities areas.

Determine the remains of the historical value of the settlement, the existing buildings (especially the core

buildings), the neighborhoods, and the completeness of the living structure of their circles of social (most important). This is to determine whether the block is only preserved as a valuable historical building group, or as a complete/partially complete area with a variety of features to participate in the subsequent urban renewal process, or it is very unlikely that the reservation will be completely renewal.

The existing cases of urban renewal in all ethnic minority areas have not solved this problem well. Regardless of the urban development, the settlements will gradually be eaten away. The settlements themselves often have no foresight and choice.

5.2 Analysis of the renewal path from the perspective of public interest.

This is one of the core contents of urban renewal work in minority areas. It is a more complex definition of public interest that requires us to fully investigate and evaluate. For example, low-intensity tourism development and high-intensity residential development are relatively common practices at present (as cases show), the former is a more balanced approach, want to protect the public interest of ethnic minorities, and want to give due consideration to government revenue, but also try to make them open public space. However, according to the case analysis, only considering the balance the consequences are not often useful. The tourism is inaccessible and has not obtained much financial benefits. The value disappears, and the space quality is not high, it has become a low-end public space; as for the latter, such as Beijing Niujie renovation, is a more extreme practice, only retaining the core building, and other basically developing high-intensity residential areas, which actually is a practice of basically abandoning the public interest of ethnic minorities, but it has formed a public space with relatively high utilization rate, and has fully exerted the value of the land. To some extent, it is a completion of urban renewal.

Comments on cases as Niujie are mixed. However, because there are so many stakeholders involved, it is not necessarily good to try to accommodate the balanced approach of all stakeholders. The specific choice of the renewal path should be carried out under the consideration of multiple interests. In the end, it should be considered that there should be trade-offs and emphasis. It should be affirmative to renew the operation with one party's interests as the main body. So depending on social study, renewal path should be determined in this step.

5.3 Determine the subject, contents and forms of the renewal.

According to the results of the public interest survey, the main body and content of the implementation are often different. In the cases of tourism development, the main part is market intervention, through the implantation of some industries, the transfer/lease of land and building ownership, and appropriate commercial adaptation, which is essentially a low-intensity development biased towards the industry. The model, based on traditional space, the government formulates appropriate policies and guides, is the implementation method of this kind of situation; similar to the high-intensity development model of Niujie, the government recovers the land, develops through the estate developer, and retains some core buildings. Characteristic public activity space, this kind of model is the government-led market operation, a more common and traditional top-down development path; it can also carry out bottom-up development, raise funds or government subsidies, and give appropriate to ethnic minorities. The right to freedom and the distribution of professional guidance, to make their own renovation and industrial upgrading. This advantage can maximize the ecology of ethnic minority areas and make the settlements truly preserved as historical remains. Accordingly, the specific method to be adopted should be comprehensively considered in combination with the survey results of the first and second steps. Then government can start to find the exact organizations to take in charge of each part of the renewal.

5.4. The linkage analysis and renewal strategy determination of the other minority nationalities areas in the same city.

According to the case study, the cities inhabited by ethnic minorities generally have very close associations between the various settlements: the demographic composition has a certain correlation, the core religious buildings generally have a division of responsibilities, and some special activities will be held in various

settlements. There will also be certain kinship.

Once we renew one of the areas, the most important thing is to clearly define the relationship with other settlements: operations such as relocation of people and changes in functions will inevitably have a wide-ranging impact. It involves the resettlement of minority populations after the house demolition and other functions to be relocated, and how to replace if not migrate the initial population. One of the important features of urban renewal in ethnic minority areas is systemic and linkage, which leads to the whole body. Therefore, the renewal of any ethnic minority area is actually a city's overall project, so that the renewal of the entire city can achieve better results.

5.5. Forming the Urban Renewal Advisory Implementation Committee to supervise for this process.

At this stage, urban renewal supervision system involving minority nationality areas is still a traditional one. Taking the urban renewal rules of Shanghai as an example, the land planning management department is responsible for the coordination, supervision and implementation of urban renewal, and other relevant departments cooperate in fulfilling various duties within the scope of duties. But in fact, this set is difficult to implement in minority areas. Within the ethnic minority there are their deliberations and management organizations, as well as the will of the imams as their spiritual leaders.

Urban renewal in ethnic minority areas should set up a special organization, which is composed of government policy makers, representatives of ethnic minorities, representatives of ordinary citizens, and professional planning and design personnel. This will not only ensure that the interests and opinions of them are fully heard. It is also possible to let the implementation measures released in the name of being widely accepted. All the contents of the previous period can be submitted to the professional department for planning and design.

In addition to the implementation mechanism, urban renewal in minority areas requires certain policy conditions and other support:

5.6. Guide all types of people in minority nationality cities to establish a view of public interest

Establishing correct public values is the premise of the greatest synergy between urban renewal work in minority areas, and it is the concept guarantee of renewal success. Governments, developers, and residents are the representatives of government power, market power, and social power in the traditional residential neighborhood renewal activities. Their value orientation and corresponding behavior have different effects on the public space inside the block. Therefore, in the renewal of traditional residential quarters, we should first establish correct public values and coordinate the interests and goals of all parties: we should regard "people-oriented" as the basis of public values and ensure social justice. In addition to establishing the correct value orientation, the government must guide developers and residents to form a value orientation that can be coordinated and unified through publicity and education, administrative regulations, and organizational management. In terms of developers, we should strengthen our sense of social responsibility and unify the realization of economic benefits with the creation of social values and the protection of cultural values. Residents should take the initiative to improve their own quality, not only strengthen their ability to protect their legitimate interests, but also actively participate in the movement to protect the city's history and culture and safeguard the public interest.

5.7. Develop appropriate policies and regulations to ensure implementation

In order to bring the renewal and renovation of ethnic minority neighborhoods to the right direction and to prevent improper development behavior, corresponding policies and regulations must be formulated. Developers are profitable. At this time, the government needs to formulate policies to guide them, so that they can coordinate the contradiction between economic interests and historical and cultural protection and social equity. Encourage developers to adopt correct compensation through appropriate compensation and incentive measures. Renewal the development method.

The measures that the government can take include economic compensation, credit support, and the development of floor area rate awards. At the same time, the construction of the legal system should be

hierarchical. In addition to the overall control and national regulations such as the Urban Planning Law and the Real Estate Law, various special regulations and local regulations should be formulated according to specific conditions, such as targeting ethnic minorities. Special regulations and local regulations on religious building protection, residents' demolition and resettlement, and public participation in district renewal.

5.8. Extensively guide the public and engage in public participation

In the renewal, a special competent department should be set up to fully mobilize the enthusiasm of all parties. It is necessary to involve them in community building in various forms, to promote the connection between residents while achieving specific community development goals, and to enhance residents' sense of community pride and belonging. The prominent feature of community development is the emphasis on broad public participation in community affairs and the legal definition of community development programs to benefit low-income people.

6. Summary

The urban renewal of minority nationality areas is difficult, and the reality does not allow us to make mistakes again and let these spaces with historical and cultural values gradually disappear. This paper mainly discusses the contradiction between the urban renewal of ethnic minority areas and the general urban renewal from the contradiction of public interest and the dilemma of implementation through case studies and theoretical analysis, and then proposes a five-step mechanism, from the evaluation of the value of the settlement to the establishment. The implementation committee will carry out the progress of the city to ensure the smooth development of urban renewal in ethnic minority areas. Finally, support measures will be proposed to assist the implementation of urban renewal work.

Grand Paris or Île-de-France? Comparing two institutional models for transitioning to sustainable transport in the Île-de-France region

Rosalie Singerman Ray¹, Magda Maaoui²

¹Columbia University, rsr2150@columbia.edu

²Columbia University, mm4964@columbia.edu

Abstract: Since 2000, the Paris region has seen a substantial transition in transport governance, as the regional transport authority shifted from the control of the state to the region. Additionally, the state created a new entity, the Société du Grand Paris (SGP), to develop a rail network, the Grand Paris Express. This research explores these institutional changes, seeking to understand both how the new institutional forms came about and what these new forms enable and constrain, particularly with respect to creating a more just and sustainable city. This research is a comparative historical case study from the 1990s to the present, looking at two processes of institutional change occurring at different scales within the same place. It uses Kingdon's three-streams model to assess the opportunities and moments for institutional change. The two processes reveal many of the tensions in governance debates, with the more formal regional authority having greater democratic accountability than SGP. Additionally, as SGP began shifting to the construction phase, its public engagement came to resemble that of a more formal and accountable transport provider, as the agency encountered communities that would feel real material changes from its projects.

Keywords: governance; sustainable transport; political windows, institutional analysis

Introduction

In 1996, dual crises of air pollution and public transit strikes forced attention on the growing transport problems in the Île-de-France region and the need to shift away from private vehicle travel (Zittoun, 2013). The Green Party made transport one of their signature issues, and politicians on the left began pushing for more investment in public transport and cycling. These efforts have brought results. Since 1997, the region has built 7 tram lines, extended 4 metro lines, and reallocated over 100km of road space away from cars to buses, bikes, and pedestrians, most notably the pedestrianization of the banks of the Seine. In addition, the city of Paris set up some of the first municipal bike and car share programs and adjusted parking pricing to encourage drivers to leave their cars at home. The policies have demonstrated results, with car traffic on Paris roads falling 46% from 1992 to 2015 and the modal share by car falling 10 percentage points in Paris and 7 percentage points in the suburbs (Heran, 2017; Halpern and Le Galès, 2018). The shift to sustainable mobility has also moved across the political spectrum, as politicians from both the left and the right tout policies to encourage public transport and cycling.

The story of Paris's significant mode shift over the past twenty years coincides with a story of increasing decentralization of power away from the state toward the region and localities. At the start of the 1990s, the national government controlled nearly every piece of transport infrastructure in Île-de-France, whether as the head of the local transit authority, the major shareholder of the two largest transport providers, the owner of the major roads in the departments, and the regulator of traffic with Paris proper. Today, the president of the region heads the transport authority, one of the transport providers has decentralized its offices and embedded officers within departments, the roads are being progressively transferred to departments and municipalities, and the mayor of Paris has just won the right to enforce her own traffic laws.

As the decentralization finalized, however, the state reasserted itself in the transport conversation with the creation of the Société du Grand Paris (SGP), an institution created with the sole purpose of constructing four new metro lines in the Paris suburbs. The lines are financed separately from other

transport infrastructure, and the regional transport authority does not retain oversight. Yet while the creation of SGP was a state project, the suburban ring subway project existed for a long time in the regional consciousness. The political coalition that made the Grand Paris Express possible includes not only the state but also networks of local and regional actors who carried the project over the long term.

Participation played a legitimizing role for both regional control and the SGP. Regional control was premised in part on the idea that as a major funder of transport projects, the region should participate in the decision-making. At the same time, both regional and local governments were making efforts to be more accountable to citizens, a major tenet of Bertrand Delanoë's 2000 campaign. Participation as legitimacy was an even stronger anchor for the SGP, which engaged in a large formal concertation process around the Grand Paris metro system and the idea of Grand Paris itself.

The institutional changes around transport governance reflect a spectrum from hard to soft governance, that is, the formal transfer of power from the state to the region, the creation of the Type II institution of the Société du Grand Paris, and significant background networking and moments of political influence. The benefit of the lens of soft governance is that it shifts the focus from the decision itself to the networks of influence and power that set the premises for the decision and the subsequent implementation (Moos, 2009). If we also take a normative stance of seeking a just transition toward sustainable transport, we can ask to what extent the various institutional forms contributed to such a transition, where justice refers both to attention to the least well-off and to the inclusion of diverse voices in the process.

To explore this question, we conducted a content analysis of official reports, and documents produced by experts. As the Grand Paris Express project is better documented than the smaller sustainable transition projects, we supplemented with interviews with planners involved in the significant smaller transportation projects, particularly the Plan des Déplacements Urbains and its flagship project, the Mobilien bus network.

Political windows: the failure of state-led transport governance and the rise of the region

While Paris has had a regional council since the 1980s, it was historically relatively powerless, both within the region and compared to other regional authorities. In 1994, for example, the regional council ceded input on the joint State-Region infrastructure plan to the technical representatives of the national government (Gonzalez Alvarez, 2006). Similarly, while negotiations with the transport operators were technically done in collaboration with the region, the region held very little power or technical capacity.

As the current transport paradigm came under threat in the early 1990s, the governance mechanisms were equally implicated. In particular, the lack of power for the Paris region not only ran counter to the trend for decentralization, but it also was evident as a culprit in Paris's delay in sustainable transport programs relative to other areas. Nantes and Strasbourg were developing tram networks and reimagining parking policy while the Île-de-France remained stuck in a car-oriented mindset with public transport projects that were both duplicative and overbudget. Public transport priorities were set by competing companies rather than a regional entity.

Public transport in the Île-de-France region is provided by two state-owned companies and a group of smaller operators. RATP, formed in 1949, owns the exclusive right to operate the Métro system and bus network within the Metro system boundaries. Their right expires in 2024. SNCF, the French national rail provider, operates a regional commuter rail network (known as Transilien) and shares operation of the regional express rail (RER) network with RATP. Bus service outside of the boundaries of the RATP monopoly but inside the region is provided by a number of smaller service providers, organized as Optile.

Responsibility for transit network planning was held by the Syndicat des Transport Parisien (STP) until 2001, when it became the Syndicat des Transport Île-de-France (now known as Île-de-France Mobilités). STP was controlled by the national government, which held the majority of seats on the

board. Major funding was provided by the state and by the *Versement Transport*, a payroll tax levied on businesses with more than 11 employees.

As resistance grew to auto-oriented development, the existing structure was inadequate. In particular, regulation of soft modes and of the roadscape that could be allocated away from cars to buses, bikes, and pedestrians, occurred at the municipal level, but such modes crossed municipal boundaries. In addition, the large infrastructure projects that RATP and SNCF wanted went over budget and did not address the new shape of the city, in which the center of Paris was being depopulated in favor of growth of jobs and population in the suburbs. Instead of suburb-to-suburb travel, both companies focused their attention in the 1990s on projects to relieve congestion on the main East-West connections through Paris, RER A and Metro line 1. The projects, the construction of the RER E by SNCF and of Line 14 by RATP, absorbed the bulk of the financing in the state-region infrastructure contract.

As an alternative, the near suburbs, which fell within the RATP boundaries, were demanding more capacity for suburb to suburb trips, as well as Metro expansions. The department of Seine-Saint-Denis worked with RATP to bring trams, which had proved successful as an agent of urban regeneration as well as transport, to the Paris region, opening T1 in 1992. The department of Hauts-de-Seine followed with T2 in 1998. Within Paris, Mayor Tiberi began exploring a tramway on the Parisian side of the Boulevard Périphérique, and installing bus lanes on the Petite Ceinture, the busiest bus line in Paris. Part of the focus on surface transportation was due to a desire to directly take road space from cars, but it also represented a financial reality, as the twin tunneling projects in Central Paris did not leave space for a suburb-suburb metro. Thus, in places where an elected body could begin to wrangle local communities and elected officials into road space reallocations and new forms of transport investment, it was happening, but that kind of control was not available at the regional level.

The rise of the region and the shift to sustainable transportation entered through the same political window. The idea of the political window comes from John Kingdon (1995), who posited that policy change comes from three streams, one of problems, one of policy solutions, and one of politics. Political windows open when problems rise to the top of the agenda in moments of political opportunity when solutions are available. The political opportunity for both was the relative failure of governance in transport, combined with the end of long-standing conservative rule in the Île-de-France region on the backs of a corruption scandal. In 1998, Jean-Paul Huchon from the Socialist Party was elected head of the region, marking a significant political shift. He lobbied for the region to have increased powers within the STP. The idea of the region playing a significant role in governance had been in the solutions stream since the 1982 decentralization law which put all the regions except Paris in charge of their own transport. Commissions in 1992 and 1994 had explored how to shift both decision-making power and financing to the region, but the political window was not open until the end of the 1990s when the region was ready for significant change (Larroque et. al., 2002).

The Green party took the same opening to push for sustainable transport policies. While the Socialist party won the regional elections outright in 1998, Mayor Delanoë had to enter into coalition with the Greens and Ecologists in Paris. He gave them the transport portfolio under the direction of Green Party member Denis Baupin. Delanoë permitted them free rein as long as there was significant public engagement. For the Mobilien bus priority project, staff from the city and the RATP held public meetings in each arrondissement, in addition to hosting an extra-municipal committee on transport. However, the participation, particularly the arrondissement meetings, were not effective participation, as the implementation decisions were largely based on politics and technical factors rather than engagement. The city director of the Mobilien project recalls sitting in public meetings with Baupin and not even being allowed to respond to angry residents. Baupin told him not to bother, as the project would be implemented anyway (personal interview, 2019).

Alongside the regional efforts, Delanoë began working with the inner suburbs on a project called Paris Metropole. While this collaborative project spanned beyond transport, it paralleled efforts by the city of Paris to create a surface transportation operating authority that would control roads, parking, and surface transport. The city pushed for such a secondary operating authority during the regional takeover process. Though the authority has not yet been created, close cooperation with the

neighboring communes remains a priority for the city and was a central goal of the 2018 bus network restructuring (personal interview, 2019).

Political windows: the genesis of Société du Grand Paris

Just as the regional takeover of the transport system was underway in 2004, engineers at RATP returned the idea of a suburban ring metro to the public discourse, under the name of Métrophérique (Auzannet, 2018). This was at least in part a play for the organization's own survival, as EU regulations were likely to open up its networks to competition at the end of the monopoly period in 2024-2030. At the same time, it was also a sound strategic move, as the suburb-to-suburb metro had been in the solutions stream since a report by the Regional Institute for Urban Planning (IAURIF), written for the regional takeover of the infrastructure planning process. Now that the region was in charge, and one which prioritized the needs of the relatively left-leaning inner suburbs, it was a good moment to push for it. However, the region placed the project in the regional plan as one project in many in an attempt to spread the plan across the region. The Arc Express project did not become a signature plan until the national government re-entered the picture.

In June 2007, Nicolas Sarkozy, only recently elected, announced his support for the Métrophérique during the discours de Roissy (Delourme, 2018). It was the first time that the government took a position on the suburb-to-suburb metro. Moreover, Sarkozy launched the Grand Paris initiative, a broader effort to rethink metropolitan Paris and a counter to the left-aligned Metropolitan Conference. Sarkozy turned the Grand Paris project into "a war machine against Jean-Paul Huchon, the socialist president" (Levy, 2010). He therefore appointed Christian Blanc as head of a state-led Grand Paris project to counter the decisions of Huchon. Blanc's approach was inspired from the financing of the Parisian metro more than a century before: very long term loans. Blanc turned the Grand Paris Express into a flagship - platform: technological performance, elaborate design and architecture for the train stations, infrastructure, cultural programming, and amenities delivered in addition to the core transportation network.

Nearly all of the Grand Paris Express planning happened among a limited number of people, and their work "vanished into the cigar smoke of their boss, Christian Blanc" (Levy, 2010). Christian Blanc became the face and the father of the Grand Paris Express, but after the discursive work performed to legitimate regional takeover, new discursive work was needed to legitimate this small, state-led project. Enter the founding discourse of Grand Paris, given by Nicolas Sarkozy in 2009 and the grand concertation, involving international architects and a formal, state-led engagement process.

The formal state led engagement process began September 30, 2010. It was guided by the Commission Nationale du Débat Public (CNDP) (Levy, 2010). The first order of business was deciding whether to present the "Grand Huit" transportation network (proposed by the State) alone or to the "Arc Express" transportation network (proposed by the Région):

- The "Grand Huit" (130km) went beyond the existing metro network and loomed large, offering to cover the grande couronne Ouest (Versailles/Saclay) and Est (Noisy-Champs/Roissy), while crossing through Paris
- The "Arc Express" (60 km) offered two tangential lines in the petite couronne, in the North (Nanterre/Bobigny) and in the South (Meudon/Créteil), with an extension to the grande couronne towards Noisy-le-Grand.

While relations had been poor between Christian Blanc and Huchon, Blanc's successor Maurice Leroy bridged the gap, opening the concertation to both proposals and beginning the negotiation process with the Region Île-de-France during his time as Ministre de la Ville (November 2010- May 2012). The way it differed from the first stage, was that it was clearly inscribed in a search for consensus with a larger pool of decisionmakers at different levels. It was formalized through the creation of the informal Club du Grand Paris which gave a seat at the table to the presidents of the department councils, the prefect of the Region (the national government's representative in the region), international architects, Paris

city hall, and representatives of the transportation sector. As one of the goals was to fix the lack of connectivity for the territories of the eastern *banlieues* of Seine-Saint-Denis: the decision process to create the metro line 15 Est generated a negotiation process with Claude Bartolone, at the time the Socialist president of the Seine-Saint-Denis General Council. This support from socialist Bartolone allowed to ease negotiations with the Region, which also had a socialist majority.

These three stages of technocratic expertise legitimized by formal concertation, regional negotiation, and the work of the departmental councils summarize well how this convergence of interests among the State, the Region, the mayors and the departmental councils paved the way for formal concertation. Métrophérique was a solution with a large latent coalition of actors that had been subsumed by other problems and the lack of an institutional structure to implement it. It had lain so long in the solution stream, however, that once the other two major projects were completed (RER E and Line 14), it was politically powerful to both the newly empowered region and a state entity looking to make a mark. By the end of the negotiation in 2012, Jean-Paul Huchon could write in a *Le Monde* op-ed, “The Grand Paris Express is not a luxury, it is a priority investment...It is not a technocratic project, it is a democratic project.” (Huchon, 2012).

Unlike in the case of regional empowerment, the political stream did not serve the same opening function for the Grand Paris Express. Instead, the political challenges of a regional and state government that were in opposition led to a proliferation of institutional actors in an already crowded scene. Since January 2016, the Grand Paris counts several institutional actors: the state, the region, SGP, the Préfet of the Île-de-France region, and Métropole du Grand Paris, which combines 131 municipalities regrouped into twelve territories (T1 to T12). The prerogatives of these actors have been defined thanks to the MAPTAM law, voted in November 2015. The law also officializes the use of public-private partnerships as go-to tools, formalizing them and making them a part of the new governance model strategy. It also revolves around a formalized participation tool, through the Commission nationale du débat public (CNDP), which researchers define as a “procedural concession” (Blondiaux, 2008), characteristic of the fact that since the 1980s, deliberative processes have gained traction, in the context of a crisis of representation, contestation of traditional forms of technical and scientific expertise (Bacqué & Sintomer 2011, Le Goff 2011).

The classic distinction between the *laissez-faire* approach to Anglo-Saxon liberalism where infrastructure provision might be seen as more subject to the pressures of private developers, and the French welfare state model is no longer that accurate. This opened the way to a slow but steady trend of public-private partnerships à la française, first made possible by the limited Loi d'Orientation Foncière of 1967 (Pollard 2018, Béhar et al. 2018), made systematic in 1985. The Grand Paris governance model epitomizes this shift, since the 2016 inauguration of political institutions in charge of planning and policymaking was preceded by the creation of the Société du Grand Paris in 2010, a single purpose company in charge of the development of the extended Grand Paris Express public transportation system (Enright 2016).

Participation, legitimacy and change

Discourses on how pragmatic and innovative these concertation processes were, formulated in order to secure the legitimacy of development projects, have started to be conceptualized in recent years. Practitioners in Paris refer to a “new generation” of urban development projects that distinguishes itself from traditional French planning. The recurring shifts referred to include a much more complex role given to real estate developers, as well as an extended range of new stakeholders involved in design, implementation and programming along public institutions. Yet, one major traditional standard remains, which is the use of discretionary expertise, and the exclusion of users from the decision-making process (Enright 2016, Béhar et al. 2018). This opens the way to arbitrary site selection, financialization, delegation of traditionally public services to the private sector, and as mentioned previously, minimal and carefully orchestrated citizen participation, seen most often as a threat to the regulatory viability of the project (Béhar et al. 2018). Behind the pragmatic and innovative governance

tools designed and implemented by a progressive mayoral administration, or campaigns of "Réinventons"¹, path-dependency prevails (Enright 2016).

The rhetoric of pragmatism and innovation behind the public-private implementation process, as opposed to a slower traditional public planning process, even becomes a justification for discretionary expertise in the hand of local elites (Béhar et al. 2018). Such a paradox is conceptualized as "urbanism 1.0" by Dominique Lorrain, who argues that behind rhetorics of pragmatism and innovation, the Grand Paris policy programs are developed in a very opaque discretionary way (Lorrain 2018). Yet the policy streams literature suggests that for implementation to occur, they will have to eventually enter into the political light, and in doing so, can at times be shaped to regional priorities.

The major argument about the role of experts that we can extract from the chronological study is that the Grand Paris is inscribed in a very old-school French framework: the Grand urbanism, the "Grand Project" (or major works) and the centralized *dirigiste* administrative model (Gonguet, 2015). Even though it appears as "new urban politics" based on growth coalitions and public-private partnerships (Enright, 2016), the first stages of its implementation were thus characterized by very limited participatory processes. The pre-implementation process involved "starchitects" and internationally renowned consultants, as a way to give a sense of imagined solidarity and legitimization to a rather top-down decision-making process. The sole shift is in the state's goal, which appears to be more market-oriented than in past decades: " authority is made polymorphic, consensual, participatory, and contractual, and spatial policies are increasingly oriented toward private concerns " (Enright, 2016, 27). Yet it would be a stretch to too firmly link participatory politics to private concerns. Models of participation less explicitly oriented to economic development, like the region's anti-car policies, can have participatory processes without public-private partnerships.

Conclusion Moving forward, what are the challenges and opportunities for each model?

While the concertation may have lent legitimacy to the Grand Paris project, implementation has stumbled. The Cour de Comptes, a national auditor, opened an investigation into the SGP underlying financial mismanagement (estimated at 13 billion euros) and suspicion of favoritism linked to Grand Paris Express contracts (Le Figaro, 2019). The investigation led to a follow-up by the Parquet National Financier (PNF), which tracks financial crime. There has also been delays in delivering construction for the Olympics, the full network will never be ready in time. The government will soon present a revised schedule to stop the delays and avoid the rising costs. Tensions between lines needed for the Olympics and lines needed to improve access for residents have led to mayors protesting the delays and refusing to make required payments (Gregoire 2018, Gregoire 2019).

The main point of criticism thus far is that it is hard to build legitimacy around a project supposed to "govern" for 12 million residents, and also the selection of priority neighborhoods and projects is not efficiently correcting territorial inequalities, and that it serves mainly the purpose of densifying and gentrifying neighborhoods located in the direct vicinity of the Grand Paris Express extended public transportation network. On the regional side, the region struggles from its sheer size and diversity. The "dusting" of projects across the region that imperiled the Arc Express in the first place continues to be a problem, perhaps more so now when the region is governed by a conservative elected from the outer ring suburbs, who owes no favors to the socialists in Paris.

Another major thread that runs through both stories is the role of the state-empowered technician. In both the Grand Paris Express and bus improvements, the main technical actor is RATP, which is state-controlled. RATP generated the vision for Mobilien, the structured regional bus network, and for the Métrophérique that spawned both the Arc Express and the Grand Paris Express. RATP engineers also staffed Christian Blanc, himself a former RATP head. In both cases, however, RATP has been losing ground. In the region's case, RATP is facing the loss of its monopoly on the bus sector in 2024, and the region is preparing to guide more of the technical planning and contract supervision. Instead of being the main engine of ideas, RATP may become just another operator. In the Grand Paris Express, RATP is losing out to public-private partnerships, already playing a role as a competitor. In

¹ Participatory campaigns to reinvent the governance model in Paris prior to its official inauguration.

one case, the experts are becoming subsumed to politicians, while in other, they follow the guise of the market. Who then generates the solutions that populate the solution stream?

Abstract: Urban growth and new patterns of urban flows demand new scales and forms of governance since administrative borders often do not reflect contemporary functional relations such as labour and housing markets. To address these issues, new arrangements for metropolitan governance have been developed across many countries. These arrangements can take many forms but often seek to reduce administrative fragmentation and manage complex issues beyond the municipal scale. These arrangements are often collaborative and negotiated; competences and processes of deliberation and decision-making are not closely defined by the rule of law. Their strategic capacity or powers are derived from ‘resources’, ‘process’ and ‘meaning’. This paper compares these three types of power in the governance arrangements for two Dutch metropolitan areas: Amsterdam and Rotterdam The Hague.

Keywords: Metropolitan regions, governance, power, Randstad

1. Introduction

Trends in decentralisation and globalisation are increasingly testing the capacity of regional economies to adapt and exploit their competitive advantages, while also offering new opportunities for regional development. All levels of government are rethinking their strategies for building competitive, sustainable, inclusive urban territories (OECD, 2016). Effective relations between different levels of government, as well as greater participation by citizens, firms, education and research institutions, and other non-state actors are required in order to improve the delivery and quality of public services (OECD, 2016).

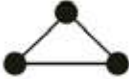

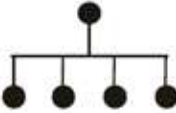

In practice there has been a rapid growth in consultation and coordination structures in response to the growing spatial interaction and integration at the supra-local level, including metropolitan regions (as well as other types of regions). The private sector and voluntary actors are increasingly participating in the management of territories. Government itself has become a multi-actor system as policy sectors (the proverbial silos) have their own agenda while the range of semi-autonomous governmental agencies add to administrative complexity (e.g. airport and port authorities, public transport providers and their managing authorities).

This has resulted in the pursuit for new governance arrangements for metropolitan areas. The OECD (2015) distinguishes between four broad categories of governance arrangements that can be found around the world (Figure 1): (1) informal/soft co-ordination, (2) inter-municipal authorities, (3) supra-municipal authorities and (4) special status of ‘metropolitan cities’ (Figure 1). Each of these arrangements is associated with different levels of competences and different types of instruments. These categories are not mutually exclusive: different

¹ This paper will also be published as a chapter in a book on the Randstad by Routledge (Series Regions and Cities) in a slightly revised version in 2019/2020.

arrangements may coexist in the same country, and even within the same metropolitan area (OECD, 2015).² More than half of the metropolitan governance bodies across the world rely on informal or soft coordination arrangements.

Figure 1. Broad categories of metropolitan governance arrangements

<p>Informal/soft co-ordination. Often found in instances of polycentric urban development, lightly institutionalised platforms for information sharing and consultation are relatively easy both to implement and to undo. They typically lack enforcement tools and their relationship with citizens and other levels of government tends to remain minimal.</p>	
<p>Inter-municipal authorities. When established for a single purpose, such authorities aim at sharing costs and responsibilities across member municipalities – sometimes with the participation of other levels of government and sectoral organisations. Multi-purpose authorities embrace a defined range of key policies for urban development such as land use, transport and infrastructure.</p>	
<p>Supra-municipal authorities. An additional layer above municipalities can be introduced either by creating a directly elected metropolitan government, or with the upper governments setting down a non-elected metropolitan structure. The extent of municipal involvement and financial capacity often determine the effectiveness of a supra-municipal authority.</p>	
<p>Special status of “metropolitan cities”. Cities that exceed a legally defined population threshold can be upgraded into a special status as “metropolitan cities”, which puts them on the same footing as the next upper level of government and gives them broader competencies.</p>

This paper examines the nature and powers of governance arrangements in two Dutch metropolitan areas both situated in the Randstad: Amsterdam and Rotterdam The Hague. To do so, it draws on the work of Healey (2006) and Haran (2010). Both Healey and Haran identify a triad of similar (but differing) factors influencing the decision environment. Healey draws on the work of Giddens (1984) in her analysis of institutional adaptation and change, identifying three key flows which shape the materialities and identities of actors and create the structural forces that they experience: ‘material resources’, ‘authoritative resources’ and ‘ideas and frames of reference’. Meanwhile, Haran draws on the work of Lukes (1974) and distinguishes three dimensions to explain the way power is used to organize the relationships between the actors involved in regional governance: ‘resources’, ‘process’ and ‘meaning’. In this paper, the powers derived from ‘resources’, ‘process’ and ‘meaning’ are used to structure the analysis and comparison of governance arrangements in the two Dutch metropolitan areas.

The *power of resources* has close ties to Healey’s dimension of ‘material resources’. For Healey, material resources refer to goods and assets, technologies, finance, labour power. Under the power of resources, Haran refers to information, knowledge and expertise, political access, control of money, rewards and sanctions including the mechanisms for their distributions like laws and regulations when referring to resources. In this paper, legal competences for different activities (e.g. spatial, transport and economic development) are also included under this form of power.

² For example, a metropolitan area may adopt one arrangement for a specific public service but another arrangement for other services.

The *power of process* is related to Healey's flow of authoritative resources, which includes regulatory power, the power to regulate the behaviour of others through formal and informal norms, codes, and laws (Healey, 2006). Haran (2010: 49) refers to the power of process as the power of actors to prevent certain issues from reaching collective decision-making agendas. This paper considers the power of process by analysing the actor network and the relations between them.

The *power of meaning* is closely linked to Healey's flow of ideas and frames of reference, the power to generate new imaginations and shape identities and values (Healey, 2006). According to Haran (2010), this power relates to the capacity to shape the perceptions and beliefs. In spatial planning this is closely related to visioning, the creation of 'images of the future' (see also Shipley, 2002) which is often intrinsically linked to visualisation and map-making or 'framing with images' (Faludi, 1996; Zonneveld, 2005). This power relates to how the structure of both metropolitan regions is perceived.

The analysis presented in this chapter is based on a mixture of primary and secondary sources, building on earlier related work by the authors (including Zonneveld & Spaans, 2014; Spaans & Zonneveld, 2015, 2016; Spaans & Stead, 2016). The paper is divided into six main parts. It continues with an overview of recent international trends in metropolitan governance. It then presents a summary of trends in sub-national governance in the Netherlands. This is followed by analyses of power in the metropolitan regions of Rotterdam The Hague (MRDH) (section 4) and Amsterdam (MRA) (section 5). It concludes with a reflection on the extent to which the powers of metropolitan governance in the two cases coincide and have experienced similar changes.

2. Trends in regional and metropolitan governance in an international perspective

2.1 Trends in regional governance

Building on the work of Lidström (2007) and Fürst (2009), a number of closely interlinked contemporary trends in regional governance can be identified across Europe and beyond (Stead & Pálné Kovács, 2016). These trends can be summarised under five headings: (1) redefining of the role of the nation-state; (2) the strengthening of lower levels of self-government; (3) increasing diversity, variation and even asymmetry of governance; (4) increasing marketization of the public domain; and (5) shifting rationales for intervention.

Redefining of the role of the nation-state

The establishment and gradual expansion of the EU has changed the role of national borders and has transferred decision-making powers both upwards and downwards: to the supranational and sub-national levels. European regional policy, primarily through the Structural Funds and Cohesion Funds, has contributed to the establishment of new regional bodies (or the strengthening of existing bodies) in various countries to administer European regional policy resources. At the same time, territorial management and planning approaches in member states are being increasingly shaped by European policies and initiatives (e.g. structural fund rules, environmental management and nature protection directives). Meanwhile, the role of the nation-state has been challenged from inside in some cases where demands for separatism or self-government have been made, motivated by regional culture or identity arguments.

Strengthening lower levels of self-government

In many European countries, examples can be found where functions have been decentralised from central government to local and regional levels of government. In some countries, this has happened as a result of the reorganisation of sub-national government, either by amalgamating municipalities or regions, or by creating new regional levels of self-government. Reforms in sub-national government have been enacted in various countries where comprehensive reforms of the whole structure of local and regional government have

taken place, including amalgamations of municipalities and regions, and the transfer of functions between different levels of government (see for example Galland & Enemark, 2013). In some cases, however, reforms to government structures and competences have not always been accompanied by corresponding shifts in funding allocations for a variety of reasons including the political difficulties or complexities of fiscal reforms (Maier, 1998; OECD, 2001).

Increasing diversity, variation and even asymmetry of governance and government

This tendency towards diversity can be seen as the result of empowerment of lower levels of government. Not only is the scope for variation between sub-national units greater, some units are also permitted to follow their own paths that may differ from the general national pattern. Various types of asymmetry can be distinguished: political, administrative and fiscal (Loughlin, 2007).³

Increasing marketization of the public domain

The increased involvement of non-state actors (including the private sector) is one of the central dimensions of the shifts from government to governance (see for example Kooiman, 1993). Many functions that were seen as typical public responsibilities during the peak of the welfare state era (when government rather than governance prevailed) have more recently either been privatized or are run jointly by public and private providers. Public organizations are increasingly taking an ‘enabling’ role where other actors are the providers of public services. In many countries, the welfare state has been reconfigured in ways that makes it less centralized and less redistributive, and more oriented to promoting the role of the market. Outsourcing is one of the ways in which non-state actors (including private and non-profit) are increasingly involved in delivering goods and/or services, a trend closely associated with the emergence of new public management. Governments can outsource the delivery of services in two ways: providing technical support (e.g. consultancy or back-office functions for government); and delivering goods or services directly to the end user on behalf of the government (e.g. public transport or waste disposal services).

Shifting rationales for intervention

Territorial governance is being redefined in the light of important societal challenges, new powers and responsibilities (see above) and new attempts to increase the societal relevance of planning. Across Europe, territorial governance is being recast as a way of managing the increasing interdependencies of actors involved in territorial development (Stead & Meijers, 2009). Because the competition for various goods and services often extends well beyond national boundaries, the pressure to introduce governance reforms to respond to these challenges has increased. Moreover, the internationalisation of trade, education and communication is also contributing to shifts in the way in which territorial governance is practiced and conceptualised.

2.2 Trends in metropolitan governance

Metropolitan governance bodies – bodies aiming at organising responsibilities among public authorities in metropolitan areas (see also Figure 1) – are extremely common in most OECD countries. Very few countries have no metropolitan governance body at all (see Figure 2), although rarely are all metropolitan areas in a country covered by a metropolitan governance body. Since the 1990s, there has been renewed momentum in the creation of metropolitan governance bodies (or in the reform of existing ones). According to the OECD Metropolitan

³ The ‘special’ and ‘ordinary’ regions in Italy provide one example of political asymmetry and diversity within a state. Different forms of territorial administration within the UK provide one example of administrative and fiscal asymmetries, where the three territorial offices representing Scotland, Wales and Northern Ireland have distinct relations and arrangements with London. Meanwhile, in Spain, the Basque Country and Navarre have more financial (and legal) autonomy than the rest of the country, and exhibit fiscal asymmetry.

Survey held in 2013 (Ahrend et al., 2014), more than two-thirds of OECD metropolitan areas currently have some kind of body or agency responsible for metropolitan governance (Figure 2). However, not all these bodies have many, or even any, legal powers.

Figure 2. Share of OECD metropolitan areas with a body responsible for metropolitan governance

Source: OECD, 2015

A majority of metropolitan governance bodies work on regional development, spatial planning and transport. However, considerable diversity exists in their legal status, composition, power, budget and staff, and consequently in their impact on policy design and implementation. Within OECD countries, around 80% of metropolitan governance bodies work on regional development, over 70% on transport and over 60% on spatial planning. More than half of metropolitan governance bodies are active in these three fields at the same time (OECD, 2015).

Metropolitan-wide planning can be achieved by either formal and informal institutions or a mix thereof depending on how sectoral competencies are divided. The effectiveness of either institutional approach depends to a large extent on the types of issues that a territory faces, the relationships among the actors, the resources at their disposal and, in general, the capacity to implement a common agenda. The policies of upper level governments, regional or national, have a major impact on the adoption of inter-municipal or metropolitan planning frameworks. (OECD, 2017: 142) The majority of metropolitan governance bodies in the OECD tend to involve forms of informal or soft co-ordination; less than a quarter of OECD metropolitan areas have governance bodies that impose regulations.

Links to political authority are directly tied to an entity's capacity or to raise funds independently and to establish binding regulation (the 'power of resources'). Informal forms of metropolitan governance can struggle to implement a common agenda where major trade-offs are required and have weaker connections to the citizens they govern in terms of democratic legitimacy and accountability. Despite these drawbacks, there are many reasons why metropolitan areas have chosen to adopt more informal approaches to metropolitan collaboration, including the critical role they play in establishing a common metropolitan agenda (OECD, 2017: 150).

Intergovernmental transfers are highly instrumental across OECD countries in establishing metropolitan forms of governance. In the Netherlands, however, such mechanisms are not currently employed. Here, the national government funds large projects of metropolitan importance directly particularly in the domain of transport and infrastructure, rather than being funded by metropolitan regions as these regions lack taxation tools.

3. Searching for regional governance in the Netherlands

Many of the general trends discussed above were also visible in the Netherlands. Here too, the 1990s marked an important point in the search for new forms of metropolitan governance. However, the quest to find regional and metropolitan governance structures started a few decades earlier while becoming highly frenetic in the years after 1990. Quite typical for the Dutch case is the fact that more than one spatial scale was involved: the level of the entire Randstad as well as the level of its two constituting ‘wings’ and the urban regions within these wings.

3.1 First efforts to find ‘suitable’ regional governance arrangements

The present administrative structure of the Netherlands goes back to the 1848 constitution which defines two levels below the national level: provinces and municipalities. In those days there were 11 provinces and more than 1,200 municipalities. Today, by comparison, there are 12 provinces and 355 municipalities in the Netherlands. Not surprisingly whether municipalities could effectively deal with spatial development became an issue in the years to come. Discussions gained momentum during the first decades of the twentieth century as urbanisation started to become a regional phenomenon through suburbanisation and rapid urbanisation, in particular in industrial and mining areas and in the west of the country. From the 1910s onwards strong pleas for regional spatial planning were made, in particular after 1924 when a large international conference on this subject took place in Amsterdam. As at that stage there were still more than 1,000 municipalities, planners called for giving planning competences to the provinces. However, national government regarded this as far too centralistic (Faludi & Van der Valk, 1994). Regional planning issues had to be dealt with by (voluntary) cooperation between municipalities.

After the Second World War the Netherlands embarked on a long quest to find suitable governance arrangements, most specifically for metropolitan regions (Needham, 2014: 94-98). For instance, the national so-called Second Planning Report of 1966 proposed to add a fourth administrative layer in selected urban regions. This asymmetric solution (only applicable in a part of the country) was eight years later followed by a proposal to create a fourth level across the entire country through 44 districts (*‘rayons’*) with planning and implementation competences. This idea was soon abandoned as in 1976 a new coalition government proposed to maintain the three levels of administration but to regionalize the middle – provincial – layer: from 11 to 26 provinces. In follow-up proposals the number went down to 24 and 17 respectively. Massive opposition from politicians, administrators, academics and civil society at large eventually led to the withdrawal of all legislative proposals in 1983. Regional governance had to be achieved through municipal cooperation and the capacity to do so had to come from the application of the so-called Joint Regulations Act (WGR: *Wet Gemeenschappelijke Regelingen*) of which a first version dates from 1950. What this act does is opening up the possibility of cooperation between provinces, municipalities and water boards, but without directly elected councils: the watershed with a full-blown administrative layer. After the collapse of the plans to establish ‘new style’ provinces a new WGR came into force on January 1, 1985. A principle objective was that all the present cooperation provisions had to be bundled and integrated to foster effectiveness and transparency, with the provinces in a kind of supervisory role. This ‘conclusion’ (i.e. intermunicipal cooperation) would only hold for a few years.

3.2 Opening Pandora’s box once more

The economic recession of the 1980s particularly effected the four largest cities of the Randstad. Mid-1988 government decided to install a heavy-weight advisory committee to evaluate policies with an effect on the social-economic position of these cities, the so-called Montijn Committee. One area this committee specifically looked at was local governance. The main conclusion was that voluntary municipal cooperation based on the WGR was insufficient. The advice what to do was twofold and essentially multiscale: (1) create four

regional municipalities in the Randstad; and (2) create an Administrative Platform Randstad. How the second proposal was taken up we will discuss in the next sub-section.

On the basis of this advice and a range of other studies and advisory reports, government decided in 1993 for the top-down creation of so-called city-provinces in seven regions, including Amsterdam, Rotterdam and The Hague (the other regions were Utrecht, Arnhem-Nijmegen, Eindhoven and the Twente region in the east of the country). This would have to be achieved in a processual sort of way, instead in one single step. The route was laid down in the 1994 'Framework Law Administration in Change' stipulating the establishment of *mandatory* municipal cooperation bodies in the seven regions in preparation of full-blown city-provinces. The temporary regional constructs acquired the rather unattractive name of 'framework law areas' (*kaderwetgebieden*).

How the situation would have to look like was clarified in a 1995 legislative proposal concerning the Rotterdam region: the new Rotterdam city-province would be formed by existing municipalities and the creation of new municipalities by splitting up Rotterdam. A similar trajectory was foreseen for Amsterdam. The idea that both Rotterdam and Amsterdam would 'vanish' led to a massive civil society uprising though. Making use of local referendum regulations a referendum was organized in both cities. The liquidation of the Rotterdam and Amsterdam municipalities was rejected with a vast majority (Lambregts et al., 2008). Initially government wanted to push through the idea of city-provinces but this idea had to be abandoned as parliamentary support in the end proved to be lacking, even in the government coalition.

In the light of history it did not come as a surprise that government changed to the trajectory of intermunicipal cooperation once more. By January 1, 2006 the Framework Law was withdrawn and a new Joint Regulations Act came into force. This version of the act provided additional competences in the field of spatial planning and public transport for the seven areas mentioned above plus one region in the south of the Limburg province. They acquired a highly bureaucratic, technical sort of name: WGR plus regions. The new competences for the public bodies created by WGR plus included the making of mandatory regional structure plans (*structuurplannen*). However, this latter competence did not last very long. In 2008 a new Spatial Planning Act came into force which took away the plan-making competences of the WGR plus regions (Janssen-Jansen, 2011: 264). Parliament considered the democratic legitimization of WGR plus decision-making as rather poor.⁴

This in itself shows the vulnerable political basis of asymmetric solutions which sit somewhere between the standard, countrywide administrative layers. For this reason it should not come as a surprise that just after eight years after they came into existence all WGR plus regions were abolished by January 1, 2015. A major reason for giving back competences to provinces and municipalities was the perceived lack of democratic legitimacy of the WGR plus regions (OECD, 2017) although this was not a dominant issue when they were created. Responsibilities for transport and related funding from national government were returned to the provinces, except for the provinces of South-Holland and North-Holland, which they had officially lost since the 2005 WGR plus Act. In South-Holland the areas of the two WGR plus regions were combined to form the Rotterdam The Hague Transport Authority (see next section). The Amsterdam WGR plus region, without any change in its perimeters, became the Transport Authority Amsterdam (TAA). Both transport authorities are mandatory forms of cooperation sharing the same legal basis. Both form the commissioning authority for public transport by bus, tram and underground railway (excluding the services of the national railway company). They also finance improvements to the regional infrastructure for goods vehicles, cars, bicycles and public transport, so investments in physical infrastructure. Both

⁴ https://www.denederlandsegrondwet.nl/id/vilqfxp1clz9/intergemeentelijke_samenwerking (accessed June 12, 2019)

entities are strictly briefed to limit their activities to transport and in no way expand their actions to other areas. As we will see in the next two sections issues outside (public) transport are addressed to network-type arrangements called metropolitan regions (Figure 3).

3.3 The emergence and downfall of Randstad cooperation bodies

Since the Randstad concept was invented as a planning concept at the end of the 1950s it was national government which was in charge of a spatial strategy for this area. However, in the early 1970s some sort of cooperation between the provinces of North-Holland, South-Holland and Utrecht started under an acronym which only civil servants can invent: Dripo (a Dutch acronym for 'three provinces'). In 1975 it was the South-Holland executive taking the initiative to broaden and deepen the cooperation by suggesting that also the four main Randstad cities should participate. However, the other two provinces feared that these cities would dominate. North-Holland was anxious that Amsterdam would reach out to the Green Heart (Quist, 1993: 30-32). This proposal and 'Dripo' in general faded into oblivion after a while.

Amidst the economic recession of the 1980s cooperation between the three Randstad provinces picked up again in various domains from 1985 onwards, including spatial planning (Quist, 1993: 49). The province of Flevoland started to participate as an observer as its main city Almere as a new town played a key role for the northern part of the Randstad. In 1994 this province became full member of *Regio Randstad*, since 1991 the official name for cooperation in the domain of planning (Lambregts & Zonneveld, 2004: 314). As an expression of a desire to deepen the cooperation the Randstad provinces decided to base their cooperation under this banner on the Joint Regulations Act.

Cooperation in the Randstad seemed to intensify even more when as of September 2002 not only the four main Randstad cities but also the WGR plus city-regions around these cities joined Regio Randstad. The joint provisions arrangement was adapted and from that moment

cooperation was not only multi-actor but also multi-level, involving twelve actors. Cooperation had a twin objective: (1) to strengthen the international competitive position of the Randstad and (2) to improve quality of life (Lambregts et al., 2008: 50).

This expansion from four to twelve Regio Randstad actors could be regarded as a logical consequence of yet another Randstad organization: the Administrative Committee for the Randstad (BCR: *Bestuurlijke Commissie Randstad*). This rather giant negotiation platform included the twelve Randstad authorities and no less than five ministries. It was created in 1997 to renew the covenants between national government, provinces, urban regions and municipalities on housing allocation and production (Dijkink et al., 2001: 30). Later on its tasks became much wider: not only the coordination of central government's spatial investments in the Randstad but also to discuss Randstad-input for the fifth national planning report which would see the light in 2001 (Lambregts & Zonneveld, 2004: 314).

Changes in government coalitions, in nearly all cases preceded by national elections, played an important role in the changing perceptions how to (re)organize regional governance as discussed above. Likewise changing perceptions about the importance of the Randstad for the country as a whole and the perimeters and internal structure of the Randstad had similar repercussions. Mid-2002 a new coalition government took office which was less convinced of the need to put the level of the Randstad at centre stage (Lambregts et al., 2008: 51). The Randstad was divided in four programme areas and concrete policies and investment strategies were coordinated with the authorities in each of these four regions (Amsterdam; Utrecht; Rotterdam The Hague; and the Green Heart). However, a later coalition government again attached greater importance to the Randstad. Warned by ever lower rankings of the Randstad in international comparisons it established a high level committee which was asked to advise on its administrative structure. The assumption was that administrative bustle (*'bestuurlijke drukte'*) was seriously undermining all efforts to improve the competitive position of the Randstad. Early 2007, in a few months time, this committee issued the daring advice to create one single metropolitan government for the entire Randstad that would take over a range of (mainly planning) competences of the provinces and the four WGR plus regions.

Another coalition than the one which established the Randstad advisory committee set aside this strongly formulated advice. Weary of governmental reform in general, support for this negative decision came from several research and advisory bodies. In 2006 the Netherlands Institute for Spatial Research published an elaborate report showing that the Randstad is not a single, integrated urban region but on the whole is formed by two sub-regions (Ritsema van Eck et al., 2006). About a year later the OECD acknowledged that although the Randstad may represent a relevant scale in relation to certain issues, it did not consider the introduction of a Randstad authority a necessity and instead favoured the strengthening of the governance capacity of city-regions (OECD, 2007 as discussed by Lambregts et al., 2008: 52). On top of that at parliamentary request, the Netherlands Institute for Spatial Research (De Vries & Evers, 2008; see also Evers & De Vries, 2013) made a comparison between the governance within the Randstad and how this is organized in a (small) sample number of other urban regions: the general assumption is that the situation in the Randstad is far worse when compared with examples abroad. The assessment agency concluded that this is definitely not the case. In 2008 the government advisory council on spatial planning recommended that the creation of coalitions around strategic projects is far more effective than an overall restructuring of the administrative system (VROM-Raad, 2008).

By the time this latter advice was published the twelve partners of Region Randstad already took the decision to end their cooperation body by January 1, 2008. Two dominant reasons are named in a frank letter by its chairman, the Crown's Commissioner of the province of South-Holland (Franssen, 2007): (1) Randstad Region partners are becoming ever less prepared to prioritize the Randstad scale; and (2) the present organisation is too heavy

and too 'administrative' while the shared ambitions are too weak. The letter also points out that there is no match between how Region Randstad works and how government organizes programmes which seek to support the economy of the Randstad. Under the so-called Randstad Urgent Programme which started in 2007 all (35) projects are supervised by high level administrative duos: one administrator from national government and one from local government, a sort of implicit reply to the VROM-Raad advice.

Since the disappearance of Region Randstad in 2008 there is no longer a cooperation body at this level. However, 'Region Randstad' is still used as a label for various joint lobbying and promotion activities by the four Randstad provinces in Brussels.

4. Metropolitan region Rotterdam The Hague

4.1 Introduction

In the early 2000s, the southern Randstad or South Wing became conceptualized as one of the urban networks in the Netherlands. This new national planning concept meant that groups of cities could form networks tied together by functional relations, physical infrastructure and connected government. When the director of the Department of Spatial Planning and Transport in the province of South-Holland assumed office in 2002, he set up the South Wing Studio (*Atelier Zuidvleugel*). His opinion was that the South Wing was suffering from an abundance of plans, strategies and fierce competition between local planning actors and municipalities and that an institution which would be independent from daily political routine and which would have time to reflect would help the province as well as other planning actors to develop a regional frame of reference for decision-making (Balz & Zonneveld, 2015: 877). The focus of this Studio was design-oriented and helpful in bringing relevant stakeholders informally together and introducing them to the level of scale of the southern Randstad.

Around the same time (in 1997) an informal multi-level government cooperation in the southern Randstad was set up (Dijkink et al., 2001). Members included the province, the two main cities, the two WGR plus city-regions and three WGR regions. This Administrative Platform South Wing (*Bestuurlijk Platform Zuidvleugel*) covered the city-regions of Rotterdam and The Hague with extensions towards Leiden to the north and Dordrecht to the south to improve the coordination of urban development in the area. Its aim was to undertake preparatory work for a new covenant between the region and national government regarding investments in infrastructural and other spatial projects in the southern Randstad (Dijkink et al., 2001: 30). In 2000 the decision was taken to make the Platform a permanent structure supported by a small secretariat located in the House of the Province of South-Holland in The Hague. It did not have decision-making or executive tasks, but formed the setting for negotiations with central government in investments in which the province had the strongest agenda-setting role (Spaans & Zonneveld, 2016).

The Metropolitan region Rotterdam The Hague or MRDH (*Metropoolregio Rotterdam Den Haag*) arose in 2010 when national government announced the abolishment of the WGR plus city-regions. As the WGR plus city-regions were also the transport authorities for their territory and as such received considerable national budgets for public transport, the announced abolishment initiated a quest for these budgets and intensified the power play between municipalities and province. A new arrangement had to be set up to replace the city-regions. One option was that the infrastructure tasks would go to the province. The mayors of both Rotterdam and The Hague chose to block off this route as this meant that a large central government budget would find its way annually to the province. The Metropolitan region placed itself at the forefront. In the law regarding the abolishment of the WGR plus regions, national government indicated that because of the complexity in the Randstad wings the new transport authority would cover the geographical area of the Metropolitan region Rotterdam The Hague. But the exact elaboration was left to municipalities and provinces. This resulted in the Metropolitan region becoming the transport authority and resulted in a formal

arrangement: fixed perimeters and formal duties (which go hand in hand) but – like the city-regions before that – without an elected council. In December 2014 a joint provision was signed for the transport authority. On January 1, 2015 all eight Dutch city-regions were abolished and the MRDH formally appointed by central government as the Transport Authority.

As MRDH gained in power, the informal cooperation for the larger area in the southern Randstad – the Administrative Platform South Wing – repositioned itself in 2016 as Network Southern Randstad focussing on strategic spatial-economic issues and cooperation with national government on national public investments in this field (Zuidvleugel, 2015).

As said the current Metropolitan region Rotterdam The Hague (MRDH) was formed by the integration of the two former WGR plus city-regions of Rotterdam and The Hague. The MRDH cuts a large chunk out of the territory of the province of South-Holland as it houses more than 60% of the population and 36% of the land area. The geographical area that spans 23 municipalities which vary considerably in population size and nature. It covers a metropolitan authority tasked with transport and economic development responsibilities for this territory. One of the core ambitions of the MRDH authority is to bring the economies of Rotterdam and The Hague closer together while generating growth and well-being (OECD, 2016).

4.2 The power of resources

The previous section explained that the MRDH emerged as a new metropolitan-scale institution with the ambition of becoming the transport authority but at the same time it also embraced additional ambitions. While in the stage of emergence the MRDH envisaged an even broader scope, it narrowed down to a twofold focus: transport authority and economic development. The broader scope at the start covered three coherent strategies (1) to exploit the potential of being a single daily urban system by improving internal connectivity; (2) to make better use of, and invest in the knowledge and innovation potential of the region; and (3) to fully exploit the wide diversity in amenities, services and landscape assets of the region (Meijers et al., 2013).

When we compare the two pillars of the MRDH, the Transport Authority (TA) is much more formalised and with a considerable higher budget than the economic development pillar. The MRDH's budget is composed of public transport subsidies from national government⁵ and contributions from the participating municipalities for the economic development pillar. Important to stress is that MRDH has only limited possibilities to broaden its financial resources as it is not allowed to levy taxes or impose other fees or charges. In the Netherlands most taxes are collected at the national level and then redistributed to the local and provincial levels. Municipalities collect approximately one sixth of their budget by levying local taxes.

In 2019 the budget in the field of public transport was 0.74 billion euro (the budget is not indexed which means that its value is going down due to inflation), which is used both for operation of public transport and investment in new infrastructure. The Transport Authority pillar employs 56 full-time staff in 2019⁶. Legal competences and financial resources in the field of economic development are much more limited, which is also reflected in a more limited staffing: 12 full-time staff members in 2019. For this task the MRDH does not possess any 'hard tools' as its responsibilities are based on a voluntary agreement among member municipalities without any enforcement mechanisms. The annual budget of about 4.8 million

⁵ Largely based on the Broad goal-oriented grant for transport (BDU or *Brede Doeluitkering* in Dutch) which is a financing programme for regional traffic and transport projects funded by central government.

⁶ Data from Metropoolregio Rotterdam Den Haag (2018) *Begroting 2019 en meerjarenbeeld 2020-2022* Metropoolregio Rotterdam Den Haag, Rotterdam: MRDH.

euro (for 2019) comes primarily from the municipal authorities, in the form of a fixed amount per resident from each member municipality: 2.58 euro in 2019. According to the OECD (2016) such a funding arrangement for the economic pillar of the MRDH is common across the OECD and that its per capita budget is comparable to other informal metropolitan associations without regulatory powers, but that in terms of staffing the MRDH has a smaller secretariat compared to other OECD metropolitan governance bodies that oversee a similar population size. A remark is however that the MRDH has a more limited set of responsibilities.

4.3 The power of process

Shifts in leadership form an important underlying reason for the emergence of the MRDH. For a long time there have been tensions between the three major appointed administrators – the mayors of the two main cities of Rotterdam and The Hague and the Crown's Commissioner of the province of South-Holland⁷. This did not help to function as a cohesive policy network (Spaans & Zonneveld, 2015). When in 2008 in both Rotterdam and The Hague new mayors were appointed matters changed drastically politically. Although they were from two different political parties they got on very well which their predecessors certainly could not. It is through them that there is now the MRDH as a genuine politically approved informal governance arrangement (Spaans & Zonneveld, 2016). Although the MRDH and the province of South-Holland had a problematic relationship at the start, their co-operation has improved since then (OECD, 2016: 12). As both governance bodies each have their own responsibilities in a partly overlapping geographical area they simply have to cooperate in economic and transport planning. After the abolishment of the WGR plus city-regions in 2015, the Province of South-Holland and the MRDH signed a management agreement in 2016 and renewed and refined this in 2018, which focuses on the common fields of traffic and transport and economic business climate. The Network Southern Randstad complements this cooperation.

The MRDH has been established in a formal joint arrangement under the Joint Regulations Act of 2016 (MRDH, 2018a). The voluntary, bottom-up collaboration among municipalities is a positive, distinctive feature of the MRDH compared to other OECD metropolitan regions built around two large cities (OECD, 2016: 148). The organization mirrors how provinces and municipalities are organized: a General Board and an Executive Board which cover both pillars of the MRDH. The current organisation of the MRDH reflects the balance between the two major cities on the one hand and the smaller municipalities on the other. The Executive Board includes the mayors of Rotterdam and The Hague (who act as chair and vice-chair) and representatives from three other municipalities. and prepares decisions for the General Board.

The mayors of the two major cities rotate every two years as the chair of the General Board which is the highest decision-making body of the MRDH. This body comprises 27 members and meets four or five times a year. Representatives in the General Board have a varying number of votes, depending on the population size of the municipality they represent⁸. Decisions within the general management require an absolute majority of votes, but given the Dutch culture of political consensus, it is generally expected that most decisions will be taken unanimously. Interesting is that the two major cities together do not have the majority of the votes although they represent more than half of the inhabitants of the MRDH (OECD, 2016: 145). The hesitation of some of the smaller municipalities to join the MRDH due their fear of being overruled by the two cities was taken away by this. Member municipalities are represented in different administrative committees.

⁷ Mayors and Crown's Commissioners are appointed and not elected in the Netherlands.

⁸ Each representative of Rotterdam has 15 votes, each representative of The Hague has 13 votes, the representatives of Delft, Zoetermeer and Westland have 9 votes and so on, up to the smallest municipalities, whose representatives have 2 votes each (OECD, 2016: 145).

Although the MRDH as a governance body is not directly elected, it can be considered as indirect legitimacy: bottom-up from the local level. Residents of the MRDH are given the right to speak at MRDH meetings. Participation is possible if the resident has an interest in a topic that is on the agenda of the meeting⁹.

4.4 The power of meaning

The MRDH deliberately restricted itself to the policy fields of transport and economic development. Responsibilities of the Transport Authority MRDH relate to public transport in its territory, while the province has competences (and related budgets) for provincial infrastructure (roads and waterways). As OECD (2016) puts it: economic development is a competency of the province but it is also a field of work of the MRDH. The responsibilities for spatial planning however have remained a function of the province. The initial sensitivities between province and MRDH made probably had as a result that the MRDH did not want to give fire to any additional potential problems. It therefore did and still does not develop any development visions on maps for its territory; if any they take the form of pictures and text than maps (see Figure 4).

Figure 4 Meaning of MRDH

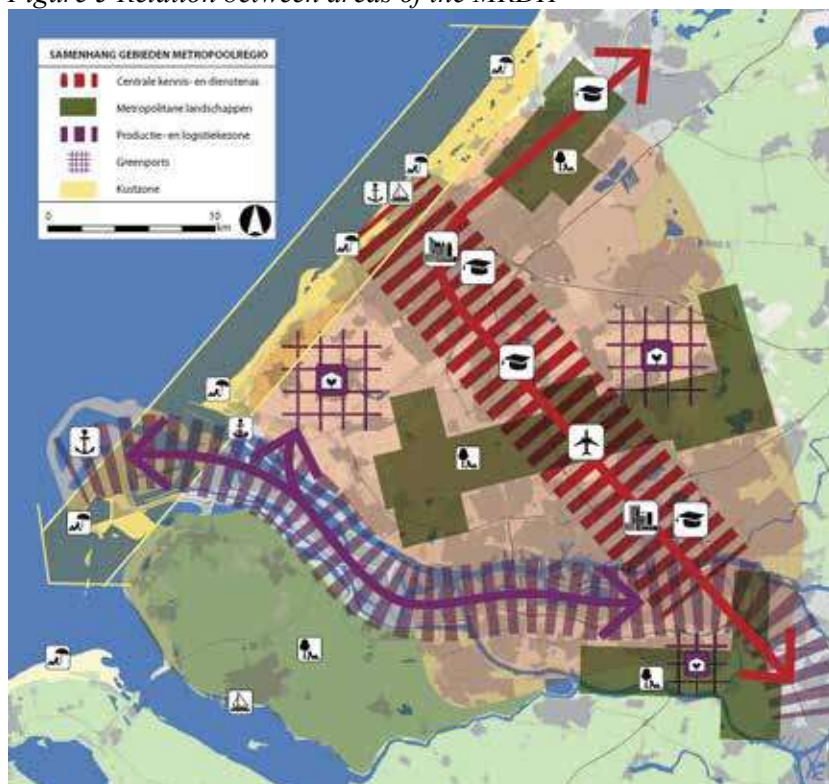

Source: MRDH, 2018b: 8

Publications on the website of the MRDH hardly include any visualisations and those included refer to visual analyses as in the MRDH Atlas (MRDH, 2014). Meaning in the sense of ‘framing with images’ is not applied by MRDH. The aim of the MRDH to increase economic growth by fostering economic integration of the region, may need spatial planning policies by the province that contribute to this goal by providing sufficient space for the economy to grow (OECD, 2016: 125). Achieving these ambitions require that policy areas of both MRDH and province are well co-ordinated. Figure 5 shows an attempt by the MRDH to stress the importance of such an integration by relating economic clusters to each other. But

⁹ <https://mrdh.nl/bestuur> (accessed on April 23, 2019).

this type of visualisation is often a one-off use and is not used in external framing of the MRDH area.

5. Metropolitan Region Amsterdam and Transport Authority Amsterdam

5.1 Introduction

Cooperation in metropolitan regions is often multi-scalar as we have seen above. The Amsterdam region is an obvious example as there are two cooperation structures which cut different slices out of the wider area spatially connected to Amsterdam while they also have different ‘powers’. First there is the region covered by the Transport Authority Amsterdam (TAA). Legally it is the successor of the WGR plus city-region Amsterdam, terminated on December 31, 2016. The new entity grounded on the Joint Regulations Act took over. The boundaries did not change: the area includes 15 municipalites, all within the province of North-Holland. The land area is 38% of the territory of this province and it houses roughly 54% of its population (about 1.5 million), percentages which are comparable with those of the MRDH.

The second, much larger entity is the Metropolitan Region Amsterdam or MRA (*Metropoolregio Amsterdam*). Having a population of about 2.5 million it is located in two provinces: North-Holland and Flevoland. Based on a covenant signed on March 6, 2017, its membership includes 32 municipalities, the authorities of the two provinces just mentioned as well as (and that is highly interesting) the Transport Authority. The MRA covers a large area: 59% of the geographical area of North-Holland falls within the MRA and no less than 77% of its population. The figures for Flevoland are 42% (area) and 69% (population). Comparable with the MRDH is that the Transport Authority Amsterdam falls within the OECD category known as ‘inter-municipal authorities’ while the MRA obviously fits within the category of informal or soft co-ordination.

The MRA and even more the TAA has a track record in cooperation going back in time. The MRA cooperation started in the late 1990s under the banner of North Wing Consultation (*Noordvleugeloverleg*). After seven high-level conferences joined by administrators from the entire area, the structure was consolidated in its present, elaborate form. The smaller scaled Informal Agglomeration Amsterdam Consultation (*Informeel Agglomeratie Overleg Amsterdam*) started about 30 years earlier, in 1969 (Van der Lans, 2006). It went through successive periods of ever stronger cooperation, each phase indicated by a slightly different name, eventually leading to the present legally based stage of Transport Authority (see Lambregts et al., 2008; Haran, 2010; Janssen-Jansen, 2011; Levelt & Janssen-Jansen, 2013; OECD, 2016; 2017).

5.2 The power of resources

If we compare MRA with the TAA then obviously the first one is lighter in the sense of not having a statutory basis. In theory the cooperation within MRA could also be based on the Joint Regulations Act, but politically this was not acceptable amongst its membership (Stadsregio Amsterdam, 2016: 5). In essence the MRA is a network although one could argue like the OECD does (OECD, 2017: 153) that it is also a political body as it is based on a political agreement, discussed and accepted amongst all its members, meaning 32 municipalities and two provincial councils. Although ‘light’ the predecessor of the MRA, the North Wing Consultation was considerably lighter as there was no written agreement at all. Its main resource was based on *process*: meetings between administrators on a regular basis leading to several political agreements (we will come back to this below). The fact that this kind of cooperation has continued for nearly two decades and is politically formalised in a covenant basically means that although MRA lacks the ‘power to implement’ (OECD 2017: 157) it created a valuable resource namely trust.

Having no power to implement means MRA cooperation is ‘cheap’ in financial terms. Organisationally the cooperation is based on annual contributions from its members. As specified in the 2017 covenant the municipal members contribute € 1.5 per inhabitant. While in the MRDH this is 72% more, in the MRA also the provinces contribute. North-Holland pays the same as Amsterdam and Flevoland the same as its biggest town, Almere. Both North-Holland and Amsterdam also contribute extra to the Economy Platform, one out of three platforms (see below). For 2019 this leads to a budget of about € 8.25 million (MRA, 2018). About a quarter of this budget is needed for running the MRA bureau. The total number of staff is limited: about 12 fte (MRA, 2016; 2018). As the MRA is not a legal entity all staff members work on the basis of secondment from municipalities, especially Amsterdam. There is a strong multiplier effect in terms of manpower. According to a rough estimate (MRA, 2016) about 60 tot 80 fte across all MRA members are working on the implementation of the so-called MRA agenda, plus the cooperation itself like the preparation of meetings (see below).

The transport authorities in the Amsterdam region and the Rotterdam The Hague region have similar competences. The budgets are different though. Annually the TAA receives about € 390 million from national government, which is much less compared with the MRDH as the latter region has a far more complex urban structure. Every year there is about € 4.5 million available for research while the TAA bureau (mainly staff) costs about € 7.5 million (VA, 2018: 20) which is about four times more compared with the MRA. This means that about 3% of the annual budget is not directly spend on (public) transport and infrastructure.

Both the MRA and the TAA spend some of their budget on research. The MRA focuses on analyses of the housing market, the state and structure of the MRA economy and on energy transition. The TAA has a much larger research budget and the focus is primarily on accessibility studies. One particular project is about the modelling of (future) transport called VENOM: Traffic Model Metropolitan Region Amsterdam (VENOM, 2016). Interestingly the research area is not the TAA region but the MRA area. The spatial logic is obvious: the TAA

area does not cover the functional urban area of Amsterdam while the MRA area does much more strongly. This is reflected in the VENOM partnership which is currently in its third period (2017-2020). Next to the TAA, partners include the two provinces involved in the MRA, the Ministry of Infrastructure and the municipality of Amsterdam plus ten other local, regional and national partners.

5.3 The power of process

This particular power or capacity is about how shared policy agendas come about and how the TAA as well as the MRA creates authoritative capacity within their constituencies as well as within their broader political context. As both entities are situated between constitutionally defined administrative levels with directly elected councils, a rather crucial issue concerns how legitimacy and accountability is organized while at the same time dominance of Amsterdam is mitigated. The latter is a more sensitive issue compared with the MRDH as Amsterdam in terms of population and economy heavily dominates the MRA and even more the TAA.

Comparable with the MRDH the TAA has a General Board (called Regional Council) as well as an Executive Board. The Regional Council has 51 members. Although the number of seats a municipality has is related to population size the Joint Provision uses a gliding scale. While more than half the population of the TAA lives in Amsterdam, the number of seats in the Council is less than a quarter. Members are appointed by the municipalities through their councils and the majority is recruited from these councils. The Council decides on the distribution of the financial funds across (four) programmes and projects. The Daily Board is rather small, with four members. The chair is an alderman of Amsterdam, holding a portfolio which includes transport and mobility.

The MRA has what the OECD calls a ‘flexible geometry’ (OECD, 2016: 177). Concrete activities and work processes rest on platforms. Of the three platforms the Transport Platform works quite exceptionally: most MRA municipalities do not participate in this platform, only those parties which participate in the TAA. The municipalities which do not participate in the TAA are represented by the two provinces. The MRA Mobility Platform obviously functions as a kind of interface between the MRA and the TAA. Some projects falling under this platform are not even limited to the perimeters of the MRA, in particular a project called MRA-E which seeks to stimulate electric transport in all municipalities not only in North-Holland and Flevoland, but also neighbouring Utrecht.

The Economy Platform focuses on employment and competitiveness. One of its main feats it inherited from the period of the North Wing Conferences which preceded the MRA cooperation, namely the decision made at the fourth, 2005 North Wing conference to establish a platform to create a joint policy on the development of locations for offices and trade and industry: PLABEKA (*Platform Bedrijven en Kantoren*). As municipalities in the Netherlands tend to compete with each other in this area (Needham, 2007: 74-75), this is no mean achievement. Connected to the Platform Economy albeit not a genuine MRA ‘institute’ is the Amsterdam Economic Board. The composition follows the classic triple helix formula. It has an advisory role both for the Amsterdam municipality as well as the MRA.

Most MRA municipalities are represented only indirectly in the Platform Economy as nearly all municipal members participate on behalf of one of the seven MRA *sub-regions*. This implies not only that MRA co-operation is characterised by a flexible geometry, but is also multiscalar. Sub-regions play a crucial role in the Territory Platform which of all three platforms has the broadest focus. However, the platform does not call itself (in translation) Spatial Planning (see for this interpretation OECD, 2017: 149). The Dutch equivalent (*ruimtelijke ordening*) has the connotation of defining land-use through zoning plans. As this is a statutory competence this could not be dealt with by a network organization as the MRA. However, within the Territory Platform municipalities in MRA seek to coordinate house

building programmes, on the level of the sub-regions as well as on the level of the entire MRA. This is roughly the housing equivalent of PLABEKA. Both arrangements obviously have spatial implications, but the legally binding decisions on land-use are taken by the individual municipal councils according to the credo to be found on many MRA webpages and in published material: no competences are transferred from the participating authorities to the MRA.

There are connections between the three platforms. These are dealt with by four so-called portfolio consultations, their members are recruited from the ranks of municipal aldermen as well as the two provincial executives. The domains covered are: Sustainability; Building and Housing; Landscape; Art, Culture and Heritage.

5.4 The power of meaning

What capacity do the TAA and the MRA have to shape perceptions and beliefs, both within the partnerships as well as the outside world? In its publicity material the TAA emphasizes its *functional* relevance: ‘working for a region in which people can quickly and easily reach their destination’ (TAA, n.d.). Interestingly, if one visits the website and clicks on ‘area’ the menu does not only show the municipal members but also the MRA which suggests that the TAA is not just active within the perimeters of the area formed by its 15 municipal members but in a much wider area, forming an integrated mobility system.

As the TAA is a mandatory form of cooperation, there is less need to work on its profile and relevance. In contrast, the MRA is a voluntary sort of organization with a much wider focus and a much bigger area compared with the TAA. There is therefore much more needed to show relevance, in particular to keep its membership together. In such a context framing becomes particular important: creating perspectives how to understand or perceive a particular, complex situation (Rein & Schön, 1993), in this case an area. This can be done through words and images.

To start with the first, two particular concepts are important. Going through the material produced within the context of the MRA, there is a particular emphasis on the Metropolitan Area as a *daily urban system*, a space forming a coherent area for its inhabitants.¹⁰ This obviously suggests it is only ‘natural’ to regard this area as a logical object of policy cooperation.

The second highly relevant concept here is the conception of the North Wing of the Randstad as Metropolitan Region Amsterdam. At the 7th North Wing Conference, December 2007 the decision for the name change was taken, only two months after the decision to abolish the Randstad Region. Both events were connected to each other. North Wing obviously is linked to Randstad as the concept originates from a discussion about its structure and morphology. Doing away with the Randstad paved the way for another ‘label’, much more attractive due to the connotation of an area being a metropolis: a world class regional city, based on Amsterdam.

Also images play a role in the perception of the MRA. Early 2008, after a year of intense debates, conferences and design studios a 138 pages vision document was published (MRA, 2008). Its key image served as a kind of logo for the years after (Förster et al., 2016: 17-20) (see Figure 6).

¹⁰ See for instance: <https://www.amsterdam.nl/bestuur-organisatie/volgs-beleid/ontwikkeling/metropoolregio/> (accessed 15 May 2019).

Figure 6 The 2008 vision of the MRA

Source: MRA, 2008: 50

In 2016 a new policy map has been created. This time it is not called a development vision but an action map (*actiekaart*). It is part of a glossy of 60 pages bearing the names of dozens of authors, under the auspices of the Platform Territory (MRA, 2016). It is not a replacement of the development vision but an addition, showing all the projects which are carried out in the region over a period of about four years (2016-2020), obviously suggesting the MRA cooperation has drive, momentum and practical relevance.

6. Conclusions

The Netherlands is obviously no exception when it comes to the rescaling of governance. What is striking is the duration of the ‘quest’ and the many turns that have been taken over the course of time. The four broad categories of metropolitan governance arrangements as identified by the OECD have all been discussed at some stage. A fifth model was also considered: an new fourth layer of administration across the entire country, including elected councils. The fourth model, special status of metropolitan cities (the proposal to create city-provinces) finally seemed to become the trajectory for seven regions but resistance from civil society and eventually parliament led to the option of inter-municipal authorities (the WGR plus regions).

Government and parliament has changed its mind time and time again: the perceived lack of democratic legitimacy was the insurmountable stumble block. Since 2010, just two metropolitan regions exist in the country, both situated in the Randstad. In these two regions, there is currently a supra-local authority in the domain of (public) transport with some measures to safeguard some form of legitimacy by giving elected members of local councils an advisory role. The two authorities are almost exclusively dependent upon government funding as municipalities (and provinces) have a very slim tax basis. Clearly, the abolition of the multi-purpose city-regions in the Netherlands runs counter to trends in metropolitan governance as observed by the OECD.

For a large-scale Randstad authority, governance complexity simply proved to be too great while the level of functional integration between the various parts of the Randstad, as expressed by for instance commuting patterns, is lacking. Next to the two statutory Randstad

transport authorities soft-coordination takes place under the banner of ‘metropolitan regions’. The MRDH is more focused on economic development while the area is the same as that of the transport authority. The MRA is much more comprehensive in its ambitions and is ‘working’ for an area almost twice as big compared with the Transport Authority.

Looking at the MRDH and MRA in more detail, we arrive at the following conclusions in relation to the three categories of power on which our analyses are based. When it comes to the *power of resources* both regions are almost exclusively dependent on national government funding, at least in the transport domain as already stated. Outside this domain there are (very) limited resources for staff and projects, although especially in the MRA there seems to be a large multiplier effect in relation to staff due to the comprehensiveness and multi-scalarity of the cooperation.

From the perspective of the *power of process* we conclude that the two metropolitan regions seem to slowly converge in the way in which they are organised. Both have, for instance a daily board and a supervisory board, the latter mostly recruited from municipal councils. Nevertheless they also show two major differences: the province (i.e. North-Holland and Flevoland) is a prominent participant in the MRA and joined as of the start. At the phase of emergence of the MRDH the province was even foreclosed. Currently the province participates in some of the MRDH committees.

The second major difference is geographical in nature: even though there might surely still be discussion about the exact external borders, it is the intention of the MRA to be inclusive and cover the whole daily urban system of Amsterdam in its metropolitan governance arrangement. In the MRDH two urban agglomerations (Leiden and Dordrecht) which functionally are part of the daily urban system in this area are not represented in the metropolitan governance arrangement. From this perspective there seemed to be a fundamental flaw in the set-up of the arrangement. This may have an impact on the degree to which policy integration in the focus policy areas can be reached.

With respect to the *power of meaning* we observe a major difference in the fact that the MRA is actively using visions, maps and spatial images as a way of bringing coherence in the issues at table between the actors involved and in the projects and programmes at stake in the region. Accessibility, economy and spatial planning seemed to be much more aligned than in the MRDH where spatial images are nearly non-existent and spatial planning is not a policy field with which it wants to relate. Economic development is the the integrating frame here.

Institutional change and regional transition

Advisability of Reintroducing the Building Code document to Canton Sarajevo Spatial and Urban Planning Legislation

mr.sci. Nataša Tabori, dipl.ing.arh.

Institute for Canton Sarajevo Development Planning, Natasa.Pelja@zpr.k.gov.ba

Abstract: In most European countries urban planning is a process controlled by many instruments, among which is a building code document. Sarajevo, as a part of former Austro-Hungarian Monarchy, got its first Building Code in 1880, followed by a second Building Code in 1893. Ever since, the Building Code Document is missing in Sarajevo's spatial regulative, which resulted in unclear building procedures and urban "cacophony". In 1936, there was an attempt to make a unified Building Code for all cities in former Kingdom of Yugoslavia, but it failed in its implementation. Today, in Canton Sarajevo, the procedure of obtaining the urban permit has no clear structure and rules for how to build in a specific urban area. Obtaining the building permit depends on individual aesthetic criteria of municipality clerk who is creating an individual frame of rules. This makes procedures unclear, not transparent and often open for corruption. The result of unclear procedures is urban and architectural "cacophony", which is especially visible in the urban area of Sarajevo valley. Situated in South East Europe, after the fall of Berlin wall in 1990 the city has faced some dramatic changes due to Yugoslav wars and the transition processes, among which is transition from the former socialist political and economic system to the capitalist system which specifically affects spatial planning and development process.

Keywords: Building Order; City Transformation

Introduction

From when exactly do we have written traces of the idea of order in European urban planning and how exactly did this idea transit from the Ancient times until today? Most European cities have ordained urban planning systems and the building code as an urban planning instrument, but what happens in those European cities whose idea of order was somehow lost in transition during the last century and they don't have building code for more than a hundred years? Is it advisable to reintroduce a building code document in former socialist countries in Europe and how it can affect its spatial planning systems?

Building code document is a spatial and land-use planning instrument which is constantly being novelized by a specialized boards and committees responsible for urban planning. It is the reason why in a contemporary urban planning management different models are being developed to optimize all planning processes and to ensure fulfillment of the urban planning goals through urban planning instrument realization.

In this PhD Research, which is still being conducted by the researcher, past review studies are given for the research subject which is "Introducing a building code document" in cities which previously did not have this kind of documentation, specifically to Canton Sarajevo. The main goal of the research is developing a model which will enable systematic management of urban planning process. Starting

hypothesis of the research is that it is advisable to reintroduce the building code document to Canton Sarajevo Spatial and Urban Planning Legislation. The research is referring to Architecture and Urban Planning as the main area, as well as Urban Legislation, as a sub area.

The results of the research have both scholarly and managerial perspectives in Canton Sarajevo spatial planning education and management.

The idea of order in European urban planning

One of the first systematic attempts to create written rules for cities was that of Vitruvius in his book from the first century B.C.-The Ten Books on Architecture (Vitruvius, 1914) known as *De Architectura*. Idea of Order existed in Ancient Greek architecture and city planning, but not in an ordained written form as Vitruvian Books, therefore this absence of such a document will motivate Vitruvius to write it. According to McEwen (McEven, 2003) Pierre Gros, "...the acknowledged leader in current Vitruvius studies" (Gros, 1971), "...concluded that Vitruvius's project was essentially normative one, motivated by the desire for rational systematization" (Gros, 1973). The Ten Books on Architecture will remain the reference for normative form in architecture and town planning until the late 18th century: "The only major work on architecture to survive from classical antiquity ...the treatise known to posterity as *De architectura* in time became the text of architectural theory to which, at least until the 18th century, all other texts referred" (McEven, 2003). The Age of Humanism led by Trisino, Palladio and Alberti will give its interpretation of Vitruvian order in architecture and urban planning, but it will not produce a new normative form (Wittkower, 1988). Absence of new normative form in architecture and urban planning will last until the 17th and mid-19th century when first London, and then Paris, facing the problems of hygiene in the city will take the whole set of actions for ordering their cities in a new form. This waste set of actions taken to transform growing cities in 19th century will be characterized as Haussmanization and cities like Vienna or Barcelona will follow its logic of order in urban planning. Law, order, uniformity – all these are special product of Baroque Capital (Mumford, 1970). Because of the new order we may speak of the width of streets, building heights, façade treatment, boulevards, railway stations and city networks (sewage, water etc.). It will make an introduction of a modern city development as we know it today.

This idea of order based on classical principles will remain in Europe until the appearance of Bauhaus, Cubists and Le Corbusier whose idea of urban order will be diametrically opposite to the comprehension of a city development until then. Burchard quotes Saalman who points out the ambivalence of Congrès Internationaux d'Architecture Moderne (CIAM) led by Le Corbusier towards Haussmann while seeing him, on one hand as a nineteenth century prophet of the new planned order (Burchard, 1974), while on the another hand Haussmann's idea of order, though, would be severely criticized by Charles-Édouard Jeanneret - Le Corbusier and CIAM for not going further with Paris transformation: "It is not that Haussmann and Napoleon III went too far, but they did not go far enough" (Burchard, 1974). Le Corbusier went far enough and proposed first "La Ville Contemporaine" in 1922, and then "La Ville Radieuse" in 1935 (Curtis, 1986), the new urban order of a city for three million people (Mumford, 1970). He drew mechanic-centric plans for monumental skyscraper cities, with multiple streets (Mumford, 1970).

Le Corbusier's Ville Radieuse idea affected many cities: "Le Corbusier's numerous urban projects of the 1930s show how he attempted to modify his abstract typologies to a variety of pre – existing topographies and cities" (Mumford, 1970).

His student Juraj Neidhard spread his ideas of the new order in Sarajevo and other cities in former Yugoslavia, after his experience in Le Corbusier's Atelier in Paris from 1933-1935 (Kapetanović, 1990). Karlić Kapetanović wrote: "While other architects of Sarajevo designed primarily urban residential buildings in the spirit of modern movement, Neidhard – bearing in mind the CIAM conclusions – was building a vision of social standard which was completely adapted to the building and visual trends of modern architecture in symbiosis with the autochthon traditional Bosnian house, with prevalently Oriental concept" (Kapetanović, 1990).

La Ville Radieuse preceded to the postmodern age of our cities and the postmodern idea of order: "This concept of order as an internal organization (or contract), based upon flexible relationships, rather than upon categorical bonds, has no longer any relationship with either the old absolute totalitarian – continual and stable – notion of classical composition or with the modern – more relative, removed and fragmented (but equally determinist) – position. Rather it relates to a more open and paradoxical conception of the idea of order as disposition... A new type of flexible order that shows itself more predisposed to the generation of open dispositions (processes) than to that of closed designs (objects)" (Manuel Gausa, et. al., 2003).

This new idea of order, but foremost, switch in urban scale characterizes works of Rem Koolhaas (Koolhaas & Mau, 1995). Verschaffel, when writing about Reading Rem Koolhaas mentioned that Koolhaas poses vitally important questions: "What is going on? Where does the specific combination of an unlimited growth, demographic explosion, globalization and capitalism lead to? What does it do with the World?" (Verschaffel, 2013).

But before Koolhaas's distinguished criticism: "... the ideas and concepts underlying the western architectural tradition we still use to 'navigate' through these turbulent times are not in themselves wrong or meaningless, but belong to a very specific context and history, and should not be considered essential or eternal, and not valid everywhere. Europe is not the measuring stick for the world" (Verschaffel, 2013), we will go back to the 19th century and European idea of order, which was transposed in a document called Building Order/Building Code / Code Civil / Bauordnung / Regolamento edilizio etc.

Building Code Document History

Paris was the first European capital to establish the building code document, due to specific circumstances in the city's history and precedent laws and subordinate regulations, brought from the end of 18th to the middle of the 19th century.

Landau in his analysis on Paris street fabrication wrote: "Hygiene and health, after the terrible epidemics of cholera in 1832, typhoid fever (there were 7,000 deaths from typhoid fever between 1872 – 1877), and tuberculosis are at the center of the concerns of the technical elite and those responsible for the disease – administration. The issues of water supply and sanitation in the city are among the most urgent to address. The smells – Paris smelled bad – are omnipresent; realistic literature testifies to this. Aeration, ventilation, dust control mobilizes the research and innovation capabilities of engineers and companies. The aspiration to comfort and well - being, carried by the new urban social layers, poses the problems of distribution of energy to individuals: heating, electricity, telephone. The issue of daily migrations, pedestrian traffic, private cars and public transport remains a hunting problem for everyday life and the growth of the economy" (Landau, 1992).

Landau gave very precise description of the processes which lasted for a century and have led to regulation modification and completing in a document named Code Civil in French, or a Building Code

in English. The new regulation form of urban planning was rapidly accepted in other European countries, or more precisely empires, among which was Austro-Hungarian Empire, at the time and its capital Vienna: "... we talk about a big project, a Program, according to Haussmann's definition, which had to be "completed" and "perfected" to transform the old Paris. It seems that Joseph Alexander von Hübner, Austrian Ambassador in the Second Empire period, shared Haussmann's opinion. He knew Haussmann privately, met him often and considered him the inspiration and soul of all those works which he admired in French capital. It is interesting to notice that the ambassador stayed in Paris from 1851 to 1859, and soon after, Vienna will announce the competition for systematization of the Ring, which will provoke Austrian Capital to experiment with its own model of urban reconstruction, different from Paris, but at the same time, analog to the French capital, by the initiatives for the role of public buildings and introducing the infrastructure networks" (Tamborrino, 1998).

Anna Hagen, when writing on Viennese building codes and planning instruments in the 19th century elaborates on four important dates in Vienna's building regulation history in 19th century: 1829, 1859 and 1868 and 1883. Under the circumstances like historic urban circumstances of Paris – cholera epidemic (Hagen, 2015), no sewage and water system, it was obvious that the city had to organize itself in a new way.

Hagen concludes that urban form is a sum of all the elements which form the city in relation to building regulations (Hagen, 2015). She quotes Harald Stühlinger defining two different levels of building standards that influence the city's image. On one hand, there are hard factors, such as building dimensions and street width, and on the other hand, soft factors, such as details of the surface design elements such as paving or façade openings and protrudes (Hagen, 2015).

Vienna, as the capital city of the Austro-Hungarian Empire spread the idea of order in urban planning in all parts of the former monarchy.

Sarajevo, as a part of the Austro-Hungarian Empire got its first building code and regulatory plan, shortly after the Annexation of Bosnia and Herzegovina. Before elaborating on Sarajevo building code regulations, we will analyze in brief Sarajevo urban history background.

Sarajevo Urban History since Ancient Times

Sarajevo was inhabited since Neolith. Today's main Sarajevo roads are situated on Roman *Cardo* and *Decumanus*, with its crossing in the city center, near today's building of the Institute for public Health (Mutapčić, 2018).

Figure 1 Roman City (SOURCES Bublin M., Sarajevo throughout the history – from Neolithic settlement to metropolis)

The name Vrhbosna (Verboxenie) as the name of the region to which Sarajevo belonged officially appeared only in 1244 (Skarić, 1937). We have very limited knowledge of this period, apart many particularly beautiful tombstones with drawing engravings (Bos. stećci¹) which have been founded in Sarajevo area” (Skarić, 1937).

¹ Stećci – see Figure.2

Figure 2 Stećak
(SOURCES Institute for
Canton Sarajevo
Development Planning)

Figure 3 Sarajevo in the Middle ages (SOURCES Bublin M.,
Sarajevo throughout the history – from Neolithic settlement
to metropolis)

Turkish invasion begun in the 14th century. The city has been built on the both sides of Miljacka River around deputy's castle (Tur. Saray), which has been built on the left river Miljacka's bank. The name Sarajevo is combination of two words in Turkish: castle (Tur. Saray) and field (Tur. Ovasi) meaning the field around the castle (Skarić, 1937). The logic of Ottoman city was to build the city center in the valley and residential areas on the hills. The city center (Tur. Čaršija), was situated in Baščaršija², the name which remained until nowadays. The population of Sarajevo was partly employed in the army and partly were tradesmen, merchants and craftsmen, who had their shops in Baščaršija (Skarić, 1937).

Figure 4 The formation of the City in the Ottoman period (SOURCES Bublin M., Sarajevo
throughout the history – from Neolithic settlement to metropolis)

² Baščaršija - Sarajevo Old City, the city center

Figure 5 Sarajevo in the XVI century (SOURCES Institute for Canton Sarajevo Development Planning)

Sarajevo residential houses (see figure 6), built in neighborhoods (Bos. mahalas) on the hills, were amphitheatrically surrounding Baščaršija in the Ottoman period. The houses had, wherever it was possible, a garden of the same size as a house...The reason, Skarić wrote: "...was the love, which characterizes Sarajevo citizens until nowadays, for nature, greenery and flowers" (Skarić, 1937).

Figure 6 Residential areas in the Ottoman period (SOURCES Bublin M., Sarajevo throughout the history – from Neolithic settlement to metropolis)

On August 19th 1878 Austro-Hungarian troops have occupied Sarajevo, capital of Bosnia and Herzegovina. On February 17, 1908 Bosnia and Herzegovina got its Constitution and on June 15, 1910 the first parliamentary sitting of Bosnia and Herzegovina Parliament took place. The city was developing. It was changing its appearance. It was losing its decidedly oriental character and was increasingly becoming a European city (Kreševljaković, 1969).

Figure 7 Sarajevo in Austro-Hungarian period (SOURCES Bublin M., Sarajevo throughout the history – from Neolithic settlement to metropolis)

During the period of the Kingdom of Serbs, Croats and Slovenes and the Kingdom of Yugoslavia (1918 – 1941), between the two world wars, Belgrade has become the capital of the Monarchy, while Sarajevo lost its role of the capital city.

Bosnia and Herzegovina became part of the Independent State of Croatia (NDH) in 1941. The Sarajevo County has become the seat of the Great District of Vrhbosna. As the state declared to be supported by the Nazi Germany and Fascist Italy NDH regime started to implement race laws (Nurnberg laws and decrees, Law for the Restoration of the Professional Civil Service etc.), which ended up with the massive liquidation of Jews, Gypsies and Serbs. During 1944, allied forces bombarded Sarajevo several times.

Communist party and partisans entered the liberated city as winners on April 6, 1945. It was essential to make legislative base for huge reforms of the society and among first laws were: Agrarian Reform and Colonization Law in 1945 and Workers Self - Management Law.

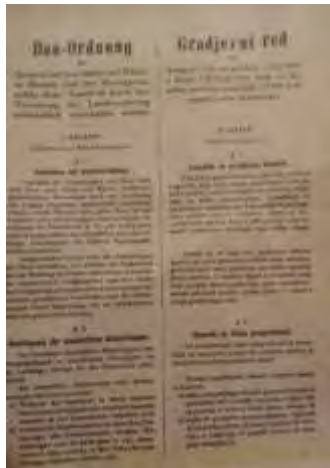

Figure 9 The Building Code 1893 (SOURCES Archive of Bosnia and Herzegovina)

Figure 10 Regulation of river Miljacka basin during the period of Austro – Hungarian Monarchy (SOURCES Institute for Canton Sarajevo Development Planning)

There were few attempts to create the new building code: in 1936 during the period of the Kingdom of Yugoslavia and in 1976 when the City Assembly wanted to create set of rules, although only for housing buildings. It was the Decision on general technical conditions for design and construction of residential buildings and apartments.

The Decision on general technical conditions for design and construction of residential buildings and apartments and the Project of Research and organization of drafting the urban norms on content of neighborhoods were serious attempts to introduce higher standards and building quality in residential architecture and urban planning and a good preparation for its implementation in the City of Sarajevo Land-Use Plan for the period 1986 – 2015 in the eighties, but the whole process was interrupted by the Yugoslav wars.

Yugoslav wars culminated with the siege of Sarajevo, which lasted from April 1992 till November 1995. It was: “the worst conflict Europe has seen since 1945, with more than 250,000 deaths and two

million people displaced.” (Benkova, 2016). This tragedy for the City ended up when the Dayton Peace Agreement (UN, 1995) was formalized on November 21, 1995 in Dayton, Ohio and signed in Paris, almost a month later. The Agreement, signed by the presidents of Republic of Bosnia and Herzegovina, Republic of Croatia and Federal Republic of Yugoslavia: “brought an end to the tragic conflict in the region” (UN, 1995), by subdividing the Republic of Bosnia and Herzegovina into two Entities: the Federation of Bosnia and Herzegovina (FB&H) and Republika Srpska (RS) and a special unit – the District of Brcko (DB). The Entities are divided with the “inter-entity boundary line” (UN, 1995).

Today, Canton Sarajevo is one part of former City of Sarajevo (Bos. Grad Sarajevo), which was consisted of ten municipalities and covered the area of 2,096 km². Another part of the former City of Sarajevo is in Republika Srpska and it is called East Sarajevo (Srpsko Sarajevo on the figure 10). Parts of municipalities Stari Grad, Novo Sarajevo, Novi Grad, Ilidža, Trnovo and the whole municipality of Pale belongs today to the City of East Sarajevo.

Canton Sarajevo covers the area of 1,277 km² or 60, 92 % of the former City of Sarajevo’s territory. Canton Sarajevo has its Constitution (Sarajevo, 2019), upon which it is consisted of nine municipalities. Today’s City of Sarajevo administratively is consisted of four central municipalities (Stari Grad, Centar, Novo Sarajevo and Novi Grad) and it covers 141, 5 km² (see Figure 11).

Figure 11 Outline border – former City of Sarajevo, Grey area – Today Canton Sarajevo, Federation of B&H Entity Darker grey area – today City of Sarajevo, White area – Srpsko Sarajevo (today East Sarajevo), Republika Srpska Entity (SOURCES Bublin M., Sarajevo throughout the history – from Neolithic settlement to metropolis)

In today Bosnia and Herzegovina each entity and all ten cantons in FB&H have their own legislation framework, which makes: "rather un-coordinated system, both vertically and horizontally" (ESPON, 2018).

The milestones of Sarajevo Spatial planning legislation can be seen on the following timeline:

Figure 12 From the building codes in 1880 and 1893, Building Law and building code in 1936, General Urban Plan in 1965, Spatial and Land-Use Plan in 1986 to new Spatial Plan in 2006 and Land-Use plan currently in procedure from 2016 (SOURCES Institute for Canton Sarajevo Development Planning)

The Spatial Planning Tools in Canton Sarajevo are hierarchically organized as in the following table:

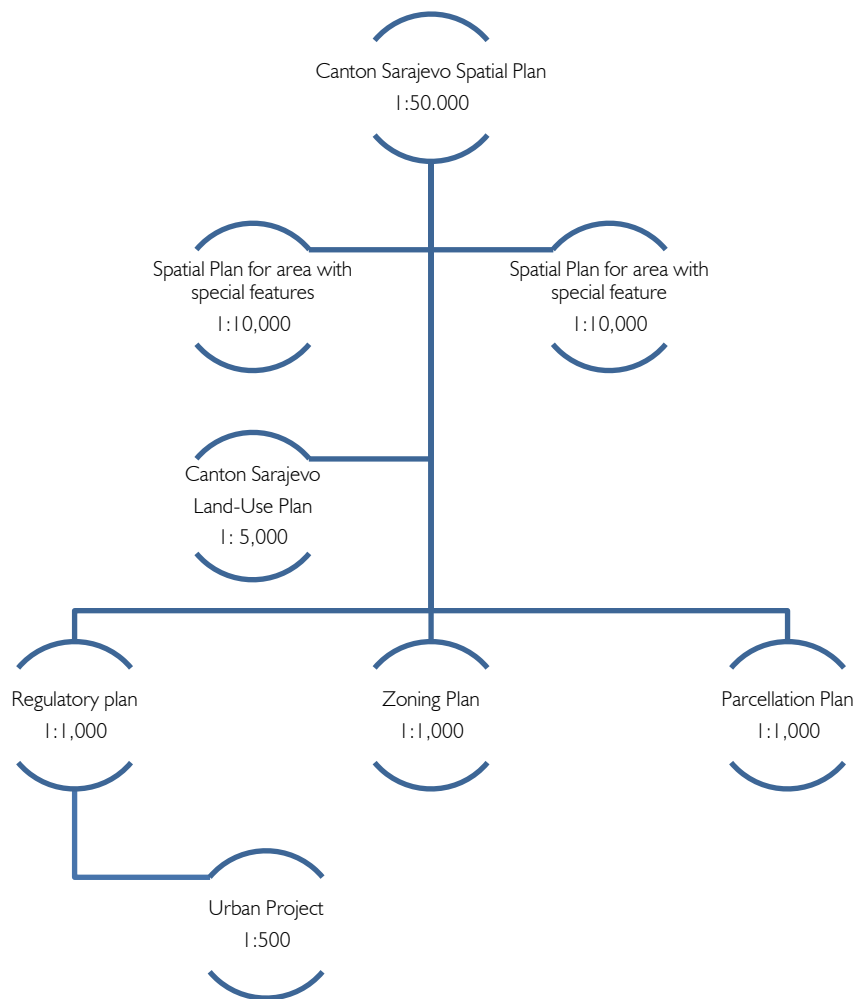

Figure 13 Spatial Planning Tools Hierarchy in Canton Sarajevo (SOURCES Institute for Canton Sarajevo Development Planning)

The elements and the content of textual and graphical parts of the spatial planning documentation are defined by the Decree on uniform methodology for creating the spatial planning documentation. Textual parts of spatial planning documentation are the following:

- Text of a Plan,
- Decision on Plan Implementation and
- Decision on Plan Adoption.

It is important to emphasize that the Decision on Plan Implementation is a legislative form which can be, to certain extent, comparable to a content of a building code, although in a very limiting form. It is written by an urban planner who prepares a plan and it varies from plan to plan in its content.

Graphical parts of a plan vary in accordance with spatial planning documentation level and type of a plan.

According to Canton Sarajevo Spatial Planning Law spatial planning documentation is basis for obtaining planning permission. Planning permission is issued based on urban and technical conditions

interpreted by municipality individual and his or her aesthetic criteria and ability to understand spatial planning documents and valid legislation, which makes the whole process challengeable in the matter of objectivity and rationality. There is no manual, nor additional spatial planning document in a form of an instrument which could easily be understood by authorities and citizens in a complex process of spatial planning documentation implementation and what is more important, which will make the process of obtaining the planning permission transparent, objective and based on equal right for all interested stakeholders.

Moreover, from the early nineties until today there is an "institution" of the "professional opinion", which can be demanded by a municipality in specific cases (when there is no valid detailed spatial planning documentation) for the purpose of obtaining a planning permission. This document may pose in question the objectivity in the legal procedure, since the professional opinion is written by an individual or a group of professionals organized in boards or comities, upon "not formally defined aesthetic, environmental and any other criteria" which is, as commented by Aganović in 1991: "...professional and social alibi for illegal procedures, brought in the municipalities... which is provided by "special", or "professional boards", in every municipality separately, without uniformed impact of the city on these processes, notwithstanding all passed spatial planning documentation of various government levels and responsible institutions" (Aganović, 1991a). Existence of a building code on a city/cantonal level for each city/canton in contemporary urban circumstances of Federation of Bosnia and Herzegovina would certainly give the solution which would contribute to extinguishing of improper forms such as professional opinion etc.

The problem of informal settlements has become official through the process of legalization, which became the only housing policy for informal building areas. Beside social, economic and political aspects of the phenomena, informal settlements may be connected to spatial planning documentation frequent renewal, but as well as to absence of certain rules and regulations for the areas in which informal settlements are erected. The solution for this phenomenon was given in the City of Sarajevo Council report from 1991: "...proper exploitation and channelizing of enormous potentials of private investments and initiatives, should be given through uniform and rigorous criteria at the City level" (Aganović, 1991b).

The last time the building code was mentioned and commented among City's spatial planners and professionals was at the Symposium „Sarajevo – Town and Region in Time and Space in the Year 2000th“, which took place in Sarajevo on April 23 and 24, 1981 and was organized by the Academy of Sciences and Arts of Bosnia and Herzegovina, University of Sarajevo and Town Council of Sarajevo: „Fortunately Austro-Hungary hasn't interfered in old parts of the city, apart for exceptional cases, the rigorous „Building Code for the city of Sarajevo“ was implemented, bureaucratically narrow-minded, but at least respected, which prevented more serious violations of the public interests“ (Academy of Sciences and Arts of Bosnia and Herzegovina, University of Sarajevo, Town Council of Sarajevo, 1982).

The severe criticism of the building code document was moderated with the recognition of this document's main objective - protection of the public interest.

After the urban development peak that Sarajevo has reached in the eighties, urban decay has started. It was precisely described in the report by the former Head of the Institute for the City Planning Development Midhat Aganović released by the City Assembly in 1991. We will not go into all fields

of this brilliant and primarily realistic work has embraced, but for the purpose of this research we will mention, as Aganović has written, the necessity to introduce urban standards: "Mentioned deformities in the City's spatial development are caused by: ...- the absence of urban norms, the absence of scientific work and the professional interest for this problem" (Aganović, 1991c).

Aganović continues: "Standards, norms and other regulations on preparation and equipment of residential areas, which are being implemented in the City are highly beyond our realistic economic possibilities. The City doesn't have any urban standards. Our residential areas and apartments in those areas, which have been built in the recent years, are not any different from the neighborhoods built in the European countries, whose gross domestic product (GDP) is even ten times bigger than our GDP" (Aganović, 1991d). The author, rightly, made the connection between the standards and the economy, but what is more important, he made the comparison between the standards in Sarajevo and the standards in the European countries, which is one of the main premises of this research.

Aganović was precise about the root of the problem: "Every municipality, upon its own standards, or with no standards at all alienates those values, without which urban life can hardly be performed" (Aganović, 1991). The author was considering public space, parks and plants, when speaking of urban quality life (Aganović, 1991e).

He was: "Amazed that in our society and the City hasn't matured yet awareness of the necessity to create and to enact uniform standards and norms in the field of spatial, urban planning and housing that would be the expression of our objective possibilities and needs-appropriated to the reached and planned level of the overall development. That is why we can't be surprised that enormous financial means have been invested to pretentious solutions which have accompanied our planner's efforts and aspirations to accomplish, in the recent 20 years, urban and communal standards of highly developed societies, whose GDP is beyond 20.000\$" (Aganović, 1991f).

In the end Aganović concludes that: "To ensure function of all integral parts of the City's complex and unique organism, the City should take the responsibility to: ... - create the development documentation, surveys, expertise, analysis, norms, standards and other enactments related to the City's life and development" (Aganović, 1991g).

Midhat Aganović, as one of the city's key figures in the field of spatial and urban planning during the communist period, was concerned with Sarajevo's future development in the beginning of the nineties. The situation will be aggravated with the war destruction and the post war reconstruction of the wounded urban tissue and the society, but the main problems of the urban development will, unfortunately remain until today.

In 1999 Federal Ministry of Spatial Planning and environmental protection with IMG (International Management Group) have published the Manual of standard building specifications for architectural design, norms, standards and other sign and execution of works of construction, reconstruction, sanitation and adaptation.

After overviewing the content of the Manual, published in 1999, and analyzing the manual itself we may conclude that its purpose was to summarize and to make data base of all valid norms in building and planning praxis in Bosnia and Herzegovina, in both Entities, yet it was not written in a form of a

building code. Its (Manual's) segments, though, are comparable to certain segments of building codes in European countries.

The Manual which was mentioned above was the only attempt in the postwar years, in Sarajevo, to make, at least, as a brochure, the comprehensive overview of all the standards which building code may contain.

Spatial planning tools in Canton Sarajevo, currently, do not recognize building code as a mandatory document. So-called Decisions of Implementation which are mandatory elements of every spatial planning document textual part are not unified in its form, for all spatial planning documentation, nor are classified according to canton municipalities. They (the decisions of implementation) are written by the planners and can't create systematic elaboration of all the factors of an urban form.

Creating of an urban form is the main purpose of a building code. Stühlinger is defining two different levels of building standards that influence the city's image, or city's form: hard factors, such as building dimensions and street width, and soft factors, such as details of the surface design elements such as paving or façade openings and protrudes (Hagen, 2015), by which we may conclude that this basic distinction can be used for creating a building code document. All city elements contribute to its urban image: "Very often the unjustifiably neglected details (park benches, fountains, squares, street illumination, sculptures etc.) can contribute significantly to a nicer and more humane way of living and the overall beauty of city landscape" (Bublin, 2008a).

Some of the authors of articles and books about spatial planning and urbanization process in Sarajevo, in the post war years, have recognized the need to: "...institutionalize the legislative and managerial environment for the preparation and realization of development programs and plans" (Bublin, 2008b). They do not speak about the building code specifically, yet it may be interpreted as a clue in that direction: "in contemporary developed societies, cities are institutionalized, which means the existence of certain public institutions with transparent work. Those cities have codified their laws, city regulations and standards, which is a basis for city functioning and development" (Bublin, 2008c).

Building code is as an instrument of controlled spatial and urban development, because. "...cities, as the most complex social systems, may function and develop only if properly managed, since the practice of spontaneous development no longer works out (Bublin, 2008d). There is a relationship between a building code, as a public policy instrument and the land-use planning: "There are number of public policy instruments that can affect land use. Most important among them are land-use regulations imposed through the land-use planning process and environmental and building code regulations" (OECD, 2017).

The importance of a building code is sublimated in the following sentence: „At present, public policy uses primarily two mechanisms to intentionally influence land use; it allocates public investments across space and it restricts how individuals and businesses are permitted to use land. Its main instruments are the spatial and land-use planning process and environmental and building code regulations“ (Bublin, 2008e).

Acknowledgements

I would like to express my deep gratitude to Professor Dr. Thomas Dillinger, my research supervisor, for his patient guidance, enthusiastic encouragement and useful critiques of this research work, which is still in the process of creation.

I would also like to thank the management and my colleagues at the Institute for Canton Sarajevo Development Planning, for supporting my research work from the start.

Finally, I wish to thank my husband and children for their support and patience throughout my study.

04. Institutional change and regional transition

The new dynamics between regional and urban governance: rural areas as connection element

Luca Torrisi

Università degli Studi di Palermo, luca.torrisi@unipa.it

Abstract: The dynamics of the expansion of the territory make us think about the fact that territorial development does not exclusively concern urban transformations but also synergistically involves rural areas. As part of the ongoing PhD thesis (tutor Prof. Maurizio Carta) we analyse the richness of the relationship between urban and rural and the vision of a landscape that is not only made of intensive production. The involvement of themes that can interact with each other makes it possible to strengthen the quality of production and its physical extension. This contribution considers the presence of networks among the agricultural entrepreneurs and it discusses the territorial context and the local communities. The synergies between users and rurality, not only intended as agricultural production, lead to a new competitiveness in this field. The increase in productivity is promoted through innovative processes that use new technologies and the social involvement connected to the quality of agriculture. The case of the Inner Area of Madonie is an example: a territory that has led to think of innovative strategies spread throughout the territory and not aimed to a single Municipality, to cope with the development difficulties connected also to the morphology of the site.

Keywords: rural areas, agriculture, landscape, local development

Introduction

Many European countries, in particular Italy, are characterized by the variety of issues concerning their territory. Specifically, Panunzi (2017) states that geography and landscape find their own representation in social, cultural and economic characteristics. These components inevitably interact with each other and, at the same time, cause gaps between the various territories more through human action than natural causes. The differences are reflected between north and south as well as between city and countryside, leading to the need for a rebalancing that leads to the overcoming of marginality, for a sustainable revival in the cultural and economic sphere. The Italian territory, given the different naturalistic and environmental conformation, is characterized by different levels of spatial periphery and infrastructural, social and economic disadvantage (Marchetti *et al.* 2017) but also by wealth of resources and natural heritage in the cultural, landscape and biodiversity fields. These conditions are

found in the territories identified as inner areas¹, which are affected by the actions that humans have performed on the quality of nature and are characterized today by demographic problems although they are highly polycentric and with a widespread historical and territorial heritage (Marchetti *et al.* 2017).

For many years the inner areas have been labelled as marginal and difficult contexts, characterized by difficulties in production and habitability. In these areas it has thus intervened with the logic of economical subsidies instead of using programming strategies. The absence of specific strategies led from the mid-nineteenth century to large migratory waves and, consequently, to the abandonment of fields, pastures and villages, despite the quality of floristic and faunal biodiversity, landscape, cultural heritage and food and wine (Marchetti *et al.* 2017).

As far as the production of the agricultural sector is concerned, especially in the South of Italy, agricultural employment rates in the inner areas are higher than those in other areas, even if intensive and mechanized agriculture has resulted in a reduction of the number of people employed and the depopulation of these areas with population transfer to the cities (Moroni, 2008). Today, employment in agriculture (Istat, 2010) for young people under 39 is equal to 9.97% in Italy and 12.01% in Sicily. The trend towards the abandonment of agriculture shows contrasting values in the percentage of the number of farmers up to 39 years in Italy (-0.47%) and in Sicily (+ 1.69%). Even the percentage of part-time management of agricultural enterprises has high values in Italy (98.30%) and in Sicily (99.50%). Values indicative of the fact that the income deriving from the agricultural activity alone is not sufficient for the complete sustenance of the entrepreneur (Mortellaro, 2017). However, there is an important presence of quality brand productions in Italy (1.56%) and in Sicily (2.67%) which lead to the activation of local production routes (D'Angelo, 2015). Therefore, the strong rural potential of inner lands, particularly in the Southern part of Italy, can be a strong point in local development strategies. Thus, policies to enhance natural resources are activated to promote agricultural products by the means of appropriate territorial marketing strategies (Mortellaro, 2017).

Polycentric territorial development and the overcoming of boundaries

The territory and, consequently, the planning are currently subject to a change in their nature. The change in the territorial balances, connected to the displacement of the population from the hilly and mountainous areas (population decrease) to the flat areas and to the cities (increase), has been developing in the last years (Palmieri, 2017). The decrease in the population that has characterized (and is still marking) a specific and significant portion of the national territory has worsened, as a consequence also of the country's financial crisis. This decline has led to an institutional weakening,

¹ The inner areas are defined by the SNAI as areas distant from the centers offering essential services (education, health and mobility), rich in important environmental and cultural resources and highly diversified by nature and after anthropization processes (SNAI, 2013).

the contraction of services and public facilities (Borghi, 2017) and a change in the capacity of channeling broad public resources, often understood as a form of assistentialism (Provenzano, 2015).

The relocation of the population to the cities and the decrease in rural areas in favour of urbanization processes are highlighting new dynamics within the territory that lead to think of the latter not as an element in itself, but as a system consisting of networks and capable of generating innovation (Carta, 2014).

Therefore urban planning processes are increasingly looking outside the municipal boundaries and, therefore, to systems and networks between municipalities through instruments such as conventions, inter-municipal unions, consortia, valley or river communities, program agreements. These are forms of relationship, which have given the possibility to elaborate common strategies able to overcome the limits of the administrative boundary. It is possible, in this way, to promote development in different sectors that can also concern surrounding municipalities with similar interests, because they share the identity of the place to which they belong and of the social groups related to it (Pazzagli, 2017).

Therefore, it is necessary to work on the knowledge, on the valorisation and on the integration into a system of the territorial heritage, because the activation of these endogenous values contributes to improve the quality of life and to generate new lasting economic flows (Magnaghi, 2010). Territory, environment and landscape capture value as common goods and as a model for sustainable development from an economic, social and environmental perspective. Values that also concern, perhaps mainly, the inner areas that need knowledge of the resources and of heritage of the territory as exclusive and non-reproducible resources (Becattini, 2015). The transformation of these territories, also characterized by the presence of towns with small population and territorial surface, was regulated in Italy in the 1990s by the Law on local autonomies (Law 81/1993) and on the decentralization of functions and administrative simplification (Laws 59/1997 and subsequent, known as "Bassanini reforms"). Not surprisingly, in this period the "identity associations" had spread: those are relations between the Municipalities that deal with typical products or cultural heritage and associations for the protection of the cultural, environmental, tourist, food and wine heritage. Factors that, despite having experienced difficulties in the following decade, have been leading in recent years to the territorial promotion of small Municipalities located in inner lands. Furthermore, these factors are allowing the relaunch of local development and the enhancement of the cultural and identifying heritage of the territories. Therefore urban planning processes are increasingly looking outside the municipal boundaries and to systems and networks between municipalities through the concept of urban regions (Balducci, Fedeli, Curci, 2017). The dynamics once linked to the urban sector have today shifted to the new regional dimension, consisting of networks (not borders) and the generative power linked to the social, environmental and economic system. This polycentric complexity of the territory leads to a territorial development that does not exclusively address urban transformations, but that actually ends up in synergistically involving rural areas. The territorial system aims to include urban and rural areas within a system that can be read as unitary by the dynamic structure of the "rur-urban archipelago" (Carta, 2017). This model combines the polycentrism of the territory with the identity that typifies the territory itself, experimenting innovative forms of planning that guarantee a new balance between rural and urban and highlight, in the relationship between urban and rural, both productive and environmental visions. The network system is made up of connections that are not only immaterial (Barbieri, 2015), but also material ones that increase the efficiency of territorial systems to make them developed and economically advanced.

Strategies for the renaissance of rural areas

The implementation of innovative policies concerns not only local development, but also rural development, starting from the presence of a current situation in which marginal areas, particularly in the South, have suffered over time from fragility due to the economic and productive fabric and to public administrations also for the realization of basic services (Vinci, 2010). The national scenario, supported by statistical analysis, currently sees a continuous increase in the conditions of marginality due to economic and social fragility. This situation is related to the demographic decline due to depopulation and emigration and, in areas mainly devoted to agricultural production, also to the decrease in both employment and economic development.

This representation, however, is followed by the presence of global, community and national strategies referring to the 2014-2020 programming which also promotes actions related to rural areas, although they are often parallel and not connected to each other.

An example is the global action of the 2030 Agenda for Sustainable Development: an action program involving 193 Organization of United Nations (OUN) member states.

In rural areas it intervenes on food security and, more generally, on sustainable nutrition and agriculture. This serves to obtain sufficient food throughout the year with sustainable cultivation and food production systems, keeping the ecosystem and the diversity of seeds and plants to be cultivated intact. The Agenda also deals with the environment and, in this case, with the healthiness of the water, guaranteeing its sustainable management and adequate hygienic conditions, making it clean and drinkable. From an economic point of view, the program wants to promote lasting, inclusive and sustainable growth to promote innovation. These aspects concern, in addition to agriculture, the industrial sector, supporting the entire economic development and well-being, using technological development and research.

At the same time, actions are being promoted for a new rur-urban collaboration that will allow the development of rural areas starting from the adoption of a decentralized urban organization capable of facilitating the growth of potential and the reduction of territorial differences. As in the case of INTERREG IVC projects, funded by the European Union Regional Development Fund, which often aim at urban-rural cooperation for the implementation of practices related to economic, environmental and innovation aspects.

In parallel, strategies of Italian interest are implemented, as in the case of the National Strategy for Inner Areas named “Strategia Nazionale per le Aree Interne” (SNAI). This strategy, in the rural areas, aims at their promotion through strategies aimed at developing places such as the reversal of the decrease in the used agricultural surface and of the number of farmers in the rural areas identified on the basis of the classification of the national territory. The National Green Community Strategy that promotes economic development with both productive and environmental value is an example. The Green Communities are defined by communities that are formed, compacted and facilitated through actions that develop the attractiveness of a public able to become an active part of the dialectical exchange between nature and culture (article 72 of the law 28 December 2015 n. 221). It also favors the presence of a sustainable development plan that looks at energy, the environment and the economy.

Parallel to these strategies, the Rural Development 2014-2020 of the National Rural Network must be considered through the involvement of different stakeholders, highlighting opportunities for young people and promoting innovation in the agri-food and forestry sector by identifying a financial security to manage national and regional level programs, co-financed in a multi-year framework.

The “Resto al Sud” measure involves the regions of Southern Italy and considers the difficulties young people face in finding employment and the difficulties of the agricultural sector. The goal is to start up businesses to develop the economy in the agricultural sector. In accordance with this measure, the rule on the whole of unused lands named “Banca delle terre abbandonate o incolte” provides for the identification of lands and areas built in a state of abandonment by the Municipalities, in order to be assigned in concession for agricultural activities.

Sustainability and circular economy in rural areas

The propulsive centers, expensive in the use of raw materials, have had a different use of resources than the internal areas due to the physical distance that often separates the two realities. Thus, the internal areas have managed to preserve social, environmental and identity values: a necessary starting point for re-thinking relations with the rural dimension and for generating new forms of creativity. Therefore, we need a model capable of implementing a process that is able to fully use the resources that characterize the territory without, however, exhausting them in order to increase the life cycles of resources (Webster, 2015). Especially for small towns, we need to adopt strategies aimed at sustainability: reducing the consumption of soil in the recovery of the relationship between humans and nature and recycling of production waste (Carta, 2015b). Through a more conscious use of the available raw materials, it is possible to operate in accordance with local, sustainable and environmental development² starting from new strategies linked to social and economic development connected to the identity of the territory. The ability to a continuously renew, activate or reactivate places and resources, in order to facilitate opportunities for cultural, social and economic growth (Carta and Lino, 2015). Thus we arrive at the hypothesis of a "2.0 local development" (Carta, 2015a) which considers innovation as the possibility of a new metabolism for the local territory. Local innovation considers the use of the circular economy (McDonough and Braungart, 2002) as a method capable of restoring the initial capital and allowing new flows of goods and services. The principles of the circular economy are reflected not only in the consolidated city, but also in rural areas, relying on an economic and productive aspect that is increasingly diversified by the production of edible products and promotes new economies around local identities, in particular in territories from the historic agricultural vocation. The model developed by Webster (2015) links biological instruments and technical tools to determine a circular economy model. The relationship between technical tools of the circular economy (recycle, renew and regenerate, re-use and redistribute, maintenance) and

² Local development is not intended as an endogenous development, with a decisive and exclusive role for local agents and with an obligatory development path (Coffey-Polese 1984). Its meaning is connected to the plurality of development models and to the interaction between local subjects (public and private) that share a development idea based on the valorization of the resources of the territory (Garofoli, 1999).

biological tools (agriculture, re-establishment of the biosphere, biochemical raw materials, biogas, anaerobic disposal and composting, extraction of biochemical raw materials) generates new models of economic development and self-sufficiency (Guallart, 2014) capable of relating aspects of a technical nature with biological elements. The ideals transmitted by the circular economy are a fertile field, particularly in territories with a historically agricultural vocation, where new knowledge on the use of resources can allow the overcoming of the ideal that sees productivity as a factor of greater importance than the quality of territory (Bisciglia *et al.* 2019).

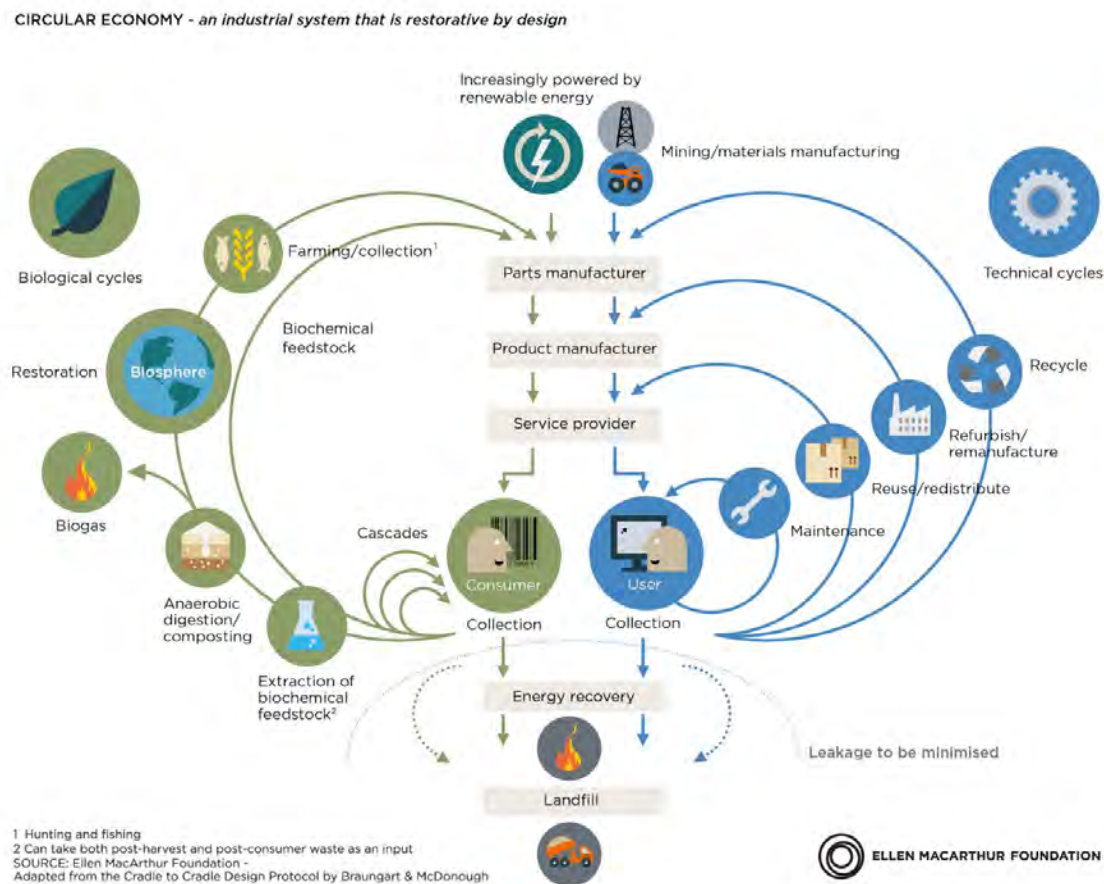

Figure 1. Use of resources in a circular economic system. Source: Webster, K., 2015, *The circular economy: a wealth of flows*, (COWES: Ellen MacArthur Foundation Publishing)

There is an ideal that looks to the green economy for the clean and safe production of goods, materials and energy, for the reconstruction of natural ecosystems and for the reduction of emissions and pollution factors, with greater efficiency in the use of non-renewable resources (Webster, 2015). This, however, once again leads to a reading of the territory that differs from its identity and from the landscape peculiarities, which are capable of adding value to the entire system. Polycentric territorial development requires a wide-ranging sustainable approach and considers the economic, social and environmental aspects. In addition to the circular economy, in economic matters it is necessary to look at economies increasingly geared to the intangible aspect. As Carta (2015b) states, we need economies based on access rather than on property, on sociality rather than on egoism, on well-being rather than on having, on efficiency rather than on consumption or on the sharing economy. In the environmental topic, strategies are needed to reduce the ecological footprint by upgrading the

agricultural activities and increasing the quality and uniqueness of the products. Furthermore, in the social topic, coordination between public and private actions and the empowerment of local communities is needed (Carta, 2017). All these actions are driven by recovery, recycling and restarting of communities, productions and settlements.

Rural development between sustainability and agriculture

The development of rurality is implemented in rur-urban life models not only aimed at marginal contexts and at the quality of agricultural production, but also connected to new features and services (Magnaghi *et al.* 2010). Their task is to give an innovative and multifunctional role to the open spaces and agricultural spaces of small and medium urban contexts with an environmental, landscape and settlement vision.

The development of rurality that follows these principles wants to overcome the utilitarian vision of the environment and the territory, focusing on the territorial continuity and on the integration of activities in rural areas. These must be able to involve farmers in the production of market goods and in the realization of services through practices of territorial governance of economic, social and cultural value. The territorial continuity guarantees a synergy between city and territory, in which the city forms an inseparable body with its territory (Cattaneo, 1972) and carries on the good conduct of the campaign and the quality of life in the city.

The objectives of rural development look at multifunctional agriculture for the development of local agro-urban systems and at the development of agricultural parks in not only fragile territorial contexts but also metropolitan ones (Vinci, 2010). To do this we need a progressive development and growth of awareness with respect to the recognition of the essential role of the rural territory and of proximity agriculture as factors not only in maintaining and offering the main ecosystem services, but also as a determining factor of local development and innovation (Magnaghi *et al.* 2010).

Therefore, for the recognition of the value of the territory, and in order to promote innovation and local development, it is essential to adopt interventions that focus on environmental sustainability.

The resulting data of the institute for environmental protection and research named “Istituto Superiore per la Protezione e la Ricerca Ambientale” (ISPRA) show data on land consumption in Italy in 2016. From these it is clear that the last few decades have been characterized by an unhealthy relationship between humans and nature, which has led to a condition of reduction of natural resources and an increase in the consumption of soil due to the implementation of continuous building processes.

In this context, the presence of responsible planning devoted to environmental sustainability carries forward political management and economic growth along with ecological value (Cohen and Nagiski, 2016). Therefore the role of rural areas within territorial systems is relevant, given the importance of production, but also of natural, social and cultural values. Therefore rural areas play an essential role in sustainable development and their preservation and protection is necessary (Lekić *et al.* 2018). As regards the purely agricultural aspect, in order to adopt actions aimed at sustainability and that, at the same time, look at economic growth, it is necessary to fight both the excessive use of land due to the intensification of agriculture in the most productive areas, and the tendency to marginalization and

abandonment of agricultural land in less productive areas. These dynamics have an influence on the environmental sustainability of the agricultural sector in territorial terms. They find a role in the social (ability to increase job opportunities and access to resources and services inherent to agricultural activities), economic (profitable use of resources in the area, or without the loss of quality and resources) and environmental (landscape, biodiversity and quality of natural resources) field.

In the sustainable development linked to rurality, in addition to the issues related to agricultural production, the additional activities that concern rural areas, although not directly connected with the agricultural production itself, must be included.

Sustainability applied to rural areas must make it possible to avoid the presence of new phenomena of rural depopulation thanks to interventions connected also to social and cultural areas.

The presence of social problems in rural areas has led to the development of strategies and policies aimed at the development of sustainable rural communities starting from the *plans for residences* (The rural coalition, 2010). Traditional agricultural systems and other activities, such as crafts, can contribute to the sustainability of rural areas by proposing strategies able to strengthen the sense of place of the residents and transform the local community into a more resilient and adaptive socio-ecological system (Gobattoni *et al.* 2015).

The productivity levels of the rural areas must be raised through a renewal of the collaboration between public and private sectors capable of generating collaboration networks between the various subjects through the implementation of specific actions.³ These interventions aim to enter the territory and generate new networks capable of generating new services and new economies starting from the already existing identities.

Reference models for rural development

In the rural field, relations between development and agriculture are increasingly intense. Synergies that involve different subjects and which, together with a vision of rurality separated from the agricultural activity alone, lead to a new competitiveness of the primary sector.

The presence on the territory of innovative processes related to the theme of rurality, allows the definition of new relationships but also facilitates the partnership between public and private, the activation of new circular economies and the use of technologies and territorial development laboratories applied to the rural theme.

³ They are: the use of platforms accessible both physically and virtually. Digital sensors and instruments for monitoring the pedoclimatic conditions related to production. The sharing of public and private spaces and services to reduce management costs and increase efficiency. Circular economy. The innovative re-use of agricultural production waste. New job opportunities not only in agriculture but, more generally, in manufacturing. The activation of territorial development laboratories (living labs and incubators of ideas) to generate innovative companies.

The case of Rural Hub is an example, later Rural Hack: a hackspace coordinated by Prof. Alessandro Giordano of the University Federico II of Naples, which has put together rurality and technology. In fact, Rural Hack interweaves the agricultural production dictated by the rural tradition with the technological innovations of young digital and agri-food entrepreneurs.

In the last few years in Campania there has been a trend reversal, from a statistical point of view, capable of increasing the employment rate of young people in agriculture and also the growth in the number of registrations in agricultural schools. Rural Hack pursues a new rural economy to make territory, society and economy coexist through companies that look not only to the economic aspect, but also to the quality of the territory and of the environment and social involvement.

The usefulness of the combination of technology and agriculture for the protection of the environment and productivity is evident, for example, in the case of the San Salvatore company in Paestum: a producer of wine. During the manufacturing processes, the presence of a parasite was found, which may occur only in certain conditions (temperature, soil pH, humidity); this forces them to apply specific treatments periodically. The use of sensors, able to detect the presence of those specific characteristics, allows the company to carry out the treatments at that precise moment, thus using the technology to save time and money, reduce pollution and, at the same time, make the activities of the company more productive.

Another way to connect technology and agriculture has been carried out by Farm Hack: an open platform based on an open source technology that aims to unite anyone who wants to collaborate and contribute to the creation of resilient agriculture. Farm Hack is an American platform that connects farms of different sizes (large and small) to each other to increase local economies and improve productivity and profitability of sustainable agriculture and local production. The Farm Hack community makes it possible to share the creation of tools for agriculture aimed at sustainability in production. An example is Culticycle, which replaces the tractor in the operations of cultivation and sowing without the use of fuel, or Fido which introduces a technological system for monitoring greenhouses.

FarmHack involves 35 retailers in Europe (in particular France, Germany and the United Kingdom) and the United States of America. The number of users now referring to Farm Hack is today 189 users, who can relate to each other through a platform divided into 9 main categories (including technologies applied to agriculture, job opportunities, agronomy), which contain within them 222 topics and 1.500 posts.

Another significant example, in the mix between quality of agricultural production and social involvement, is CumpaRete. This association, today, connects 19 Cilento (a specific part of Campania) companies in order to define a network among the local producers of the region. The objective is linked to cooperation and innovation in agriculture, with the idea of bringing together lands of different sizes and networks among farmers. They indirectly intervene on the landscape and, therefore, on the environmental quality.

The network has not only an environmental value, but also an economic one. The presence of socio-cultural relationships centered on relationships of sharing and interpersonal collaboration puts entrepreneurs in communication with different interests. In fact, these deal not only with agricultural

production, but they find in agriculture a differentiation of the services to be offered and possibilities of production and transformation, both in methodologies (innovative or traditional) and in the finished product.

Innovation in the agricultural field involves going beyond the use of agricultural land for food production purposes. This can allow purposes that can permit the limitation of the abandonment of agricultural activity and the consequent environmental degradation.

There are uses aimed at the production of agro-energy (especially biogas, starting from the exploitation of agricultural raw materials and residual substances of all kinds), to agro-cosmetics (research and development of products deriving from the agricultural sector), to tourism (tastings, naturalistic excursions, involvement in harvesting or sowing activities, show cooking), to the pharmaceutical industry (production of plants for pharmaceutical use).

New urban-rural relations for sustainable development

The implementation of sustainable processes, dedicated to multi-functionality and sustainability of the territory, contributes to detecting the potential of the relationship between urban and rural areas in order to promote new synergistic forms of governance. Starting from the overcoming of administrative boundaries, it is necessary to look at the enhancement of natural and cultural resources and innovative strategies for development in agriculture, in order to strengthen the economic, cultural and environmental profitability that comes from the establishment of a rural-urban network approach.

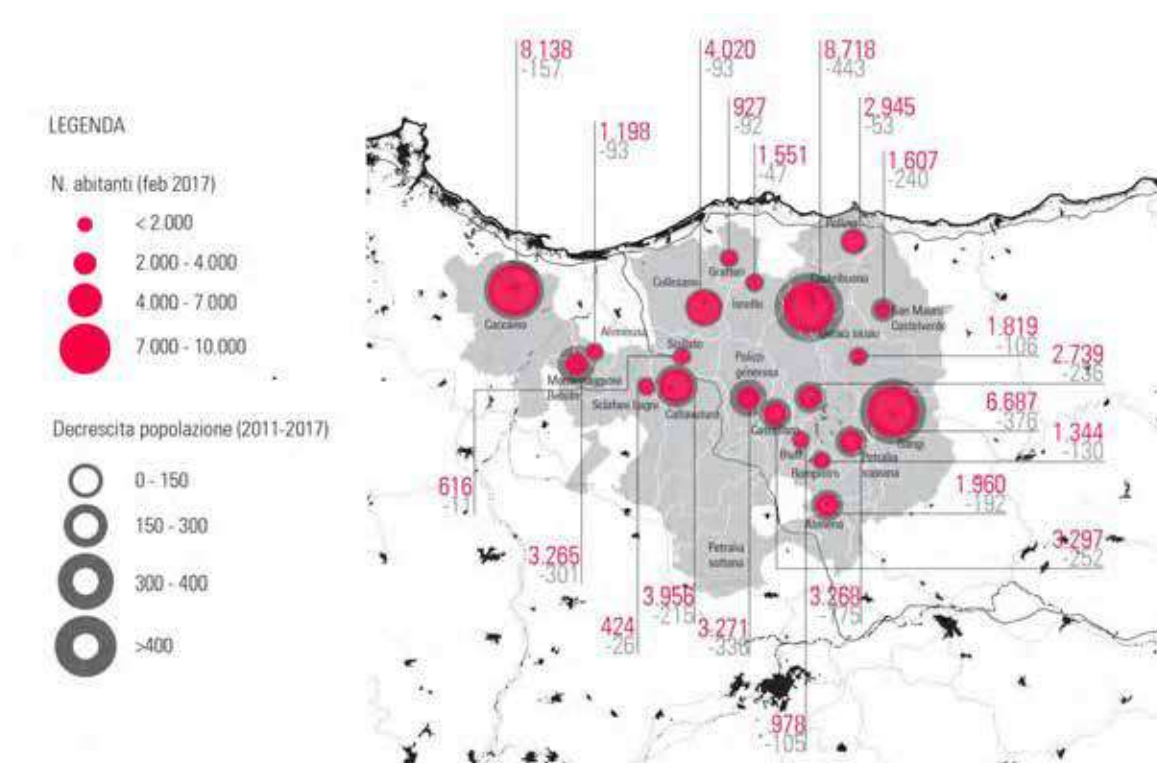

Figure 2. Population decrease in the municipalities of the Madonie Inner Area. The author has processed the image. Data source: <http://demo.istat.it>

The case of the Inner Area of Madonie is an example: a territory characterized by an extension of 1814,40 km² and the presence of 62.728 residents⁴, which makes a double reading possible. The municipalities belonging to it, in fact, have a dual approach: the identified Municipalities (as in national law 56/2014) are part of both the metropolitan city of Palermo (with the same boundaries of NUTS3 level) and the network of the inner areas of Madonie (national strategy). Economic and social fragility is connected to the demographic decline due to depopulation and emigration and, in the areas mainly dedicated to the primary sector, also to the decrease in both employment and economic development. This double reading is a symptom of the heterogeneity of the readable Madonite territory as a rural settlement model characterized by the presence of "islands of excellence" of the Sicilian cultural and landscape (Carta, 2016) capable of establishing relations both internally and with other "islands" external to the identified 'archipelago'. The Madonie territory has the ability to establish relationships both internal and external to the identified network, because it is recognizable as an active socio-economic actor. Furthermore, the presence of both human and economic capital and landscape and cultural values identifies the need for new and different methods, approaches and tools for territorial planning (Orlando, 2016). In addition to having the characteristics described, the Madonie Inner Area has been chosen as an experimentation area by the SNAI thanks to the use of strategies capable of generating innovation, as well as new and differentiated resources for the territory. The case of the Madonie development society named "Società di Sviluppo delle Madonie" (SoSviMa) is an example: a public-private association that interacts with public and private subjects of the Madonie in order to promote development of appropriate strategies for the use of the local resources. SoSviMa has a different area of action than the one identified by SNAI because it brings together a total of 29 Municipalities. In fact, some municipalities in the Imerese area, Caltanissetta and Enna are also included.

The strategies adopted for the development of the Municipalities of the Madonie area that historically have an agricultural vocation involve innovation to different parts of the territory. It is precisely in the agricultural sector that strategies have been developed for uncultivated and abandoned land, but also training courses for unemployed citizens in order to increase the employment of young farmers.

The energy needs of the Madonie territory are today met through renewable energy sources only with a percentage equal to 52% of the total energy requirement. A part of these renewable energies is replaced by the production of energy from biomasses: a figure destined to grow, based on the "Accordo di Programma Quadro", signed in September 2018. Specifically, the areas dedicated to agricultural production and interested in the creation of a network of small platforms for the treatment of woody and agricultural biomass are: areas with extensive crops (580,000 ha); olive groves (75,000 ha); vineyards (39,000 ha); orchards and citrus orchards (15,000 ha).

For agricultural production, some specific productions have been recognized as Slow Food Presidia:

- Scillato apricot (150 Q / year),

⁴ The data have been processed starting from the census data and the data relating to the surfaces of the administrative units. The author has processed the data.

- *Ape nera sicula* honey (1.5 T / year),
- *Badda* bean (15 Q / year)
- *Manna* (1500 kg / year)
- Polizzi pepper (1500 kg / year)
- *Provola delle Madonie* (59 T / year).

To these products must be added others that have not been awarded particular certifications, but which are recognized as identifying productions of the territory (*Basilisco* mushroom, Polizzi hazelnuts, *origano Vulgaris*, *Crastu* oil, Petralia Soprana salt) which are however a value for the madonite system.⁵

With the contribution of the Slow Food Foundation for Biodiversity, farms are engaged in the recovery of local varieties of ancient grains and olive oil, of which the Condotta Slow Food Alte Madonie is proposing the enhancement for the specific nutritive and pharmaceutical characteristics, together with the other productions of the Presidia. The promotion of typical products exceeds the theme of production and also involves agritourism initiatives. The multifunctionality that allows the rural environment allows to connect the productive activity of the agricultural and pastoral companies with the tourist activity in the rural areas.

The distance of the inner areas from the metropolitan propulsion centers has allowed the Madonie to maintain social, environmental and identity values. Today they allow to rethink the territory starting from the relationships with the rural dimension. In fact, in addition to productive specialization, there are attempts to enhance the natural and cultural heritage. Their development makes it possible to think of new forms of experiential tourism capable of involving both the resident population and external users. The values, differentiated among the single municipalities, were evaluated on the basis of the qualitative and quantitative methodologies developed in the field of research of Local Cultural Systems (Carta, 2003), which evaluates the cultural, naturalistic, touristic, agricultural, productive components in order to identify the peculiar identities and specializations and, therefore, the attractiveness of a given territory.

Methods and technologies
for transformative planning

Methods and technologies for transformative planning

Territory as media and social media as territory

Francesco Aliberti¹

¹*Università Sapienza di Roma, francesco.aliberti91@gmail.com*

Abstract: How can planners find within social media new spontaneous ways through which people imagine, represent and socially produce a territory? This is what I have investigated in a peripheric neighborhood of Rome, trying to highlight how, through the acknowledgement of digital habitat embedded in a territory, it is possible to understand citizens' narration and hopes for their territory, as well as to find new ways to enhance participatory processes. I investigate how the habitat developed through a daily and routine use of mobile technologies of communication could make emerge new action spaces. I have identified insurgent democratic practices and new ways of citizens' engagement with their own city political issues, given a recurring distrust regarding official and established politics. Hence, since physical territory is a media of a diverse range of social relationships, also social media have become a portion of that territory where people can develop debates and conflicts regarding "major" themes and the image they would like to build for their territory. If researchers and planner accept that these contradictory and emotional digital places are in fact new portions of territory, alternative imaginations of space can be identified, generating new forms of collective appropriation of urban space.

Keywords: Social Media, Social production of space, Participatory processes, Ethnography.

Introduction

How our ways of inhabiting the city have changed after the spread of digital media?¹ This is what I have investigated in a peripheric neighborhood of Rome, Italy, conducting a three-year-long ethnographic research inside several Facebook groups related to that territory. To answer to such an open question, first we need to think the practice of "dwelling" a place as the production of locality process (Appadurai, 1996), that is the meaningful context for individuals' and groups' action. This context is practiced in the everyday life, through the social practice of imagination (ibid.). Defining dwelling as a production of meaning process, a suitable course of action cannot be to observe digital media use as an analytical tool that can guide us through urban space (Ratti, 2018), but rather analyse the spread of narrations and auto-representations that this technology allows. This form of communication is mostly visual, and it can be produced by international organizations but also by countless individuals in their daily routine, and is starting to characterize more and more our everyday life, narrating our places, the space we cross and the kind of sociality we use in them. Observing this narration, the territory results as a hybrid between physical and digital spaces whose boundaries and meanings are

¹ The terms to refer to the variety of artifacts that can hook up to different portals on the web are at the same time many and few. I propose to define them in general as digital electronic media or more simply digital media. The term "media" comes to refer to the ability of these artifacts to create networks of communication between people and spaces. The electronic and digital adjectives serve instead to qualify the type of reference technology, i.e. technologies that are powered by electricity and which are developed on (or can be reduced to) a binary code.

constantly being negotiated. The individual finds himself to be knotted in this encounter. Moreover, the production of meaning, not being centralised but scattered, breaks the traditional border of social classes, allowing new forms of debate, confrontation and discussion between people and groups.

Identifying these changes could be very important for planners: the spreading of narrations producing the sense of places, presenting themselves as a fundamental part of the inhabiting process, lead to the origin of hate speeches and invention of stigma, but also of new forms of participation and collaboration, new ways of regrouping with neighbours in order to take care of the territory, making an effort to produce it as a meaningful context. Thus, we are in front of new spontaneous ways through which people imagine, represent and socially produce a territory. If researchers and planners accept that these contradictory and emotional digital places are in fact new portions of territory, they can play an important role in these processes. Accepting the importance of online debates within the production of local imaginations, even when they are unpleasant, is a necessary step forward that we have to take to help new forms of collective appropriation of urban space developing, and also to counteract against various form of hate speech.

Also, Considering the territory as a media of social relations and the same media as a part of the territory, it is possible to observe their relation to see in what terms they contribute to help individuals and groups to cope with the intricate and often indecipherable interaction that is the relationship between global possibilities and local capacities. To address these issues, I committed myself into the habitat developed through a daily and routine use of mobile technologies of communication, internet and the social media of Montesacro, a peripheric neighborhood of Rome.

Field study and method

The choice of this particular area of the Italian capital is not accidental. First of all, I needed to indagate the use of these technologies not on exceptional cases, but on practices linked to the everyday routine within urban space. In this sense, my research can be defined as a “anthropology of ‘us’ “, meaning an ethnographic research geographically and socially distant from classical and ‘exotic’ cases of study. The protagonists of this research, the inhabitants of the “III Municipio”, also called “Montesacro”, are in fact people from middle class, and the neighbourhood itself is a liminal area of Rome, geographically and socially. The “III Municipio” of Rome is a rather extensive area of the capital², characterized, as is easy to imagine, by a variety of neighbourhoods with different historical and social characterization. Located in the northeast area of the capital, it is undergoing changes due to a moment of expansion, generational change and especially the emergence of new forms of associations and forms of land management from below. It is an area marked by a certain geographical and social mediocrity. The word should not be understood in the negative sense, but instead indicates how this area is inhabited by a middle class and is geographically in the middle of different trajectories. Its "natural" border is the GRA³, which divides it from the countryside and from the many neighboring municipalities; the area is also crossed by two road axes that are historically a link between the "true" center and the "real" suburbs outside the motorway ring: the Via Nomentana and the Via Salaria. The two ancient "vie consolari" are the roads built by the ancient Romans which, starting from Mentana in the Lazio region and from Porto D'ascoli on the Adriatic Sea, cross in the III Municipio to arrive at Porta Pia and Piazza Fiume (city centre). The Tiber laps the western border of the quadrant, while it is the smallest Aniene river to cross it, one of the main tributaries of the river that gave birth to the capital. Referring to the common sense and the ways in which this territory is represented, apart from rare exceptions, it appears to be a rather anonymous area; in Rome in fact you can hear about (more

²According to official data of December 2016, it counts 205,019 inhabitants

³ The “Grande Raccordo Anulare”, the highway that surrounds the almost entirety of the city of Rome.

or less rightly) of criticality as Tor Bella Monaca or Corviale, or of upscale places such as Parioli and the Prati district, or, of course, of the "most beautiful places in the world" located in the historical center. But you will hardly hear about the III Municipio, for better or for worse. This is not an area known for its social or economic criticalities (even if present), nor for particular qualities (although existing). Of course, it's an hour's drive from the countryside, but it doesn't take much less time to get to the Colosseum.

Starting from this self-perception detected in the territory, it is possible to imagine the necessity of its inhabitants to produce a new meaning, also to respond to the changes in action. Montesacro is therefore a precise context, a small-bourgeois area of the Roman suburbs, within which to observe the uses of digital media and the paths traced by them, at the individual and collective level, so that we can identify continuity and disjunctures in the locality's production processes and in the management of the urban space.

Having to work within such a vast territory, I chose to divide it into several cases of study. In this paper I will focus in particular on the case study regarding what happens within Facebook groups related to the Municipio. I have approached this context through the classical methods of ethnography. On the one hand, I tried to build networks of knowledge within the territory, attending various public occasions or simply strolling around, on the other, I joined the various Facebook groups to which I was interested, first getting to know the managers and moderators and then entering into their daily life. The next attempt was to unite the two contexts into one where I could pass seamlessly from an offline meeting to a chat or observing a post uploaded to Facebook.

I also tried to observe the use of Facebook and in general digital media within a precise frame, that of "incidental narration" (Bausinger, 2011). In fact, I noticed that the use of these technologies, and in particular the stories uploaded on Facebook that we are going to talk about, were not performed in a way obvious or blatant, but exploiting one of the most recent features of digital media: their "incidentalness". If, in fact, until a few years ago also an action like the Internet connection was marked by a whole series of rituals capable of putting them "outside" the normal flow of a day, the use that today we make of even the most futuristic technologies - Let's think about how "magical" is that my voice or my face can be heard and seen live at the other end of the world - is no longer an exciting and exceptional fact, limited to a precise context, as could be the games room of a bar or the computer of your office. Today digital media are used in a routine manner and subjected to the context, almost hidden and, in fact, incidental. The narratives of the territory in which we live made online, which we are now about to meet, are thus presented as incidental multimedia narratives, narratives calibrated through the affordances and the languages of digital media.

Narrating the "other"

During my research within this territory, I confronted myself with different contexts and different people: I met young adults who were moving alone for the first time, I entered some schools and I interacted with many of the groups created on Facebook with reference to the Municipio or to the various neighbourhoods that are part of it. In this paper, I will focus in particular on what I could observe by inserting myself in the circuits of these Facebook groups.

Within these spaces, I have identified insurgent democratic practices and new ways of citizens' engagement with their own city political issues, given a recurring distrust regarding official and established politics. Focusing on immigration policies and the consequent production of identity, I observed how citizens, through continuous and conflictual micro-narrations of their neighborhood life, produce stereotyped representations of the "other". At the same time, these micro-narrations have led citizens to reflect on both their attachment to the territory and transformative actions capable of producing a different one. So, now we will observe how by setting the ethnographic gaze on the processes with which stereotypes and even hate speeches are produced, it is possible to identify the reasons behind these processes and to imagine intervention strategies to shift the attention on forms of construction of community and bottom-up design practices of the urban space.

First of all, I have to describe what kind of people daily attend these Facebook groups. These groups can be composed of a few hundred people or touch peaks of 30000 users, but of course not all the members of the groups participate actively in their lives or the discussions that are born within them. The people who are engaged daily in these discussions in fact tend to be individuals between thirty-five and seventy years of age. They are people who live the changes of their territory and in general the changes that are summarized in the words "globalization" and "modernity" through a growing feeling of insecurity.

The novelties brought by these processes make less strong the "traditional traditions" (Bausinger, 2008) on which the groups model their daily routines, thus leading to the emergence of these feelings of anxiety, frustration, forms of displacement (de Martino, 2002) that must be solved by rebuilding the meaning of living in a given context. In this territory and in general throughout Rome, this problem is addressed mainly through the construction of the rhetoric of "degradation".

To make understandable the "disorder" that they experience in their daily lives, the inhabitants of Montesacro imagine a minority "which is determined [...] as "contaminated", and then becomes scapegoat of the "disorder" [...] which crosses current local social dynamics» (Simonicca, 2009, my translation), which is often detected in immigrants and secondly in younger generations. This disorder, therefore, is articulated within the word "degradation". For this rhetoric to work, however, it must be articulated, discussed, put into play. As I have seen during my research, the space for public discussion within the III Municipio is very little. This happens, on one hand, because of the growing distrust of institutional spaces for these discussions, on the other for the actual absence of physical places where to meet. The groups on Facebook have then slowly become the favourite places for these discussions, both when it comes to groups created by some political association or volunteer, but especially in larger generalists groups where the discussions seem to arise in a "spontaneous" manner.

In fact, within these groups it is very difficult to discuss political issues and in particular the topic of immigration. Looking at the case of one of the largest of these groups, we see how before we can enter to be part of it, we should stop to read a hefty regulation. Among the most repeated rules there is the prohibition to discuss the topic "foreigners" or "immigrants", penalty the ban, i.e. the expulsion from the group. Within the guidelines in fact, it is specified, precisely in relation to these rules, that its purpose is to build a lost idea of community, providing a platform where to exchange ideas, information and simply know each other in the scraps of time offered by the frenzy of everyday life, between neighbors who inhabit the same territory. To pursue this goal, you must avoid any discussion that could overturn the limits of education and become infuriating, create quarrels and long even endanger the integrity of the group

So what are the prohibited arguments? They tend to be summarized by the golden rule of the group, also positioned graphically above all others and detached in the body of the text: *You cannot talk about politics*. The concept is reiterated more precisely: "One cannot speak of Roman politics or worse national". The following rules appear to be a series of postulates of the same, or however clarification to indicate any theme that can slip into a discussion between opposing parties with different interests.

It is not therefore allowed to speak of religion, because at the end of the day everyone can believe what he wants in respect of others; you cannot talk about football (the combination between the two arguments does not want to be sarcastic), since undoubtedly the discussion would slip into unreasoned arguments and therefore in discussions; it is forbidden, clearly, in any way to talk of issues concerning race or nationality. In a nutshell, you must not speak of any form of alterity, which is in fact declined in some equally prohibited generic themes: the Rom, the immigrants (again), the vegans and the animalists (a sort of home-made foreigners), the gender and, finally, the cyclists.

These rules can make you smile as much as worry, but their sense is obvious: discursively exclude all otherness, create a forced localism that tries to conceal that in Montesacro there are not only white heterosexual omnivores

(and to what it seems no lovers of cycling) but also second generations, Rom, homosexuals, vegans etc. The reason is not necessarily an antipathy towards these categories, indeed, but just the willingness not to address these topics for which the group is simply not ready.

And yet, the political issue, articulated mainly through "the problem of immigrants", is the most addressed on these groups, through very special tactics (de Certeau, 2001).

In fact, these attitudes are opposed with particular sagacity to two strategies: that explained in the regulations of the groups that basically prohibits even just to appoint the other and the less visible but very powerful of the judgement of the society (ivi). In fact, at formal level, being racist is absolutely deleterious and disadvantageous. The common sense seems to think our society as naturally anti-racist, also thanks to many campaigns to raise awareness of the topic. In short, racism understood as the act of formulating discriminatory judgments on a person as belonging to an ethnicity or nationality other than their own is cleared at several levels as something wrong.

So how do these people evade the formal and moral prohibition of defining the characteristics of the other? By engaging in the rhetoric of degradation, they document, almost always through the use of photographic images, various problems of the area due to the presence of an "other" and its attitudes.

By inserting myself within all these groups I could see how my Facebook home was quickly flooded with photographs able to document the "degradation" in every way possible. For example, often appeared photos of garbage bins whose contents had been spilled outside. Among various accusations to the municipal waste management system, there is no shortage of comments like: «Someone did the shopping, huh? », indicating how some "stranger" had searched in the trash something to take away. On the same trend travel the many photos of the "remnants" of the abusive markets near the metro stations "These here make everywhere dirty and steal customers from the ITALIAN shops that pay taxes". A broken fountain testifies that "it has been tampered with... Someone takes a shower and then the water no longer passes, because it is clogged the drain». And if it is not repaired is because then "comes the sly that if the disassemble and if the pieces came". The photo of a car with a broken window, the window of a shop that has suffered the same fate and others, do not simply tell a theft, but bring the discussion quickly to move on the number of "foreigners" that has been increasing in the last years.

The perpetrators of this degradation, however, never appear in photos and only after some time are nominated within the speeches. The other is defined in these examples as a ghost that hangs over the territory, however invisible.

The alterity in fact appears personified in its different representatives only when this image can testify the existence of a single value that seems to be transversally shareable: the sacrifice for the territory. Who wants to fight a racist post seen a few hours earlier, not being able to start a discussion on racism because of the regulation, shares the photo of a "foreigner" at work while cleaning the sidewalks in exchange for little money, with a sign at his side that explains how he wants to integrate with the work and demonstrating gratitude and certainly not 'begging for pity'. This seems to be the only way to remind everyone that "immigrants" are always human: communicating their willingness to sacrifice themselves free of charge, or almost, to contribute to the territory where it arrived.

There are therefore two ways of defining the other within the groups, one in negative and the other, theoretically, in positive. In both cases the discussion takes on tones capable of attracting the attention of the moderators only after some time. In the second case, that of the "foreigner" good and worker, the discussions begin only when someone doubts the honesty of the operation, implying that it is only a farce, maybe foraged by someone who earns something behind. In the first case, however, the discussion degenerates when someone finally names the other as guilty of the degradation portrayed in photos, whether it is the Rom, one of the most

popular culprits, or the more generic "blacks", "Africans", "refugees". If someone tries to question the actual guilt of these people or, worse, try to justify them by talking about the social reasons behind any degrading gestures, then accusing those who brought into play the presence of the other on the territory to have prejudices, the debate is unleashed.

"Who thinks it is right to help these poor people... Realize that soon they will not ask for more, but take what they need and it is your fault» is explained very often in the comments; as you can see the accusation of racism is fought with that of "perbenismo" ("perbenism") that is the will to treat well someone who evidently does not deserve it for the purpose of being "fashionable", to resemble young people and therefore not be considered "old", inadequate or ignorant. These would be the only reasons for defending foreigners, without a real awareness of the problems of the territory and above all an interest in finding a real solution.

Through these indirect tales, the debates and the ensuing conflicts, come to produce the two extreme boundaries in which the other as an individual can be defined, both reasoned through the mediation of the physical space and the relationship with the territory. The other can be totally predatory and disinterested in the territory, or it can be totally aimed at sacrificing itself for it, thus making itself worthy of consideration.

At the same time, they also build two polarities of the attitude that is correct to maintain when we talk about certain issues: you cannot be racist, but, of course, it is equally shameful to be a "perbenist".

Indeed, perbenism is the biggest problem according to these people, because it prevents us from catching the real crises and because it would be the tool that politics uses to prevent dissent and exploit tragic situations for profit purposes. «I am more afraid of the perbenists. I put everything in the same basket? Tell the raped girls. I just want to find out that we're proud to be Italian». Of course, even those who fall in the other side, that of racism, are controlled. After having undergone the righteous ire of those who believe that these are shameful behaviours, not only their posts are often erased by the moderators, but they are also regiven by those who share their battles. Racism is, to all intents and purposes, wrong, one must be able to define the other as dangerous and liable to be eliminated without being racist. They are rhetorical that have a very delicate balances and whose dynamics may seem absurd if viewed from the outside, but that work in their context, precisely because they are based on the precise tactics.

As this dynamic may seem poor in meaning, it is precisely the one through which is built the imaginary in relation to the arrival of migrants in the territory. To grasp its effectiveness and the ability to continually build and reiterate such strong stereotypes about the "other" and the "us", we must therefore grasp the narrative and everyday aspect of it. What I have just told can look like an extreme situation, but in reality it is part of a sphere of very common behaviours, of which all of us in some measure are carriers, aimed at trying to include certain concepts in the "common sense" of our own group. This is what the researcher has to do, try to understand how and under what conditions the ways of building the "common sense" carried out on Facebook are capable of producing certain social effects. To think about in the dynamics just told, there was nothing that was not already said talking about racism; What is peculiar is the way of giving value to a discourse that is formally discredited at institutional level. The sum of each of these small subjective and occasional stories succeeds in fact (at least in the eyes of the group) to evade this problem by constituting itself in what we could define a "collective narrative", that is, something whose size and scope is more than just the sum of the individual parts.

It is precisely when the participation in this collective narrative becomes a kind of a daily ritual that its power and the capacity of its concepts (for example the arrival of the other linked to the degradation of the territory) become almost obvious and come to light. The continuous sharing of images with the more or less concealed purpose of narrating the other becomes almost a performance to be staged, able to become central in the description of the other, but especially of the territory itself and its inhabitants. These performances seem to have almost the value of rituals: they are in fact repeated in a form that, although not explicitly defined by any

authority, is quite recurrent and fundamental because they can survive the censorship. In addition, these performances seem able to define the membership of a cultural group by acting through the simplification of the characteristics of the "us" and the "other". They are therefore daily narratives capable of constructing taxonomies, i.e. rules for classifying behaviours and individuals. It is precisely through these rituals that the inhabitants of the III Municipio (re)produce the relationships between the different "collective identities" that recognize and put in hierarchical order their values. (Simonicca, 2006)

The definition of the "other" and of the "us" that is built within this dynamic reveals therefore also the deepest motivations for which it is put in place, which are then those proposed already by the regulations of the groups: to recreate a neighborhood idea that is supposedly lost in the past and make sense of the disorder present in the territory.

A few months after the end of my ethnographic research, I decide to return to attend the different Facebook groups regarding Montesacro. I am in front of a post that has obtained hundreds of responses and interactions. Within it is asked a simple question: "Who still thinks that Rome is the most beautiful city in the world?"

The answers I can read in the comments reveal something surprising. In fact, they summarize with great efficacy, in their accumulation during the hours, all the discussions, the comparisons, the shares of photos and in general all the conflicts and all the narratives that had alternated on the Facebook wall of the group in the precedent months.

Some in fact respond with photos of some famous monument, as if to say that Rome is still beautiful, despite the difficulties of the moment. Someone respond that something is actually changing for the worse and it is finally time to ask these questions; someone else instead perform effective summaries of the various discussions between racists and perbenists, proving to remember them all perfectly. All those debates and all the narratives do not seem to have been lost in the powerful and unstoppable flow of the social network, but instead they are inserted not only in the memory of the people, but in their routines, in the daily ways of production of locality. The continuous reference, implicit or explicit, to what has already been discussed on the groups is not linked to the "infinite memory" of the Facebook platform, because some posts that are cited are far dozens of minutes of scrolling the mouse along the wall of the groups, as long as they have not been deleted by the moderators. While "lost" in the flowing of Facebook, the discussions have therefore left a sign. Arrived in January of 2018, I return to include in my routine the observation of groups and participation in their activities and I realize that something has actually changed. The "War Bulletin", the endless succession of photographs concerning different types of degradation, has not disappeared, but has changed to some extent.

The biggest change is perhaps the almost total absence of narratives concerning the "other". To comment on the various photos regarding the degradation, you no longer end up talking about the "foreigner" as the main culprit. I want to be clear, I do not mean to say that racism has disappeared from Montesacro, but simply that the incidental narratives no longer find appropriate tactics to construct a deterministic relationship between the presence of the other and degradation. The question that arises to me is: why? It does not seem to me possible that this change could simply be due to an increased ability of the moderators to expel and censor those who assume racist attitudes, nor that simply the subject has passed out of fashion. The other did not disappear only in narratives aimed at defining it as a cause of degradation, but also in those photographs in which it is portrayed at work for the common good of the territory. It is therefore possible, and it is this possibility that I want to explore now, that precisely the characteristics of the incidental narratives for how they are performed on Facebook have had an effect on the construction of these speeches.

As I hope to have clarified, the deepest purpose of the discussion fossilized for months on the subject of the "other" was not so much to discuss the figure of the foreigner, but to define an "us", the identity of the inhabitants of Montesacro. In particular, the "us" on which they, the members of the groups, are that figure put

in crisis, disoriented and apparently incapable of finding themselves in the current structure of the neighbourhood. The rhetoric of degradation and also the various culprits from time to time identified serve in fact to articulate in a sensible way (which, I want to specify again, does not mean appreciable, but only meaningful) the feeling of displacement, of an emotional detachment that the inhabitants of Montesacro live towards their neighbourhood and their city. And it is this detachment, it seems to me, the main problem that is dealt with through the incidental narratives, not so much that a road is impassable because of the holes in the asphalt, that the trash bins are crowded in another street or that there is a growing number of black people waiting for the bus. In fact, to create a discussion able to accumulate almost a thousand answers is not a technical question like «how come the municipality is struggling to manage the cleanliness of the neighbourhood?», but a much broader, almost existential question: «Why did we stop thinking that Rome is the most beautiful city in the world? And, if it's not the most beautiful city in the world, what city do we live in then? And what role do we have in it? ». To understand the almost dramatic extent of this question it is necessary to enter deeply within the cultural intimacy of the inhabitants of Montesacro as Romans and of the relationship that the citizens of the capital build with the history evoked by the City.

«The monuments are no longer enough! We hide behind the monuments, but we do not live in it, it is true that Rome sucks» Screams a lady in one of the comments to the post in which this question was posed. «If you go abroad even once you realize that no major city is reduced in this state».

In the game between global imaginations and local possibilities, the territory came out defeated and they together with it. They cannot adhere, nor want, to those global imaginations that excite their children or grandchildren, they cannot escape from the Roman reality, physically or figuratively: they cannot, in short, ignore Rome. On the other hand, they are not even able to ignore that something is wrong in Rome, which perhaps is no longer the centre of the world, but a periphery. And it's not even the most beautiful city in the world. To affirm that the monuments are not enough to guarantee a certain quality of life means to break up in a violent way that relationship naturalized between physical and historical quality of the territory and quality of the life of the inhabitants: to have an archaeological finding under their own house is not very useful if they no longer know what role to occupy in the globalized world. One of the most effective imaginations to be put to work to produce the locality in the Roman context cracks, to the point of bringing the inhabitants of the district to seek other rhetoric in which to take refuge.

The relationship with the territory is therefore damaged, not only because of the difficulty of managing the changes, but especially because the inhabitants feel that they cannot intervene on the territory, not to have any form of agency on it. The discursive expulsion from Montesacro leads to subtract the space of the Facebook group to the dynamics of the social network to make it the place to rediscover this role. While the loss of a producer of meaning such as the history of Rome leads to a different one, this feeling of insecurity and uncertainty leads to the genesis of episodes of violence, albeit at the moment only verbal, in an excess of and self-determination, strengthening the essentialization of cultural diversity (Appadurai, 2005); whether this diversity is found in "foreigners" or in the youngest, it is still in a "other".

The incidental narratives that occur online present themselves to some extent as forms, perhaps not strictly of "active citizenship", but certainly as a way to regain an agentivity with respect to the territory. These modalities mainly consist in identifying the ethical and moral qualities capable of keeping the neighbourhood networks in their feet. This however means that to find the meaning of living in Montesacro, outskirts of Rome, it is not enough to rely on the physical qualities of the territory, intending with these also the cultural heritage constituted by monuments and historical sites, but it is necessary to rediscover a certain quality of the citizens.

«Of course, Rome is the most beautiful city in the world. It's not an answer to your question, it's a fact. Us Romans however, we are assholes»

This is the argument that, in more or less similar forms, begins to return in the comments to that post I was talking about earlier and this seems to me a positive consequence of the discussion: the awareness of the need for a certain degree of engagement in daily life which one cannot do less to feel full-fledged inhabitants of their own territory and the rediscovery of the value of neighbourhood networks and of a collective and non-individual approach to the policies of management of the neighbourhood.

This is one of several case studies with which I have compared myself during my research. In other cases as in this, the interaction between digital platforms and territory is the one that exists between two different spaces capable of being mediums of various forms of social relations.

In fact, physical space has always been a medium of communication, in the sense that it has always been able to generate "meaning" in relationships. It is a medium insofar as it is able to influence (but not to determine) action, but also built through social action. The territory as a social and cultural product presents itself as the medium of that intricate and often indecipherable interaction that is the relationship between global possibilities and local capacities (Bonis, 2001). The novelty to be taken into account is that parts of those platforms created by the digital media and managed by international organizations can be tactically torn (de Certeau, 2001) and sewn up within a local context. Precisely these spaces subtracted and localized informally become the privileged places of the social and political discussion of the neighbourhood, those where, even if in an incidental way, more strongly is practiced an idea of neighbourhood as space of the meeting between contiguous, the comparison and the "free" exchange of opinions and information, whose only advantage is the establishment of a better community, although the forms through which this happens are often very conflictual.

Conclusion

I believe that the conclusions I have just tried to draw can open up to a number of considerations in relation to possible future scenarios, in the field of social research but not only, on which I would finally like to concentrate.

Firstly, by reasoning on the methodology of research, it seems to me increasingly difficult to imagine future investigations in the field that, in any context, can be exempt from working within the digital territories as in the "physical" one. I hope it is evident the importance of these spaces in the daily life of those who have access to it and consequently how it is no longer possible to think of a work on the field that does not consider the enormous agglomeration of meanings and narratives produced; this would lead to the exclusion of a fundamental part of the social life of individuals.

But I think that reflection on the subject should not stop at the point of view of "pure" research (as long as it can exist). Instead, we can reason on these issues also in proposing action-research practices. If it is true that in the digital portions of the territory, which are performatively and continually produced, the discussions appear to be extremely polarizing and violent, I think this happens because the spaces of the social networks remain in our society among the few where it is still possible to articulate a debate, to trace a space for conflict (even violent), to build a space for its own diversity (real or suppository). Moreover, precisely because of the possibility to "domesticate" our own digital spaces that is offered by the various platforms that possess them formally, the possibility of customizing them and making them familiar, they are often closer and intimate (Herzfeld, 2005) of many physical places, which especially in the context of the city are increasingly difficult to "modify" by an average user. Thus, what is encountered within these intimate spaces and "neighbors" assumes a value and meaning much more important than what comes from external sources, even when they are official. A council, an opinion, even a medical or generically scientific information, are easier to accept if they come from someone who is actively and politically engaged within these networks, just like, in our daily lives, we more easily accept advice from a friend or relative than from a stranger. In this sense, I think it is necessary for us researcher to be more inclined to "get our hands dirty", to accept that even behind the rhetoric and the most unacceptable

speeches, is concealed the attempt to find a sense of one's existence, remembering that this is a common trait of that humanity that, in any case, unites the researcher and the subjects of any study.

In the case of rhetorics such as racism, the aim is to be able to deconstruct that and to propose an idea of humanity that is more *sensible*, i.e. that has more meaning, of that proposed by racism. This certainly is not a simple task. Researchers must agree to lose themselves between networks (digital and not), sometimes to compromise, to displace themselves, in order to find themselves together with the people with whom they work. I would say that in this there is nothing to lose, if not our certainties.

Technology readiness for cities: the near-future case of autonomous passenger drones

Timothy Donnet

QUT Business School, timothy.donnet@qut.edu.au

Abstract: Autonomous Aerial Vehicles (drones) are a transformative technology at the cusp of being adopted for real world passenger transport in cities (Moore, *et al.*, 2018). Passenger drone research remains focused on the advancement (Gao, *et al.*, 2018), opportunities (Zhang, *et al.*, 2018) and technology readiness (Torens, Dauer & Adolf, 2018) of drone features and systems. The technology-focused planning literature dominantly focuses on Smart City frameworks for enhancing technology integration into urban planning (Caragliu, Del Bo & Nijkamp, 2011), with an emerging focus on the implementation of specific technology strategies (Bayat & Kawalek, 2018; Yigitcanlar *et al.*, 2018). However, the literature stops short of interrogating the technology readiness of cities that will inevitably attempt to implement specific technologies (i.e. autonomous passenger drones) into their urban fabrics. That is, cities will be pressured to allow (or race to adopt) fleets of drone taxis to ease pressure on already stressed and near capacity ground transport networks; but where will drone operations be seen as safe, practical, desirable, or at least tolerable, additions to the urban rhythm and hum? How compatible are existing urban development patterns and policies to a future that includes aerial passenger drones landing in neighbourhoods and buzzing across their skies? This paper summarises the currently known opportunities for aerial passenger drone technologies for improving urban system performance and proposes an inclusive method for cities to enhance their readiness for the forthcoming technology. The method is applied to the city of Brisbane (Australia's third largest city) to explicate the practicality of interrogating city technology readiness in the context of aerial passenger drones, highlight jurisdictional and governance tensions, and detail learnings from implementing the method with implications for smoothing the transition to implementing transformative technologies.

Keywords: Transformative technology, autonomous aerial vehicles, technology adoption methods technology readiness

Cities with flying cars in a not-so-dystopian future

In 1927, Fritz Lang brought forward a dystopian vision of future cities in the visually stunning silent film, *Metropolis*; characterised by the densely packed skyscrapers, with aviation placed at the heart of the city. Aviation has since been elevated as a core economic feature of cities, with Kasarda's (2004) Aerotropolis and Stevens, Baker and Freestone's (2007) Airport Metropolis concepts focusing on the interdependence and synergistic opportunities of cities and air transport infrastructure. Within the context of urban planning, aviation has almost always been seen with respect to its utility for connecting cities to the rest of the world – allowing planners to promote ground transportation routes that align with passenger and cargo movements through the urban and hinterland environments, and that zoning appreciates the noise footprint and physical separation of structures required of flight activities. However, any science fiction fan seeing the 1989 sequel, *Back to the Future II*, saw a future where the skies above cities were not filled with aircraft, but with flying cars. When everyone has a flying car, there's little need for the *Metropolis*-style airport at the heart of the city. Fast-forward three decades, and suddenly we are in a future where personal on-demand aircraft are becoming a reality.

In 2018, Uber Elevate announced its intentions to begin commercial flight operations of a fleet of electric vertical take-off and landing (eVTOL) aircraft, which would open up new transportation opportunities for on-demand aviation (Uber Elevate, 2018). This proclamation suddenly became more real when Bell (an established helicopter manufacturer) announced its partnership agreement with Uber Elevate as the preferred supplier of air taxis at the Consumer Electronics Show in January of 2019 (Engadget, 2019). Projections estimate that an eVTOL flights dramatically reduce travel times, for example commuting 55.4 miles between San Francisco and San Jose could be reduced from 1hr 40mins to just 15mins but only cost 16.2% more than a regular uberX fare (Uber Elevate, 2016). Essentially, Uber Elevate is proposing on-demand personal intra-urban air transport that will be priced to be available to the general public. While much of the focus for the rapid emergence of the technology has been on the readiness of the technology for the market, there is a question posing as the proverbial elephant in the room:

What is the readiness of cities to adopt this near-future technology?

For some cities, the approach appears to be akin to a technology start-up company, where experimentation and failing fast to learn success (see Zellner and Campbell, 2015), frames their risk appetite. Abu Dhabi for example, announced its appetite to trial the (at the time commercially untested) Ehang 184 drone taxi in early 2017 as part of the city's goal to automate at least 25% of intra-city journeys by 2030 (Olsen, 2017). Singapore also gave the green light to German company Volocopter to begin inner-urban flight testing as soon as the second half of 2019 (Robertson, 2018). While city-states may have the available urban densities, funding and alignment of governance structures to facilitate the rapid integration of technologies into their urban fabrics, cities that are framed by speed-limiting bureaucratic and regulatory hurdles may struggle to prepare their urban infrastructures, stakeholders and interconnected systems for adopting autonomous and/or piloted airborne drone taxi systems. This paper proposes a framework that could be used by cities to self-evaluate their current maturity or readiness for this technology, as a means of helping cities prioritise and resource activities that (if desirable) pave the way for airborne taxis. The framework is discussed in the context of Brisbane, Australia, due to the progressive policy environment for unmanned aircraft

systems (UAS), and highly interconnected and overlapping jurisdictions that highlight potential complications for technology adoption.

Adapting a Big Data adoption model for airborne drone taxis in cities

For a decade, Big Data has been seen as the technology that all organisations, cities included, should buy into. While a plethora of authors have provided advice on specific technologies and skills required to make *Big Data happen* in organisations, Davenport and Harris (2017) provided clarity to organisations, large and small, when it came to understanding *are we ready for Big Data, and if not, how do we get ready for it?* Their DELTTA model and stages of analytical maturity provide sounding boards for organisations to evaluate their capabilities and deficiencies against an array of criteria that are essential for creating technology adoption strategies. DELTTA, as a model specifically developed to make explicit the functional requirements of Big Data, stands for the way the organisation uses (D)ata, how data is treated as an asset for the (E)nterprise, the level of support for Big Data approaches by the organisation's (L)eadership, how data is used to support the defining and achievement of (T)argets, the resourcing of (A)nalysts to support the organisation's aspirations and use of data, the integration of the (T)echnology required to advance Big Data use in the organisation, and the sophistication of (A)nalytical techniques applied within the organisation. These functional requirements become the criteria by which an organisation assesses its resourcing and competence to determine the *maturity* of the organisation with respect to Big Data. Davenport and Harris (2017) define five levels of maturity: Stage 1: Analytically impaired; Stage 2: Localised analytics; Stage 3, Analytical aspirations; Stage 4: Analytical companies; and Stage 5: Analytical competitors. There are finite descriptors for each level of maturity for each of the DELTTA criteria, which can be found in Davenport and Harris' (2017) book.

By assessing the maturity of an organisation across each criteria, areas of strength and liability can be identified to aid decision making for resourcing, change, and development. By deconstructing the model into a process to first create the criteria for the model, and then populate the model with objective levels of maturity, a framework can be created to assess the readiness of a city for a new technology. This is demonstrated in the following section, where this approach has been applied to the context of Brisbane, Australia.

A framework for assessing the readiness of Brisbane for airborne drone taxis

Mobilising Healey's (2007) revelation that "the relation between planning activity and its context [...is...] an activity in which context and activity are co-constitutive and co-generative", the act of reviewing and refining a planning jurisdiction's capabilities and readiness for a new technology creates a moment of opportunity to refresh its assumptions of power and inclusion in the context of technology adoption. This presents the first step of the process for creating the framework – *defining the reference group*. For example, transportation networks in Brisbane have largely been negotiated between State and Local Government planning jurisdictions. The prospect of including an intra-urban airborne transportation option into the city's suite of transportation modes (which currently include public rail and public bus, along with roads, toll roads, toll tunnels, etc.) legitimises new stakeholders with legitimate power to require specific design features and system oversight of how the airborne drone taxis intend to interface with the built environment. These stakeholders include the Civil Aviation Safety Authority (CASA), the country's aviation safety regulator; and Air Services

Australia (ASA), the country's airspace operator. Further, it's important that experts in the technology are legitimised into creating the framework in order to ensure that any assessment of readiness is accurate to the technical requirements. Experts could include design engineers of shortlisted airborne drone taxi operators, academics with rich technical knowledge of UAS requirements, or independent UAS engineers. Any attempt to construct the technology readiness framework for airborne drone taxis should include these stakeholders.

The second step in the process is to *define an array of criteria* relevant to the contextual and institutional requirements of readying the city of the technology. Deconstructing Davenport and Harris' (2017) original model provides some insight into the normative aspects required for technology adoption. This includes (1) the compatibility of existing infrastructure systems to take advantage of the new technology, (2) how stakeholders appreciate and include the utility of the technology into its operating fabric; (3) the interest and support of top leadership with respect to the technology; (4) the prevalence of use of the technology to achieve relevant goals for stakeholders; (5) the human resource capabilities and capacities to understand and apply the technology to support the goals of stakeholders; (6) the technical/physical requirements to support the adoption and use of the technology; and finally (7) the level of sophistication applied to integrate the technology into existing and emergent routines. In the context of the technology – airborne drone taxis – the criteria for the framework are defined in this paper as:

1. *System compatibility*: How will airborne drone taxis interface with the urban environment (i.e. need to take-off and land)? What hazards exist, and will they require specific standards for identifying sites for operations (i.e. are there existing sites, or is there a need to build new/bespoke landing pads to accommodate the technology)?
2. *Stakeholder adoption*: To what extent do residents, workers, tourists, etc. expect the technology to be desirable and in demand for their daily activities? How will the placement / availability of landing pads impact on the ability of airborne drone taxi services to be adopted into the routines of residents and other travellers?
3. *Leadership support*: To what extent to leaders of salient stakeholder organisations demonstrate a willingness to adopt, even champion, the inclusion of airborne drone taxis?
4. *Integration*: To what extent can the technology improve the city's goals for "an easy commute", "connecting communities" and "embracing innovation" (Brisbane City Council, 2019)?
5. *Expertise*: To what extent are planners empowered to transform the urban environment to leverage the opportunities created by airborne drone taxis?
6. *Infrastructure*: To what extent is the city and its stakeholder willing to invest in creating new or adapting old spaces to integrate airborne drone taxis into the urban environment?
7. *Scheduling*: To what extent is the city and its stakeholders able to adapt existing transportation routines and behaviours to create seamless flows of people with the support of airborne drone taxis?

These seven criteria provide a starting point from which levels of maturity can be defined - between veritable luddite and world-leading exemplar - for the integration of airborne drone taxis into the fabric of the city. Defining the maturity levels is the third step in developing the framework and requires careful consideration of the practicalities of bringing together diverse stakeholder needs to

pre-empt the opportunities and hurdles that are possible in the context being examined. The example below provides some insight to the levels of maturity expected from the diverse array of interests present in the case of Brisbane:

- *Stage 1: Unwilling to participate.* This is characterised by stakeholders who are potentially hostile or unwavering in their opposition to the notion of airborne drone taxis in Brisbane.
- *Stage 2: Cautious but willing.* This is characterised by stakeholders who may distrust the technology, or distrust one another, but are open to negotiate and review the facts to determine if the technology is plausible.
- *Stage 3: Recognition of importance.* This is characterised by stakeholders who agree on the potential utilities, benefits and hurdles present for the technology, and are actively seeking opportunities to solve problems and create synergies amongst stakeholder interests. This could include the reserving of space in carparks for future landing pad developments and changes to regulations.
- *Stage 4: Realised value.* This is characterised by stakeholders who have adopted new processes and invested in change to support the adoption of airborne drone taxis. This could include the creation of new organisations and/or regulatory bodies to support and oversee operations and physical changes to the urban environment.
- *Stage 5: Hallmark of the city.* This is characterised by stakeholders who actively champion the technology with external stakeholders, demonstrating that airborne drone taxis have become a distinctive feature of living in Brisbane. This could be characterised by joined-up infrastructure to ensure flows of people from one mode of transport to another is seamless.

With the levels of maturity now defined, the fourth step is *applying the framework to the context* – mobilising the expertise and diverse views amongst the reference group to critically evaluate the readiness of the city to the technology. This requires careful consideration for how each of the levels would be characterised for each criteria, essentially creating a five by seven evaluation matrix that would be applied to the context of adopting airborne drone taxis into the city's suite of transportation options.

The research framed in this paper has not progressed beyond this point at the time of writing. However, the remaining steps in the process are easy to explain and will of course be more difficult to implement. Step five requires *open consultation amongst stakeholders* to explain the maturity of the system of stakeholders, as well as identifying the maturity levels of individual stakeholders. This allows for transparency in identifying strengths and limitations amongst stakeholder capabilities, capacities, and compatibilities of their interests with one another. Davenport and Harris (2017) suggest that when planning to shift from one level of maturity to the next it is prudent to do so only after all criteria have reached a similar level. That is, it may be a fruitless exercise to invest energy and resources to enhance Infrastructure from Stage 3 to Stage 4 if Stakeholder Adoption remains at Stage 2, as a sceptical community may only become more resistant to negotiations if development was to take place before they had their concerns heard and advocated.

What is important to recognise for the framework is that it is a live tool that should be (step six) *updated throughout* the course of attempting to evaluate and potentially adopt a technology into the city's ways of doing things. The framework encourages ongoing critique and development, and maintaining an eye on how debates and decisions for resourcing transformative change impact on the overall *health* of the multi-stakeholder technology adoption effort. As such, the framework is presented as a tool for planning and technology decision making.

Transformative planning requires tools to foster agility

Planning for transformation often focus on socio-spatial and institutional dimensions (Friedman, 1987). In this paper, the focus is at the level of specific culturally embedded assumptions and habits (Healey, 2007) with respect to the task of adopting a specific technology into already defined planning regimes and relationships. That is, by undertaking the task of preparing the urban environment, stakeholders and interfaces between the city and other jurisdictions (i.e. civil aviation authorities / regulators) the city acts as a facilitator between the service providers (airborne drone taxi operators) and its market. Without the support of local planning initiatives, technologies that require specific physical interfaces and social awareness are impeded, if not totally rejected, from the possibility of technology adoption. Even if the populace of the city is in favour of adopting a specific technology, if the physical environment is not suitable, then the ability for the technology to operate is void. For this reason, it is imperative that cities continually scan the environment for emerging trends and technologies that may require a significant change in the physical environment, and poll its populace for their desirability. Where there is an expected desire and positive outcome for the city, the use of a systematic approach to investigate, understand, decide and act on emerging technologies is prudent, and fosters the agility of the city to more readily adopt transformative technologies as the technologies mature in the technology readiness scale.

For those who used to look up with awe at helicopters flying executives around Manhattan, it appears that your day to take to the sky is coming soon. The airborne drone taxi won't be the last technology to transform cities, but it appears that it will be the next.

The system of socio-spatial diversity monitoring in the city of Gdansk, Poland

Anna Gralewska¹

¹*Department of Spatial Management University of Gdansk, gralewska.anna@gmail.com*

Abstract: This paper presents methods for the system of socio-spatial diversity monitoring in cities on the example of the a monitoring system for degraded and regenerated areas in the city of Gdansk. The main focus is on the use of spatial databases for the monitoring system and the possibilities of using its results for further work - especially spatial planning or scientific purposes. In the beginning, the author will discuss the conditions for the implementation of monitoring in Polish cities - the legal basis, data availability and institutional support for the spatial monitoring processes. Next, data sources and methods of the implementation of monitoring will be discussed, along with an indication of the most difficult obstacles and ways to overcome them. The next part will present the chances of using monitoring data both for the needs of spatial planning and for scientific purposes, for example in the characteristics of Gdansk residential areas and assessment of their level of social capital. The study aims to lead to a discussion on the willingness of municipal units to conduct effective spatial monitoring and the use of its results for real changes in the urban space.

Keywords: socio-spatial diversity, monitoring, regeneration processes, factorial ecology, sustainable development

Introduction

From the very beginning of its existence, cities were places that gathered people with different social status. With the development of urban civilization, resulting in an increase in the number of inhabitants and their territory, the problem of the social diversity of cities has deepened considerably. Some scientists, however, believe that the main reason for this is the growing number of social characteristics that distinguish urban residents. Shevky and Bell (Shevky and Bell 1955, 3) regarded the city as *'a product of the complex whole of modern society; thus the social forms of urban life are to be understood within the context of the changing character of the larger containing society'*. Nevertheless, cities do display distinctive residential patterns and such areas may be termed morphological regions, neighbourhoods, urban social areas or urban regions, according to the type of approach and the semantic tastes of a researcher (Knox and Pinch 2000).

The paper presents the main conclusions from the implementation, conduct, and evaluation of the system of socio-spatial diversity monitoring on a micro scale in the example of city of Gdansk¹. The focus is on the monitoring system for degraded and regenerated² areas which is a part of Gdansk Municipal Regeneration Program. The article also considers how monitoring can serve to improve the efficiency of the spatial planning system for long-term sustainable development.

First, there is a need to establish definition needed to the discussion. It is fundamental to present the idea and assumptions of factorial ecology, which is the theoretical basis for the creation of the socio-spatial diversity monitoring of Gdansk. As Michael Pacione explains (Pacione 2005, 371) *'factorial ecology offer a means of constructing urban social areas based on a mathematically rigorous procedure and using a larger set of diagnostic variables than the seven employed in classical social-area analysis'*. In addition to, and sometimes instead of, classic dimensions represented in Murdie's model (Murdie 1969) it is common for factor ecological analyses to identify other dimensions of residential differentiation (Knox and Pinch 2000). Social-area analysis based on factorial ecology has been used in many studies as a tool for constructing a social typology in the city, as well as a prelude to the ecological analysis of social characteristics such as crime, social activity or electoral behaviour. Moreover, as Paul Knox and Steven Pinch declared, factor analysis *'it is now generally the preferred approach for dealing with the complex question of measuring urban sociospatial differentiation'* (Knox and Pinch 2000, 105).

Institutional and legal framework of socio-spatial diversity monitoring in Poland

At the outset, it is worth emphasizing that there are no legal provisions in Poland that contain a require of socio-spatial diversity monitoring in municipal spatial policy. The only legal requirement connected with the monitoring of urban space is contained in art. 32 of the Act of 27 March 2003 on Planning and Spatial: this regulation obliges the municipal offices to realize an analysis of changes in spatial development at least once during the term of office of municipal council, which is five years. The mentioned article does not indicate any detail or method of how to monitor these 'changes in spatial development' - in practice this unfortunately means that most of municipal offices do not conduct any spatial analysis, and only submit statistical data (such as the number of building permits, the number and the area of local spatial development plans or the area of transformed agricultural land).

Clearly this does not mean that spatial analysis is not carried out by Polish municipal offices at all. Mainly in larger (more than 200,000 inhabitants) Polish cities, usually the capitals of voivodships,

¹ Gdansk is the port city in northern Poland, a capital of Pomeranian voivodeship, with 466 631 registered inhabitants in the end of 2018 year.

² It is important to clarify the definition of the regeneration used in the paper, which comes from the Polish legislation (Act on regeneration, 2015). The regeneration process is defined as *'a process of counteracting crisis situation in the degraded areas, lead in complex approach due to integrated actions in favor of local community, space and economy, concentrated territorial, conducted by regeneration stakeholders, basing on local regeneration program'*.

there are special units within the municipal office, which are dealing with analysis, especially for the needs of spatial planning. Nevertheless, the issue of socio-spatial diversity analysis remains the domain of Polish universities. There are several well-known Polish geographers which are focusing on socio-spatial diversity like Grzegorz Węclawowicz (1988, 2007), Henryk Domanski (2004) or Stanislaw Liszewski (2009). Liszewski (Liszewski 2009) has been writing that in order to determine the socio-spatial structure of the city, it is necessary to look for regularity in the spatial distribution of social groups of its inhabitants and the connections that occur between them. Indication of where the social groups are located, the comparison of their living conditions and the consideration of why certain socio-spatial structures have been created in the city are according to Grzegorz Węclawowicz (Węclawowicz 1988) the main goals that should be accomplished by the study of the socio-spatial diversity.

However, what is worth emphasizing is that the monitoring system discussed in this paper was created in the municipal office, specifically in the Gdansk Development Agency, which is a municipal institution responsible for spatial planning. A direct cause to initiate the system of socio-spatial diversity monitoring in Gdansk was the Municipal Regeneration Program (MRP). It is a strategic document which includes diagnoses, plans and coordinates actions to achieve the expected changes after regeneration process. It is also used as an integrated regeneration project which is required for financial support for regeneration activities from EU Funds (Axis 6 of the European Social Fund and Axis 8 of the European Regional Development Fund) through Regional Operation Programs. Since 2015 the regeneration processes in Poland are being conducted out within the Act of on Regeneration, which enrolments obliges municipal offices to fulfil the guidelines set by the experts representing Marshals' Offices (polish provincial offices) during the preparation of the MRP. The Act on Regeneration also includes the obligation to rely on the analysis in the designation of regeneration areas and in their monitoring, which, combined with different regional guidelines, contributed to the creation of many various methods of spatial analyses concerning on changes in urban space, especially with differences on the scale of detail.

A system of socio-spatial monitoring in Gdansk – study case

As it was mentioned, the system of socio-spatial diversity monitoring in Gdansk was created for the Municipal Regeneration Program. Initially it was assumed that it will aims at assessing the degree of program implementation progress, identifying barriers, difficulties, but also new areas requiring support outside regeneration and degraded areas. After time, its scope expanded. It is worth mentioning that analyses for the needs of MRP are carried out in several areas using a variety of methods, and the monitoring is only the first step - the next are the survey of residents and the observation of the implementation of individual projects. However, this does not change the fact that in practice the monitoring system initiated for the needs of MRP became a full-fledged analysis of socio-spatial diversity in the city and a valuable material for many other studies and actions.

Gdansk monitoring system for the Municipal Regeneration Program distinguish oneself among other Polish cities systems, above all due to the exceptional scale of detail, reaching results aggregated separately for each hectare of the inhabited area of the city of Gdansk. The majority of Polish municipal offices carrying out spatial monitoring only to the level of settlement units or, in the case of larger cities, districts. In the case of the monitoring in Gdansk, every effort has been made to obtain as much detailed data as it is possible.

The distinguishing feature of Gdansk monitoring system is also its frequency. According to Gdansk MRP itself, the analysis will be realised in the cycles of at least 3 years - however, the success of the first socio-spatial diversity analysis has made the monitoring regularly carried out every year. Such a frequency of repeated analyses allows to observe even the smallest changes in the city social area. It also enable to look for a correlation between the analysis results and current local or global events more precisely, than it would be possible in the case of monitoring with three-year cycles.

The socio-spatial diversity monitoring covers whole area of the city of Gdansk. After considering the availability of spatial data and after selecting the indicators for analysis, it was decided that their results will be presented only for inhabited areas - this also means that the total area covered by monitoring changes every year (mainly because new residential buildings are created). However, this does not prevent the possibility of comparing the annual results, because the synthetic index is calculated individually for each hectare of the inhabited area in the city of Gdansk. The aggregation of data into one-hectare squares allows an easy comparison of selected areas according to the values of indicators, as well as it simplify the creation of a synthetic index summarizing the results of all components indicators used for the analysis. A comparison of the results of the analysis of the socio-spatial diversity for the selected area of Gdansk in two following years is presented in Figure 1.

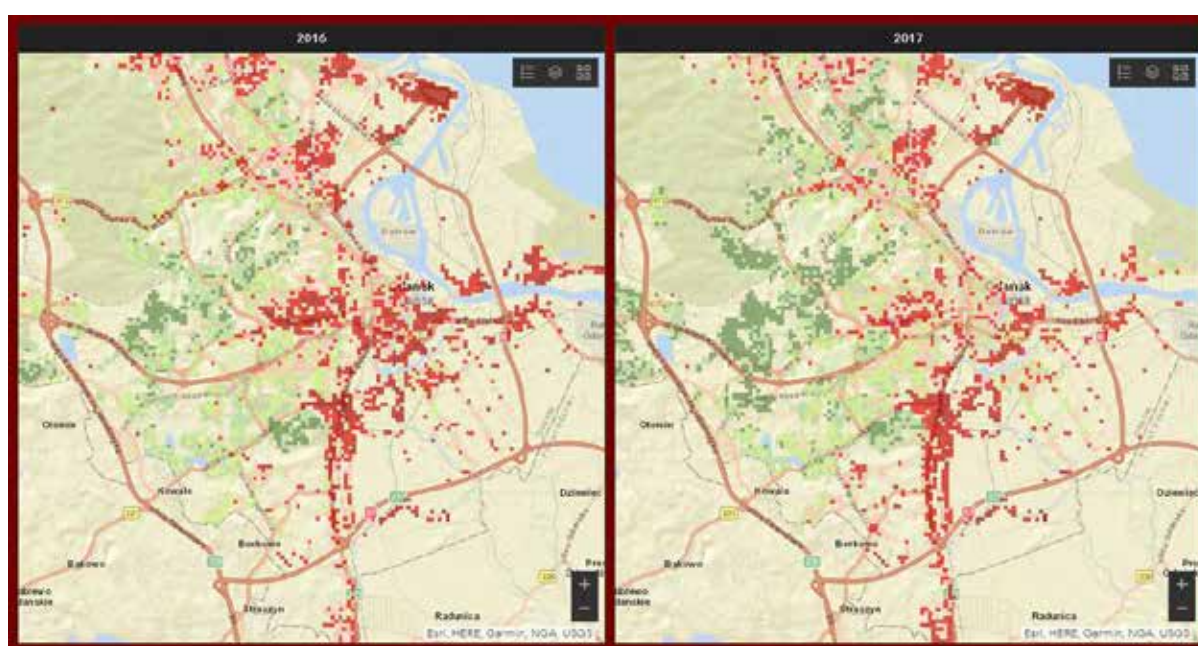

Figure 1 The comparison of the results of syntetic index of the Gdansk MRP monitoring in 2016 (left) and 2017 (right). Source: Gdansk Development Agency (<https://tiny.pl/twt1l>, access: 05.05.19)

As mentioned earlier, the system of socio-spatial diversity monitoring in Gdansk is based on the principles of factorial ecology. *'Factorial ecology employs the multivariate statistical technique of factor analysis in order to derive a smaller set of diagnostic factors from an initial larger set of variables measuring the social, economic and demographic characteristics of census tracts in a city'* (Pacione 2005, 371). The method of obtaining and processing data in accordance with the principles of factorial ecology is presented in Figure 1.

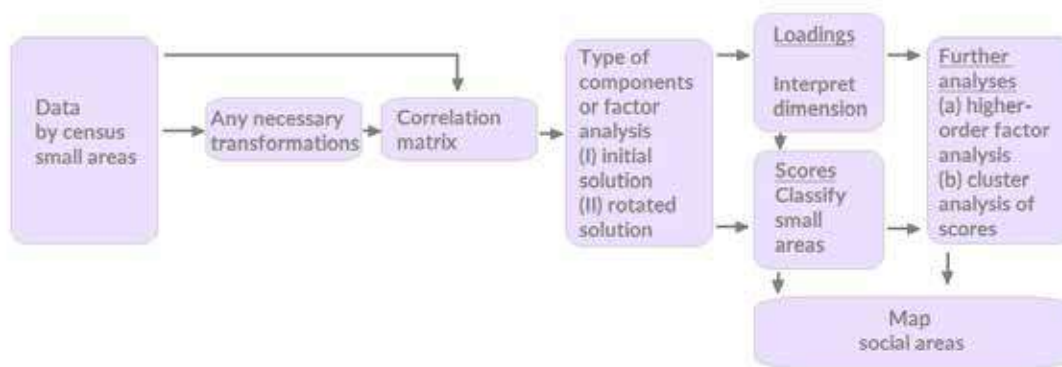

Figure 2 The method of factorial ecology. Source: Own study based on Pacione 2005

The system of socio-spatial diversity monitoring in Gdansk is based on synthetic indicators. The census data for synthetic indicators are always from the previous year of the analysis year. Additionally, for the base year for the whole monitoring system, the year 2016 was recognized. It will additionally refer to research in the following years. The selection and sourcing the appropriate census data was a key decision, but also the most time-consuming stage in the implementation of the monitoring.

In the first place, the choice of indicators was based on guidelines from national, provincial and local level documents. The main recommendations for the selection of indicators were:

- The guidelines of the Polish Ministry of Development;
- The guidelines of the Marshal's office (which is managing the disbursements of the funds from Regional Operational Programs and the EU),
- The indicators and goals adopted earlier in the diagnosis to and in the project of MRP for the city of Gdansk.

In this way, ten issues were selected - five social issues and five functional issues - for which appropriate (possible to be assigned to the location) indicators were sought. The socio-spatial diversity analysis is carried out in a set of permanently fixed 20 indicators for the social and functional domains. Table 1 presents the set of indicators with its sets.

Table 1 Twenty indicators used in Gdansk socio-spatial diversity monitoring. Source: own study based on Turzynski et al 2016

SOCIAL DOMAIN	EDUCATION	SAFETY	SOCIAL CAPITAL	DEMOGRAPHY	POVERTY
	<i>the percentage of graduation</i>	<i>the crime rate</i>	<i>the voter turnout</i>	<i>the dynamics of population</i>	<i>the poverty rate indicator</i>
	<i>the exam results</i>	<i>the family violence rate</i>	<i>the civic budget turnout</i>	<i>The population aging</i>	<i>the rent debt rate</i>
FUNCTIONAL DOMAIN	ECONOMY	ENVIRONMENT	SOCIAL SERVICE	HOUSING	INFRASTRUCTURE
	<i>the level of unemployment</i>	<i>the noise exceeded</i>	<i>the availability of health services</i>	<i>the percentage of old buildings</i>	<i>the availability of sewerage systems</i>
	<i>the social entrepreneurship</i>	<i>the availability of green areas</i>	<i>the availability of public transport</i>	<i>the standard of living</i>	<i>The availability of water supply network</i>

The data selected for the analysis were aggregated to the lowest possible level – the address points, which were the joining point for all data used in monitoring. In selected cases it was only possible to obtain data in area aggregation (school districts, electoral areas). In such cases, a value of indicator for an area was assigned to each address point in this area. For transforming census data into spatial data the geographic information systems (GIS) tools were used. GIS applications allows to process spatial information, edit data in maps, and present the results of all these operations (Maliene 2011).

Next, all the indicators were valorised. The appropriate classification of stimulants (indicators such as entrepreneurship or electoral turnout) and the destimulants (crime rate, poverty) was important for the proper synthesis of their results. The fundamental stage in creating the index of synthetic socio-spatial diversity was giving validity to individual component indicators. Giving appropriate weight to the indicators required extensive knowledge, discussion but also intuition. Synthetic indicators used in socio-spatial diversity monitoring presents values on a conventionally accepted scale, in percentage to the assumed reference value or in another way allowing for the interpretation of the state or trends. Individual geometric cartograms were created for all indicators used in the analysis. They are presented in a figure 3

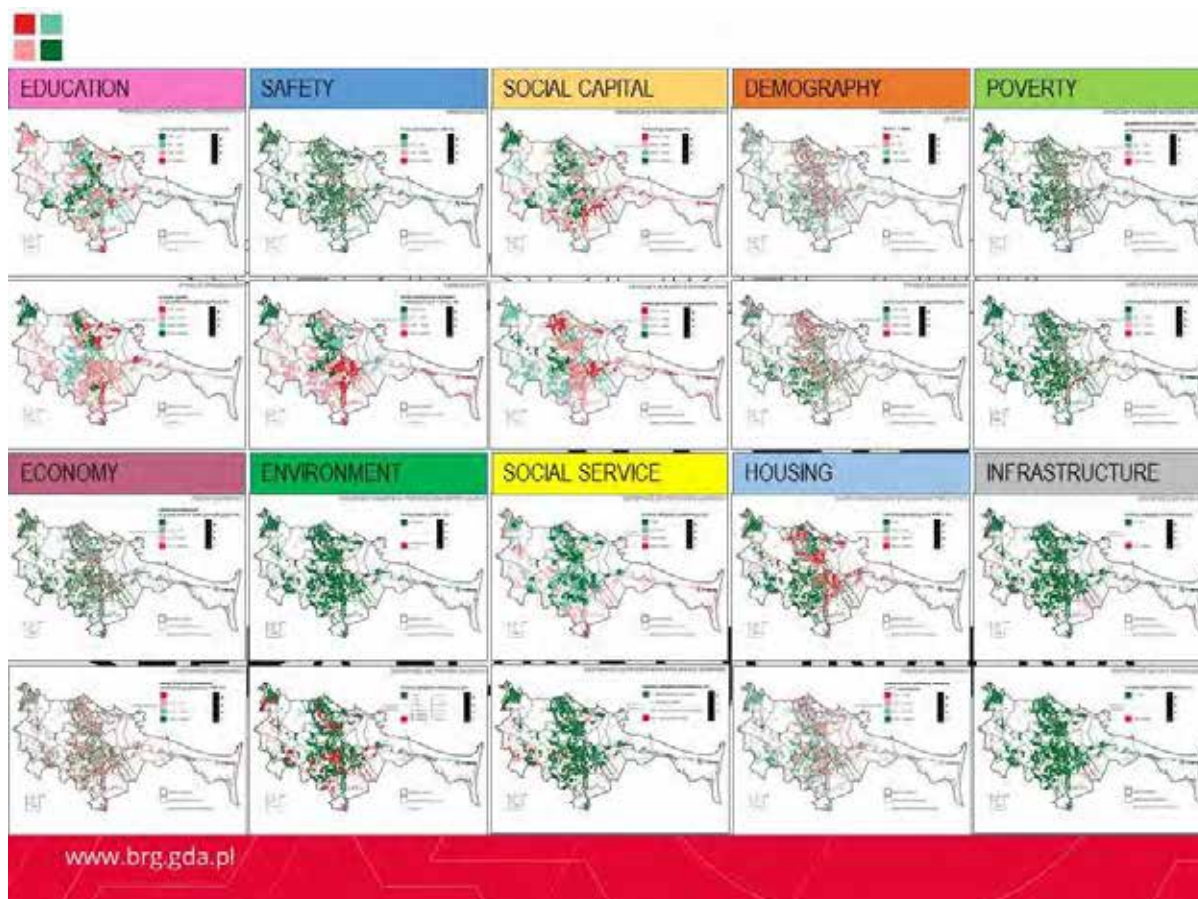

Figure 3 A set of result maps of particular components of the socio-spatial diversity monitoring in the city of Gdansk for 2017. Source: Turzynski et al 2018

Running a system of socio-spatial diversity monitoring in Gdansk has encountered many problems along the way. The greatest barrier was the availability of appropriate census data that could suitably represent this issue. It can be regarded as a success that twenty indicators have been selected and they are indicating various aspects of life of the inhabitants of Gdansk. However, the lack of availability of fundamental data usually used to determine social diversity, especially those relating to the sphere of social classes, has contributed to the disregard of this important aspect directly. Many of the census data are considered by the Polish law as sensitive data (such as, for example, wealth or income level) so that they are not available even for public or scientific institutions - even for the needs of research - all in the name of the protection of personal data. This does not mean the sphere of social classes has been completely ignored in the study. Using the data collected by municipal institutions (for example, the Municipal Social Aid Center) created indicators such as the synthetic poverty rate, housing standard or rent debt ratio in together allows to determine the generalized picture of social classes distribution in the city.

Another important barrier in initiating the monitoring system was the lack of regularity in statistical surveys conducted by the Polish Statistical Office (PSO). This office is responsible for such data as the size of households, the level of education or national and ethnicity affiliation of the population.

These data are collected through the National Census of Population and Housing³ - a nationwide common survey program which consisted in involving census enumerators visiting all inhabited units and noting down information obtained directly from respondents on census forms. Last census took place in 2011, and there is no reason to believe that another will take place soon. The Polish Statistical Office justified the reason for this state that "such organization of the census turned out to be very expensive and laborious" (Polish Statistical Office 2014, 1). Therefore, despite the large potential usefulness of data collected by PSO in research on socio-spatial diversity, the irregularity of their collection excludes them for monitoring purposes.

Last but not least, the colossal problem in implementing the system of socio-spatial diversity monitoring turned out to be lack of awareness among employees of public units, which are collecting census data, on the meaning and rules of the spatial databases. Although the subject of GIS is not a novelty in Poland; despite the fact that the majority of universities conduct teaching courses in this field; even though GIS is becoming more and more popular in many spheres of public life, including marketing and advertising - despite all these premises, knowledge about the principles of data collection for future spatial database purposes is still underestimated. Unfortunately, even within one municipal office, the procedures of collecting registration data are varied, also in the case of the data attribute fundamental for monitoring method - the address, or more precisely the form of naming of address points. The problem exist because Polish streets are often called in honour of commonly respected people also known as patrons. Some institutions indicate names of such streets only with the last name of the honoured person, others use the last name with the surname, but there are also those which additionally add professional and military titles of the patron, such as a doctor, a colonel or a priest. Unification of the data record initially took a considerable amount of time. When data sets were collected again for the purpose of the next monitoring, a special application was created using SQL code, which automatically reduced various ways of saving addresses to one common form of address description through programmed name correlations.

The problems mentioned above are just some of the barriers faced by the authors of the Gdansk monitoring system of socio-spatial diversity. Among the others, one can mention the change in the method of classifying the source data about the civic budget (one of the indicators from the social capital sphere) or the change of the national education system (through the abolition of middle school) along with the change of school district's boundaries. Nevertheless, the results of monitoring are considered as a very useful imaging of the Gdansk urban space. These maps do both: confirmed the theories of social inequality between the upper and lower terrace of Gdansk (as the younger upper terrace has much better living conditions than the lower terrace) and also indicated new areas that are at risk of social degradation. Still, only long-term monitoring (at least five-year long) will allow for a meaningful analysis and then one can draw conclusions that will enable the elaboration of the necessary corrective actions.

³ More information about the census is available on the Statistics Poland website: www.stat.gov.pl/en/national-census/national-census-of-population-and-housing-2011/

Future use of socio-spatial research results

The system of the socio-spatial diversity monitoring was initiated in Gdansk only two years ago and has already gained recognition. The spatial analysis at the micro scale was appreciated by the regeneration committee (a council of residents, an advisory body in the processes of regeneration), experts from the Marshal's Office, spatial planners and officials working in the municipal office. The cartograms with partial results of the monitoring, which are made available in the form of an interactive maps, are particularly popular. The main recipients and their ways of using monitoring results for purposes other than MRP are presented on the figure 4.

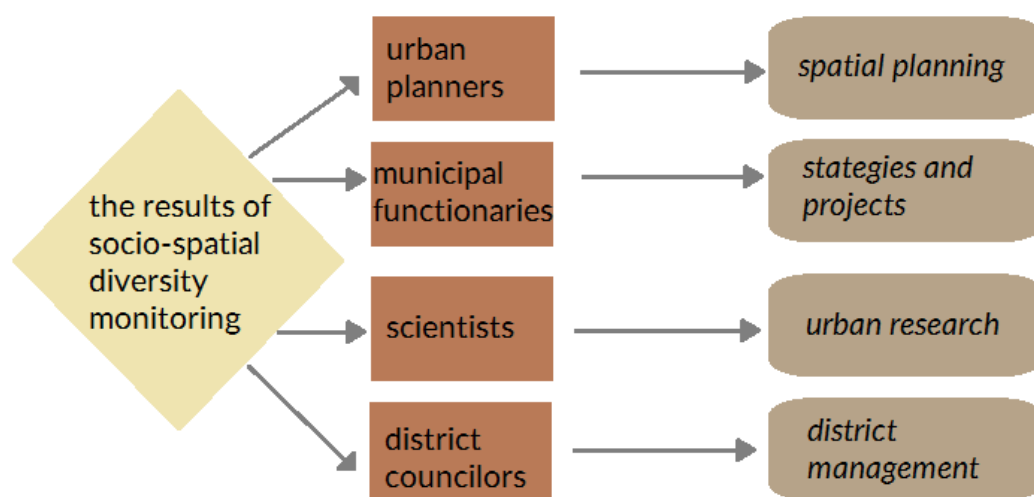

Figure 4 Current wide use of the results of the monitoring. Source: own study

The author of this article is also one of the authors of the described monitoring system. For a young scientist, whose research are concentrated around Gdansk neighbourhoods - their neibourhoodliness and their importance to the creation of social innovation - participation in the study of the distribution of socio-spatial diversity together with the subsequent consideration and analysis of the results had a significant scientific value. The work on the monitoring left a mark on many stages of the author's scientific work regarding the classification of the neighbourhood space of the city of Gdansk. Firstly, the synthetic collection of data on electoral districts or school districts allowed for these aspects to be taken into account in the delimitation of the borders of Gdansk neighbourhoods. Secondly the initial picture of social classes and the social capital level distribution in the city contributed to the assessment of the social cohesion of the neighbourhoods. The scientific application of Gdansk socio-spatial monitoring results may be significantly wider, which is why the Gdansk Development Agency makes them available online in the form of open data.

Lesson learnt

The publication of results of the system of socio-spatial diversity monitoring initiated discussions about the participation of the city's unit in research on the city space. So far, significant majority of spatial and social analyses (including those for the needs of development strategies) realised in Gdansk, as well as in other Polish cities, have been outsourced to expert companies, think-tanks or

universities. Currently, the possibilities offered by GIS tools allow for the more active participation of the municipal office itself in the analysis and research of the city space. This solution has many strengths - the office is the administrator of the necessary census data, well knows the needs and the purpose of the analysis and it has a broader knowledge about possible sources of deviations. In order to not be left behind by the developing research techniques, this approach requires constant dialogue with scientific units as the ones that lead the way in initiating and disseminating new research methods. The second necessary condition is also the requirement of continuous training of municipal office employees in the field of spatial databases and GIS itself, broadening knowledge about them and cultivating good practices.

Running a system of socio-spatial diversity monitoring in the city of Gdansk has shown that this topic is not yet properly installed in the realities of Polish institutions. At the same time, the process of work on monitoring and the response to its publication showed how much research of this kind was needed. Analysis of socio-spatial diversity on a micro scale, in reference to each hectare of a residential area is considered an innovative solution on a national scale. Another novelty is the fact that the monitoring system has been developed and run fully by the municipal planning unit. This is the first step for greater involvement of GIS tools in municipal offices, but also, it's a sign of a greater openness to prototyping, testing new solutions and new methods in Polish administration.

Urban Planning and Nature: Parametric Modelling as a Tool for the Responsive Greening of Cities

Fabiano Lemes de Oliveira¹, Dana Hamdan²

¹*University of Portsmouth, fabiano.lemes@port.ac.uk*

²*University of Portsmouth, up871445@myport.ac.uk*

Abstract: Using advanced parametric computational tools – and considering variables such as the size of urban areas, their population and recommended indicators of amount of green space and its proximity to residents – this paper proposes an approach to simulate optimum urban morphologies based on the application of defined large-scale green planning models such as the green belt, green wedges and hybrid approaches. Parallel patterns of growth and shrinkage have marked cities in the last decades. Furthermore, planning cities for climate-change related events and social transitions is a pressing action. Yet, while there has been an upsurge of research on the beneficial effects of green spaces and their efficient planning and implementation in cities, explorations regarding standard-based spatial simulation and modelling of future green scenarios need further research. This paper first contextualises current processes of urban and landscape transformations. Secondly, it defines the parameters used in the model and assesses the performance of selected green planning models. Finally, it shows how the proposed computational approach could become an effective quantitative tool for improving the processes of envisioning future sustainable and re-natured urban environments.

Keywords: spatial simulation; parametric modelling; green spaces; green areas; planning models

Introduction

Planning for climate-change related events and social transitions is a pressing action. With predictions of an increase of urban population to 70% by 2050, with potential resultant natural capital loss, discourses on re-naturing cities, nature-based solutions and green infrastructure have recently come to the fore as paradigms for the re-conceptualisation of sustainable and resilient urban scenarios. The benefits of nature for humans have been systematically studied across several disciplines and promoted in public policies worldwide, including the provision of adequate amount of accessible green space in cities. For instance, the United Nations Sustainable Development Goal 11 states that by 2030 cities should provide universal access to safe, inclusive and accessible green and public spaces.

While the multiple benefits of ecosystem services in urban areas have been boasted, urbanity remains an important value in urban design and planning discourses. The question of balance is important, but often not precisely posed in urban studies. Current understanding of cities as significant *loci* for the integration of ecological and socio-cultural systems points to the importance of urban form in supporting or hindering such relationship.

Given the need for cities to both accommodate anthropic needs and non-human life, while reducing our impact on the planet; an integrative and systemic approach to planning and delivering new, greener urban environments is required. As such, explorations regarding standard-based spatial simulation and modelling of future green scenarios need further research. The central aim of this article is to investigate how the use of planning models could allow cities to be greener by the virtue of their form. Through a parametric computation modelling approach and considering key indicators for the amount and distribution of green spaces in urban areas, it explores the potentialities and shortcomings of models such as the green belt, the green wedges and hybrid approaches. In so doing, it analyses how the application of such green planning models perform in terms of proximity of residents to green spaces. Subsequently, the article discusses how hybridism can lead to optimum urban morphologies. The proposed approach allows green infrastructure solutions to maximise the benefits of each individual strategy, helping generate hybrid, site-specific and responsive visions for environmentally just greener cities.

Cities and green space planning models

Perspectives from urban planning and design on the roles of urban form in providing a framework for a harmonious relationship between built-up and green areas have regained attention. Lynch (1981) detailed city models such as the Core, Start City and Linear City; which were subsequently investigated by Frey (1998) in relation to sustainability indicators. Building on these studies, this paper explores such typologies at city scale, focusing on how associated green planning models based on the green belt, green wedges and hybrid approaches including greenways perform in terms of provision and distribution of green spaces.

Green belts have, since Howard's Garden City idea, marked planning debates. Originally conceived to control urban sprawl, create a buffer zone between urban areas and safeguard agricultural land; already in the early twentieth century green belts received severe condemnation for strangling the cities' ability to expand and for keeping most of the open spaces at the fringe, away from the densely populated central urban areas, where most of people lived (Eberstadt, 1911). Eberstadt's criticism with regards to the unbalanced distribution of green spaces in green-belt cases was aimed at the very core of its inherent structure: that it can allow for the outer ring of urbanization direct access to green space, but not for the inner areas. In the current context of global population growth, this model has been deemed inflexible to cope with the need to accommodate more urban dwellers, to enhance the presence of nature in cities and to bring ecosystem services close to inner-city dwellers (Amati and Taylor, 2010; Lemes de Oliveira, 2019).

The green wedges model is defined as a particular articulation between open and built-up spaces in which wedges of greenery opening out towards the edge of the urban area are interspersed between development areas. It was conceived as a way to ensure that urban growth could happen without compromising the amount of green spaces available in cities and their accessibility to inhabitants. (Lemes de Oliveira, 2017). If provision of large-scale green spaces close to dwellers is this model's main intrinsic positive characteristic regarding its form, its main shortcoming is the potential disaggregation of built-up areas as the wedge widens beyond walkable distances. Size matters also as it has an effect on the range of human activities and ecosystem services possible (Forman and Godron, 1986). Stockholm's Regional Plan, for instance, defined that green wedges should be at least 500m. However, examples vary and in cases, in their thinner ends, green wedges can become more alike tree-lined streets and greenways, and in the other end of the spectrum, urban forests.

Greenways, as corridors of landscape through an urban area, offer flexibility in implementation. Normally narrow in width and long in extension, such areas have the potential to reach various portions of the urban fabric, providing excellent accessibility (Ahern, 1995; Hellmund and Smith, 2006). Examples such as Cheonggyecheon in Seoul, Madrid Río Park in Madrid and Emerald Necklace in Boston are associated with watercourses and present varying widths from nearly 40m to more than 250m. Greenways' often-narrow width can be limiting to the provision of activities and ecological functions (Smith and Hellmund, 1993).

The question of quantity, accessibility and distance

The question of how much green space cities should have as well as their adequate distribution have been objects of much consideration. The provision of ecosystem services is dependent on adequate amounts of natural environment provided and the larger the space the more ecological habitats and human activities can be accommodated. The benefit being directed both at human and other species. Various studies found that the total amount of green space within the living environment seemed to be the key variable to directly influence people's health (Keniger *et al.*, 2013; van den Berg *et al.*, 2015). For instance, De Vries *et al.* (2003) reported that the total amount of green space within the living environment is a crucial factor, and that an increase of only 10% of green space could result in the decrease in the number of symptoms equivalent to a reduction of 5 years in age. In addition, such effects could be seen within a 3km radius.

The identification of clear standards is problematic, as many terms with varying definitions and interpretations are used, such as open spaces, open areas, green spaces, public spaces etc. However, area-based and population-based indicators have been considered. With regards to the former, already in the 19th century classic planning treatises such as the tome by Baumeister suggested a ratio of 50% of open spaces and that of Stübgen 30% of green spaces (Baumeister, 1876; Stübgen, 1890). The ratio of 30% appears in several approaches in planning history and bears relevance with contemporary targets, as can be seen in the cases of New York (The City of New York, 2011) and Copenhagen, which have each a quarter of their area destined to accessible green space; and London, with over 30%. The surge of eco-cities in China in the early 2000s saw ambitious targets. For example, Songdo in South Korea was planned to have 34% of land dedicated to green and blue spaces and Dongtan in China, to be close to 40% (Lemes de Oliveira, 2013).

In regards to a population-based approach, it is noteworthy mentioning the one defined in the UK by the National Playing Fields Association. Originated in the 1930s, it defined the Six Acre Standard (24,000 square meters/1,000 people). This has served as a benchmark in various plans since the post-war period. At the beginning of the War, the average open space provision for some of the largest cities in England was less than 3 acres (12,140 square metres) per 1,000 people (Lemes de Oliveira, 2017). Abercrombie and Foreshaw's County of London Plan 1943 aimed for seven acres per 1,000 people, four within the boundaries of the council and three beyond. For the Greater London Plan 1944, Abercrombie increased the ratio to 10 acres per 1,000 people. Highly influential, this plan became a fundamental reference for planning cities and regions in the postwar period. The Six Acre Standard is still applied today.

Proximity to a green space within a 10-minute walk (800m) frequently appears as a key indicator (Fields in Trust, 2018; Frey, 1998). Yet, several authors relate walking time, distance and size of green spaces (Stessens *et al.*, 2017). For instance, the Accessible Natural Greenspace Standard (ANGSt) recommends that all should have access to green space of at least two hectares in size, no more than 300 metres (2-3 minutes) from home; a 20 hectare site within two kilometres (25-minute walk); one 100 hectare site within five kilometres; and one accessible 500 hectare site within ten kilometres of home. When focusing on walking distances, studies tend to limit the distance considered up to 3km. Maas *et al.* (2006), for instance, showed that in areas where 90% of the environment around the home was green, only 10.2% of the residents felt unhealthy, compared to 15.5% in areas where only 10% of the environment was green. This was also perceived in the range up to 3km. Figure 1 shows the parameters employed in this study.

Figure 1. Correlated *time-distance-scale* parameters to urban green spaces

Distance decay in the use of green spaces is commonly found, with high association between distance and use (Nielsen and Hansen, 2007). Grahn and Stigsdotter reported that green spaces within 300m of home rendered on average 2.7 visits a week, but if the distance was of one kilometre the frequency of visits dropped to once a week. Notwithstanding this, larger green spaces even if further away often allow for a wider range of activities for various groups (Lemes de Oliveira, 2017). Taking distance, walking time and size of green spaces in consideration, Stessen *et al.* (2017) brought together these key indicators in relation to the different urban scales, from local to metropolitan. This article builds on this approach to inform the computation model and test the planning models described previously. It focuses on the area-based approach as described below.

Modelling balance between urbanization and green spaces

Methodology

The computational model was created using Grasshopper, an algorithm-based plug-in for Rhinoceros. It allows for the concomitant managing and manipulation of several parameters and simultaneous visualisation of outcomes. The model combined information about a city's size, amount of green space required and accessibility on foot according to their distribution in the key green space planning models under study. The computational model allows for the analysis of cities of virtually any size. However, this paper concentrates on medium-sized cities, applying the models on 40 km² and 70 km² using 30% green space as a constant (figure 2-4).

The model was employed to explore the intrinsic potentialities and shortcomings of such green space planning frameworks. The accessibility to green spaces in each green planning model was measured and compared. The idea of a nested hierarchy as described in Stessen *et al.* (2017) was used in seeking common ground in relating multiple scales both of urban areas and green spaces, and the time dimension. The analysis is kept to local, neighbourhood, district and city scales. As such, the percentage of areas accessible within 5 minutes, 10 minutes, 25 minutes, and more than a 25-minute walk have been measured and visualised for each of the green planning models.

Specific indicators for the green space planning models were limited to achieving a width of 500m at the centre of green wedges; a minimum width of 40m for the thinner ends of green wedges and for greenways; and in the case of the green belt that it was concentrated outside the urban fabric, and distributed as one or two green belts.

The green space planning models

[Green belts]

Two green belt cases were applied to two city sizes, for a total of four test models. The first case presented the entire green belt, which is assumed as 30% green space of the city's total area, as a single belt on the perimeter of the city. This was applied for the 40 km² and 70 km² cities. The second case involved splitting the assumed 30% green space into two green belts: the first one at the perimeter of the city and the second at half of the city radius, functioning as a greenway. Similarly, this was applied to the 40 km² and 70 km² cities.

In the first case, belt widths amounted to 583m and 772m for the 40 km² and 70 km² cities respectively. The percentage of the area accessible within a 5-minute walk are 27.7% and 23.7%, reaching 52.9% and 44.2% when considering a 10-minute walk. Just over 86% in the smaller city and 75% in the larger have access to a green space within a 25-minute walk (figure 5). In the second case, belt widths are narrower, amounting to 385m and 500m for the 40 km² and 70 km² cities respectively. The accessibility ratios rose to 60.1% and 42.2% within a 5-minute walk and to just above 97% and 82% within 10 minutes (figure 6). Clearly, the two-belt model provides significantly higher walkable area, especially in creating zones within 5 and 10 minute walking distances. In the smaller city nearly 100% of the built-up area is within a 10-minute walk of a green space. In cities of both sizes, this model ensures that 100% of the urban area can access a green space on foot within 25 minutes. On the other hand, it is worth stressing that the analysis focused on accessibility to green spaces, hence does not consider the ecosystem services that can have better performance for instance at larger continuous green spaces, which could suggest a better performance for the single belt model.

Figure 5. Walkability assessment of a single green belt at the perimeter of a 40 km² city (left) and a 70 km² city (right)

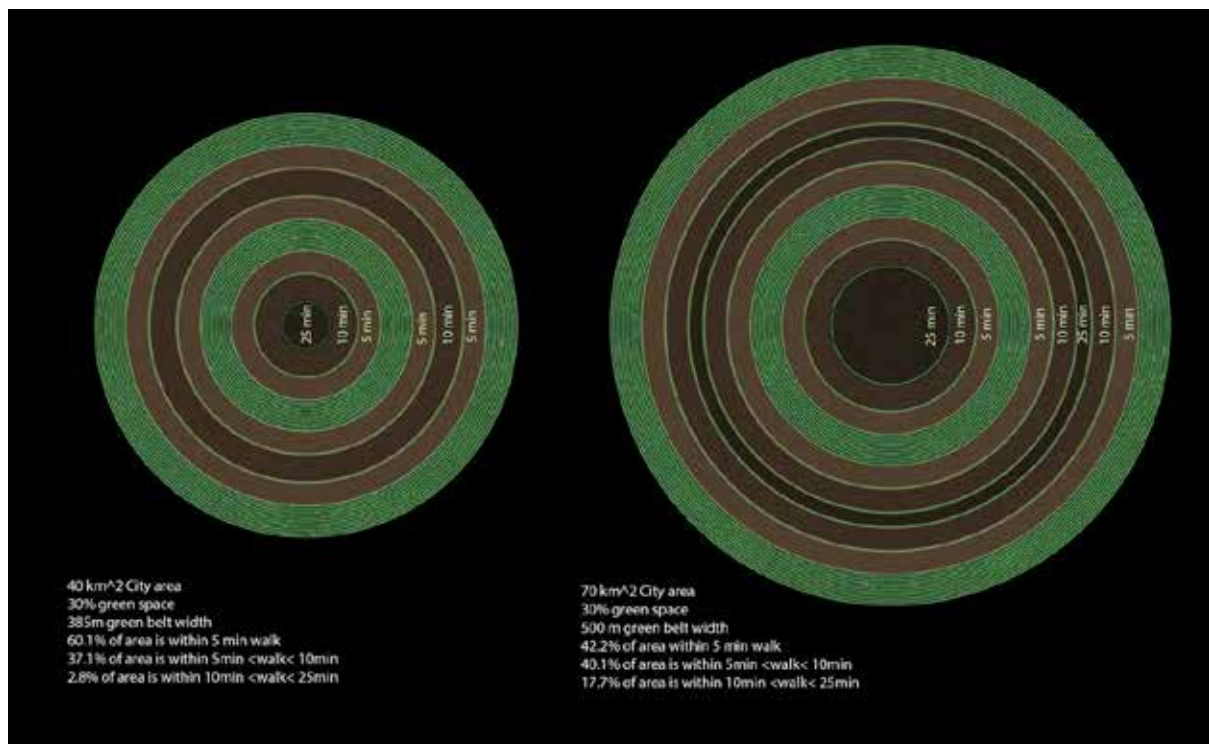

Figure 6. Walkability assessment of two green belts at the perimeter and mid-radius of the city. Applied to a 40 km² (left) and 70 km² cities (right).

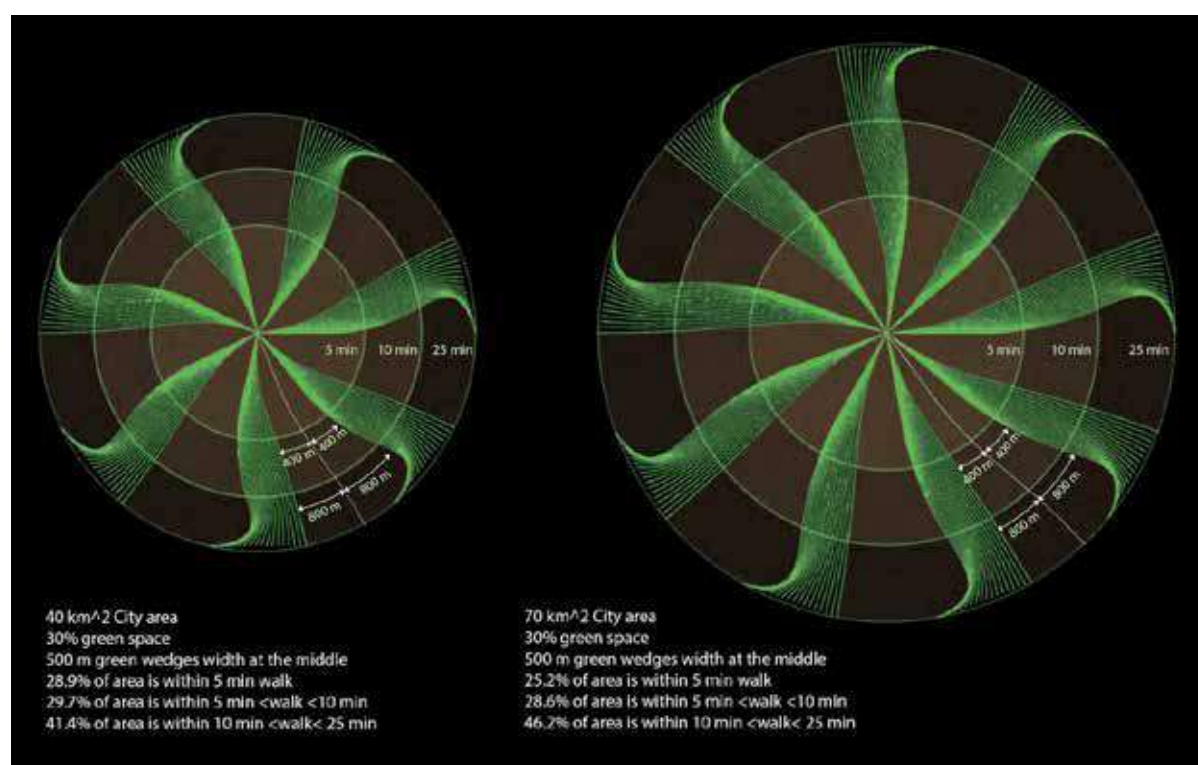

Figure 7. Walkability assessment of green wedges model applied to a 40 km² (left) and a 70 km² city (right).

The green wedge model was also explored. The created algorithm calculated how many green wedges were needed using as inputs the city size, considering 30% of the city area as green space, which was split into equal parts equally distributed, and 500m as the minimum width of the wedges at the middle. Such 500m cross-section at half the radius of the city was employed in order to facilitate the provision of a range of ecosystem services in the green wedges (Lemes de Oliveira, 2017). The location at which the distance between the green wedges is 800m (5-minute walking time to a green wedge from the centre line) was defined in the algorithm using basic trigonometry. Similarly, the distance of 1600m between the wedges (10-minute walk) and less than 4000m (less than 25-minute walk) were graphically represented (See figure 7).

The model generated 7 green wedges for the 40 km² and 9 for the 70 km² cities respectively. The percentage of the total area accessible within a 5-minute walk are 28.9% and 25.2%, reaching 58.6% and 53.8% when considering a 10-minute walk. Both cities would allow for all to access a green space on foot within a 25-minute walk.

The green wedge model is better performing than the single green belt model in terms of accessibility for both city sizes across the different scales. However, the two-belts model also provides 100% coverage within the 25-min range and significantly outperforms the green wedge model in the local and neighbourhood scales, as when placed at the end of the 10-minute zone it provides a counterpoint to the wedge's tendency for distances to increase as they widen towards the edge of the city.

When discussing performance measures of green spaces, green wedges (as represented in the models) could create a more fragmented urban form in comparison with the single green belt model, as well as less continuous green space. However, the longitudinal distribution of green space across the radius of the city can provide better distribution of green areas across the city's different zones, which can contribute to a more equitable

provision, as well as facilitate certain ecosystem services such as air flow and exchange and reduction in the heat island effect.

[Combined model: green belt and green wedges]

In order to analyse the combined effect of green belts and wedges on accessibility to green areas on foot, two scenarios were considered for both the 40 km² and 70 km² city areas, for a total of 4 tests models. All the test models have 30% green space of the city area. The first scenario uses 4 green wedges, while the second considered the same number of green wedges as in the models presented previously (7 and 9 wedges for the 40 km² and 70 km² respectively). The width of the wedges was kept as 500m at the middle of the radius for the 7 and 9 wedges. The width of each green belt is 120m and 170m for the two city sizes, which was calculated parametrically using the algorithm to ensure that, combined with the wedges, the total amount of green space reached 30% of the total area. It is worth pointing out that the model allows for a range of combinations of sizes for belts and wedges, for instance where the wedges can be thinner and the belts thicker. However, in this paper we limited the analysis by treating the wedges' thickness as a constant, consequently allowing the belts' thickness to vary.

In the 40 km² city, both models with 4 and 7 wedges achieve 100% of green space accessibility within a 10-minute walk, with the latter performing better in the 5-minute range (64.2% compared to 54.4%). In turn, in the larger city, the 4 and 9 wedges combined models achieve 100% accessibility within the 25-minute range and the same ratio (77.8%) at the 10-minute range, with the one with more wedges performing better (59.5% compared to 39.3%) within the 5-minute walking distance (see figure 8). When analysed against the non-hybrid models, the combined wedge-belt models of 7 wedges for a city of 40 km² and 9 wedges for a city of 70 km² outperform all the other models.

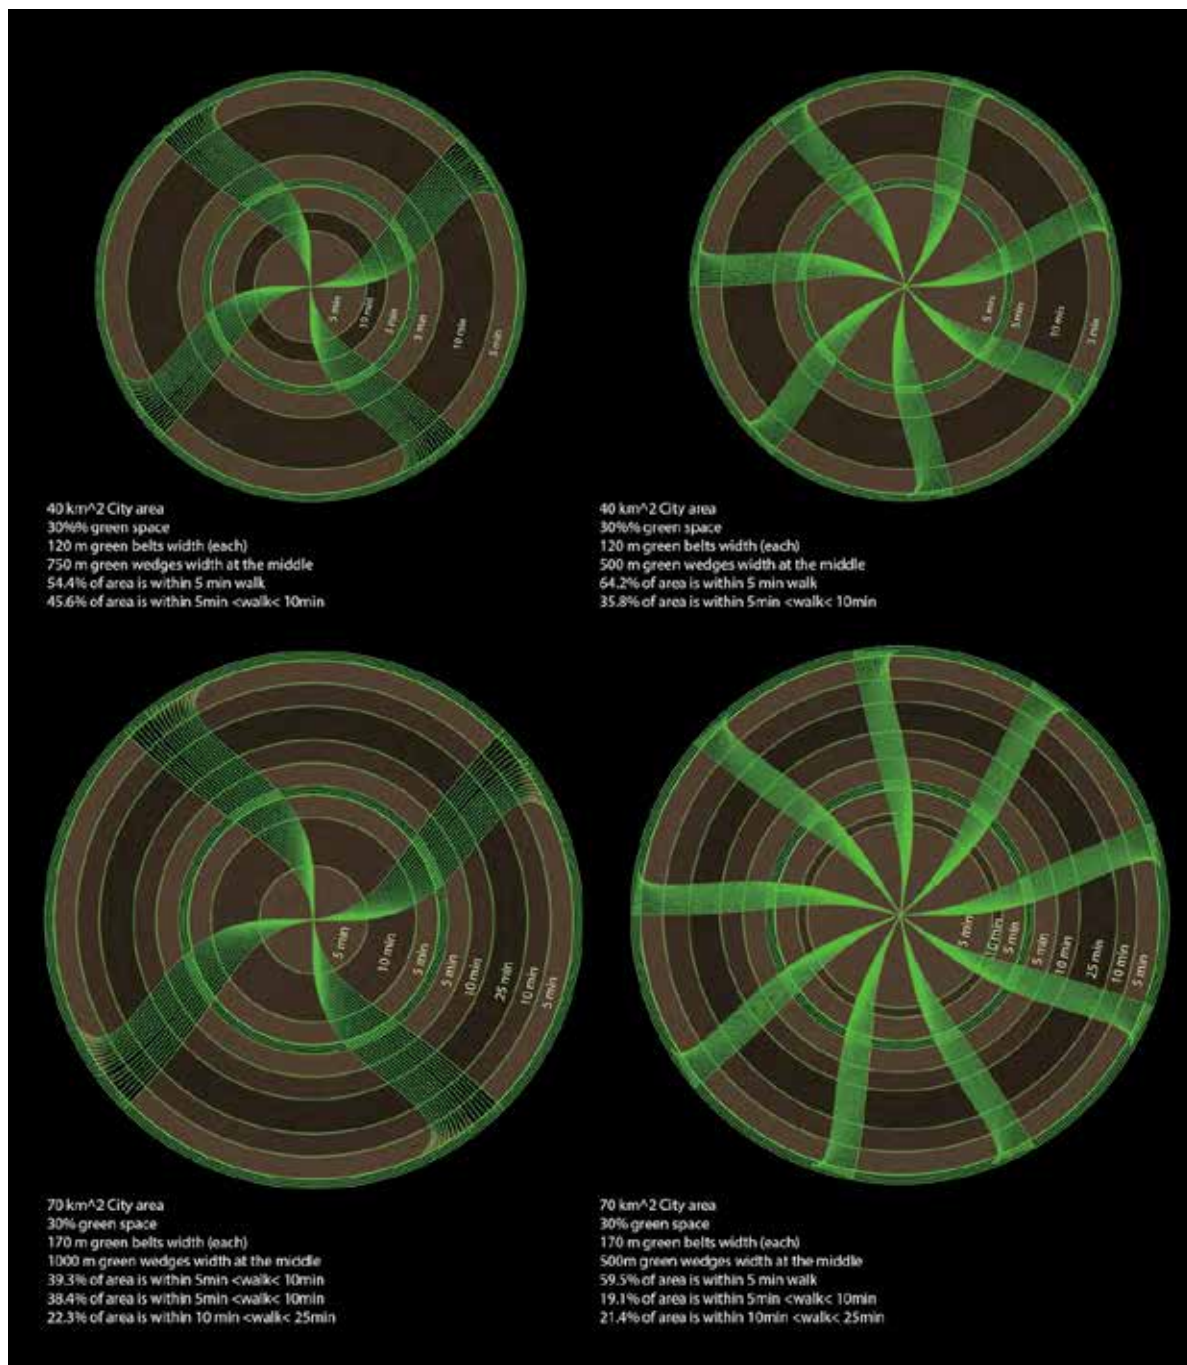

Figure 8. Walkability assessment of combined models of green wedges and green belts applied to a 40 km² (top two) and a 70 km² (bottom two) city using the following possible distribution of the wedges: 4 wedges (left) and 7 and 9 wedges (right), and two green belts in each scheme.

Table 1. Summarises the walkability performance of each of the green space planning models

Green model	5 min walk	5 min<walk<10 min	10 min<walk<25 min	More than 25 min walk
Single green belt	27.7%	25.2%	33.3%	13.8%
	23.7%	20.5%	31.4%	24.4%
Two green belts	60.1%	37.1%	2.8%	N/A
	42.2%	40.1%	17.7%	N/A
Green wedges	28.9%	29.7%	41.4%	N/A
	25.2%	28.6%	46.2%	N/A
Combined wedge-belt (4 wedges)	54.4%	45.6%	N/A	N/A
	39.3%	38.4%	22.3%	N/A
Combined wedge-belt (7 and 9 wedges)	64.2%	35.8%	N/A	N/A
	59.5%	19.1%	21.4%	N/A

Conclusions

This paper shows that city models can be valuable imprints for the re-balancing of our cities and nature, and in particular to the provision of ecosystem services close to where people live, work and recreate. The definition of parametric modelling tools that allow for concomitant consideration of a range of attributes related to the size and distribution of both green and non-green areas can support cities in defining re-naturing strategies, in particular in times of change. Urban form matters with regards to the provision of adequate amounts of and accessibility to green spaces in cities.

The standard green belt model can concentrate the largest amount of green space and provide good accessibility to green spaces in the outer fringes, at the expense of accessibility from the central area, which falls out of the 25-minute walking range. The green wedge model in turn allows for good accessibility across the city. The research has shown that its application alone can ensure that nearly a third of the built-up area can be within a 5-minute walk of a green area and close to 60% of the city can be within the 10-minute range. Additionally, this model ensures that 100% of the city is within the 25-minute walking range and that an equal distribution of green spaces across the city can be achieved. They can also provide a direct green link between the city centre and the non-urban areas. The two-belt model presents the highest performance of the non-hybrid models, with the large majority of the city within the 10-minute range (See table 1).

The combined wedge-belt models with 7-9 wedges are the highest performing in terms of walkability. They can also provide enhanced environmental benefits. The wedges are connected by the belts, and the green space reaches all the zones of the city including the city center. This is unlike the two-belts model where the two main green spaces do not reach the central zone of the city, which usually is where the urban heat island effect can be more manifested.

Given the fact that cities are undergoing constant transformation potentialised by competing pressures and challenges, seeking socio-cultural and ecological-environmental equilibrium is crucial for the ongoing sustainability and resilience of urban habitats. Parametric tools can allow for the manipulation of complexity in inputs and continuous assessment of outputs. The range of planning models can flexibly consider aspects of urban cohesion and the maximisation of specific ecosystem services in the decision making process, contributing to the creation of cities in balance with nature.

Short Review of “Mapping the Landscape of Behavioural Theories: Systematic Literature Review”

Heeseo Rain Kwon¹, Elisabete A. Silva²

¹*Department of Land Economy, University of Cambridge, hk394@cam.ac.uk*

²*Department of Land Economy, University of Cambridge, es424@cam.ac.uk*

Abstract: The “behavioural” approach is receiving increasing attention in many disciplines, however, there is yet limited understanding of the available theories and how they can be applied. Through a cross-disciplinary literature review, this paper identifies 62 behavioural theories from 963 publications and classifies them into four groups: (1) those that explain the factors that affect behaviour such as the theory of planned behaviour and prospect theory, (2) those that focus on behaviour change strategies such as nudge theory, (3) those about learning and conditioning such as reinforcement learning theory, and (4) those that focus on the modelling such as neural networks theory and game theory. Based on the review, the paper discusses the lack of understanding of terms, classification, guidance on the use of appropriate theories, inclusion in data-driven research and modelling, and dialogue between theory-driven and data-driven approaches. Furthermore, it emphasizes the role of behavioural theories in bridging the divide between the traditional theory-based, aggregate, quantitative and equation-based approaches and the new data-based, disaggregate, qualitative and language-based approaches such as agent-based modelling. This conference paper is a shortened version of: Kwon, H.R. and Silva, E.A. (2019) Mapping the Landscape of Behavioural Theories: Systematic Literature Review, *Journal of Planning Literature*.

Keywords: behavioural theories; data-driven research; theory-driven research; agent-based modelling

Introduction

The term “behavioural” in the context of behavioural sciences has become fashionable in recent years as an innovative and alternative approach in many disciplines, including those closely related to planning. Along with this trend, many academics and practitioners have developed interest in applying various behavioural theories in their research: neural networks theory, reinforcement learning theory, game theory, the theory of planned behaviour, nudge theory and prospect theory to name a few. Understanding and applying behavioural theories can be greatly beneficial in many disciplines including urban and environmental planning because behavioural theories can take into account a variety of factors that affect people’s decision-making process and provide a framework to model, explain and predict behaviour which may enhance the effectiveness of policy design and behaviour intervention.

Although many of the theories about human behaviour have been in existence for some time, the concept of behaviour is so broad that it is difficult to figure out which theories can be considered behavioural theories across all fields of academic research. Some existing literature attempted to review and summarize behavioural theories, mostly focusing on behaviour change and intervention, for example, in the health sector (Michie *et al.*, 2005; Munro *et al.*, 2007; Davis *et al.*, 2015), environmental science (Morris *et al.*, 2012; Schlüter *et al.*, 2017) and transport (Savage *et al.*, 2011). While the UK Government Social Research (GSR) produced a behaviour change knowledge review for more general application by contacting key individual experts (Darnton, 2008, p.

75), there is not yet a publication that systematically reviews the academic journal database across all disciplines to provide a comprehensive landscape of behavioural theories. In addition, there is much more room to synthesizing how we conceptualize, model and formalize behavioural theories in the era of data-driven research and big data analytics in addition to guiding our understanding, selection and use of behavioural theories for particular uses.

To fill this gap, this paper takes a step forward from the existing literature by performing a systematic literature review using ‘all database’ in the Web of Science (WoS) to identify theories of general human behaviour across disciplines. At present, only a few popular behavioural theories are being applied in planning such as the theory of planned behaviour in transport (Castanier *et al.*, 2013) and prospect theory in housing and real estate (Dunning, 2017). By taking a general approach rather than zooming into the planning-related fields, this paper presents a comprehensive list and map of behavioural theories that have potential to be applied in planning.

This paper will first explain the methodology of the review and provide a conceptualization of the type of behaviour. Then, it will present a comprehensive list, classification and map of the 62 behavioural theories and analysis of the selected literature. Finally, discussions will be made about the implications for further research and the importance of behavioural theories in the era of big data analytics. The complete version in the *Journal of Planning Literature* provides tables, diagrams and in-depth analysis that are not discussed here in detail, and provides two appendices with further information regarding the key theories and publications (Kwon and Silva, 2019).

Methodology

There is an immense amount of literature on behavioural theories across disciplines: 96,700 publications on WoS all databases contain “behavio(u)ral theor(ies)” in topic from 1900 to 2017 (Web of Science, 2018). To filter the most significant and relevant papers.

First, from all database on Web of Science (WoS), we used the search keyword “behavio(u)ral theor(ies)” for title only and received 963 results in the time frame from 2000 to 2017. Second, we used different thresholds for times cited according to the year of publication and narrowed down the results to 467. We tried to include more recent publications to observe the current trend of research method while being stricter to older publications to only include the ones that were fairly recognized by other researchers. Third, we further narrowed down the publications to 156 by limiting the scope to general human behaviour in a general living environment, i.e. excluding non-human behaviour and specific behaviour such as patient behaviour regarding medication. Fourth, we listed 87 theories used in the 156 relevant results with the following information: founder, year of publication, number of WoS search results (2000-17) and search keywords used, top 5 research areas, top 3 publication years, and a short definition of theories based on the literature review (Appendix A: see Acknowledgements). Fifth, out of the 87 theories, only those with more than 10 WoS search results (2000-17) were kept, resulting in 62 theories. From the 156 publications, 47 that cover all 62 theories were chosen as key publications.

Classification and mapping of the selected behavioural theories

We conceptualized “behaviour” as a process where a stimulus (or situation) gets imposed on a person, he or she develops intention (or motivation), and this leads to a response (or decision) and decided to call a theory a “behavioural theory” if it explains some aspects of this response- or decision-making process. Then we classified the 62 theories into four groups based on their focus: 1) factors that affect intention (17 factors), 2) strategies that influence intention, 3) learning and conditioning that modify response, 4) and modeling of response.

The first group focuses on the factors that affect the process of decision-making. The theories from psychology tend to focus on more subjective and personal factors like attitude, subjective norm, psychological distance, fear appeal, beliefs and values, and heuristics while theories from sociology tend to focus on social interaction. On the other hand, the theories from economics, business, management, and finance tend to focus on more objective and non-personal factors like different interests, institutions, and rationality and utility. Also, some theories originate from one discipline but are mostly used in other disciplines, for example, behavioural economics is largely about applying psychological theories to economics such as prospect theory.

The second group focuses on the intervention strategies to influence the decision-making process and gets used largely in public policy to affect pro-environmental and pro-social behaviour such as nudge theory and behavioural spillover theory, and business management to affect consumer, employee, and business behaviour such as behavioural priming theory and diffusion of innovation theory. The third group concerns learning and conditioning theories from psychology that can modify the response which are largely applied in computer science lately for the topics of artificial intelligence and machine. Finally, the fourth group focuses on modeling the response-making and decision-making process, which includes more mathematical elements compared to other groups. Such theories about modeling get used in the areas of computer science and neuroscience the most for modeling techniques such as machine learning, agent-based modeling, dynamic network analysis and microsimulation. We included these theories as behavioural theories because, while they do not directly provide an explanation about how behaviour works, they help us model and understand the response- or decision-making process and are crucial theories that can link the behavioural approach with data-led research in the era of big data analytics.

Analysis of selected literature on behavioural theories

The list of 156 publications includes more of the recent publications possibly due to the selection threshold by times cited in the methodology. 87% of the literature are articles in a variety of journals while the rest are books or book chapters, in research areas mainly psychology, social sciences, computer science, environmental sciences, transportation, and engineering. 66% of the publications are available in full text online, free to many educational institutions. Also, 70% of the 156 publications were classified as empirical, i.e. using real world data and 30% as theoretical. Regarding the research method, most publications (97%) were identified to mainly use a quantitative approach, i.e. numbered data analyzed using statistical procedures, while only 3% mainly employed a qualitative approach although these two approaches are in a spectrum rather than being dichotomic.

As for the data collection methods, first-hand survey was the dominant method followed by interview, second-hand database, and simulation. Some innovative methods were observed, such as observation of investment decision-making behaviour through an online computer game, a survey using a web page with a user interface to collect carbon footprint report, and analysis of multi-object tracking behaviour by conducting simulation exercise on participants. With regard to the analysis method, regression was being used most frequently followed by correlation analysis, structural equation modeling and factor analysis and path analysis. As for the sample size, publications had 100 to 499 samples the most, followed by 500 to 20,000, less than 100, and big data such as 104 weeks of transaction screening through simulation with an ambiguous unit of data. Out of the 156 publications, the most frequently occurring theory was the theory of planned behaviour (in 33 publications) followed by prospect theory (in 11 publications). The summary of these 156 publications can be a useful guide to get an overview of how behavioural theories have been used in research since 2000 and what the current trends are (Appendix B: see Acknowledgements).

Discussion and conclusion

To better understand the landscape of behavioural theories, this paper performed a systematic literature review of 963 publications and identified 62 key theories. These theories were then classified into four groups (factors, strategies, learning and conditioning, and modeling) based on their focus and were mapped in a diagram with

the labeling of which research area the theories originate from. As a result, the literature review pointed to the following discussion points, which are the areas that require further research.

First, this paper's literature review suggests the lack of understanding of behavioural theories and behavioural sciences. The definition of "behavioural theory" is yet unclear that depending on how broad and narrow the definition and criteria are, some theories identified by this paper may not be considered behavioural theories and other theories outside this paper's list may be considered behavioural theories. Also, the understanding of what "behavioural sciences" entail is vague. A better clarification of the available theories and the fields involved is important to be able to transfer models and compare results.

Secondly, there is lack of classification of the type of behaviour and behavioural theories. Because different behaviour gets affected by different variables, classification of behavioural theories can help researchers identify which theories to use based on the purpose. While this paper attempts to classify the theories of general human behaviour across all disciplines in four groups, there is a lot of room for improvement, for example, identifying the hierarchy, family tree and overlapping concepts of theories.

Thirdly, there is a need to develop more guidance on the selection and use of appropriate behavioural theories. Lack of guidance often leads researchers, policymakers and practitioners to choose more common and well-known theories rather than the ones that may suit the target behaviour and population better and to only loosely refer to theories rather than using them rigorously. While the concepts of behavioural theory and behavioural science have an evolving nature with dynamic patterns within the debate, it will be greatly beneficial to have a table that shows a clear connection among the list of theories, key variables, the types of behaviour, and the social or environmental context that they are applicable to in the future with more in-depth analyses and comparative studies.

Fourth, behavioural theories can be more included in data-driven research and agent-based modelling. Computer science, artificial intelligence, and big data analytics are very important in the behavioural research at present, all part of the bigger effort towards the development of data science which is closely related to planning in the era of smart cities. The traditional theory-driven approach is largely linked with global equation-based modeling (EBM) while the new data-driven approach is closely linked with new language-based coding constructs such as agent-based modeling (ABM). Today, these approaches are gearing hybrid models (Wu and Silva 2010; Silva 2004; Wu and Silva 2013, Silva 2011) and such hybrid approach can suggest a new direction for the modeling of complex urban systems as part of the planning support science, for example, for the efforts to establish a "digital twin" of a city to aid planning-related decision-making. Behavioural theories can play a critical role in bridging the traditional theory-based, aggregate, quantitative and equation-based approaches with the new data-based, disaggregate, qualitative and language-based approaches such as agent-based modelling (Parunak, Savit, and Riolo, 1998; Ahmed and Klischewski, 2017).

Finally, behavioural theories are ever more important because they can answer "how and why", provide rationale for the rules, variables, assumptions and parameters of models, and help researchers generalize results (Wise and Shaffer, 2015). Furthermore, this paper proposes complexity theory as the overall theoretical concept (de Roo and Silva, 2010) and suggests that behavioural theories can play an important role in spatial planning in the bigger picture of integrating spatial and a-spatial approaches of modelling human behaviour.

A Transdisciplinary Perspective on City Technologies: Touchpoints between Informatics and Urban Disciplines

Lucia Lupi

*DIST - Interuniversity Department of Regional and Urban Studies and Planning
Politecnico and University of Turin, Turin (IT)*
lucia.lupi@polito.it

Abstract: Current digital technologies are not oriented to support the practices of transformative planning and more in general the management of complex social processes in urban environments. The active engagement of scholars and urban practitioners in defining nature and applications of future city technologies meant to address this type of challenges is crucial. However, this path requires to move beyond the disciplinary boundaries and conventional research practices of urban disciplines. Assuming a transdisciplinary perspective is essential to effectively combine the consolidated knowledge on city dynamics and urban transformations developed within urban disciplines with the knowledge and expertise in the design of digital technologies in the domain of Informatics. To contribute in establishing synergies for developing a transdisciplinary research agenda on city technologies, this paper outlines a schema for bridging urban disciplines and informatics, in particular, Urban Planning, Urban Design and Urban Studies on one side, and Computer-Supported Cooperative Work, Human-Computer Interaction Design and Information Systems on the other side. This work maps correspondences and affinities between different fields on both sides, highlighting some essential approaches or concepts in each of them that could benefit from the integration with their counterpart in order to advance our understanding on how to rethink digital technologies for serving social change aims and transformative planning practices.

Keywords: Transdisciplinarity, City technologies, Transformative planning, Social Change

1. Introduction

Nowadays digital technologies applied in cities or to city activities are focused on monitoring urban infrastructures and environmental parameters, elaborating the fluctuations of individual behaviours and social trends from online social networks, and analysing and predicting part of urban phenomena mainly related to traffic issues and energy consumptions. As expected in every other sector of activity, like public administration or enterprise, the practice of urban planning is supposed to benefit from the application of these technologies by improving the capacity of planning departments and professionals to make informed decisions and implement better management of local resources. However, none of these technologies takes into account the essential aspects of transformative urban planning practices such as the negotiation among different stakeholders

involved in urban transformations, the mediation between divergent goals and socio-economic and political instances, the collaborative construction of plans, projects, policies, initiatives for generating local development.

Current urban technologies, intended as technologies looking at the city in its tangible dimension, both physical and functional, are not meant to address the needs associated with the social and political complexity of cities that are only partially reflected by the physical and functional transformations of urban environments. The practical consequence of this state of affairs is that current technologies can provide limited support to the collaboration between urban practitioners and stakeholders engaged at a local level. But at a higher level, this technology gap led to identify a new class of digital technologies, that I am going to call city technologies, that are meant and designed for supporting social change processes in urban regeneration initiatives, co-production of services, and establishment of open governance models for urban resources.

Research on how to design these city technologies presents countless challenges and obstacles. By focusing only on academic milieu, the main challenge is actively engaging scholars and urban practitioners in defining nature and applications of future city technologies at a theoretical and empirical level by undertaking paths beyond the disciplinary boundaries and conventional research practices of urban disciplines. Indeed, while transdisciplinarity is recently gaining popularity in urban research, embracing a transdisciplinary perspective for transferring concepts, theories, and methods consolidated in urban disciplines to new objects, digital technologies and not plans, is not immediate or easy.

This transferring of concepts and methods across disciplines to practically address socially relevant real-world problems (Scholz 2000, Klein 2002 and 2012, Nicolescu 2006, Wickson et al. 2006) requires first to understand logics and approaches of unfamiliar fields and research contexts, and secondly to critically reflect on what disciplinary contributions our discipline can bring to the process. To contribute in establishing synergies for developing a transdisciplinary research agenda on city technologies, this paper outlines a schema for bridging urban disciplines and informatics, by mapping the correspondences and affinities between different fields on both sides, and by highlighting some essential approaches or concepts in each of them that could benefit from the integration with their counterpart.

The remaining of the paper presents the rationale for embracing a transdisciplinary perspective on the design of city technologies (section 2), and then traces the respective contributions of urban and informatics disciplines on this topic (sections 3 and 4) to conclude with their mapping (section 5).

2. Embracing a Transdisciplinarity Perspective

There is a growing consensus on the position that developing information technologies for addressing urban challenges requires a transdisciplinary approach to keep an ecosystemic and ecological vision of issues and specific dynamics of a city environment and accordingly designing the appropriate technological solutions (Foth et al. 2011, Bilandzic et al. 2011, Kukka et al. 2014). On the other side, research domains that traditionally adopted a transdisciplinary approach to deal with issues related to urban ecology models and urban sustainability opened their sphere of interest to information technologies that nowadays are an avoidable component of city life (Black et al. 2005, Buizer et al. 2011, Du Plessis 2011, McPhearson et al. 2016).

Transdisciplinarity (TD) is conventionally considered as complementary to multidisciplinary and interdisciplinarity (Nicolescu 2002 and 2006, Ramadier 2004, Max-Neef 2005, Darbellay 2015), and specifically oriented to address complex multidimensional problems by serving broader goals across multiple disciplines (Klein 2004, Russell et al. 2008). In this sense, urban problems are the most emblematic examples of wicket problems (Rittel and Webber 1973), and they are the privileged domain of investigation and

experimentation for TD research (Klein 2002, Ramadier 2004). In particular, rethinking existing technologies to better support city processes requires knowledge and expertise on different aspects of the problem and practices related to the use of technology in different urban contexts.

To deal with complexity, Transdisciplinarity is characterized by methodologies oriented toward experimental pluralistic disciplinary fusions. At the same time, Transdisciplinary methodologies and approaches are expected to be responsive to the unpredictable changes and fluctuations of context and problems under analysis (Wickson et al. 2006, Klein et al. 2012). Within this frame, “scientific rigor” is defined as taking into account all existing information to build the arguments and the proposals for addressing a problem (Nicolescu 2002). In this type of explorative processes, Transdisciplinarity become a “*conceptual tool to produce interlanguages*” (Klein 2002) and a “*space for synthesis across, between and beyond disciplines*” (Nicolescu 2002).

In order to outline how holistically approach the research on the design of technologies for cities by adopting a Transdisciplinary perspective, I considered:

- Urban Planning (UP), Urban Design (UD) and Urban Studies (US) because of the stratified, consolidated and applied knowledge about city dynamics and urban transformations
- Information Systems (IS), Computer-Supported Cooperative Work (CSCW) and Human-Computer Interaction Design (HCID) as sub-set of Informatics disciplines characterised by a focus on developing technological solutions embodied into complex social settings.

Fig. 1 Diagram of the proposed disciplines to bridge in the research on city technologies

These disciplines have in common the following three essential characteristics:

- **intrinsic permeability**, because all of them are interdisciplinary fields incorporating and transforming external inputs and knowledge from social science, humanities, or engineering
- their **normative nature**, usually expressed by converting theories and empirical findings into normative knowledge for the transformation of the context in which they operate through planning and design interventions.
- their **future-oriented approach to the analysis of current problems** driven by the purpose of understanding how the presents conditions could progress or be innovated.

However, the linguistic differences between the two macro-domains of Informatics and Urban research, and the common misconceptions that experts of one side frequently have about the nature, methods and scope of their counterparts constitutes major obstacles to create a bridge among them for facing the challenges of defining

better technologies for cities. To facilitate the definition of an interlanguages among the selected disciplines and the construction of a common operational space, in the next two sections I am going to highlight the major types of contributions that each discipline can bring to the research and design of city technologies, as well as their complementarity in terms of topics, methods and strategies.

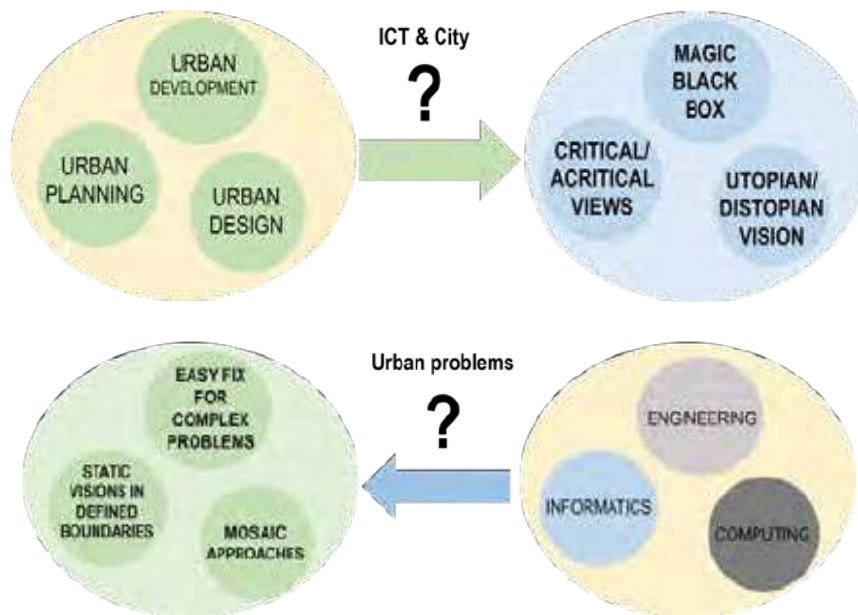

Fig. 2. Illustration of some common misconceptions and positions about urban disciplines and informatics regarding Information Technology and Cities

3. Integrating Urban Disciplines in the Research on City Technologies

The wide macro-domain of research on cities and urban phenomena includes several disciplines, among which many have goals not directly related to the active transformation of the urban context, such as geography, sociology or political science. While their contributions are often essential to clarify important aspects of city dynamics, the approaches and practices of urban planning and urban design (and partially urban studies as well) have substantial affinities and potential application in the research on the design of city technologies. These affinities, in addition to the points highlighted above, can facilitate the construction of a bridge between urban research and research in informatics.

The key type of contributions of these disciplines to the research concerning city technologies come from:

- a) the **Approach of Urban Planning** in building shared rules within frameworks of competing goals (economic and social, but also among different stakeholders)
- b) the **Design Tactics of Urban Design** to shape public spaces for multiple types of users, activities, systems of values and meanings associated to the “urban interfaces”
- c) the **Scope of Urban Studies** to identify the factors determining the local development and build conceptual tools to interpret urban phenomena.

Fig. 3 Schema of the elements extracted from urban disciplines applicable in the research on City Technologies

a) Urban Planning

Urban Planning as academic discipline and professional practice includes both urban planning and city planning traditions, respectively defined as “*design-oriented physical planning*” and “*policy-oriented socioeconomic planning*” (Gleye 2015). Under both perspectives, there is often a convergence of urban planning theories and practices on defining and constructing shared negotiated rules in the public interest, and instantiating these rules in plans or policies to infrastructure future public and private actions for the transformation of a territory considered as built environment complex, economic area or socio-political entity.

While the focus of Urban Planning is on the physical and functional transformation of territories, the modalities to approach the problem of defining shared rules among different stakeholders (public and private players operating in the city) could offer a fundamental contribution in the design of city technologies. Indeed, city technologies cannot simply follow the rules of commercial applications focused on individuals as customers, but requires to be integrated in more complex logics and dynamics shaping the city context. This requires to move the unit of analysis from the individual to upper level social structures (groups, organisations, communities, networks) embedded in a dense net of formal and informal norms regulating their reciprocal interactions and their action in the city.

The need for a shift from the paradigm of the “*user-centred design*” to the “*stakeholder-centred design*” is already indicated as one of the major future challenges for digital technologies (Forlizzi 2018, Forlizzi et al. 2013). To this regards, the lessons learned from the experimentation of collaborative planning practices as well as the insights coming from the critiques to their limits (Innes et al. 1999, Booher et al. 2002, Healey 2003, Brand et al. 2007, Innes et al. 2010, Gunder et al. 2018) and the inputs of communicative, pragmatist and phenomenological approaches to planning issues (Friedmann 1987, Forester 1988, Whittemore 2014, Gunder 2010, Gunder et al. 2017) could provide a solid base to build stakeholder-centred design practices looking at the same time at the public interest and at the practical matters of contextual constraints. However, it is important to acknowledge that the “*design dimension of planning*” as defined by Punter and Cardona is one of the most silent and untraced areas of urban research despite its importance, and therefore not necessarily the practice of planning that is grounded on design plans, policies and interventions is adequately conceptualised (Punter & Cardona 1997).

The second important aspect concerning the peculiar way in Urban Planning to approach the construction of shared rules in multi-stakeholder frameworks is the conceptualisation and pragmatic handling of power-related issues (see Schragger 2016). Power and unbalanced forms of power between different social formations in the urban area seems to be an inescapable condition of any city dynamic, both at individual and collective level (Castells 1978). Most of XIX-XX centuries top-down approaches of urban planning tended to favour established forms of power sustained by central and local governments in charge of urban transformations. However, for decades and in particular in the XXI century, the effort of urban thinkers and practitioners start to focus on the way to re-centre and distribute power in civil society acting within and around the net of norms regulating urban life (Friedmann 1987, Miceli 2012, Gunder et al. 2018). In this sense, the radical theories and practices in urban planning such as the “*assemblage theory*” (see Farias 2011 or Gunder et al. 2018 for a detailed account) bring a unique perspective on power relationships: they exist and are not necessarily balanced, but can be actively shaped and reshaped through interventions that enhance the agency of the different actors in the city (De Roo & Hillier 2016). Therefore, the knowledge of power relationships is seen not as an end as common in critical studies, but as a means for action in complex real settings where contingencies profoundly determines whether and how it is possible making plans, projects and policies.

The analytic, pragmatic and strategic approach to power dynamics cultivated in urban planning practices and partially reflected in urban planning theories can be translated also in the analysis and design of Information Technologies. In this new domain, this kind of approach can help designers, researchers, and technology providers in developing a lucid understanding of the consequences of complying, pushing or attempting to disrupt current power dynamics through specific design choices, and by leveraging on the understanding of the current state of affairs to decide the appropriate strategies to pursue these goals. In particular, the approach of urban planning is valuable to frame the design of city technologies as the design of an intangible urban infrastructure based on the social, political and economic reality of cities. Moreover, there is already a fundamental awareness in this discipline that “*Urban planning is all about information*” and that “*Information is power*” [Forester 1988] because determine what we can or cannot understand, transform, negotiate in local actions. This awareness should make easier transferring logics and methods to handle and assess urban information in the domain of Informatics that is literally build around the management of information in digital systems.

What I tried to highlight with the above mentioned arguments is that the contribution of urban planning to the design of city technologies has no reason to be self-referential and focused to understand how to use already existing technologies, or rather limited within the sphere of GIS technologies because of the familiarity with the visual modelling of cities and urban phenomena through maps. On the contrary, it can be extended to rethink the assumptions and systems of technology-mediated relations among people operating in urban environments.

In particular, the inputs of Urban Planning approaches are therefore essential to the research on city technologies in two ways:

- for developing better models of the users of digital technologies in cities and more comprehensive models of urban activities as multi-actor activities
- for structuring transferable strategies to compose different interests and priorities of a variety of city stakeholders intended to be the targets and users of digital technologies in urban environments.

b) Urban Design

Urban Design as complex polymorph and integrative field of design practices for centuries, and more recently established also as academic discipline, concerns primarily the design of the public interfaces of the city by taking into account history, culture, politics, economy of places (Cuthbert 2008 and 2011). On this ground, Urban Design principles are historically aimed at shaping places by reflecting the “*dynamic multiplicity*” of city actors and their needs, perspectives, aspirations (Madanipour 2006), as well as at creating spaces intrinsically opened and able to communicate specific values and identities while leaving the “users” free to use that spaces in multiple ways (see e.g. Carmona 2014, Moughtin 2007, Burton et al. 2006, Sternberg 2000, Trancik 1986).

The importance of transferring urban design principles to inform the design of digital technologies for creating virtual public interfaces supporting people’s interactions in cities is already acknowledged and examined by recent works (De Wall 2014, Arango 2018). But what is worth mentioning here is that emerging but influential schools of thought in the design of digital technologies pushes for re-orienting the Research and Design agenda toward principles very much closer to theories and practices typical of Urban Design. For instance, by supporting the value of pluralism in the different views and uses of digital artefacts, by avoiding to flatten users to universal reductive models and considering them as embodied in social and cultural systems, by considering designers as advocacy leaders for groups marginalised in the current practices of technology development, by supporting participatory practices involving the public in setting goals and solutions of technology stratified within an ecology of other technologies already in place (Bardzell 2010).

On this background, the inputs of Urban Design tactics can benefit the research on the city technologies in two ways:

- by helping to model the fluidity of roles and identities of people in the city, and support their agency accordingly to these roles and identities as goal for city technologies
- by hybridizing the design of tangible and virtual public interfaces to make digital environments more consistent with the openness and fluidity of urban systems reflected in city technologies.

c) Urban Studies

Urban Studies is the wide field studying problems, solutions and processes of local development through the analysis of the context in its socio-cultural aspects, focusing on the interactions between people and urban environments, and looking at the organisations of urban systems. Urban studies correspond more to the definition of a common interest across multiple disciplines, than being a domain with defined boundaries, and incorporates the strands of social sciences, political science, urban economics and humanities (Hutchinson 2009) framing local processes as multi-dimensional processes, in which the cultural, economic, social, political components of the context are strictly interdependent and require to be analysed and assessed in an integrated way.

The focus of Urban Studies is mainly theoretical and empirical, instead than applicative as Urban Planning and Urban Design that usually convey the understanding of the context in interventions as plans, projects or policies. As regarding the theoretical contributions, the key inputs of Urban Studies concerns mainly the interpretative frameworks of city dynamics, such as for instance the ASID model (Agency, Structure, Institutions, Discourse model) developed by Moulaert et al. (2016). The value of these models for the design of city technologies rely on the fact that they provide a general schema to build the understanding of local phenomena to be supported by

or through technology, going beyond the observable elements that are the main object of current urban deterministic and predictive models.

As I going to explain below, the study of people and organisational practices in their context is the backbone of disciplines such as Computer-Supported Cooperative Work, but it is relevant also in Information Systems research and in Human-Computer Interaction Design. However, models and analytic framework developed in Urban Studies can extend and deepen the analysis of practices in city context by considering also the structural and representational components of social interactions and consequently their potential transpositions in a virtual shared space. This is particularly important for the development of future digital technologies as “*common artefacts*” accordingly to the definition of Bødker (2015), shared by a multiplicity of actors interacting in a dynamically changing context shaped by a variety of factors and dimensions difficult to analyse and transpose in design solutions (Bødker 2006).

As regarding the empirical contribution of Urban Studies to the design of city technologies, there is also the possibility to build on the critical factors studied in urban transformation projects, city management and social initiatives for orienting the definition of the scope of technology as support to the everyday practices of local stakeholders.

In synthesis, the inputs of Urban Studies in the research about the design of city technologies could support:

- Analysing the landscape of existing technologies under the light of the applicative scenarios in different urban settings
- Modelling the specific role of new technologies in these settings
- Connecting the contingent observations referred to specific technologies in specific contexts to higher-level schema and dynamics, helping to reason on the invariants and contingent uses of technologies in cities.

Within and across the disciplines of Urban Planning, Urban Design and Urban Studies (beyond the theoretical and methodological inputs mentioned before), there are also specific thematic clusters such as the research on Smart Cities, Urban Governance, and Sustainability that are relevant for defining nature and function of city technologies.

Fig. 4 Schema of the elements extracted from the thematic clusters on governance models, ICT and sustainability issues.

4. Combining the Understanding of Cities and Technologies in Informatics

Computer Science and Informatics are two denomination often confused, or used as synonyms or simply preferred to indicate both accordingly to different traditions in Europe and USA. Nevertheless, they cover different domains related to the study, design and development of information technologies. Computer Science addresses the mathematical modelling of information and operative flows, concerning the internal features, structures, and behaviors of computer systems. Informatics addresses at the same time the technology and its context, focusing on technology design, information system development, human-computer interaction and management of technology in different operative environments (an extensive introduction on the different use of Computer Science and Informatics can be found in Smutny 2016). In addition, there is a third segment of disciplines dealing with information technologies that is Engineering, covering the study and development of software, hardware and infrastructural components of information systems. Lastly, there are also disciplines such as Socio-Technological Studies (STS) focused on studying technologies in their context, but centred on the social components of this interactions instead than on the design of new technologies. In this work, I limit the discussion to a subset of disciplines in Informatics including IS, CSCW and HCID.

Moving from Urban disciplines to Informatics, the research interest in cities is related to the revolution of the computers moving from working environments to everyday life activities as prefigured almost three decades ago (Grudin 1990). Indeed, the Grudin's expression "*the computers reach out*" refers to the fact that digital technologies started since 80's to deal not anymore only with tasks to be accomplished through the use of specific hardware and software solutions, but with the challenges of social progress supported by information technologies. Nowadays, Urban Informatics (Foth & Choi 2011) and Urban Computing (Zheng et al. 2014) are emerging as domains studying urban contexts through/with/for technology.

As highlighted in previous work (Lupi & Antonini 2019), Urban informatics, has the broader scope of rethinking the urban experience through the support or mediation of technology. Differently from Urban Computing, it is based on studying the context to define new potential solutions and intervene to sustain technology-driven changes. While the terms Urban Computing and Urban Informatics are often used interchangeably or as synonyms¹, there are fundamental differences in their goals and orientations, as well as on the technological solutions developed relying on them. Indeed, Urban Computing, like every other sub-domain of computing disciplines, is primarily aimed to extract, organise, elaborate data related to the urban fabric or produced within systems acting as a proxy for urban social dynamics such as online social networks (Zheng et al. 2014). The means to achieve these goals rely on computational methods based on the definition of appropriate algorithms to operationalise and make more efficient or effective the data elaboration for specific purposes and applications. On the contrary, in Urban Informatics, the approach to the development of technological solutions for cities is based on framing the problem to be addressed as a socio-technical problem based on the three pillars of places, people, and technology (Foth 2008) and deeply relies on participatory practices and critical explorations of technology in urban contexts. For these reasons, a solid bridge between urban disciplines and Informatics can find its founding stone in Urban informatics, more easily than in Urban Computing.

¹ Michael Batty, one of the main champions of the "Urban Science" as a new discipline combining data science and urban modelling, is actively involved in the research on "computational planning" and uses the expression "Urban Informatics" to actually indicate "Urban Computing". The same use of the expression "Urban Informatics" is conventionally adopted by most of the scholars in urban disciplines working on Planning Support Systems and Geographical Information Systems.

Fig. 5 Schema of the elements extracted from the informatics thematic clusters applied in the present research.

In the design and research on city technologies, it is essential to consider also the perspectives of Community Informatics and Social Informatics². They respectively focus on linking the use of technologies to local development opportunities (Gurnstein 2007) and exploring the issues deriving from the design, implementation and use of technologies (in particular web-based technologies) within specific organisational and social contexts (Kling 2000, 2007, Kling et al. 2005, Sawyer 2005, Sawyer & Eschenfelder 2002).

Urban, Community and Social Informatics provide therefore complementary lenses on technologies in city context (Fig. 5). Urban informatics offers a methodological framework for the design of urban experiences mediated by digital technologies (Bilanzic et al. 2011). Social Informatics provides the theoretical foundation for the analysis of the context in which technologies are integrated, rooted on a systemic visions of roles and relationships within social systems (Kling et al. 2005). Community Informatics set the background for the definition of the scope of city technologies in reference to people empowerment, social change and impact of technology on everyday life (Gurnstein 2007).

By looking at the intersection between Urban, Community, and Social Informatics, CSCW, IS, and HCID had been considered in particular reference to :

- d) the **Approach of CSCW research** for understanding nature and practices of cooperative activities supported or potentially supported by digital technologies
- e) the **Design orientation of HCID** (as branch of HCI) for clearly connecting people's needs to specific choices to consciously design the interactions between users and technologies in their context of use
- f) the **Scope of IS** of connecting human processes and information through the development of knowledge systems (Fig. 6).

² Urban, Community, and Social Informatics are not disciplines but thematic clusters uniting researchers working on similar topics, but using different theories and methods, similarly to sustainability or urban governance studies. For instance, see Sawyer & Eschenfelder 2002 about the nature of Social Informatics.

Fig. 6 Schema of the elements extracted from system design disciplines applied in the present research

d) Computer-Supported Cooperative Work

CSCW is the discipline studying how information technologies can support collaborative activities (Castersen & Schmidt 1999). The specific term “*cooperative work*” has been chosen to indicate that the object of interest are not only the activities of groups (sharing the same goals), organisations (sharing protocols) or a collectivity (sharing responsibilities), but more in general the activities performed by “multiple persons working together to produce a product or a service” (Bannon & Schmidt 1989), in the same space or distributed, in synchronous or asynchronous ways (Penichet et al. 2007), and driven by a plurality of goals, norms, value systems, contingencies.

The essential contribution of the consolidate knowledge on cooperative activities and systems in CSCW for urban technologies had been already acknowledged by scholars working on the use of technologies for planning purposes (Silva 2010) or on the construction of geographical information systems (Laurini 2014). Indeed, even though urban disciplines have the potential to unfold the physical and functional correlations of city activities, deeply understanding the “mechanics” of social interactions, as well as their translation in appropriate tools for making people collaborating through technologies, requires to rely on external disciplines having a compatible focus (practices) and orientation (openness to multi-dimensionality of the observed phenomena and problems).

Since its foundation in the ‘80s, the primary area of CSCW research has been the working environments (organisational and inter-organisational) and not urban settings. However, in recent years, a growing engagement with topics and studies outside common work contexts led CSCW community to deeply investigate location-based systems and how their uses, impacts and solutions are associated with the spaces and places (in urban settings or in the public sphere more in general) in which cooperative activities are performed (see e.g. Ciolfi & Bannon 2005, Dourish 2006). This strand of research provides the basis to already extend the concepts elaborated by studying working environments to new applicative scenarios defined by city stakeholders relationships and related activities in urban dynamics. Building upon that, the key concepts and analytic frameworks developed in the CSCW discipline can inform the research and design of city technologies regarding:

- the development of tools conceived as a “*common information spaces*” (Bannon & Bødker 1997) shared by a plurality of actors implementing their activities in the shared space constituted by the city
- the analysis of the applicative scenarios of city technologies for the appropriate support to local coordinative, cooperative and collaborative practices

e) Human-Computer Interaction Design

Human-Computer Interaction Design is the field at the intersection between Human-Computer Interaction (HCI) and Interaction Design. HCI is the discipline studying the interactions between human and technological systems relying on cognitive science, human factor engineering (a field including psychology, sociology, etc.) and computer science (intended as both computing and informatics) (Dix 2009). Interaction Design is the wide field of the “*design of interactive product to support people communicate and interact in their everyday and working lives*” (Preece et al. 2015). HCID³ originates from the convergence of the two fields grounded on scientific (and humanistic) knowledge on one side, and design methods and practices on the other side, combined around shaping of experiences mediated or supported by technologies (Fallman 2003, Forlizzi et al. 2008).

Differently from CSCW or IS, the primary focus of HCI (and HCID) research are users as individuals (and not groups or organisations), assumed as voluntarily interacting with technologies. This particular focus has severe limitations to address the study and design of technologies to support city stakeholders in their actions. Indeed, as well-known in urban disciplines every type of social and practical interaction in the city (technology-mediated or not) is always overdetermined, and not voluntary, if not in part. On the other side, the HCI field is theoretically and methodologically equipped to analyse and conceptualize the experiences associated with these interactions in urban context and intentionally shaping integrative technology-mediated experiences. The inputs coming from HCID can be combined in the research on city technologies for:

- Integrating the models of the City reflected in these technologies, by taking into account an experiential perspective for the description of urban systems and activities
- Combining the design and research explorations across real-world experimentations, by isolating what is specific of interactions in urban settings respect to other settings
- Connecting Users, City as context and the role of technology in an organic interactional model.

f) Information Systems

Information Systems is the discipline examining technological systems and social systems and the phenomena emerging from the reciprocal influences between these two systems (Lee 2001) for “*the effective design, delivery, use and impact of information and communication technologies in organizations and society*” (Avison & Fitzgerald 2003). One of the most prominent concerns of Information Systems research is how can we design better information systems to help organisations and society to work better from a strategic, economic, management, and social point of view (Avison & Elliot 2006, Baden 2010). Thus, Information Systems is a

³ See the schema of the convergence between Hci and Design at: <https://hcid.sice.indiana.edu/>

design-oriented disciplines having the purpose of structuring the knowledge incorporated in the operational context of technology and in the processes to be supported by technology. Similarly to the use of the context analysis in urban planning or urban design for making plans, projects, and policies, the context analysis is used in Information Systems for designing knowledge structure and architecture of digital technologies.

Under this perspective, it is easy to understand why the earlier conceptualizations and models about smart cities and smart city technologies had been elaborated primarily in the field of IS, and not in urban disciplines (e.g. Nam & Pardo 2011, Chourabi et al. 2012). Indeed, the relationships between technology and the city framed in relation to national and local governmental structures or businesses is an important strand of research in IS. However, the hybridization with urban disciplines for generating an open model of the city not only as a corporate/government entity could potentially help also in building also better information systems to support urban activities.

The inputs of Information Systems research for city technologies can:

- Rely on the extensive corpus of frameworks, theories, conceptual tools developed in IS for dealing with design and research problems concerning a wide range of technologies, by assuming a context-sensitive perspective
- Build upon the existing frameworks for the assessment of technologies to examine the specificities of the processes, activities, organisational and inter-organisational interactions in urban context and, then developing specific assessment protocols for city technologies.

5. Concluding notes

The previous sections outlined a general schema for bridging urban disciplines and informatics, in particular, Urban Planning, Urban Design and Urban Studies on one side, and Computer-Supported Cooperative Work, Human-Computer Interaction Design and Information Systems on the other side (See Fig. 7). Their hybridization is essential for designing new technologies to address more effectively contemporary city challenges, to sustain social innovation processes at the local level, and to enable new distributed and collaborative governance models for city services and resources. Indeed, while a common approach in urban research is investigating how to apply already existing technologies to planning practices and urban initiatives, this is not enough for pursuing transformative planning aims by exploiting the potentialities of digital technologies because the appropriate solutions are not there yet. Transdisciplinarity as approach and research framework can provide the foundations to enhance the generative and future-oriented nature of consolidated knowledge on cities of urban disciplines in new domains for defining the scope, role and applications of appropriate city technologies.

The contribution of the paper is two-fold. At a methodological level, it exemplifies the adoption of a transdisciplinary perspective to bridge distinct knowledge domains by focusing on high-level similarities and complementarities in theories and research practices having a concrete problem in mind, that in this case is understanding how to rethink digital technologies for serving social change aims and transformative planning practices. At a practical level, the synthetic presentation and discussion of disciplinary fields that are often unfamiliar to urban researchers and practitioners indicate some possible entry-points to approach their theories and methods and experiment their application in urban research. On the other side, the paper highlighted how the importance of urban disciplines for developing new theoretical foundations for city technologies do not rely on the technical and procedural knowledge usually associated with planning activities, but on valuable skills and understanding of social dynamics in urban environments. A transdisciplinary research agenda on city

technologies can be developed starting from a shared awareness of the contributions of each discipline across different domains.

Future works will formalize the transdisciplinary research framework built on the disciplinary roots selected and discussed in this paper, and will report on the application of this framework in past and on-going projects finalized at the development of city technologies.

Methods and technologies for transformative planning

Towards a better understanding of upcoming challenges related to technology and data usability within design practice. Key reflections from a collaborative process in Amsterdam city.

Irene Luque-Martín¹

¹ *Researcher and Urban designer at FABRICations and Visiting scholar at University of Twente - Faculty of Geo-Information Science and Earth Observation (ITC) - Netherlands – Enschede*

Abstract: The digital turn of the twenty-first century has unleashed an unprecedented amount of high quality data. Whereas most industries have eagerly taken advantage of this information to cut costs and improve their products, designers are still searching for an instrumental approach to implement data as a design tool. Technology companies and research institutes seem to have the tools to investigate today's challenges for better cities. However, their tools are not reaching into the design practice. We argue that we need to start a dialogue between the worlds of design, data and technology to find out what the real value is of big data for the spatial design disciplines. We propose to run an experimental case study using data as force of design and share our findings with the discipline. This paper describes and reflects on a process carried out by a project funded by Creative Industries NL and the Municipality of Amsterdam to develop a Smart City-Scan (an experimental data-driven Sustainability Scan) applied in the city of Amsterdam. This project aims to map spatial challenges and opportunities for sustainable and resilient urban design, hereby creating an integral foundation for healthy urban ecosystems. The Scan is executed in collaboration with experts on sustainability, data analysts, decision makers and other urban design offices through a series of six workshops. In conjunction with this paper, we will reflect on the role of these discussions between academics and practitioners aiming to bridge the rift between theory and its application within practice, specifically regarding research on potential technological methods and tools which could be potentially useful for daily practice struggles. This paper aims to provide insights on the content discussions carried out, but also reflects deeply within the methodology and potential outcomes obtained from the multidisciplinary discourse of shaping the smart city scan.

Keywords: sustainability design; collaborative planning; urban analytics; multidisciplinary design

Introduction

Global challenges of air pollution, climate change, increasing socioeconomic inequality and the disruption of the phosphorus cycle have given rise to a number of globally shared ambitions such as the Paris Agreement and the UN Sustainable Development Goals. These ambitions have profound spatial implications, including large-scale implementation of infrastructures for renewable energy, expansion of green-blue networks and providing better accessibility to services to vulnerable populations. Such complex issues require a new generation of tools and methods in order to make adequate decisions; we cannot design the 21st century with the tools of the 20th. Yet, as we approach the middle of the 21th century and face crises unlike any others before, urban designers seem to

stick with old tools and methodologies to solve these issues. Medicine is not practiced with outdated technology; why should urban design be different?

While urban complexity increases rapidly, cities face the demand to comply to the urban agendas (such as SDG, WCR, WEEL, Breem, and so on) which define the pathway towards more sustainable and healthier urban environments. This tension between the rising complexity and the demand to develop more sustainable and healthy cities lands on designers' desk as one of the most important contemporary challenges. It demands the reflection about how could we approach to achieve those sustainable goals. Which are the available tools/methods that we can use to make it possible? What is the role of designers into this technological and data era? In regards of responding to this, Offenhuber and Ratti in the book "Decoding the city"(2014, p.7) argue a key point:

But planners, policy experts, and economists are no longer the only specialists responding to these challenges. New actors enter the stage and bring new approaches to the field. Perhaps the most significant developments have happened in the domain of data-intense methodologies.

Those new actors are related to the understanding the city as a complex system which demands the use of complexity tools such artificial intelligence, and complex theory of cities in order to approach it. As De Roo and Silva argue in their preface of "A planner's encounter with complexity":

[...] planners need to understand that complexity is not a notion expressing basic feelings about an encountered situation. On the contrary, it goes far beyond that. Complexity stands for a 'reset' of our positivist mind frame, to be able to view the world differently, to make the switch from 'normal' science to a 'post-normal' science...which represents an understanding of reality that could very well be more promising than the reality proposed by 'normal' science (2010,p.17)

Many authors in the past has framed differently the idea of complexity, but all of them aimed to try to unravel that complexity as key aspect for the potential successful design outcomes (Alexander 1964; McLoughin, 1969; among others). This complexity gives meaning and breaks our established routines, this is the driving force of serendipity in cities, which promotes uncertainty and unexpected dynamics within the urban scene.

The demand of performative analysis

Understanding urban complexity overlaps with the sustainable goals aforementioned above. This stress designer's situation and pushes them to have the urgency of find tools and methods to unravel complexity. This urgent agenda demands shift from the most fixed and static vision of cities originated and established during the last centuries and move further on methods and tools towards the understanding of performance of cities as a way to get closer to read urban complexity.

To the extent that these technologies (and how we use them) influence how we experience the city and the choices we make there, they challenge the role traditionally played by architects in shaping the urban environment, a tool which has historically –with a few notable exceptions- focused predominantly on the organization of space and material in terms of built form (Shepard, 2011, p.10)

Cities performance shows us the contemporary demands, which is essential in order to promote more healthy and inclusive cities. Understanding how space is used, we could approach how space could be better shaped. This is a matter of starting to use the advantage of our existing knowledge of the data available on performance in cities, and thereby, understanding that design could promote more accurate and tailored solutions to the performative demand.

In order to approach how we could understand the performative side of cities, it demands an update and advanced understanding of the contemporary technologies and data sources available. The digital turn of the 21st century

has unleashed an unprecedented amount of high quality data. Whereas most industries have eagerly taken advantage of this information to cut costs and improve their products, designers are still searching for an instrumental approach to implement data as a design tool. The first companies to extract this information and apply it to the built environment are companies that are not traditionally associated with the design of cities. Tech-giants like Cisco, IBM and Microsoft are developing data-driven systems to advise urban planning authorities on transport, waste management, law enforcement and energy use.

Some of these projects provide insights about the integration of data and technology into the design disciplines. Take for example Alphabet's (Google's parent company) Sidewalk Labs in Quayside, Toronto. The neighbourhood is described as being "built from the internet up ... merging the physical and digital realms" and advocates underground waste disposal, modular timber-frame construction methods and deep-water cooling systems. Although these ideas in themselves are not innovative, the fact that they are integrated and monitored with the assistance of technology is.

Moreover, they are combining its tech-centricity with a collaborative and community-oriented approach to decision making. Projects like Sidewalk Lab seem to offer a new way of looking at urban planning, bringing new questions to the table about the position of the design disciplines in the 21st century in relation to innovations in data and technology.

The endless debate

Although apparently technology and data seem normalized within design practices, the reality is that design discipline is still and continuously in an endless debate around the question: is data and technology useful for design practice? Are they replacing designers' tasks? Are they a threat or a useful tool?

This has been continuing debate for over fifty years. It oscillates like a pendulum between two extreme opposite positions. On one hand, we have the technocratic discourse believing that technology and data will come to solve all our issues. Cities are understood as a mathematical issue which can be tackled from a systematic approach, by simply generating the right formula we could solve urban problems. On the other hand, we have the humanistic discourse which believes on cities as a composition of human's interactions where systematization or formulas have nothing to say. The cities are understood as a composition of complex networks, therefore demanding a collaborative and inclusive decision-making process as a key method to understand and intervene on urban networks.

Both discourses are part of our contemporary practice, and although these were discussion from fifty years ago, it is still present on our everyday life. From Adam Greenfield stating "technology will kill us" till SideWalk Labs applying the use of data as the solution to cities' issues with a non-transparent and out of design discipline understanding. The debate about if design and decision making in cities should be informed by data and till what extend, it is not an old debate. Indeed, it is a contemporary debate which keeps oscillating between the two extreme opposite positions unless practices and theories start to make the extremes converge.

In the endless debate whether technology and data add value in design practice, there are usually two main arguments: 1) the threat towards human driven design, and 2) the ethical use of the tools and data. In regards the first argument, we could say that the starting point of discouraging the use of technology as a universal solution of cities raised around the seventies. Indeed, the article "Requiem for large scale models" published by Lee (1973) was an inflection point on the debate of the potential results that technology was offering. While the technological revolution promoted the idea of design and planning as a mathematical exercise, the technology and data availability was not the most suitable one in order to be able to tackle the urban complexity in our cities.

There was a need at that time for better analytic and quantitative procedures, and there was also a need for the development of theory. Now, the need for both theory and method is even greater. It is not about our intent to

discourage those who would apply quantitative methods to urban problems, but, rather, to redirect their talents into more valuable pursuits than repeating the mistakes of the last decade. (Lee, 1973, p.163)

The contemporary availability of data and technology

Almost fifty years later, we still reflect on the need of both theory and methods to give us tools and better understanding of urban problems. The difference today is that we do not lack either technology or data. While fifty years ago a computer used to take spatially half of a room, nowadays those computers are carried in our bags everywhere. It is not just about their size, but their capacity which is largely bigger than what those fifty years old computers were able to process. Hence, if we reduce space and increase power of those technologies, the equation of its usefulness and usability within design practices should be updated as well.

Although in a completely different scene and with completely different status of availability of data and technologies, why is seem data still a threat to designers? Coming back to the words from almost fifty years to read the still valid Lee's article (1973, p.176):

If planners fail to adopt and adapt theory and methodology as these become available, they will find themselves working less and less on the problems; on the other hand, if planners pick up ideas naively and uncritically, the field will simply jump from fad to fad. Somewhere between lies the optimum path.

Design practice needs to understand the role of the current technology and data available in order to commit to accurate, rigorous and potential successful outcomes from its practice. Hence, it is demanded designers reflecting on the usability, the usefulness and the way these technologies and data resources could potential support their daily activities.

However, even if this reflection is urgent, design discipline generally keeps oscillating whether it is suitable using data and technology either because of the fear of stealing its practice or because of the sensitivity of the ethical dimension, big companies -which are far away from what the ideological core of understanding what design is- are taking over projects and processes. They do not hesitate on experimenting the usability of technology and data, they do not doubt that complexity demands advanced tools and methods.

As important as understanding what tools, what data, and how to implement it on design practices, there is the need to gather the knowledge and experiences which already are leading towards a rupture of the oscillations of the endless debate between technocratic and humanistic. The balance between hard and soft data is a reality in contemporary practices which aim to promote a combination of the most quantitative and qualitative approaches in order to take advantage of best tools and complexities. Then they could approach analysis and interventions with a more accurate and rigorous knowledge of the urban problems.

During the endless questioning dynamic of whether data will make designers obsolete, or whether it kills the creative process and the romantic side of the profession. Other, more optimistic practitioners see the potential in big data analysis, arguing it could save time and inspire new spatial answers to contemporary questions. Regardless of which side you are on, it seems that there is a rift between the worlds of data and design. Spatial designers in practice seem largely unknowing of the potentials, challenges and risks of using big data analysis as a design tool and enter the debate with mere emotion and intuition. It is time for the debate to be fueled with empirical arguments.

The action then is not just the reflection, but the discussion and the dialogue to use this research as a gathering tool of experiences and potential outcomes from theory and practice. An empirical research to understand by dialoguing which tools and methods could potentially be useful and meaningful on design daily practices.

Tech companies and research institutes seem to have the tools to research today's challenges for better cities. However, their tools are not reaching into the design practice. As such, we argue that we need to start a dialogue between the worlds of design, data and technology to find out what the real value is of big data for the spatial design disciplines. We propose to do so by running a real-world test – an experimental case study – using data as force of design, and share our findings with the discipline.

This paper analyses and reflects on the results of an empirical process based on the development of six workshops reflecting on the data and technology usability and usefulness within design practice. It applies specifically to Amsterdam city and it is realized by a project called “Smart City Scan Amsterdam” lead by FABRICations design office in coalition with the CTO Innovation office of Municipality of Amsterdam and the GIS Lab from University of Amsterdam. The project is funded by Stimuleringsfonds Creative Industries of Netherlands with the CTO Innovation Office from Municipality of Amsterdam.

Smart City Scan of Amsterdam. Project overview.

The Smart City-Scan of Amsterdam aims to map spatial challenges and opportunities for sustainable and resilient urban design, hereby creating an integral foundation for healthy urban ecosystems. The Scan is executed in collaboration with experts on sustainability and data analysis, decision makers and other urban design offices through a series of six workshops.

The relevance of the project stems from the belief that information technology and data is changing the discipline, and that all spatial designers share responsibility in responding to this. The Smart City- Scan case study essentially serves as an example to inform and promote debate on the use of data for sustainable urban design. Throughout the workshops, the public debate, the report, and the project aims to illustrate and discuss the following points:

- What data is available and useful for designers and which sources to use;
- How to process data using indicators and technology;
- How to translate building standards, academic research and ambition documents into measurable indicators;
- The obstacles between the world of tech, sustainability, design and finding ground for mutual understanding between big data analysts and urban designers;
- The potential of using big data in urban design and to what extent the research process can be automatized, sped up and quantified using information technology and big data;
- Potentials of applying big data in making sustainability assessments, and;
- Future growth opportunities of the spatial design disciplines; i.e. whether urban design should adopt big data technology as an integral research capability.

In order to explore the role of data and technology in the design discipline it is proposed as case study the city of Amsterdam with the following coalition which contribute on different roles: 1) The Municipality of Amsterdam being advanced in urban data collection and in their urban agendas, they provide the data and the setting for the case study. 2) GIS (Geographic Information Systems) Lab, University of Amsterdam which has the technological expertise to ensure the correct use of the data and the tools. 3) FABRICations in charge of transforming data into spatial assessments that can inform the design process.

The research project will be based on the validated Sustainability Scan methodology which FABRICations developed over the past 10 years. The Sustainability Scan investigates the built environment using a holistic framework of Six Themes of Sustainability (Future Urban Regions, 2015), including vital economy, sociocultural solidarity, healthy living, material cycles, resilient systems and energy transition (see Figure 1).

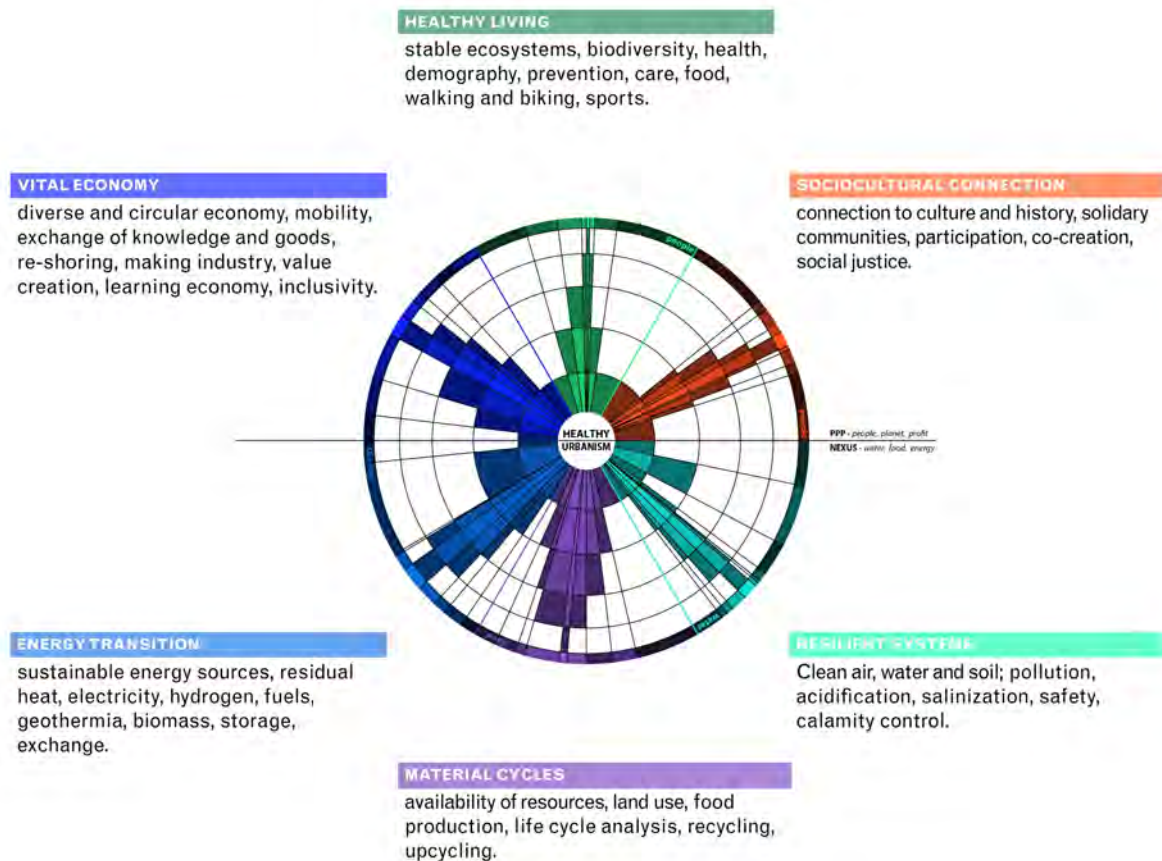

Figure 1. Six themes diagram. Future Urban Regions Research..

Six workshops. Key actors.

Six workshops were planned with two-week intervals between them. Each workshop discussed one of the Six Themes which are the theoretical background of the urban analysis within Amsterdam (healthy living, vital economies, sociocultural connected, material cycle, resilient system, energy transition). Each workshop will be composed of experts on the theme, data analysts, decision makers and practitioners. The goal of the workshops is to exchange knowledge between disciplines regarding indicators, data and technology, in order to create mutual understanding between target groups and to receive critical evaluation about the Smart City-Scan.

As key actors during the process, and mainly regarding the workshop participation, has been identified three target groups that were reached during the workshops:

- Design Practitioners Designers are included in the research process in the form of workshops and will be invited for the public debate. Furthermore, the findings of the Smart City- Scan itself (i.e. opportunities and challenges for sustainable urban design) will be of use to design practitioners working on projects in Amsterdam.
- Decision and City Makers Decision makers from municipalities and central governments and city makers (i.e. real estate developers) are an important target group for the project. The

project aims to inform them on the spatial requirements for sustainable city development, on how data can be applied to assess them and how they can contribute to promoting data-driven urban analyses. We also aim to inform them on data that would be relevant for urban designers, but that is currently missing.

- **Research Institutes.** The academic world has been exploring the potential of data-driven design for the past few years. The issue is that their progress has not been adopted by the design practice. The project aims to build a stronger connection between the academia and practice when it comes to implementing big data analysis in the spatial design disciplines. Similar to the previous target group, the project also aims to inform them on data and technology that would be useful for urban designers, but that is currently missing.

Key reflection 01: a multidisciplinary approach is a myth

Multidisciplinary is defined as the combination of several academic disciplines and professional specializations in an approach to a topic or problem. In this vein, Smart City Scan aims to modify the conventional methodologies promoting a collaborative approach. The root of this approach is promoting discussion and the stakeholder together in the beginning rather than approaching collaboration just as a check on the results already decided on previous stages.

Although the participatory approach of the six workshops was attracting diverse disciplines together. The aim to promote and then observe the interactions between diverse disciplines that could be generated. The overall idea was to gather key actors who are involved at any level/scale to the specific theme addressed on each one of the six workshops. The key groups involved: data/technology experts; designers; policy-makers; practitioners; and researchers.

Elaborating a quantitative analysis on participation from the diverse target groups approach (Figure 2), we could generally conclude that researchers have been the ones who most attended, while designers the least. This might be related to their different policies in regards of workshop attendance but might be also potentially related to the amount of invitations sent.

In addition, what needs to be highlighted is that design offices were counted as group units while researchers were individual (i.e. there were several moments where researchers from the same institution carried out different projects and research). Indeed, it was easier to find more individual researchers than several design offices. It is important to understand those details under the quantitative analysis between disciplines before doing assumptions on what profile of attendant was more attentive.

Figure 2. Six workshop quantitative participation analysis. Smart City Scan project, FABRICations.

Besides the quantitative side of participation during the workshops, at the level of qualitative interaction we found a general pattern during all the workshops: experts and key decision makers within a topic did not of one another, or even more important, they did not know what the others were developing either as research or praxis. One of the most common comments in the feedback section organized from the workshops was related to the interest from participants to know each other since workshops became a platform to facilitate a multidisciplinary knowledge exchange.

Hence, it is interesting to highlight that during the participation most of those researchers and practitioners were claiming that within their own projects they have a multidisciplinary approach. However, to what extent is the exchange between multiple disciplines really occurs? Is it usually a private exercise inside of specific teams? Is it not important to externalize efforts to understand other discipline's concerns/visions?

In order to respond to the question, the workshop provided a clear vision of the two main challenges that Smart City Scan project should face regarding multidisciplinary and that will be worth to keep researching and experimenting: on one side the importance of visualizations as potential tools to facilitate communication, and on the another hand the demand to also show the spatial implications as a way to increment the interconnectivity and

common agreements between the participants in order to understand complex urban issues from a multidisciplinary approach.

Regarding the communication, it was found that while most of the participants were linked by the understanding of the topic itself, the type of words and concepts used demanded several times clarifications and promoting of collective understanding of the language used from the facilitators. Regarding the collective construction of knowledge it was found that most of the participants had their own line of work. Indeed, for several of them it was difficult to leave behind in order to open to other's understanding and point of view of the same theme.

Figure 3. Six workshos. Highlighted photos. Smart City Scan project, FABRICations.

If what has been witnessed in the six workshops is remotely showing part of the reality, then a multidisciplinary approach is a myth. Therefore it is necessary to ask ourselves: how do we overcome the words which are mere definitions and pursue truly collaborative processes which aim to establish a common language of communication between diverse disciplines, in order to promote the construction of a collective knowledge? There is where the two challenges converge into a common goal which needs to be faced from the design practice as well as from the theory: a truly multidisciplinary process.

Key reflection 02: Data labyrinth

Data is our daily reality. We are in the era of digitalization generating an intense production of digital information every second through any activity we do. Beyond the ethical concerns (which would be addressed in the next point), there was a common concern occurring systematically along the six workshops related to the accessibility and availability of data.

In the near term, sensors will be integrated into nearly all parts of the physical urban fabric, creating a 'digital skin' composed of connected, digitally enabled objects, network nodes, communication devices and posts for monitoring and analyzing data fed into servers. (Rabari, & Storper, 2014; p. 27)

So if the data production and storage is our contemporary reality, its usability should be reflected in our contemporary practices and research. Why are designers lack to take the full advantage of data usability? As

Batty (2013; p.192) mentions: “These datasets are everywhere, although are often locked away from those like ourselves who wish to mine and interpret them for purposes of understanding and design.”

Data has become the holy grail of any urban analyst. However, the reality is that in regards to the accessibility of data it is either private (i.e. pay walls or privacy concerns) or if it is public it is encrypted. Hence, data is becoming a labyrinth for designers who aim to find the right information in the right format. The availability of data is a multidimensional issue, however, the reality is that every time the discussion about data availability appeared within the discussions of the workshop, there was always someone saying: “that data is available”. However the way it is available makes a significant difference for the user. The online availability of these data sets is merely is not sufficient (which may not necessarily be the case for other disciplines), the user should be able to extract and process the information to see its full value (cvs, shapefile, raster, dxf,, etc).

These issues are important if we begin to talk about the way designers use information to inform their design projects. In order to maximize the data usage, the possibility of integrating such information in their current systems and technologies is vital. Otherwise, practice reverts to conventional tools with the fear of having to invest significant time and effort on updating software, finding the needed layer within the data labyrinth and exhausting large amount of time processing the encrypted data formats. Designers demand data that is easily treatable and easy to integrate to their current tools.

Beyond the concerns regarding data availability and accessibility, the relationship to ownership seems rather interesting. Data is not the same universally, nor it is its accessibility. Therefore, the time invested on understanding (decrypting data) which specific data sources and software to be used will be entirely irrelevant in the next project due to varying contexts. This promotes a sense of skepticism with designers who find difficult believe the worthiness of data where the main goals of a project could be compromised due to the effort required in processing data. When the search for data becomes the project, designers lose hope on its usefulness.

The ownership of data is intrinsically related to the institutional composition of every location. Although there are some universal and worldwide data sources (such as Open street map or Google), design at its traditional scales (regional, city, sector, block, public space or building) demands accurate information. As scalability is important, the fact of using rigorous data is the same, since most of the works related to designers are meant to become physical future realities. This implies having official and institutional data sources, which are differently arranged both in structure and accessibility. In those cases, the availability is directly related to the ownership of the data.

Through the workshops, the discussions become pivotal regarding availability, accessibility and ownership. Although the original aim for the Smart City Scan was to pursue what the idea of Big Data meant to the designer, it slowly became clear that it was not about the amount of data they could get but rather to seek what was the right data. Therefore, the clarity on the conceptual question is key to not get lost in the sea of data. The question will guide an effective and productive data search which will lead to support to answer it.

Through those workshops, a reflection comes up: designers do not need big data, they need the right data. The question now revolves around the accessibility. How does an individual navigate through the existing labyrinth of data? It will depend on the ownership and availability of the data sources. However, if there is something to be can taken away from the Amsterdam case (knowing that it exemplifies an open data source for urban problems) is the importance of generating right coalitions with the owners of the right data demanded. But also, about imagining and hacking the pathways towards to the conceptual aims. The design concepts will guide the data accessibility rather not the other way around.

Key reflection 03: The ethical dimension of data

During the six workshops the ethical side of the data usability has been one of the main concerns from participants. It required a significant effort in each workshop to debate till what extent data inclusivity and the influence it had

on decisions made under interpretations on the final outcomes. However, regarding the ethical use of data is demanded to approach it as a key reflection on the project. However, in regard to the demand of the ethical use of data, it became a key reflection in the project.

While being confronted with the two extreme approaches (technocratic vs humanistic) oscillating on a pendulum, an interesting approach to these struggles from an ethical dimension began to take shape. Data is not the devil, but requires mindful use under specific principles. Indeed, in the first workshop about vital economies in Amsterdam, there were two key participants from “Tada” who work towards an understanding of the ethical dimension of data in order to make better cities. The website of the company states:

Data: a promise for life in the city. Data enables us to tackle major problems of modern cities, making them cleaner, safer, healthier... but only as long as people stay in control of the data, and not the other way round. We – companies, government, communities and citizens – see this as a team effort and want to be a leading example for all other digital cities across the globe. To get started, we have come together to set out the following shared principles. <https://tada.city/en/home-en/>

As they were key actors in introducing to organizers the demand to incorporate the ethical dimension of this project while it is important to mention their principles. They summarized their idea of how to use data in an ethical way. Their six principles are: 1) Inclusive use promoting equality; 2) Control promoting that data and technology contribute to the freedom of people, so the people stay in control over their data; 3) Tailored to the people which defends that humanity always come first leaving room for unpredictability; 4) Legitimate and monitored providing control to the citizen and users over the design of our digital society; 5) Open and transparent about what type of data purposes and outcomes; 6) From everyone – for everyone, which demands the data from government authorities, companies and other organizations from the city should be open and everyone could benefit from it.

These principles could potentially sound as a utopia, but indeed, after six workshops discussions about what data/ownership and the way it is exploded to develop interpretations, it is key to maintain those principles as guide towards being in control of the usability of certain data sources and technology.

Key reflection 04: Fieldwork is not out of fashion

“Not everything that can be counted counts, and not everything that counts can be counted.” This statement made by Albert Einstein is key in this reflection about how qualitative approaches could potentially complement the quantitative ones. In regards to the methodology that was used to approach the six themes as preparation (i.e. preliminary computations regarding each one of the six themes) there was a underlying criticism made by many participants; the use of a computational method will unravel complexity so designer will believe data as a totalitarian true ignoring their own knowledge and experience. The project was far away from this assumption, but became a leading and systematic criticism during the socially themed workshops. The main insight from participants was that in order to develop a deep knowledge of the urban challenges regarding those themes, a perspective from the other side (soft data) was crucial to consider.

[...] the models will be built through machine learning, how to understand and run cities will manifest itself largely without the need for any deep domain knowledge about cities – their history, their politics and culture, their political economy, their inequalities and tensions and battles, their modes of governance, their environment. (Interview with Rob Kitchin, p. 110)

Where will be the experience, insights, and intuition of experienced designers if we are driven by technology rather than the other way around? Cities are complex systems which are comprised of intricate socio-economic networks which cannot be easily computed. Even less the interrelations between those networks. Therefore, there is the need and the logic of integrating the hardest and most soft way of analyzing the cities.

Hard facts and models trump other kinds of knowing and undermine and displace other scientific forms of urban knowledge that are less systematic and continues, such as policy analysis, interviews, focus groups, surveys, etc. So as a new form of knowledge is developed, other forms are potentially sidelined. That, I think, will be to our detriment because for all the hoopla about big urban data and urban science, it has numerous limitations, including methodological and technical shortcomings and data quality issues. I would prefer to think about big urban data as complementing –non replacing- other urban knowledges. It's not necessarily better: it offers another perspective. (Interview with Rob Kitchin, p. 110)

In order to promote inclusive readings of the environment, it must be viewed through the lens of technocratic and humanistic methodologies. As many participants mentioned, it is key from their experience and practice to work with and for the people related to the issues. For instance, during the socio-cultural connected and healthy living workshop we received reoccurring and persistent remarks of 'not without fieldwork. As one participant mentioned clearly during healthy living workshop: "this project lacks the qualitative approach".

However, in the same discussion, another participant clarified the interesting gap of data sources, which unbalanced the conceptualization of healthy living systems. In this case regarding playgrounds, she elaborated the critique based on children dynamics who are not monitored, and who do not provide data on apps or google. It demands a qualitative approach. This tendency potentially and several times leads to data driven analysis that tends to ignore or even overlook urban issues which are based on experiential that cannot be tracked by data monitors.

A simple analysis of data is not enough. A process in which a qualitative approach is necessary to go beyond and more in-depth into reading social dynamics. However, it seems clear that a coexistence of a qualitative and quantative analysis can be complimentary. And, if design can seek a balance, then it will be able increase its accuracy and overall productiveness in urban analysis.

Key reflection 05: The trap of blind spots in the interpretation of data

Blind spots are one of the crucial issues in regards to data interpretation. It became the bottom line under several workshops , mostly within the socially driven groups. The data produced, gathered, and interpreted usually becomes fact. However, and as one of the participants mentioned during the socio-cultural workshop: "data needs to be processed to become information". If we refer to social data, then the way it is processed, and the assumptions developed become a key part of the question.

They (cities) are affected by structural forces and political and business decisions made in a multitude of places. They are full of millions of people who act in all kinds of ways and are thoroughly infused with culture, history, and politics. Even with more data, new analytics, and enhanced computation, it is therefore very difficult to create robust models of city development, and even more difficult to translate these contextually into policy. (Interview with Rob Kitchin, p. 110)

As Kitchin argues, the city goes beyond a static and physical environment. Indeed, if we aim to understand the most social themes and the urban challenges related to them (such as vital economy, socio-cultural connected, healthy living) it demands an understanding of the social dynamics of the city. Certainly, a performative analysis of the city. This discussion usually belongs to the idea of the blind spots, which are the realities we suppress from our interpretations on data. This relates to the idea of black boxes, which stem from the assumptions arise when data is treated through diverse technologies (such as modeling).

There are two examples that can clarify this black box concept. During the healthy living workshop a participant explains that if a dataset from Strava is used in order to understand the optimal spaces of exercise are, we are understanding the users (producers of data) that are providing key data which could be interpreted as a pattern or tendencies of spaces of high attractiveness. However, if the goal of the analysis is to encourage people to do more

exercise and encourage healthy living conditions, then the data source of strava is not appropriate. It creates numerous blind spots. The strava data set solely represents the population practicing exercise, it does not represent the population that do not use application. It means that the use of this data misaligns itself with the target group that needs to be addressed. The combination of blind spots, narrow interpretations and assumptions could potentially lead to conclusions that are misleading.

“This is classically known as a ‘black box’. What goes in and what comes out are known exactly, but the process by which one is transformed into the other is a mystery.” (Lee, 1973, p.167). The author promoted the idea that technology could potentially have interesting usability but not before understanding its limitations: “A balance should be obtained between theory, objectivity, and intuition”. (Lee, 1973, p.175-176)

Future research

This paper is part of a five-phase project. The first phase as the theme’s hypothesis and the second as a gathering of knowledge through the six workshops. In parallel, as the transition from the participatory process move towards the computing phase, it is now a process of which in depth interviews with key participants from the workshop promote the creation of coalitions for the development of computations. These coalitions differ from decision makers, experts, and researcher who are providing the key insights to build six test cases of the usability of technology regarding the six themes. This transition helps to go beyond these five-key reflections of the workshops, towards an in depth theme specific analysis in aims find the right conceptual ideas to be tested.

After the computation and assessment phases (parts three and four), the project’s aim to conclude with a public debate as the final phase. This discussion will be comprised of the entirety of workshop participants to come together and discuss the reflections and computation results. After, the validation of these outcomes and reflections, they will provide the design practice an additional perspective. A viewpoint that is empirical in which the main challenges, advantages and disadvantages of data and technology usability are made visible. Ultimately, the reflections and key outcomes will help guide and support designers with their agendas of making cities more sustainable and healthier.

Acknowledgements

This paper belongs to a Smart City Scan Project in Amsterdam. A project funded by Stimuleringsfonds Creative Industries NL and CTO Innovation Office of Municipality of Amsterdam. Firstly is to acknowledge the FABRICations team. Specially to Eric Frijter and Olv Klijn (Directors of FABRICations). And the core team composed by Max Augustijn as urban analyst specialist, and Chong Yao for their important interdisciplinary exercise during the workshops organization and coordination. Moreover an acknowledgement to the coordination effort and the conceptual insights from Juan Carlos Goilo (CTO) and all the participants who attended the workshops bringing and contributing meaningful insights to the project.

Track 5. Methods and technologies for transformative planning

LANDSUPPORT, a decision support system for territorial government

Emanuela Coppola¹, Francesco Domenico Moccia²

¹*Department of Architecture, University of Naples Federico II, emanuela.coppola@unina.it*

²*Department of Architecture, University of Naples Federico II, fdmoccia@unina.it*

Abstract: The objective of LANDSUPPORT is the construction of a smart geoSpatial Decision Support System (S-DSS), providing a powerful set of decision supporting tools – that will be open and freely accessible through the web – devoted to (i) support sustainable agriculture/forestry, (ii) evaluate their interaction and trade-off with other land uses, including spatial planning and (iii) support the achievement of selected land policies of both EU and UN agenda, with special emphasis to the key, “achieving a land degradation-neutral world” and climate change mitigation goals. By doing that, LANDSUPPORT will reconcile urban regeneration policy ambitions with operational reality addressing the often overlooked support for planning/management actions at the very local scale. In fact, only by this approach incorporating the local dimension it is possible to produce DSS tools to simultaneously fulfil all high demanding specific challenges such as the evaluation of “land use trade-offs”, “incentivising real actions / behaviour / investments” contributing to “sustainable management of land resource” and considering societal needs. This is exactly what the high performing LANDSUPPORT integrated scientific approach promise to do, unlike the aggregated Territorial Modelling Platform already in use for the ex-ante evaluation of EC policies.

Keywords: Decision Support System; Land take; Soil sealing; Spatial planning

Introduction

The project Horizon 2020 LANDSUPPORT (www.landsupport.eu) aims to develop a geospatial Decision Support System (DSS), based upon the Web and open-access, which points at contributing to the development and implementation of land utilization policies in Europe and will promote an integrated and participatory approach to rural development and environmental policies. Some features (land-take, green infrastructure) are particularly useful for territorial planning and environmental evaluation, understood as both strategic environmental assessment both environmental impact assessment. The INU (Italian National Urban Planning Institute) contributed to the project and attended to the presentation of alpha version of web platform, presented at the general assembly of research group in Balatongyörök, Hungary, from 27th to 29th of May 2019.

The project is built upon the experience grown during several experiments and successful projects, like “SoilConsWeb” (www.landconsultingweb.eu) and “Soil-monitor” (<http://www.soilmonitor.it>) with the collaboration of different research units. The system contains roughly 100 DSS instruments, dealing with topics of strategic interest: agriculture, environment, planning. Users can display data for the selected periods and area of interest, and then they can access modelling and services provided by LANDSUPPORT project, using

different scales. Results are shown through maps, graphic figures and reports able to be exported and allowing comparisons between different scenarios. The project integrates existing databases, with different scales, with new high-performance modelling tools that simulate agriculture and silviculture, land degradation and environmental issues.

The system will be based on cutting-edge technologies for the development environment, high performance calculation and massive raster data management and will be validated by remote sensing data. LANDSUPPORT aims to integrate decisions on many geographical scales into a single set of instruments, allowing to coordinate policy ambitions for agricultural and environmental sustainability with local operating realities, that are very often overlooked. A test will be carried out on four geographical scales: EU, national (Italy, Hungary and Austria), regional (an Italian and a Hungarian region) and local (pilot sites in Austria, Italy, Hungary, Tunisia and Malaysia). The project also provides for the organisation of end-user workshops during the development phase and training courses as soon as a first subset of tools is available. One of the Italian areas of experimentation will be the Cilento National Park, thanks to the collaboration with the LUPT Centre of the University Federico II of Naples (coordinator of the experimentation prof. F. D. Moccia).

Construction of the decisional system

With the Work Package 1, the tools of LANDSUPPORT are optimized on the basis of real demands coming from policy-makers, farmers, territorial planners and land managers at the European, national and regional/local level. The activities in the WP1 are connected to the approach of the living laboratory developed in WP7 and WP6. As first footstep of the DSS development, Work Package 2 is establishing the base of services for LANDSUPPORT, harmonized with the integrated management of raster data, vector data and metadata, that allow "any queries, in any moment and on any dimension" to be managed as explorable data. Work Package 3 will be based on this platform and develop a multi-scale and modular modelling system that will be at the heart of LANDSUPPORT's DSS tools. Meanwhile, Work Package 4 will collect, pre-process and provide a portfolio of Earth observation maps (EO) and outputs of Copernicus Sentinel satellites, with the aim of enabling continuous monitoring of highly dynamic land surfaces and providing biophysical vegetation variables, in order, evaluate and validate model results.

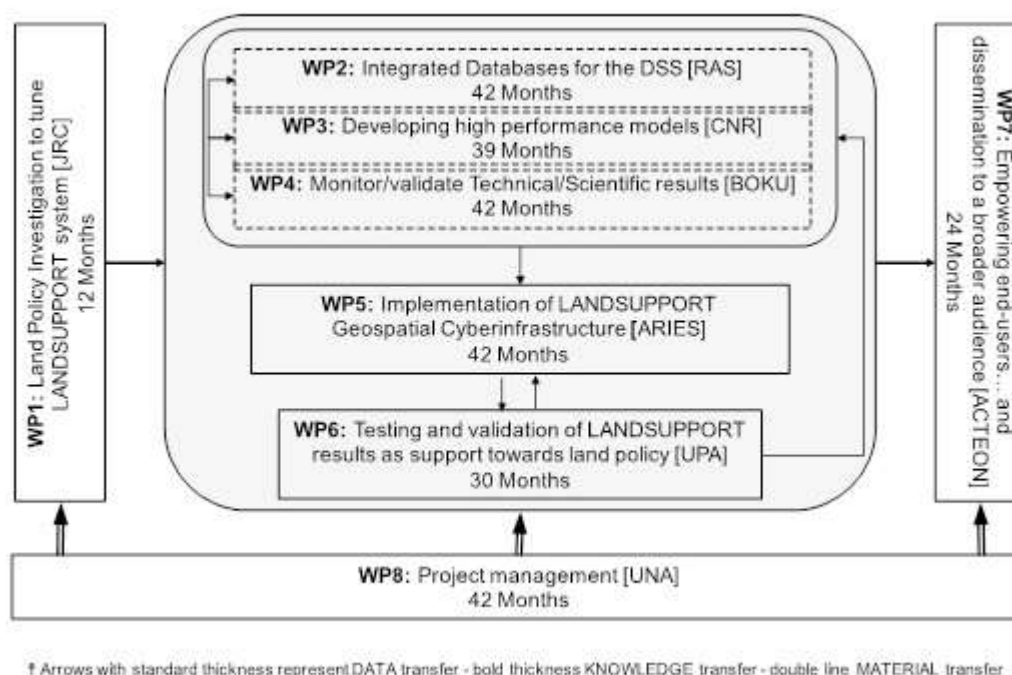

Figure 1. Project diagram. Source: Moccia, Sepe and Terribile (2018)

At this point, the core of DSS will be completed, therefore the Work Package 5 will come into play, designing and developing a highly customized LANDSUPPORT spatial DSS web application, as well as integrating engine modelling and data levels into the web-based geospatial-cybernetic infrastructure (GCI). The living-lab process is developed on two work packages, namely WP6 and WP7. In WP7, the operational needs of future users (policy makers, farmers, space planners and other land managers) will be explored during dedicated workshops at national and local level. The WP6, then, will test, evaluate and validate the results and products of LANDSUPPORT together with future users. Moreover, WP7 will also include capacity building activities with future users, as well as communication, awareness and dissemination activities aimed at a wider audience. Work package 8 includes all project management and coordination activities, while work package 9 includes all activities to meet ethical requirements.

Soil consumption, urban planning and ecosystem services

Soil consumption is one of the most severe degradation processes of ecosystems, because it is responsible for drastic limitation or even complete removal of essential ecosystem services. Although important European policy documents (Roadmap to a Resource Efficient in Europe - SDG'S) promise to mitigate this phenomenon, there are still no clear signs of change and land consumption continues to grow alarmingly worldwide. As stated by Moccia, Sepe and Terribile (2018) "We believe that immediate action is needed to reduce the gap between major policy statements and the lack of operational and scientifically robust tools to tackle land consumption". These instruments must aim to support the decisions of politicians and all those who have the task of managing, controlling and contrasting this harmful phenomenon.

Soil consumption can also be faced through an innovative web platform designed to determine different indices related to the quantification of this degradation phenomenon. The "ground consumption" function (landtake) was one of the main functions present in the previous experience of the web-GIS (Geographic Information System) Soil-monitor designed by the CRISP (Centro di Ricerca Interdipartimentale sulla "Earth Critical Zone")

Centre. The land take tool will be a powerful support to the ex-ante assessment of new urban development actions or new green corridors in the hands of European spatial and urban planners and planning public bodies. All European municipalities and other public bodies dealing with spatial planning and agriculture and not having specialised expertise. Thanks to LANDSUPPORT website, on-the-fly they can assess metrics/map/statistics/reports about soil consumption/land fragmentation, simulate land use change scenario, land use change and much more at no cost. This paramount objective will not be achieved by a top-down approach but rather by empowering any final end-user about the impact of planning. LANDSUPPORT, in fact, implements on a European scale the previous experience of web-GIS Soil-monitor - specifically designed for Italy. It is useful, in this regard, to take up the salient points of the previous experiment lead by INU Campania on Soil-monitor. The Soil-monitor platform, while being a prototype of a geospatial cybernetic infrastructure, has shown that - thanks to research - it is now possible to reduce the distance between the major environmental policy statements (e.g. SDG) and the direct implementation of measures to reduce land consumption. Soil-monitor has also been designed to support some national policies related to land consumption (AS 1181, AS 2383, Act n. 86 of 22/05/2015, Act n. 221 of 28/12/2015) associating actors related to scientific research with population, settlement, politics and economy. In order to maximise the reliability of the results delivered by the web platform, the data used for calculations are provided by ISPRA (Italian Institute for Environmental Protection and Research) with high spatial resolution. The coherence of the calculation procedures of various indicators of land use and urban and territorial planning has been tested by the National Institute of Urban Planning. The measurement and quantification of soil consumption performed by the Soil-monitor had the merit of raising awareness of the phenomenon. The calculation has been designed and implemented to be adaptable in relation to the available hardware resources, allowing real-time answers even for the most challenging indicators (for example, the fragmentation of rural and urban landscapes) required for large geographical areas of interest (a province, a region or even the whole Italian territory). The codes have been written in CUDA-C and use NVIDIA graphics card processors for massive parallel computation. The Soil-monitor made it possible to quantify:

1. Changes in land use at different times.
2. Fragmentation of rural landscape.
3. Loss of ecosystem services.
4. The impact of ecological corridors restoration.

LANDSUPPORT, on the basis of these premises, can have as its objective the mitigation and the achievement of neutral land consumption on the European scale. Beyond land consumption, another important application for planning is the “fragmentation” and the implementation of the ecological network. The Observatory on soil consumption of the INU Campania tested the Soil-monitor tool on May 10th and 31st, 2017, at the Computer Laboratory of the LUPT (Laboratorio di Urbanistica e Pianificazione Territoriale) Centre - University Federico II. Fifteen INU members took part in the test, which included a guided test and three sessions of test related to the use of indicators on land consumption, ecological fragmentation and urban hierarchies. In order to improve the application and make it more accessible to potential users, a subsequent experiment was carried out on a specific but significant territorial area, coinciding with the metropolitan area of Naples.

The results obtained from the use of indicators belonging to Soil-monitor were compared with the environmental analyses and the proposal of the main ecological network of the Territorial Coordination Plan of the Metropolitan Area of Naples (PTC) adopted in January 2016. The results of the test were presented in the 2017 Report of the Research Centre for Soil Consumption (CRCS). The results of that research are, in part, here proposed again, in order to illustrate the application at the planning level.

Territorial planning, especially in metropolitan contexts, must deal with the changing landscape, due to the persistent phenomenon of soil sealing that causes the loss of ecosystem services. Indeed, the fragmentation of ecosystems, produced by soil consumption, has a significant impact on services related to the protection of biodiversity. The Campania Regional Territorial Plan (PTR in Italian) of 2008 states that the spatial and

ecological fragmentation of the regional territory is one of the main causes of landscape degradation, and provides indications to pursue the objective of “defragmentation” through multiple interventions at different scales: regional, provincial and municipal policy guidelines for agriculture and major infrastructures design. In fact, agricultural areas, if reorganized according to environmental sustainability principles but without losing productivity, may constitute a small network of links between areas which are best preserved from an environmental point of view and which have a high level of bio-permeability. Major linear infrastructures (motorways, railways, reclamation channels, main power lines) if designed or restructured with suitable criteria, could be a complement to the backbone of the regional ecological network, contributing to the connection of large natural areas. The analysis of soil consumption led by ISPRA emphasizes even more clearly the absence of large areas with a high level of bio-permeability. The metropolitan scale thus becomes an interesting area of analysis, in order to monitor the impact of land consumption on potential green infrastructures of the metropolitan area of Naples. The web platform is an innovative tool that interacts with the ISPRA databases and the GIS information platforms, allowing not only to evaluate, monitor and quantify land consumption within municipalities, metropolitan cities and Italian regions, but compute and compare ecological indicators of great interest for environmental analysis. The web platform allows users to select any portion of territory, being able to provide as output not only the amount of land consumed over time, but also the impact on soil of a new urban settlement or ecological corridor.

Within the web-GIS can be applied and calculated two macro-categories of indicators:

- land change matrices and land cover - indicators based on Corine Land Cover map;
- land use indicators.

The latter group includes the most ecologically sound indicators such as “fragmentation” (urban and rural) index. Specifically, the layer of the Provincial Ecological Network (REP in Italian) of the Provincial Plan of Naples has been superimposed with the indicator of the rural fragmentation of the Soil-monitor showing that the REP, even if more detailed than the RER (Regional Ecological Network), does not intercept the difficulties due to the fragmentation of the area. Instead, fragmentation monitoring induced by land use allows the identification of possible connecting elements and the estimation of their fragility in order to identify planning actions.

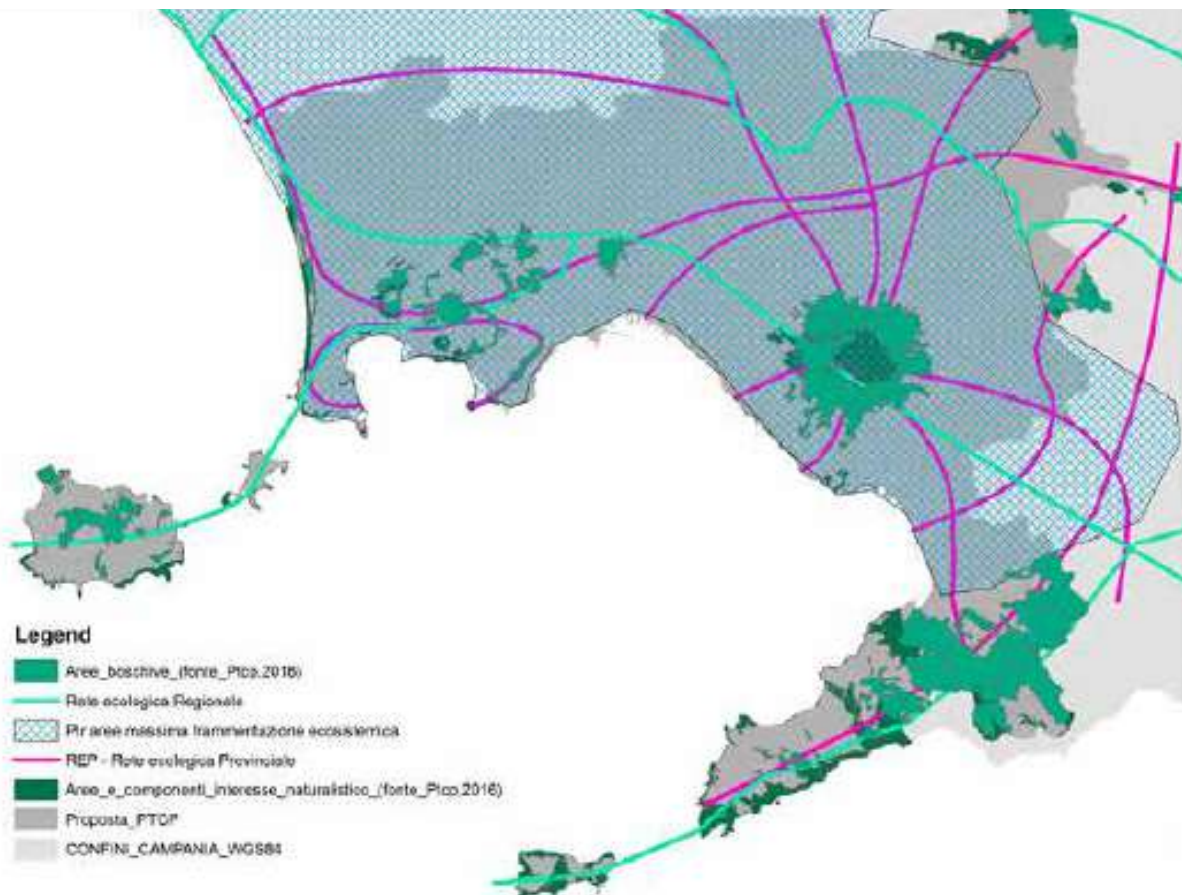

Figure 2. Ecological network. Source: Coppola, Grimaldi, Langella (2017).

The analysis of the environmental system is based on the analysis of the core areas or parks and protected areas and biodiversity starting from the reading of the Corine Land Cover map. The fragmentation map allows identifying different types of fragmentation, urban and rural. If in Soil-monitor the resolution was quite modest and suitable for the large scale (resolution of 200 metres), the resolution of LANDSUPPORT - that comes from the use of the Copernicus system - is greater (the cells are 20m x 20 m) and therefore are more useful at the urban scale.

Decision support systems applied to urban planning

As was underlined by Moccia, Sepe, Basile, and Terribile (2018) in modern society, one of the most binding problems for planners is certainly the mitigation of soil consumption and land sealing. The key role given to the mitigation of soil consumption by Moccia et al. (2018) lifts the interest of the tool on urban rather than territorial issues, since soil sealing - determined by the coverage of lands with impermeable materials, which partially or totally inhibits the ability of the soil to perform its vital functions - is a problem mainly concentrated in metropolitan areas.

Soil sealing, or the permanent covering of part of the ground and its natural soil with artificial materials (such as asphalt or concrete) for construction, for example, of buildings and roads, is the most obvious and widespread form of artificial cover. Generally, part of the settlement area is watertight, while gardens, urban parks and other green spaces must not be considered (European Commission, 2013). Other forms of artificial soil cover range from total loss of “soil resource” through removal by excavation (including open-cast mining), to partial loss, more or less remediable, of functionality, due to phenomena such as compaction, e.g. unpaved parking areas (ISPRA, 2018). Soil sealing is the main cause of soil degradation in Europe, since it involves an increased risk

of flooding, contributes to climate change, threatens biodiversity, causes the loss of fertile agricultural land, natural and semi-natural areas; together with urban sprawl contributes to the progressive and systematic destruction of landscapes, especially the rural ones (European Commission, 2012).

The data coming from the new cartography SNPA (Sistema Nazionale per la Protezione dell'Ambiente) show that, at the national level, artificial coverage of soil has increased from roughly 2.7% in the 1950s to 7.65% (7.75% net of the surface of the permanent water bodies) in 2017, with an increase of 4.95 percentage points and a percentage growth of more than 180% (and with a further 0.23% increase in 2017). In absolute terms, land consumption now affects 23.063 square kilometres of the Italian territory with a net growth of 5.211 hectares (52 square kilometres) in 2017 due to the difference between new consumption (5.409 hectares, 54 square kilometres) and restored soil. The most affected areas are the northern plains, the Tuscan axis between Florence and Pisa, Lazio, Campania and Salento, the main metropolitan areas, coastal areas, in particular the ones along the Adriatic Sea and within Liguria, Campania and Sicily (ISPRA, 2018).

Figure 3. Land consumption at regional level (% 2017). In red the national average.
Source: ISPRA, 2018.

The most striking effect of soil sealing is certainly related to water management. The complete sealing, in addition to reducing water infiltration, prevents evaporation and transpiration, decreasing soil moisture, which - among other effects - is no longer able to function as water reservoir, also decreasing the ability to recharge the aquifers. The inability of sealed areas to absorb most of the water greatly increases the surface flow and can facilitate the transport of contaminants to nearby areas (Coppola, 2016). The industrial decline of some cities has led to the abandonment of large, currently unused, sealed areas (brownfields), and on the other hand has encouraged the migration of the population to areas of new expansion, often taken away from agricultural areas or green areas (woods and forests).

Services	Indicators	Calculation tool
Carbon storage and sequestration (flow and stock)	Amount of carbon captured from natural and semi-natural forest ecosystems	Formulas taken from academic literature
Habitat quality	Presence of biodiversity according to land use classes “on the assumption that areas with a higher quality of habitats host a higher wealth of native species and that the decrease in the size of a specific habitat and its quality lead to the decline of the persistence of species”	InVEST software Habitat Quality model
Agricultural production (flow and stock)	Average agricultural value associated with land use classes	Data Agency of Revenue LIMIT: territorial extension ISTAT agricultural regions
Wood production (flow and stock)	Wood extension	CUAS
Pollination	Presence of pollinating species	InVEST software Pollination Crop model
Micro-climate regulation	Thermic increase associated with increasing energy costs	
Removal of particulate matter and ozone	Removal of two air pollutants, atmospheric particulates (PM10) and tropospheric ozone (O3), by forest ecosystems	GIS software
Protection from erosion	Potential erosion of soils	InVEST Software Sediment Delivery Ratio (SDR) software
Availability of water	Storage capacity and retention of water by soil and subsoil; degree of permeability and slope	InVEST Software Bigbang 1.0 model (developed by ISPRA)
Regulation of the hydrological regime	Reduction of the fraction of water flowing to the surface and its speed and availability of water in the soil and recharge of the aquifers	InVEST Software Bigbang 1.0 model (developed by ISPRA)
Water purification	Soil depurative ability	NDR model (work in progress)
Support to human activities	Scarcity of soil resource	Suitability

Table 1. Ecosystem services. Source: ISPRA, 2018.

It is worth remembering that, in the 1990s, there was a loss of 10 hectares of land per day in the EU solely for the construction of new motorways. In these areas the loss of soil functions is practically total, and also the adjacent areas, generally not sealed, are often severely damaged by contamination due to traffic and road maintenance products. Very often the expansion of inhabited centres corresponds to the construction of buildings in fertile areas of the territory, more subject to natural phenomena such as flooding. For example, the airport of Rome was built in an area characterized by soils of good fertility, or the numerous industrial settlements built with the funds of the “Cassa del Mezzogiorno” in the productive plains of southern Italy

(ISPRA, 2016). The comparison between urbanization and land use capacity classes (Land capability classification) showed that urban expansion has affected areas with high agricultural production potential. Such instruments should become an essential part of urban plans, industrial development plans, etc. with the aim of highlighting the risks of degradation, or ultimate loss, arising from inappropriate uses of the soil resource. Some indicators of ecosystem services have been suggested for the implementation of the new web-GIS LANDSUPPORT, namely the most accredited ones by the ISPRA Report and those of the Research Centre for Soil Consumption (CRCS).

Services	Indicators	Calculation tool
Micro-climate regulation	Difference in the level of cooling between “zero option” and various projects in relation to the presence of weak population groups	n. of inhabitants weighted with intensity of class change
Nature-based reconstruction	Potential reconstruction Recreation Opportunity Spectrum	GIS software ESTIMAP model (Zulian et al., 2018; Zulian et al., 2013)

Conclusions

Despite important European policy documents (COM 571, 2011; SWD, 2012) aiming at zero net land consumption by 2050, it seems necessary to introduce the principle that actors causing soil sealing should be obliged to re-establish the original state of the soil before the intervention or, alternatively, to compensate the community for the loss of the resource. Certainly, as many observers argue, to be effective, the fight against soil consumption must be carried out through the tools of urban planning and landscape planning, and this happens very rarely (Artmann, 2014).

Careful and skilful planning, and choose building techniques with limited negative effects, could minimize soil sealing. Spatial planning can involve large areas through the protection of natural zones and agricultural soils, but also by strengthening these areas and creating a green network of connection, in order to increase the resilience level of territories. Spatial planning can affect municipal planning with technical measures related to implementation planning through densification, i.e., building taller buildings, thus entailing limited land use. This must necessarily be combined with the challenge to climate change, where planning must take on a central role, able to guide transformation, especially in urban areas.

A knowledge-driven approach to urban transformations: densification strategy of the central parts of Bergen, Norway

Hans Jacob Roald¹, Remco Elric de Koning²

¹*Western Norway University of Applied Sciences, Municipality of Bergen, HJR@hvl.no*

²*Western Norway University of Applied Sciences, REK@hvl.no*

Abstract: The municipality of Bergen has launched a radical strategy for densification. A total of 50 percent of the need for new housing should be covered within Bergen's central parts. Bergen is the second largest city in Norway and it is known for its intimate relations between a beautiful west coast landscape and, from a Norwegian perspective, a dense urban structure. Much is at stake when introducing a radical program for densification. A report has been prepared that records the area's character and identifies and analyses potential transformation areas. With assistance from Western Norway University of Applied Sciences and consulting firm Asplan Viak, GIS is used as a tool for obtaining operational information and analysis models. The work has been financed by the Ministry of Local Government and Modernisation. Information is provided about what characterises and distinguishes Bergen's central parts. A new analytic GIS-based tool is developed for measuring the spatial attributes that constitute an area's attractiveness. This tool combines the Space-Syntax and Spacescape methods. Eleven major transformation areas are identified and issues such as ownership, possible obstacles to implementation and overall potential for development are analysed. A step-by-step implementation is proposed and recommendations are made which address critical obstacles.

Keywords: densification, transformation, Space Syntax, Spacescape

Introduction

In 1990, the dominating planning paradigm focused on transforming the inner-city public spaces from car-dominated areas to pedestrian-oriented areas. As a starting point, the question was raised: What are the basic characteristics of the cityscape? To answer this, a study was implemented showing the overall and local relationships between the natural landscape, the built-up environment and the public spaces. The method used was handmade black-and-white sketches carried out by skilled architects (Hansteen, 1991). The gained knowledge was important for establishing a successful long-term process of transforming dilapidated public areas into attractive, lively urban places. The municipality of Bergen has received several national and international prizes for this turn-around operation.

Today, almost 30 years later, the challenges are different. In the light of sustainable urban development, the task is to find out where and how to implement profitable and environmentally friendly densification. Since the 1990s, a revolution has taken place within information technology. Instead of handmade sketches in black and white, we have a number of electronic tools at our disposal for analysing complex environmental situations.

Figure 1 The character of Bergen drawn in 1991. Plan- og bygningsetaten, municipality of Bergen

In Bergen, a number of overall resolutions have been approved in order to enhance the urban environment. The major goals of the earliest resolutions are to reduce greenhouse gas emissions and to stop the growth of private car transportation. The time of urban sprawl is history. The city structure of the future is the compact city, where the inhabitants have short walking distances to their daily activities and public transport hubs. As a result, the city council has ordered an overall and long-term strategy for densification within the central parts of the municipality.

The central parts of Bergen are expected to facilitate half of the new housing stock, which is approximately 10,000 new dwellings until 2030, and another 5,000 later on. This is supposed to take place within that is already the most compact part of Bergen, an area that is already largely filled with different kinds of building structures. It contains protected heritage objects of local, national and international importance. The city's dense structure, resulting from its situation between steep mountains facing the fjords, forms the basis for a special urban atmosphere, which many regard to be Norway's most beautiful city. By introducing a radical vision for densification, much is at stake.

This leads to the necessity of a thorough investigation on urban standards and qualities. Considering these severe challenges, the question was raised: can environmental values be measured, and can geographic information systems as part of a positivistic tradition serve as a reliable tool for analyses and feasibility studies, or are we still better off with hand-drawn maps as part of a hermeneutic tradition?

The Norwegian Ministry of Local Government and Modernisation financed this work. The Ministry has demonstrated particular interest in whether and how the GIS-based Space Syntax and Spacescape methods could be integrated into one common methodology for identifying densification potentials in the study area. A special feature of Space Syntax and Spacescape methods is that they enable correlations between spatial configuration and socio-economic parameters related to city planning. This forms the background for the feasibility study: Densification strategy of the central parts of Bergen.

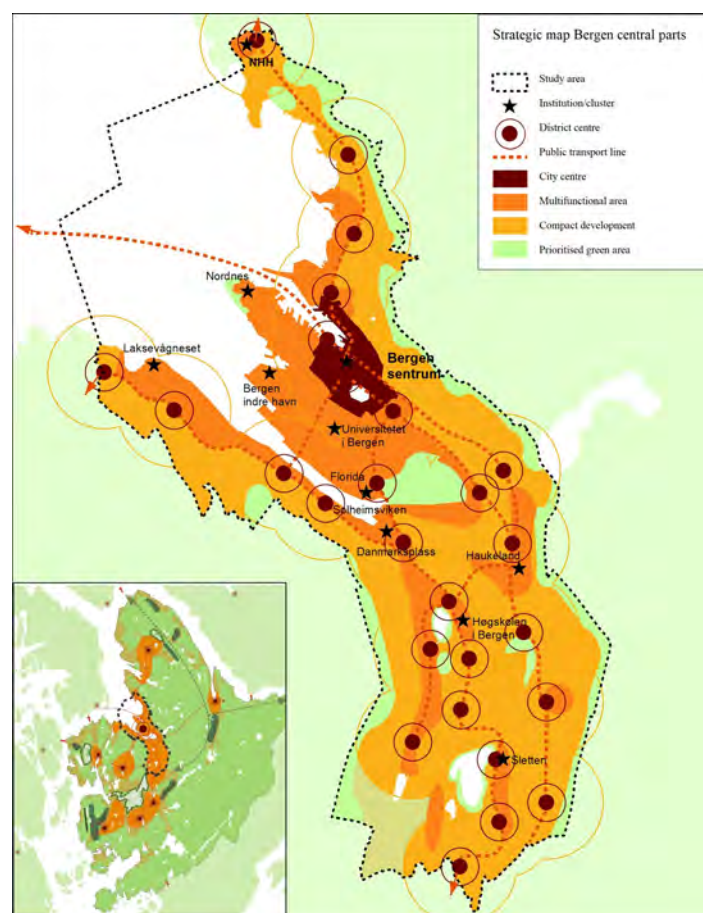

Figure 2 Strategic map for Bergen's central parts containing the city centre core, smaller subcentres, a high-priority network for public transportation, multifunctional areas and other areas prioritising compact urban development. Plan- og bygningsetaten, municipality of Bergen

The authors' contributions

Hans-Jacob Roald has been the project leader within the municipality of Bergen, during the project's constitution and implementation. He worked spare time at the Western University of Applied Sciences and is now full-time associate professor (Dosent) at the university. He was also project leader analysing the cityscape of Bergen in the 1990s. Remco de Koning has contributed to the project with Space Syntax analyses of the area as part of his doctoral research work. Acknowledgement goes to Asplan Viak AS with Trygve Andresen, who has been the project's main external consultant.

Methods

This section sets out the used methods, which are organised in two stages:

- Preliminary studies
- Applicable GIS analyses.

The preliminary studies consists of five parts:

- Clarification / appraisal of the investigation
- Creating a basemap
- Mapping building typologies
- A provisional Spacescape analysis
- A Space Syntax analysis

The applicable GIS analyses are delivering the feasibility results and are organised into four levels:

- Statistics and registrations of population trends
- Mapping individual characteristics
- Designing analyses in the form of overlapping maps
- Advanced numerical analyses of different characteristics

Preliminary studies

Densification was categorised into three different strategic approaches, following Sandkjær Hansen (2015):

- Expansion: expanding the development of the city beyond the municipal plan boundaries, i.e. towards the waterfront and the green areas in and around the city;
- Transformation: changing the structure and function within the built areas;
- Intensification: achieving higher utilisation within existing structures.

Our area of investigation is located in a valley of about 7 kilometres in length and 2 kilometres across, between steep mountainsides and the fjord. All major and important communication lines are located at the lower parts of the valley. It proved difficult to establish satisfactory access between the overall public transport network and suitable areas for city expansion on the mountainsides. Regarding expansion towards the waterfront, the most relevant areas were already in planning processes categorised as expansion. Possibilities for intensification are addressed in a later stage. The task for this study was therefore to focus on identifying and analysing possible larger transformation areas.

Creating a basemap

A basemap was created from 160 basic statistic units (called *grunnkrets*, see Figure 3). Each of these units can refer to and convey data from the National Statistics Agency and to planning and property information with the municipality of Bergen as source. By designing maps based on these units, it became possible to overlap and convert information and thus gain new knowledge. One challenge was

to assess what kind of information is relevant for co-relating with a view to gain relevant new knowledge. The second challenge related to the amount of information that can be shown in one map. A map that contains too much information can lose its meaning.

A variety of building customs

The project integrated and refined a map produced as part of a master thesis at the Norwegian University of Science and Technology (NTNU) (Lindau, 2015). The map shows that our area contains a conglomerate of building traditions. This diversity is a value in itself. The map forms a good basis for discussions addressing all new building projects, how they will interact with the established surroundings.

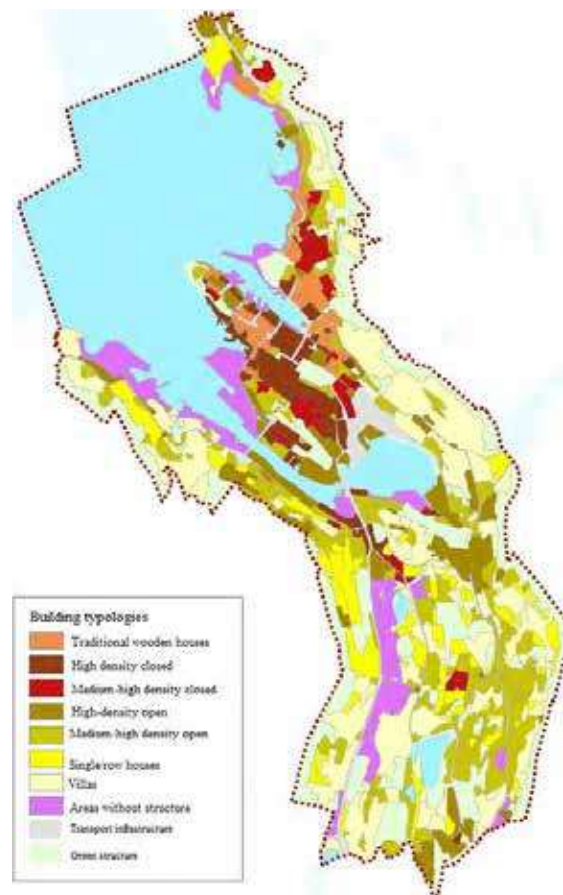

Figure 3 Base map showing building typologies

Spacescape

The consulting firm Asplan Viak conducted a feasibility study of the area based on the Spacescape methodology. Spacescape was developed by the Royal Institute of Technology (KTH) in collaboration with the Stockholm-based company Spacescape (2013). Spacescape operates with what is called the densification matrix (see Figure 4). The densification matrix is a model for carrying out comprehensive and holistic analyses based on a number of issues within the main themes *Driving forces* and *Obstacles*. In our case, a study done according to the densification circle, appeared not to be operational in the context of Bergen. This does not suggest that the model is wrong in itself. The

Swedish examples using the densification circle have been used on far larger areas than ours in a different geographical context.

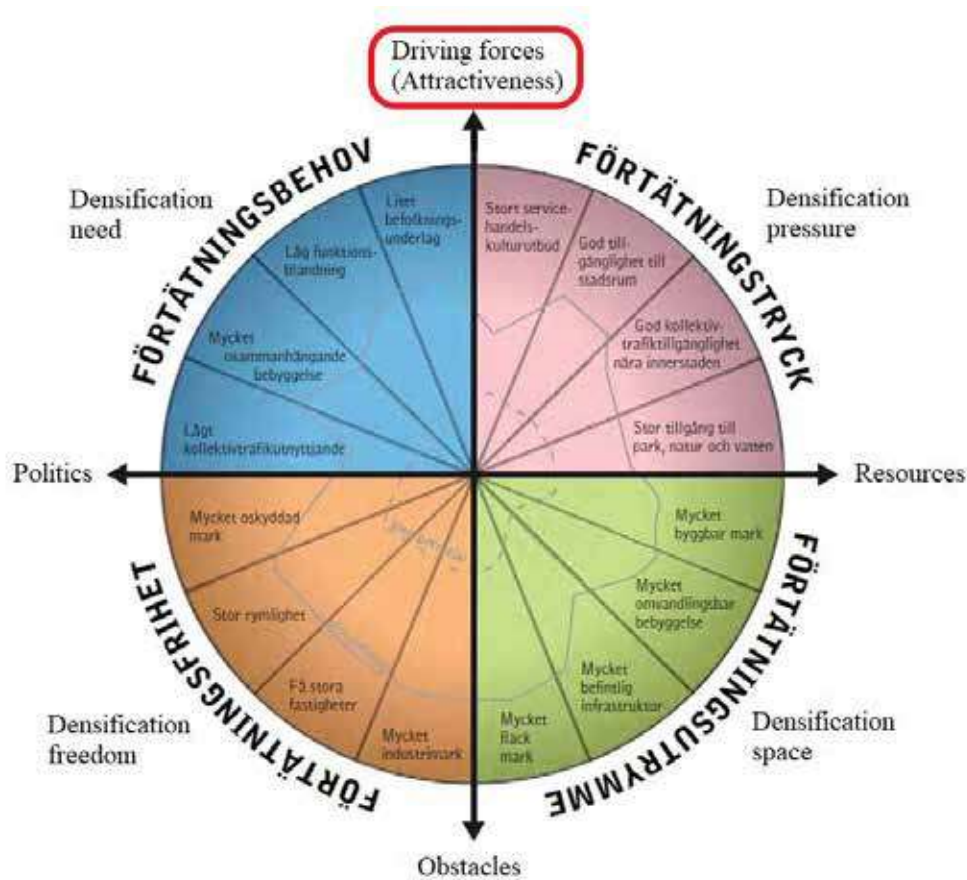

Figure 4 Densification matrix by Spacescape (2013)

Another experience is principal. Is it possible, or even desirable, to implement holistic comprehensive analyses for a city? Our statement was that no, one can never commit a city to any kind of formula once and for all. As a result, we chose to pick elements from one half of the circle, which are the themes identified as *Driving forces*. We decided the name *Attractiveness* to be more appropriate.

Space Syntax

A Space Syntax analysis was carried out. The Space Syntax method was developed by Bill Hillier and his colleagues at London's Global University. The methodology analyses the spatial conditions of the streets and road network at different scale levels, based on the total number of directional changes for each street segment relative to all other streets. It is a form of accessibility analysis. The methodology has been tested in different parts of the world. Streets with high spatial integration values tend to have the highest amount of people using them as a destination or as part of a shortest route to their destination. This is also known as the theory of natural movement (Hillier, 1998). It is also an indicator for the attractiveness for economic activities, and a mutually reinforcing process called the natural movement economic process (Hillier *et al.*, 1993). Moreover, highly integrated areas often have a high degree of functional mix and building density. The latter finding has been subject to theory building in recent years, and given the title the theory of the natural urban transformation process (Ye and van Nes, 2014).

Figure 5 Space Syntax analysis of the study area – Global Integration ($R=n$)

Results

First, population trends, age distribution and relocation were examined. First, the period 1980 – 2000 was addressed. The registrations show a decline in the population of 7 000 residents across the area. The geographical dispersal of the decline was surprising. It was during this period that the Government and the municipality invested large resources in order to upgrading renewal of the city centre with award-winning projects, as a result. This did not result in immediate population growth. When considering the period 2000 - 2017, the picture is completely different with a rise of 15 000 residents (Bergen Kommune Plan- og bygningsetaten, 2018). Here too, the trend took place well distributed throughout the area. An explanation might be that the rise of housing standards that took place in the centre core in the 1980s and 1990s resulted in an increasing positive image of urban living in general. In addition, a broad range of radical environmental measures were carried out from the year 2000 onwards. A number of institutions for higher education were either reinforced or established. All these efforts might have laid a broad foundation for a rise of residents throughout the area.

Who are these new inhabitants? An answer might be found in Figure 6 showing the population profile of 2017, comparing the population profile within the study area with the entire municipality of Bergen. The differences are significant. For the study area, the share of the population between the ages of 1 and 20 is far lower than the average, while the share of the population between 20 and 40 years is far higher. Where do they come from?

Figure 6 Population profile due to aging for the study area (blue) and Bergen municipality (red)

A survey of migration to the municipality again presents a clear picture. The municipality of Bergen consists of eight districts. Two of these districts are situated within the study area. The vast majority of people moving to the municipality prefer to live in these two districts. For the other six, the changes are marginal.

Figure 7 Changes in immigration for districts within Bergen municipality 2000-2015

Mapping single characteristics

A number of thematic registrations have been conducted. Knowledge related to issues such as density of working places, housing, service provision and more, has been produced and presented on maps. Information related to current planning strategies, production of plans, communications has been produced and presented.

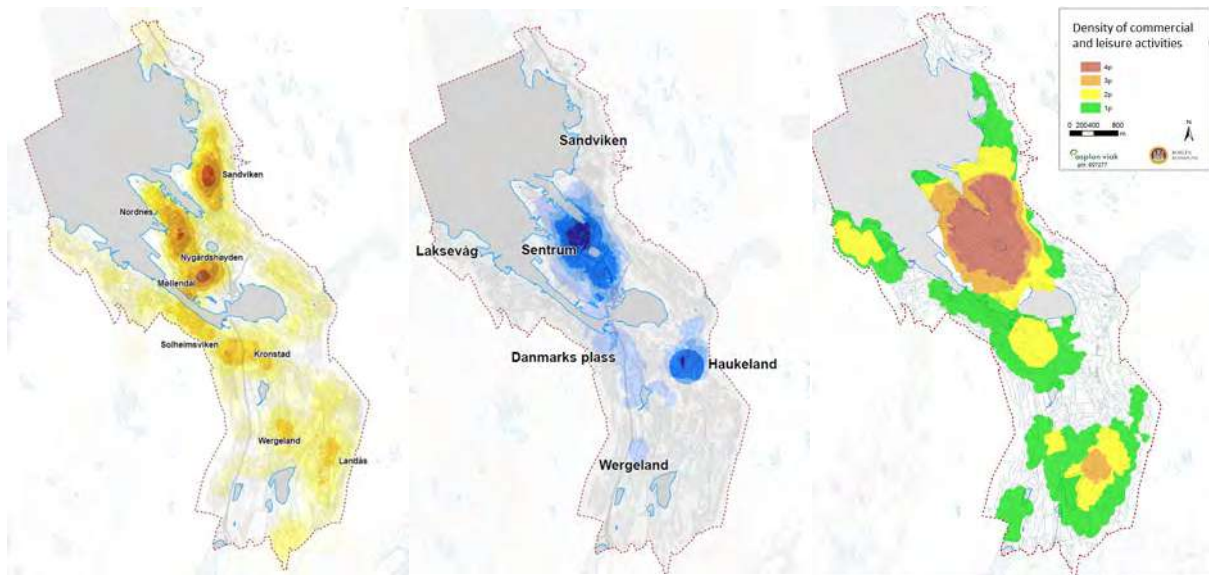

Figure 8a housing density (left), 8b workplace density (middle), 8c density of amenities (right)

Designing analyses

The easiest way to conduct map-based analyses is to add two or more maps to each other. An example is an analysis in order to define the compact city. Four topical maps were added to each other. The first three dealt with functionality and density. Figure 8a shows housing density, Figure 8b density of working activities, and Figure 8c urban activities such as trade, public and private service, culture and education.

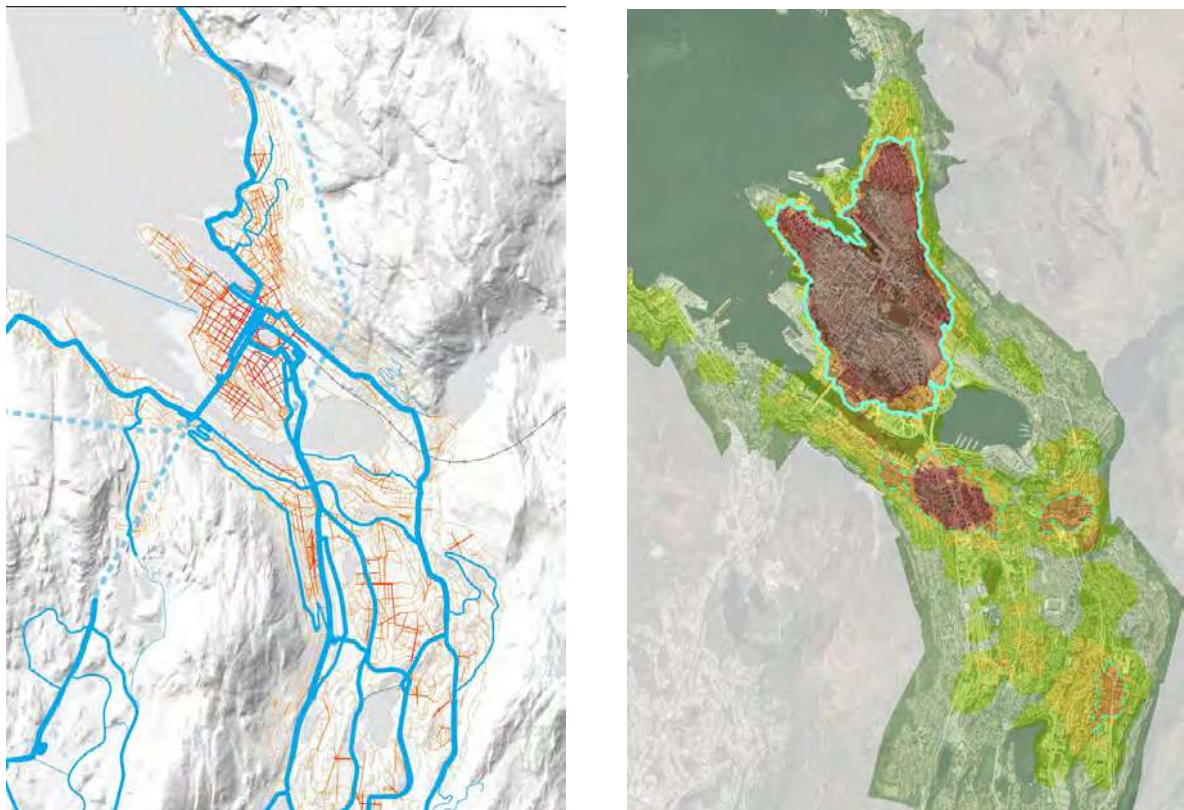

Figure 9a (left): high-frequency public transport (blue) and local integration ($R=3$);
Figure 9b (right): proximity to multifunctional areas

Figure 9a shows the degree of accessibility to high-frequency public transport combined with the Space Syntax analysis. Our hypothesis is that the combination of density of functions and good accessibility produces a picture of the compact city (Figure 9b), in this case the compact city of Bergen, and the picture is quite clear. The city centre is undisputed the most compact part within our area.

Analysing attractiveness using numerical analyses

To analyse the attractiveness of Bergen, eight variables were analysed. The choice of these variables was a result of discretionary assessment. The Spacescape method operates with seven variables. The difference is that contrary to Bergen, sun conditions were deemed irrelevant in Stockholm. Furthermore, a regular street structure was considered important for Stockholm, whilst Bergen has a more pluralistic urban structure. In addition, the population's socio-economic status and living conditions were considered relevant for Bergen, and not for Stockholm.

The following topics were mapped and weighted.

- | | | |
|----|---|--------------------------------------|
| 1. | Proximity to the city centre core | Very important 0-4 points (17%) |
| 2. | Proximity to urban businesses | Very important 0-4 points (17%) |
| 3. | Proximity to public transportation hub | Important 0-3 points (13%) |
| 4. | Exposure to sunlight | Important 0-3 points (13%) |
| 5. | Socio-economic living conditions | Important 0-3 points (13%) |
| 6. | Proximity to a waterfront | Important 0-2 points (13%) |
| 7. | Access to a park | Moderately important 0-2 points (9%) |
| 8. | Proximity to an integrated street structure | Moderately important 0-2 points (9%) |

The summary map of Figure 10 shows great variations. The main message is that the centre and its immediate surroundings have high and above average attractiveness. The other areas in orange and yellow have medium attractiveness, with the exception of the areas that lie to the west, which are below average attractiveness. There is a clear similarity between the most attractive areas and the map showing the compactness of Bergen; the more compact, the more attractive city. Furthermore, the city has a clear, more attractive “east end” and a less attractive “west end”. Especially in winter, the east side has far better sun exposure than the neighbourhoods on the shaded slopes to the west, something which is reflected in the areas’ socio-economic performance.

Figure 10 Summary map attractiveness

Findings

Eleven major transformation/development areas were identified. These were analysed according to attractiveness, ongoing planning activities, ownership, potential obstructions related to implementation and capacity. The total capacity for the eleven development areas was summed up. The potential is considerable with room for realising approximately 10.000 new dwellings and 1.000.000 m² public programme. Based on a discretionary assessment, a division was made into 50% dwellings and 50% urban functions. This could increase the total housing stock with as much as 25%. This will in turn trigger a need for several new schools, kindergartens and nursing homes.

When it comes to implementation, all densification projects are difficult to implement. Moreover, some areas are faced with critical factors such as unclear ownerships or underlying diffuse agreements. Such areas are considered immature regarding starting a planning process, or even programming. Most of the critical factors are related to factors outside the power and authority of the municipality.

Two interesting overlapping maps were designed. The first combines the eleven development areas with land ownership (Figure 11a). For some development areas, the public sector is the dominating owner. As for others, the private sector is the dominating owner. When it comes to planning and implementation, the strategy dealing with privately owned land is quite demanding regarding fulfilling public goals, in this case cross-sectoral goals specified by the municipality. A challenge the municipality has to face is that the central government has organised its activities into a large number of companies acting as if they are private and with economic income as a prime objective.

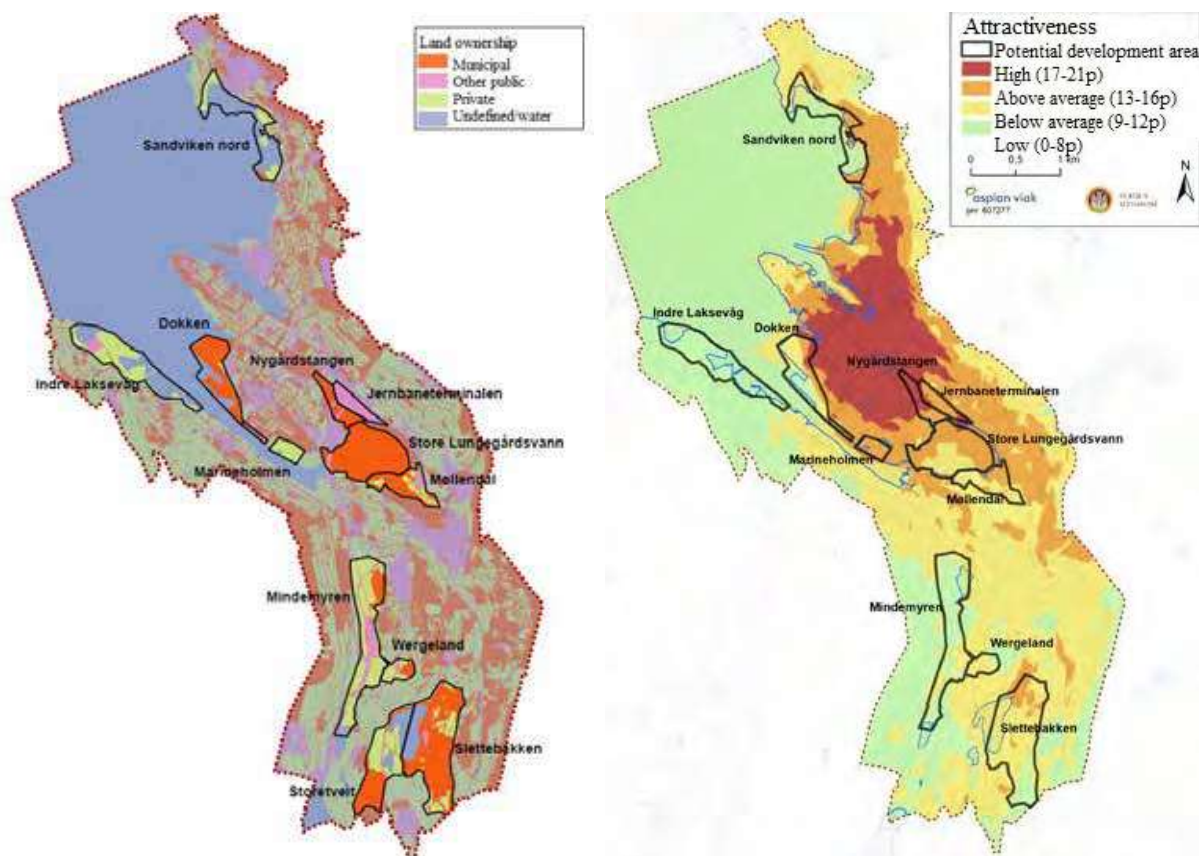

Figure 11 development areas overlapped on a: land ownership (left) and b: summary map attractiveness (right)

In the second map (Figure 11b), the eleven development areas are added to the summarising map of the factors that were determined to contribute to attractiveness. This map demonstrates a great variety of degrees of attractiveness within the different development areas.

Conclusions

The densification strategy study has been interrelated as part of the study program at the Western Norway University of Applied Sciences, both the application of urban analysis in itself and the development of GIS based methods. The relevance of the content of the urban analyses is underlined by the facts that they are a result of a request from the City council and The Norwegian Ministry of Local Governmental and Modernisation. The methods that were used serve as examples on how to use and compose GIS analyses for a given area. Advanced numerical analyses are used to teach and encourage students to design complex analyses that address divergent challenges and use and investigate different sorts of parameters.

The study presented in this paper has delivered on the requests from the central governments. A methodology for investigating potential densification areas in the city of Bergen was put forward, and a new method for analysing attractiveness was produced in which Space Syntax and Spacescape are integrated. The launched densification strategy offers an opportunity for politicians and citizens within the municipality to discuss expectations, preferences and priorities, and subsequently building programmes for each of the development areas seen in a long-term and holistic perspective.

Considering the compact city, attention should be paid to areas outside the compact centre: specifically the three semi-compact areas, the public transportation hubs, and the low-density neighbourhoods in general.

The first recommendation that is made is for the local government to concentrate its attention and efforts on the eleven major development areas that were identified. This is where the potential for development and, in the long term, the benefits will be greatest. This applies to the use of administrative competence and capacity as well as the effect of planning efforts. Second, a systematic implementation is recommended. A timetable for implementation was drafted. The areas that were confronted with critical factors concerning implementation were placed at the end of the time table. The time horizon for implementation is recommended to be extended from 2030 to 2050. Setting a hard target of densifying the compact urban valley by building 10.000 new dwellings, and thus increasing the number of residences in the Bergen valley with 25 per cent within 12 years, could have a negative impact on the standards of quality that are desired. Already, examples of densification projects that do not hold desirable qualitative standards have been seen. Furthermore, a long-term strategy ought to be rooted in coordinated, long-term public budgets. In Norway, many planning activities are initiated by the private sector, leading to a number of examples where the need for social infrastructure has been overlooked. It is evident that if the initial densification projects do not pursue quality and create enthusiasm, the whole linkage between sustainability and densification can fall.

The map showing great varieties of attractiveness within the eleven development areas (Figure 11b) sends an important message to the involved stakeholders, both investors and planning authorities. By deconstructing the attractiveness map, we can uncover which factors score high or low and thereby which factors should be refined or strengthened in order to raise the attractiveness of the area. While topological aspects such as sun exposure and view are difficult to alter, others, such as accessibility, diversity, and access to amenities, public transport and green areas can be improved. For areas with lower attractiveness, these factors deserve extra attention, creative ideas and higher economic efforts.

This raises a major challenge. One basic prerequisite for urban transformation in the Norwegian planning context is that as a rule, developers, mostly private partners, are obliged to cover the expenses on necessary new infrastructure. This is enshrined in a so-called predictability decision, a decision that gives the municipality a mandate to demand financial contributions from the developers through a formalised economic development deal. Here, one is confronted with a dilemma. For the most attractive areas, it can be expected that the developer is willing to accept relatively large investments in new infrastructure. Attractive areas will be even more attractive. For the areas with low attractiveness, the situation is different. It can be expected that the opportunities for profit are lower and, as a result, the opportunities for greater joint contributions to lift the quality of the public domain could be lower. This can result in a negative spiral where the areas that require the most efforts and resources, will receive the least. This finding can contribute to the debate on relations between transformation, the predictability of decisions and living conditions.

Previously, the central government had a policy and a rather high budget for improving living conditions. Grants for public investment in socio-economic vulnerable areas were considerable. Now, the central governments have almost abdicated their earlier obligations and left the responsibility for planning and financing almost entirely to the municipalities and the local private investors. This article invites to a debate about on the state's almost inadequate housing policy.

Abstract: Information Technologies are changing paradigms bringing new challenges to Public Administration and its structures need to be renewed in all aspects, not only in technological and material resources, but also in the cultural models and processes in public government. Ethics in the manipulation and processing public data is necessary in the federal, regional and municipal levels. However, it is within the local power sphere where the information and construction of registries occurs in a more sensitive way, due to the direct contact with citizen and society in general. Also, the Local Power is the federative body responsible for the main urban problems of Brazilian cities, accountable specially for Urban Public Policy. Within this perspective, the article presents as object of analysis the recent experience of the city of São Paulo through the city GIS called “GeoSampa”. This platform is part of the Municipal Information System (article 352 of the 2014 Master Plan) and it is a structural element of the Local Urban Public Policy. The GeoSampa initiative has shown to be innovative and resulted in a positive impact for the city and for the local government. But despite the achievements, it is necessary to evaluate the challenges that GeoSampa brings to the surface.

Keywords: GeoSampa, Planning Support Systems, (Big) Spatial Data Sources, Public Database, Public Administration.

Introduction

The objective of this article is to analyze the experience of the GeoSampa, an urban webmap platform of São Paulo city, also part of the Municipal Information System (article 352 of the PDE 2014) and a structural element of the Urban Public Policy of the Municipality of São Paulo. The objective is to understand the role of GeoSampa in its two fronts of action: as an instrument of transparency policy and free access to public data and as a binding tool for decision making, in *lato sensu*, in territorial policies. We will seek to understand the role of GeoSampa within the institutional structure of the city of São Paulo as public policy, the scope of the instrument and its challenges.

Information Technologies have brought new paradigms and challenges to Public Administration in all aspects, not only in technological and material resources, but also in the cultural models and processes in public government. It is common to encounter lack of integration and inability to share information between departments in Local Public Administrations. In case of the city of São Paulo, the systems of several municipal bodies have been developed over the years in an individualized way and according to the institutional demand. For example, some of the data base often populated without any

institution of a standard and without normative binding that determines its legitimacy. This scenario resulted in a non-standard or redundant information, not reliable for corporate use.

On the other hand, structured and strategic data bases are often susceptible to restriction culture, as they are considered classified data. In general, government departments which have some structure to maintain a organized data base, often do not allow the usage of the data outside of their department. In the city of São Paulo these situations were very common, once public servants do not have free data access culture and practices. Also, they were afraid to be held accountable in case of wrong or mistaken information. Although such information should not be opened to public use in general, specific groups of power end up having access to that information in order to guide their own interests.

Overcoming this scenario, the city of São Paulo built a strong integration of cadastral data of its different departments and implemented a transparency policy through the construction of the city GIS, called "GeoSampa". This platform was launched in december of 2015 and is known to be the main portal of detailed and georeferenced information about the city of São Paulo. The publication of the data is organized by thematic layers that can be linked to the departments and bodies responsible for that specific data.

The intensive usage of this webmap enlarged the access to urban and territorial information, preserving the confidentiality of sensitive attributes to citizen protection. We will try to understand the role of Geosampa within the institutional structure of the city of São Paulo as an essential element of Public Policy, the scope of the instrument and its challenges.

Urban Information and data in São Paulo

GeoSampa is managed by the Production and Information Analysis Coordination (GEOINFO), a department under the responsibility of the Municipal Department of Urban Development. In general terms, GEOINFO is a traditional department within the structure of the city of São Paulo, which originates in the former General Coordination of Planning (COGEP) instituted in the early 1970s and was directly linked to the mayor's office. With the development and improvement of governance and public management, the COGEP was dissolved during the 1980s and was divided into three departments that are responsible for urban planning in the city: the Department of Urbanism (DEURB), that monitors in macro-level the application of the city urban direction determined in the Master Plan; the Land Use Department (DEUSO), which has as its primary responsibility the control of land use and occupation; and the Information Department (DEINFO), currently GEOINFO, which was responsible for consolidating the statistical and spatial information and analysis to support the development and improvement of the urban policy of the city of São Paulo.

The COGEP detachment to the mayor's office demonstrates institutional relaxation in terms of territorial policies: if COGEP was previously directly linked to the highest decision-making and directing body of the city, from the 1980s it became only a secretary. It demonstrates that urban and territorial policy no longer forms part of a strategic vision of government and becomes just a government agenda. DEINFO then becomes part of an Urban Planning Secretariat (now Urban Development Secretariat) and no longer a strategic support body to the city highest power. We will

see later that this current institutional structure can be a barrier to the evolution of GeoSampa as an effective tool for decision making in urban and territorial policies.

The 1990s were marked mainly by the resumption of the construction of a democratic process in Brazil as a whole, as well as strengthening the municipal power over federal and state power allowed by the Federal Constitution of 1988. In this sense, if before the main political guidelines and strategic decision-making processes were still centralized at the federal level, since 1988, the institutional responsibility, especially in what concerns urban issues, is linked to the Municipalities. This strengthens the demand for the Municipality to have total control of its territory and increases the pressure over the municipality to respond urban problems more quickly. In addition to several other factors, the city of São Paulo, through Decree nº 33.532/93, creates the Geographic Information System for the Municipality of São Paulo (GIS-SP), with the purpose of start the work of building a unique information system integrating the various systems and databases dispersed throughout the institutional structure of the city.

Despite the creation of a GIS by legal determination of a decree, the activities of integration and systematization proved to be a very arduous task, since the work culture of the different department were unlike and conflicting. In addition, there was no general understanding of the importance of standardized, effective and organized data collection. Also, the integration of system sometimes was not really a welcoming policy inside technical departments, once it would demand even minor modification in the workflow. Thus, the initiatives for the implantation of the GIS-SP, although important, were very timid and without great advances during the decade of 1990.

In the early 2000s, one of the main products of this period was presented to the city hall technical departments: the implementation of an internal digital map to the city's network called "Geo.SP" (Figure 1), in which the official fiscal information and hand-written documents of public lands could be verified. Also, the historic orthophotos were available in the platform. This tool was for internal use to assist the analysis and answers of the technical level documents within the administrative processes.

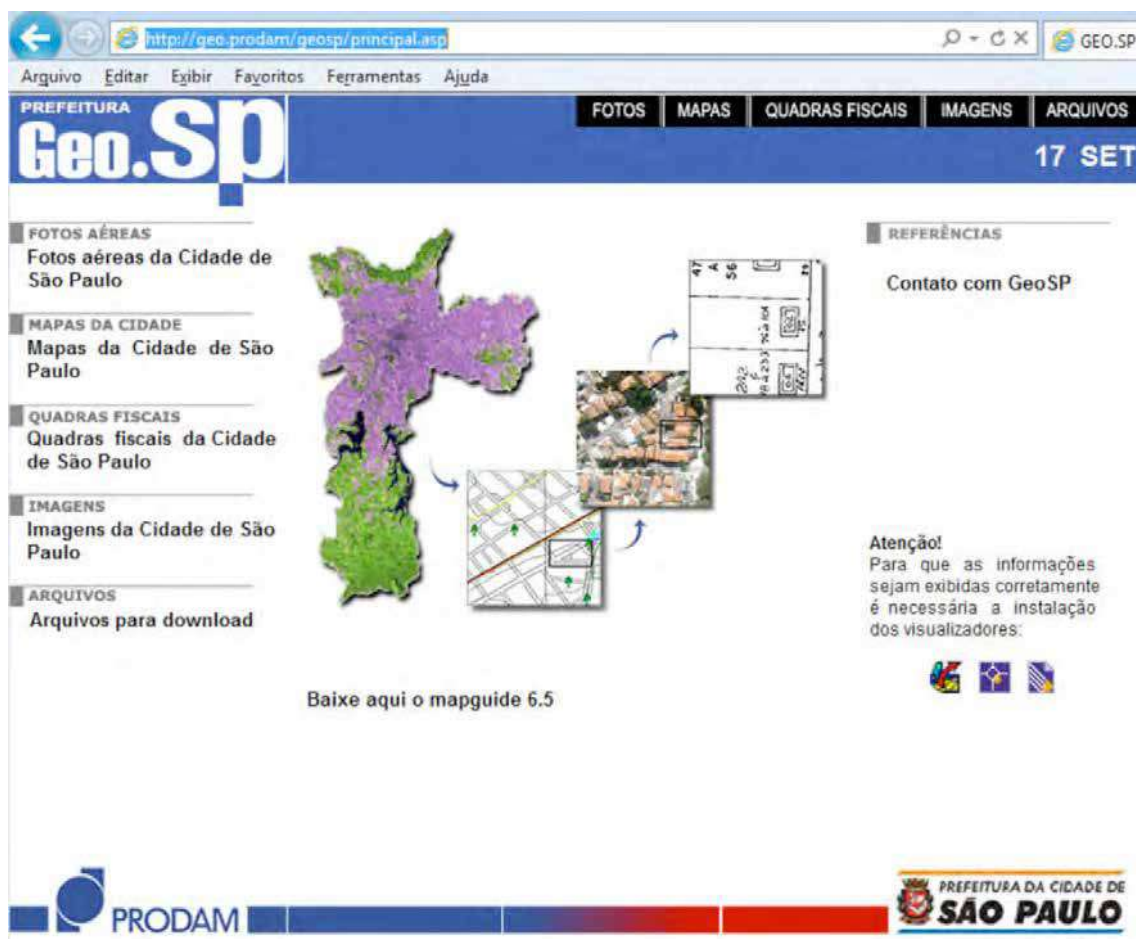

Figure 1: Geo.SP platform – digital map os São Paulo in the early 2000's.

Source:https://mundogeoconnect.com/2014/arquivos/palestras/8_mai_b-andrea-croso-weick.pdf

In 2007, the Digital City Map (MDC)(Figure 2) was also developed and made available internally. Based on the flight survey carried out through 2004 to 2005, this map is an evolution to Geo.SP since it brings the possibility of layering the different urban information, making it one of the main working tools for the technical analysis of doubts related to the space and territory of the city (WEICK, 2014). The blocks and lots (parcels) of cities were returned on the administrative base map, taking an important step towards the future composition of GeoSampa. Until then the city had never had the vectorization of the layer of parcels, main key as a space unit for the integration with other registers and applications of public policies.

Figure 2: Digital City Map (MDC) launched in 2007.

Source: <http://www.cobreap.com.br/2013/trabalhos-aprovados/2904.pdf>

The two experiences reported above demonstrate the care that these data were treated by being made available only internally to the city hall for exclusive resource for consultation and analysis for lower levels of decision-making, which we will call in this article of 'technical decision-making'. It should be noted that the data were available for consultation only, and raw data were not available for free handling. Moreover, although they were not characterized as classified information, their disclosure was refused by the information agencies.

GeoSampa and Urban Data

Starting in 2013, the GIS-SP working group is strengthened and building a truly corporate tool becomes a government goal. Thereby, with the necessary political support to acquire financial,

material and human resources, GeoSampa (Figure 3) is developed not only for internal consultations, but for the citizen in general reversing the logic adopted until then in which the data and the information of the city were being preserved under the discourse of a supposed secrecy.

Figure 3: GeoSampa *internet* platform.

Source: geosampa.prefeitura.sp.gov.br

It is important to emphasize that public data are extremely important for the configuration of a democratic city. However, it is necessary to evaluate the border between free access to information and citizen data protection. This is a subject that we do not intend to discuss in this article, but its understanding and delimitation is important to avoid the mining and transformation of the public data into a merchandise.

Together with the portal construction activities, GEOINFO were carried out to integrate the various technical teams that work with data and information in an attempt to verify an effective information policy. This group worked on several work fronts, such as verifying the existence of a repeatable database with the same content, unifying those datas and finally validating the information with the competent information body. Another important work was the construction of an understanding of what is a corporate information and the awareness that the transparency and provision of data for public access is also a duty of the server. Despite the efforts, cultural barriers and accountability of the human error of the public servant that eventually public registries may have, still inhibits the realization of a totally open system. As improvements, we have the internal awareness that information can be covered with secrecy at the same time that part of it can be made available to the public, which allowed the availability of GeoSampa.

Internally to the municipality, there was a migration in 2013 of the use of the MDC for GeoSampa in a natural and spontaneous way, since GeoSampa has more visual and easy communication resources that interact better with the final user. To this module, the technicians of the city call *GeoSampa intranet*. This versions contains a lot more layers than the free opened GeoSampa, since more and more departments started to engage on sharing their information in the platform, with the condition of

being released internally only. It is certain that this great hub of information help public servant to better analyze problems and make minor decisions on their daily work. Therefore, among other uses, GeoSampa intranet became an enhanced tool to help with the 'technical decision-making' process.

After the tests and improvements, in 2015 GeoSampa is made available to the public with free access. We will refer to this module as *GeoSampa internet*. We must remember that for the citizen this is the first urban data platform that has been made available, which is why it is so important as a landmark in the policy of access to information. Another important aspect of GeoSampa internet is that the information is available in many different ways, not only for consultation, but also through open source data allowing the final user to manipulate and use them freely. Certainly, it is an important experience if we compare with other cities in national scale. GeoSampa internet had helped not only citizens to access informations of a complex zoning law for instance, but also, and specially, the real estate agents and several research centers. It means that to handle all GeoSampa internet potential, the final user has to have a previous knowledge of map language, for example. It is true that in certain level, a map already is a technical basis language, but as a challenge to complete better transparency policy, GeoSampa internet needs to improve better communication aspect to reach more out democratically.

As we can verify, GeoSampa allowed databases and informations previously dispersed within the different departments to be organized, treated and made available to free access. Moreover, it allowed the policy of transparency of information reach another level of performance and responsibility acknowledgement by the city hall. However, it is important to verify the potentialities and the challenge that the current scenario proposes for the instrument.

GeoSampa as instrument of Urban Policy

GeoSampa as verified embodied the responsibility of being an essential element in the data transparency policy. If before, Geo.SP and MDC, created mainly to support the interests of tax by Treasury Secretary, were used only for minor decision-making, GeoSampa, besides allowing an improvement in the decision-making instruments by the technical team, made the information access policy of the city of São Paulo reached another level. However, we must discuss the real potential of an integrated system such as GeoSampa in the construction of a territorial public policy, its role and the possible impacts.

Article 352 of the Master Plan establishes the Municipal Information System, which was later regulated by Decree nº 57.770/17. By reading both legal texts it is understood that GeoSampa is not only a GIS, but also a urban planning system to help higher decision-making levels to design better plans and policies. In this sense, it seems that GeoSampa as currently dictated does not yet play a binding role for decision making at governance and strategic levels, which in this article we will call 'government decision-making'.

In order to reach this level of impact, it is necessary to analyze the institutional structures of the city hall. Recapitulating, the body responsible for the management of GeoSampa is GEOINFO, a department linked to the Secretariat of Urban Development. In addition to the technical management of the platform, GEOINFO has had as its function to carry out the various integrations of the teams,

also aligning concepts and understandings about what is ‘data’ and what is ‘information’ within the city of São Paulo. However, we understand that there are limitations to its performance since it does not have any power to regulate broadly over other secretariats of the city hall. In this sense, the department centrally linked directly to a higher decision-making over all secretariat, as was COGEP previously, seems to be a better fit structure for GeoSampa to evolve as an effective tool in strategic decision making. It is worth mentioning that GeoSampa contains information about the territory in a broad way and knowledge of the territory is paramount for any public policy, not just urban development policy. GeoSampa would be than a strategic tool at the service of high levels of decision-making, not just decisions related to urban development. However, centralizing the performance and management of GeoSampa to the mayor's office, for instance, also does not seem to be an optimal solution, once the data transparency policy, more than simplify data access, also includes the *bona fide* of the information.

Regardless of the solution to be adopted, it is important to bring freedom to the managing body to regulate the integration of the information of several secretariats without bureaucratic ties so that they can break traditional cultural barriers like those that tend to treat all the information as confidential and that duplicates databases for not trusting other internal departments.

Final Conclusions

The intent of this article was to discuss the potentialities and challenges that current scenario brings to GeoSampa. Throughout this paper we verified the changes of the role of GIS in the city of São Paulo, since the evolution from an internal tool for ‘technical decision-making’ to become a reference on transparency policy. Although this development there is an public interest, provided by law, to use GeoSampa as a ‘governance decision-making’ tool. To achieve this level of performance this paper brought suggestions that may help improve GeoSampa as a governance tool bringing the managing body in a strategic position allowing it to centralize the regulation of how public data may be used to support ‘governance decision-making’. This would bring more transparency on the reasons and arguments adopted in any territorial public policy.

Concluding, for this new phase of evolution and growth of the GIS application in the city of São Paulo, to really go beyond the scope of a ‘technical decision-making’ tool to a ‘governance decision-making’ tool, it is fundamental to consolidate a strategic vision of the its use, applied from the transversality between databases, now facilitated by many mechanisms of the I.T., giving continuity to the updating, crossing and availability of its datasets.

Exploring the relationship between urban vitality and the distribution of amenity typologies

Patrizia Sulis¹, Ed Manley²

^{1,2}*Centre for Advanced Spatial Analysis - UCL*
patrizia.sulis.14, ed.manley@ucl.ac.uk

Abstract: The availability of large datasets containing spatiotemporal information about human mobility in cities can reveal useful insights about how people use urban space across different times, and be employed to improve urban qualities. Urban vitality represents a critical quality, strictly related to the continuity of the presence of people in places. Vitality may be significantly driven by the types of amenities distributed in the city. This work explores the quantitative relationship between urban vitality and the variety of amenities in London, employing datasets sourced from smart cards, social media and activity location. Vitality is calculated as the temporal variation of patterns in the presence of people in a place. It is compared with the amenity typologies located in such place, combined through a clustering analysis of the spatial distribution of amenities across the city. Results suggest that urban vitality increases in areas with a variety of typologies acting in synergy to attract people, rather than in areas characterised by a predominance of a specific type of activities. This paper enhances the theory-informed quantitative understanding of urban space, integrating data analysis methods with urban planning: this approach has significant potential for informing robust and holistic policy and decision-making.

Keywords: urban vitality; urban amenities; cluster analysis; spatial distribution.

Introduction

Urban amenities represent points of attraction in the mobility patterns of cities and may act as drivers for the liveliness of places. For this reason, the spatial information about urban amenities is commonly used in urban analysis as an established and reliable source of spatial information for understanding dynamics in cities.

This work attempts at exploring the quantitative relationship between the urban vitality and the location and spatial distribution of amenities in the city, also following the suggestion made by Jacobs (1961) regarding the spatial features fundamental for vitality. In order to evaluate the results obtained using the new sources of human mobility data recently available, this paper selected some urban data sets that are widely used in urban analysis and are well-established as reliable sources for the description and the understanding of how urban space works.

This paper investigates how the different typologies of the amenities located in a city might influence the variation of its vitality over time. The values of hourly temporal trends of urban vitality, calculated as in (Sulis et al., 2018) employing human mobility data sourced from the smart card and social media data sets, are compared to the spatial distribution of amenity typologies using POIs sourced from Ordnance Survey. In particular, vitality values and temporal trends are compared to specific combinations of amenity typologies, which are calculated through a cluster analysis that associate areas showing the similar spatial distribution of typologies. Evaluating the

quantitative relationship between these two spatial features is relevant to understand if the vitality of a place may be driven by a specific typology of activities, or if the synergy amongst different types contributes to the continuity of the liveliness and presence of people across the day.

This work represents an example of how it is possible to combine new and standard data sourced and methods and integrating them into the procedures employed for analysing and planning urban space. Quantifying the relationship amongst urban metrics that also describe different spatial domains (i.e., mobility and morphology) possibly result in unveiling how spatial elements and phenomena characterising a place interact and influence each other. This aspect represents a significant factor to consider when planning and designing any development in cities: tasks such as urban strategy, modelling and policy-making would all benefit from the results of this analysis.

This paper is structured as follows: after a presentation of previous work, the data description and methodology employed in the work are illustrated. After that, the paper describes the results related to the correspondence between the temporal patterns of vitality and those of amenity distribution in a place, highlighting the main results. The discussion of the results, the relevance of the approach and the limitations of the methodology concludes the paper.

Previous work

The recent deluge of spatial information (Batty, 2013) coming from different technological sources and devices recording the human-space interaction has made possible for researchers to explore urban dynamics in cities from an unprecedented level of detail, how people move around in cities, also from a temporal perspective. Numerous studies explored the spatiotemporal patterns of human mobility in cities employing different data sources (Isaacman et al., 2010; Noulas et al., 2012; Hasan et al., 2013; Hawelka et al., 2014; Lenormand et al., 2014; Louail et al., 2014; Grauwin et al., 2015; Zhong et al., 2016).

Besides more general approaches, some investigated very specific ideas related to human mobility, i.e., the digital signature of mobility patterns of specific city users as tourists (Girardin et al., 2009), the patterns of preferences of people within a neighbourhood (Calabrese et al., 2010), or the patterns of routine of users in the district (Cranshaw et al., 2012), unveiling patterns at a very detailed scale. All these studies contribute to unveil urban space in terms of how it is used, somehow adding a quantitative perspective to the quality of spaces that were estimated with more empirical tools (Gehl, 2010).

Amongst urban qualities, liveliness or urban vitality (Jacobs, 1961) represents a critical one to understand how successful a city is. Recent work attempted at quantifying this quality using extensive data sets about human mobility recently available (Sung et al., 2013; De Nadai et al., 2016), also considering the fundamental features of temporal continuity highly regarded by Jacobs (Sulis et al., 2018).

To explore more human mobility and what drives it, some work also employed multiple data sources to explore the relationship between different urban features such as human mobility and the locations of urban activities (leisure, commercial etc) to establish if human activity is driven by that and to which measure. Previous work shows interesting results in terms of comparing the average values of human activity (from mobile phone data) and location of urban amenities (Reades et al., 2009), or the correspondence of absolute values of vitality (as a proxy of human activity) and specific categories of amenities related to leisure (De Nadai et al., 2016).

Following these work, and the idea suggested from Jacobs of the importance of variety in amenities in relation to urban vitality, this work employs the hourly values of urban vitality calculated as the temporal variation of the presence of people in urban places in (Sulis et al., 2018): the variation is calculated at three different temporal scales (hourly, daily and weekly), employing human mobility data sourced from the Oyster smart card and the

Twitter platform. The vitality values are compared to the spatial distribution of urban amenities related to the leisure domain, in the attempt of evaluating the quantitative relationship of these features and the possibility of amenity location driving the level of the liveliness of places in the city of London.

Data description and methodology

Description of data

This work investigates the quantitative relationship between urban vitality and the distribution of POIs in cities. The analysis explores how the different combinations of amenity typologies located in a place (the mixed-use mentioned by Jacobs, 1961) influence the temporal patterns of vitality in cities. This approach may reveal more accurate insights about a specific combination of amenities possibly driving the vitality of a place. The metric of vitality was calculated using different sources of human mobility data as presented in (Sulis et al., 2018). These values are here compared to spatial information about city amenities collected from Ordnance Survey.

The data set sourced from Ordnance Survey contains information about the location of Points of Interest (POI) in London. The POI categories selected for this analysis are related to the leisure domain, since the focus of this analysis is on urban phenomena influencing the presence of people in urban public places: only the categories related to non-shopping leisure (e.g., eating out, tourist attraction, entertainment) are selected, following the idea of streets as public space. Figure 1 shows the spatial distribution of the data included in the Ordnance Survey data set, and it illustrates the density of amenities within the London wards.

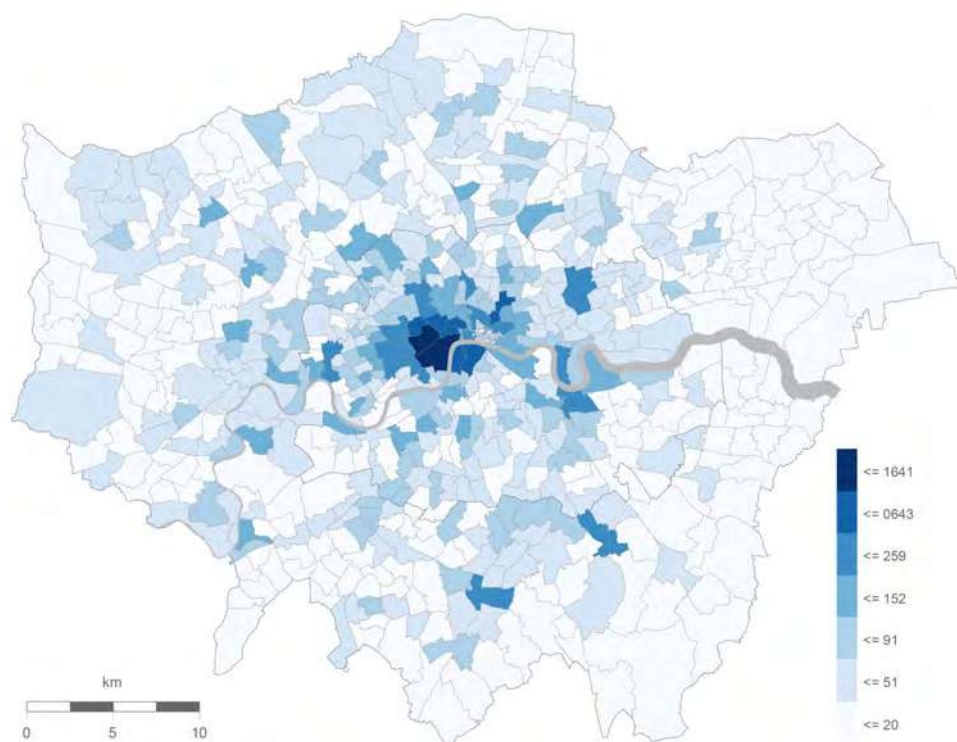

Figure 1: spatial distribution of urban amenities

The main advantage of employing this type of data is that it represents a source of spatial information about cities that is frequently used in urban planning and considered a well-established and accurate source of data for investigating the use of places and the mobility of people in cities. Furthermore, the information supplied by this type of data, especially the geographical location and the category of the activity, can be combined with other

metrics about urban places, e.g., human activity density obtained from the other data sets, making possible to investigate the relationship amongst the different types of data describing the same urban phenomena.

The possibility of enriching the data with additional information (e.g, opening hours) and the detailed categorisation of amenities also makes possible to explore how specific typologies drive or influence more than others the human mobility patterns and the presence of people in places during specific times, and the impact of this possible influence.

Methodology

At first, a profile of the amenity distribution characterising each area of the study is extracted from the data set: this profile contains the total number of amenities for each typology present in that area. These distribution profiles are then used to run a cluster analysis to infer the similarity of the areas according to their patterns of amenity distribution, assigning each area to a specific group. This approach represents a more accurate method for representing the specific characteristic of each area concerning the spatial distribution of urban amenities than the simple sum of activities located around each place. The labels assigned to the areas are subsequently compared to the temporal variation of vitality, to observe if they are recurrently associated, and eventually verify the correspondence between a specific combination of amenity typologies and the liveliness of a place.

The distance metric considered to be the most appropriated to be applied in this specific case is the Jensen-Shannon Divergence (JSD), applied to calculate the distance metric amongst the amenity profiles of the research areas. This method is specifically designed to measure the similarity between two (or more) probability distributions P, Q : in this case, it is measuring how similar the spatial distribution of amenity typologies is between two different areas in the city. The JSD metric is calculated according to Equation 1 below:

$$JSD(P||Q) = \frac{1}{2} \cdot D(P||M) + \frac{1}{2} \cdot D(Q||M)$$

The square root of the divergence is the equivalent distance metric required for the cluster analysis. In this case, the JSD is applied to a matrix of vectors, with each vector representing the POI distribution calculated for each research area. The matrix employed in the analysis has been normalised in advance by the sum of the activities located in each area.

After calculating the distance metrics, the analysis requires a suitable algorithm to cluster the distributions of POI typologies. In this case, the one chosen for the cluster analysis is HDBSCAN. Results of the cluster analysis are presented in the following section.

The labels obtained in the cluster analysis of the profiles of amenity distribution are compared to the trends of the temporal variation of vitality. This comparison detects the occurrence of the same association between amenity labels and vitality trends in the areas, which may be used to unveil if the specific distribution of amenities in an area influences the liveliness and the continuous presence of people in a place. To compare these two features, the analysis employs a confusion matrix. The algorithm counts each time that the same pair of vitality trend and amenity label are associated. This value may be employed to evaluate the relationship between the vitality of an area and the diversity of amenities in the same area.

The code used to calculate the confusion matrix is the following:

```

L = len(np.unique(df['vitality_labels']))
B = len(np.unique(df['activities_labels']))

labels_M = np.zeros((L, B))

for i in df.index:
    x = df.iloc[i]['vitality_labels']
    y = df.iloc[i]['activities_labels']

    labels_M[x, y] = labels_M[x, y] + 1

```

The confusion matrix is calculated for different combinations of labels:

- temporal variation of vitality (week) + distribution of POI typologies;
- temporal variation of vitality (weekend) + distribution of POI typologies.

The results (illustrated in the following section) show which amenity labels are more frequently associated to a specific vitality trend and pattern of human activity in a place, corresponding to a specific distribution and amount of amenity typologies. This correspondence might suggest that a particular combination of typologies influences and possibly drives a certain level of vitality in an area. These results, also showing different label associations occurring during week and weekend days, can then be used to further analysis and empirical investigation.

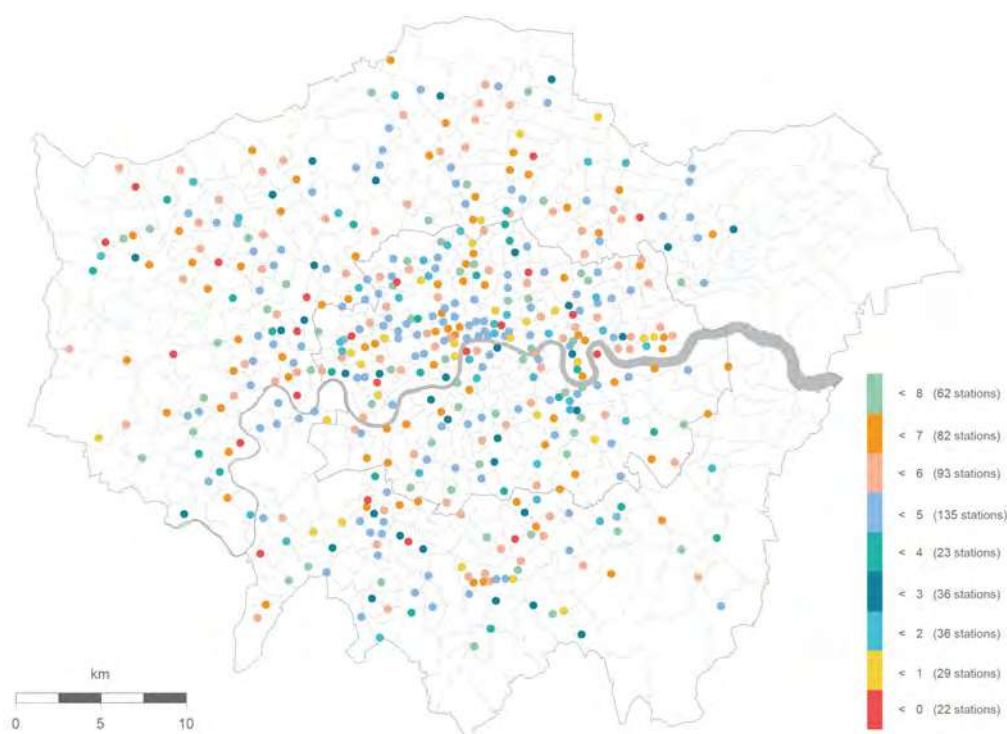

Figure 2: spatial distribution of labels in London

Results

This section presents the results of the cluster analysis applied using the Jensen-Shannon distance and HDBSCAN combination. Observing the spatial distribution for each label (Figure 2), it is possible to obtain revealing insights about the patterns of similarity of amenity distribution in the city of London.

Labels 5 and 9 appears to be the more varied and balanced ones, with the presence of many typologies related to city attractions and entertainment. Label 5 appears to be the most common label, with an even distribution around the city. This aspect may be related to the fact that the analysis considered areas very closed to the public transport network, which generally acts as an attractor for activity locations. Other interesting labels to observe in relation to the combination of amenity typologies are the labels 1 and 6. Label 1 shows a spike in the presence of restaurants in the profile, and it appears to be mainly located in the inner area of the city. Label 6 instead appears to be quite evenly distributed on the map, whereas the profile shows a significant presence of libraries amongst the other typologies.

These labels are compared to the temporal trends of vitality using a confusion matrix. The results show a neat distinction in the label associations during the weekdays. The majority of the associations occurs with label 5 and label 7, which correspond to two rather different amenity distribution profiles. The temporal trends of vitality associated to these two labels are also different: trends representing a temporal continuity in the vitality are associated to label 5, which presents a nicely balanced distribution of a variety of amenity typologies (eating, entertainment, attraction). On the other hand, the vitality patterns characterised by a two-peak profile are predominantly associated with label 7, showing a presence of amenities pertaining exclusively to the eating category. In the weekend, the majority of label associations are still occurring with label 5 and 7; however, the distinction in the vitality trends appears less defined, therefore more analysis is required.

The most representative associations of vitality trends and activity distribution labels are illustrated in Figures 3 - 4 below.

Figure 3: typology distribution for label 5

Figure 4: temporal trends of vitality associated with label 5

Discussion

This section discusses the results obtained in the analysis, also in light of the relevance and the potential applications in the urban planning methods. Firstly, it is important to underline how this work showed that it is possible to explore and measure relationships amongst different spatial features of the same place employing a quantitative method. Estimating this relationship represents an additional enhancement in the process of unveiling details about the spatial phenomena occurring in cities.

About the relationship between vitality trends and specific combinations of amenity typologies, results do not appear to present a specific association of precise vitality trends with activity labels. What can be noticed, however, is a clear distinction in the association between continuous and two-peak vitality trends and specific distributions of amenities. In particular, results seem to suggest that the continuity in the patterns of vitality (and therefore human activity in places) might be influenced by a balanced variety of activities located in the area (in this case, different leisure activities). This aspect may represent a hint towards what Jacobs described, that the mixed use of amenities contributes to attracting different people for different purposes, therefore ensuring their presence during the day and resulting in the vitality of a place. On the other hand, the two-peak patterns appear to be mostly associated with less varied amenity distributions in the areas. This may suggest that the presence of people in such places is mainly concentrated around specific times of the day (e.g., opening hours of certain amenities).

Unveiling such information about spatial features represents an advantageous factor to be employed in urban planning. Understanding which combination of amenity typologies (which types and in which quantities) most influence the liveliness of a place, and its success in behaving as a public space, is a very relevant element for both analysis and planning phases. It represents a condition that can also be employed in policy-making, for example to target areas that appear to be more secluded in terms of human mobility patterns and the use of the space at different times in the day. Identifying the most successful combinations of amenities that are contributing to the liveliness of a place can also be employed to intervene in other areas with specific policies targeting either the typologies of the amenities to locate in the area or the opening hours of activities already existing, in combination to other urban elements present in the area.

All the aforementioned examples about the applications of the metrics into the planning procedure must inevitably be evaluated considering the existing context and urban situation of the city, district, neighbourhood where the urban development is happening. Most importantly, a critical point to highlight here is that the metrics employed are context-sensitive and prone to a certain level of uncertainty. The urban context on which the spatial analysis is performed results into the metrics being specific to that context: they cannot be applied lightly to other urban

situations, or generalised into overall standards. The approach and the methodology can be adapted and applied to other case studies and data sets, contributing to comparative analyses of the same spatial phenomena occurring in other cities.

One of the limitations of this study is related to the data sets employed in the analysis, in particular concerning the accuracy and the availability of the amenity location data obtained from the different sources. Whereas it is important to make the data available and open to everyone since it is built thanks to the users' contribution (as it is the case of OpenStreetMap), the completeness and the homogeneity of the data collected may lack in quality. On the other hand, the accuracy and details of the Ordnance Survey data set employed in this analysis come at the expense of the availability and usability of data for everyone. Another limitation is related to the technique used in the cluster analysis: the HDBSCAN algorithm labels some of the objects as noise, making necessary to reassign some of these objects to the closest cluster. Despite this limitation, this type of cluster algorithm appears to be the most suitable for the data sets employed, based on the evaluation of the preliminary results obtained with other techniques.

Conclusion

This paper illustrated an attempt of establishing the quantitative relationship between the temporal patterns of the vitality of a place and the specific combination of amenity typologies present in the same place. This relationship is explored using a comparison between the temporal variation of vitality and the spatial distribution of amenity typologies in each area.

The results obtained from the analysis suggest that a quantitative relationship might be established between the liveliness and presence of people in a place and the number of activities of that place. Results also suggest that certain combinations in the distribution of amenities (a balanced variety of different amenity typologies) appear to be associated with specific temporal trends in vitality. This might represent a hint that the former might drive or at least encourage the latter. This hint can be further explored in future work both with data analysis and empirical research in the urban space.

The method and results presented in this work also represent an example of the potentialities intrinsic in combining new and standard spatial information and techniques into the methods conventionally employed in urban analysis. Unveiling how different spatial elements characterising the same place interact and influence each other represents a relevant aspect that may inform and support urban planning in many different phases.

This approach also contributes to two other objectives for urbanism:

- integrating different types of data sets, using big and small data together, and attempting at establishing the relationship between different types of urban data pertinent to the same urban context and influencing the same urban phenomena;
- showing how new data sources can be successfully integrated with conventional data sources in urban planning and analysis.

² Tongji University, Department of Urban Planning, College of Architecture and Urban Planning, China, wwq@tongji.edu.cn

Abstract: In the age of social media, the interaction of online and offline activities has produced a more diverse form of interaction between people and space. Weibo is the largest social media in China, where users share their insights by uploading photos and text. Historical streets carry important urban cultural imprint while its protection is facing the problem of enhancing attractiveness under the rapidly urban development. This study collected the Baidu Street View image and geo-tag Weibo photo of Hengfu historic conservation. Images were recognized through the machine learning algorithm, in order to realize the accurate measurement of the image elements. Building and greenery were the focus of attention of the crowd, and some streets have improved people's contact with greenery through the design of vertical greening. Second, we combined the campaign of the hot events such as 'Leave fallen leaves' in social media, with the semantic recognition of the text of users 'Weibo'. This paper analyze how the streets interacted with the online crowd with the help of social media, and analyze why some streets are more attractive while others lack attention and record, and put forward suggestions for urban design of historical street in future.

Keywords: social media, machine learning, historical street, visible greenery

Introduction

The rapid spread of information has greatly affected the behavior and needs of people, thus reconstructing the needs of people for physical space. For example, the appearance of Amazon and other online retailers make thread to normal bookstores. Some independent bookstores have been revitalized by the use of social media campaigns to strengthen their ties with the community (Ryan, 2017). Readers share the bookstores they've been to and advised book on Instagram. Independent bookstores host many events to bring people together and provide more personal customer experience.

As an important component of urban space, streets also face the same situation. Video games, animation and internet reduce people's interest in outdoor activities. It's important to realize people's attitude about urban space through traditional field study and social media. For urban designers, it's reasonable to connect the advantages of social media and physical street space. The quality of street

space affects the experience from pedestrian, the vitality of public activities, and even the shaping of urban characteristic (Jacobs,1961).

The use of social media in design is accompanied by a shift from top-down to bottom-up perspectives. With the help of new technologies, we could better measure urban space and evaluation from human-scale (Ye Y,2018;). Sina Weibo(microblog) is the largest social media platform in China, with 411 million monthly active users in 2018. Users can sign the location when they reach the urban physical environment and publish relevant text and pictures to describe the activity experience. As a kind of Location Based Service data, Weibo data is widely used in social activity, tourism evaluation and crowd flow (Jiang, W,2015; Wu, L,2014; Yan, L,2018;). Yan analyzes the relationship between Weibo check-in data and air pollution. It's found that air pollution has a negative impact on urban activities. Weibo pictures based on street position also reflect the arrival of users and a record of urban life, and a small number of studies use it to research about urban image, urban memory and other topics.

Literature review

The use of social media in urban planning and urban design

Research on social media and planning focus on the distribution of urban activities, public participation, urban heritage conservation, and so on. Social media contain a wide range of feelings and memories related to the urban past (Van,2019). Storytelling and mapping could be used to invited citizens to join in historical area conservation, providing opportunities to understanding urban history and big events.

In China, social media enable planners to focus on a wider range of information and to communicate planning information (Sun,2013). Sun host a talk about change from AutoCAD to Sina Weibo. There was an example that one planner protested about unreasonable demolition of historical buildings through Weibo and caused a lot of retweets from planners to citizens. Traditional media also reported this situation and finally the government canceled the demolition and promised to protect those buildings. Although it's difficult to deeply discuss professional knowledge though social media, we can use it to collect voice from citizens and present planning views.

Image recognition and urban design

In recent years, with the development of new urban science (Michael,2013), image recognition, machine learning and other new technologies have been applied to urban studies. Image recognition is one kind of new technology that use Convolution Neural Network Algorithm to extract image elements. At Urban scale, researchers used a large number of images from interaction website to social media. Palomares studies the distribution law of tourist hotspot in 8 major cities in Europe based on Panoramio Pictures (GarciaPalomares,2015). There was some interesting things like connection between urban image and pictures which people post in the website (Liu,2016).

At street scale, Street View can be used to accurately measure the morphological and factor of urban space (Yu,2018) . Some map website like Baidu and Google have collected multi-year streetscape photos then could be used to study the quality and spatial change of streets in Beijing (Tang,2018). With image recognition, street view could accurately measure the city environment space, refines the related streets streetscape research to improve street quality.

Table 1. Urban Study used Image recognition

Research aspect	Urban scale		Street scale	
	Urban Image	Tourism	Quality of street	Street Greenery
Analysis point	Image features, architectural colors	Tourism agglomeration and urban spatial perception	Time-phase change, physical and interface features	Visible street greenery, accessed street greenery
Data source	Image interaction website (Flickr)	Image interaction website, social media	Street View	Street View
Typical Research	Liu selects the photos from Panoramio and Flickr, using the deep learning technique to identify and classify the photo contents (Liu,2016).	Based on Panoramio Pictures, Palomares studies the distribution law of tourist hotspot in 8 major cities in Europe. The tourist route and activity space of local residents are analyzed (GarciaPalomares,2015).	Based on multi-year streetscape photos, Tang studies the quality and spatial changes of streets in Beijing (Tang,2018).	Li X uses Google Street View to measure the proportion of street greening, compared with the living environment of residents. (Li,2015).
Research features	Use a large number of open source image data and recognition technology. Compare the images of different cities horizontally.	Users take the upload photos spontaneously, and consider subjective feelings and objective vitality distribution	Because the streetscape images can be collected for many years, it is beneficial to the measure the quality and characteristics.	In-depth study of street Greenery, a street space element is perceived by residents in daily contact

Method

Research framework

As seen in Figure 1, to map the historical streets on social media, this study selects visible street features, recorded street features and people's recording about program 'Leave fallen leaves' as the major study objects. First, street networks of the area were collected from Open Street Map(OSM). This is for subsequent image collection and presentation on GIS. Baidu Street View(BSV) was collected through the Baidu API by Python. Second, we collected text and picture from Sina Weibo during August, November and December, 2018. Text posted during the Program period were analyzed through semantic recognition to find out what's the focus of people's expression about this programme.

Third, the measurement of visible and recorded street features were achieved by image recognition. We used TensorFlow, a neural network algorithm platform developed by Google and Cityscapes Training set, a datasets in driverless environments launched by Mercedes-Benz. Both BSV and pictures from Weibo were analyzed to get human-scale indicators which had rarely been studied before. Image recognition could classify the features such as greenery, sky, building, people, road, etc. We can find out which road or what features is more recorded by people. Finally, based on the analysis on the program ‘Leave fallen leaves’, this study figure out the hot words and organizers’ reaction to social media views.

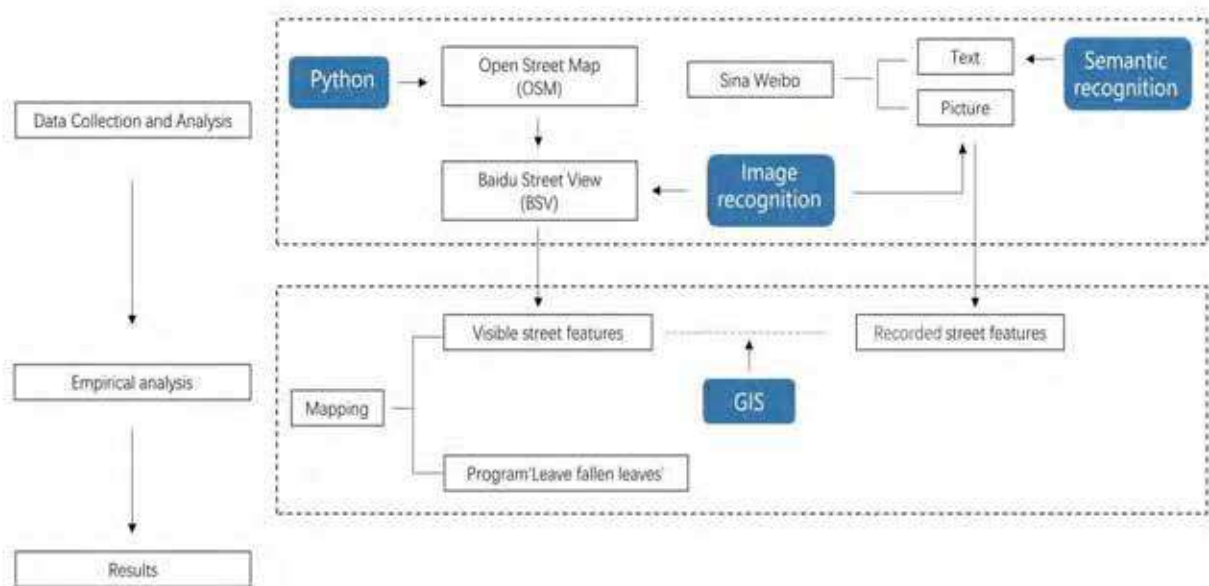

Figure 1. Research framework

Study area

For this study, we selected the Shanghai Hengfu historic conservation area, of around 7.75km², as the study area(Figure 2). It's the largest historical conservation area in Shanghai central urban area, with the highest number of style-protected roads. The consevation area formed its style in the first half of the 20th century, with 66 roads and a total length of 9.78km. The streets in the area have pleasant scale and embody the characteristics of modern space form and public activity place in Shanghai.

Figure 2. Shanghai Hengfu historic conservation area

Data collection and analysis

The measurement of street features started from the collection of Baidu Street View and Weibo pictures. The study was carried out in the winter of 2018 to collect 66 streets in the area (Figure 3), the total street length of 9.87km. The average sampling spacing is about 25 meters and a total of 4,159 sampling points are identified. The Baidu Streetscape API (<http://api.map.baidu.com/pano>) is called by Python via HTTP URL to obtain Street View images from the perspective of each sampling point. The study crawl a total of 4159 BSV images (image resolution of 512*256 pixels), covering all areas of the Hengfu historic conservation area.

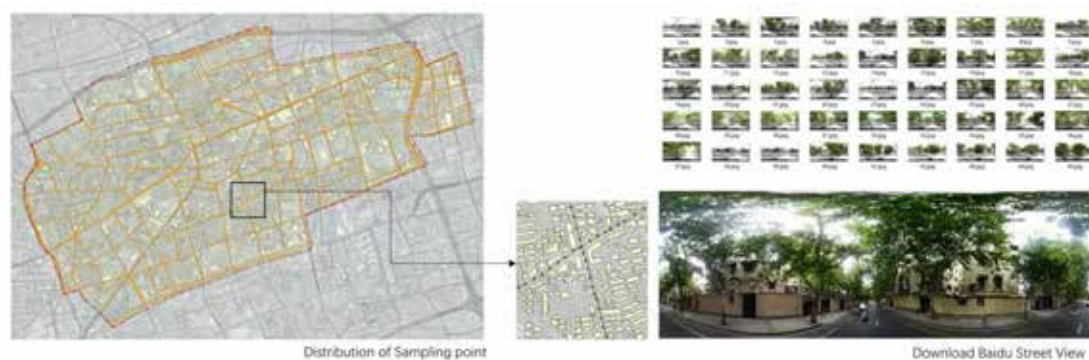

Figure 3. Baidu Street View Data collection

The neural network algorithm platform is developed by Google TensorFlow and Mercedes-Benz launched the Cityscapes training set, with the help of machine learning automatic image recognition. The Street View pictures are divided into roads, sidewalks, buildings, vegetation, skies and other elements (Figure 4.). The sampling point results are then based on the ArcGIS platform, through Spatial Join analysis to each street, to achieve visual rendering of the results. Pictures from Weibo are also analysis by image recognition.

Figure 4. Image recognition of Baidu Street View and Weibo picture

After text was collected from Weibo, Semantic recognition could quantify feature words extracted from the text to represent the information. Social media is an effective window to observe human emotions. This study uses Jieba (<https://github.com/fxsjy/jieba>), the best Python Chinese word segmentation module.

Results

The vitality of different historical streets

This study collected a total of 878 photos from Hengfu historic conservation in August, of which 349 photos were collected from Rd.Wukang (Figure 5) . We filter the upload valid photos with street view, including portraits, building facades, streets views, road, etc., to reflect the user's attention to the street. It's reasonable to exclude those invalid photos including food, indoor, selfie, emoticon that do not reflect the street space. Style-protected roads collect more Weibo photos in quantity and density, indicating that people pay more attention to the streets and particular streets are more energetic. People focus on some historical buildings like Normandy Apartments as 66 photos are about Normandy Apartments of 349 photos collected based on Rd.Wukang

Figure5. The number of Photos uploaded on Weibo in August, 2018

The comparison of visible and recorded street features.

From the result in Table 2. It's obvious that in reality Greenery(57.3%) , Sky(21.5%) and Building(14.0%) are the main component of street views. We could find that Building(38.5%) , Greenery(28.8%) and Sky(4.9%) are the focus of attention of the crowd. As we all know, there are a lot of protected buildings and style-protected roads in this area. It's special cultural atmosphere attracts special shops and hot restaurants to open in this area. Many citizens and visitors enjoy going to Hengfu historical conservation area and taking pictures of some hot restaurants or historical buildings. Some microblogs mention walking activities about historical buildings which leaders would plan walking route and introduce their history. Those activities also increase the volume of Weibo pictures about buildings. They post their experience and photos on social media to show their feelings. It's interesting to figure out that the greenery of BSV is nearly double than that of Weibo picture.

Table 2. Image recognition result of Baidu Street View and Weibo Pictures(%)

	Road	Sidewalk	Building	Wall	Fence	Pole	Vegetation
Weibo pictures	0.090	0.032	0.385	0.016	0.015	0.007	0.288
BSV	0.013	0.015	0.140	0.001	0.011	0.002	0.573
	Terrain	Sky	Person	Bicycle	Car	Truck	Motorcycle
Weibo pictures	0.011	0.049	0.038	0.003	0.016	0.023	0.002
BSV	0.010	0.215	0.004	0.001	0.007	0.006	0.001

By assigning the greenery value of each sampling point to the nearest street segment, the visible greenery of each street segment can be obtained by the average. The average visible greenery of all street is 58.23%, of which the visible greenery of style-protected roads is 63.39%, the visible greenery of other roads is 50.22%. Walking in the style-protected road can experience a richer street greenery and bring more happiness. Roads like Rd. Julu and Rd.Hengshan have higher visible greenery while some highways like Rd.Yanan have lower visible greenery. The urban street landscape includes the public space formed by the natural history and the walking trees in the space, under the guidance of the Protection Plan of Shanghai Historic District, the street space and the walking tree are used as the greening subject in the open space of the scenic area, and the "need to increase the scope of greening planting" in the non-greening land has a positive effect on the results of the current high visible greenery.

Comparing the results of Street View image recognition with the results of Weibo photo image recognition (Fig. 6), there are three kinds of cases that can be explored in greenery:

- (1) The high rate of greenery in BSV and Weibo pictures, that is, the perceived record of street greening in urban space by users, such as Rd. Hengshan (Street View greening rate 51.92%, Weibo photo greening accounted for 37.4%), Rd. Julu Road (Street View greening rate of 72.4%, Weibo photo greening accounted for 35.91%)
- (2) Greenery in BSV is high while in Weibo pictures is relatively low, that is, the greenery in urban space is not perceived by users, or other content attraction is higher. For example, the Weibo photos of Rd. Wanping and Rd. South Xiangyang focus more on small shops or building facades.
- (3) Greenery in BSV is high while in Weibo pictures is relatively high, that is, the greenery in urban space is magnified and get more record. For example, Rd. Yongjia and Rd. Anfu maintain great greening landscape. Urban design increase the vertical greening, enhancing the crowd's perception of greening. It may be considered to increase vertical greening in subsequent street design if it's appropriate. And it would increase the perception of greening among the population.

Figure.6. The comparison of greenery

The discussion about ‘Leave fallen leaves’

Since 2013, Shanghai has conducted the program ‘Leave fallen leaves’. It is expected that in mid-November, most of these landscape roads, which do not sweep the leaves, will enter the best viewing period, and the falling leaves will be woven into a variety of "carpets". So that the autumn in Shanghai is full of vitality and temperature. In 2018 there are 34 roads were chosen as Landscape Road, involving district Huangpu, Jinan, Xuhui and so on. The program started at 2018/11/15(Figure.7).

Figure.7. The timeline of ‘Leave fallen leaves’

Hengfu historical conservation area is in District Xuhui and some roads are chosen as Landscape Road. Last year officers invited some artists to create some art work which is about ‘Silk road’, an ancient commercial road connecting Eastern and Western. The exhibition started in 2018/11/23 and contained 12 sets of art work which use leaves, branches, soil, stone and other elements. While one day later some complains about the exhibition appeared on social media because citizens thought those work is too surprising and strange. As seen in Figure.8, it could be track that on Nov, 24 and 25 there was a peak to identify more than 20 users had posted program-related microblog. Some microblog directly expressed their opinions to organizer that those art works were not fit landscape. Some planners also share their opinion about artwork and how to better treat fallen leaves. On Nov,26 the organizer quickly changed the artwork and replied to people on social media.

Figure.8. The number of Weibo post during the program

Since December 1, Shanghai has been in the most beautiful leaf season and there were 2nd peak of the discussion. Many people went to the landscape streets and post beautiful pictures on their social media with tag #Leave fallen leaves. With the track of tag, we collect text and conduct Semantic recognition to figure their attitude and emotion. As seen in Figure 9, the words in the top ten of the release volumes are ‘Fallen leaves’, ‘Leave’, ‘Shanghai’, ‘Landscape’, ‘Rd. Fuxing’, ‘Sidewalk’, ‘Citizens’, ‘Beautiful’, ‘Work of art’, ‘Question’. It shows people keep the program in close connection with city and even a specific road. Some microblog mention those art installation just copy an icon and carry a subject directly to Shanghai without creation, triggering more discussion. Although there were some complain before, we figured that ost people expressed a positive attitude about the program and share their thanks to the beauty of street.

Conclusion

This study attempted to map historical streets on social media with the help of new urban science. By the help of new technologies like Image recognition and new urban data, the visible and recorded street features could be measured. Building, greenery and sky were the focus of attention of the crowd. It's also helpful to organize walking activities to help people focus back to streets. Through the comparison of two kind of pictures, we find some streets have improved people's contact with greening through the design of vertical greening. The streets interacted with the online crowd with the help of social media. The case from 'Leave fallen leaves' show what's peoples' attitude about street landscape. Urban planners may use social media to get people's attitude and conduct public participate.

Despite the contribution of this study in mapping historical streets on social media, there is some limitations that require further research. For example, if the difficulty of collecting Weibo text and pictures by Python could be overcome, the quantity of objective would increase and present more objective state. Furthermore, the attraction of streets is also connected with the type of shop and activities hold by businessman, it would be better to join more social activities and expression on social media.

Abstract: Abandoned places are common "everyday" landscape elements whose characteristics are not always adequately known. It is necessary to activate innovative knowledge-making tools to understand the complexity of these places in order to fill the lack of information concerning their characteristics and the relationship between their fragility and the repercussions on physical space. Open data represent a great opportunity to produce new knowledge both for the preservation of a vulnerable heritage and to support urban regeneration processes. Through open-data participatory mapping actions, the community knowledge can easily emerge in a structured way. Official digital sources are often unable to adapt and upgrade processes of place knowledge making. For this reason, a set of digital infrastructural facilities must be conceived and implemented, adopting the most advanced information technologies, in order to produce open-source, interoperable and interactive Dataset. The digital infrastructure requires a wide variety of heterogeneous data sets, collected and managed to remain open both for endless sharing and for technical verification actions. Openstreetmap is an emblematic example of a re-adaptable tool for mapping abandoned places: the modular depth of its geodatabase allows it to be customized with great ease. Using this tool, the information is made accessible to a large community to be used and shared.

Keywords: Abandoned places, Spatial analysis, Big data, Open data

Introduction

The fragilities of the Italian territory are characterized by a multiplicity of 'minor' aspects that are difficult to detect, map and interpret. Abandoned places are very common 'everyday' landscapes elements which are not always characterized by widely evident phenomena of environmental and physical degradation. It is necessary to activate innovative knowledge-making tools to read and to understand the complexity of this places, filling the lack of information concerning their characteristics (i.e. taxonomy, localization, etc.) and the relationship between their fragility and the repercussions on physical space. Open data and citizen science represent a great opportunity to produce new knowledge both for the preservation of vulnerable urban landscapes and to support urban regeneration projects and policy decisions. Through open-data participatory mapping actions,

¹ Sections 1, 2 by Emanuele Garda; section 3 by Stefano Saloriani; section 4, 5 by Daniele Villa.

the local and community knowledge can easily emerge in a structured and organized way. Official digital sources are often unable to adapt and upgrade processes of place knowledge making. For this reason, a set of digital infrastructural facilities must be conceived and implemented, adopting the most advanced information technologies, in order to produce open-source, interoperable and interactive Dataset (i.e. Landscape Digital and Geographical Models). The digital infrastructure requires a wide variety of heterogeneous (qualitative and quantitative) data sets, collected and managed to remain open both for endless sharing and for control and technical verification actions. Openstreetmap is an emblematic example of a re-adaptable tool for mapping fragile and abandoned places: the modular depth of its geodatabase allows it to be customized with great ease. Using a tool like OSM, the risk of making the information inaccessible and non-reusable is avoided ensuring that a very large community (i.e. citizen, policy makers, stakeholders, etc.) can use and share. In this way, the raw material of territorial research becomes a common ground without complicated steps that may ease further subsequent interpretations and actions.

In the following sections, this paper describes some characteristics of the abandoned places phenomenon and the mapping of buildings or areas made by different actors (public institutions, universities, local associations). It is to be taken in consideration that there are many taxonomies and ways to define the abandoned places and that the mapping case studies are responding to an increasing need of information. In those experiences, the authors set limits to build the last sections of this paper in which is underlined the importance of the new typologies of data collection and re-use in a more updated and open methodology.

Neglected spaces and territory

Quiet villages, rural settlements, huge factories, neighborhood shops, interrupted construction sites: in recent years the abandonment of places has generated a massive variety of examples. This kaleidoscope of materials, geometries and memories is shifting the debate to the description and interpretation topics starting from the deep and extended changing in the territory (Merlini, 2009)

The universe of non-used spaces is composed by different places and vocabulary studied by many authors: keywords like *Terrain vague* (Solà-Morales, 1996), *Vacant land* (Pagano and Bowman, 2000), *Shrinking city* (Oswalt, 2005), *Junk space* (Koolhaas, 2006) and *Terzo paesaggio* (Clément, 2004) are the most explicit demonstration of this fertile debate. As mentioned, the recent economic, financial and social mutations are changing and increasing the new examples of abandonment in addition to what is present already namely a past situation in which for the society was common the alternance between use, disuse and reuse of the territory.

After the “dismissal brownfield” era a huge need of knowledge and interpretation update is emerging within a radical and profound renewal phase of urban planning discipline (Di Giovanni, 2014), is emerging a huge need of knowledge and interpretation update. At the same time, some central expressions appear in an increasingly plural debate: for example, some recent re-use oriented research have placed emphasis on the concept of recycling whose importance has increased adding new

significance at the social and economic means (Viganò, 2011) of re-use².

The “Re-cycle–strategie per l’architettura, la città e il pianeta”³ exhibition at MAXXI in Rome or the “Re-cycle Italy”⁴ national research need to be read in their capacity of activate a new research (and project) path.

There are some characteristics that are causing a variety of the abandoned place that could be used as a guide, individually or combined, for the analysis and project objectives.

The structure and the ways in which the various buildings are composed and characterized in the spatial asset represent one important condition. In the urban space it is possible to find single abandoned buildings with different volumes and functions or complex structures of many buildings. Another important interpretation is the moment of construction that, combined with the original function, allow the definition of specific historical phases.

For a better understating of these places, a crucial role is played by the causes of abandonment that may led them to a slow and progressive agony or rapidly occur after an unexpected event (landslides, earthquakes or floods). In the first case, the elements of a long decline are usually stratified (Marini, 2016) and combined in the so called “ghost town” as for example (Civita di Bagnoregio, Balestrino, Craco, Pentetattilo etc.). Here, the voluntary emigration, the decline of vital traditional economic sectors, the political events, the different forms of environmental risk and marginality (Teti, 2017) led to a radical decline.

From a geographical point of view, the abandonment is a multi-level phenomenon that combine different “spatial orders (Bolocan, 2014). There are at least five levels of extension:

- “Micro-abandonment”⁵ that may affect individual units such as dwellings, shops or small businesses located in the same architectural volume or in the same block⁶.
- A second level is composed by entire buildings with any kind of functional distinction, for example rural settlements, industrial buildings, commercial buildings, shopping malls, etc.
- A third situation is defined by abandonment processes that affect wide parts of the city. This happens in urban settlements with huge productive platforms whose decline follows constantly the traditional industry decline.
- A situation in which an entire city is abandoned, such as the already mentioned “ghost town”
- The last case is the abandonment of large geographical areas including buildings and open spaces such as the so called “inner areas” in Italy. These contexts had experienced a steady decline in population and in economic activities that is leading to a complete emptiness.

Atlas and abandoned places

The archipelago of mute rubble and ancient ruins (Tarpino, 2012), described in the previous paragraphs, ensues the increasing need of knowledge about abandoned places. As mentioned, it is a plural and continuously in mutation geography affected by nonstop re-colonization and new abandonment processes that needs to be understood (quantity, localization, morphology, function etc.). For these reasons, recently we have assisted to an increasing number of initiatives aimed to grow

² Recycling is “non è semplicemente riusare, ma, seguendo l’analogia con il mondo organico, proporre un nuovo ciclo di vita, assumendo che di vita e di cicli si tratti e che l’analogia contenga ancora qualche utilità” (Viganò, 2011).

³ The exhibitions materials are reported in Ciorra, Marini (2011).

⁴ It is a Project of National Interest (PRIN) funded by the Department of Instruction in 2011.

⁵ To better understand the micro-abandonment concept see Garda, Gambazza (2016).

⁶ There are similar examples in Antwerp where inside the XIX century “urban belt” there are many abandoned places that gives space and porosity to the city (VIGANÒ 2010, p.197).

the awareness regarding the abandonment spaces. More than 90 cases can be found on the “Osservatorio del riuso”⁷ website and we group them in three different categories: (i) Observations promoted by public institutions of local or regional importance (ii) Research and exploration promoted and produced in/by the universities (iii) Bottom-up experiences promoted at local level by associations or informal groups of citizens. The first category must include the census of the abandoned places made by Lombardy Region, Assimpredil, Ance and Provinces in 2008-2010. It is a partial mapping of the entire regional territory that leads to the recognition of 745 brownfield sites. This first project led to the creation of a free database⁸ and an accessible web portal that didn’t received any updates since the opening. It has an accurate scale of details despite the extent of the census, and it is possible to find information about the perimeters of the areas, the buildings, the urban destination and their constraints. A second example is the “Degraded and abandoned areas and buildings” database of the Milano Municipality, available on its Opendata web-portal⁹. This case was started in 2014 and finished in 2019 with the adoption of the new planning document (PGT) of the city. Compared to the previous case this census has a local scale and it is focused on the need to recognize a plural geography identifying different situations especially at the functional level (dwellings, shops, businesses, production, etc.). The third case is the “Census of the public real estate”. The Department of the Treasury annually updates it and allows the users to download all the information available in a .csv format. It has a good detail scale with a quite complete set of information but there is not the possibility to visualize the database on a webmap directly on the Department of the Treasury website (in the previous cases was possible). In order to visualize the information, an expert user should geo-locate the address of each space or combine the data with some dataset of the cadastre. This is a limitation in the possible use of such an important dataset. Another institutional case was made by the *Diathesis Lab*¹⁰ of the University of Bergamo between 2013 and 2014. This research found 805 abandoned areas using both quantitative and qualitative criteria. The results are online on a web platform¹¹ but the data are not available for the download. The scale of this contribution is vast and the information are divided by the municipal boundaries without the spatial location of the abandoned places. There are not registered update since the project conclusion.

A second University experience is the “Atlas of abandonment” made by the University Statale di Milano and the PIM¹² in 2016. In a two years process, 580 unused areas in 38 Municipalities of the Metropolitan City of Milan for a total of 776 hectares have been analysed. This case recalls the taxonomy mentioned above finding many examples of abandoned places. As for the previous research, data download it’s not possible and the updating of the information seems interrupted.

Moving to the association levels and citizen groups, many examples can be found. The first one is *[im]possible living*¹³, an abandoned spaces re-activation experience based on community knowledge as a first source of information. They had created some call for ideas to find new functions for some

¹³ <http://blog.impossibleliving.com/> (last access in May 2019).

empty space. Nowadays this case is not active anymore, but their approach remains crucial and replicable.

Moreover, there is the project of *Triesteabbandonata*, a story-telling project composed of photographs and abandoned places descriptions. In this blog the download of the dataset is not allowed, and the places are not located in a map. This experience deserves to be mentioned for the use of a tool such as the photography to describe the phenomenon in a qualitative way and thus renouncing to the comprehensiveness but underling the complexity of the abandonment. The *Coalizione Civica* association has started a census of un-used buildings in Bologna ¹⁴ with the aim to sustain social and cultural operators that are involved in the temporary re-use of abandoned places. The most important goal of the association is a web maps (produced using MyMaps by Google) that allows the download of the data related to more than 400 un-used mapped spaces. Even it is not an “official” dataset and sometimes is unformalized or incomplete, it remains a huge support for the citizens.

The last case is related to the discontinued railways that are a particular category in the galaxy of the abandonment. We are referring to a specific case composed by built materials, open spaces and the physical infrastructure. In particular, the example of *Ferrovie Abbandonate*¹⁵ collects in a non-public or open database the information related to more than 7.500 km of abandoned railways. Since it is a peculiar abandonment category subjected to slow changing or conversion processes there is no need to guarantee a constant updating of this database. After the first collection of information the project is focused on the organization and promotion of cultural events to strengthen the sensitivity for the disused railways enhancement. This case is emblematic both for the multifaceted nature of these spaces and the reasons of the abandonment and for their geographical location. Unlike the previous cases associated with places in large urban areas (Bologna, Trieste and Milan), the abandoned railways concern peri-urban or extra-urban situations.

Observing all the cases mentioned, this contribution developed a comparison that reveals some common points between the experiences. Specifically, the public initiative projects suffer from the lack of a constant update of the information collected. This is the case of the Lombardy Region database but also of similar initiatives such as the regional Umbrian database whose information dates back to 2012 (<http://geo.umbriaterritorio.it>). Sometimes the problem lies in the structure of the data which cannot always be reported on the map easily (i.e. the case of Department of the Treasury), or the data are not enough complete because the surface or the function of the places are missing. This very last point is related to the scale of the project that when is broad could lead to a loss of the detailed information.

For the research and exploration promoted and produced in/by the universities the biggest problem is the impossibility of data reuse by third parties. This has to be added to the lack of information updating as for the institutional projects. Further, the research are characterized by a certain degree of sectoriality so the information are often concerning only one building typology or a single function. It is important to underline that these experiences are able to combine several research methodologies ranging from surveying, to photographic stories, to infographics up to written stories. This means that the contributions made by this researchers and universities are dealing in a correct way the taxonomy of the abandoned places using many tools to understand it.

¹⁴ <https://www.coalizionecivica.it/mappare-territorio-vuoti-urbani-bologna/> (last access in May 2019).

¹⁵ www.ferrovieabbandonate.it/index.php (last access in May 2019).

The temporality seems to be the major characteristic of the bottom-up experiences promoted at local level by associations or informal groups of citizens. Cases like [im]possible living are closed because the association or the promoter of the project fails to build a solid base formed by other citizens who continue in the activities of census and updating (end of funding, closure of associations, etc.). These initiatives are mainly characterized by the precision in the identification of information, as it is the result of a direct knowledge of the cases. Another feature is the scale of analysis usually limited to some areas of specific interest (municipal boundaries, neighborhoods, etc.) since the objective of the project is to reveal problems or giving a voice to citizens who perceive little interest by the institutions. As mentioned, the most important aspect of this category of projects is their collaboration and involvement with the citizens and their knowledge of the places.

So far, the phenomenon of the place abandonment is multiscale and composed by a huge taxonomy of materials. This complexity must be included in the forms of representation and census that need to have a wide degree of flexibility accomplished by using many tools (maps, storytelling, photos, different scales, different actors, etc.). The possibility of updating the data is a crucial issue because the phenomenon is in continuous changing and the possibilities to obtain funds to do the analysis are decreasing. In conclusion, it is important to underline that having an open dataset or a platform that can be flexible, modifiable and adaptable becomes fundamental for this type of project. Moreover, it is essential to promote initiatives to be shared with the citizens and their knowledge in order to involve and empower them.

Open Data and VGI as enabling infrastructure

As mentioned, a key factor, especially for the mapping projects of abandoned places, is the possibility to (re)use and update the information. Unfortunately, many datasets are based on old survey even if their structure and level of detail is complete, complex and rich. An approach that could help in solving this problem is the paradigm of OpenData production: “an information that can be freely accessed, used, modified and shared by anyone and for any purpose, subject to the requirements of origin (attribution request) and opening (sharing in the same way) (Open Knowledge Foundation 2016). Recently, it’s becoming clear the importance of this kind of approach because we are witnessing to a great revolution that involves the territorial information systems. The access to geographic information has drastically changed in the last ten years with the introduction of terms such as Neogeography (Turner 2006), Volunteered Geographic Information (Goodchild 2007) and web-mapping (Plewe 2007). Particularly interesting for this contribution are the Volunteered Geographic Information (VGI). These are georeferenced information coming from collaborative mapping projects that represent the set of geographic information generated and shared by a community of users (Goodchild 2007). Between the most known project we found OpenStreetMap¹⁶ (OSM;<http://www.openstreetmap.org/>) and Wikimapia (<http://wikimapia.org/>) inspired by the Wikipedia approach, Google Map Maker (<https://www.google.com/mapmaker>) and Mapillary

¹⁶ OpenStreetMap is the most widely used collaborative mapping project in the world. It was founded in 2004 with the aim of creating a world-wide map constructed and editable directly by users, freely shared and usable by anyone with an ODbL license (Open Database License).

(<https://www.mapillary.com/>).

The VGI represent an innovation in the panorama of geographic data especially as a potential tool for solving the previously mentioned problem of cartographic material update involving the citizens knowledge. This is important for the public bodies mostly when the official cartography is lacking (Haklay et al. 2014). The constantly modifiable nature of the information characterizes the VGI as a new concept of knowledge: a cartographic representation that puts the "absolute power of the map, which admits neither criticism nor correction" into crisis. (Farinelli, 2003, p. 37). More and more open data-VGI hybrid systems are proving to be the most effective enabling technologies vectors for innovative methods of mapping and enhancement of fragile and abandoned areas. This depends on many different factors but, first of all, on the possibility of interpolating extremely diversified data families coming from sources closely linked to the territory: this allows to make visible parts of that kind of local embedded knowledge that is often hidden or partially forgotten. In other cases the use of local information sources is able to detect elements of the cultural landscape that are abandoned only because they are no longer part of the collective memory or have ended up unused due to an inability to enhance the stratified and lesser-known weave of our territories. The following case study is a very suitable example to understand the need to identify new tools that allow to better identify those 'minor aspects' discussed at the beginning: sometimes 'making visible' is the first concrete step to activate and make possible collective re-use and boost policies.

The case of the Sabbioneta embankment: making fragility visible.

In many cases, territorial fragility is not strongly evident, above all when the texture of the landscape is rich in anthropic, urban and cultural places of great relevance, as in the case of most of the Italian territory. Building awareness and looking in deep at latent fragility also means to focus the great variety of non-outstanding landscapes, according to the interpretation coming from European Landscape Convention, including the so-called everyday landscapes, recognizing them as rich grounds of potential resilience for positive transformations aiming first of all at the quality of life for people.

In order to mitigate weaknesses, while first of all making visible and then boosting non-outstanding landscapes' partially hidden potentials, the importance of open-data based knowledge and awareness actions is increasingly evident both for enhancing and supporting decision-making processes and to promote good practices in the management of the cultural landscape.

A possible example can be represented by the pilot action "Cerchio d'Acqua" (<http://www.amiciambientesabbioneta.it/cerchiodacqua/>), which focused on a network of hydraulic and landscape elements partially abandoned and hidden in the agricultural area around the well-known small city of Sabbioneta. Sabbioneta is a very rare example of walled newly founded renaissance town designed in the late 16th century by duke Vespasiano Gonzaga in northern Italy on a sandy bank of the Po river. Sabbioneta was inscribed in the UNESCO World Heritage List in 2008 also because of its uniqueness in representing the concept of ideal city planning, maintaining a structural relationship with the agricultural and water landscape. The main idea of "Cerchio d'Acqua" action (a 2y. research activity founded by local and regional authorities) is to push the gaze of its citizens outside the superb renaissance walls to recognize and enhance the tiny but important specific elements of the landscape connected to water management as a significant part of the original project of the city. To realize new landscape knowledge and tools designed to map and improve citizens involvement, the project developed an approach aimed at the interaction between different geospatial FOSS (free and open source software): a digital ecosystem that allows to map, visualize, share,

participate.

The first approach involved a detailed OpenStreetMap-based cultural landscape re-mapping. The geo data uploaded to the OpenStreetMap DB enabled the implementation of a brand-new tailored FOSS geo-blogging app designed for the local community use to start shared maintenance processes, landscape self-protection, and achievement of effective recovery and improvement of the water small embankments (arginelli fluviali). The shared boost of the cultural landscape has developed also through collective meetings and walks outside the walls along the huge water embankments system: this is why it was necessary to think about the use of a free web-based tool able of stratifying the 'ways of looking at the landscape' that citizens have experienced during the project: the result is a massive visual survey, inside and outside the town, developed through Mapillary and integrated into the communication channels of the project.

This sort of approach, in addition to making easier and more efficient the integration of very different digital tools may represent a step forward for overcoming some recurring critical issues in local projects of fragile landscape enhancement:

- very often the territorial information sources are ancient, analogical and difficult to find: the digitalization is therefore a primary necessity that cannot be postponed;
- digitize to then re-hide information in closed and proprietary systems generates the same future inconveniences;
- the growing social demand of sustainable cultural tourism around non-outstanding landscapes requires a growing availability of functional, open and updatable datasets;
- the creation of FOSS and open source digital hubs makes it possible to keep local projects alive even after they have ended through an incremental storage of data that can be reused at any time;
- we need to rethink the potential of ICT in a more inclusive perspective in order to better support the bottom up processes of awareness and collective participation, also for this reason the crowd based Wiki-like model continues to be a winning reference.

Community-based planning and social innovation

The self-build housing in Madrid (Spain): 40 years of struggle

Eva Álvarez de Andrés¹

¹ DUyOT-ETSAM, Universidad Politécnica de Madrid (Spain), eva.alvarez@upm.es

Abstract: In a context of increasing commoditization and financialization of housing and the city as a whole, the self-construction of "informal" housing has constituted an alternative in many countries both in the North and in the Global South, however precarious it may be, for those who have been excluded from the "formal" system. Although these forms of production tend to be considered residual in the Global North, they keep creating dissident spaces that interrupt the process of accumulation of capital and challenge the private property, which is one of the fundamental pillars of capitalism.

This article analyzes the policies and actions carried out in Madrid (Spain), from 1978 to 2018, in relation to self-built settlements. This analysis shows how the policies and actions carried out have been determined by the place occupied by the affected community, both physical and social, as well as by the way that community is linked to the rest of the power structures.

Information regarding historical cases has been collected from existing official documentation, as well as through interviews with the actors involved in them. An analysis of current policies has also been carried out through action-research carried out in a self-built settlement for three years. The information collected has been processed through an analytical framework based on the Giddens' approach, with a focus on the role of two key actors: the state and the community (allocative structures and authoritative structures).

It is considered that this work contributes to assess the achievements of innovative community-based practices, such as the *"Plan de Remodelación de Barrios"* as well as the results of such practices in terms of satisfaction of community needs and of deeper structural changes.

Keywords: Social innovation, conflict, space of autonomy, bottom-up processes.

Introduction

UN-Habitat estimated that, by the year 2020, 1.392 million people will live in *"informal"* settlements, double what was estimated in 1990 (UN-Habitat, 2007, Table B3). Housing is an asset that is increasingly inaccessible to the lowest income groups. This has contributed to the development of "alternative" forms of access to land, housing, or basic services such as water or energy, constituting a significant way of building the city (Davis, 2001; Pastrana et al., 2012; Vaccotti, 2017). This model of self-production of space has become, for many people, the only way to access housing or basic services in the city, even in very precarious conditions (Secchi, 2013).

These forms of self-production of space, commonly called "*informal*", have been occurring to a greater or lesser extent throughout history, and highlight how, despite the efforts invested in formalizing urban life and its development, the formal system seems to represent only the tip of the iceberg of a deregulated subsystem, partially regulated or not regulated (Herrle & Fokdal, 2011).

The concept of "*informality*" has been defined and redefined since the 70s. At first it was considered only as an appropriate concept to define the "survival" mode of the urban poor. In the 80s and 90s the term "*informal*" was adopted by experts in housing and planning, and applied to self-produced settlements by low-income communities. Although, studies such as those of Durand-Lasserve & Royston (2002), have highlighted how "*illegality*" has been used as a pretext to carry out massive eviction processes of the most deprived sectors.

From this perspective, more and more authors question the usefulness of the term and put the focus on the need to analyse the phenomenon from its complexity, that is, from a more holistic perspective that allows to link the economic, social and governance factors that make it up (Álvarez et al., 2015; Alfaro et al., 2018). In this sense, Álvarez et al. (2019) affirm that "*informality*" is first and foremost a political question, which has to do with the place it occupies, a certain community, within the social space and the way in which it is linked to the rest of the power structures.

The objective of this article is to analyse the policies carried out in the Community of Madrid (Spain), in relation to self-managed settlements, in the last 40 years (1979-2019). This work has been based on the case study method (Yin 1994) and focuses on the analysis of the patterns of relationship between actors and the way in which this determine access to housing and basic services in the city (Herrle & Fokdal, 2011, Alfaro et al., 2018). To this end, the policies carried out in Madrid against self-induced settlements from 1979 to 2015 have been analysed, as well as the current process of "*dismantling*" one of the last settlements self-managed of the Community of Madrid, Las Sabinas (Móstoles) (2013-2019). It is considered that the comparison of the results obtained, in both cases, helps to show the extent to which the implemented policies have been determined, as Álvarez et al. (2019) affirm, by the social place occupied by a certain community and the way in which is linked to the rest of the power structures.

The article is organized as follows, after this first section of introduction, the results obtained in both cases are presented to finally draw conclusions.

Policies in relation to self-managed settlements in Madrid (1979-2015).

This section briefly presents the context, that gave rise from 1979, to two processes that occurred in parallel: on the one hand, the "Plan de Remodelación de Barrios" (PRB) (1979-1998), as response to the demand of the working class of a decent house, at the beginning of the democratic period, and, on the other, policies aimed to serving of the population considered "marginal" that were planned in parallel to the PRB and that were developed until the closure of the "Instituto de Realojamiento e Integración Social" (IRIS) in 2015.

Context (1936-1979)

At the end of the 50s, as a result of the migratory field-city processes, self-produced settlements accounted for 16.6% of residential land in Madrid (Carmona and Rodríguez, 2007; Lago, 2014). During the Franco period, the administration pursued self-produced settlements and neglected the demand of these families for access to decent housing and basic services, claiming that these were neighbourhoods built "*illegally*" on rustic land. Facing the institutional abandonment, around 300,000 people continued self-building their homes and self-managing their access to basic services. Over the years, these lands were gaining centrality and in 1963, were declared urban land and plans proposals began that, under the pretext of improving hygiene conditions and the urban environment, assumed the eviction of families to new peripheries. In this context the neighbourhood associations and those who supported them, mobilized by rejecting official plans and demanding "*decent*

housing, here and now!". Their struggles were gaining legitimacy and managed to transfer the idea that they should be allowed to remain in the periphery that they had been colonizing.

The "Plan de Remodelación de Barrios" (PRB) (1979-1998)

In 1979, in the context of a recently inaugurated democracy, the PRB, led by the neighbourhood associations, was implemented. The PRB was a process of more than 15 years of negotiations between the actors involved, affected, institutions, technicians, etc. Once finished, had been achieved (Castro & Molina, 1996) the rehoused in-situ 150,000 people in 39,000 houses and, thus, the opportunity for these families to consolidated the efforts invested in their neighbourhoods for decades. The houses were granted under ownership, which allowed families to remain in them over time, since the financing conditions were very favourable (less than 10% of family income).

Although around 3% of the families affected by this process were excluded of the PRB, of these 93% were gypsy families. A community historically, socially and economically discriminated (Montes, 1994). From that moment, the self-managed settlements in Madrid stopped being a generalized problem that affected broad sectors of society and became a problem of "marginal" sectors. In 1984, the Housing Institute of Madrid (IVIMA) aimed at promoting housing ownership for the middle class is created, while a plan to "*control the phenomenon of shantytowns*" was developed.

Housing plans for the "marginal" population (1986-2015)

In 1986, the Consortium for the Relocation of Marginal Population (CRPM) was created with the aim of "*eradicating*" the slums of the city of Madrid (located 87% in the districts of the South-East) and take advantage of the land freed for *the new* urban developments in the city. In the 12 years since the creation of the CRPM, only 35% of those initially involved have been relocated, of which 55% are in neighbourhoods known as "*special types*", that ended up turning into ghettos, or provisional camps that ended up lasting decades. The failure of this experience, as well as conflicts between different levels of administration for the management and development of these processes led in 1998 will close the CRPM and the Institute for Re-housing and Social Integration (IRIS) was created. The IRIS started with the recognition that all families had a right to decent housing and conducted a new census of families who were living in self-managed settlements. According to Nogués (2010), between 1998 and 2006, 43 "*slums*" were "*dismantled*" and 1,223 homes were adjudicated, located 90.5% in the South and South-East of the CAM (in the lower income municipalities). It is estimated that the investment in flats by family relocated was about € 110,000, which was equivalent to a floor in property regime, although the families were relocated on a rental basis. There is no information on whether all the displaced families were relocated or not, although it is known, for example, that between 2005 and 2006, 421 "*slums*" were demolished and 232 families were re-housed, which indicates that at least 55% of them were in those years of the families affected by these "*relocation*" processes were seen on the street without a housing alternative, and forced to "*start from scratch*" in others self-managed settlements such as La Cañada Real or Las Sabinas (Móstoles) that were never included in the censuses of the IRIS. In addition, there is no official information available about how many of the families who were relocated under social rent have been able to stay in the flats, since the payment of housing, community and services entailed 50% and sometimes even 95% of the income of these families. With the outbreak of the crisis in 2007 the situation is only getting worse, the precariousness of the families increases while the administrations are without liquidity, which led to CAM selling, in 2013, around 2,000 social housing to "vulture" funds. According to unofficial sources (El Plural, 20/07/2013), it is considered that the last house delivered to a "*slum*" by IRIS was carried out in 2011. In 2015, it was estimated that around 4,000 families were still living in self-managed settlements in the CAM and the public administration decides to close the IRIS and start up the Social Housing Agency (AVS), integrating in the same agency the IVIMA and the IRIS, two institutions that had been created to respond to the demand of housing, a demand that since the crisis of 2007 had only increased.

In almost three decades, since the creation of the CRPM to the closure of the IRIS (1986-2015), it was observed that, unlike the PRB, these processes were led by public administrations, without participation in the decision-making process of the affected by them. In 30 years, barely relocated to 4,000 families, 10% of those who were rehoused in half the time in the PRB, these rehousing not only were not in-situ but in 90% the homes granted were located in the South-East periphery of the CAM (in the municipalities with the lowest incomes). In addition, the houses were granted on a rental basis, with no public information on how many of the families affected by these processes were left out of the rehousing and how many remain today in the flats in which they were rehoused. The analysis of the current relocation process of the Sabinas (Móstoles), which is presented below, is carried out, among other things, in order to clarify what happens with these issues in a relocation process.

Policies in relation to self-managed settlements in Madrid (2015-2019): The case of Sabinas (Móstoles).

In 2015, the AVS inherits from the IRIS the relocation agreement, signed between CAM and the municipality of Móstoles, from the settlement of the Sabinas. A neighbourhood located in the path of the Guadarrama River, along 4 cores (2 in Móstoles and 2 in Arroyo Molinos), which have been self-managed for decades and which is estimated to comprise some 375 families.

After decades of institutional abandonment in which families have to self-manage their access to water, energy, and live without waste collection service, without access to public transport, etc. Finally, in 2013 the relocated agreement was signed. This agreement establishes the obligations of the two administrations involved (financial contributions, actions to be developed, etc.), as well as the requirements that families must meet to be rehoused, among which is set: a minimum registration of 5 years in the town and not having been awarded public housing in the last 20 years. According to the information provided by the social services of Móstoles, at the time of signing the agreement 45% of those affected by it does not meet the requirements, so the alleged "*relocation*" process implies the "eviction" without any housing alternative for these families, something that goes against Article 47 of the Spanish Constitution.

Although the agreement is signed in 2013, the "*relocation*" process does not begin until 2018. This delay is due, among other things, to the fact that the municipality does not provide the corresponding funds until 2015, and although the families suffer the consequences of 5 more years living in precariousness and uncertainty, there is no consequence for breach of it for the respective administrations. In addition, when the AVS starts the relocation, it maintains the requirements established in 2013, so in practice a 10-year census is required and not 5 as established by the Decree approved in 2018 by the AVS. On the other hand, so far the agreement has been carried out exclusively, in only one of the four nuclei, which is inhabited by 90% by gypsy families from other self-managed settlements from which they were evicted without any alternative housing. In this neighbourhood of 100 families, 50% do not meet the requirements established in the agreement (the majority does not comply with the registration requirement, despite the fact that almost all of them have been in the neighbourhood for more than 5 years), while, no any alternative being foreseen for this families. From the information available it is known that 40 homes have been granted under social rent, 84% located in the South-East of Madrid, about 50 km from the centre. Of these, at least 20% have been rejected or are in the process of doing so due to a break with their social fabric, distance or the impossibility of facing the payments that sometimes involve up to 100% of family income.

In the case of Las Sabinas (Móstoles) the results obtained show how once again the plans for the population considered "*marginal*" have been carried out without the participation of the people affected in the decision-making processes. This has led to the fact that despite the fact that more than 5 million euros have been invested, they have been used inefficiently and inefficiently. The administration continues to blame the "*victims*" without questioning their mismanagement and their inability to sit down and negotiate the process with the people affected by it.

At present, there is still no precise census of how many families live in self-managed settlements in the CAM or in occupied dwellings. Given the lack of effective response from administrations and the context of housing emergency in Spain (Gutiérrez, 2018), it is expected that "*informality*" will continue to increase.

Conclusions

The objective of this article is to analyse the policies carried out in the Community of Madrid (Spain), in relation to self-managed settlements, in the last 40 years (1979-2019). This work has been based on the case study method (Yin 1994) and focuses on the analysis of the patterns of relationship between actors and the way in which this determine access to housing and basic services in the city (Herrle & Fokdal, 2011, Alfaro et al., 2018). To this end, the policies carried out in Madrid against self- induced settlements from 1979 to 2015 have been analysed, as well as the current process of "*dismantling*" one of the last settlements self-managed of the Community of Madrid, Las Sabinas (Móstoles) (2013-2019).

- The analysis of the PRB, has shown how a process led by those affected achieved the relocation in-situ of 150,000 people in 39,000 homes granted under ownership and under very advantageous financing conditions (close to 10% of family income). that has allowed these families to consolidate the efforts invested over the years.
- However, this process leaves out just 3% of the population, in a 93% gipsy population, a historically discriminated community (Montes, 1994). Since then, the self-managed settlements in Madrid have become a problem of "*marginal*" sectors.
- Since then, all of them, the CRPM (1986-1998) and the IRIS (1998-2015), as well as the AVS (2015-current), have excluded those affected from the decision-making process. This has meant that in more than three decades the 10% of the population that relocated to the PRB has barely been relocated in just 15 years. Of the current process in the Sabinas is also observed that the "*relocated*" process, is foreseen without housing alternative for the 40% of those affected, something that goes against Article 47 of the Spanish Constitution itself. In all cases in which housing has been granted, this has been on a social rental sistem, representing between 50% and 100% of the income for some families. In addition, the houses have been granted each time in peripheries furthest from the centre.

In short, the comparison of the results obtained helps to show the extent to which the implemented policies have been determined, as Álvarez et al. (2019) affirm, because of the place a community occupies within the social space and the way of linking that they achieve to generate.

Finally, note that although the results obtained in this research are context-dependent, it is considered that similar results could be obtained in other cases in similar conditions of violation of rights and unequal power relations.

New roles for Administrations, Planners and Citizens in the Self-organization view

Chiara Belingardi¹

¹DICEA, Sapienza Università di Roma, chiara.belingardi@uniroma1.it

Abstract: In contemporary debate about citizens self-organization it emerges the ambiguous role of practices, and policies in response. These can create a new way to intending the city through the creation of new institutions, or commodifies and privatize social services. Some of these practices can be de facto an enclosure to a close community of people, while others can provide public services as or more effective than the institutional ones (Cellamare, 2012). Using the category of spatial justice as a framework to read the practices of self-organization and the policies linked with them can provide some tools. Spatial justice can provide some questions regarding openness and fairness (Soja, 2010; Falco, 1978). About the right to the city, it is possible to use it as a category for trying to understand how citizens are involved in the design of the city as a whole (Lefebvre, 1968; Harvey, 2012). Both of them can generate a number of single groups of citizens and single spaces or can create synergies with effects among every part of the city. Citizens self-organization left some questions un-answered: about the role of public administration, especially if practices step over legal / illegal border and recall the concept of justice.

Keywords: citizens self-organization, spatial justice, right to the city, new institutions

Introduction

The paper compares two municipal policies, aiming to regulate citizens self-organization: the law n. 446/2016 of the city of Naples *Identification of spaces of civic relevance to be inscribed in the category of Commons* and the *Guidelines for the cooperation among citizens and administration for care and regeneration of Commons* approved by the city of Bologna in 2014.

These deliberations are interesting to be compared as they are an attempt to regulate citizens participation and self-organization, but produces different results, in terms of freedom for the citizens in acting / self-regulating / organize themselves, in terms of the role they design for citizens and public administrations, in terms of promotion of the right to the city and generation of spatial justice. The two policies result from different social contexts, political interactions and historical moments.

The *Guidelines for the cooperation among citizens and administration for care and regeneration of Commons*, approved by the city of Bologna in 2014, aim to create a legal framework to let citizens take care and manage public places (both buildings and open air). These civic spaces are here named Commons. The Guidelines are the result of a participatory process. In the process, taken as case study, four groups of citizens asked and obtained spaces to take care of. LABSUS (an association of professionals with the aim of promoting citizens participation) followed the process to help in solving problems faced by citizens and administration. Another objective of the Guidelines is to ease the cleaning of the historical porticoes that characterize the city's historical centre: as the porticoes are protected as historical goods, normal people couldn't make any interventions, even for their maintenance.

The law 446/2016 of the city of Naples is the last of seven public acts that the city of Naples produced to recognize and safeguard the Commons (intended here as the output of social interactions) from privatisation. The laws are the results of a long participatory process carried out especially with people involved in the creation and government of the commons (the community), and other citizens. The laws aim to design new regulations to recognize the plurality and the mutability of the community governing of commons.

The paper compare the two policies, through the framework provided by the concepts of spatial justice and right to the city. This is a theoretical paper, so it won't deal with case-studies. The aim of the paper is to compare the municipal laws and to define if right to the city and spatial justice could be tools to evaluate policies. Case studies are intended as the most important part in the evaluation of policies. On the other hand, it is useful to have some tools to evaluate policies before their approval.

Spatial Justice is intended here as the social wellbeing produced through the set of spatial elements that influence everyday life. Space is not an unmodifiable element in the human experience, but as an element which can improve or worsen life conditions by its modifications. In this sense Spatial Justice is strictly connected with the *Right to the City*, intended as the right of people to manipulate the urban space in function of the society they want to live in (Harvey, 2008).

The contribution is organized as follow: the first part will describe the concepts of Right to the City and Spatial Justice. The second part will describes the two policies, their conditions and context and their outputs. The third part will compare the policies, in terms of consequences, power and distribution of responsibility among citizens and institutions. The conclusion will put what emerges through the comparison in relationship with the concepts of spatial justice and right to the city, to see how the policies generates or go against the two.

Spatial Justice and Right to the city

Spatial Justice and Right to the City are political concepts: it is not possible to give a definition of both without explicit a standpoint (Fainstein, 2010). In particular the Right to the City can have different definitions, more or less radical.

Spatial Justice regards the spatial and environmental items that contribute to or generate social justice (Soja, 2010). In this field it is possible to remember the human factor, as pointed out by Harvey in *Social justice and the city* (1973): people with higher incomes or higher instructions have more chance of enjoy amenities. On the other hand the perception of the value of facilities and public services can change depending on the everyday life. The creation of amenities is strictly connected with the use of the buildings. In this paper social and Spatial Justice is intended as a responsibility of Public Institutions, in a political arena.

The Right to the City can have different meanings. Since its formulation, in 1968 (Lefebvre, 1968) the concept had two possible interpretations: a radical one, meaning the right to change the city to reach an environment more just, pleasant and democratic. This should be achieved through the direct action of citizens, supposed as equally participant in the building of a new city and a new society (Lefebvre, 1968; Stanek, 2011; Mayer, 2012). The second interpretation is less radical, meaning the right of citizens to access the services a city can offer. Both way are a claim toward a more just society. The difference is in the deepening of the changes that are intended to be needed to achieve a just society in a just city: for the last interpretation, citizens are intended as users, while for the first one they are intended as builders/creators. In this paper the Right to the City is intended as the right to build the city as the society people want to live in, giving the city as the physical image of the society (Harvey, 2008).

People often take the urban environment as a backdrop. Since it hardly changes with the same fluidity as other elements of daily life, it is perceived as fixed. Narratives about urban development and changes often are around great projects. The consequence is that people have little regard for spatial justice and it is an unusual category

in the demands of social justice. Notwithstanding public space is perceived in general as a main part of the public sphere. So its privatization, or the denial of access and free use of it to groups of people can be intended as an impoverishment of the democratic life in general (Bollier, 2014), and an act of injustice.

Yet there are many space-dependent factors that affect daily lives (Soja, 2010): paths people have to do to reach points of interest, accessibility of spaces and their use for collective purposes, quality and quantity of urban amenities and services people have near their houses. All of these factors contribute to form part of what can be defined as indirect income (the possibility of people to have a good quality of life using public services instead of personal incomes), especially when it comes to the quality and quantity of public services available near home. However, with regard equipments, it should be noted that their presence is not enough: to be able to enjoy certain conditions are necessary. David Harvey in *Social Justice and the City* (1973) call them *amenities* and says that they are individuals who have a higher income or more capacity can more easily enjoy them. Luigi Falco in *Gli standard urbanistici* (1978) points out how important the equal distribution of public services on the city territory is, as it is difficult for people of popular classes to reach them. Therefore, the distribution of high quality public services within urban areas contributes to the rebalancing (or imbalance) of the quality of urban life – the quality of everyday life among citizens. The same can be said about accessing and using public spaces (both in the open and in the buildings) to spend leisure time, organize collective activities, recreate or do political activity.

Due to the diffusion of neoliberal policies and the welfare state crisis, there is a progressive reduction in public services in terms of quality and quantity. As a result, people are increasingly forced to use their own resources to satisfy their needs. These resources can be both economical or social ones. The results can be very different. On the one hand, for example, there is the creation of public policies from the bottom (Paba, 2010), which have a positive impact on the society as a whole. On the other hand there can be created practices of closures, dependency, privatization. The main problem in both cases is the exclusion of people who don't have resources, neither economical, nor social ones. The very excluded are to remain excluded.

To give an example of the difference among the different practices, it is possible to refer to the practices about the recovering of urban spaces. Facing the erosion of the public care of spaces and gardens (as public administration can use less resources in hiring people for these kinds of job), we see the flourishing of re-appropriation practices such as those of community gardens, or phenomena like *Retakers*, or *Angeli del Bello*. These groups mainly organize themselves around the necessity of cleanness of the urban environment. So they organize days in which invite citizens to clean streets, walls, gardens, and public spaces in general. In their cleaning desire, they include also wall paintings and street art. And urban populations that create disorder, like homeless, mendicants, hawkers, and so on.

But where creative space-sharing practices are established, which actually produce an increase in the quality of life for the neighbourhood, it is possible to talk about the creation of commons. According to Harvey in *Rebel Cities* (2012): *The common is not, therefore, something that existed once upon a time that has since been lost, but something that is, like the urban commons, continuously being produced. The problem is that it is just a continuously being enclosed and appropriated by capital in its commodified and monetized form, even as it is being continuously produced by collective labour.* (ivi, p. 77).

Comparing these two examples of ways in which citizens intervene in urban spaces, it is possible to see some ambiguities in people interventions and involvements. For this reason, in this paper it is proposed to use some tools or framework as guidelines to see the practices. Also it is important to explicit the point from which the practices are observed.

Bologna: “Guidelines for the cooperation among citizens and administration for care and regenerations of commons” (2014)

These Guidelines were approved by the city of Bologna in 2014. They were written in cooperation between the Public Administration of Bologna and LabSus, an association created to promote the idea of subsidiarity, intended as cooperation between citizens and Administration in the management of urban spaces and public services. The core of the Guidelines are the Collaboration Agreements, which are subscribed between Active Citizens and Public Administration. These agreements are conceived as a tool to give citizens more possibilities of acting in line with the general interest, but are not really innovative in the distribution of power or responsibility among the actors. In general, Active Citizens have the responsibility of taking care of a civic good (a building, a garden, ...): they have the responsibility of management, cleaning and little maintenances. To make changes or going over these boundaries (e.g. self-building of furniture, adaptation of the space, self-representation in the space – Pasquali, 2008) they have to ask permission, following the same rules of public spaces (professional design, buying furnitures, security controls). In some cases citizens have to insure their activities with a private company, using their own money. In a case of conflict between Active Citizens and Municipality, the second will have the final word.

The agreements signed among citizens and administration contain:

- a) the objectives of the collaboration;
- b) the duration of the collaboration;
- c) the modes of the collaboration, the roles of the subjects, the reciprocal commitments and the limits;
- d) the modality of the collective fruition of the common;
- e) the consequences of eventual damages and the insurance;
- f) the guarantees against damage;
- g) supports given by the City to active citizens (including the eventual coverage of the insurance costs);
- h-m) other things as the supports of communal employees, the publicity of the agreement, the property of the furnitures and other objects.

From the spatial point of view it is important to note that the changes that active citizens can make to the space, as well as furnitures they want to put in, to use it best or to adapt the space to their exigences or to express themselves, are subject to the same rules as the ones to make in the classic public spaces. There is the need of a professional design even for minor changes. Active citizens cannot self-build, but they can find the money by fundraising. In case of damages, the responsibility is in charge of citizens.

Moreover the document indicates that the city promote the social innovation and the creation of collaborative social services. The public administration considers its buildings and spaces as resources for collaborative services and urban creativity.

Naples: “individuation of spaces of civic relevance to be inscribed in the category of Commons” (2016)

The four Deliberations of the City of Naples are the result of a long participatory process: a dialogue between the Municipality and the people involved in the care and government of abandoned places, which were recognized as common and appropriate by the community. In particular the City recognize the existence of some places which are characterized by frequent and lively social interactions, intergenerational solidarity, innovation, common elaboration of thinking and deep roots in the territory.

The fourth Deliberation (the last one), approved in 2016, says: *In the municipal territory, certain buildings and / or areas owned by the Municipality of Naples that are currently used by groups and / or committees of citizens according to logic of experimentation of the direct management of public spaces, thereby demonstrating in such a way that they perceive them goods as places that can be used collectively for the benefit of the local community, experiences that in their factual expression have been configured as "Houses of the People", places*

of strong sociality, elaboration of thought, intergenerational solidarity and deep roots in the territory. Thus the law identifies two paths for the management of these buildings: the first one is the entrustment of the building/space to a well-defined legal entity following an agreed management plan; the second one is based on the recognition of that good as civic and collective use (a sort of renewal of a traditional Italian institute for collective properties and commons).

The second institute appears more interesting. It can be classified as a retro-innovation: the renewal of an ancient use in a contemporary framework. In Italy (as in other parts of the World) the “civic uses” are an historical institute in which are formalized the collective properties and the collective rules of management (and use) of common goods. Most of the civic uses that are currently still existing are localized in the countryside, but there are many traces of commons even in the urban spaces (urban spaces used as commons. See Belingardi, 2015; Rao, 2008; Kelly, 2011). The innovation of the Naples’s deliberation is the fact that this policies distribute the responsibility of management and care of a civic to an informal group of people, recognizing that they have the interest in take care of it (as demonstrated by Elinor Ostrom, 1990), commons are the best way to preserve a good, by using it).

While the Guidelines of Bologna are criticized for not taking in account of the existing practices, because their design was based on new experiences, a limit of these policies can be found in the opposite. The dialogue is among the city’s administration and existing practices already stables (as they can be). The deliberations consist in the recognition of commons already created by a community, without taking in account practices that are at the beginning, or commons that are still to be recognized, but have the potentiality.

Anyway the publicness of commons, their connections in the social tissue of the city, can inspire more communities in taking action. One of the characteristics listed by Paba in his description of the *public policies from the bottom* (Paba, 2010), is: “*si diffondono (e mutano nella diffusione) per disseminazione, gemmazione, contagio, imitazione - adattamento, proliferazione orizzontale*” (ivi, p. 108). Moreover in some cases the absence of rules, even if is perceived like the absence of a guidance, can be a help for a community to find its own way of self-organizing.

Comparing the policies

After this brief description of the two policies, here is presented a comparison of the both, based on three different items: the decision (meaning who decide that a place is a common), the resources (meaning how are found the resource for its management), the govern (meaning who decide about the rules for governing the common).

1. The decision: who decide that a place is a common?

Answering this question means to answer a more general question about the power of self-determination of a practice and the power inhabitants have in the general plan of the city, or in the decision about urban spaces.

In the Bologna's Guidelines the decision is in charge of the public administration: there is a City Committee that periodically identifies among the assets of the City some places (buildings or open air) in partial or total disuse or deterioration which are liable for care and regeneration interventions to be realized through partnerships between citizens and the municipality. The liability is based on location, structural and functional destination. The Guidelines indicate the possibility for active citizens to choose the building or space to take care of, but it is not clear under which conditions the public administration will accept.

The policies of Naples indicate as “commons” building or areas used by citizens accordingly: is the use, the “experimentation” made by groups of citizens that gives the status to the space. So the City recognize the practices as they exists, and don't determinate the citizens actions before. The policies descend by the current

debate about commons at international level. In particular the debate is about the essence of commons. This is due to the fact that different authors and disciplines have different definitions (Belingardi, 2015). Currently most of the theorists agree in saying that is the community action of government to give to an asset the status of “common” (Giardini, 2010; Mattei, 2011; Dardot and Laval, 2015). In particular Dardot and Laval (2015) in their definitions of “common goods” (biens communs in french) wrote that the use of a good (communs) is so much important that the lemma can easily loose the “good”. As already said this can represent a problem in the moment of creating a common, because the process of creation can imply the illegal appropriation of a building (as it is demonstrate by the stories of the ones already declared commons by the Administration). On the other hand, if the community has the duty of the recognition by acting accordingly, this cannot be assumed by the public administration.

From a general point of view, the Guidelines started with four cases, but since 2014 have been signed more than 110 agreements between the public administration and active citizens. Some of them are already finished, and some other were about cultural actions (performance, readings,...) or one-day actions of cleaning which doesn't concern recovering or maintaining specific areas or buildings.

The Naples' policy recognize seven building as commons. It is not clear if there will be other deliberations to recognize other practices, that can start in the future or are already running but are not included in the list. Surely there are some other practices which strive to be recognize as common.

2. Money and work: who gives resources for caring a common?

The Bologna's Guidelines indicate that the Municipality can contributes to covering the costs incurred in carrying out the care or regeneration actions of urban commons. Among these costs can be included the design, the fee of professionals, the (private) insurance (in some cases) and other costs that cannot be covered trough the municipal assets (tools, workers, or other). One of the objectives of the Guidelines is maintaining a good urban environment with a minor cost for the public administration, so they encourage active citizens' fundraising. The municipality facilitates citizens' initiatives to raise funds for the care or regeneration of urban commons, guaranteeing transparency on the destination of the money collected and on their timely use. In the agreement it can be planned a variable commitment mechanism of municipal resources, increasing with the growth of resources earned by active citizens.

The Municipal policies of Naples poses the question of the economical valorization in a wider framework: the aim of governing a commons is not in the practices itself but in the general repercussion in term of social and cultural services the governments generates. The policy therefore says that the public administration is committed in finding through participative procedures way to generate income to sustain economically the recover and the government of the commons. To be precise, the policy indicate the activities as commons, and the building as the civic environment that host the development of the common. For this purpose it is possible to search and find new way of innovative financing (e.g. crowdfunding, fundraising, ...).

3. who govern the common and take the decisions / what commoners – active citizens can do

The Bologna Guidelines indicate that the management of the commons will be planned in the agreement. Active citizens are allowed to do what is contained in the agreement. Differences and changes in the management or in the care of the space could generate the interruption of the agreement by the administration. Also active citizens are not allowed to make any change in the space without authorization. All the actions of care are decided in the agreement and it is not clear how active citizens or public administration can talk about any changes that is needed. The absence of such a space is quite important: as the whole policy is based on citizens volunteering, the actions of caring and managing can be guaranteed only in presence of time and competences of people, that can change (while can change the everyday life conditions of active citizens).

The institute of civic use of the Naples' policies gives the control on the space to the commoners: people who use it, care about it, and govern it. This kind of control is not like the absolute property right conceived in the age of the Enlightenment: commoners don't have the right to destroy, damage, dismiss or sale the common. In this framework, they can act as they collectively decide, also basing of availability and competences and life conditions of the commoners.

The comparison here is only roughly outlined. For a deeper analysis of the two policies more items and characteristics should be compared. Overall it would be necessary to study the effects of the policies, the practices that generate, and for this a deeper analysis is needed. However the purpose of the paper is a theoretical comparison.

For a final comparison the two policies are analysed in terms of generation of Spatial Justice and Right to the City.

Using the category of spatial justice as a framework to read the practices of self-organization and the policies linked with them can provide some tools. Spatial Justice can provide some questions regarding openness and fairness. These questions could be: are people increasing or reducing the spaces they can freely use? Are people increasing or reducing the places in which they can create community (as these spaces can be both public spaces, or collective/commons spaces)? Are people increasing or reducing the time to travel from their home to points of interest (including public services, cultural services, recreational and common places, public spaces,...)? The two policies take in account the spatial distribution of the practices?

Both the policies here presented point to the recovery and sharing of abandoned or unused spaces (and in this sense can facilitate the access to the spaces for citizens). The openness of the spaces will mostly depend by the practices. The Bologna Guidelines tends to individuate a defined group of people to care the commons, while the Naples policies tend to spread to an undefined community the action of *commoning*. On the other hand Naples' policies explicitly talk about strong and lively social interactions, intergenerational solidarity and so on, as characteristics for a practice to be recognized as common. In this sense it is possible to say that the last one is a policy that guarantees more Spatial Justice than the first one. Spatial distribution of the commons is not taken in account by the policies, even if it is possible to say that in general the increasing of places that can be used by citizens foster Spatial Justice.

About the Right to the City, it is possible to use it as a category for trying to understand how commoners and/or active citizens are involved in the design of the city as a whole. Both of them (citizens and commoners) can generate a number of singles practices and singles spaces or can create synergies with effects among every part of the city. The questions emerging from the Right to the City issue could be: how many practices and how many people are involved both as protagonists or user of the spaces? Which is the role citizens have in the modelling of the rules to govern/take care of the common? Are active citizens/commoners intended as privileged actors in the design of the city as a whole? Which is the role citizens, active citizens and commoners have in the govern of public spaces and in the planning of the city in general?

The answers to such numerous questions can vary quite a lot depending on the openness of the city administration and its objectives and policies; also they can vary depending on the strength of the practices and their ability to build network.

About the two policies here presented, it is possible to note that the number of Agreements of Bologna is higher than the number of Commons of Naples. But it has to be taken in account that the Agreements can have a short duration (even only a day), while the Neapolitan Commons are intended to last for a long time. About the design of the city in general, it is not mentioned in the two policies, but the Neapolitan one was designed through a dialogue between citizens and administration, while the one of Bologna was the result of a participatory process,

that involved only four practices. The results of both in terms of spreading the practices and the management of public spaces in general should be seen in the future.

Conclusion

In the paper are compared two municipal policies about self-organization of citizen. The comparison evidences some difference in the philosophy of the policies and in the conception of the action of citizens. To evaluate the policies in deepen it is necessary to compare the effect they will have and the practices they allowed and created. Finally the comparison of the two policies is interesting in how they understand the role of (active) citizens and public administration, and the self-organizing practices.

In the Bologna Guidelines active citizens self-organize themselves in order to help the public administration in the management of public spaces. So their role don't go beyond the help needed, nor in the sense of choosing and commoning the space, neither in the sense of a broader participation in the design of the whole city.

In the Neapolitan laws citizens are intended as the ones who recognize a place as a common and act in consequence, so they have the responsibility of the action. The policy doesn't go beyond the singles practices, to a wider view.

In the contemporary debate about citizens self-organization it emerge the ambiguous role of the practices, and policies in response. They can create a new way to intending the city trough the creation of new institution, or they can commodifies and privatize social services, even if there are gift relationships among people involved in the practices. Some of these practices can be de facto an enclosure to a close community of people, while others can provide public services as or more effective than the public ones (Cellamare, 2012).

Spatial Justice and Right to the City may provide some tool, mainly as questions, as guidance in order to critically read practices and policies of self-organization.

Territorial conflicts in metropolitan areas. A regeneration project for the resurgence of a community

Elisa Caruso¹, Valeria Lingua²,

²*Department of Architectural – University of Florence, valeria.lingua@unifi.it*

Abstract: These guidelines provide instructions to format your full paper. The process of political and administrative rescaling affecting Italian cities and regions under the Law 56/2014, with the consequent establishment of metropolitan cities, has triggered new forms of territorial conflicts. In this paper, conflicts have risen to a privileged observatory to investigate government problems at the regional scale and to identify possible ways for an inclusive governance of Metropolitan territory. The main purpose is to propose a reflection on the territorial conflicts about metropolitan identity and on the role of the small villages in the promotion of forms of aggregation with a bottom up approach, as resource for the strategic government of the territory and the management of territorial conflicts (Lingua, Putilli, 2017). Focus of this paper is a case study concerning a process of empowerment of a group of citizens engaged in the promotion of a local project that has become a pilot project of regeneration of community places in the frame of the Strategic Metropolitan Plan of Florence. A tiny group of citizen who shared the same common destiny for absence of a connection with the municipal water supply chain. Instead of carrying out a territorial protest and they become an identity movement and, through the recognition of the patrimonial value of places, engaged a multiactorial and multiscalar renewal project aimed to the rebirth of the local community. The joint effort for the self-construction of the lacing of the aqueduct has become the kick off for the realization of an integrated project for the requalification of the complex of Sant'Angelo Vico L'Abate as a place of religious aggregation, social and producer of wealth and new economies. The contribution deals with the reconsideration of territorial conflicts in regional cities as a strategic action for the interaction between local and metropolitan institutions and, above all, as a strong point for enhancing governance at the regional level (Mariano, 2012) for the construction of a shared vision for development of actual and future of the Metropolitan city.

Keywords: participation; conflict; bottom-up processes; inclusive capacity.

Contemporary geographies of vast area

The recent configuration of local authorities, which began in the 1990's, has opened up new institutional, socio-economic and urban considerations. The fragmented reality of the Italian territory and the plurality of urban plans no longer corresponding to the real processes of metropolization (Mariano, 2012), have made additional policies necessary to support the political-administrative rescaling of the territories. One among all the implementation of Law 56/2014, which redesigns the boundaries and competences of local administrations regulating unions and mergers of municipalities

and providing for the establishment of metropolitan cities¹ without calling into question the definition of their boundaries and imposing a new geography of the institutions. This imposition, characterized mainly by the disinterest of political and civil society, is concretizing a process of territorial reorganization «which could also jeopardize the very spatial configuration of the Regions» (De Luca, Moccia, 2017).

The process of structuring, still evolving and with obvious repercussions on the genesis of new forms of conflict, requires some reflection on the ability to promote a metropolitan culture and a shared vision of the vast area. The new metropolitan dimension, in fact, does not seem to belong to the inhabitants who, instead, through the rediscovery of a sense of belonging to the places claim sovereignty over their own territory.

The forms of conflict have assumed a role from which one cannot prescind in the territorial geography and in the planning of vast area, in particular, during the last few years a phenomenon of micro-has been observed growing conflict (Fregolent, 2014) calling for an active involvement in the choices regarding the transformations of the territory.

The increasing number of conflicts requires for a symmetrical reflection on the social dynamics triggered by the processes of political-administrative rescaling of the territories of vast area and on the resumption of civic activism to microscale.

The two reflections are closely linked by two key elements: the crisis of representative democracy on the one hand and the emergence of new territorial conflicts linked to the territory on the other.

A new narrative of territorial conflicts

The point of view taken in this paper focuses on how territorial defined conflicts, characterized by a transversality of issues, can represent a privileged observatory (Puttilli, Lingua, 2017) to understand its dynamics and identify the policy for an inclusive governance of the metropolitan territory.

The characteristic feature of territorial conflicts, which have grown considerably compared to social conflicts, consists of a community that defends the territory and the living spaces from external aggressions (Bobbio, 1999). The causes of such conflicts are many and can be summarised as follows: increased environmental awareness; lack of strategic planning; the growing fragmentation of society and the crisis of representative democracy.

Recent years have seen an increase in media debates on climate change, one of which was the recent Global Climate Strike For Future movement, have contributed to the greater diffusion of the environmental theme and the adoption of more respectful personal behaviors towards the environment, increasing the desire to live in areas with higher quality of life. The flight from urban centers to the inner areas, a trend that sees many young people with a medium-level of education - high, can be traced back to the explanation of the proliferation of local conflicts of identity.

It can be noted that these are no longer environmental protests, but new forms of protest that tend to deal with issues related to the defence of the territory, of the landscape and of the historical and cultural heritage with a view to safeguarding and putting into value the common and collective good.

Luigi Bobbio (2011) explores the multiplicity of territorial conflicts by identifying six types of interpretation and describing the possible actions to be taken.

The first narrative highlights the development of local particularism that goes to hinder the satisfaction of the general interest and takes the epithet of nimby; the second one called agitation, emphasises the real object of the protest and the interests behind it; the third article examines the conflict caused by a disproportion between costs and benefits and sets as its object the sacrifices that a community has to suffer unjustly; the fourth interpretation argues that the conflict results from unacceptable risks (risks to health, the environment, safety, quality of life); the fifth, called places against flows, maintains that protests are triggered when a community with a strong local identity feels attacked; The sixth, finally, moves completely away from nimby logic and interprets territorial conflicts as a reaction to the new model of dominant development.

¹ With the Law 56/2014 the Metropolitan City becomes a large-area institutional reality with a statute governing its functioning, strategic functions, planning and programming.

In order to understand the nature of such conflicts, it is appropriate to take into account the different dimensions through which they can be examined and to give them a separate interpretation. The research path stems from the analysis of one of these interpretations in particular that on the places against the flows, characterized by the ability to transform the protest into a local identity and which has as its real object the contention of the sovereignty of the places.

The democracy claimed by the opponents, as interpreted in the narrative, is characterized by a micro scale in which the protest has the capacity to strengthen or even generate local identities, contrasting in a clear way the “we” to the “their” (Della Porta and Piazza 2008, Fedi and Mannarini 2018).

In this context, it is necessary to highlight the conditions of malaise (Fregolent, 2014) of active citizenship that with voice capacity defends the right to common goods, identity and sovereignty of places, thus declining the narrative described by Bobbio in a form of territorial conflict with an identity character.

In Italy there is a belated attitude characterized by a negative approach to conflict situations, without grasping the advantageous aspects contained in the conflict. Situations that are usually associated with citizens' committees or nimby groups, identified as opponents or as «subjects of participation against» (Gelli, 2014), rather than as subjects of effective participation.

In contrast, current pathways undertaken by committees or active citizenship groups are increasingly resorting to activities that produce both knowledge and mobilisation of social capital resources and propose, through their local animations, ideas and alternatives. Their capacity to form networks and to work on a supra-local scale, to raise their level of political and cultural awareness and to involve experts capable of providing counter-measures projects, implements their effectiveness as well as their innovative potential and the ability to positively affect policy design (Paba, 2009).

In order not to reduce the debate to a simplified vision, and to understand its dynamics, it is necessary to analyse conflicts taking into account simultaneously the multiple dimensions through which they can be examined (Bobbio, 2011). According to the narrative supported in this contribution, it is difficult and reductive to demonstrate a specialization of conflicts because they belong only to the social, environmental sphere or to the mere territorial localization.

This narrative proposes the recognition of identity conflicts understood as complex conflicts with social, environmental and local dynamics that intersect. Characterized and represented by contrasts for the re-appropriation of spaces and places of life, for the claim of the right to civic uses and for the re-appropriation of territories and uncultivated lands.

Currently there are many identity bottom-up experiences active on the territory; all are in fact and separately cooperating to build a more advanced generation of forms of local development self-sustainable (Dematteis, Magnaghi, 2016).

Starting from this assumption it is useful to interpret the conflict as a tool of participation, kick off of an empowerment path put at work to enrich the panorama of available options (Giusti, 1998).

Taken this point of view, the paper puts the reflection on how the innovative forms of community - which spring from an active and conflictual citizenship, analyzing how essential traits the genesis and evolution - promote integrated territorial projects using asset values as policy tools.

These are groups of communities capable of mobilizing socio-territorial energies for the defence and valorization of the peculiarities of the places and able to indicate alternative projects and, through the collective use of the good, research forms of social management of the good itself and of the territory.

In this perspective it is useful to seek forms of community in which the citizens, initially animated by a common discomfort, direct the conflict towards the production of counter-projects actively mobilizing to give course to different proposals (Calvaresi, Pacchi, Zanoni, 2015), generating a dense network of collaborations and synergies.

The argument is that the micro stories born from conflictual situations, which have initiated a process of collective learning to defend the common good as a value of identity, are the precondition for the formulation of alternative development models and the promotion of territorial inclusive governance with visioning capacity.

The empowerment path as an essential trait

The evolution of the conflict of identity in this session of the contribution takes the main focus. The innovative character of the narrative resides, in fact, in the process of collective learning generated by conflicting situations. Process that triggers the awareness of the inhabitants of the patrimonial values of their territory by starting the reconstruction of collective knowledge for the care and enhancement

of the places of life (Magnaghi, 2012) and moving from a position of opposition to a proactive attitude.

The conflict is thus interpreted as a growth of consciousness of place which, acquired through a path of cultural transformation of the inhabitants, is able to reconstruct the elements of community in relational and solidarity forms and to induce alternative actions. In this way, the conflict takes on a new explicit character, in that it is recognized as a producer of community.

The empowerment path can be summarized in three essential phases: 1) the genesis of the conflict situation; 2) the aggregation of a small group of people who share the same discomfort situation; 3) the production of knowledge and opposition activity on the territory with voice capacity. Once reached the final phase of the path, through the formation of new networks and synergies, the group passes from the local to the supra-local scale, thus triggering the switch from subjects of the participation against, to subjects of proactive participation.

As the group expands and networks between associations and active citizenship groups are developed, the multidisciplinary dialogue also involves experts capable of providing counter – links projects and alternative ways of linking contextual knowledge with expert knowledge. Expertise is frequently found among research bodies and among universities that make scientific expertise and method available to the community. Researchers are increasingly playing a key role in starting collaborations between universities and communities to make their innovative contribution to the collective learning process (Saija, 2016).

In this context the argued process becomes collective production of community and social construction of projects of territory investing in the spatial dimension of vast area. These processes translate conflict into proposal, transform lament into constructive work, «find and exploit the margin of unused energy of the community, underline the prevalence of positive action collective» (Mumford, 1952 cit. in Paba, 1997 pp. 193-219).

In order to substantiate the reflection on the narration of conflicts, understood as builders of community and policy for the implementation of integrated projects of territory, we refer to the path of a small group of inhabitants who, distancing himself from a situation of conflict, he adopted a proactive attitude towards the common good and initiated a community project.

Focus of this paper is a case study concerning a process of empowerment of a group of citizens engaged in the promotion of a local project that has become a pilot project of regeneration of community places in the frame of the strategic Metropolitan Plan of Florence. A tiny group of citizen who shared the same common destiny for absence of a connection with the municipal water supply chain.

Until 2017, the inhabitants of the metropolitan countryside around the Sant'Angelo Vico l'Abate complex were not served by the public aqueduct and were supplied thanks to the beaten wells near each house. In 2013, despite the difficulties and lack of resources invested so far by the Municipality, the competent authorities and the property, the inhabitants joined in the water Consortium Sant'Angelo" to establish a connection to the public water system. A case of good community practices: an intervention of self-construction that in two years has realized three kilometers and two hundred meters of piping thus bringing the drinking water in thirteen families.

Instead of carrying out a territorial protest and they become an identity movement and, through the recognition of the patrimonial value of places, engaged a multiactorial and multiscale renewal project aimed to the rebirth of the local community. The joint effort for the self-construction of the lacing of the aqueduct has become the kick off for the realization of an integrated project for the requalification of the complex of Sant'Angelo Vico L'Abate as a place of religious aggregation, social and producer of wealth and new economies.

The project “Sant’Angelo returns to its origins”² is promoted totally from below and is born from four families of young local entrepreneurs, owners of farms who, working daily the land and taking care of the territory, have witnessed the progressive abandonment of the countryside and the places of agricultural, social and religious life that revolved around the complex of medieval origin and the Church of San Michele Arcangelo.

The widespread presence of Catholic places of worship in the open territory and in the inner areas, focuses on the issue of the use of the ecclesiastical building patrimony. The parish communities established in the territory have distinct ways of relating to such places; today, in fact, we are facing not only a type of religiosity different from the past, but also different links between the inhabitants and the places of worship, which are often under-used, if not abandoned, thus losing their settled role as a reference point for local communities and territorial landmark.

The contingent risk of selling the ecclesiastical patrimony and the consequent loss of the artistic and identity historical value, affect many places of the Italian territory.

The case under study has seen an alternative proposal materialize thanks to the vision of a small group of inhabitants who, after the experience of self-construction of the aqueduct, knew how to dialogue with the property and start a collective path to give new life to the complex.

The property, the Diocesan Institute for the subsistence of the Clergy, welcomed the project proposal made with strong passion of the inhabitants and immediately identified a religious partner as the neighboring Parish of Gesù Buon Pastore a Casellina.

The four families have presented a project - in advanced state - with the objective of the redevelopment of the complex respecting the use of the premises and the care of the areas of external relevance, proposing to create a business network in order to manage the whole complex by providing human resources, skills and means.

Through the multidisciplinary dialogue a collective path is thus activated in which all the actors involved share the common objective of putting into value the good and regeneration of communities. Thus taking on the responsibility of carrying out together a collective project of caring for the common good, a community of commoners was created. Through the growth of the consciousness of place and collective re-identification, the commitment to care for the place and the vocation to consume in relational, solidarity and community forms (Magnaghi, 2012) and to produce happiness were rediscovered.

Although the relations were always calm, a dichotomy was created between the two parties involved; while on the proposers side the project was considered of great interest and attractor of new networks, on the property side it was not very concrete and feasible because of the irrelevant presence of resources available and for the number of people involved directly and indirectly.

At this stage of the course there was a need to be able to manage the complexity of the process, to regulate and stabilize the orientations and expectations of key players (Jessop, 2003) without creating further conflicts between the Parties. It is in this frame that is involved, as expertise, the Department of Architecture of the University of Florence that, with a research project-action, has played an active role in the process of local development.

With a view to revitalising the complex in a collective key and with an innovative approach to meta-governance, a system of actions and processes of participatory, communicative, animation and events has been launched, able to re-activate Sant’Angelo Vico l’Abate not only as a place of aggregation, but also as a place of exchange and work, a showcase of good practices for the territory. It has thus become a laboratory of community ideas, of sharing of spaces and knowledge in which everyone, inhabitants, priests, administrators, students, researchers and professors have put their experiences to system producing innovative ideas.

² In the framework of the drafting of the Metropolitan Strategic Plan (PSM) of the Metropolitan City of Florence, cooperation relations have been established between the Promoting Committee of the PSM (formed by Metropolitan City, University of Florence, Ente Cassa di Risparmio di Firenze, Chamber of Commerce) and the Diocesan Institute for the subsistence of the Clergy of the Archdiocese of Florence (IDSC). At a later stage, the Sant’Angelo APS association presented the Sant’Angelo project, a return to the origin” to the group of the University of Florence.

From a fragmented community, but aware of the historical and identity value of the place, a community project of regeneration of a community space has been realized, able to activate networks and connections of vast area and to bring back the complex to assume the role of territorial reference point.

The researcher, also with emotional and communicative skills (Foster, 1987) took on the role of social facilitator; was a weaver of networks and relationships that accompanied the inhabitants during the journey of awareness and jointly identified alternative models of development capable of activating new economies on a territorial scale.

The activity from below and the enrichment of knowledge produce new policies of valorization and networking of common goods, generating wealth for the local community and the metropolitan area. It is limiting, in this case, to analyze the path in terms of ability to influence the design of policies, while it is more interesting the ability to construct policies starting from the re-identification in the patrimonial assets, materials and intangibles that connote the identity of a place.

To this end, the case of Sant'Angelo Vico l'Abate was taken at random pilot for the definition of a model of action aimed at building policy for the development of new economies and new lifestyles related to management and collective care of local heritage, activating innovative forms of social action and wealth production.

The effectiveness of the 'proactive approach held by the inhabitants in the empowerment path is demonstrated by the inclusion of the community project between the metropolitan strategic lines and, within the framework of the drafting of the metropolitan Strategic Plan (PSM) of the Metropolitan City of Florence, between the forecasts and the actions finalized to stimulate new forms of the inhabit for the inner areas.

Conclusions

According to the approach discussed above, this contribution provides additional elements to the discussion of territorial conflicts of an identity nature. The main purpose is to propose a reflection on the territorial conflicts about metropolitan identity and the role of small villages in the promotion of aggregation with a bottom up approach.

The contribution concludes with some reflections and, of course, without definitive answers highlighting considerations on the method of investigation of the conflict and the effect produced on planning policies on a territorial scale.

Draws attention to the need to adopt a new criterion for the narrative and conflict management through practices involving contextual knowledge and expert knowledge, thus conferring an open and positive conception of the conflict itself.

The method of investigation of the dynamics recognizes like point of force the conservation of its complexity (Dematteis, 1995) putting to the center the same conflict and its distance of collective learning.

Introduces a narrative that starts from the bottom up and from the small communities, animated by conflictual situations, able to activate new forms of social action and reproduction of wealth through the collective use of good and heritage, taking on in fact the patrimonial values as a generator of community and territorial awareness. It is thus possible to build new policy tools from the valuables and re-identification of assets.

The effect of the switch from «participation against» to proactive participation, taken as the argument of this survey, is a resource for the growth of communities and for the strategic planning of vast area.

The observation and investigation of the empowerment path generated by conflicting situations can create cartographies in which to graphic this new narrative of the conflict. Literature is rich in attempts to map the numerous expressions of participations against (Gelli, 2014).

This contribution, instead, proposes a graphicalization of the propositive expressions that create network and activate synergies to the territorial dimension, thus building a graphic narration of the geographies of the values. Adopting a trans-scale approach and taking into account the different territorial scales to which the conflict is expressed and on which its effects are reflected (Lingua, Puttilli, 2017).

This approach, which redefines propositional participation as policy tools, is of great interest for the identification of a shared vision. The bottom-up experiences, in which the re-identification of values becomes a tool for the production of integrated projects, they are put to system drawing possible

futures in a position to defining strategies and shared actions and to reconstruct a collective image of belonging to the metropolitan dimension.

After this re-identification and working in a synergic and integrated way, the micro-stories emerged in the path and the macro stories become part of a wider intervention strategy and converge in formal acts of government (Lingua, 2016).

The last reflection focuses on the topic of the involvement of the University, in the activity of third mission³, as knowing experienced in the empowerment path of a community for a mutual exchange of knowledge and resources.

Through action research on the ground, universities make an innovative contribution to the process of collective learning through the figure of the «researchers in the action» (Saija, 2016) and facilitate a shared vision with a territorial dimension.

In this context the University also has the important function of experimenting with meta-governance approaches as the subject can manage the complex process between of plurality of social actors with diverging interests to promote and achieve common objectives by means of mobilizing and deploying a range of ideas and resources (Torfing, 2012).

The researcher in action has a significant role in moving societies toward resilient governance systems (Innes, 2010) modelling collaborative practice and demonstrate its value in the field of research.

The work carried out during the pathway triggers local-scale activities and projects that are networked on a supra-local scale and generate trans-scalar policies or projects.

The territory can assume the concrete connotations of community laboratory, useful for the restoration of relationships of trust and the production of social capital in which the conflictual dynamics create new awareness of citizenship and put into value the peculiarities of the identities of the places generating new policies for a and inclusive governance.

It's an innovative approach that ask new skills, although there is needing 'a full blown cultural transformation' (Peters, 2010) which the university can promote.

CITIES AND SELF-ORGANIZATION. A DISCUSSION STARTING FROM ROME

Carlo Cellamare

DICEA, Sapienza University of Rome

carlo.cellamare@uniroma1.it

The explosion of self-organization

In the contemporary city, we are today more and more witnessing different practices and processes of “re-appropriation of space”: regeneration of empty buildings, spaces of cultural production, urban gardens, green areas given renewed significance and re-shaped public spaces, and so on. Beside this, we could also mention experimentations that are activating new social services and welfare spaces, and finally squatting projects, which are defining different modes of co-existence, housing and service provision.

This is a vast field of activity and experience, with the widespread involvement and the leading role of the inhabitants, organized or not in committees or associations, and other local actors. Such experiences are both illegal and legal, and question the relationship and the very meaning of the institutions.

We should even consider in particular micro-practices that are able to broaden and transform the city from the bottom up, alongside more stable forms of social production. A specific kind of “city making” built upon a mix of practices, social relations and modes of local activation.

As a consequence, the way we are looking at the city is radically changing: questioning the relationship between the State and the citizens, these processes of re-appropriation are re-configuring both the mechanism of place making as well as the organization of social relations and local services, thus questioning the very concept of “public” and “publicness” in the city.

These practices of re-appropriation are representing different modes of city organization as well as different cultures of action/policy making in the contemporary city. They are also representing different modes of what “public” means in the city: some practices of re-appropriation are acting as collective actions that take into consideration the mechanism of social inclusion, while others are acting in a way which could be described more as private, or specific to some groups only, rather than designing public/collective actions.

In many cases, these are practices and processes of re-appropriation of the city that are also processes of resignification of spaces and production of places. Among these practices, many of them are re-opening spaces or re-activating some specific territories/neighbourhoods benefiting from very localized creativity and capitalizing on social relations that are fully embedded in local societies.

We should also critically consider that practices of re-appropriation are often substituting the role of local policies and in some case promoting actions that are illegal/informal in a context where institutions are losing financial capacity as well as accountability.

These experimentations are so focused on action that are simultaneously redefining the modes of social conflict as well as the routines and spaces of citizenship participation. These practices can be considered sites where to experiment and shape political capacity, thus questioning the very functioning of local democracy.

This context gives us the possibility to critically analyse the processes of re-appropriation that are changing the contemporary city, not only in big cities but also in small localities. We should be attentive to possible points of strength but also to ambiguities and challenges linked to these experimental processes.

First of all, considering the tension between the possibility to define different models of local activation and cultural/political production and, at the same time, the problematic erosion of the capacity of institutions in answering local needs. We should consider whether practices of re-appropriation are de facto substituting the role of institutions as well as weakening the transformative impact of traditional social conflict.

Some cities like Rome are strongly shaped by these practices and this condition is being mirrored all around Italy and Europe. If we consider the Global South, some of these practices have historically played a

relevant role in the production of local economies as well as in shaping parts of the city (Hou, 2010; Mehta, 2004). This pushes us to consider the role of more structural dimensions in the critical analysis of re-appropriation practices.

In the current climate of weakening welfare states, we should consider whether and how these practices of re-appropriation are substituting the important role of institutions, thus reinforcing neoliberalism, and, as a consequence, an unequal distribution of disadvantage.

Self-organization in the recent evolution of the city

Self-organization has always existed, it has been a fundamental component of the city. It was often the ordinary way of construction and evolution of the city, where the interventions of authority and political power were concentrated in some spaces and in some works of the city. Self-organization was placed within the evolutionary principles of pre-modern society.

Modern society, above all starting from the constitution of the modern States and the relative monarchies (but the democratic States have not been different in this), has instead tended to control or to absorb such processes (Bourdieu, 1994). In this sense, modern society has introduced all forms of control of space, which can be traced back to the logic of the panopticon (Bentham, 1791; Foucault, 1975; Scandurra, 2003; Decandia, 2008).

The same urban planning, although born with the needs of good management of the city, the solution of the health-sanitary problems of the cities in rapid growth, the rethinking according to mobility and efficiency, represented in many ways a form of control of space, as well as management of the soil regime. Haussmann's Paris is the best known and most striking example (Scandurra, 2001; Harvey, 2003).

Despite all, self-organization has survived, has continued to live in the ordinary life of the city although in conditions of subalternity, often considered illegal, putting back into question that separation between institutions and inhabitants.¹

On the opposite, as we said before, today we are facing with an explosion of experiences of self-organization, even beyond the dimension of protest and the great social and urban movements that have characterized all the continents, from the Arab Spring to protests in the squares of Greece and Turkey to the great movements that have gone through New York and the United States (Harvey, 2012a, Graeber, 2007). Above all in countries where people experience the inadequacy of local institutions and administrations and their inability to respond satisfactorily and according to the public interest to the social needs that emerge in urban contexts, the territories tend to develop widely self-organization forms and overcome the autonomy of the politician and, in particular, of the institutions. They even aim to manage without them.

These processes must also be read within a change in the political and institutional context. In fact, in conjunction with a strong and prevailing affirmation and action of a neoliberal-style society, it is emerging a progressive orientation of the State to support such models and trends. The State seems often to be more allied or dominated by economic forces and private interests (and therefore the political dimension is subordinate to the economic one) than committed to protecting the public interest of citizens. This orientation of the "public", which is part of a historical process of retreating of the welfare state since the 80s of the last century, is so strong that citizens often perceive the State apparatus, and in particular local administrations, such as the main enemy to face. Within this context, we can also better understand the growing attention that, in different ways and in different contexts, has been addressed to the theme of the "common good" and "common goods", and more extensively of the *commoning* processes. Therefore, if the modern State had expropriated the capacity for planning and collective management of their life contexts due to a "superior" public need, today it is seen as the less adequate interpreter and no longer people recognize its capacity for define a "public interest". Faced with this problematic loss, it is therefore clear and profound the need to reconstruct processes that define a public and collective dimension of coexistence. Similarly, the need to reconstruct "community" dimensions of coexistence within diversities emerges with force, where social relations gain centrality to qualify daily life.

¹ Even in cultural terms, in the context of urban planning as a discipline and scientific research, a different tradition has been kept alive, which found in Geddes (1915) and in many other scholars its main representatives (Paba, 2010).

Finally, the forms of self-organization also represent an overcoming of participation as it has been progressively interpreted. The participation of citizens in the collective and political life of the city has a noble and very important meaning. The difficulties and distortions of the concrete experiences have disqualified it, disappointing expectations, creating processes more characterized by the construction of consensus if not the development of forms of “social buffer” with respect to problems and conflicts, causing great frustration and increasing the distrust in administrations. Faced with dissatisfaction with participation, when transformed into a farce, forms of self-organization are a way of seeking solutions in autonomy.

Discussing self-organization

As a consequence of this evolution of the political and social processes that cross the cities, there are different dimensions, not always co-present, that we can grasp in the experiences of self-organization. Firstly, there is a dimension linked to the spontaneous process of the inhabitants of use and management of the living context, of the construction of the city and of the production of both physical and symbolic, both material and immaterial space, of self-organization in daily life, of care and management of the places of collective life. To interpret these processes, to grasp the “structural coupling” between space production and re-signification processes, we need to develop an approach able to read and interpret urban practices, and the world of signs and meanings that they carry with them. As Castoriadis (2001) said, “the symbolic leans on the material”.

A second dimension is linked to the contestation of the prevailing models and of the dynamics of political, social and economic transformation of which we spoke previously. It is often activated starting from resistance to forms of urban speculation, from the reclaiming of disregarded rights and better urban living conditions, from opposition to subaltern urban development models to prevailing economic and private interests, which are part of the extractive capitalist dimension (Mezzadra, Neilson, 2017), of the commodification of the city (Harvey, 2012b), of biopolitics (Foucault, 2001). Not remaining in the dimension of pure resistance, these experiences develop strong planning and tend to practice alternative perspectives. All this gives rise, in the first place, to a strong political intention, a clear stance towards the prevailing cultural and political models, which generates a re-appropriation of the city’s spaces and their re-signification. Secondly, as we said, it is an action not only of resistance, but also of construction of alternatives. Although supported by a deep critical reflection, the dimension of action prevails in these experiences. The realization of change is a fundamental objective. In this dynamic, it is to recognize that such experiences have the ability to construct a real and meaningful politics. Thirdly, they constitute the attempt, as far as possible, to build spaces of autonomy, which others define spaces of freedom, i.e. spaces where rules of coexistence defined by alternative models and values take place.

The third dimension is completely different and can easily generate distortions. However, it is often dictated by practical needs and is also found in very radical experiences, such as squatting experiences and housing movements. This is the need to make up for the shortcomings and / or absences of the public administration, to give concrete answers to urban and social problems in a context of progressive retreat of the welfare state. Some examples are the construction of autonomous responses to the housing problem (squatting experiences, but also the illegal housing or large slums all over the world), or to the lack of green areas and public spaces (from which the great proliferation of self-managed green areas and shared gardens), up to the theme of work. It is clear that this (implicitly) substitute action of the shortcomings of the public administration must be accompanied by recalling it to its commitments and tasks. However, this dynamic generates some distortions. Firstly, there is the risk of creating a social buffer, although this may be unavoidable. Given the lack of listening and response from the public administration, social need is urgent and calls for an answer. Unintentionally in this way, the public body is relieved of a problem and there is a risk of reducing social conflict. Secondly, in autonomously seeking answers to problems, “only those who make it go forward”. There is the risk of putting in difficulty the weaker subjects (except when the forms of self-organization expressly aim at mutual aid, as in the struggle for the home) and give space to the stronger ones, generally represented in the contexts of hardship and poverty by illegal economies and organized crime. Thirdly, there are open spaces for the re-examination of what the public interest is, which can be guided by a profound and serious political reflection, but can also emerge from unregulated

processes dictated by private interests (as often happens in the territories of unplanned built areas). In fact, there are several “public cultures” (Cancellieri, Ostanel, 2014). The differentiated character of political processes and positions can cause possible distortions, if not also anti-democratic dynamics. The same “popular economies”, born in South America as an alternative to extractive capitalism, give space to ambiguities that now put them under critical lens (Gago, 2015).

Because of this third dimension, the experiences of self-organization can today be characterized by profound ambiguity. Their interpretation does not arise in the wake of a romantic or apologetic vision, but leads to a critical approach, based on discernment, on the ability to critically read practices and processes of self-organization through the values and ideas of the city they bear.

Self-organization as a structural fact and the relationship with politics

The historical process of development of forms of self-organization calls for some considerations and some questions. A first consideration is the recognition, unlike what happened in modern society, of the multiplicity of subjects that build the city and “produce space”. To make the city are not only institutions or economic forces, but many other active subjects, who may also have the ability to be or become protagonists, in some cases with better outcomes and modalities of the institutions themselves.

The question is therefore “who is caring for the public interest if the institution does not do it any more?” and how it is then produced and defined. The city is a “field” *à la* Bourdieu, a place of conflict between these forces, where spaces of autonomy can be built.

The second consideration is that self-organization is a structural fact. It is not just an anomaly, a factor of protest, but a form by which society reorganizes itself.

Self-organization is (or has returned to be) a fundamental engine of “making city”, not only in terms of care, maintenance and responsibility of the local living space, but also in terms of “production of space” in all its dimensions, material and immaterial, of a structural factor that builds the city. The question is rather whether this structural character is linked to the recognition of existing ordinary practices and political intentions that construct spaces of autonomy or if it is rather the consequence of the change in the ways of acting of state structures and the retreat of the *welfare state*. In the latter case, the prospect is the disintegration of the city as a *polis* and as *civitas*, as an organic body that - despite its differences and conflicts - is self-governing and produces its own culture of coexistence. It follows a situation in which, on one side, the social subjects, especially the weaker ones, are abandoned to themselves and, on the other, we must develop a difficult path of reconstruction of the “common good” in a context of preponderance of economic forces and functionalization of social skills and abilities to the “extractive capitalism”.

A final consideration is to highlight how the experiences of self-organization are social laboratories and of cultural production. They are today the spaces where the production of politics and political culture takes place. In this sense, such spaces are today to be enhanced because those ones where the future can be thought (Appadurai, 2013).

Rome between self-organization, institutional policies and neoliberalism

Rome is a city crossed by many practices of re-appropriation and by many processes of self-organization, making it an emblematic urban context to discuss “self-produced” cities (Cellamare, 2014; S.M.U.R., 2014). These are very different realities: from local communities that self-organize and self-manage their territory to the multiple forms of occupation and squatting (for housing and non-housing purposes); from urban gardens to “restored factories”, from self-produced and managed public spaces to occupied cultural production sites (theatres, cinemas, ecc.), from self-managed local services (gyms, etc.) to illegal built zones and to many other different experiences. A very rich and varied world; nevertheless ambiguous and problematic.

It is a city in turmoil. There is a swarm of activity that goes through the daily life of Rome and that builds and rebuilds the city every day. They are practices and processes that often return some urban “wastes” to the city’s life cycle; practices and processes that are also processes of re-signifying places; a parallel world but also integrated with that of institutional policies and administration, and no less real than that and, in particular, no less capable of actually and concretely constructing the city.

These practices and processes do not transform the city only in its physicality, but also in its symbolic dimensions, in the forms of living and cohabitation: practices of transformation of the “urban”, and for this we speak of “self-made urbanism”.²

The Roman peculiarity is linked not only to the diffusion and coexistence of very different forms of self-production of the city, but also to the fact that Rome is the capital of a modern western state and a country in full capitalist and neoliberal economy. In the ordinary sense, informality and self-construction are often associated with “poor” or “developing” countries, with a weak government capacity and a strongly lacking welfare. In Rome we find informality and self-organization in a context characterized by a strong institutionalization and an advanced economy, very neo-liberal oriented. Rome emblematically demonstrates how these things are not incompatible, but rather represent a system of government, a specific “regime” of this city.

Although in a highly institutional context, a tradition and a strong public administration culture is lacking in Rome, differently from other European countries more consolidated in the organization of the modern State. Historically it has constituted an extremely weak bank against speculative pressures. In many ways the public administration has often played a role of connivance, in favor of speculative activities and of an economy strongly “bent” in the neoliberal sense, while maintaining some levels of services and welfare structures, even if lacking. The outcome is a city, as confirmed by studies and statistics, with a strong social divide, with very rich groups and an extensive social layer in great difficulty, in conditions of real or perceived poverty. We have even other related effects: a weak economy and exploitation of existing resources rather than development, a strong housing speculation that has always marked the history of Rome, an administrative culture of *laissez-faire*.

The same forms of self-organization can be considered functional to this system, as in many cases they play a role of “supply” with respect to the shortcomings of the public administration.

It is not just a matter of inadequacy of the administration, but of a real “style of government”, related to a specific “urban regime”. On the one hand, it keeps the struggling social strata under conditions of weakness and subordination, engaged in the constant effort to make up for the shortcomings, and containing their conflicts within a defined margin. On the other hand, it leaves “ample room for maneuvering” to the speculators and the stronger socio-economic subjects, in the search for their own margin of convenience. That of Rome becomes an emblematic “style of government” where there is a retreat of welfare and an affirmation of the neoliberal economy.

In Rome, one can certainly speak of a “policy of occupations”. For many years, it has been treading between accepting and weakly contrasting occupations for housing, while still keeping them in tension and pressure, at risk of eviction. They constitute a self-produced response to the problem of housing, but cannot be formally recognized and therefore totally accepted.

The whole history of illegal housing, moreover, so characteristic of the urban history of Rome, constitutes a system that determines reciprocal dependencies and conveniences and a patronage form outside a democratic system of government. It is placed at the crossroads of these two dynamics, the “self-making” and the “letting go”.

The “self-made” city, therefore, on the one hand, is at the crossroads of a system of political management, economies, cultures and social relations; it represents a real “socio-economic system”, within a context such as the Roman one characterized in recent years by a progressive political and institutional lacking. At the same time, the contexts of urban self-organization are, and have been, also social laboratories. In these contexts, experiences have been multiplied in which attempts have been made to experiment with innovative forms of cohabitation and living, ideas of cities that are alternative to the neoliberal urban development model.

In some cases, as in social centers and today in the occupied cultural production sites (Teatro Valle Occupato, Cinema Palazzo, Cinema America, etc.), but also in occupations for housing purposes, these experiments are thought out and continually discussed, so much so that they become the places in Rome for the elaboration and re-elaboration of a reflection on the “right to the city” (Lefebvre, 1968; Harvey,

² Considering urbanism as a way of life, taking up the well-known reflections of Wirth (1938).

2012; Isin, 2000)³ and on “commoning”. It is a reflection that emphasizes a rethinking of the city’s production processes, an idea of living that returns the complexity of living, social relationships, life in common, etc. Often just the problematic nature of these places, such as occupations for housing,⁴ leads to a profound reflection on the sense of coexistence and on ways of constructing it, underlining the relational dimension of living, the fact that the city is interwoven with relationships that are to be lived in (Pisano, 2013).

In many other cases, and perhaps they are the majority, there is not necessarily an intentionality. Experimentation arises from the ordinary practices of daily life, from the development that self-organization processes have spontaneously had, often due to the conditioning and pressures they have suffered and to which they have tried to give answers: the lack of a home, illegality or irregularities, the position in the labor market in conditions of subalternity, the stigma of the periphery or the “urban ghettos”, the resourcefulness from below, the status of immigrant (regular or irregular), etc. The experimentation was therefore often a need, a path to try to come out of the problems.

Paths of “regeneration from below” in Rome

The term “urban regeneration”, already an originally ambiguous concept, has become in many ways - in common and widespread use - a slogan. The expression “regenerate from below” which is used here has a provocative character. We intend to affirm that, in many cases, and especially in the Roman case, there is an inadequacy of public policies in the “regeneration” of the city, while some policies produced “from below” are often much more adequate. The reference is to some widespread self-organization experiences in Rome that, although they should be read and interpreted in a careful and critical manner, express an ability to define policies, develop projects and implement paths of social innovation and integrated management that in some aspects seems to be failure by the public administration. It is strongly absorbed and conditioned by the management of the ordinary, by the need to negotiate (on the downside) with the private sector to obtain financing that can be used in urban transformation, by the lacking of the welfare state, by the growing difficulty of answering questions social issues and to direct models of economic development. By “regeneration” (“from below”), we mean here an integrated approach that can deal with both the physical and structural aspects of the city’s set-up and the immaterial aspects, from the social ones to work and local economies, to those of production cultural, within complex processes that activate the latent or already existing and active social projects and energies.

The forms of self-organization certainly reveal great potential. Firstly, they express a social protagonism that involves the activation of important social organization skills. Secondly, they allow the construction of social fabric and symbolic values. They also perform a service “for” and “on” territories. They are then the expression of processes that aim to reconstruct democratic dynamics within a historical phase of crisis of democracy. In this, in fact they are the places where today really politics is produced. This is a politics that could be defined as “significant” because it is really able to express the emerging and relevant meanings to the social conditions of everyday life, that “magma of emerging social meanings” that Castoriadis (1975) associates with the “instituting society”.

We focus only on two examples that are, at the same time, extreme cases and very interesting occasions. These are extreme cases because they develop in difficult contexts, neighborhoods of public housing characterized by severe poverty, unemployment, concentration of social hardship, buildings and urban degradation, presence of criminal economy and drug dealing. These are very interesting experiences because, despite these great difficulties, they are realities in which the capacity for self-organization responds with energy and intelligence to problems, proposing interesting projects. In particular, it focuses on the problem of labor and local economies and connects the possibility of providing services to local contexts. It is the answer to the issue of poverty, unemployment and criminal economies, the first step to then proceed also to urban regeneration.

The interest of these and many other experiences in Rome pushes to support the development of “policies for self-organization”, i.e. policies characterized by certain criteria: enhancement of local projects and social

³ For example, numerous seminars, work groups and reflection activities on these issues have been held in contexts such as Cinema Palazzo and Teatro Valle Occupato (Occupied Valle Theatre).

⁴ Here the strong diversity, first of all social and cultural, is at the same time a wealth and a problem.

protagonism, involvement of local actors and their capacity of action also in the management of processes, role of coordination and planning of the public entity, role of guarantee of public interest by the local administration, ability to associate the development of local economies with urban regeneration, organization of long-lasting processes over time and rooted in the local social context.

Tor Bella Monaca

Tor Bella Monaca, a public housing district of the 80s with 30-35,000 inhabitants, in the collective imagination represents one of the symbolic places of degradation. Tor Bella Monaca is a totally “public” neighborhood, but also the less “public” one. The perception of the distance between institutions and public administration is not as strong elsewhere as here. The percentage of occupations, the lack of maintenance, self-managed cleaning (and not “public”), arrears and deregulation at times total, the lack of interlocutors to which to contact or respond, the failure to reassign the houses left free make this place the emblem of the absence of the “public”. The more they are places deserted by politics, which has left the field of the suburbs for many years.

To highlight the complexity of the situation and the problematic of everyday experiences, just think of the difficulty of living public spaces, even if they are present in the neighborhood. Public space is the place disputed by the inhabitants at the drug addiction and selling, it represents the place of daily struggle with drugs. This is why it is often an unpleasant place to avoid; and at the same time the place to be reconquered.

In these districts, and in particular in Tor Bella Monaca, some social local groups operate (both in the simple collaboration between inhabitants and in the organized forms of associations and committees) in such a good way that radically deny the negative and homologating image that often exists.

In Tor Bella Monaca, despite the majority of inhabitants (except for the defaulters, of course) pay with the rent a quota for the cleaning of the stairs and the maintenance of the common areas, the maintenance and cleaning of the stairs is not done. The inhabitants then organized themselves to provide for themselves. Generally, families are organized by stairs, self-assessed (for what they can), collect money and use them to pay a person (possibly of the same scale) that cleans the staircase. Even more complicated is self-organization to provide for the maintenance of common areas and in particular the green areas, but despite this (think, for example, a tower with 75 apartments and housing units such as difficulties in collaboration can meet) you can get excellent results and the green areas appear of great quality. The commitment of some associations and committees is particularly relevant and effective, for example the Tor Più Bella association in the area of via Santa Rita da Cascia or a group of particularly active inhabitants in the area of via S. Biagio Platani. In both cases (but they are not the only ones) the inhabitants make a daily battle to maintain the quality and take care of and make accessible to all some condominium spaces, adjacent lots spaces, unused spaces on the ground floor of buildings (used for services to the district), some green areas and small urban parks, abandoned by the Municipality. This is a daily battle because it means facing daily drug dealing that tends to colonize and degrade the common space (destroy the street lamps, eliminate the lights, ruin the doors to leave the accesses, etc.) in order to freely play their own illicit traffics.

Similarly, a great deal of work is done by the local ASIA union, which deals with the problem of housing and allocations. They discourage abusive occupations made only for interest and trafficking in favor of the black market, while supporting those who actually need it (also signaling when the houses are empty or unused, but are not reassigned). Among other things, ASIA and the associated Local Committee are interested in the use of the ground floor spaces of buildings, theoretically intended for commercial activities but currently abandoned, to carry out a neighborhood laboratory and services for neighboring residential complexes. We need to point out the work of the El Chè (ntro) social center and the connected Cubolibro, a self-managed library, but also the Ciclofficina and a ceramic workshop. In the whole district, there is no municipal library. A group of people, especially young people, set up a “public” library, even if made by “private”, collecting donations, even by the inhabitants themselves. It provides books and supports children in extracurricular activities. Obviously, it could be considered “irregular”, but it is the only “public” service of this type. All these activities (as well as the neighboring disability union, SIDI, which has its national headquarters here) reuse (irregularly) abandoned buildings, providing services to the neighborhood.

Close to Mengaroni square, too, a network of associations carries out its activities using the "ex-barn", a building renovated with *Urban Program* funds and (in this case) regularly assigned through a call.

More close to the R5 residential complex, a group of mothers occupied a small abandoned building (once used as a nursery), renovated it with the help and support of some families in the nearby residential complex, turning it into a well-organized playroom open to R5 children.

Some of these social groups have started a collaboration path and, with the support of Action Aid, through a collaboration with the local high school, they have developed a program of redevelopment of the neighborhood, which was then shared by the Municipality .

Therefore, we can define some criteria that are the ingredients of the "regeneration from below" programs that are being discussed, also with the collaboration of the University: reuse of abandoned public spaces (in particular, small buildings for services and rooms on the ground floor of buildings, originally intended for commercial purposes); destination to productive activities (craftsmanship) or service to the district; involvement of local actors (already active) in their management and enhancement of local projects; development in this way of services to the neighborhood; activation of work paths connected to the activities characterizing these areas (building maintenance, maintenance of the green areas, management of social services, management of common areas). Around these criteria, the retraining programs are being structured and some funding paths have been activated.

Piscine di Torre Spaccata

The district of *Piscine of Torre Spaccata*, not far from Cinecittà, between Tuscolana and Casilina streets, in the southern suburbs of Rome, is another very interesting context. It is also a district of public housing, certainly smaller than Tor Bella Monaca, but with problems quite similar. In this case, a factor of great interest emerges. A Committee (CSL - Local Development Committee) has been set up that brings together various local subjects, including - in addition to the Local Committee - especially active subjects, be they productive, socio-economic, cultural, such as TeatroCittà, artisans, gym, traders, etc. Here the focus is on re-launching the neighborhood through economic, productive and service activities, which on the one hand bring work and income and on the other perform a service for the neighborhood (just think of the gym and theater that are very popular with the inhabitants and that develop projects, also funded by public bodies). In this way some important "collateral" effects are obtained such as facing drug selling, to which concrete alternatives are constructed and thus trying to remove such problem. As well as the reuse of abandoned spaces, often easy prey of degradation, worsening the typical building degradation of a public housing district, where the "public" is no longer able to carry out its management and planning role. These are the spaces on the ground floor of buildings, usually intended for commercial activities, for which the current legislation provides for rent at market prices, making them inaccessible to local operators and in fact ordinarily unusable.

The CSL has obtained in "custody" these spaces, as well as those of the local neighborhood market, by a previous municipal administration, and its objective is full utilization, through alternative administrative procedures, developing the productive and service activities that are so qualifying for the neighborhood. In particular, attention is now focusing on the local market, undergoing a sharp reduction in commercial activities (as in most of Rome's local markets, in difficulty with large retailers and in particular shopping centers). The goal is to transform it into a multi-purpose civic center where some commercial activities are maintained, integrated with the craft activities, with restaurants and bars, with green areas equipped for children's play, with urban gardens and with service activities in the neighborhood. At the center of attention is local development, considered as the fundamental purpose of the redevelopment programs. Particularly interesting is the proposal of a managerial entity that integrates three different subjects: the economic operators, the representatives of the local realities (not only the CSL) to direct the activities at the service of the district, the representatives of the Town Hall (to guarantee the public interest).

Some final comments

From these experiences, we draw some final comments. These are experiences where policies are developed that should make the "public": recovery and reuse of existing buildings, reduction of land consumption, development of productive activities as a motor of redevelopment, provision of services on a

local basis, search for solutions to the housing problem, self-recovery, enhancement and use of environmental heritage, etc.

They are also realities that are often a garrison of civilization and solidarity, rich in planning and where forms of open and inclusive coexistence are realized, despite the evident difficulties in which they are placed. They highlight how a problematic node for the redevelopment of the suburbs, should be the ability to recover a role of planning and government by the public administration, the ability to develop forms of enhancement of these projects and these capacities for initiative, a new role that could be defined as “enabling” on the part of the institutions in the relationship with the territories. Those that can be defined as “policies for self-organization”.

In the awareness of the ambiguity and the problematic of situations and beyond possible romantic visions, one can discover a quantity of resources, commitment and planning that is the redemption potential of these places and the real ability to build the future.

The Serious Game: a learning tool to enhance the communities in the context of sustainable cities

Cravero S.¹, Lami I.M.¹, Abastante F.¹

*Department of Regional and Urban Studies and Planning, Politecnico di Torino, Turin, Italy-
sara.cravero@polito.it, isabella.lami@polito.it, francesca.abastante@polito.it*

Abstract: In smart communities, people need and user's awareness is key issues. Recent literature contains several social elements in the urban planning field and recognizes the fundamental role fulfilled by human factors. Users are the focus in delivering new urban services and in achieving sustainability in the longer terms, they are observed as key actors to attain real sustainability. Nowadays, this goal seems closer thanks to new interactive technologies that allow applying innovative learning methods as well as social research methods. Among the learning tools, the Serious Games (SGs) represent a very promising medium to be adopted in this context. They have multiple learning objectives and can be applied in many areas for all targets of people. One of the most important features of the SGs is to make interesting and entertaining issues improving the knowledge of users' actions and teaching SGs could represent a strategic hub to promote educational programs and involve the adoption of new lifestyles based on the idea of energy saving. The main challenge is to understand the several possibilities and application fields where this tool can be applied, discovering its countless potentiality.

In this contribution the characteristics of SGs are analyzed, their application fields, their benefits, and rescues descending by their use are synthetically presented and discussed.

Keywords: Serious Game, Smart Cities, Sustainable Communities, Citizen Design Science, User-centered design

Introduction

Nowadays many cities are tackling urban and social challenges in terms of sustainability. Those challenges are related to territorial conflicts, poverty, quality education and gender, climate action and responsible energy consumption and production. In this perspective, an emerging but pivotal concept is one of “smart cities and communities”. Although a shared definition is still missing, the smart cities involve several aspects and therefore they can be analyzed through different sustainable perspectives as social, technological, economic and environmental. This intersection among different and sometimes conflicting disciplinary areas makes the proper understanding and design of the smart cities and communities a very difficult task (Albino et al., 2015; Dewalska-Opitek, 2014).

For this reason, the 2030 Agenda for Sustainable Development provides strategic directions to support the future development of cities and communities, identifying 17 Sustainable Development Goals (SDGs), which are defined as an urgent call for actions by developed and underdevelopment countries, in a global partnership (sustainabledevelopment.un.org).

Notably, the SDG 11 -Make cities and human settlements inclusive, safe, resilient and sustainable-its about the issue related to urban growth and its safety development in several cities all around the world. Among the different aspects highlighted by the SDG11, the citizens' involvement has great importance. Every project, decision, and action are done in cities has an impact on the citizen's quality of life. Allowing citizen to participate in urban projects and initiatives, and making them active stakeholders in urban activities or analysis, it could improve the achievement of specific goals for cities development. Accordingly, the Citizen Design Science (CDS) is recognized as being an interesting approach to involve citizens in urban design from a sustainable perspective. It concerns the citizens' involvement towards the planning and the management process in a city, through an easily accessible design, (Mueller et al., 2018) based on three fundamental pillars: the Citizen Science, that refers to the participatory aspects and the kind of data collections, the Citizen Design that implicates the active design by citizens and finally, the Design Science essential for transforming the citizen's design proposal into tangible urban drawings and plans (Mueller, et al., 2018). In the CDS framework, it is possible to identify different methods used to support the citizens' involvement in smart cities. They usually refer to questionnaires, focus groups, and workshops. However, according to the literature (Leydesdorff and Deakin, 2011; Nalbandian et al., 2013; Joshi S. et al., 2016), the need for new participatory methods emerges.

With this respect, the aim of the paper is to analyze the different definitions and dimensions of smart cities and CDS concepts and methods, as the Serious Game tool with its application towards sustainable issues. The Serious Game (SG) methodology is one of the applications used in the Citizen Design Science context, and in this article has been done a first classification of the most innovative SGs realized, during last 10 years, towards sustainability context, starting from previous existing work.

This text is organized in 3 main sections: section 1 concerns a review of relevant literature on the smart cities, the communities and the concept of user-centered design discussed in CDS. In section 2 an overview about SGs is presented, through a literature review between 2007 and 2018, with a description of the main characteristics of this type of games with their relative benefits and rescues coming from their application. Section 3 is dedicated to a serious games catalogue realized in the last ten years, more about quantitative and qualitative application considerations.

Smart cities and communities

A shared definition of smart cities is still missing; therefore, some authors try to underline its core components and characteristics. A city can be defined “smart” when “investments in human and social capital and traditional (transport) and modern (Information and Communications Technology, ICT) communication infrastructure fuel sustainable economic growth and a high quality of life, with a wise management of natural resources, through participatory government” (Caragliu et al., 2011). In other words, cities are defined smart when the city government has the ability to optimize the exploitation of both tangible and intangible assets, enhance the citizens' quality of life, boost resources' productivity, and solve emerging issues (Komninos et al., 2013; Shaffers et al., 2011). Moreover, strategies to execute and manage smart cities projects vary among cities, as well as organizational and managerial researches in this field are scarce (Michelucci et al., 2016). Smart cities are interdisciplinary: they require

investigation and cooperation across several disciplines, spanning from economics to social sciences, from politics to infrastructure management and others (Celino and Kotoulas, 2013).

Trying to determine a definition and its domains of application, two main kinds of research can be subsumed from the literature review. The first stream of research is technology-centered and focused on application domains that are heavily based on modern ICT application in different fields, such as in energy consumption, public transport or waste and water management. The latter stream of research is more people-centered because, even if technology and infrastructures are still important as enabling factors to reach objectives, nowadays the research is more focused especially on soft domains such as welfare, social inclusion, culture and human capital (Caragliu et al., 2011; Toppeta, 2010).

The relevance of citizen's involvement in the urban context has definitely increased in the last years. "The ability for all people to communicate with one another and agencies and groups that represent them provides a new sense of possibility to the idea that smart cities are based on smart communities whose citizens can play an active part in their design" (Joshi S. et al., 2016). There are different ways to involve and take actions where citizens can give opinions and take part in urban initiatives. During last years, smart city plans are characterized by a more bottom-up approach, through new forms of collaboration and participatory governance, where the analysis of people's needs and the definition of social objectives drive the selection of specific enabling technologies (Leydesdorff and Deakin, 2011). It is exactly at this time that the role of technologies becomes interesting and relevant. Today we can immediately find out a lot of information about what is happening anywhere in the world just surfing the internet. Naturally, this is not the only way to get familiar with the smart cities' participatory initiatives. Known methods are questionnaires, focus, and discussion group, workshops, typically used for enhancing the participation and collaboration among people, sharing opinions and ideas. The debates and comparisons between citizens become more interesting if they can discuss with local governance or municipality. From literature (Nalbandian et al., 2013) emerges that better results can be obtained when, during these moments of confrontation, governance and public actors participate and collaborate together with all citizens.

Furthermore, the cities can be defined smart also when they include active political participation, citizen services and good use of e-Government instrument, for improving the decision-making process, the public policymaking and the public governance, everything at the same time. One of the substantial characteristics of smart governance is to enhance citizen participation both in private or public collaboration. The implementation of smart governance infrastructure can facilitate service integration, collaboration, communication and data exchange. The relationship between public managers and citizens become an important component to define the role of the management in leading smart cities initiatives. With this regard, Corrigan and Joyce (1997) discuss the right of the citizens, to be included in the decision-making process of their municipalities: public managers' interaction with the society is essential for the creation of effective services created for the community. The link between public managers and the community facilitates the partnership among sectors, groups, and individuals (Nalbandian et al., 2013). Three challenges for public managers can be identified in order to pinpoint what is administratively sustainable and political acceptable: "to create and enforce a chain of responsibility that needs to avoid political alignment; to synchronize jurisdiction and other forms of external authority with the problem to be solved; to integrate the real citizen's need in the local government and administrative structures" (Nalbandian et al., 2013).

Smart devices, Internet of Things (IoT) and ICT by far outnumber human beings in smart cities. Public administrations can use ICT as a tool to group people together and stimulate innovation, knowledge, problem-solving and, more in general, economic growth (Caragliu et al., 2011; Hollands, 2008). The rise of IoT application and the large-scale adoption of web technologies and tools in urban environments have proven that internet-based solutions can successfully address societal challenges (Celino and Kotoulas, 2013). IoT provides the connection between all these objects to facilitate and make people's lives more comfortable and efficient in all situations (Khajenasiri et al., 2017).

Citizen Design Science

The citizen science has been defined, by the UK Environmental Observation Framework (UK-EOF, 2011), as a "volunteer collection of biodiversity and environmental data which contributes to expanding

our knowledge of the natural environment, including biological monitoring and the collection or interpretation of environmental observations”.

Bonney et al. (2009) define three different levels of Citizen Science. There are contributory projects which mean mostly crowdsourced data collection, collaborative projects consisting in data collection and data analyses of citizens and last, co-creative projects where researchers and citizens work together in a project, for the most part of the time. Citizen Design Science is most related to the last line of the research approach. The CDS is based on 3 main pillars. The term Citizen Design is not yet commonly found in scientific literature. Generally, it is used to describe a specific kind of participatory design. The word ‘citizen’ is referred to people that live in cities and belong to urban communities; ‘design’ indicates the way of performing the participation in the creation and design phase. Thus, the Citizen Design is a dynamic designing of the urban habitat by citizens (Mueller, et al., 2018). One of the first application of the Citizen Design method was adopted and described by Kevin Lynch's strategy of mental mapping. This study was presented in "The Image of the City" (Lynch, 1960). The task was very easy, ask participants of the studies to draw through simple five elements, places and objects that are most remarkable in a city, from a personal point of view perception by landmarks, nodes, paths, districts, and edges.

Instead, the Design Science defined by R. Buckminster Fuller (Papanek and Fuller, 1972) as a systemic form of designing, is continuously understudying, especially in the fields of innovative technology and creativity. In the last century data science and big data are seen as possibilities to bring unnecessary breakthroughs. “The difficulty addition for Citizen Science in urban design is that it is not clear how the input of activities through citizens’ engagement can be translated to the language of designers and how the local knowledge from citizens can be used as contribution to experts’ works in urban planning” (Mueller et al., 2018). There are a series of different approaches which follow the philosophy of the citizen design such as: the work published by Edwing and Handly (2009) showing a way to measure a city area through walkability aspect; or the text of Bryson et al., (2013) that combined the idea of design science together with participatory design in urban planning giving guidelines for participatory processes; and Stimmel (2015) suggested a designed thinking method for urban planning in smart cities including a "human-centered process that comprehends the phases of empathy, creativity, and rationality". Inside the Citizen Design Science, every element is essential for others to make this strategic science a successful application. If there isn’t Citizen Science, the dynamic part where people can truly design expressing their ideas, they will stay just on a low and theoretical level. Citizen Design Science, especially with the citizen design pillar, aims to underline the importance of people involved in the planning process, saying that would be impossible without the creative design aspect. “The allure of citizen design is also the gaming aspect and the fascination of new technology for younger people. Not only is it a no right or no wrong process, but people can also express their ideas in an unanticipated way which could mean a higher motivation to participate” (Mueller et al., 2018).

The role of technologies is to provide tools in Citizen Science context, using them to employ people for evaluating the participatory design phase.

In this regard, participatory design is considered when people are directly involved in the design process. Citizens or people generally involved in urban projects, may serve as a simple idea input but they can also make decisions in a process. It is possible to recognize two different approaches: the bottom-up and top-down. In the first approach designers and stakeholders are together involved implementing rules in the design tool and they prepare a relevant design task that citizens are requested to solve. Thanks to the citizens’ feedback the designers can evaluate them and extract useful design criteria which influence the designers’ master planning.

In the latter, one citizen can only try to solve issues shown by governance or other professional profiles, without the collaboration, for example, with designers, architects, and engineers and with other citizens too. Sanders (2002) said that people express their experiences by saying, thinking, doing, using, knowing, feeling and dreaming. Of course, discussion, focus group interviews, questionnaires, and observation events, or the use of “tools” and “do tools” can help to access the experience of sharing ideas. The “make-tools” can be a possible solution to transform ideas and personal abstractions in realistic proposals. Especially, interactive tools allow people to express themselves in different ways, actively creating or managing objects and situations, they can also express themselves in a new and unusual way.

In summary, CDS is a crowd creative strategy for smart cities to integrate the citizens' experience and expectations of the urban environment through their own design proposal for newly planned or redeveloping existing urban and social areas. This science describes a new strategy of urban design with the purpose to overcome the technological perspective of current urban planning methods towards a participatory planning method, more user-centered. Interactive tools can create the opportunity for a large number of people to simultaneously provide direct feedbacks without high expenditure. Active design in workshops with citizens is the most common approach to overcome the limited creativity of participatory planning tools. Methods which combine these two solutions is what is possible to define as the Citizen Design Science.

The Serious Games, definitions and a classification

The first definition of SG was written by Clark C. Abt (1987), the pioneer of this expression, inside his first publication called "Serious Game". He defined a game as a "particular way of looking at something, anything". In addition, he also said that "reduced to its formal essence, a game is an activity among two or more independent decision-makers seeking to achieve their objectives in some limiting context. A more conventional definition world says that a game is a contest with rules among adversaries trying to win objectives".

The author describes the SGs as a "game that can be played seriously or casually by people. We are concerned with serious games in the sense that these games have an explicit and carefully thought-out educational purpose and are not intended to be played primarily for amusement. This does not mean that serious games are not, or should not be, entertaining".

According to Abt theory, Costikyan (2002) defines a game like "a form of art" in which participants, called directly players, can make decisions to manage resources through game actions and activities searching of the game goal.

Zyda (2005) provides another interesting description for identifying that SG could be defined as a mental contest, played also with electronic devices in accordance with specific rules, which "uses entertainment to further government or corporate training, education, health, public policy, and strategic communication objectives."

SGs have multiple learning aims, they can be applied in many areas and targets all age groups (Mouaheb, et al., 2012), they can be considered also as teaching tools, a means of entertainment, and an information and communication technology system. The goal for an SG methodology consists of the reduction of problems complexity to such a level of abstraction, that the players can easily interact with it, discussing it and comparing with each other (Johan de Heer et al., 2010).

In other words, the SGs are defined as a methodology which proved to be effective methods applied to many research and practical fields (such as education, management, industries, and health care) but they are not so much used in social learning context of smart cities and generally urban planning. Indeed Abt (1987) reported that games may deal with important behavioral issues, and they can concern considerable problems in almost all academic and intellectual field. "Education, analysis, and evaluation are all rich fields for the use of the serious game. In education, games are used by teachers for classroom instruction in social studies, sciences, and humanities, and for guidance counseling." He also mentioned the possibility to apply this tool for testing alternative military strategy, for evaluating, for instance, regional transportation plans, public responses to the environment and other issues related to sustainable urban contexts. One of the main strengths of the SGs is that they can support effective decision processes being able to acquire data directly from people in general, through a very simple approach based on entertainment. Basically, this tool is not applied in urban planning or smart cities context, because it is generally used in the educational field and other sectors such as health care, engineering, defense or politics (Ouariachi et al., 2018).

According to Ouariachi et al., (2018) the education embraces SGs because teachers recognized their potential: "game is motivating, provide on real-time immediate feedback, they can adapt themselves to the level of the learner, they encourage distributed learning, and they can be used for other excellent teaching techniques" (Gee 2003; Gentile 2011). An interesting consideration can be made also about the use of games, understanding what are the numbers and the prevalence of games' trend. From Statista (2018) the market of serious games is one of the fastest growing areas in educational media and it is expected that can grow from 3.2 billion U.S. dollars in 2017 to 8.1 billion in 2022. "Creating awareness

and promoting attitudinal and behavioural changes on sustainable issues is crucial, and serious games can play an important role by allowing players to experience unfamiliar circumstances that are not possible in real life: for instance, being a mayor with the power to change a whole city towards a more sustainable place, balancing pollution, energetic productivity and citizens' happiness as players experienced" (Ouariachi et al., 2018). Among these different definitions, an interesting consideration concerns the importance and the role of the adjective "serious". In fact, all the expressions above do not mean that the addition of serious term indicates a limit for the game for being enjoyable. On the contrary, it suggests that its rule can be used to impart knowledge in a playful way. The term serious is used by Abt to indicating the sense of study, relating to matters of great interest and importance, raising questions not easily solved, and having important possible consequences. In fact, the serious game expression can be identified as an oxymoron where the seriousness of thought and problems are linked to the experimental and emotional freedom of active play.

A Serious Games' classification

Research about existing realized games in terms of sustainability themes has been done, focusing on the last decade. The work was made according to guidelines and researches described in two main scientific publications, Stanitsas et al. (2018) and Ouariachi et al. (2018), and according to the consultation of some serious games online sites or database such as Serious Game Classification, Games for Change and Games 4 Sustainability. In a Serious Game Classification online database, the games are classified according to their gameplay, their purposes, their markets and target of users, alongside with user-contributed keywords (serious.gameclassification.com). Games for Change is a community founded in 2004 with the aim to empower game creators and social innovators to drive real-world change using gamification method and technologies. The final target is to help people to learn new thing improving a sense of community and trying to contribute to make the world a better place to live. About their activities, they organize an annual festival for serious games and students' challenges, training students and educators to run game design (gamesforchange.org).

Game for sustainability is an online platform where users can learn and practice sustainability through serious games applications and find links with the themes of sustainable development goals. Starting from the different objectives involved in this online database and platforms, to conduct this research, some specific keywords have been selected and used such as serious games, educational games, applied games, environmental games, gamification, and game-based learning games. Through this keywords selection, the first step has been to trace the documents, searching in online databases such as Scopus, Web Science and Google Scholar, several articles and papers concerning serious games applications. Subsequently, it was made a documents' selection through abstracts and full-text reading, in accordance with relating appropriate information.

For this search were investigated some different subject areas such as computer science, engineering, social science, and environmental science. Among these, there were analyzed several document types including journal articles, whole books, and book chapters, conference papers, and dissertations. The scientific contents identified in these works include documents that represent models, techniques or a literature review made exploring and describing SGs, through their history, their application, their assessment, showcasing study practices for an educational contribution (Stanitsas et al., 2018). In practice the analysis was made considering the most famous serious games realized in the last decade, identifying their genre and type, of the underlying specific target users and their game theme/topic. Finally, it has been trying to find a link between the aim of serious games and simulations arranged by the Sustainable Development Goals. Sometimes the goals are expressively mentioned, especially in Games 4 Sustainability site, while other times the date are not found, definitely for the games created before 2015.

The criteria used for doing this first classification have been reported in table 1 while the results of the research are shown in table 2.

<i>Year</i>	<i>Serious Game Names</i>	<i>Genre and Type game</i>	<i>Target</i>	<i>Game Theme/ Topic</i>	<i>SDGs</i>
From 2007-2018	Title of every Serious Game realized in the last 10 years	Distinction based on the typologies classified as: <ul style="list-style-type: none"> ▪ App game ▪ Board game ▪ Card game ▪ Online game ▪ PC game ▪ Video game ▪ Web game and the genres classified such as: <ul style="list-style-type: none"> ▪ Adventure ▪ Education ▪ Policy exercises ▪ Puzzle ▪ Strategy ▪ Simulation/ and strategy ▪ Role-playing game (RPG) 	People directly involved in the games, simply called players, they can be: <ul style="list-style-type: none"> ▪ Children, Youth ▪ The general public (GP) ▪ Students 	Description of the main themes or topics takes on inside the games. For this classification, games were analyzed on the basis of sustainability concepts. For instance: <ul style="list-style-type: none"> ▪ (Sustainable) Urban planning, development, and management of smart cities ▪ Renewable energy source ▪ Waste management ▪ Water cleaning and management ▪ Sustainable immigration and cultural integration ▪ Sustainable actions for the environment 	List of Sustainable Development Goals identified in 2015 by the United Nations. They are 17 priority goals that cover important issues to solve in 2030 by developed and developing countries

Table 1, Criteria used for doing the SGs' classification

Some considerations can be made after this first classification. The first result is that 67 games have been found and analyzed. These are the most famous and important games realized in the last decade towards sustainable themes and issues. The most part of the information games was found starting from 2014 especially about the SDGs connections and the increase of online and video games.

Indeed, most parts of games are online, followed by hybrid simulation game and PC/video game. In this field, technology and the internet play an important role and, as expected, the board and card games are the minority. About the theme and topics tackled by the games, the majority of them have been designed to educate students and professors sometimes, with the general public too. This stakeholder is typically a motivation group of entities that need to be clearly aware of sustainability topics for personal own reasons. Generally, the issues of these analyzed games are to increase awareness of sustainability issues and stimulate interest and engagement. The general public, on the other hand, is a group of players who have no direct interest in engaging with these games, more reason to involve them to enhance their curiosity and improve their awareness about these themes (Stanitsas et al., 2018). The majority of the games wants to educate players towards sustainable themes resumed in macro areas such as water and waste management, renewable energy source, sustainable immigration, and cultural integration, (sustainable) urban planning, development, and management of smart cities. Therefore, the largest quantity of games found belongs to the environmental aspects. The other games belong to the economy, quality education in general terms, politics, and culture. Environmental management games tend to be highly popular nowadays, especially due to ecological destruction and the huge increase in the use of the Earth's natural resources (Damania et al., 2018). The Socio-Economic, Socio-Environmental and Eco-Efficiency dimensions are almost equally developed (Stanitsas et al., 2018). One of the most interesting consideration can be made towards the connection between sustainable education games themes and the 17 sustainable development goals. In a particular way, the SDG11 is really focused on the development and management of smart-sustainable cities and their communities. Nowadays many cities all around the world are tackling social, economic, urban challenges in order to support the growing population and the environmental impact of urban sprawl. Citizens are main characters inside these contests. One of the target indicators proposed by SDG11, the 11.3, is to enhance inclusive and sustainable urbanization, involving citizens in planning and management in all cities. About this is interesting that, especially in the last 5 years, As reported in table 2, most parts of the games are designed for the sensitive general public or specific stakeholders to raise their awareness. The SGs can be innovative, interactive and dynamic tools able to combine, at the same time, sustainable goals with the stakeholders' involvement. For instance, this game classification may be extended and better correlated to other SDGs such as clean water and sanitation, quality education, climate action, affordable and clean energy, and responsible consumption and production. Moreover, these games'

classification is just a small part inside the games' world, the research can be improved adding other information and consulting other scientific research done and online catalogs. The classifications' criteria could be increased for instance with a distinction between type and genre. Other features can concern the gameplay, the creators' name, the eventual price, languages, the duration and especially about the game availability.

<i>Year</i>	<i>Serious Game Names</i>	<i>Genre and Type game</i>	<i>Target</i>	<i>Game Theme/Topic</i>	<i>SDGs</i>

Conclusion and future development

This paper framed the smart cities concepts, reporting an overview of the current literature review, and the central role that they covered in the last years. Smart cities and communities are one of the 17 SDGs identified by the 2030 Agenda. As written in SDG 11, one of the targets decided for smart cities and communities is to "enhance inclusive and sustainable urbanization and capacity for participatory, integrated and sustainable human settlement planning and management in all countries". (sustainabledevelopment.un.org). These themes are key issues, the communities and the involvement of their citizen are in the middle of attention, covering a fundamental role for improving the smart cities future development. Architecture and urban design are excellent and interesting fields where is possible to apply Citizen Science methods because one yet unsolved task is to describe unambiguous criteria for liveability and sustainability in cities. At the same time, this issue is challenging because there is no a clear definition of liveability so it can have different meanings for people, especially if they are coming from different regions, places, and cultures. (Mueller, et al., 2018) Towards sustainability, the 2030 Agenda defined precise 17 goals with relatives' targets in order to save the planet, especially for the future generation. Nowadays, people' involvement becomes the main topics discussed. The citizen participation and involvement in urban activities have become active and relevant part during transformation periods. The growth of involving methods in an urban planning context has given to citizen the opportunity to share their ideas with other citizens and especially with governance too. Activities such as discussion groups and workshops are particular moments and occasions when citizens thought became reality. The methodology known as Serious Games can be used to better improve the interaction among the different stakeholders involved in an urban context. The work made on the use and application of SG methodology in an urban context, about sustainable themes, shown that this interaction is possible. The perspective to design a learning tool for involving citizens in an urban context and also teaching them sustainable behaviours is possible. The first classification of SGs realized towards sustainable goals has been done, and literature reviews towards themes such as urban planning, sustainable living, and energy saving, shown great interest in the scientific community.

Research on Urban Community Micro-regeneration from Perspective of Multi-actor Participation: the Case of Yangpu District in Shanghai

Jialin FANG¹, Guiqing YANG*²

¹ Doctoral candidate of Tongji University, fangjialin0411@163.com

² Corresponding author, Professor of Tongji University, yguiqing@163.com

Abstract: In today's megacity community, changes of family composition and content of life, as well as the aging of the built environment urgently require urban managers to respond timely. Community micro-regeneration is one of innovative implementation paths to stimulate community vitality through spatial intervention based on multi-actor participation with limited time and resources. Since 2018, Shanghai Yangpu District has hired a 'community planner' to provide professional consultation about community micro-regeneration for each grassroots administrative unit. A multi-participated, low-cost and easy-to-promote micro-regeneration model has been explored to find space issues and solve problems. Based on multi-actor theory and collaborative planning theory, this paper discusses the composition of multiple actors and their impact on the planning process and results. Through methods of participatory observation and semi-structured interview, whole process of one pilot project was tracked. The study pointed out that government departments, community planners, community residents, community organizations and professional organizations work together to formulate plans through institutionalized channels, adopting open working methods and continuous interaction should contribute to the participatory, fairness and controllability of community planning. In the process participation awareness and execution capacity of all players need to be improved to avoid increasing negotiation costs and restricting micro-regeneration effect.

Keywords: community micro-regeneration, multi-actor, collaborative plan, Shanghai

1. Introduction

As a space for small and medium-sized human settlements, community is a guarantee for personal development and dignity, health and safety, happiness and good life, and the development of sustainable human settlements. The population and population heterogeneity of megacities are increasing, resulting in increasingly complex situations in urban and rural communities. For example Shanghai, with a permanent population of more than 24 million including a floating population of nearly 10 million, is facing with increasingly contradiction between the decline of environmental facilities and the growing demand for life content of residents, and growing gap between living space and public resources available to different income groups. As the complexity and variability of community affairs intensify, power gradually approaches citizens and communities. The idea that management needs to be done by cooperation rather than by any individual or organization is recognized, and the concept of 'governance' is applied to community public affairs.

Governance can be understood as a change in the relationship between public, private, community and voluntary sectors to cope with an increasingly complex, uncertain and vibrant world (Kooiman, 1993). Since the 1990s, government has ceased to be the center of power above society and people. The dialogue between public and private actors has become a new trend, and the concept of modern governance has gradually been established, disseminated and widely used (Gaudin, 2002). In 2014, the Shanghai Municipal Committee and Municipal Government issued the 'Opinions on Further Innovating Social Governance to Strengthen Grassroots Construction' (hereinafter referred to as 'Opinions'), taking urban and rural communities as the focus of social governance, 'putting resources, services and management as much as possible to the grassroots level to enable the grassroots administrative unit to have the right to provide better and more accurate services and management for the masses'. The 'Opinions' also gave the grassroots administrative unit called '*jiedao banshichu*' in Chinese 'planning participation rights' for the first time. The accumulation of community governance theory and the empowerment of Shanghai's '*jiedao banshichu*' provide new ideas for improving community built environment and promoting community development.

Community space is closely related to the characteristics and quality of residents (Parker *et al*, 1968). Community space is the place where residents' daily individual and collective activities occur, and its attributes and characteristics affect residents' daily life and even behavioral psychology. Small-scale public space is a kind of civilian public space at community and neighborhood level and the place-making has a positive effect on promoting neighborhood communication and enhancing community sense and fairness (Yang *et al*, 2017). With this regard, physical planning can be seen of practical significance for mitigating conflicts arising from urban social structural changes and social

spatial reconstruction (Yang, 2013). Recently more and more city managers regard community public space micro-regeneration as a path to achieve public space's perceivable quality improvement with limited time and resources, and realize the sharing of common wisdom and common creation. Yangpu District of Shanghai piloted a few community micro-regeneration projects in 2017 and expanded to the whole district in 2018. 'Community planners' who are professional in urban planning were introduced into community to help mobilize and coordinate the forces of different parties to participate in community planning and examine and control the quality of the plan. So who are the multiple actors? How do they affect micro-regeneration planning process and result? This paper would like to respond to the above questions based on observation and analysis of a micro-regeneration project in Yangpu District.

2. Literature review and research design

2.1 Literature review

Community micro-regeneration is one of the types of urban regeneration. It is a method of regenerating inventory space to prevent community decline and improve environmental quality under the guidance of connotative development and refined management concepts. Multi-actor refers to interrelated network of individuals or organizations directly or indirectly related to community development in a certain region and period. They participate in community public behaviors. The micro-regeneration of small-scale public spaces closely related to daily life is a way to realize regeneration of community functions and enhance residents' sense of community. It is also a feasible way for the masses to transfer from private sector to public domain. Meanwhile through participation of multiple actors, it is possible to accumulate more knowledge and resources for projects, so that planning results can effectively work and gain wide recognition. Therefore community micro-regeneration is of great significance to the current community construction and community governance, and must be achieved through the participation of multiple actors.

The research on micro-regeneration of urban communities involving multiple actors mainly involves knowledge fields such as public management, sociology and urban planning in China. The former two pay more attention to governance structure or interaction mechanism of multiple actors in community space creation events, focusing on analysis of institutional supply, actor relationship, governance model, etc. (Wu, 2015; Ge, Li, 2016; Zou, Yu, 2017). Space is mostly used as a platform or object of public behavior. Urban planning discipline values the combination of space and society, and explores methods and strategies for multiple actors to participate in community planning. Such research includes but is not limited to, the constantly expanding and developing participatory planning practice centered on the value of community citizens in Taiwan (Wang, 2018), collaborative planning practice

in Guangzhou in a low-income community (Yuan, Chen, 2015), Xiamen's community-based participatory planning practice with theme of Joint Creation (Li *et al*, 2018), Colorful Community Action Planning practice in Shanghai Pudong New Area (Zhao, 2018) etc. However there are relatively few studies on urban micro-regeneration mechanisms in urban planning. Wang Benzhuang (2005) studied the roles and actions of the three types of actors of government, NGOs and community groups in order to achieve a win-win situation in the process of Taiwan community building. Wang Chenghui (2018) summarized types and mechanisms of existing community micro-regeneration, analyzed effectiveness and hidden concerns of existing mechanisms, and proposed an improvement strategy based on the good governance model. These studies have contributed to the accumulation of theory and practice of community micro-regeneration in China. Based on relevant theories, this paper examines the details of community micro-regeneration in order to clarify the composition of the multiple actors and their relationship, as well as the process by which they interact and influence the planning decisions according to their power resources.

According to China's planning law, multiple actors involved in urban planning often include government, compilation unit, construction unit, experts, the public, and other stakeholders (Wang, 2008). Wu and Hua (2005) classify them into four categories: management departments, various interest groups, urban planners and public. According to the 'Opinions', grassroots social governance system of Shanghai is the combination of 'leadership of the communist party', 'government dominates', 'participation of all parties in society' and 'mass autonomy'. As a way to achieve governance through planning interventions, all of the above aspects are the main considerations for community micro-regeneration. Multi-actor participation is often related to community public affairs including who participates, when to participate and how to participate. The theoretical circle has reached a consensus on the increase of actor types and number of participation in community behavior, as well as the necessity of establishing a re-contact with the public (Atkinson, 1994; Stoker, 1996). The discussion on participation phase is also more consistent. Taking Canada as an example of developed western countries, public participation phase of community planning includes 'decide to prepare a plan', 'solicit concerns and suggestions of the community', 'present the draft plan', 'decide on the plan by-law', 'province approves the plan', 'implement the plan' and 'review the plan' (Hodge, Gordon, 2014, pp.342-344). In China taking Beijing Qinghe community plan as an example, public participation runs through the whole planning process of task formulation, goal formulation, plan making, implementation as well as management and maintenance (Liu *et al*, 2017). Discussion about the way of participation is controversial. Some scholars advocate indirect participation, but many believe that more direct participation is needed (Roberts, 1997). There are also scholars who fear that the more open the participation process is, the more divisive the problem will become; and that 'the

broad but shallow interests represented by citizen' will be overwhelmed by 'the narrow and deep interests represented by organized groups' (Olson, 1965, cited in Innes, Booher, 2004, p.421).

The inclusion of government departments, citizens, profit and non-profit organizations and planners in a common framework of collaborative planning approaches that address problems through cooperation, dialogue, learning and action, is a useful attempt to involve multiple actors in planning (Innes, Booher, 2004). Community space has its intrinsic public attributes, so government departments has always been part of the collective activities of participation in space management and development, but the role of government in space governance arrangements can be variable (Healey, 2010; Adams, Tiesdell, 2013). Although there are few formal rights to planning decisions, the professional and technical knowledge of planners is sufficient to influence planning decisions. In collaborative planning process, planners should not discuss community issues solely from the standpoint of experts, but rather into interactions as actors in planning implementation (Sun, Yin, 2004). With the awakening and improvement of residents' community consciousness, their sense of participation has gradually increased. However it is more difficult for the public to talk directly with government or other organizations or groups as individuals, so community organizations can participate in collaboration as a medium (*ibid.*). This approach to building collaborative networks through power-sharing and addressing challenges through different collaborative approaches can both provide better public services to communities and facilitate the realization of public values.

2.2 Research design

This study is a qualitative study. Methods of participatory observation and semi-structural interview are used to study a case of community micro-regeneration practice. Firstly, according to literature and Shanghai policy, this paper combs out the types of multiple actors involved in this case and the public participation process of community micro-regeneration, which are the observation objects of this study. Secondly, the author carries on the tracking research to the case's planning process and several exchange interviews to different participating actors. Based on this, the article delves into and records the community micro-regeneration process: how multiple actors deploy appropriate power, resources, and knowledge through cooperation to create better community public space.

This paper takes the micro-regeneration project of greenbelt in the east side of S Neighborhood of X Community of Yangpu District as the case. The community is located in the northeast of central Shanghai and is positioned as internationalized, intelligent and ecological community. The S Neighborhood, which was completed in 1999, is one of the few old residential areas. The green belt is a protective green space for urban trunk roads and confluence pipelines, with an area of about 1.68 hectares. When completed, the land is zoned within the boundary range of the neighborhood, and the

developer has not formally handed over its management functions to the homeowners. At present the property company manager hired by the owners committee maintains the greenbelt with meager funds from property management fee. Green Belt has long been occupied by garbage, dead wood and debris, and the fast-growing poplar has fallen every year, as shown in Figure 1. *Jiedao banshichu* and district greening bureau hoped to transform land tenure into a public nature for unified management, but homeowners opposed it. In 2017, the developer had designed the landscape renovation plan and shelved it for some reason. The project was selected as a community micro-regeneration project in Yangpu District in 2018, which is a new opportunity for improvement. This case was chosen because all community micro-regeneration projects in Yangpu District are under the same institutional background; hence this case has certain representativeness.

Figure 1. Project location and status before regeneration (sources: the author)

3. Community micro-regeneration practice with multi-actor participation in X Community

In January 2018, Yangpu District piloted the ‘Community Planner System Implementation Measures’, which matched 12 community planners with 12 communities to provide long-term guidance for community regeneration work within the jurisdiction. The micro-regeneration of community public space is one of the projects. Micro-regeneration is a community place-making plan led by district committee and district government, coordinated by the district planning bureau, and organized and implemented by grassroots administrative units under the professional consultation of community planners. The spatial objects of community micro-regeneration are the public spaces and slow-moving systems inside street corners or old residential areas.

3.1 Community micro-regeneration planning process

Planning process of the project of X Community continued from the beginning of 2018 to the end of the year. According to literature and local policy, this paper divides the participation phases of community micro-regeneration planning into phases of planning recruitment, goal articulation, project survey, plan formulation and planning decision-making, and planning approval. In this process, relevant departments and individuals communicated, negotiated, disputed and compromised for their own interests and purposes, and jointly sought solutions to problems. Figure 2 shows some working scenarios of the important participating nodes at each stage. The following is a discussion of the process and result of the participation of multiple participants in different phases.

Figure 2. Important participating scenarios (sources: the author)

Planning recruitment. In January 2018, Yangpu District held a signing ceremony for community planners with the district government. The task arrangement was determined at the meeting: the district planning bureau took the lead in work coordination, related training and publicity, and the grassroots administrative units fully carried out the community regeneration work with assistance of community planners. At the meeting, X Community and community planner Y successfully paired up.

Goal articulation. Officers of grassroots administrative unit in X Community worked together with community planner Y to analyze the requirements of upper policy, current status of community and development appeals comprehensively, and discuss the common value of micro-regeneration work to guide the practice. These values include: 1) problem orientation: starting from the housing problem and improving the living environment of residents; 2) extensive participation: respecting the wishes of residents and combining professional design with residents' participation; 3) people-oriented space: creating comfortable space for citizens' individual and collective activities; 4) combination of

long-term planning and short-term planning: leading the work with overall plan, and boosting confidence with recent work. As the first project of X Community, the project is expected to be of strong willingness for residents to transform, suitable for neighboring activities, and can show the cultural characteristics of the community after regeneration.

Project survey consists of two parts, project selection and project awareness. During the selection phase of the project, the administrative officer and community planner collated and analyze public spatial and public environmental issues complained about by the crowd through the 12345 hotline in recent years and examined all alternative projects. Combining the residents' needs of transformation and the potential of space enhancement, the greenbelt was finally determined as the annual project. Then community planner, design unit and implementing unit have focused on on-site and off-site research on the project. At the same time, the residents' committee and the owners' council of S Neighborhood organized a collection of concerns and suggestions from community members. After bringing together the multi-actors' information, officer of grassroots administrative unit organize the consensus meeting, so that the multiple actors get together to know and understand each other, and explore problems and resources. The community planner, and representatives from the residents' committee, the owners' council, the developer, the district greening bureau, design unit, implementation unit participated. At the meeting, the community planner briefed the participants on the Community Planner system and the positioning of micro-regeneration work, and explained to the residents the starting point for choosing the project and the expectations for the project, as well as the residents' right to veto the project. Representatives from the residents' committee and the owners' council expressed the willingness of residents to implement micro-regeneration. This determines that the work would be advanced in the S Neighborhood.

Plan formulation and planning decision-making. The phase includes a series of workshops. After the decision to initiate plan making, the community planner proposed a conceptual plan as shown in Figure 3 for discussion. The plan aimed to create a cozy space for residents' culture and leisure activities. The venue was divided into functional areas for children, adolescents and the elderly. Usually the greenbelt was closed to daily activities of residents of S Neighborhood, and would be open to surrounding areas when the grassroots administrative unit holds monthly or quarterly cultural events. The residents' committee was concerned about the safety of opening the door and the difficulty of subsequent management of the site and facilities. The owners' council hoped to speed up planning and implementation progress as soon as possible for residents to use, and raised questions about funding source and who will maintain the greenbelt in the future. The officer explained that construction is supported by the district finance special funds, and the post-management will still be dominated by the neighborhood as they wished. The district greening bureau hoped that the project

can be linked to the regional public greening project, and pointed out that the plan should consider residents' ability to manage, and the facilities should be safe and easy to maintain. The administrative officer hoped that the project can satisfy with residents' needs and serve the surrounding residents, and the plan should be more conducive to safety and management. At the meeting a number of opinions were collected, and the next step was to modify and deepen the plan by the design unit.

Figure 3. Conceptual micro-regeneration plan (sources: community planner Y)

At the workshop in early March, based on principles of cost control, ease of implementation and durability, the design unit revised the conceptual plan to form a draft plan. The design unit then reported it to the grassroots administrative officer, community planner, district planning bureau and implementation unit, and the draft plan is shown in Figure 4. Representative of the district planning bureau indicated that she had participated in the discussion of the project for the first time. In view of the large size of the project, she suggested that the plan should be refined as early as possible in order to carry out construction schedule and costing. The problem of site maintenance after completion needed to be considered clearly in the early stage. Residents in X Community usually paid high attention to living environment thus communications were important. More details needed to be cautious, as it was not recommended to carry out extreme activities in the greenbelt. The grassroots administrative officer suggested a holistic approach to subtraction, with a focus on the activities of the children in the south and the integrated functions of the central community, supplemented by the elderly and adolescents. The cultural main line of the program needed to be strengthened; in addition, it was necessary to carefully consider the existing trees in the site. The poplars that have reached the life cycle would be moved completely. It was not recommended to arrange large-scale lawns and extreme sports venues in the site. The community planner suggested that the plan should be able to be divided, protect the rights of residents and consider the possibility of opening up to the surrounding area. The overall style of the project was mainly wild and simple, and it was not suitable for luxury

and exquisiteness. Trees in good condition could be kept. The function of cultural education should be strengthened; the design of environmental language should be original and highlight the local characteristics; the process of participatory design should be strengthened, and the sense of ownership of residents should be enhanced.

Figure 4. Draft micro-regeneration plan in March (sources: the design unit)

Based on the opinions, the design unit made simple modifications to the draft plan, including removing the extreme sports venues and retaining the trees in the multi-purpose square, and communicated with residents in late March. The residents' committee chaired the meeting, and the owners' council, resident representatives, community planner, and the district planning bureaus attended. Residents included residents adjacent to the greenbelts and other residents of the neighborhood. The more concentrated opinions of the residents were that they did not agree with the greenbelts to set up separate doors. Some residents could accept large-scale activities in specific days, and outsider could enter and leave from the current gates. The differences were that residents on the east side wanted to focus on greening and fitness trails, reducing activity venues and facilities, and other residents tended to have adequate activity venues and facilities. Some residents thought that venue for children could be kept, for the elderly could be weakened, and for young people was not necessarily needed. There were also residents who had expressed a desire to reduce this kind of discussion and quickly implemented the construction. The administrative officers still advised the residents to consider sharing with the surrounding residents, and the new doors could be closed on a daily basis and only opened during the event. The functional activities of the site should be commensurate with the demographic structure and human activities, and adolescents and young people were not without the need for community space, and space design needed to promote greater interaction between different people. In addition, the deepening of the detailed plan in conjunction with the multiple actors' views needed to be implemented as soon as possible.

Another workshop was held in mid-April, with the participation of the grassroots administrative officer, the community planner, the residents' committee, the owners' council and the design unit. According to the mapping of present situation, the design unit analyzed the preserved and transplanted trees, adjusted the spatial layout, simplified the functions and facilities, reduced the hard square and increased the greening, as shown in Figure 5. The administrative officer hope to refine the plan as soon as possible to make a budget, and the replaced tree species should be dust, noise reduction and safety. The community planner insisted that the plan needed to strengthen the accuracy and depth of drawings to guide construction; the current environmental design, site cohesion, materials and so on were not refined. In addition, the design should show the characteristics of the neighborhood, can design the characteristics of the motif, and the motif will continue to deduce through the site. The Council and the Industry Committee did not express their views on the proposal.

Figure 5. Draft micro-regeneration plan in April (sources: the design unit)

At the workshop in late April, the design unit reported the draft plan and the refinement to the grassroots administrative officer, the community planner, the residents' committee, the owners' council and implementing units. The participating subjects adopted the draft plan in principle and proposed further amendments to the draft plan: community micro-regeneration is a very meaningful work than just a planning and design task, so the human element should be embodied in the planning process and planning plan; the cultural connotation still needed to be strengthened and the main line should be prominent; greening planting is primarily to ensure safety, and trees, shrubs and grass should be matched reasonably etc. Based on the comments the design unit formed a plan to submit to the district planning committee for approval in early May. The plan was as shown in Figure 6.

Figure 6. Micro-regeneration plan for approval in May (sources: the design unit)

Planning approval. The plan was not approved at the plan review meeting held by the district planning committee in August because the budget of the project being 7.7 million was too high. The committee's proposal for district special funding for a single project was between 2 million and 3 million.

Plan modification and planning re-approval. The grassroots administrative officer and the community planner responded quickly as they were first informed of the special funding requirements. The officer negotiated with the developer and received support for the transformation cost of 2.8 million. The community planner suggested that the design unit divide the plan into two phases: the short-term implementation plan and the long-term plan. Based on financial support available in the current year, the plan would be simplified, with public activity space as the mainstay, guaranteeing basic facilities and reducing manual intervention. The plan also needed to reserve the interface for regeneration if re-acquisition of funds would be available in the future. The relevant district departments and the grassroots administrative unit also believed that the plan is feasible, and the door to open to the outsider would not be established in the near future. The modification scheme was shown in Figure 7. The district planning committee in November approved the plan and issued the minutes of the meeting in December. Since then, the micro-regeneration plan had been finalized.

Figure 7. Approved micro-regeneration plan (sources: the design unit)

3.2 Multi-actor structure and relationship

It can be seen that there are four types of diversified entities in the X Community, namely administrative departments, community residents and community organizations, community planner, and professional institutions, as shown in Figure 8. Specifically, it includes the district committee and district government, the district planning bureau, the district financial bureau, the district greening bureau, the grassroots administrative unit (*jiedao banshichu*), the residents, the residents' committee, the owners' council, the community planner, the developer, the design unit and the implementing unit. As for the government departments, the grassroots administrative unit as the main body of implementation, participated in the whole process of micro-regeneration, the district committee and district government participated in the planning recruitment and planning approval process, and the relevant district bureau offices helped to guide in the planning and formulation process. As users of community space, community residents directly participated in the planning process in a small number of times, and their opinions were scattered. More often, they are voiced and represented by the residents' committee, the owners' council to conduct dialogues with other actors. The community planner participated in most of the planning process in addition to the planning approval, which not only played a role in the quality of professional design, but also acted as a coordinator of the planning action. Professional institutions participated in the planning process of the corresponding stage for their own interests. See Table 1 for details of each actor's participation in important planning nodes.

Figure 8. Types of actors in the planning process (sources: the author)

The relationship between multiple actors is shown in Figure 9. The district committee and district government hires community planners to support the work of the grassroots administrative unit, and guides the relevant bureaus of the district to provide technical and economic support. The grassroots administrative unit is the implementation body of micro-regeneration work. Under the guidance and support of the district committee and district government, it organizes and raises the necessary resource for micro-regeneration and manages the whole planning process. With the assistance of the community planner, the grassroots administrative unit guides and mobilizes residents to participate in planning and decision-making process, introduces design units and implementing units with certain project experience in the region through procurement services, and coordinate the developers to provide certain economic support. Residents actively feedback their needs and comments, and participate in interaction with other actors through the residents' committee and the owners' council.

3.3 The performance of Community micro-regeneration

As Simon (1997) puts it, all decisions are compromises. The final choice is only the best course of action that can be chosen at the time and the decision-making environment will inevitably limit the content and quantity of alternatives, thus setting the maximum possible degree of achievement. So, to what degree does the practice process achieve the desired goals? What about the result of the micro-regeneration plan?

In terms of target feedback, this paper believes that the planning formulation process has a high degree of matching with the expected goals. Firstly, the project is the public environment issue that community residents reflect the most and the loudest to the administrative departments. Secondly, the planning process involves multiple actors in various stages, especially in the residential areas for publicity and consultation, and organizes designers, residents' committee staff and volunteers to listen to comments and answer questions at a fixed time and place. Thirdly, the functions and venue design are mainly based on communication and activity space, and the rich and multi-level greening is equipped with simple and convenient facilities, which is friendly for users. Moreover, the plan includes two versions of short-term plan and long-term plan. In the near future, through greening and transformation, the venues and facilities will be arranged to provide recreation space for the residents of the neighborhood. The long-term expectation is connected with the public space layout of the region, and cultural events are open to the surrounding areas in some time periods. At present, it seems that the long-term plan has achieved greater resistance. On the one hand, residents are still controversial about opening up. On the other hand, whether the project can obtain financial support in the future is still uncertain.

From the perspective of plan itself, the plan has experienced several changes from the February concept plan, to the initial plan in March, the revision plan in April, the review plan in May, and the final approved plan in November. To facilitate the discussion below, these five plans are referred to as V₁, V₂, V₃, V₄, and V₅, respectively. As can be seen from Figure 10, in the process of plan formulating, the grassroots administrative unit, the community planner and the design unit participated in the whole process; the district planning bureau and the district greening bureau provided guidance in some aspects; the residents personally participated in few consultations, and more of them were participated by the residents' committee and the owners' council; the implementation unit participated in many discussions, and the developer only participated in the discussion of the concept plan and the final plan. In general, the grassroots administrative unit, the community planner, the residents' committee and the owners' council, as well as the design unit and

the implementing unit play a major role in the formation of the plan; and the funds provided by the district government and the developer determine the extent to which the plan can be achieved.

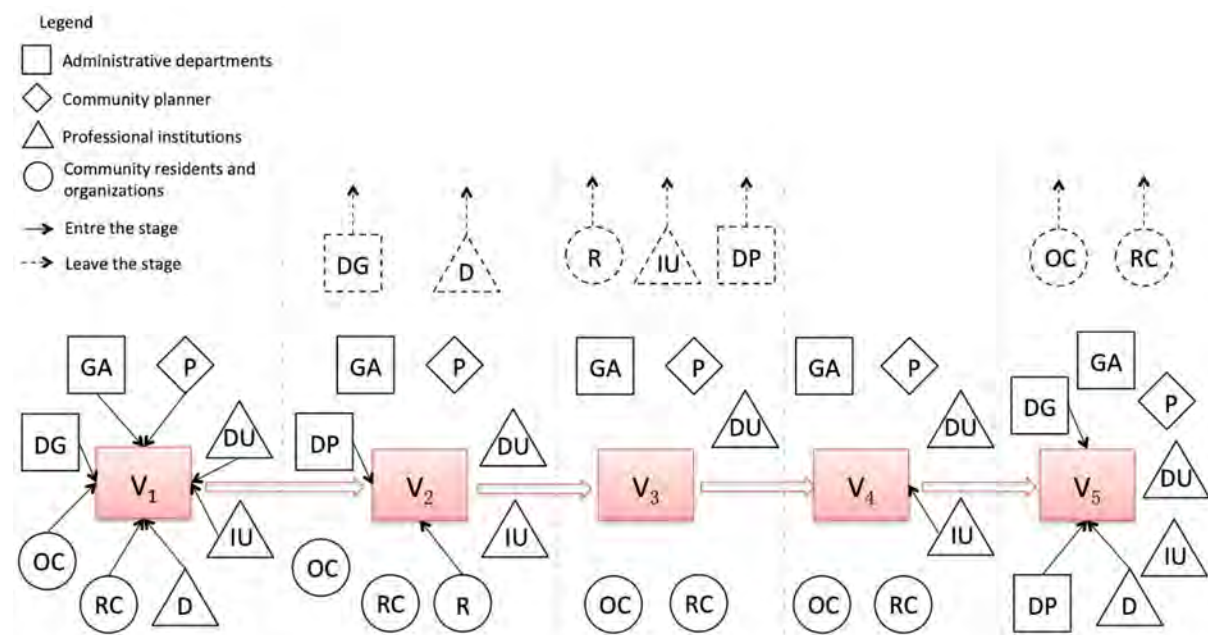

Figure 10. Multi-actor participation in the planning formulation process (sources: the author)

From the perspective of the program itself, the initial concept plan divides the functional area into children's activities, community cultural display, old-age activities and youth activities. It has experienced intermediate activities to retain children's activities and community cultural displays, weakened old-age activities, and eliminated youth activities. Activities will eventually form a functional area that is dominated by children's activities and community culture, supplemented by old-age activities and youth activities. In terms of site and facility design, due to factors such as budget, service scope and site safety, from the V_1 to V_5 , community squares, community stages and multi-purpose squares serving regional cultural events were cancelled, chess and stone tables and chairs, facilities such as the tree plaza and the children's park have also been cancelled or simplified. See Figure 11 for changes to the design elements of the site and facilities. The final short-term implementation provides leisure, fitness and social activities only to residents of the neighborhood. This is the result of multi-actor negotiation and compromise based on available resource conditions.

Figure 11. Changes in design elements of facilities and site at each plan (sources: the author)

4. Research conclusions and reflections

This case is a practice of urban community micro-regeneration under the policy of community governance of Shanghai and the community planner system in Yangpu District. The idea of innovating social governance to strengthen grassroots construction and the ‘community planner system’ ensure the legitimacy of multi-actor participation in community planning process. Under the leadership of the district committee and district government, the administrative departments at different levels have worked hard to break down barriers and accumulate more resource and personnel for micro-regeneration, with the grassroots administrative unit as the main body. As technical experts, community planners provide quality assurance for micro-regeneration, and as coordinators of the planning process, promote the more orderly participation of the multiple actors. Residents' daily public life needs have produced projects, and residents participate in planning formulation and decision-making through community organizations such as the residents’ committee and the owners’ council. Professional institutions participate in planning through their knowledge, resources and technology to support the work. Overall, the practice is participatory, fair and controllable, and can be an effective way to improve the quality of living, promote public interaction, and strengthen community governance.

However the relationship between multiple actors and the ability of them to execute limit the effect of micro-regeneration to a certain extent currently. Whether it is fund raising, or participation network organization, the administrative force always dominates; it is a challenge to the organization and management capabilities of the public sector, and it also limits the growth of the resident

self-governing capacity. At present, public sector reform is still in its infancy, and better sharing of information between departments will take time to grind together. In particular, the grassroots administrative unit is the main body of responsibility and has close ties with all sectors, which has a high demand for staffs' knowledge and ability to organize and manage the project. As a direct beneficiary of the results of the residents, the residents have tried to express their needs and opinions on public affairs, and to participate in planning decisions, but they still lack sufficient skills and abilities to participate. What's more, the residents refuse to provide more support for the creation of public spaces, including a small portion of financial support in the construction of the project, or an appropriate increase in property costs for future maintenance of custody, which is not conducive to operation and maintenance of the project. The emerging position of community planner, which provides professional advice and technical support for projects, as well as political thinking and engagement, is also a challenge to the energy, experience and competencies of urban planners. In addition to urban planners, it is possible to have more attempts by professionals from other fields as community planners. The micro-regeneration project involves more space participation activities, but the profit is lower according to the current design fee. More consideration is needed on how to improve communication skills of technical service units rather than talking about unintelligible jargon, as well as increase their motivation to participate without compromising their economic interests.

Abstract: Despite the importance of cultural ecosystem services in decision-making processes, the application of an appropriate methodology for valuation of cultural ecosystem services among communities with the same and common cultural values has been underestimated. This has become a challenge for urban planners, social and environmental groups and other stakeholders. Urban development projects have a great impact on ecosystem services that are of fundamental importance to communities. As a growing population demands more space for ambitious urban projects, these demands present substantial challenges to urban ecosystems particularly in areas with crucial environmental, and cultural values. The concept of ecosystem services contributes to a better understanding of the values people attach to nature, based on how they can benefit from the ecosystem services. This provides us with an applicable framework for the investigation into the importance of ecosystem services in human life well-being, enhancing dynamic social and cultural relations as a prominent basis for planning and management. Cultural Ecosystem Services (CES) are included in basic categories by presenting some important explanations for the necessity of an ecosystem framework. The values defined as cultural values have been elusive in part due to their complicated characteristics of intangibility and incommensurability in a valuation process. A lack of appropriate methodology and tool for valuation of CES has resulted in underestimating these values in the decision-making procedure. This paper firstly investigates CES and Participatory Action Research (PAR) as a possible valuation tool. Secondly, because of the importance of potential participation within the procedure, it investigates a sense of ownership that might result from PAR. Thus, the process aims to explore why this participatory-based approach can be defined as a reasonable tool for cultural ecosystem valuation by giving local people a greater knowledge of cultural values, and in-depth awareness of the consequences of socio-environmental actions in planning.

Keywords: Cultural Ecosystem Services; Participatory Action Research; Sense of Ownership

Introduction

“You tell us to take compensation. What is the state compensating us for? For our land, for our fields. But we don’t live only by this. Are you going to compensate us for our forest?”

What is the price of this? How are you compensating us for fields either—we didn’t buy this land; our forefathers cleared it and settled here. What price this land? Our gods, the support of those who are our kin –what price do you have for these? Our adivasi [tribal life] –what price do you put on it?” (Mahalia, 1994)

Global biodiversity is increasingly threatened by a range of drivers of change, including population and economic growth, land use change (development projects) and climate change. Therefore,

biodiversity continues to deteriorate at unprecedented rates (MA, 2005; Stern *et al.*, 2006; UN, 2009; Butchart *et al.*, 2010; TEEB, 2010; LPI, 2018). Among all these uncertainties, the concept of ecosystem services has gained worldwide attention as a worthwhile approach in terms of integration in decision-making related to ecosystem values, which already have been underestimated as peripheral issues (MA, 2005; TEEB, 2010). The ecosystem services (ES) concept has been advanced and widely adopted as a framework for identifying and weighting the social, cultural and ecological value in comprehensive management schemes (Daily, 1997; MA, 2005; Foundations, 2010; Tallis, 2011; TEEB, 2009; Blicharska *et al.*, 2017). The fundamental typology for ecosystem services in this research is based on the Millennium Ecosystem Assessment (MA, 2005) which distinguishes four types of services: provisioning, regulating, cultural and supporting services. Despite the integrative role of the ecosystem framework, the ecosystem service approach (TEEB, 2011) cannot take into account all dimensions of value and much value remains segregated in ecosystem research and practice, in fact, the doors have been closed to a lot of social and cultural aspects (Daniel *et al.*, 2012). In recent years, there has been a growing interest in the valuation of cultural ecosystem services and recognition of the importance of these values in decision-making procedures apart from monetary and dollar values. Cultural values have been included with ecosystem services in all eminent typologies (Costanza, d'Arge *et al.*, 1997; Blicharska *et al.*, 2017). Searching for those important cultural and moral values which are not dismissed as elusive externalities provides suitable space in order to facilitate appropriate treatment of different stakeholders and perspectives (Milcu *et al.*, 2013; Blicharska *et al.*, 2017). As mentioned above, apart from the importance of these cultural values, in a lot of cases cultural ecosystems have generally been valued in totally economic terms (Chiesura and De Groot, 2003) or there has been an unrealistic perception to these values. With the exception of recreation and ecotourism, the vast majority of the CESs have intangible nature and it is precisely the intangibility that is seen as the reason for their poor assessment (Milcu *et al.*, 2013; Burkhard *et al.*, 2014; Blicharska *et al.*, 2017). At present, it is, therefore, fair to argue that CESs are not yet adequately integrated within the ES framework, and, consequently, the development of parallel management strategies and policies is often unsatisfactory (Bieling and Plieninger, 2013; Blicharska *et al.*, 2017). The processes and mechanisms necessary for implementing this valuation in action especially at local levels have received relatively little attention. Thus, having an approach that is designed and used to work with local grassroots organizations has been avoidable (Milcu *et al.*, 2013; Burkhard *et al.*, 2014; Blicharska *et al.*, 2017; Hølleland *et al.*, 2017). A range of techniques has been used to measure the benefits extracted from biodiversity and associated ecosystem services. In this paper, the main concentration is on non-monetary approaches (TEEB, 2010). Non-monetary valuation (NMV) has a long tradition in some fields of environmental policy-making (e.g. in describing protected areas (Kukkala and Moilanen 2013), and different international initiatives have acknowledged its role in ecosystem services (ES) valuation (e.g., the MA, TEEB, IPBES). These techniques range from structured survey techniques such as questionnaires (Terer *et al.*, 2004) and interviews (Kaplowitz, 2001) to more participatory approaches such as participatory rural appraisal (PRA) (King and Faasili 1999) and participatory action research (PAR) (Mendoza and Prabhu, 2005; Tetui *et al.*, 2017). While these methods do not provide the monetary valuation of biodiversity, they can provide useful information on the importance of biodiversity to people in ways that monetary methods cannot (Málovics, 2009). But, the challenge in this area is a conventional disconnection between conducting research and putting results into practice through the mechanisms which focus on either research or capacity building but rarely both (Tetui *et al.*, 2017; Málovics, 2009). Indeed, the benefits of these valuation researches because of insufficient attention given to bringing together research and practice are always open to scepticism (Tetui *et al.*, 2017; Málovics, 2009). Many of participatory methods such as PRA and PAR were developed for use for marginalized groups, indigenous communities. The knowledge and insights derived from this experience may provide

useful awareness to provide opportunities for embedding valuation into local decision-making (Fazey *et al.*, 2011). Participatory Action Research (PAR) includes working collaboratively with the organization and training its members to conduct research with communities using participatory and deliberative methods (Christie, 2012). By using this approach, the aim is promoting inclusivity and participation in decision-making and building the capacity of the organization to include communities in the centre of social, cultural, and environmental uncertainties (Wakeford *et al.*, 2018). It aims to contribute to working with local communities to investigate whether cultural and environmental well-being and awareness grow through the successful establishment and management of cultural values in ecosystem framework and policy-making process. The objective of this paper is to justify the PAR as a possible mechanism for the valuation of the cultural ecosystem services, where it gives local people a greater sense of ownership, a more sophisticated view of ecological-cultural linkage, a greater definition of cultural values, and more awareness of the socio-ecological effects on environment.

Current popular terminology for ecosystem services framework

The ecosystem services approach is currently still evolving as a research field with a strong influence on international policy (Hølleland, 2017). The concept of ES was first coined in the early 1980s by Ehrlich and colleagues (Ehrlich and Ehrlich 1981; Ehrlich and Mooney 1983). By drawing attention to the many services ecosystems provide for human beings, their aim was to raise public interest and concern for ecosystem protection (Setten *et al.*, 2012). Following the United Nations' initiation of the Millennium Ecosystem Assessment (MA) in 2001, the concept of ES has gained new relevance and impact as a political and practical tool because the aim of the ES framework is ultimately to enable decision-makers to make appropriate management decisions (MA, 2005). The ES concept puts human needs and preferences in the centre of the ecological universe and measures the health of ecosystems based on their ability to provide humans with benefits – referred to as 'services' (Katz-Gerro and Orenstein, 2015). Following this purpose, the MA established a framework for identification, quantification, and valuation of the ecosystems' services. As illustrated in Table 1, the MA categorizes ES into four main classifications with a number of subcategories: supporting, provisioning, regulating and cultural services. As such, ES range from the provision of food, clean water and regulating services such as flood and disease control, to a variety of mainly intangible assets in the category of cultural services.

Ecosystem services	
Supporting services	Nutrient cycling; Soil formation; Primary production
Provisioning services	Food; Fresh water; Wood and fiber; Fuel
Regulating services	Climate regulation; Food regulation; Disease regulation; Water purification
Cultural services	Aesthetic; Spiritual; Educational; Recreational

Table 1. Ecosystem services. Adopted from MA(2005)

Cultural Ecosystem Services(CES)

Despite the great amount of research on the ecosystem services concept and approach in the past decades, the scientific literature clearly shows a lack of knowledge about the CES dimensions and lack of agreement about their role in the ecosystem approach (Schaich *et al.*, 2010; Setten *et al.*, 2012; Tengberg *et al.*, 2012; Blicharska *et al.*, 2017; Hølleland *et al.*, 2017; Díaz *et al.*, 2018). Consequently, there is a lack of integration of CES aspects into the ecosystem services approach, which can be explained by their intangible nature, evaluation difficulties, and methodological and conceptual issues (Milcu *et al.*, 2013; Burkhard *et al.*, 2014; Blicharska *et al.* 2017; Hølleland *et al.*, 2017; Díaz *et al.*, 2018). One problem for including cultural ecosystem services in environmental decision-making processes is not having an agreed-upon definition for cultural ecosystem services. Cultural ecosystem services were defined firstly as the non-material value benefits associated with ecosystem services. Costanza (Costanza *et al.*, 1997) defined cultural ecosystem services as the "aesthetic, artistic, educational, spiritual, and or scientific values of ecosystems". As seen in Figure 1, the Millennium Ecosystem (MA, 2005) expanded this definition to include the "the non-material benefits people obtain from ecosystem through spiritual enrichment, cognitive development, reflection, recreation, and aesthetic experiences," including cultural diversity, spiritual and religious values, knowledge systems, educational values, inspiration, aesthetic values, social relations, sense of place, cultural heritage values, and recreation and ecotourism. As illustrated in Table 2, similar definitions are found in succeeding ecosystem frameworks such as The Economics of Ecosystems and Biodiversity study

Figure 1. Subcategories of cultural services. Adopted from MA (2005).

developed by the G8 and hosted by the United Nations Environment Programme (TEEB, 2010) and the Common International Classification of Ecosystem Services (CICES) developed by the European Environment Agency (CICES, 2017). Such definitions seek to present the ways that ecosystems generate knowledge and support experiences (recreational, aesthetic, social, and spiritual), but they have tended to combine services/benefits and values (MA, 2005). A clearer characterization of services and values can be realized if cultural services are seen as producing a large number of intangible and non-market benefits (e.g., social cohesion) including different kinds of value (e.g., moral, religious, aesthetic)(Bieling, and Plieninger, 2010; Setten *et al.*, 2012; Tengberg *et al.*, 2012; Blicharska *et al.*, 2017; Hølleland *et al.*, 2017; Díaz *et al.*, 2018)

MA, 2005	TEEB, 2010	CICES V 4.3, 2017
Cultural diversity	Aesthetic information	Physical experiential interaction
Spiritual and religious values	Opportunities for recreation and tourism	Intellectual and representative interactions
Knowledge systems	Inspiration for culture, art, and design	Spiritual and/or emblematic (interactions)
Educational values	Spiritual experience	Other cultural outputs
Inspiration	Information for cognitive development	
Aesthetic values		
Social relations		
Sense of place		
Cultural heritage		
Recreation and ecotourism		

Incorporation of cultural ecosystem services in urban planning

Table 2. Overview of the different subcategories of cultural services used in the different ecosystem frameworks (MA 2005, Kumar, 2011, CICES 2017)

Incorporating cultural ecosystem values into urban planning and policy-making could help to increase awareness of nature as a critical component of human health and well-being (Gomez *et al.*, 2008). In order to acknowledge the importance of cultural ecosystem services for urban citizens, policy-makers and planners

must be aware of the link between biodiversity, ecosystem functions and people's experiences of nature. Urban planning and management must take into account how biodiversity loss not only has a negative impact on the provision of food and water and the regulation of climate, but also on citizens'

mental and physical health and well-being (Gomez *et al.*, 2008). Incorporating the diverse cultural values of ES within urban planning and policy will help to ensure that citizens' needs and concerns are included and more comprehensively addressed within planning processes, and that the basic principles of environmental justice have been strengthened. Cultural ecosystem services are an important element of the transition to more inclusive, just, environmentally aware and sustainable urban environments (Chan *et al.*, 2012). Existing knowledge and the practice of incorporating values of the ecosystem services in the planning process provides a potential opportunity for implementation of cultural ecosystem service dimensions and the ecosystem services approach at the local and regional planning levels. Tradition, shortage of resources (money and time), and a lack of methods for valuation of intangible aspects are some reasons for the discrepancies between theory and practice (Eliasson *et al.*, 2015). Accordingly, there is a great need to increase the availability of resources and improve the methods for evaluating intangible values in order to enhance the inclusion of intangible aspects in practice (Boswell, 2011). This also encompasses a shift in the direction of urban development planning in general, including a move away from strict protective measures and the utilization of CES for urban regeneration toward more creative, participatory interventions of using the past, particularly intangible CES, for the benefit of present needs (Eliasson *et al.*, 2019). Working with cultural values requires attention to how, when, and where values are articulated, as well as to what this articulation responds to. Consideration of both specific and broad processes can help environmental managers and policy-makers engage with seemingly intangible and contradictory social dimensions.

The valuation process for ecosystem services

The valuation of ecosystem services has a crucial role in supporting decision-making processes that directly or indirectly affect the natural environment. However, today's most popular monetary valuation methods based on the paradigm of neoclassical welfare economics face extensive criticism from various disciplines (Getzner, Spash *et al.*, 2004; Spash, 2006; Kumar and Kumar, 2008; Vatn, 2009; Greenhalgh *et al.*, 2017; Langmeyer *et al.*, 2016; Kenter *et al.*, 2016). Valuing an ecosystem service is thus equivalent with giving values to its different components where valuing the components is an important task even at the individual level. Moreover, measures and weights may vary from one beneficiary to another. This means that values given to different components of ecosystem services are incommensurable and cannot be easily aggregated (Martinez-Alier, 2014). Kumar and Kumar (2008) ask for more comprehensive ways of valuation because "when we focus on cultural, memory and linguistic variables we are valuing not only the intrinsic value of ecosystem services, but also their effects on human health or social structures, their aesthetic contributions, and their significance for future generations." For the scope of this paper, incorporating qualitative, participatory and deliberative methods into the cultural ecosystem valuation contributes to having a broad perspective regarding these incommensurable values (Martín-López *et al.*, 2012).

Cultural Ecosystem Valuation(CEV); Incorporating qualitative, participatory, and deliberative methods into the cultural ecosystem valuation

The term (non-monetary) cultural valuation emerged and has proliferated in a time when the ecosystem valuation literature has been dominated by monetary valuation and raised controversies around commodification (Martín-López *et al.*, 2012). Non-monetary methods include quantitative and qualitative research techniques (i.e. surveys, interviews), participatory and deliberative tools (focus groups, citizens juries, participatory or rapid rural appraisal (PRA/RRA) and Delphi panels), as well as methods expressing preferences in non-monetary but quantifiable terms (i.e. preference assessment,

time use studies, Q-methodology)(Christie and Fazey *et al.*, 2012). Those non-monetary techniques with focusing on the human expressions of preferences adjust to a more homogeneous subgroup within non-monetary valuation. Terms such as ‘qualitative’ or ‘subjective’ valuation (Aretano *et al.*, 2013) suggest that results reflect the subjective perceptions of stakeholders. Discourse centred (Wilson and Howarth, 2002) and ‘psycho-cultural valuation’(Kumar and Kumar, 2008) reflects broad umbrella concepts that consider preference formation as part of the valuation process and emphasise that personal and group values are important to understand. Sociocultural valuation has been applied as an umbrella term of non-economic methods analysing social preferences towards ecosystems (Martínez *et al.*, 2013). Due to the large heterogeneity of preference-based non-monetary valuation techniques, it is difficult to arrive at the same level of methodological consistency as seen in monetary valuation. Qualitative approaches (such as in-depth interviews and focus groups) provide opportunities for the researcher to probe more deeply into people's preferences than could be achieved using either quantitative or economic techniques (Baird and Flaherty, 2005). Such detailed insights may be extremely useful for uncovering local cultural and spiritual values that might not be directly transparent to external researchers. Participatory and deliberative approaches offer an alternative approach to the design and administration of valuation studies. Given that participatory approaches such as PRA and PAR were developed to meet the needs of social science research among marginalized groups, and indigenous people (Chambers, 1992), such approaches can help to ensure that valuation is applied through traditional, cultural or thinking practices, which will help to avoid the problem of imposing a western way of conceptualising environmental goods and services (Asia Forest Network, 2002; Jackson and Ingles, 1998). Participatory and deliberative approaches also provide respondents with ‘time to think’ about and reflect on their preferences, which has been demonstrated to improve the accuracy of valuation surveys (Whittington *et al.*, 1992; Kenter *et al.*, 2011). Such approaches may also help to: promote dialogue and deliberation with local people and decision-makers thus fostering ownership and responsibility of problems; promote learning and awareness; and build local capacity to analyse problems and make more effective collective decisions (Chambers and Cleaver, 1997; Reed, 2008; Wadsworth, 1993; Hughes and Seymour-Rolls, 2000).

Participatory Action Research (PAR)

Participatory Action Research (PAR) is a study design that treats the target communities as a part of knowledge generator and it is an approach from social science research as a shift away from the conventional approach. PAR works through diagnosis and addressing complicated human, environmental and social science issues. The specific characteristic of PAR is starting from social and educational research and expanding to research principles of participation and reflection, empowerment and enfranchisement of the group with social targets (Hughes and Seymour-Rolls, 2000). The PAR name reflects its three principles of participation, action, and development of knowledge with the potential to figure out wider issues of social justice, community inclusion and empowerment of marginalized groups (Wallerstein and Duran, 2010). It aims for a process to identify, prioritize and address social and environmental concerns and bridge the gap between communities and academics (Wallerstein and Duran, 2010). Community-based PAR has been defined by the National Institute of Environmental Health Science (NIEHS, 2001), and includes six principles:

- 1) Defining community as a unit of identity
- 2) Ensuring projects are community-driven
- 3) Promoting active collaboration and participation at every stage of research

- 4) Fostering co-learning
- 5) Disseminating results in useful terms
- 6) Ensuring research and intervention strategies are culturally appropriate. (O'Fallon and Dearry, 2002)

Groups that utilize PAR, attempt to redistribute power relations by working as a team to decide what is reached, how it is researched and its benefits across all stakeholders involved. In such collaborations, communities play a central role in decision-making, participants seek to collaboratively identify social-environmental problems, adapt potential solutions, and devise strategies to overcome challenges within highly respectful and analytical deliberations and discussions in order to collectively generate the final solution for problems (Susman, 1983; Baum *et al.*, 2006).

The different frameworks agree on PAR being an iterative process based on principles that promote local capacity building toward a collective social change (Susman, 1983; Stuttford *et al.*, 2012; Loewenson *et al.*, 2014).

According to Susman, the PAR cycle has five phases: problem diagnosis; action planning; taking action; evaluation; and specifying learning achieved. The cycle repeats with a refinement of the problem or a new one (Oscós-Sánchez *et al.*, 2008). At the centre of the PAR cycle the main principles are building and empowering communities and a system by which the important and inclusive characteristic of dialogues and actions can be made at different levels. Reflexive critique is about providing the opportunity for stakeholders to diagnose the problems and their perceptions about problems. This procedure happens in a very respectful and critical atmosphere. Collaborative resources are divergent participants, each with a valuable contribution to the process of research. On the other hand, the risk is about conflict created through the procedure of seeking challenge or change.

The plural structure principle demonstrates that there are several views and options in dealing with social problems (Tripathy *et al.*, 2010). Finally theory, practice, and transformation indicate the fact that peoples' actions are based on tactically-held assumptions that inform their actions based on built or enhanced theoretical outputs (Susman, 1983).

A sense of ownership: Demonstrating the potential for participation in local planning

The term ownership has been specifically used in community development contexts (Simpson *et al.*, 2003; Bessant, 2005; Bowen, 2005; Zimmerman & Meyer, 2005). The term is popular in environmental policy literature and in scholarship associated with sociology, education and curriculum development, and organizational behavior (Schneider, 1985; Barufaldi, 1987; Gusfield, 1989; Himmelman, 1996; Kearney and Kaplan, 1997; Wondelleck and Yaffee, 2000). The body of literature is loosely predicated on the assumption that if individuals are intimately and authentically engaged, dedication to the process and outcome will be created, leading to greater chances of political support and implementation (Lachapelle, 2008). Gaining a better understanding of the many characteristics of ownership in a planning process is critical toward furthering the study and application of community development since it can lead to better analysis of complex interactions, a greater chance of public involvement, and increased support toward the realization of community development goals (Lachapelle, 2008). Lachapelle (2008) demonstrates that a sense of ownership is proposed and applied to community development research and practice based on three essential characteristics and related questions:

1. A sense of ownership in process (who has a voice and whose voice is heard?);
2. A sense of ownership in outcome (who has influence over decisions and what results from the effort?);
3. A sense of ownership distribution (who is affected by the process and outcome?).

This first characteristic involves the processes by which voices are heard and considered legitimate or valid. Through a focus on ownership in the process, community development research and practice can construct methods that explicitly examine who has a voice in a development process and, more importantly, whose voice is heard (Bardwell, 1991; Gray, 2003; Fischer, 2000; Watts, 2000; Ferguson and Derman, 2005).

The second characteristic of a sense of ownership involves who has influence over the outcome through decision-making (Lachapelle, 2009). The sense of ownership provides a clear focus on the influence or direct authority over decision-making and the execution of actions. Consequently, a sense of ownership is predicated on power and empowerment, two terms that have received adequate discussion in theoretical and applied community development scholarship (Harley *et al.*, 2000; Pigg, 2002). The third characteristic of a sense of ownership demonstrates its distribution across various social, political and ecological scales. This last characteristic involves analysis of those who are affected by a decision as well as how the effects of a decision are distributed, accepted, both spatially and temporally (Pigg, 2002). Thus, a sense of ownership makes explicit connections and interactions, both spatial and temporal in community development research and practice (Harley, 2000).

Application of Participatory Action Research to Cultural Ecosystem Valuation, Why PAR?

PAR has been used to bring about social change in many different settings, particularly in the fields of community development, education, environment, and within organisations (Selener, 1997). One of the main features of PAR is the bringing together of theoretical and analytical processes for understanding a development problem, combined with action for social change (Kemmis, 2001). Because PAR researchers work closely with their study communities, an inter-subjectivity attitude between researcher and informed participants takes place (Reason and Bradbury, 2008). Stinger (1980) refers to a similar approach that he refers to as community-based action research and emphasises the social and cultural values that support it to make the research process democratic for all participants. PAR is used to facilitate a process that empowers a sense of ownership. This process is adapted to building common knowledge and innovative solutions for the benefits of local people. The approach is used to animate local stakeholders to create change in a manner that was previously not experienced with other non-participatory approaches. In terms of sequence, stakeholder involvement is experienced as being invigorated (Tetui *et al.*, 2017). It has to be pointed out that, a problem with many communities based on assessment is the reliability of these communities on traditional conventional mechanisms of data collection, report writing, distribution of results to the public with an overemphasis on external experts (Reed, 2008).

Indeed, they can include in-community methods by extracting data from local people but they cannot achieve methods with and by the community, therefore, empowering local people to make decisions and implementation of the outcome are superficial (Campbell and Vainio-Mattila, 2003). Such community research projects cause stakeholders to be in powerless positions (Fabricius *et al.*, 2007) by increasing dependency on external factors thus future efforts for empowering community becomes more difficult day by day (Cook and Kothari, 2001). Furthermore, they inhibit the progress of future

human adaptive abilities and configuration. Importantly in these kinds of community methods, local beneficiaries are separated from the critical stages of reflection, analysis, and interpretation because most of the learning takes place in distant research institutes which result in elimination of learning potential in the procedure of facilitating conceptual and behavioural changes (Blackstock, 2007). Achieving a pragmatic approach to cultural valuation of ecosystem services with in-depth learning for individuals from different contexts provides opportunities to enhance local adaptive capacity and learning.

Conclusion

A Participatory Action Research is a reimagined path to cultural ecosystem valuation and managing social-ecological systems that benefit people and support ecosystem integrity. For the scope of this paper, due to an urgent need to encourage learning and empowerment of local people in the valuation process, an ongoing emphasis on co-production and co-synthesis of knowledge between disciplines and stakeholders needs to be paid more attention. Assessments must take into account social-environmental heterogeneity and not ignore the places where people live, as that may be the exact location where they perceive and receive the most benefits. Documentation of the PAR approach mainly occurs to address social problems such as mental health, educational justice and community development. Similar documentation in cultural ecosystem services valuation is much less common, especially among marginalized groups and indigenous communities. This paper outlines one path of operationalizing this process by redefining the PAR as a possible mechanism, but do not deny there are many other ways to work toward valuation of cultural ecosystem services. Implementing the PAR, where the effects of decision-making on people and environment continue to be evaluated and revised over time, will ensure the community-based process for assessment of the cultural ecosystem services. However, understanding the potential for implementation of PAR for cultural ecosystem valuation in various contexts and at different scales needs further discussion and study of the PAR approach in a more pragmatic way.

e-mail: dewang@tongji.edu.cn

Abstract: Under the background of market transformation and rapid urbanization, the differentiation of social stratum and living space is becoming more and more obvious in China. The complex background and multiple patterns of residential areas have shaped a variety of living space, which can reflect different life styles and qualities. This article takes Shanghai as an example. It takes advantage of mobile phone signaling data on large sample of residential scale, compares and analyzes the spatial characteristics of living activities in various residential areas, and explores the scope, structure, rules and influencing factors of living activities from the overall level of the city. The study summarizes the living space of typical residential areas in Shanghai into four typical patterns: single center, strip, multi-center and tadpole-shaped. At the same time, from the perspective of the life circle, we will further evaluate the community construction in Shanghai and propose planning guidance. Combining small data such as questionnaires to make up the shortages of mobile phone signaling data and to further the study of living space from the micro level. Further, by combining mobile phone signaling data and questionnaires, the article tries to evaluate the quality of the living space, and applies the results to the evaluation of the community life circle and planning guidance.

Key words: living space, typical patterns, community construction, mobile phone signaling data

0.Introduction

China is in the period of comprehensive economic and social development. Urban development has shifted from scale growth to focus on the improvement of connotation quality. From the perspective of treating residents as homogeneous and diversified to paying attention to the diverse needs of different groups, we have begun to pay attention to urban life in addition to focusing on production. The construction of space and the improvement of the quality of life of residents.

The residents' weekend activity space has a high matching relationship with the urban living space, and the weekend activity behavior becomes an important perspective to see the urban spatial structure. As a relatively homogeneous internal entity, the residential area has a specific built environment, resident attributes and housing attributes, and has become an important unit in the analysis of weekend activity behavior. This paper analyzes the spatial pattern of weekend activities in different residential areas, and explores the boundary, characteristics and spatial distribution patterns of activities. To a certain extent, it can reflect the characteristics of urban living space, the level of construction, existing problems, and the development of urban tertiary industry and living space. The formulation of policies such as transportation facilities has practical significance.

1. Research review

In the traditional group behavior study, the data of residents' daily activity behaviors are mostly based on the questionnaire survey and activity log method (Zhang Ping, Yang Dongyuan, 2012). The questionnaire data obtained has rich individual attribute information and can be used for different attributes. The crowd conducts detailed and in-depth analysis and discussion; but because of the small sample size, the contingency due to sample selection is highly likely to influence the final research results.

With the advent of the information age, mobile positioning technology has been continuously developed and widely used, and the use of new technologies to study the daily activities of residents has become more and more common. At present, domestic research on residents' activity behavior is mainly based on GPS data, microblogging sign-in data and multi-data comprehensive application. GPS data is often combined with civic activity logs for analysis. Chai Yanwei (2012) studies urban life circle planning in Beijing based on time-space behavior. Shen Yue (2013) conducts daily activities for residents of giant communities in the suburbs of Beijing. In the study, Tana (2015) conducted a study on the behavioral measures of the daily life of residents in the suburbs of Beijing and the relationship between space and behavioral activities. Wang Bo (2014, 2015) used Sina Weibo to check the data to study the spatial characteristics of Nanjing urban activities. Liu Zhongjun (2017) used the multi-data of Gaode POI, Sina Weibo to sign the data, and the public comment merchant data to study the urban activity space in Zhangzhou.

Mobile phone data has the characteristics of high coverage and high holding rate. Its large sample size and rich individual spatiotemporal behavior information provide a new opportunity for residents' weekend activities and urban space research. The existing research in China focuses on the discussion of commuting behavior, occupational and residential relations, and little research on the activity space.

Cell phone data has achieved a breakthrough in sample size, but there are few studies on weekend activity and space in China. This paper uses the mobile phone signaling data to use the residential area as the analysis unit to generate the activity "small data" at the residential level through the individual weekend activity "Big Data" to identify the spatial distribution pattern of weekend activities of residents in different residential areas in Shanghai, and summarize the characteristics.

2. Research objects, data and technical routes

2.1 Selection of residential area samples

Shanghai residential areas are widely distributed from the central city to the surrounding areas. The housing types cover shanty towns, workers' new villages, general commercial houses, villas, and affordable housing. The traffic and living facilities in different residential areas vary greatly.

The sample is based on the representativeness of the residential area and the reliability of mobile phone data. The residential area with an area of more than 1km² and internal and surrounding is selected to ensure a certain scale and uniformity. The identification of the largest base station point is recorded by the internal data of the

residential area. As a resident of the community, the resident population must have a value greater than 300 to ensure the reliability of the data. On this basis, considering geographical differences, housing types, and rail transit convenience, 253 residential districts were selected within the Shanghai area, which is consistent with the type and quantity distribution of residential areas in Shanghai (Figure 1).

Figure 1 Distribution of sample points in 253 residential areas in Shanghai

2.2 Data Processing

2.2.1 Raw data

The research mainly uses the mobile phone signaling data of Shanghai 2G mobile users in the first half of 2014. The Shanghai area records an average of 16 million to 18 million different mobile phone identification numbers per day, and the average daily signaling record is about 600-800 million. There are tens of thousands of base stations distributed in the city. The distance between base stations ranges from several hundred meters to several kilometers. The base stations in the central city are dense. Each piece of signaling data includes information such as user ID, time, base station location number, and event type (such as answering a call, sending a text message, and updating a location).

2.2.2 Residential area identification

Each mobile phone signaling data records the number of the user contacting the base station, and when performing location identification, the base station location is used to estimate the actual location of the user. In the study, for each record point of each user from 20 days to 6 o'clock in the next day, remove the remote point, select the point with the smallest average distance from all points as the residence of the day, and repeat the operation to get 14 days of possible residence. A set of locations, using the above distance and minimum method to select a stable place of residence. The data identified a total of about 13.71 million users with stable residences. The sample size is about 57% of the resident population of Shanghai Liupu. The Pearson correlation coefficient between the street level and the Liupu permanent population data is 0.910, and is at 0.01 level. Significantly related, it is feasible to describe the method of mobile phone data to identify the resident population.

2.2.3 Activity stop identification

Clean the mobile phone signaling data, kick out the remote point, and calculate the time interval (the first point and the last point) of the user continuously in the same place. If it exceeds 20 minutes, it will be regarded as a stop; in practice In use, the active place to stay must be removed from the place of residence.

2.2.4 Data selection

This study is aimed at weekend activities, using a standard weekend consisting of four days of data from Saturday and Sunday in a two-week Shanghai mobile phone signaling data in 2014 to reduce the chance of a single weekend.

2.3 Technical route

Based on the selection of residential areas, the average activity direction, travel distance, and number of trips of 253 sample weekend activity spaces are described as a whole; through the weekend, the nuclear density distribution map of the residential area, the travel distance frequency distribution map, and the time-lapse travel time and other visualization methods. Comprehensively judge and identify the distribution pattern of weekend activity space, summarize the characteristics of various modes, and analyze the activity circle of each residential area to further supplement the model features.

3. Overall situation of the event space

3.1 Average travel directions

The average travel direction refers to the connection between the coordinates of the place of residence and the average coordinates of the active place of residence, and the degree of deviation is characterized. According to the analysis results (Fig. 2), the weekend activities have a consistent directionality, pointing to the direction of the city center; from the travel offset distance, the offset of the central city is the smallest, and as the distance from the central city increases, The offset distance also increases, and when it arrives in the suburb of New Town, there is a significant shift in the offset distance.

3.2 Average travel distance

The average travel distance is the average of the distance traveled by residents of the residential area during weekend trips (Figure 3). There is a case where the distance from the central city becomes larger and the average travel distance increases, until the new city has a more obvious fall.

3.3 Average number of trips

The average number of trips in the sample ranged from 3 to 8 and there was a large difference (Figure 4). The number of trips by Pudong residents is significantly lower than that of Puxi residents. As the distance from the central city increases, the average number of trips increases.

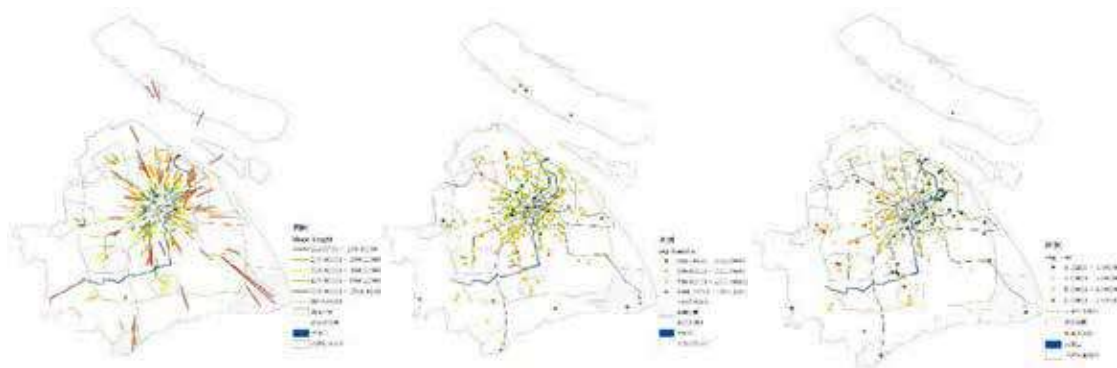

Figure 2.3.4 Average travel direction, average travel distance, and average travel time of residential samples

4. Spatial distribution pattern recognition

4.1 Pattern classification

Through data processing, based on the characteristics of the weekend activity nuclear density distribution map, the travel distance frequency distribution map, and the time-separated travel time of each of the 253 sample residential areas, the weekend activity space of residents in Shanghai residential areas can be divided into four modes. Class (Figure 5): single center, strip, tadpole, multi-center; according to the internal differences of each category, it can be further divided into 7 sub-categories (Figure 6).

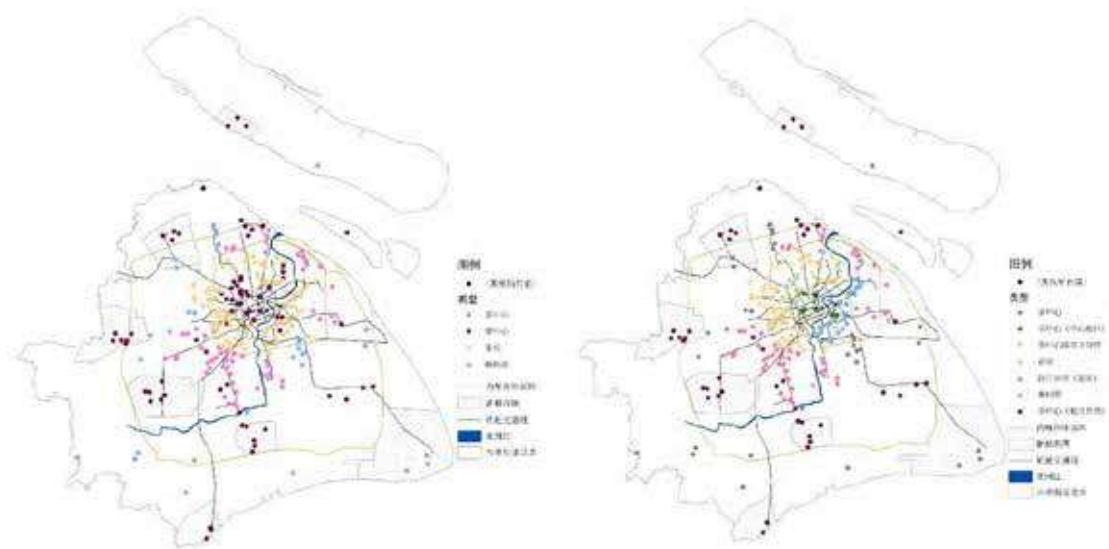

Figure 5.6 Residential area sample pattern classification

4.2 Characteristics of each mode

4.2.1 Single center

The common characteristics of the single-center mode samples are: single-point agglomeration of the active space distribution, the travel distance probability distribution decays very fast, the activity ratio is extremely high within 2km, and the average travel distance is relatively short. It can be divided into three sub-categories according to form and location (Fig. 7): single center (inside inner ring), single center slightly directional, single center (urban periphery), a total of 74, accounting for 29.2% of the total number of samples.

(1) Single center (inside the inner ring)

The samples are concentrated in the inner ring. The built environment of the inner ring is high in maturity, the living space is relatively well constructed, the service level of various public service facilities is high, and the accessibility is high, which can satisfy most living and leisure needs. Possible causes of distribution. The average travel distance is less than 5km, and the relative peak of travel is ushered in at 10:00-11:00 and 14:00-15:00 on weekends. The overall “m” type is relatively flat (Figure 8).

Figure 8 Single center (inside the inner ring) [Sanqingli] Nuclear density distribution, frequency distribution of travel distance, travel time distribution

(2) Single center is slightly directional

This mode is mainly distributed in the periphery of a single center (inside the inner ring), and can be further divided into two categories according to the degree of agglomeration (Fig. 9). The higher the degree of agglomeration, except for the directionality of the activity space, is very small compared with the single center (inside the inner ring) (Fig. 10); the lower the degree of agglomeration is concentrated in the northwest direction between the inner ring and the outer ring, presenting the group Blocky, located between the single center (inside the inner ring) and the degree of agglomeration (high), the surrounding environment is not mature enough to cause the difference, the travel distance attenuation is relatively slow, and the average travel distance is between 5-7km (Figure 11).

Figure 9.10 Single center slightly directional (sub-category), single center slightly directional (high) [Shiguang Xincun] nuclear density distribution

Figure 11 Single center slightly directional (low) [Ganquan community] nuclear density distribution, travel distance from home, frequency distribution, travel time distribution

(3) Single center (outside the city)

Most of the samples are distributed in the new suburbs of the suburbs. The built-up environment in the new city has a high maturity and can meet most of the living needs. The urban peripheral areas outside the new city have low maturity. If residents give up the service facilities in the new city, they will have to pay. Large distances and time costs go to the central city. Obviously, the necessity of doing so is low, so most of the new towns have a single-center model. The average travel distance is farther than the single-center mode of the central city. Within 10km, the relative peak of travel at 10:00 and 17:00 on weekends is more polarized than the travel time in the central city.

4.2.2 Ribbon

The common characteristics of the strip pattern samples are: the sample is concentrated between the inner ring and the outer ring, and the central area is surrounded by the single center mode. The activity space distribution extends to the center of the city. The travel distance probability distribution is relatively gentle, and the activity within 2 km is active. It is relatively high and the average travel distance is medium. It is divided into two sub-categories by the Huangpu River (Figure 12), a total of 90, accounting for 35.6% of the total number of samples.

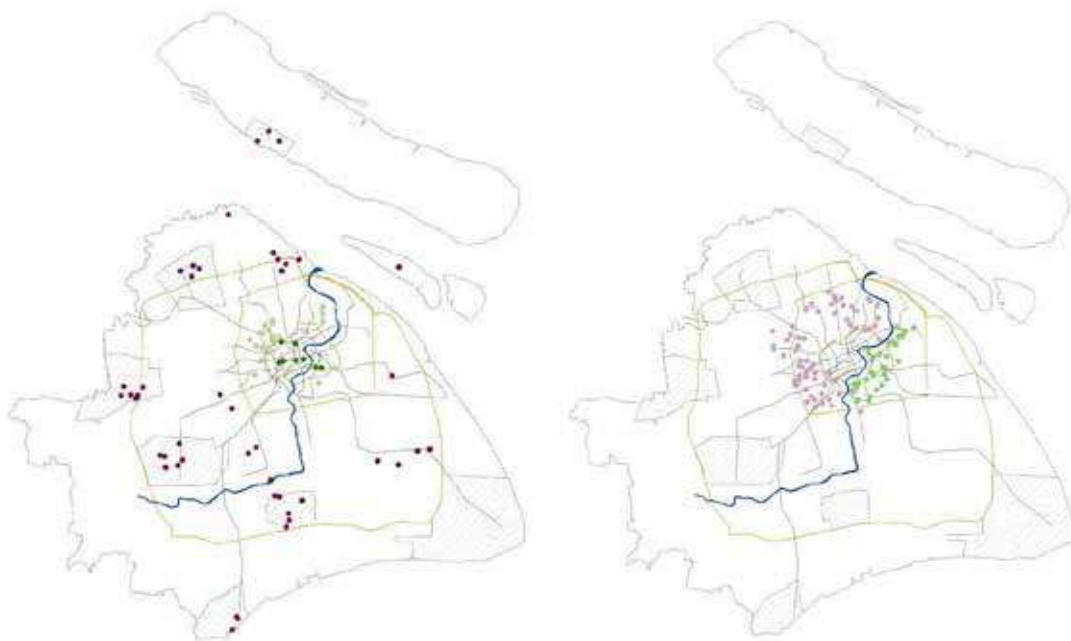

Figure 12 Single Center (Subclass), Band (Subclass) Mode Distribution

(1) Ribbon (Puxi)

This mode ushers in the relative peak of travel at 10:00 and 14:00-15:00 on weekends, and the overall “m” type with a flatter upper end. It can be further divided into two categories according to the degree of agglomeration (Fig. 13). The higher the degree of agglomeration is close to the single-center mode of the central city, the average travel distance is 5-7km (Fig. 14); the lower the degree of accumulation is close to the outer side of the band with a high degree of aggregation, the distance attenuation is more gradual, and the average travel distance is 5-10km (Figure 15).

Figure 13.14 Band (Puxi) [subclass], banded Puxi (high) [Gubei District] nuclear density distribution, travel distance from home

Figure 15 Band-shaped Puxi (low) [gaojing district] nuclear density distribution, frequency of travel distance, travel time distribution

(2) Ribbon (Pudong)

The scope of this model activities spans the Huangpu River. The attraction in the central area of Puxi is large enough. The Pudong construction is relatively immature compared to Puxi, which is the possible cause of its distribution. The average travel distance is 5-7km. The relative peak of travel at 10:00, 14:00-15:00 and 17:00 on weekends (Figure 16).

Figure 16 Band (Pudong) [Dezhou New Village] nuclear density distribution, travel distance from home, frequency distribution, travel time distribution

(3) Influence of Huangpu River on strip mode

A comparison of the belt patterns in Puxi and Pudong (Fig. 17) found that residents in residential areas in Puxi rarely travel to Pudong on weekends, and there is a clear dividing line along the Huangpu River. A large number of residents in Pudong's residential areas will travel to Puxi. .

This is directly related to the urban development process of Pudong Puxi. The old city of Shanghai is concentrated in the Puxi area. After years of development and internal self-coordination, the maturity is quite high and can meet the needs of life to a great extent. Pudong was in the 1990s. Great development, production space first, living space construction is relatively lagging, richness, grade, quality, quantity and Puxi gap.

Figure 17 Band mode active boundary Puxi (left), Pudong (right)

4.2.3 tadpole shape

The sample of the tadpole shape is concentrated on the outer side of the outer ring and along the area of the rail transit, showing the morphological characteristics of the single core-long tail. The community built environment has a certain maturity, the service level of public service facilities is general, and the transportation along the rail transit is convenient, which leads to a sharp increase in the demand and possibility of activities in the areas along the line. This is a possible reason for the formation of this form.

The activity ratio is the highest in the range of 5km, and the distance attenuation is very gentle after 5km, and there is basically no ups and downs. The average travel distance is between 5km and 10km.

The relative peak of travel is ushered in at 10:00, 14:00-15:00 and 17:00 on weekends (Figure 18).

56 samples of the skull pattern, accounting for 22.1%

Figure 18 tadpole shape [Oasis Xiangdao Garden] nuclear density distribution, frequency of travel distance, travel time distribution

4.2.4 Multi-center

The sample is distributed outside the outer ring, between the main city and the new city (Figure 19). The residential area has a low maturity environment and a poor service level of public service facilities. The competition between the new city and the service area of the central city and the residential area is attractive, which makes the activity space of the residents appear multi-centered.

The activity ratio is the highest in the range of 5km, and the distance attenuation is relatively flat after 5km. There are several small peaks and the average travel distance is more than 7km. The relative peak of travel is ushered in at 10:00 and 16:00-18:00 on weekends.

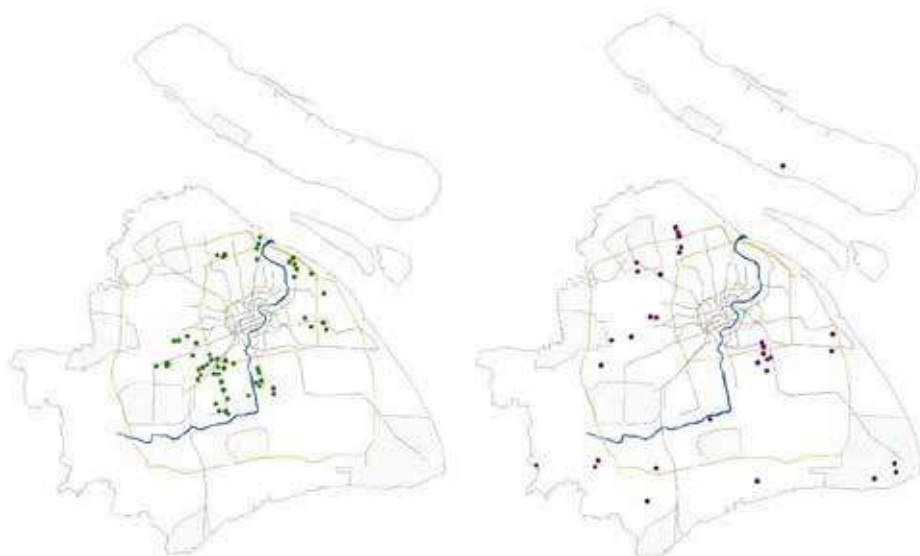

Figure 19 tadpole, multi-center mode distribution

There were 33 multi-center model samples, accounting for 13%. According to the traffic location conditions, it can be divided into two categories. If the traffic environment is poor, there is no rail transit within 3km. The performance of the weekend activity space is closely related to the new city. The samples with such characteristics are mainly distributed south of the northwest-south line of Shanghai (Figure 20).

Figure 20 Multi-center (poor traffic) [Tinglin New Village] Nuclear density distribution, frequency of travel distance, travel time distribution

If the traffic conditions are good, there is rail transit within 1.5km, which is more closely related to the main city. This type is mainly distributed north of the northwest-south line of Shanghai. The influence factors of different regions are different, and the shape of multi-center is also different. When the density of rail transit is large and affected by multiple rail transits, it presents a “multi-center + multi-band” pattern; When the degree is not enough, it shows a pattern of scattered across the river; when it is not affected by the maturity of the new city's built environment, it presents a multi-center form of “new city + central city” (Figure 21).

Figure 21 Multi-center (good traffic) [Ronan New Village], [Kangqiao Baoyu], [Yihao Jiayuan] nuclear density distribution

4.2.5 Summary of mode features

The models and their related characteristics and influencing factors are summarized and summarized . There is a certain circle relationship in the distribution of weekend activity space patterns. The number of travels in different time periods increases from 10:00-11:00 and 14:00-15:00 to 10:00, 14 as the distance between residential areas and urban centers increases. :00-15:00, 17:00, and finally to 10:00, 17:00, that is, the residents living on the edge of the city on weekends travel early in the morning, later in the evening. At the same time, the average travel distance also increases with the distance from the city center. The frequency of travel distance from home is roughly slowed down with the increase of distance from the city center. There are several small peaks in the sample outside the outer ring, between the central city and the new city.

For each mode, the main influencing factors are the location, the maturity of the surrounding communities, the facility convenience, and the rail transit conditions.

Summary

This paper uses mobile phone signaling data to identify, classify and characterize the weekend activity space patterns of residents in 253 typical residential areas in Shanghai. It describes the non-commuter travel characteristics of residents and explains Shanghai to some extent. The level of urban living space in the city.

However, there are still many deficiencies in this study. The internal spatial structure and model causes of each model have not been further explained. The relationship between housing type, location, service facilities, traffic conditions and weekend activities is not enough to explain the lack of quantitative support. The general pattern of the association between housing type and activity space.

At the same time, due to the lack of personal attributes and the judgment conditions of the nature of the mobile phone data used in this time, the research has limitations. If you want to deeply analyze the weekend activity behavior and spatial distribution of a certain group of people or an activity, you need to cooperate with the activity log. Questionnaire survey to analyze.

Abstract: This article starts from the hypothesis that design can contribute to a transition towards a more sustainable future for our cities if it supports work and living environments to 'collaborate' in making this future. The literature section discusses how work environments are increasingly disconnected from their surrounding living environments and the importance of bringing these worlds together again in a collaborative city-making process that takes form through – what we call – “supermix coaching”. In order to understand the existing relations between living and working, we explored how 9 Belgian companies developed over time and how important turning points changed their relations with their surrounding living environments. We discuss how companies, policy and people living and working in the city can make use of the insight in these turning points to give form to a supermix coaching process. This involves a more conscious collaborative design of actions on a microscale (architectural space, technology and human actors in the company and its immediate environment); that are then further developed on the mesoscale (the region and the city) and the macroscale (global context).

Keywords: work, life, mixed-use, design

The growing divide between work and life

Economic activities in the Flemish part of Belgium are located in several types of environments, such as in housing environments, city centers and suburbs, business parks, agricultural environments,... Whereas there are disperse economic activities in agricultural environments, business parks are almost exclusively meant for economic activities. Cities know as well a high concentration of economic activities (in combination with other activities on the same parcel or nearby). In the last decades, partly because of the increasing transport possibilities and proportionally low transport costs, many companies became part of specialised networks. The companies operate on a specific scale, and recruit workforce and customers on that scale. This evolution is reflected in their business-models: for certain companies, the link with the local (living) environment is less obvious than in the past. Although companies with no obvious link with their local environment can simply

coexist with their environment without problem, they are missing out on opportunities to give form to sustainable cities where working and living environments interact. Companies can relate to and interact with their living environments in many ways and on different scales. They can be the source employment or an identity of a city, because of the strengths of their local production, processing and distribution processes. When they become disconnected from their living environments, they can simply coexist with their environments and the strengths pass unnoticed. In certain cases, this coexistence may lead to difficult situations: the companies are seen as issues of concern, like unemployment, sound pollution or traffic and can force the companies eventually leaving the city space. Although there are processes particular to companies that cannot be mixed with housing, it is not uncommon for companies that do not conflict with environmental and safety rules to move outside the city (Vlaamse Overheid, 2014a, 2014b).

The strategy of mixing living environments and companies' production and service based activities within the city space is commonly addressed as "mixed-use" (e.g. Coupland, 1996). This concept has been a part of several Flemish policy documents (Ministerie van de Vlaamse Gemeenschap, 1997; Vlaamse Regering, 2018). However, in recent literature the concept of "supermix" was foregrounded to take the step of mixing functions in the city a step further (We Made That, 2017). The "supermix in the city" proposes to develop a sophisticated design strategy to create hybrid spaces beyond different isolated zones of work, living and nature; not by merely bringing functions together, but by radically aiming to strengthen and diversify workspaces in the city that benefit the community. To be able to reach this aim, this contribution explores the potential for cities to tap more consciously into the collaboration between work and living environments - two "worlds" that seem more and more detached from each other - in a more sustainable future. The focus on collaborative city-making (in this case between work and life) as a strategy to achieve a supermixed environment that supports more sustainable futures for our cities, builds on the work of authors, like Gehl on making cities for and with people in his 'Cities for People' (Gehl, 2010) and Manzini and Friedman 'Design When Everybody Designs' (2015). The latter have mapped what design experts can do to trigger and support meaningful social changes by focusing on emerging forms of collaboration.

We will start with a literature study that explores the concepts of mixed-use and supermix, to then discuss how a supermix in the city can be enabled through design. In a fieldwork section, we aim to further deepen this concept by understanding how companies, citizens, policy makers and work environments are already developing collaborative activities that support this supermix. In the discussion section we will further try to understand the nature of this collaboration in order for designers to give more consciously form to it on different scale levels. We will conclude with a short summary of the results.

From mixed-use to supermix

Mixed use has been a popular strategy by urban planners and designers in developing more sustainable cities. There is a rich body of literature on this topic, which can only superficially be touched upon here. We discuss the current discourse on 'mixed use' (levels of mixed use, the scale on which it operates and its difficulties) and the strategy of the 'supermix'.

Already in 1961 Jacobs proposed in 'The Death and Life of Great American Cities' to mix diverse uses to create vibrant neighbourhoods. She defined these on two levels: mixed primary uses of residential and economic, employment or service functions that are focused on attracting flows of large numbers of people. Mixed secondary uses refer to bringing into the mix the resulting demand for shops, restaurants, bars and other small-scale facilities. In the current discourse, Grant revealed three levels of a mixed-use strategy: the first level is focused on increasing the intensity of land use, the second involves increasing the diversity of uses by encouraging a compatible mix (e.g. mix of commercial with residential uses) and the third level aims for integrating segregated uses by overcoming regulatory barriers, related to environmental impacts, noise, or traffic (Grant, 2002, p. 73). Next to the level on which it operates, mixed-use has been also defined by many on

different scales: the building block (Coupland, 1996), the neighbourhood (Jacobs, 1961) and the local scale (Grant, 2002). Finally, many have discussed the difficulties of implementing mixed use in practice (Grant, 2002). As Hoppenbrouwer & Louw state in relation to an Amsterdam-based study that the centrally determined goals of mixed-use “require local solutions to deal with frictions between environmentally sensitive and environmentally intrusive functions (Hoppenbrouwer & Louw, 2005, p. 982).”

This has motivated many people to search for more locally sensitive approaches, without losing touch with the ideal of creating more sustainable cities where work and living can co-exist. After a study of 1000 businesses that operate from industrial sites, the design practice ‘We Made That’, introduced the concept of “supermix”. They define supermix as a strategy to rethink the city that considers forests, villages or water and as “facilities” and “resources” and develops working, living and nature in separate “zones”. They conceptualise the supermixed city, which is a city that actively searches interaction between diverse actors and activities that are developed in these zones in a common strategy and creates hybrid spaces. Very important is that the supermix concept does not start mainly from a housing-led strategy, as is often the case in the mixed use strategy. They also provide room for further development of industrial sites in the city and to create a more diverse range of work places and thus employment opportunities in the city, such as retail environments, manufacturing industry or schools that can accommodate housing, (health) care or nature. Last but not least, it considers a supermix strategy as a sophisticated and situated design process and not as a universal method (We made that, 2017) (Future Architecture Platform, 2017, p. 17 & 27).

Methodology: Towards a supermix approach

Our hypothesis is that if we want to develop this sophisticated and situated design strategy, we need to further explore how a supermix strategy can take form through collaboration between work and living environments. In order to do this, we need to take into account the different actors that play a role in this and how this design process unfolds in space and over time.

First, different authors have stressed different actors in collaborative city-making. Very important – and still often forgotten - actors to involve in city-making are the people who live and work in the city and who give form to the city and who “intelligently” and collectively can take the city into their own hands through the communal production of public meeting spaces, platforms and technology (e.g. Gehl, 2010, Foth and Brynskov 2016). Also non-human actors, such as information technology and platforms and nature play a role in improving the quality of life in the city (Mahizhnan, 1999 and Latour, 2017). The private and public institutions play a role too, because they govern the people and the spaces where they live and work, such as the companies in the city space, the municipalities, public organisations and urban planning agencies, the vendors of city services, and developers of platforms (Huybrechts, Benesch & Geib, 2017; Lodato & Disalvo, 2018).

Second, as became clear from the study of literature, acknowledging the three key actors in collaborative city-making, being people, technologies and institutions, also involves the articulation of the spatial scale on which they operate. It is important to note that collaborations between work and life do not develop solely in the neighbourhoods or in the small circles around the companies, but involve decision-making and relations with actors on various spatial scales (Ibid.). These include the micro-scale of the single spatial artefacts (buildings, playgrounds etc.), the meso scale of the city and the region (road networks etc.) and the macro scale of the country, Europe (e.g. the impact of EU policy) or beyond Europe.

Third, to be able to articulate how a supermix strategy develops over time, we need to pay particular attention to turning points in how a company develops relations with its environment. In Huybrechts, Hendriks & Martens (2017) we describe turning points as moments in a history of a particular place or organisation where it is plausible that the course of things could have taken a different direction. For instance, a company decides to grow and as a result also decides to create more parking space for its employees. This changes its relation with

the neighbourhood. Discussing these turning points during design processes makes it transparent to others how the decision-making in the design process is affected by the personal role of actors (who is acting); the overarching macrostructure or by coincidence. This gives designers concrete input and inspiration to start imagining minimal rewrites of these turning points in the form of (designed) actions that could support a supermix strategy better.

We thus can define the collaborative city that nurtures a supermix strategy as the city that (1) provides platforms for the development of collaborative design processes between three main actors: people, non-human actors (technologies, buildings or nature) and institutions (the local, regional and supralocal governments and companies) (2) in different moments in time and (3) on different spatial scales.

From mix to supermix: the project and its approach

To now deeply understand how, when and where collaboration takes place that (can) enhance the productive relation between work and daily life in the city, the Flemish government gave the assignment for an in-depth study of the field. The study built on previous studies in Flanders such as 'Kameleon' (Leiedal, 2016), 'Labo XX werk' (Verhaert, 2016), and 'Made in Brussels' (2017). They involved a consortium of academic researchers, intermunicipal organisations and spatial agencies into a design research into the past, present and future of 9 companies' interactions with their living environments, 3 in 3 Flemish regions/cities, being (the environment of) Kortrijk, Roeselare and Herentals. From big to small these involved a large-scale media company and brewery, a medium-scale to large-scale company providing services for the health field (cleaning/sterilising sheets, materials, logistics), a social employment company, a wood company, a glazier, and a small-scale lawyer firm, a wine shop and an electrician.

The first step in the research, carried out by the intermunicipal organizations, consisted of an analysis of regional history and regional planning context. In addition, they shared knowledge on their previous studies, such as project 'Kameleon' where an analysis was also carried out of the extent to which the companies are today intertwined with their environment. The focus was on spatial, economic, social, ecological and mobility characteristics. They also identified the specific permits context and officially registered complaints for each of the companies. Next to that, a mapping of economic activities was conducted in order to be able to capture the specific position of the companies in a work-living-environment (Giaretta, Zaman, Penninx, and De Mulder (2019). Given the fact that some of the field researchers have a background in participatory design research (Robertson & Simonsen, 2013), in the second phase, the strategy was developed of gaining a deep understanding of the existing collaborations between citizens, institutions (companies and policy) and the 'things' that mediate their collaborations (technology, buildings, green and public spaces) and how they exchange or conflict with each other on different spatial scale levels (Huybrechts, Benesch & Geib, 2017). This happened in close dialogue with a participatory design process that aimed for changing collaborations between these actors necessary to support a supermix strategy.

The process started with interviews, observations and field mappings on site with the 9 companies during the period from March to June 2018. The resulting bottom-up insights were processed in 9 visual historical timelines that represent the various turning points (e.g. a growth of a media company and its need for parking space) in the interactions between the companies and the surrounding living environments and the various actions that the companies had taken to deal with those turning points to keep a good relation with the living environment (e.g. share parking space with the neighbourhood). In September 2018, a series of co-design workshops took place between the companies, the intermunicipal companies, the local and Flemish government and the neighborhood. In those workshops, the (1) timelines with turning points and actions were discussed and (2) collective actions were designed that could direct the supermix between living and working in an even more qualitative way than before. These actions were then evaluated between the same groups of actors, extended

with a group of interested members of Flemish municipalities and governmental organisations in collaborative sessions

As a result, we were able to present an overview of important turning points in the relations between work and daily life. We also were able to formulate actions that were/can be taken by businesses, governments and citizens to deal with these turning points and that (potentially) support a supermix strategy. We studied enough cases to start discovering recurring patterns, to make the results of this study sufficiently responsive to future economic, social or ecological shifts and trends.

Fieldwork results: turning points and actions

The research process resulted in a deep understanding of what it means to design for closer collaborative interactions between work and daily life. First, through making the timelines of turning points with the companies, it became clear that there are frequently recurring events, where designers, policy, companies and neighbours can pay attention to when they want to prevent work and life to grow even more separate and enhance the collaborative interactions. These entail:

- changes in the family structure of the business (e.g. children taking over the business),
- growth of the business (e.g. more employees),
- spatial changes (e.g. a move to another location),
- technological changes (e.g. digitalisation of production),
- changes in the regulation (e.g. new environmental policy),
- sectoral changes (e.g. decline textile manufacturing),
- organisational changes (e.g. globalisation of the company),
- changes in the economic and political landscape (e.g. economic crisis),
