- changes in the real estate market (e.g. companies selling and buying property for development of residential housing to gain income),
- changes in local entrepreneurship (e.g. competition between growing amount of lawyers)
- mobility transitions (e.g. increase of traffic slows down company transport)
- challenges with parking opportunities
- celebrations (e.g. anniversaries of the company)

Second, the actions that were developed by businesses to anticipate on, remediate or react on these turning points that disturbed the relation between work and daily life, were mapped. Very roughly clustered, these entailed:

- Anticipation on spatial change or changing regulation

- Re-organisation of space, mobility, employment, products, services and activities,
- Investment in sustainable and innovative infrastructure and in the human network
- Sharing of space, information, people
- Co-design of services and products, the border space between living and working, permanent or temporary shared space, (spatial, environmental,...) plans

From fieldwork to co-designing supermix coaching

From the fieldwork it became clear that in the field the shift to more mixed work and life environments, was made by gaining insight in turning points and taking more conscious design actions. During the co-design sessions it was therefore concluded that this activity wants to anticipate on possible conflicts in the relations between work and life and is thus not a process of designing solutions, but rather a design coaching process. We call this process “supermix coaching” which involves coaching of companies, policy makers and communities in anticipating on certain turning points of companies’ development through conscious design actions that restore or enhance their productive collaborative interactions with the city. It makes use of insights in turning points that require supermix actions on the one hand and “designed” supermix coaching actions on the other hand.

During the co-design sessions, this supermix coaching activity was made more concrete on how it could address the different spatial scale levels. This was done by designing actions that were based on the reality of these companies, but at the same time transcended this daily reality and aimed to give form to a supermixed city. During the co-design sessions with the involved policy makers, businesses and community representatives; we translated the observed daily actions into supermix actions that can be taken collaboratively by businesses, policy makers and citizens to restore, improve or enhance the supermix in the future in relation to important turning points in the development of companies in their environment. We will describe these actions here, starting from the micro-perspective – being the perspective we took first – to then build up to the macro.

Micro

We started with observing and co-designing on the micro-scale of the architectural space, people and technology and share some first conclusions there.

First, from the perspective of the architectural space, it was interesting to see how certain spaces facilitate interactions between the company and the environment more than others. It showed that spaces can be consciously designed as urban interfaces between living and working to encourage some type of material and digital sharing, such as (entrances to) car parks, workspaces or border areas. Currently, regulations pay little attention to these interfaces, and directing funds to them is cannot be taken for granted. So funds and regulations that facilitate sharing need to change or be created. Concretely, the co-design sessions articulated that in supermix coaching spatial design requires a movement from private design of business premises to hybrid ‘public/private design’ of...

- spaces or visualisations that make occupation, time or type of use tangible to encourage sharing.

An example: The law firm is situated in the middle of the city, with limited space as a result. They have meeting spaces, which are sometimes insufficient, but also sometimes empty. They already exchange people and knowledge with other small firms in the city. The firm could benefit from this network to exchange their meeting spaces in the city. This could be supported by digital applications and urban screens that visualise data on which moments in the day, the meeting spaces are occupied and available for use by others.

- (parts of) business premises as private spaces with public properties, semi- or public spaces. This can be space for networking, instead of conflict avoidance, to facilitate events, such as individual or collective company visits, neighborhood parties, etc.

An example: The wine company organised yearly neighborhood networking parties and wine tasting to improve the relations with the neighbourhood. The brewery even created a more permanent meeting space between neighbourhood and company by collaborating in the creation of a neighbourhood restaurant with beer tasting.

- border areas as shared spaces, such as parking garages and buffer zones.

An example: The media company turned a border area into a green and wild ecological space. This could be further developed – in collaboration with the neighbourhood and the city - to contribute to the whole city's green corridors (Image 1 Border area).

Image 1. Border area became a green ecological space @Jenny Stieglitz

- re-organisation of space so that the most private and sound-intensive spaces are on the inside and the more public on the outside.

An example: the beer brewery created the outside circle of its building for more public functions and the inside for more sound intensive and private functions. This could be a design strategy for many companies.

- hybrid spaces that interface in-between work and knowledge exchange with the outside world (which is more interactive than sharing information) at a local and supra-local level.

An example: The studied media company used technology to share their sustainability reports in a systematic way with their surrounding environment. Based on these reports they invite neighbours to come and inspect technical installation live in the company. This sharing of information could be more interactive, in the sense that the digital platform can become a platform for conversation – instead of only information - on sustainability issues in the neighborhood.

- space that makes the company's products and services a clear asset for the neighborhood.

An example: The wood company has a historical relation with the surrounding community. They sponsor and craft artefacts for the community, such as the Christmas nativity scene. Today new housing is developed next to the company. Instead of thinking about how the in-between zone functions as a buffer to reduce noise and enhance privacy, the wood company can become a partner by designing a wooden playground as a display of their product and a public space for the neighbourhood.

- space and mobility as interface between local and supra-local interests.

An example: Initiatives such as the Rodenbach Brewery's 'House of Food' are an example. This house was the result of a retrofitting of part of the business premises of the brewery in collaboration with the region, EU and the neighbourhood as a European center of excellence in food, which fulfills a touristic and potentially a neighborhood café function (Image 2: House of Food).

Image 2. House of Food @Jenny Stieglitz

Secondly, we found that the supermix coaching actions are only effective if the human actors, the company, the local residents and policy have the openness, the desire and the resources to strengthen the relationship between work and life.

We observed that company owners with a family relationship with the living environment or who lived close to or in their company took more actions that would benefit the collaborations between work and life. Also neighbourhood residents who had a long relationship with the company environment were more positive about collaboration with work environments. Examples are the brewery Rodenbach, where the houses around Rodenbach used to be occupied by employees. Also many craftsmen in our study, such as the wood company and the electrician lived on their business premises, with their atelier close to home. We saw that the scale of the company defines its interactions with the environment. Large companies such as the media company, the brewery and the healthcare service company maintain a good relationship with the environment through

investments in (expensive) sustainable machinery, good communication and participation platforms. Small businesses such as the law firm and the wine shop network more organically and are more likely to participate in collective initiatives, such as company or neighbourhood network associations or shared car parks.

In many situations, however, we observed that the real estate logic was that dominant that the relationship between work and living was irreparably disturbed, because companies are very easily tempted to sell their company grounds in the city. Companies indeed indicated they benefit from selling real estate in the city, but that they would also like to negotiate with the government about new residential developments in their environment, about the destination of zones and about support in finding creative solutions in the optimal use and management of several - too small - premises. At this moment governments were most involved in the purchasing of parts of the real estate when the business premises had a heritage value in order to give it a public-private interpretation, as was the case in the 'House of Food' at the brewery Rodenbach. However, the co-design sessions made clear that it is important that designers give form to platforms that facilitate the collaborations between businesses, governments, neighbourhoods and real estate also outside of heritage cases, because of the large impact of real estate development on qualitative city planning of work and living relations. This can give birth to new typologies that can encourage company owners to live close to their companies or allow (smaller) companies to explore new shared activities.

Finally, our fieldwork and more particularly the 9 timelines showed that technology has both encouraged as disturbed collaboration between actors in the city, in two major waves. The first automatisisation wave created the need for larger spaces to be able to install machines and the second digitalisation wave led to a reduction of the machine park and a surplus of space for the environments, which offers opportunities for a mix between work and life. Both had an impact on less local deployment of staff. However, technology can be designed to create collaborations between work and life, like it was used in the case of the media company who shared sustainability reports. Based on the co-design sessions, we can conclude that in order to support a supermix coaching strategy, designers can take the responsibility to design these kind of technological evolutions together with the company's employees, the neighborhood and policy in ways that benefit the environment. In this way, there is also a better coordination between technological installations at various locations in the city and possibilities for shared use of, for instance, energy. We observed that it are often the companies that share their environmental impact with the neighborhood, like the media company, but neighborhood and policy do the opposite too little. If all parties collaboratively register their consumption/emissions, they can make sustainable improvements together. As a result, companies can become hubs for local energy knowledge hubs or cooperatives. Also, technological development of more sustainable modes of transport and their organisation (eg on shared electric car parks between companies and neighborhoods) can be picked up jointly by cities, companies and neighbourhoods.

Meso

On the meso-scale of the city, we see that the way in which a city develops has a great impact on mixed use. This means this can also be designed more consciously. First of all, the history of a city defines how living and working interact. This is immediately clear if we look at the built heritage of the city, which is sometimes owned by companies. Less tangible, but just as important is the more intangible historical landscape. For example, the city of Roeselare has a historically good breeding ground for the growth of one-man businesses in the urban fabric, because it had the 'Nieuwmarkt' - a big market - from the start of the 20th century, where small businesses sold their goods. The textile industry - and more specific flax- put the region around the city of Kortrijk in the 19th century on the world map, in response to the agricultural crisis. Within the flax community - often former farmer's sons - a unique economic network was created. Today, the spaces that remain from this past are still very useful for companies, because they offer space for workshops and storage. The former entrepreneurs from the flax industry also still have entrepreneurial blood in their veins and have used it for other types of industry and trade: the electrician, the health services company and the wine shop all started in the flax

industry. Next to this, the available space on business parks in the area is rather limited: this makes the relocation of a company from the urban fabric to a location outside the city more difficult. Conversely, the culture of some cities sometimes disturbs a good relation between work and daily life. For example, in environments such as Herentals, there was a tendency for companies to move to business parks outside of the city centres due to a surplus of space. This stimulated a ‘business park’ culture for companies.

The co-design sessions led to the insight that in order to prevent the disappearance of the (potential) built heritage that could support a supermix strategy, designers should initiate collaborative retrofitting exercises of (parts) of buildings between companies, policy and neighborhood. This is an opportunity, for instance in case of the buildings of the brewery Rodenbach, the old flax workshops that are used by the electrician as industrial heritage and the characteristic home of the lawyer firm. Designers can also bring the intangible entrepreneurial culture that is very close to the history of the city to life again, in a contemporary way. It was suggested during the co-design workshops that new city residents should not only visit the town hall, but also the main companies in the city to nurture more understanding of inhabitants about the way companies work (Image 3. Law firm heritage)

Image 3. Law firm heritage @Jenny Stieglitz

Second, the road connections of business sites with and outside the city proved to be very decisive for the fact whether a company wants to develop its business in the city or not. They must therefore be closely studied and collectively redesigned where necessary. Some of the bigger businesses started up participation platforms (regular meetings on the business’ premises) to discuss city planning of road and mobility networks between a company, policy and the neighborhood. These platforms sometimes grew out as being the main participation platforms of other shared issues on the level of the city planning, as we saw in the case of the media company. The co-design sessions demonstrated that cities and the companies still under-explore the potential of setting up these platforms in a supermix coaching strategy, because they sometimes have negative experiences with "complaining" neighbors. Designers could supply companies with good practices, knowledge and methodologies to develop these types of platforms in a positive way and to enter into a productive dialogue with the environment (Image 4. Participation platform).

@Jenny Stieglitz

Macro

Viewed from a macro-perspective -the global context and contemporary trends - it became clear from the fieldwork that (large) companies in the manufacturing industry, such as the glazier or the social employment company, are finding it increasingly difficult to develop their production activities in Flanders. This is partly due to competition from low-wage countries. To remain competitive, they chose to make a shift in their business models and they started to involve aspects of real estate: in Flanders the ground value of housing is higher than that of (productive) economic activities. And so, space for economic activities tends to be converted into space for housing. The competition with low-wage countries has resulted in a predominance of small businesses in our entrepreneurial landscape. This research shows that we can learn a lot from companies that have always operated on a smaller scale, such as the law firm we studied. They show us that "collective organisation" and "sharing" benefit the somewhat smaller-scale and even the larger-scale company that wants to remain active in the European city. For instance, after an increase of law firms in the city, the law firm we studied built an intense network with other small (law and other) businesses in the city, shared administrative staff or co-organised multidisciplinary trainings in a shared training centre to turn competition into collaboration. The co-design sessions show that designers can facilitate this kind of shared practice even better by getting to know the right regulations; by studying good practices and by supporting these by interesting spatial strategies (e.g. designing shared educational centres for diverse businesses and neighbourhoods in the city) and technologies (e.g. shared training platforms). (Image 5 law firm, shared educational centre)

Image 5. Law firm, educational centre @Jenny Stieglitz.

Though small scale companies can be exemplary, we noticed that large companies or companies, who operate on a more regional or global scale, do not necessarily pay no attention to their living environments. Some good practices, such as a good collaboration between company, residents and policy, were found there too.

Conclusion: a toolbox for supermix coaching

This conclusion returns to the research question at the beginning and from there draws some conclusions on the future of collaborative and sustainable city making. The article questioned how designers can give form to, strengthen or innovate collaborative city making that enhances the supermixed relation between work and daily life in the city, through understanding how and when collaborations (can) take place between technology, the people living in the city, the local, regional and supralocal governments and companies.

Our answer is clear: there is a need to develop pro-active collaborative design work and policy that involves in "supermix coaching" via two activities. On the one hand, we can achieve this by gaining insight into the turning points in the interrelationship between living and working environments. On the other hand, we do this by taking more conscious collaborative design actions in relation to those turning points. These turning points and actions can now play a role in the "supermix toolbox" of members of the companies, policy or the people in the neighbourhood who want to draft closer relations between work and living environments. We also stressed the importance to consciously address them first from the situated micro level of the architectural space, the human actors and technologies to make them concrete and attractive for those who are immediately involved. Based on that, the perspective of the meso scale of the region and the city and the macro global context and contemporary trends can be developed. Given the fact that working from micro to the macro is a reversed perspective for most urban designers, planners and policy makers, many aspects of the supermix coaching practice still have to be poured into instruments to make them workable on these different scale levels in the field. The richness of the 9 cases, however, has provided a good basis to get started. As a first design output, we have gathered two elements in a manageable kit: the timeline that supports mapping turning points in the relation between companies and their environment and an action toolbox. This kit can be used in new cases during the practice of supermix coaching, in order to be able to anticipate on possible divisions and tensions

between living and working and to explore new interesting collaborative ways of giving form to transitions of our cities together.

Title

PUBLIC PARTICIPATION IN THE COMMUNITY PLANNING IN CHINA

Text

In the 1980s, Chinese scholars in the field of planning began to introduce the theory and experience of Western public participation to China, and meanwhile carried out the practices. After 30 years' development, public participation in Chinese planning is involved in macro --, meso --, and micro levels of planning, namely urban comprehensive planning, control detailed planning, and community planning. Furthermore, more and more attention is paid to the micro level community planning.

In 1969, Arnstein divided public participation into three levels, namely nonparticipation, tokenism and citizen power in the article "A ladder of citizen participation". And the eight types are arranged in a ladder pattern with each rung corresponding to the extent of citizens' power in determining the plan, it includes manipulation, therapy, informing, consultation, placation, partnership, delegated power, citizen control. According to Sherry R Arnstein's ladder theory, we observe thirty Chinese public participation cases in the field of community planning. These cases imply that, first, 77% cases are on the rungs at the degree of tokenism, whereas about the other 20% cases reach the rungs at the degree of citizen power. Besides, most of the cases of tokenism are on the rung of consultation. Only two out of the thirty reach the rung of delegated power. We make further analysis for this result.

Firstly, most of the public participation in community planning in China is on the rungs at the degree of tokenism, especially the consultation gradient. And there is a trend toward a higher gradient——placation. Most of the public participation's action occurs only in the two stages of opinions survey and results publicity. The government will selectively delegate power to the public without affecting the final goals and consequences of the planning implementation, so that the public can only cooperate with the decision-making department to achieve the prescribed goals and tasks, but which ignore the procedural and dynamic characteristics of the planning. In the meanwhile, due to the lack of protection mechanism of legal system, the public participation in the evaluation and supervision mechanism is insufficient, which makes public participation is only become a mere formality. On the rungs at the degree of tokenism, in order to appease the public, the government will adopt the "reward system" and "substitute subsidies with rewards" policies to stimulate the enthusiasm of public participation and reduce the risk of aggravating conflicts. To some extent, residents have more rights to know and say, but limited options and voting rights, which does not have a substantial impact on the goals and results of the planning. In the meantime, the public participation relies heavily on the community planners' and village planners' work. These planners build a platform on

which stakeholders of different interests and perspectives can have their voices. Besides, recently the digital media technology has also promoted the diversification on the public expression of opinions with its characteristics of high-speed transmission and significant influence. Although the government will make concessions under the pressure of public opinions, online communication lacks pertinence and effectiveness, and has not made a substantial apparent advance on the level of public participation.

Secondly, on the rungs at the degree of citizen power, the size of the urban area where public participation process is taken place, the degree of marketization, education level, etc. can effectively influence the depth of public participation. The planning form is mainly based on the old city renewal, and the development mode is market-oriented. In particular, it usually adopts a higher level of public participation when it comes to clear and concrete interest issues such as demolition compensation. Above all, the cases of the delegated power are all through the masses' spontaneous construction of cooperative organizations to encourage the residents to participate in the community planning actively.

Analysis of the above problems, at first, based on education and training to the public, the knowledge of urban planning shall be popularized throughout the society. And the ability and enthusiasm of the public to participate in public affairs shall be fully cultivated and enhanced. In the preliminary stage, this requires the assistance of the government and planners. At the same time, we must focus on training local people with planning potential to become community planners, which drives the masses to participate in urban planning and construction. Meanwhile, the community should create more public communication space, which not only can strengthen the interpersonal communication, also can make public participation as a part of the residents' daily life by organizing various forms of community activities, such as community planning knowledge competition, public comment activity and so on.

In the last, the study shows that public participation in China is still in its infancy, legal guarantee and public awareness need to be improved in the future urban transition.

Entrepreneurial Neighborhood Planning Based on Multi-Stakeholders Co-Creation

Chenhan Jiang¹, Chen Li²

¹*College of Architecture and Urban Planning, Tongji University*

²*College of Design and Innovation, Tongji University*

Abstract: Recently, promoting the transformation of old residential neighborhoods from living areas into vibrant communities becomes a new topic in the urban planning field. Researchers and practitioners explored top-down and bottom-up social innovation approaches like community-based planning to converge creative talents, activate entrepreneurial opportunities and renew such areas. However, there are still some confusion about mechanisms or methods to facilitate various roles of participators forming creative neighborhood for collaboration. In response to the problem, this study proposes the research question is how to plan and design entrepreneurial neighborhood based on locality and the contributions from multi-stakeholder collaborations. Action Research(AR) is the main research method in this study, research findings could be put forward through the framework which combines the typical AR cycle and localized context: 1) Problem formulation based on related works; 2) Investigation including expert interview, participatory observation, and environmental quality data; 3) Implementation and actions based on the case of NICE 2035 Living Line. 4) Reflection and iteration for theoretical outputs through feedbacks analysis like participators satisfaction, built space assessment or environmental experience; 5) Conclusion which responds research questions mentioned above.

Keywords: Entrepreneurial Neighborhood; Urban Renewal and Planning; Action Research; Social Innovation

Introduction

With the acceleration of urbanization, community planning has been extended into many new meanings in the current context. For example, social innovation-oriented neighborhood renewal and relationship building, circular economy-oriented sustainable neighborhood environment design, or neighborhood integrated business distribution planning and iteration to activate the resource stocks. Many scholars and designers have conducted exploratory experiments, including how to increase creativity and vitality in the limited space of the neighborhood, and leading more opportunities for innovation and entrepreneurship, which has become a frontier topic of contemporary neighborhood planning. However, due to the numerous stakeholders who are involved in this network, how to balance the contributions and requirements of each role, coordinate the co-creations to contribute better planning advice, has been a common problem faced by academics and practitioners. Especially in the contemporary Chinese context, the neighborhood problems are more complicated: the outdated facilities in old neighborhoods, the aging residents with reduced vitalities, the brain drain and the rigid neighborhood relationships. Therefore it is necessary to reconsider the relationship between multiple roles in the renewal and planning design and adapt to the original neighborhood planning structure and commercial format.

The research in this paper responds to the above problems by taking action research rooted in the Shanghai project and combining the collaboration of multi-stakeholders. The proposed planning and design recommendations applicable to this scenario could provide a reference value for similar neighborhood contexts and issues.

Related Works

In traditional neighborhood planning, designers often consider some fundamental issues, such as physical environment and infrastructure, natural resources, road and traffic, residential buildings, community organizations, public services, etc., but the groups they involved are often only neighborhood residents instead of considering all stakeholders. With the development of science and technology, new business formats are emerging. More and more entrepreneurs are originated from the community. This type of business is known as community-based entrepreneurship, and policymakers and scholars are increasingly concerned about the impact of this type of activity on people, local, and place. (Peredo and Chrisman, 2006; Somerville and McElwee, 2011). Current research in the field of entrepreneurship and neighbourhood research is often separated (eg Peredo and Chrisman, 2006; Lyons et al., 2012; Daskalaki et al., 2015; Fortunato and Alter, 2015; Reuschke and Houston, 2016), mainly because the current enterprises and entrepreneurs are generally located in commercial areas in terms of spatial distribution. But what people may ignore that the neighborhood, as a locational resource, has a positive impact on entrepreneurs both in terms of infrastructure and interpersonal relationships. Firstly, the neighborhood and community can provide opportunities and show requirements for entrepreneurial projects. Research shows that community-based agencies are better positioned to meet consumer needs and geographically closer to their clients (Gilbert, 2004, 114). Secondly, for many self-employed businesses, the neighborhood and home are regarded as the geographical starting point to start a new enterprise. (Mason and Reuschke, 2015; Mason et al., 2011, 2015) Finally, the neighborhood context has a potential impact on entrepreneurial spirit and enthusiasm, from building social resources (Schutjens and Völker, 2010), creating new business opportunities, and delivering proven business experience (Williams and Williams, 2012, 676, citing Feldman, 2001 and Minniti, 2005), etc., all show significant.

At the same time, however, entrepreneurs are also potentially promoting and changing the planning and development of a neighborhood in a new era. Since the demands of new entrepreneurial opportunities are originated from the neighborhood, it can make up the gaps in the services of neighborhood institutions and provide better products and services for them. For example, cooperatives, develop standard housing, sustainable energy (solar panels, wind turbines), agriculture, handicrafts and aged care (Mori, 2014; Wagenaar and Van der Heijden, 2015; Bauwens, 2016). Therefore, bottom-up and community-based entrepreneurial activities are increasingly seen as solutions to public service deficiencies and community rebuilding efforts (Reinout Kleinhans, et al., 2017). Ordinary people's wisdom based on daily life is the source of social innovation, as well as essential design inspiration and wealth (Lou, 2018). Furthermore, neighborhood entrepreneurs have a very positive impact on promoting the development of the national economy and enriching the new neighborhood business formats. Entrepreneurship not only increases the economic strength and innovation of countries, regions, and cities but also enhances the economic development of neighborhoods and communities (OECD, 2003; Baumol et al., 2007). Finally, community-based entrepreneurship can promote residents to collaborate, unite, and work together to create a better living environment (Peredo and Chrisman, 2006; Somerville and McElwee, 2011; Bailey, 2012). About practice cases, the following figure shows some renewal and planning approaches and features of such neighborhood planning.

Case	Role of Stakeholders Involved	Pillar Industry and Core Driving Force of Innovation	Resources Outside the Neighbourhood	Space Constituents of the Neighbourhood	Planning Mode
DuodaCE	College Students, College Professors, Students in the surrounding areas of the university Entrepreneur, Mentor Companies, incubators	University knowledge and technology are transferred into start-ups. Student entrepreneurial ideas are supported by DuodaCE.	Start-ups can receive the experience and resources of mature companies, as well as support from incubators and investors.	College Network & College Cluster	Place-based entrepreneurship learning and practice
Lian Li Hui	Neighbourhood residents, Neighbourhood service organisations, entrepreneurs, External business institutions	Residents' demands in practice are transferred into business opportunities, and neighbourhood service efficiency and service quality are improved by introducing external business service companies and encouraging entrepreneurial opportunities within the neighbourhood.	The community is open to the outside, and some neighbourhood services are supported by internally initiated start-ups or externally introduced commercial services.	Residential Buildings + Neighbourhood Public Activity Spaces + Neighbourhood Business Service Spaces	Neighbourhood as incubators, give birth to entrepreneurial opportunities from rental lifestyle
Open Construction Activities of Niping Community OYS	University students, University professors, Neighbourhood residents, Community service organisations	The university's knowledge, talents, and technology are introduced into the community. University students, teachers, and neighbourhood residents participate together in the renewal and building of the community to help the neighbourhood improve the public environment, public services, and improve the life quality as well as the cultural and artistic environment.	The neighbourhood's public environment and new neighbourhood interaction modes are designed and supported by university students and professors.	Residential buildings + neighbourhood public event spaces + interactive art devices	As an experimental base, the neighbourhood in itself designs and creates to proceed co-creation and innovation, construct an atmosphere to help creative place-making. The residents' creativity and autonomy are increased.

Fig.1 Case Study about community building and renewal

Action Research Based on Project NICE 2035

The concept of AR was first created by American sociologist Kurt Lewin (1946), who believes that social researchers should not only analyze the actual situation of immediate stakeholders but also should help them change their conditions through actions. Another well-known contributor of AR, Brazilian educator Paulo Freire (1973) believes that this kind of work should be carried out through problem-formulation and the creation of self-consciousness. AR is a scientific way of thinking rather than a traditional method of periodic research. In the AR research process, stakeholders' involvement can help them deepen their attention and understanding of the problem (Boothroyd, Fawcett, & Foster-Fishmann, 2004). In practice, stakeholders should not only participate in the investigation and discovery of questions but also need to think about how to take action to solve the problem. This process will be carried out by stakeholders with the participation of researchers. (McIntyre, 2008) Due to the uniqueness of different research environments, we must consider the social values of various participants. Therefore, to involve the research objects into the research process as collaborators is a specific AR method. (Baskerville 1999) Ideal action research needs to be provided with some principles: Firstly, both the researchers and the residents should be fully involved. Secondly, all the knowledge obtained should be able to apply immediately with an explicit exceptional framework. Thirdly, the research should be a process that linkings theories with practices (Baskerville and Wood-Harper 1996).

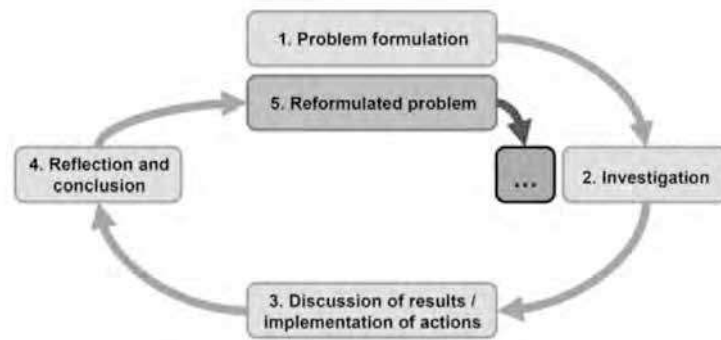

Fig.2 The general process of action research (McIntyre,2008)

As the constructive research method and tentative exploration, action research (AR) as the primary research method is selected in this paper. NICE 2035 Living Line neighborhood renewal project in Shanghai Siping community is the research subject. This project is a social innovation practice initiated by Professor Lou Yongqi and Siping committee. “NICE 2035” is the Neighborhood of Innovation, Creativity and Entrepreneur towards 2035, and NICE means “good life.” On the basis of the renewal and renovation of the traditional Shanghai old community, a series of innovative laboratories including mature brands and start-up projects have been introduced, forming a composite entrepreneurial neighborhood and ecosystem including product development laboratory, creative education space, physical prototype store, co-work space and incubator (Lou & Ma, 2018). Moreover, due to the knowledge resources from Tongji University nearby, this project has introduced a variety of stakeholders, including community residents, start-up teams, innovation laboratories from universities and enterprises, capitalist and experienced third-party operations teams. In this practical case, we collected user data for co-creation points insight, implement effectiveness analysis, and reflection towards such neighborhood planning strategies according to AR cycle. The research framework of this paper is divided into five stages: first, problem formulation; second, investigation, including stakeholder motivation, co-creation demands, and ability contribution based on user interview; third, discussion results, which is summarizing insight points based on investigation and formulating collaboration matrix; fourth, implementation and action, including neighborhood planning exploration and attempts in this case combined with localized community characteristics and unique problems; fifth, reflection, including summing up user feedbacks towards the planning strategies which could guide other similar cases.

Phase1 : Problem formulation

In the above discussion, several cases of the entrepreneurial community generally reflect a common feature, which is community stock resource transformation and formulating an innovative and entrepreneurial network with commercial opportunities and locality. China's old communities have their unique problems, take Shanghai as an example, like old and backward infrastructure, dense population, the demographic structure of elderly and school-age children, traditional single lifestyle, and low-cost catering and retail business model. But such issues are full of challenges and opportunities. As can be seen from the OYS community micro-renewal case mentioned above, the wisdom of ordinary people based on daily life is the source of social innovation, and also valuable design inspiration and wealth. Sophisticated lifestyles and local issues also contain entrepreneurial opportunities. For example, various of behavioral data and interactions can provide a large number of test opportunities and analysis samples for new-born business models, which could allow the entrepreneurial teams to get user feedback in a real context and real-time mode, and they could also

adjust and iterate business models with real customer preference and satisfaction. With this concern, multi-stakeholder and diverse living behavior have become the essential driving factor in the activation of such communities, especially how to reconstruct neighborhoods relationships, extract behavioral characteristics and residents' needs from the daily lifestyle of residents, and turn them into available data and resources. This wide range of stakeholders includes community residents, innovative talents, community managers, nearby school teachers and students, some mature businesses from diverse fields. Therefore, in this study, how to match the multi-stakeholders ability contribution and demands, plan community physical facilities and cultural activities to make them work well, turn problems and consumption generated by the traditional community into opportunities for innovation and entrepreneurship, have become the core research question.

Phase2 : Investigation

Take the NICE project as a research object; investigation includes the roles and capabilities of various participators in this network. We analyzed the motivations and needs, and then identified the opportunities for innovation and entrepreneurship brought by them. The interviewees are divided into two parts. The first category is innovative entrepreneurial content providers, like start-up teams, innovation labs from universities and enterprises, and experienced third-party operations teams. The second category is community residents, including the following roles: residents living here (such as retired people), young people living outside here (renting in the community), living here working outside young people (locals), people who work and live here (student or local). The interview data is shown in the table below.

	Open Time and Participation Motivation	Current Activities and Frequency	Interactions with Community Residents	Role and Contribution in this Collaborative Group	Resource Requests for Project	Future Interactions with Other Labs	Future Interactions with Local Community	Demands for Operation Team and Supporting Services
Fablab	<ul style="list-style-type: none"> - Officially opened in May 18 - University resources could radiate knowledge to a wider range - This community has better primary and secondary schools (student sources) - Community residents have big demand for Maker Education, and less competitive brands 	<ul style="list-style-type: none"> - Primary to junior high school Maker Education course (for teenagers, weekly & holidays) - Open night with small sharing shows, would attract more potential users and interact (for community residents, weekend) 	<ul style="list-style-type: none"> - Workshops for community residents (one in three activities for the Siping community and two thirds for other communities) - The neighborhood committee helps promotion and notification 	<ul style="list-style-type: none"> - Support other labs with design solutions and prototypes (product design and development, 3D printing, model making, product realization) 	<ul style="list-style-type: none"> - The neighborhood committee promotes publicity and sets up special start to communicate with local residents and keep abreast of user feedback 	<ul style="list-style-type: none"> - Support other labs to better co-work to reduce time and management costs - Implement prototype products for display - Design innovative course modules according to different labs' content and topics (future kitchen, future mobility lab, future material lab) - Peripheral product development 	<ul style="list-style-type: none"> - Engage with several elementary schools in the community and embed the course package into the school curriculums 	<ul style="list-style-type: none"> - Integrate different laboratory resources and proactively promote
Sound Lab	<ul style="list-style-type: none"> - Cross-border innovation with sound and technology 	<ul style="list-style-type: none"> - Interactive performances such as the opening of other labs 	<ul style="list-style-type: none"> - Recording lessons based on users' own sound demo 	<ul style="list-style-type: none"> - Provide recording venues and equipment for potential users brought by students, community residents and other labs, and accumulate sound material for future commercialization - Experimental music (Audio to 3D product) opened by Aston Martin Lab 	<ul style="list-style-type: none"> - Team building and open experience activities for understanding of content between labs - Mobilize more labs for collaborative development courses 	<ul style="list-style-type: none"> - Cooperate with the School of Communication or the School of Sound to develop products based on education resources in Tongji University - Develop courses in collaboration with Fablab to experiment with small projects related to sound and communication 	<ul style="list-style-type: none"> - Sound production 	<ul style="list-style-type: none"> - There are many elderly groups in this community, how to match the needs - Promotion channels for young people (WeChat) - How to avoid some interference to local residents in this project - Rational use of co-working space
CREATER (Operations team)	<ul style="list-style-type: none"> - Closely related to its own development business (renovation and operation of Cultural and Creative Park) - Providing future lifestyles, including living and artistic leisure life. 	<ul style="list-style-type: none"> - Asset property - Environmental optimization - Manage lab daily activities - New project opening 	<ul style="list-style-type: none"> - Promote the bread baking experience (collaborative with food lab) as the first phase for resident interaction 	<ul style="list-style-type: none"> - Integrate distributed resources and offer supported services 	<ul style="list-style-type: none"> - As a pilot to collect feedback from stakeholders, test the business model and copy other sections in the future 	<ul style="list-style-type: none"> - Match community needs and labs advantages - Promote collaboration between labs to attract investment 	<ul style="list-style-type: none"> - Relationship reconstruction between architecture art and business (community renewal) - Integration cultural content like creative fairs - Old alley art museum - Folk artist performance 	

Tab.1 Interview for innovative labs, start-ups and operations team

User Information	Awareness of the Project	Understanding Channels	Attraction Point for Participation	Space and Environment Satisfaction	Suggestions for Future Lab Activities	Suggestions for this Project
<p>Resident 1</p> <p>Age: 35 years old</p> <p>Gender: Female</p> <p>Education: Bachelor</p> <p>Occupation: Finance</p> <p>Living time in this community: living in 2009</p>	<p>I paid attention when I sent my child to the neighborhood center for class, but didn't know much about it.</p>	<p>I noticed the weekend activities (Fablio) and the Aston Martin Studio opening event. Firstly know the</p> <p>I first knew this project was attracted by the Sujatan Road renovation activity a year ago.</p>	<p>Because it's very close, if there is an open event I will participate. I have not received many notifications from the neighborhood committee so far.</p>	<p>I feel the space is clean and tidy because the previous chess room and housing agency have been transformed into these labs. Need more interactive facilities on Sujatan Road, so that children could come over the weekend.</p>	<p>-Design more interactive activities for children, many with children to play</p> <p>-Courses similar to the Neighborhood Center (Yoga, Calligraphy, Children's Activities)</p> <p>-Also create an online community to push information</p> <p>-Experience activities related to traditional festivals</p> <p>-Making peripheral products</p> <p>-Popular science activities</p>	<p>User survey is important</p> <p>-Establish a public number push event</p> <p>-Use the existing channels of the neighborhood committee to push</p> <p>-Integrate with the Neighborhood Center activities</p>
<p>Resident 2</p> <p>Age: 57 years old</p> <p>Gender: Female</p> <p>Education: Secondary school</p> <p>Occupation: retirement</p> <p>Living time in this community: living from birth to this day</p>	<p>I often go through this street after work, but I don't know very well.</p>	<p>I have seen it outside the co-work space, but not sure whether it will be open to the outside.</p> <p>I have seen the opening event of Aston Martin Lab, which is very attractive.</p> <p>I have not received any notice or promotion information from the community committees for activities of such labs.</p>	<p>Bakery and Cafe</p>	<p>Feel modern</p> <p>Increase the open time</p>	<p>Quiet activities</p>	<p>-The quality of senior citizens in the community is not good</p> <p>-Innovative things can be considered if the changes are not high</p>
<p>Resident 3</p> <p>Age: 22 years old</p> <p>Gender: Female</p> <p>Education: Undergraduate</p> <p>Occupation: Student</p> <p>Living time in this community: living from birth to this day</p>	<p>I go through this street four or five times a week, but I did not have fully understanding for this project.</p>	<p>I saw this space when I went to work through the lab. I was particularly interested in the creative space and Sound Lab, but I didn't have the chance to go in because of the space long term.</p>	<p>Open day</p> <p>Experience activities of the Hair future kitchen</p>	<p>The office space is cool, hope it could provide more space for residents to use (insomnia in the middle of the night)</p>	<p>No special preference</p>	<p>WhChat or Weibo promotion channels would be better for residents discussion and feedback collection</p>
<p>Resident 4</p> <p>Age: 22 years old</p> <p>Sex: Male</p> <p>Education: Bachelor</p> <p>Occupation: Clothing Management</p> <p>Living time in this community: 2 years, renting a house</p>	<p>I often go through this street after work, but I don't know very well.</p>	<p>I learned about this project when I noticed the opening event of Aston Martin Studio. I was attracted by some special event like some cold meal, but I have not entered because my work time is so late.</p>	<p>Experience activities of the Hair future kitchen</p> <p>Co-work space, want to know the rental details because it is related to my career</p>	<p>Need more space for residents interaction</p>	<p>Add some fitness facilities or experience activities, such as a small gym in container (there are few gyms near the community)</p>	<p>-Home promotion is better for elderly.</p> <p>-Young people can use posters or online promotion</p>

Tab.2 Interview feedbacks from local residents

Phase3 : Discussion result

As the above interview analysis showed, each stakeholder in such entrepreneurial neighborhood networks has its demands and skill contribution. Therefore, the collaboration matrix could clarify this relationship and also guide the next step for such a neighborhood planning strategy. The horizontal and vertical axes represent different stakeholders, respectively, and the intersection is a resource demand and collaboration opportunity for one type of stakeholder to another (As Tab.3).

	Elderly residents	Young residents	University students	Innovative labs (E.g. Education, art and other products)	Start-ups	Operations team	Neighborhood committee
Elderly residents		Neighborhood relationship building	User survey and research	User survey and research	User survey and research	Increasing neighborhood creativity and innovation	
Young residents	Neighborhood relationship building		User survey and research	User survey and research; Attracting potential customers	User survey and research; Attracting potential customers	Increasing neighborhood creativity and innovation	
University students	Knowledge support for living environment improvement	Knowledge sharing, better work opportunities		Knowledge and professional skills sharing	Knowledge and professional skills sharing	Skills support	Increasing neighborhood creativity and innovation
Innovative labs (Education, art and other products)	Leisure time with local residents; Searching education resources for children	New knowledge and skills; Better fitness facilities or third place for leisure or work	Project-based learning and practice; New concept and business model test		Experience activities development; Workshops and courses content design; Space and materials sharing and co-work	Practice cases to support self-development	Increasing neighborhood creativity and innovation
Start-ups	Service products; Free and effective exhibitions	Better work opportunities		User research learning and feedback analysis; Develop events and experience activities; Business model co-design		Practice cases to support self-development	Increasing neighborhood creativity and innovation
Operation teams	Open space for communication; more parking space			Promotion methods improvement; Physical and virtual infrastructure support	Promotive methods improvement; Physical and virtual infrastructure support		Daily activities management
Neighborhood committee	Diverse promotion methods (WeChat and WeChat)			Policy and promotion support	Policy and promotion support	Collaborative promotion	

Tab.3 Collaborative Creation Matrix from Multi-stakeholders in NICE2035 Networks

Phase4 : Implementation and actions

Based on the collaborative matrix, the NICE project conducted community planning and update design exploration based on localization characteristics. The first step was to broaden the entrance and upgrade the surrounding business. Cleaned up the dirty and scattered retail stores, planned the first batch of laboratory office space, redesigned the guide system, entered at the entrance of Fuxin Road. After renewal and upgraded business, the stores along the lane 1028 was future mobility laboratory, neighborhood center, future kitchen lab, and a local open-air market, and such local lifestyle oriented cultural labs formed clean and futuristic block impression and creative cluster (As Fig. 3).

Fig.3 Lane 1028 in Siping Community Renewal Planning (Source: NICE2035 project team)

The second step was building more open spaces, such as co-work which break the boundaries of traditional work space and living space. Such approaches made the labs daily office and events more flexible and accessible for all participators, while the open interior design also integrates the roles between the laboratory and the exhibition space, allowing staffs and residents have various ways of interaction. Meanwhile, under this context, the research, service test, and development from laboratories and start-ups could also be carried out in the space (As Fig.4).

Fig.4 Co-work space in NICE 2035 (Source: NICE2035 project team)

The third step was putting the innovative and entrepreneurial content engine into the neighborhood based on the lifestyle of ordinary residents. For example, introducing food, education, art, sounds, mobility labs, and related start-ups, and co-created new operations and marketing forms. Like pop up, stores, workshops, and open nights to attract residents to participate in activities and test new services or products, finally formed an aggregation effect (As Fig.5).

Fig.5 Open events from innovative labs in NICE2035 (Source: NICE2035 project team)

Phase5 : Reflection and Findings

After the survey for spatial utilization and user satisfaction of this entrepreneurial neighborhood practice through the six-month observation and record during the growth and development period after the project was released, the research findings in this paper is drawn. It could be summarized in three aspects of planning and design strategy, including business model and content, physical space, and relationship construction.

Micro-community and multi-content. For facilitating such entrepreneurial neighborhood, planning strategy should introduce innovative laboratories of different business formats in the entrepreneurial community, such as food, education, housing and mobility, and finding opportunities for entrepreneurial opportunities in daily activities. Use the residents' daily behaviors and lifestyles as a test field for iteration and improvement of start-up projects, services, and business model in real-world scenarios, both for incubation or mature project iterations. This diverse content could enable each participator in this network and allow them to support each other and co-create more innovative cultural or technology concepts, and also form multiple cross-parallel collaborative ecosystems and finally construct multiple micro-communities under a local context.

Versatile modular space and smart neighborhood. The original format is a necessary stakeholder in neighborhood planning; designers should consider the balance between community needs and such original business format like open-air market, fruit and vegetable retail, bicycle repair, or hardware store. The flexible solution is designed modular and multi-functional space, which means residential and shop integrated model space (front store and back housing). This modular space could be built with container material with high flexibility to disassemble and change space functions according to a different using purpose. About the space content, lightweight but lifestyle-based format like micro fitness center, cafe, mini art gallery or playground could be the interactive and attractive ways to be introduced. For using feedbacks and changeable space decisions, planners should consider creating smart communities with multiple sensors and wireless network probes to analyze crowd dynamics and social media data to support more in-depth research and space iteration.

The narrative neighborhood, neighborhood relationship reconstruction. Due to the traditional and old neighborhood with dense population in this paper's context, elderly residents are essential stakeholder in this network. Therefore, how to reconstruct resident relationship become the critical point for neighborhood creativity and entrepreneurial culture. Designers should explore more interactive approaches to connect people emotion link and built the identity, like various art installations, outdoor exhibition, redesign the traffic walking route to make the entire neighborhood has more communication space and narrative clues. And another point is inviting community residents to engage in participatory design and planning for micro renewal and infrastructure improvement. This approach will restructure neighborhoods and self-identity, and also dispel and avoid negative sense caused by the new laboratory and staffs in their living area.

Conclusion

This study starts with a research problem of how to build an entrepreneurial neighborhood based on multi-stakeholder co-creation. Through five steps of the action research cycle, the research questions are gradually defined, and then, the collaborative contributions and potential opportunities of the stakeholders are derived through different roles of stakeholders' interview. NICE2035, as the practice case is introduced in this paper as the main action research subject, with participatory observation and

reflection on the planning and design implementation of this neighborhood, the research result of planning strategy is drawn. The traditional Chinese community as a kind of research object is relatively complex and challenging to activate its vitality. Thus, this research finding as a context paradigm could guide and influence more similar cases, and provide design and planning reference for related problems.

Explorations on the Activation Route of Gated Community Boundary Space based on Community Micro-Renovation——A case study of Shanghai

KAI Xin¹, YANG Guiqing²

yguiqing@163.com*

Abstract: Gated communities, as a typical residential morphology, are common in Chinese cities nowadays. Their features mainly include the planning and development of large plots and blocks and the use of gated fences to define the boundary of property rights. As a consequence, it is convenient for communities to achieve daily access control. However, the gated communities objectively produce an important number of negative community boundary spaces, which go against the vitality of urban streets. Since the causes of gated communities originate from deep social, economic, and cultural factors, the "open community" requirements proposed at the Chinese national level are difficult to implement effectively. The concept of "urban micro-invasive surgery" aims to create gradual, organic and small-scale interventions of renovation at the level of the community. On the premise of ensuring the rights and interests of the community residents, the community micro-renovation process activates the community boundary space and integrates potential social capital. Moreover, it enhances the daily vitality of the community. Based on a community micro-renovation project conducted in Pudong New Area (Shanghai, China) and a sample survey of residents' satisfaction and willingness, this paper explores the possibility of transforming negative community boundary spaces into public spaces for residents' daily social interaction activities.

Keywords: community micro-renovation, gated community, boundary space activation, social capital

Introduction

As the process of urbanization accelerates in China, gated communities, as the most significant form of housing developing, are gaining momentum in the city. In gated communities, walls or fences are frequently used as the community boundaries for daily management based on entrance guarding. Despite the fact that it has meets people's requirement for privacy and security protection of the community, it ignores the interaction between community and public space. Most of the gated community is characterized with the layout of dead-end road and puts emphasis on clear land division, causing the separation with the surrounding land and "producing" a lot of negative boundary space of the community. All these problem are detrimental to the cultivation of the vitality of urban public space and constrain the daily social activities, as a result of which the social network and social

capital are "wiped out". All that is harmful to the cultivation of residents' sense of community belonging and awareness of settlement (Yang Guiqing, 2017).

The improvement of spatial environment quality and the connotation-oriented development are gradually emphasized by the urban construction. In urban planning theory and practice, the promotion of small scale block and the opening of gated communities have become a new heated topic. In 2016, the advice of "promoting block-based system, and gradually opening the large scale gated community" of the party central committee and the state council has sparked heated debate across the country. The doubt of whether the demolition of the fence will violate the rights of the residents of the community results in the difficulty of implementing the proposal of "open community" nationwide.

Community micro-renovation, as the urban "micro-invasive surgery", provides a new path for the activation of the boundary space of the gated community. Different subjects could be guided to participate in community construction and governance through community micro-renovation. On the premise of guaranteeing the interests of residents' property rights, the boundary space of gated community can be enlarged through gradual and micro organic renovation, so as to enhance the daily vitality of communities and integrate potential social capitals.

Then the question is how to have a deep understanding of the gated community boundary space? How to "activate" it through community micro-renovation? What is the relationship between the activation of boundary space and social capital? What is the will of the residents? How to implement the activation of boundary space? How to solve the possible problems that may be caused by this? This paper, combined with the investigation and observation of Weifang Community Renovation Project included in "Colorful Community Plan" in Pudong New Area of Shanghai, will further explain the above problems.

Concept Definition

The definition of the following key words is given in order to make our discussion go smoothly.

The first one is the "gated community boundary space". In this paper, "gated community" is defined as "the residential functional area whose most of the boundaries are surrounded by walls, railings or green belts, etc., and where the entrance guarding measures are adopted at the entrance of the community to limit the access of residents or vehicles outside the community". "The boundary space of the community" is defined as the physical form of the boundary line of the community land, the interface between the public and private field of the property rights, specifically referring to "the wall, fences, shrubs, door or other separated objects surrounding the gated community, including part of the buildings and semi-public spaces within the boundary, as well as the urban public space like part of streets and green belt outside the boundary".

The second one is "community micro-renovation". Compared with the renovation of the extensive cities featured by demolition and construction on a large scale, "community micro-renovation" is characterized with micro renovation object, micro implementation of practice and micro guiding entry point" (Shan Ruiqi, 2017). It is designed for recreational use and social interaction, which has adopted the opinions and interests of different stakeholders (Yang Guiqing etc., 2017). Through the micro planning and construction, the community will be renovated and transformed gradually.

The third one is "social capital". In this paper, the "social capital" refers to a kind of social resources that exist in the social structure of residents and are mainly represented by trust, mutual benefit and harmony. Residents can utilize or activate such social resources through activities with strong purpose. In that case, social capital has important significance for enhancing cohesion of the community and encouraging the joint participation of community construction (Zhai Binqing etc., 2016).

Literature Review

Gated Community Boundary Space and Its Influence

The early studies on the boundary space and its influence of gated communities could be found in many classical literatures. For example, Jane Jacobs proposed the concept of "Street Eyes" (Jane Jacobs, 1961) in *the Death and Life of Great American Cities*. She argues that when the street was frequently used, its surrounding residents in the buildings could clearly see the activities happening on the street, in which case the street would be considered safer. Oscar Newman's (1973) also mentioned in *Defensible Space* that residents' constant observation of the community public space is one of the most effective measures to ensure security. The Congress for the New Urbanism (1996) also strongly opposed the large-scale community in single function, advocated the mixed use of functions, and focus on the design of the boundary space of the community. For example, the street should not be too wide, so that it will be convenient for the pedestrians to cross.

Many scholars have studied the classification of the gated community boundaries from the perspective of its elements, permeability and function as seen in Table 1. We can see that whether the boundary is clearly visible, whether the entrance guarding is strict, whether the vegetation is attached, whether the public function is achieved will affect the the gated degree of the boundary space.

Table 1 the classification of gated community boundaries

Scholar	Classification	
Jill Grant etc., (2004)	Fence	Visually opaque fences, visually transparent fences, electrified or barbed fences, low fences or bollards, etc
	Door	Revolving door, fence barrier gate, sliding gate, etc
	Sign	Signs of pavement and deceleration of speed, pavement texture or color changes, security guards platform, glass gatehouse, "private domain" or "no parking"
	Security	Fixed time security, all-day security, patrol guard, card or password access system, automatic access system, surveillance camera, armed security personnel, residential burglar alarm, etc
	Landscape	Green hedgerows, land form changes, water landscape, sand and stone landscape, etc
Liu Xiaomin (2007)	Wall	Common wall, hollow-out wall, decorated wall, greening outside the wall
	Fence	Common fence, greening inside fence, greening on fence, greening outside fence, comprehensive greening of fence
Zhang Shaosen (2009)	Soft	The boundary space formed by a combination of fences, walls, or hedges
	Hard	The boundary space directly separated by the building
Xu Miao etc., (2015)	Architecture	Residential buildings with ground floor business, commercial or public buildings without residential functions
	Fence	Fences without being decorated by vegetation; the fence decorated with some vegetation
	Landscape	Natural landscape, fort

Source: summarized and arranged by the author according to the literature.

The gated community boundary space has both positive and negative influences as seen in Table 2. On the one hand, it has a positive impact on the residents inside the community, in terms of security, privacy, identity symbol, sense of belonging, and ensuring the quality of service facilities of the community. On the other hand, for the public space outside the community, the boundary of the gated community turned the public space into the private space, which is unidirectional and irreversible. The negative influences caused by it mainly include the reduction of the number of urban public space and the diversity of urban landscape resources, privatization of the urban landscape, decreased efficiency of urban road system, unsystematic network of walking, difficult maintenance of street life and intensified social isolation and so on.

Table 2 Positive and negative influences of the gated community boundary space

Type of effects	Scholar	Detailed description
Positive Effect	Jill Grant etc., (2004)	Protect the residents and its property security in the aspects of material, keep privacy in the visual and spatial aspects Improve the value of land and protect the internal public service facilities Restrict the access of others outside the community Displays the rights and creates the identity symbol of the community
	Xu Miao (2015)	Provide a necessary comfortable and safe environment to form a common sense of belonging Promote social exchanges and form the social relations among the community Residential separation between the rich and poor will be good to the social harmony limitation of the number of users to ensure the existing environmental quality
Negative Effects	Moughtin etc., (1999)	Reduces the activity on the street, which makes people acquiesce to the illegal behavior outside the boundary space of the community
	Qin Ruiying (2008)	Increases the social distance between different social groups Impose psychological burden on residents inside and outside the walls Reduce contact and communication between residents of different social groups, which aggravates the social isolation
	Li Pei (2008)	The privatization of urban landscape resources reduces the public recreational space
	Li Yin etc., (2009)	The separation of private roads inside the community from the urban public road system decreases the accessibility and efficiency of residents to the open spaces and public places.
	Australia”Design Quality Manual” (2012)	The fact that motor vehicle drivers are more likely to accelerate as they cross the gated boundary increases the risk of safety problems
	Karim (2015)	The planning of such gated communities can only be considered as "large-scale housing production", instead of "the community for life"

Source: summarized and arranged by the author according to the literature.

Community Micro-renovation and Cultivation of Social Capitals

Cities are the outcome of gradual progress rather than the result of a sudden change. Henri Lefebvre (1974) proposed in *The Production of Space* that space is not only a product, but also a process of recombination of social relations and practical construction of social order. Edward Soja (1983) argues that life is to join the social production of space, to shape the constantly evolving space and be reshaped by it.

Then the question is, how can the "community micro-renovation" of the gated community boundary space achieve the goal of increasing the everyday vitality of communities and integrating the potential social capitals? Louis Wirth (1938) proposed in *Urbanism as a way of life* that population density, land value, rent, distance, health, reputation, aesthetic taste, noise, smoke and other public harms, make different parts of the city suitable for people of different social groups to live. However, the numerous population in cities leads to the individual variability, relative shortage of intimate relationships, and fragmentary relationships characterized by anonymity, superficiality, transience and correlation. In that case, although people of the same social status and the same needs are living in the same area, but the lack of emotional exchanges between individuals still makes them tend to be insulated from each other. Therefore, "community micro-renovation" can serve as a catalyst to provide opportunities and space for residents to communicate, raise their sense of identity and belonging, which will finally contribute to the increase of social capital.

Generally speaking, large-scale urban renovation projects seldom listen to the opinions and suggestions of local residents. On the one hand, it is partly because that the larger number of participants will delay the time and increase the cost of the project. On the other hand, it is due to that the interests of residents sometimes violate the vested interests of developers and local governments (Zhai Binqing, 2010). On the contrast, "community micro-renovation" often starts from the practical problems, which focus much on the quality improvement of the abandoned public space and the renovation of the functions in community, such as the community entrance, small square, small park, etc., to realize the perfection of the micro function with a small amount of basic investment, which will ensure a lower entry threshold for the practice itself, and realize a variety of cooperation forms at the same time (Shan Ruiqi, 2017). Therefore, community micro-renovation can be used as a constant attempt of residents' habits of cooperation, which will contribute to the cultivation of social capital.

The gated community boundary space, on the other hand, is considered as one of the focuses of community micro-renovation. With regard to the activation mode of boundary space, Xu Miao etc., (2015) holds that it can start from the enclosure scale of area, boundary effect, shared service and the control of facility and other aspects. Qin Ruiying (2008) believes that the the limitation of the height and materials of walls, fences or plant for coverage in gated communities will do a favor for the road lighting to get rid of the bad effect on residents' sight and for the formation of visible walls. The limitation of the developing scale will ensure the street connectivity. What's more, through the practice of "Breaking Down Walls", community cohesion can be enhanced.

Summary of the Progress of Study

In conclusion, the negative impact of gated community boundary space on urban public space has received wider attention in academic fields. The study on the activation path of boundary space in gated communities is constantly deepened from the perspective of material level. However, it can also be found from the relevant study progress that few scholars have ever associated the activation of

gated community boundary space with community micro-renovation, and the study on the relationship between community micro-renovation and social capital is still inadequate. Therefore, the exploration on the basis of micro-renovation of community of activation path of gated community boundary space will help to guide and promote the practice of "Breaking the Wall" of the gated community, to promote the good effect of the network society and to well implement the "renovation work" of the city. At the same time, it will also contribute to the enrichment of the theories of the existing community planning and construction of our country.

Theoretical Cognition

Historical Causes of the Gated Community Boundary

It can be found from the evolution of living style that the traditional gated living form of China has experienced a long history, and the tradition of the consciousness of urban space boundary has been continued and inherited as a living habit with a profound social, economic and cultural factors.

In the feudal era, the rulers, in order to consolidate the monarchy and facilitate management, adopted the management and regulation modes of "Lifang" and "Fangxiang" System to organize and manage the residents in city (Wang Zhuoyuan etc., 2013). This gated residential boundary is more obvious in the traditional Chinese big family-based social group, which helps to prevent theft through higher walls and strengthen the family rule and ideological confinement (Yuan Ye 2010). In modern times, the emergence of "Lilong" enriches the types of community boundaries. Taking Shanghai as an example, in order to save land, most of the "Lilong" residential buildings are located close to the street, and a relatively open boundary is formed through the buildings arranged along the street.

After the founding of the People's Republic of China, the socialist planned economy system was implemented by China. In the field of housing construction, the mode uniformly invested, constructed and distributed as a kind of welfare by the country was basically adopted, and the government took on all the responsibilities of investment, planning, construction, distribution and maintenance. The community planning at this era was mainly affected by the planning theories of "Neighborhood Unit" and "Residential Community", and emphasized the internal function, organization and living environment of the community, as a result of which a large number of communities with gated boundaries were produced.

As the policy of reform and opening up, China has entered the period of commercial residence. The rental model of large blocks of land gave rise to the emergence of large number of gated community buildings. What's more, the community property management system also led to the emergence of large scale gated community boundary to some extent. As the gated property management mode was featured with scale-based effect, the larger the community area was, the lower the average cost per person or per square meter would be. In that case, property companies tended to apply gated fences and walls as boundaries for community management. The introduction of the *Property Law* made it clear that owners had legal rights to public service facilities and roads inside the community (Xu Miao, 2010), as a result of which the private property rights were strengthened, but the contributions of community boundaries to public space were failed to be defined, thus failing to guarantee the property rights of public space. And, the guidance on the design of public boundaries in the relevant

regulations of building distance for setting the boundary and the road traffic design is also inadequate, causing the low spatial quality of gated communities.

The Sociality of the Gated Community Boundary

The gated community boundary is not only the fence on the material basis, but also characterized with its corresponding social attributes. The sociality of the gated community boundary is related to the social groups inside and outside the boundary space, including the subjects inside the boundary, such as residents, property companies, developers, and other residents outside the boundary as seen in Table 3. While the gated community boundary are the result of social interactions inside and outside the boundary. At present, the physical form of the gated community boundary mainly reflects the requirements of the consumption and the construction management inside the boundary, but fails to show the consideration of the urban image and traffic environment outside the boundary, which means it fails to make a positive contribution to the urban public space. This lack of urban public space will transform people's behavior to a certain extent. The exclusivity of space makes people more indifferent to each other, which will finally aggravate social isolation.

Table 3 The sociality of the gated community boundary space

Sociality	Relevant Social groups		Requirements for the gated community boundary
Inside the boundary	Consumption	Residents	Protecting the security and privacy, ensuring the normal use of the public service facilities inside the community, limiting the entry of people outside the community, reflecting the symbol of identity and status
		Developer	The maximum developing interest and cultivating a sound environment inside the community
	Construction and management	Property right management	Intensive and convenient property right management inside the community
Outside the boundary	City image cognition	City images of roads and street	Forming the unique and recognizable city image
	Traffic environment cognition	Walking environment	Safe, comfortable and convenient walking environment
		Driving environment	Convenient traffic environment

Theoretical Cognition of Boundary Space Activation

The gated community boundary space should not be treated as a simple problem, but as an opportunity to improve the exchanges among people in metropolises. The vitality of urban public space of the boundary space is mainly influenced through the aspects of perimeter and interface, with perimeter influencing the connectivity of public space, and interface influencing the quality of space as seen in Table 4. The activation of boundary space can also start from the two aspects of narrowing the perimeter and opening the interface.

Activation of the boundary space should be targeted at enhancing the quality of public space, and promoting social interaction, providing convenience for residents. First of all, it should decide which boundary space of which gated community needs to activate, which should be combined with the surrounding public service facilities of the community, such as schools, shopping malls, the layout of the traffic station, and determine which gated community caused a larger block of travelling residents, what boundary space has the largest flow of people and other situations that worth transforming and upgrading according to the traffic situation of boundary space. Secondly, the activation mode of narrowing the perimeter means opening a new entrance, so it is necessary to determine whether it is open only to pedestrians or to both pedestrians and the vehicles, and determine the opening times of the day. At the same time, it is necessary to solve the problems caused by opening new entrances and exits, including how to guarantee the safety and property rights of community residents, whether public services and commercial service facilities such as kindergartens, vegetable farms, sports centers and parking lots are open for business, and whether security systems of the building need to be enhanced. Thirdly, the activation mode of opening interface means to increase the function of the interface and promote the openness of the interface. It is necessary to decide whether to add small commercial or outdoor activity facilities, whether to open the line of sight, and whether to enrich the details of buildings and walls by means of wall reconstruction and graffiti. When the sidewalk outside the boundary is too narrow, it is also needed to consider the community land area inside the boundaries; if the community land area is abundant, it should consider whether the fences or walls could be withdrawn a little back from the land border to extend the width of the sidewalk outside the boundary. It means that the land inside the community will be used as a public space. In that case, it is also necessary to consider how to encourage the main body of the community, such as the residents and property company. For example, when the width of open public space should be more than 6 meters and the area should be more than 150 square meters, and the main body inside the community can obtain additional commercial building area, etc.

Table 4 Ways of affecting urban public space by gated community boundaries

Elements of the gated boundary	Ways of influencing the public space	The affecting measures
Perimeter	The perimeter of the community boundary is related to the size and scale of the community. High connectivity means more short connections of the transportation network, more intersections and fewer end roads, which allows people to have more choices of route and avoids community isolation.	<p>(1) the average boundary circumference ≤ 1500 feet (457.2 meters);</p> <p>(2) 500 (152.4 m) \leq interval of recommended road intersections ≤ 600 feet (182.9 m), maximum intersections intervals ≤ 800 feet (243.8 m);</p> <p>Internal connectivity (the number of open road intersections per square mile (259 hectares)) is at least 140 per square mile</p>
Interface	When the gated community boundary adopts different interface forms, the comfort, image and space quality of the boundary space will change greatly, which will also affect the frequency of people to use the space and the occurrence of activities. Apart from the basic commuting activities, the active interface will also encourage residents to generate extended activities and some occasional activities.	<p>(1) function of the interface: whether there are commercial or outdoor activities</p> <p>(2) the openness of the interface: completely open: (the line of sight is transparent and can pass freely, or can imply the pedestrians no entering for private space only through the green fence or other barriers that can be crossed; Semi-open (can't pass freely, but the line of sight is transparent, or the details of buildings and walls are clear with the focus of the line of sight); Completely closed (not visible with no free access)</p> <p>(3) Entrance and exit of the interface: completely open (no restrictions or only time-sharing restrictions on vehicles and pedestrians outside the community); Semi-open (no restrictions on pedestrians, strict restrictions on vehicles outside the community); Completely closed (strict restrictions on pedestrians and vehicles outside the community; could only be permitted with the access card, inspection permit, or security verification by the security guard)</p>

Case Study

Overview of the renovation of Weifang Community of Shanghai "Colorful Community Plan"

In 2016, the "Colorful Community (Inner City) Renovation Plan and Pilot Action Plan of Pudong New Area " (hereinafter referred to as "Colorful Community Plan") was carried out in Shanghai, which was led by the multiple main body involved in the whole process such as the government of Pudong New Area, the relevant functional departments, design alliance, experts and representatives of local residents and the media. It aims at the daily 15-minute life circle of the residents to improve the function of renovation and quality of the community.

This paper mainly analyzes Weifang Community involved in the "Colorful Community Plan". Weifang Community is used mainly for residence with mixed old and new residential areas and diverse types as seen in Figure 1. Among them, the gated communities of multi-storey public housing prevail, mainly located along the two side of North Nanquan Road. Commercial housing gated communities were mainly built after 2000, mainly along the side of Bin River on the West Pucheng Road.

Figure 1 Distribution and area of different gated communities in Weifang

Source: Drawn by the author

The average land area of the gated communities in Weifang Community is 11.7 hectares. Through the calculation of community connectivity as seen in Table 5 and Figure 2, it is found that the average perimeter of gated community boundary of Weifang Community is 1385m, which is much higher than the value of 457m recommended by LEED-ND. The average interval of community intersections is 362m, which is also higher than the recommended value of planning. The community connectivity is 32 intersections per square mile, which is far less than the 140 per square mile recommended by the plan. Therefore, it can be seen that the overall size of the community is large and the connectivity is general.

Table 5 Connectivity analysis of gated communities of Weifang

Average perimeter of community boundaries	Average intervals of community intersections	Community connectivity
1385m (The total perimeter of the 18 land is 24930m)	362m (The maximum length is 626 m)	32 intersections per square mile (the total area of the land is 243.5ha, or 0.96 square miles, which is the total area of the 18 mainly residential land.)
Compared to the planning requirements of LEED-ND (2009)		
≤457m	152m to 183m is appropriate, and the longest intersections are not more than 800m apart	At least 140 per square mile

Source: Drawn by the author

Figure 2 Intersection distance and connectivity of gated communities in Weifang

Source: Drawn by the author

Six types are involved with regard to the boundary of gated community of Weifang Community , including underground floor business, gated building facade and walls, vertical greening of the fence, greening on both sides of the fence and the fence itself as seen in Table 6. Only 34% of the boundaries are commercial, mainly formed by "Breaking Down Walls to Open Stores" in gated communities of public housing. And 65% of the boundary is block, including 22% fence, 17% wall, and 25% greening on both sides of the fence, which provides some greening space for the sidewalk. Besides, only a few borders are gated building facades and vertical greening fences. It can be seen that the boundary

function of gated communities in Weifang Community is relatively single, which is not conducive to the shaping of boundary space vitality.

Table 6 interface function and proportion of the boundary of Weifang

Interface function of the boundary		Length (m)	Proportion (%)	
Taking the building as the boundary	ground floor business	5668	34	35
	gated building facade	117	1	
Taking the block as the boundary	walls	2811	17	65
	vertical greening of the fence	193	1	
	greening on both sides of the fence	4277	25	
	fence	3744	22	
Total		16810	100	

*There are a total of 18 residential blocks with a total perimeter of 24930m, of which 67.4% are residential

*There are a total of 18 residential blocks with a total perimeter of 24930m, of which 67.4% are residential

The evaluation of the vitality of the gated community boundary is divided into three grades: active, medium and poor as seen in Figure 3, 4 and Table 7. Generally speaking, the gated community boundary of public housing with commercial function is more active, while the gated community boundary of commercial housing is less active.

Level A: Active

Level B: Medium

Level C: Poor

Figure 3 Different levels of vitality of gated boundaries of Weifang Community

Source: Drawn by the author

Figure 4 The vitality analysis of gated community boundary in the Weifang

Source: Drawn by the author

Table 7 Boundary vitality evaluation of gated community of Weifang

Vitality of the boundary	Mixed function situation	Spacial form of the boundary	Numbers of the entrance and exit	Activities of the pedestrian
A Active	Commercial activities and outdoor activities caused by breaking down wall to open shop or commercial group house	The boundary space form is semi-open or completely open, the pedestrian line of sight is transparent, or the details of buildings and walls are clear and rich, with the focus of the line of sight and the diversified boundary space	Many: 10-20 Entrance and exit/100m	Apart from the commuting activities, there are other extended activities such as shopping, eating, having outdoor coffee, chatting, dancing, playing, exercising and others.
B Medium	Part of the commercial or outdoor activities	Only a small amount of boundary space is of the open form, and the boundary space is monotonous and lack of details	Medium 10-20 Entrance:/ 100m	Apart from the commuting activities, there are other occasional activities such as stopping to rest, obtaining information, observing, communicating, running and taking photos
C Poor	No commercial or outdoor activities	The boundary space form is closed, mainly taking the form of gated wall or fence with no ornamental details	Few 0-5 Entrance / 100 m	Pedestrian activities are mainly based on necessary actions concerning passing by.

Source: Drawn by the author

Questionnaire survey and analysis

In order to understand residents' attitudes and opinions on the gated community boundary space, a questionnaire survey was conducted on residents of Weifang Community. A total of 150 questionnaires were issued and 146 valid questionnaires were recollected.

According to the questionnaire survey, most residents hope that the action of "Breaking the Wall" will start from the water front space Community and the school playground as seen in Figure 5. Only 17 percent of residents think the walls of enterprises need to be opened, and 11 percent think the walls of residential communities need to be opened. What's more, as seen in Figure 6, 29 percent of residents said they did not think any of the walls needed to be opened. For the question that "are you willing to open the community by removing the wall?", 74% of residents say they are not willing to remove the walls to achieve an open community, only 14% are willing to, and another 12% say they don't care.

Figure 5 The number of residents that agree to open the wall

Source: Drawn by the author

Figure 6 Residents' attitude towards the demolition of the wall to achieve an open community

Source: Drawn by the author

For the question that "what is your biggest concern if the walls are removed as seen in Figure 7? (multiple choices, up to 3 choices)" 76% of the residents think that removing the walls of the residential area will increase the risks of security as people with no household responsibilities could enter or leave the residential area at will. The second problem is the problem parking. 49% of residents are worried that vehicles outside the community will occupy the parking spaces in the community, causing parking difficulties for residents. Besides, 42 percent of residents think that the demolition of the wall will cause noise problems to the community. 40% of the residents think that the sanitary and the environment of the residential area would become worse after the demolition of the wall, and the difficulty of governance would increase. However, 26% of the residents think that after the demolition of the wall, the public service facilities inside the community will be shared with residents outside the community, which will affect the normal use for residents inside the community. Finally, only 4 percent of residents hold that "the community is private territory and cannot be violated".

Figure 7 Questionnaire result : What is your biggest concern if the walls are removed
Source: Drawn by the author

According to the attitude of residents, it can be found that the main reason why residents are not willing to demolish the wall of the community wall is that they are worried about a series of problems of safety, environment, parking problem, noise and others caused by the opening of the community. If we want to open the community by removing the walls, we must get rid of the concerns of the residents from the above aspects, especially the aspect of safety.

For the question that "if the wall of the community needs to be renovated, which way do you prefer?" as seen in Figure 8, 72% of the residents want to beautify the fence without removing it, such as growing plants, adding art equipment and graffiti. 35% of the residents think that the site of the wall can be relocated, the abandoned vacant land of the community can be transformed into an activity square and opened to the citizens, and fitness equipment and seats can be added. 33% of the residents think that the location of the fence can be moved a few steps back to open up the greening space and activity space of the community to the citizens. 16% of residents say that the wall could be directly demolished, and the shops (such as retail stores, restaurants, etc.) could be opened at the original place of the wall.

Figure 8 Questionnaire result: if the wall of the community needs to be renovated, which way do you prefer Source: Drawn by the author

Generally speaking, most residents prefer to carry out appropriate transformation on the basis of preserving the fence, while only a few residents choose to demolish the fence. It can be seen that residents have formed a traditional consciousness and living habit for the gated community boundary space. Therefore, the renovation of the wall should be gradually implemented, starting with the beautification of the gated wall, and then opening the space inside the community, which will gradually help to weaken the sense of separation of the wall, and finally form an open and shared community space.

Introduction of Specific Implementation of the Projects

The micro-renovation of Weifang Community activates the gated community boundary space mainly from two aspects: reducing the perimeter and opening interface of gated communities as seen in Table 8.

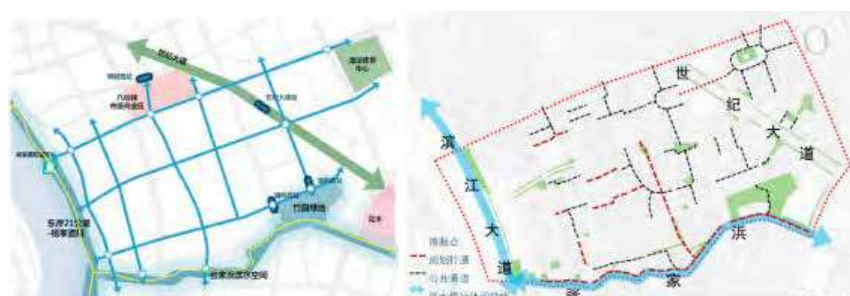

Table 8 List of projects of colorful community of Weifang in Pudong New Area

Activation mode of the gated communities boundary space	Specific project	Project progress
Decreasing the perimeter	Action of breaking down the wall	Planning period
Opening the interface	Transformation of the surrounding area of Zhuyuan Ring Road	Completed
	Wall painting of the surrounding area of Weifang No.1 Village/Zhuyuan Kindergarten	Completed
	North Zhangjiapang Road Pocket Park	Under construction
	Improvement of the public space of Weifang No. 10 Village	Publicity of the collected plans
	Improvement of public space of Weifang Head Lane of NO. 6 and No.7 Village	Publicity of the collected plans
	Micro renovation of Weifang No. 4 Village	Planning period
	Micro renovation of Weifang Jiejiao Street	Planning period
	Micro renovation of Jiejiao street of Pudian Road	Planning period

Source: Drawn by the author

From the aspect of reducing the perimeter of gated communities and improve the overall connectivity of public spaces, in order to enhance the overall connectivity of the public space, land conditions and the under-construction projects are considered as seen in Figure 9. Binjiang Green Road of the Huangpu River, the Zhangjiapang River and the Zhuyuan Green Space are determined as the main point of interest for public activities of the area surrounding the city streets, and YuanShen Sports Center, deputy center of the flowers and trees and the city-level Babaiban Business Zone are considered as the important public service facilities surrounding the community. These three public service facilities are taken as the connectivity point o to guide the network optimization. In combination with the current situation of each gated community, the author tries to improve the spatial

accessibility, reduce the long and continuous gated boundary and connect the whole road network of the community by partially breaking the boundary wall of the gated community boundary space, excavating the potential ways, and transforming and widening some existing ways to improve spatial accessibility, reduce long and continuous gated boundaries, and connect the whole road network of the community. As most residents prefer to preserve the community wall, the action of breaking down the wall is still in the planning stage and has not been included in the library of key projects.

(1) Analysis of important public service facilities around (2) Public channels formed by planning proposals

(3) Gated community boundaries broken by planning proposals (4) Public space networks after breaking gated community boundaries

Figure 9 The design strategy for narrowing the perimeter of gated community boundaries and improving the overall connectivity of public spaces.

Source: Shanghai Urban Planning and Design Institute ,2017, Pudong New Area Colorful Community Action Plan in Weifang Community Planning.

From the aspect of improving the gated community boundary space interface and enhance the vitality of public space. Since most residents are in favor of preserving the fence while improving the interface, the micro-renovation project with the open interface as the planning strategy progresses is put into quick implementation. Two implementation projects are selected for brief introduction.

The first implementation project is the reconstruction of the area around the Zhuyuan Ring Road as seen in Figure 10. The surrounding area of Zhuyuan Ring Road is commercial houses built after 2000, most of which are occupied by parking, and residents have limited space for walking. The existing walls are old and badly damaged, and the greening landscape is monotonous. Therefore, it is necessary to plan and transform the road section, increase the pedestrian exclusive road and repair the current situation of temporary parking disorder. Besides, it is needed to improve and update the dilapidated

walls, enhance the overall openness of the space, and enhance the integration of activity facilities and environment.

Figure 10 Community micro-renovation of the surrounding area of Zhuyuan Ring Road

Source: Pudong New Area Planning and Land Administration, 2018, Collections of Achievement of colorful community construction in Pudong New Area.

The second implementation project is wall painting surrounding Weifang No.1 Village/Zhuyuan Kindergarten as seen in Figure11 and 12. In Weifang No.1 Village, the original shops along the street were demolished due to illegal construction, and a concrete wall was erected after the demolition, becoming a "scar" in the community. The community micro renovation calls for the over 20 children from the kindergarten and primary school to paint and graffiti the walls together with their parents under the guidance of professional painters. There are two water tanks near Zhuyuan Kindergarten. The wall of the water tank falls off and a lot of construction waste is piled up around the tank, which affects the overall aesthetics of the community. On the basis of the community micro-renovation platform, teachers and students of Shanghai Visual Arts College were invited to Weifang Community to transform it, and to select the graffiti painting scheme according to the votes of community residents. These community micro-renovation implementation projects all stimulate community vitality and cultivate social capital while improving community boundaries.

Conclusion

Currently, the fact that the design of gated community boundary only focus on the division of land-use and property rights in management has led to problems such as the decline of people's communication and social isolation. This is detrimental to the face-to-face communication between people in internet period, which means the good neighbor spirit is restricted. This paper hopes to take the gated community boundary as an opportunity to promote the daily vitality of communities and integrate potential social capital through community micro-renovation. Two ways are proposed to activate the gated community boundary space: breaking part of the boundary space and improving the boundary space interface. At present, Shanghai, Beijing and other cities are carrying out the campaign of "demolishing illegal street shops". Although this has a positive effect on the regulation of illegal constructions, it is not conducive to the good neighbor spirit, social network, social capital and diverse communities. From this point of view, the current urban renovation and development of community boundaries should be investigated and analyzed carefully.

“Stop the Child Murder”: How a grassroots movement for children’s safety formed a new paradigm in urban design

Garyfallia Katsavounidou¹

¹*Department of Spatial Planning and Development, Faculty of Engineering, Aristotle University of Thessaloniki
gkatsavou@plandevl.auth.gr*

Abstract: Dutch cities are nowadays considered among the most pedestrian- and bicycle-friendly in the world. However, back in 1971, pedestrian deaths by motor vehicles had reached record levels, with 3,300 people dead, 500 of whom were children. Following the tragic death of his young daughter in such an accident, a journalist wrote a polemical article, entitled “Stop the Child Murder”, which became a national sensation. With the same motto, in the densely populated district of De Pijp in Amsterdam, a group of children organized themselves to demand safer streets and to claim open space for play instead for car parking. In a documentary filmed locally, we watch children actively claiming their rights, putting up barricades to exclude motor traffic, standing up to adults expressing opposite opinions. Soon after, many local streets in De Pijp were transformed into “woonerven” (living streets), where children can move around safely and play in the proximity of their houses, thus setting the norm in the Netherlands. In the paper this historical case of a grassroots movement successfully instigating institutional change is critically presented in order to understand its local specificities and to extract useful lessons about the tools, agents and methodology of community-based urban transformation.

Keywords: children’s right to the city; children’s activism; *woonerf*; livable street paradigm

Introduction

Active participation of citizens in the shaping of urban space, in the sense of political grassroots movements (Castells, 1983), of collaborative planning (Healey, 1997) and in the various forms of more recent participatory approaches, such as place making (Palermo and Ponzini, 2014) or tactical urbanism or handmade urbanism (Rosa and Weiland, 2013), is at the core of human-centered urban design and planning. The history of people-centered urbanism is abundant in examples of bottom-up processes that have contributed to a paradigm shift in the physical design of cities. From the story of Aldo van Eyck’s playgrounds in postwar Amsterdam which constitutes an extraordinary case of participatory democratic process (Lefaivre and de Roode, 2002) to the opposition movement against the dissolution of historic neighborhoods in downtown Manhattan led by Jane Jacobs, which she eloquently describes in her seminal work (Jacobs, 1960) to the preservation of the Highline in downtown Manhattan (Lopate, 2011) and its transformation into a vibrant public space, the catalyst of change has been the people: citizens, residents or users who organized themselves and succeeded in disrupting top-down practices, claiming their right to the city (Lefebvre, 1968) in the most concrete and physical sense. It is an important lesson to be learnt for urban planners and designers: against a deterministic urban model, often based on aged regulations and ways of thinking, citizens provide an innovative perspective, unveiling real, everyday needs and pointing to flaws in dominant models of production of urban space (Rosa and Weiland, 2013). This is

the framework for the discussion of the story of the mainstreaming of the *woonerf* concept in the Netherlands as it took place in the early 1970's, as a result of a nation-wide campaign for the safety of children from traffic and their right to use the streets as public space. The *woonerf* concept soon became a street model in urban design (Ben-Joseph, 1995) and was replicated in many other parts of the world; it is known in English-speaking countries as home zone (Biddulph, 2001). In the paper, the importance of the bottom-up movement that led to the widespread adopting of the *woonerf* in the Netherlands and to the subsequent state regulation, is presented both as a positive and optimistic case of a successful cooperation among the various stakeholders (residents, professional planners and designers, municipal and state authorities) when a direct and urgent demand was made by the users of urban space themselves, and as a specific instance that showcases the transformative power of a movement that "put children first" as well as the inherent dynamism of children-city relationship (Katsavounidou, 2012).

The story of the *woonerf*; daring to challenge the car

In most European countries, we nowadays live in a historical period in which, thankfully, policy makers and citizens alike have come to the realization that car traffic is not compatible with a vibrant city for people. But this has been a very slow and time-consuming change of mentality: in the 1960's the challengers of the widely-accepted domination of the car in urban space were few and marginalized. The French Situationists were among the pioneers; in the article entitled "Situationist theses on traffic", from 1959, Guy Debord prophetically points out:

It is not a matter of opposing the automobile as an evil in itself. It is its extreme concentration in the cities that has led to the negation of its function. Urbanism should certainly not ignore the automobile, but even less should it accept it as a central theme. It should reckon on gradually phasing it out. In any case, we can envision the banning of auto traffic from the central areas of certain new complexes, as well as from a few old cities. (Debord, 1959)

A few other voices opposing the car-oriented urban development model that was prevalent at the time included Jane Jacobs (1958; 1960) and the great thinker Lewis Mumford, who, in his essay "The American way of dying", wrote about the car, the "sacred cow" of America as he called it:

Some of the critics have dared to say that the Sacred Cow of the American Way of Life is overfed and bloated; that the daily milk she supplies is poisonous; that the pasturage this species requires wastes acres of land that could be used for more significant human purposes; and that the vast herds of sacred cows, allowed to roam everywhere, like their Hindu counterparts, are trampling down the vegetation, depleting wild life, and turning both urban and rural areas into a single smudgy wasteland, whose fancy sociological name is Megalopolis. (Mumford, 1966)

Despite, however, critiques such as Mumford's, the overarching climate of the era was that of an almost unanimous acceptance of the car as a permanent feature in city centers. Therefore, the case of Delft in late 1960's arose as a true beacon for change, challenging as it did the design of the typical street and subverting the overall-accepted premise that, since cars were introduced to cities, streets "belonged" to them. It is the first time indeed that what Donald Appleyard (1980) calls "street dwellers' rights" were put forth:

- The street as a sanctuary: streets should be safe for all pedestrians and bicyclists, especially children;
- The street as a livable, healthy environment, free of excess noise and polluted air caused by motor vehicles;

- The street as a community, serving as the common space where neighbors can engage in common actions;
- The street as a neighborly territory, enhancing the sense of belonging, pride and responsibility;
- The street as a place for play and learning: children should be able to use street space for spending time outdoors, and should have the freedom to roam safely in their neighborhood;
- The street as a green and pleasant land, where elements of nature can be incorporated in the physical design, providing relief from the grayness of the city; and finally
- The street as a unique historic place, with its own history and embedded with people's memories.

The Delft case is telling in the respect that these parameters were initially put forth in the form of demands made by residents to the city, but soon became an academic issue in the planning field. The local call for action was supported theoretically by Nick de Boer, Professor of Urban Planning at Delft University of Technology. De Boer especially emphasized the importance of street space for the well-being of children. Especially in lower-income neighborhoods, play areas were very scarce, and therefore the street space was extremely valuable in that respect. He presented solid arguments that streets should be redesigned in a way that would allow the co-existence of cars and people, thus allowing for people's activities to take place while the car could go through, nonetheless as a mere "guest" in the street (Ben-Joseph, 1995). Thus the idea of the *woonerf* ("residential yard") was formed, materialized in terms of physical design to give the impression of a "yard", thus psychologically influencing car drivers to slow down and be careful; the street became the in-between living space for the people (see Image 1). The three most important design features of the Delft *woonerf* were the following:

1. Sidewalks and roadways were integrated into a continuous, shared surface
2. The linearity of the street was replaced with a winding layout for the car path
3. With the active participation of the residents, front gardens, trees, planters and benches were introduced.

Image 1. A typical *woonerf* in Delft, as it is today. Source: <https://www.humankind.city/2015/12/woonerf-inclusive-and-livable-dutch-street/>

In retrospect, one can argue that the *woonerf* idea re-attributed to the street the attributes that characterized it for centuries of human habitation, before the advent of the car: the street had always been a communal space, a neighborly territory, a place for play (Gehl, 1987). Its historic function is still evident in many pre-modern examples, such as medieval Italian or Greek towns and villages, continuously inhabited to this day. While, however, in Italy and Greece in the 1960's and 1970's, historic urban centers were ruined and marred by congestion and pollution, the little town of Delft was showing that a return to the primordial function of the street as a livable environment was indeed possible.

***Stop de Kindermoord*”; a grassroots movement for children’s safety from traffic**

By late 1960's the idea of the *woonerf* had already started to take shape, as described above, albeit in a small and scale – it was only implemented for the redesign of a few streets in residential districts of Delft. It was not tested in more dense and compact parts of cities or in streets with heavier traffic. In the Netherlands at that time, most cities were not at all pedestrian- or bicycle-friendly. In fact, in the year 1972 casualties by motor vehicles in Dutch cities had reached a tragic record: 3,264 deaths and about 70.000 injuries. Among the dead, 457 were children under the age of fifteen (Feddes and de Lange, 2019). A year before, the six-year-old daughter of Vic Langenhoff, a journalist, had died in such an accident. After this tragic death, Langenhoff ran a series of articles on national newspaper *De Tijd*, entitled “*Stop de Kindermoord*” – or “Stop the Child Murder”. “One of the 3000 people who died in traffic accidents in 1971 was my youngest child, who was 6 years old. She was on her way to school when she was hit by a car coming around a blind bend at full speed”, he wrote, and emphasized that “our society will never be just until a child can spontaneously run to meet his or her father without risking being run over by a car” (Feddes and de Lange, 2019).

Langenhoff's articles caused a sensation throughout the country and were the source for the “*Stop de Kindermoord*” initiative across the Netherlands, which resonated strongly in the capital, Amsterdam. The Dutch society more and more agreed that something had to be done to stop the main cause of needless deaths: the automobile. Maartjie van Putten, a then 23-year old mother, and one of the leaders of the movement, said in an interview about that era: “Automobile traffic in Amsterdam had increased dramatically. On our street there was a primary school and children were run over frequently. When I saw Langenhoff's article I thought: my God, what kind of society are we creating?” (London Cycling Campaign). People's reaction took the form of active protest, picket marches, and activist demonstrations (like the powerful message evoked through the site installation of 150 white crosses that symbolized the deaths by motor vehicles – see Image 2). Families took the streets to claim a safer and more children-friendly environment for the city dwellers (Image 3). One of the most remarkable protests took place outside Amsterdam's Rijksmuseum where the participants laid down with their bicycles pretending to be dead.

Image 3. “Stop the Child Murder” protests in the Netherlands in 1972. Source: <https://lcc.org.uk/pages/holland-in-the-1970s>

These intense campaigns throughout the country, under the “Stop the Child Murder” motto, created an impetus for institutional change, as well. Quite soon, people’s demands were heard very seriously by government and municipal authorities. A national official committee was formed and state transport advisors in fact visited Delft to see how the *woonerf* principle worked in situ and how it could be implemented as a rule in street design. A few year/s later, in 1976, Dutch street design legislation integrated these principles and defined the specific design requirements of the *woonerf* (Ben-Joseph, 1995):

- Pedestrians may use the full width of the roads within a *woonerf*; playing is also permitted on the roadway
- The impression that the highway is divided into a separate roadway for motor vehicles and a footpath should be avoided
- Features should be introduced which will restrict the speed of all types of vehicles

- Drivers within a *woonerf* may not drive faster than at walking pace

Thus the idea of the “living street”, the street as a space first and foremost for people and then for the movement of vehicles, became an institutional reality. The *woonerf* principles have since then been introduced, in variations, in the design codes of the UK, the US, Israel, and Japan (Ben-Joseph, 1995; Biddulph, 2001). “Putting people first” is the common denominator of the various forms of “calmed traffic” streets, as the sign of the *woonerf* explicitly shows – see Image 4.

“Aren’t we entitled to a play street?”: what happens when children are really being heard

From the advent of the modern era, one could say that children in city centers are a paradox merely by being present. The child, as conceptualized in the modern society, is the epitome of the vulnerable, and the dense city center is the incarnation of all ills: the stressful rhythms, the anonymity of the crowd, the lack of community, the scarcity of nature and open spaces, the increased criminality – all attributes of the stereotypical image of the downtown seem to be on the antipode of the ideal conditions for a child to be raised. This stereotype is indeed the basis for the predominant choice of suburban living – and suburban expansion of cities – that has characterized western urban civilization for most of the second half of the twentieth century. There have been different voices, however, putting forth a different, much more inclusive conceptualization of childhood: children need the city psychologically and socially as much as the city needs them (Ward, 1978; Dolto 1990).

In the case of postwar Amsterdam, which is quite typical of western European cities, urban planning experts and administrators alike assumed that families wanted to escape the historic center – who would want to raise children in the mixed-use, densely built, bustling center, when spacious new housing estates were built in the suburbs? The reality is that many people preferred to stay in the city, and even new families settled there in the baby boom generation.

A penetrating film of the era is Roeland Kerbosch’s *Namens de kinderen van de Pijp* (“On behalf of the children of the Pijp”), which aired on Dutch television on March 16, 1972 and created a strong wave towards a reassessment of how city space should be used and by whom. In the film we watch a group of children living in De Pijp, a district of 40,000 inhabitants at the time, in central Amsterdam. The everyday environment where the children live, as we see it in the background, is a dense, mixed-use typical 19th century urban fabric, with multi-storey apartment lining fairly narrow streets, with shops on the ground level. Streets are used for parking and vehicular circulation, while narrow sidewalks are where people are confined to.

Image 5. Scene from the film *Namens de kinderen van de Pijp* (“On behalf of the children of the Pijp”) (1972).

Source: <https://bicycledutch.wordpress.com/2013/12/12/amsterdam-children-fighting-cars-in-1972/>

The child protagonist, however, is seen walking in the middle of the street, claiming his right to use street space (see Image 5): he complains about the fact that his neighborhood has no open spaces, trees or greenery, like the suburbs, but it has “a great school” and he has many good friends. In an essay assignment for school, the children discuss the conditions of their neighborhood and put down the problem quite plainly: “All these cars are unbearable; there is no space left”; they emphasize that cars cause accidents and air pollution. So we watch the children forming an advocacy group, asking passersby to sign their petition to the city officials to close two streets from traffic and create “play streets” instead. The adults’ reactions are telling of the conflict: while many people stand by the children, there are some who are resistant to change: “You cannot ever close a street; streets are for traffic”, they proclaim. Others diminish the agency of minors: “Ten, twenty children can’t do anything!”. Indeed, when children meet with city officials (see Image 6), they get many promises but nothing happens: “You keep asking but if the city doesn’t act, you have to do things yourself”, the hero of the film says on camera. And this is what they do: they put up barricades to close the streets to traffic, they bring their toys and play in the middle of the road, they ride their bicycles and roller skates, they sing and chant “Get these cars out of the way, we want to play!”

Image 6. The children of the Pijp meet the Aldermen. Source: <https://lcc.org.uk/pages/holland-in-the-1970s>

We also watch a community meeting, during which adults stand by children's demands, stressing out that "this is much more important [than playgrounds], more important than political talk". The children and the parents are not curbed by violent reactions (one driver knocks down the barricade and they put it up again and again). "That's how you campaign! Show what's wrong and how it can be better. And then the city will follow", the child says.

The impact of the film on raising awareness of children's rights to safe and healthy streets cannot be overstated. In a newspaper comment the next day of its airing, a critic wrote: "This film moved me deeply. The situation for the children living in this slowly decaying neighbourhood was portrayed in a beautiful way through their own eyes. Amsterdam alderman Han Lammers had a tough time with them although they just want to play like their parents could. It won't be easy to close down streets to traffic as was revealed by the scene with the enraged driver who turned violent at the adults who helped the children with closing the street." (from the *Leeuwarder Courant* 17th March 1972 as quoted in *Bicycle Dutch*). As a matter of fact, however, many streets were actually turned into *woonerven* that same year (1972), including Hemonystraat, the very street where the children had protested in – and it still remains so today, as shown in Image 7.

Image 7. Hemonystraat, one of the streets that the children of the Pijp fought for, as it is today. Source: <https://bicycledutch.wordpress.com/2013/12/12/amsterdam-children-fighting-cars-in-1972/>

Conclusions

The story of the "Stop the child murder" movement in the 1970's Netherlands is at the same time paradigmatic and exceptional. The uniqueness of it lies in the cultural specificities of the Dutch society, its long tradition of civil society, and the high value it attributes to the concept of play. This is shown diachronically, from the famous painting "Children's Games" by Peter Bruegel the Elder (1560) – which shows a Dutch townscape where adults and children alike play all kinds of games – to the co-creation of the constellation of playgrounds (more than eight hundred) in Amsterdam after World War II, designed by Aldo Van Eyck, instigated by hundreds of letters of citizens to the municipality (Lefaivre and De Roode, 2002). In the Dutch mentality, play is considered the quintessential entitlement of children, while at the same time children are respected as citizens and their participation in decision making is considered a given. These fundamental cultural aspects undoubtedly played a major role in the success of this grassroots movement, but probably are not easily reproduced, given the fact that not many societies share them.

Apart from this exceptionality, however, the “Stop the child murder” movement is typical in the sense that is yet one more case of children’s empowering role in urban transformation. Two other such cases of a dynamic involvement of children in city matters come from quite diverse cultures – Brasil and Albania. In the first case, the former mayor of Curitiba, Jaime Lerner, a pioneer in implementing people-friendly practices in his city, literally “used” children to make the case that streets do not belong to the cars: back in 1971, when Rua Quinze, a central street in Curitiba, was turned into a pedestrian mall, a group of motorists had organized a demonstration that was supposed to go through the street. Lerner enlisted hundreds of children who on the same morning of the scheduled demonstration swarmed the mall, armed with paper and crayons and “occupied” it, thus turning the motorists away: it was quite an “unbreachable defense” (Freeman and Tranter, 2011: 194). In the case of Tirana, Albania, the mayor Erion Veliaj, since he was elected in 2015, has been implementing many children-friendly measures, including creating a significant number of new playgrounds and parks, but has also been cooperating with children to show that the city has to change towards a more sustainable development: children’s bicycle marches are organized to claim the need to restrict car traffic and children are trained in recycling practices at school, and subsequently train their parents at home (Veliaj, 2017).

One should point out, however, that these two instances of children’s involvement are more top-down than bottom-up. In that respect, the Dutch case, especially the case of the children’s advocacy group in De Pijp, is truly revolutionary: it showcases the power of children as active agents, their unique way of seeing urban issues in a pragmatic and practical way, their determination and inventiveness. For bottom-up process around the world, it is therefore important to take into serious consideration the innovative character that children’s perspectives can dynamically bring about: children’s ideas and energetic participation can be instrumental for change, both in the collective mentality and in institutions. Interestingly enough, when involved actively in such practices, children prove to us that the conceptualization of the child as a stereotypical symbol of vulnerability and innocence is in fact turned on its head. And finally, it shows how much the city has to gain if children are educated and treated as active citizens, as in the case of the Netherlands. These are valuable lessons for all communities worldwide.

URBAN MICRO-RENOVATION BASED ON ACTION RESEARCH METHODOLOGY: A CASE STUDY OF YIFENGLI, HONGKOU DISTRICT, SHANGHAI

Qing LI¹, Ni LIN²

¹*Tongji University, liqing08@tongji.edu.cn*

²*Tongji University, linni@tongji.edu.cn*

Abstract: After near four decades of the rapid development, a number of cities in China have made great achievement. While plenty of the brand-new places are created, many "old cities" are left behind in a shabby condition. Lilong, a typical cultural heritage of residential townhouse with the combination of Chinese and Western architecture styles, belongs to such one. In order to change the situation, Shanghai government has launched the movement to ameliorate inhabitants' living condition in Lilong since 2012. However, the satisfaction of residents is not very high though a considerable expenditure had been spent, partly because of lack of knowledge and experience on how to reach a successful participation. To deal with the issue, the authors engaged in a case study, the micro-renovation project of Yifengli of Hongkou District, Shanghai, with the action research methodology. The project could be divided into three stages of initiation, implementation and perfection. Stakeholders are engaged in the whole process, including the different groups of local residents with different attitudes, local government and university consultant team which takes the leading role. Through the interesting and inclusive involvement at every stage, stakeholders gathered together in identifying the problems, discussing the choice, evaluating the planning and design, taking action and reflecting and continuing to modify actions. The project has gone relatively smoothly although the different stakeholders presented divergent interests. The outcome is desirable beyond the expectation of inhabitants. The study argues that the action research methodology is a meaningful tool not only for bringing out the positive change in the urban built area renovation, but also for spurring the social cohesion.

Keywords: Community micro-renovation; Participatory action research; Residents autonomy

Introduction

Europe and the United States had experienced a large-scale urban renewal of the old city after the Second World War, which had led to some serious problems such as social isolation, community decline and cultural disintegration. In order to change the situation, urban renewal model has been shifted into people-oriented model to help community residents achieve self-dependence. In this context, many community planners got engaged in community participation to help residents find a path to develop. (Zhang, 2014).

After near four decades of the rapid development, a number of cities in China have made great achievement. While plenty of the brand-new places are created, many "old cities" are left behind in a shabby condition. In order to change the situation, cities also launched a large-scale reconstruction in the inner-city, which had caused a series of social problems. Although some good and viable methods in urban renovation have been created in Western countries, it is not clear if they are applicable to the context in China. One of the reasons is that the government focused more on the growth of economy and its efficiency rather than the social sustainability in the past. China's "urban renewal" has its own unique political, economic, cultural and regional characteristics (Zhai and Ng, 2009). In addition, the long-standing "top-down" renewal model has not been balanced with the "down-top" approach.

How to make the inhabitants' voices heard? Where to make the inhabitants' voices heard? Is it useful to let the inhabitants dominate in the renovation? They are the questions for the government and also for the inhabitants and the academic. The urban space is often shaped by elites while most of the residents who live there could only passively accept them and adapt to the changing. As a result, even though expenses were high for the projects of urban renewal, the satisfaction of residents is not very high. In the mean time, the concept of "public participation" has been introduced into the urban renovation in China, but it seems so difficult to implement. As for many inhabitants, they were used to the government's unilateral decision-making. Also, for the market, this method costs a lot of time and force, which means some projects were stuck in the quarrel and discussion among stakeholders. And with respect to the government, this is an inefficient method to some extent in transforming the urban development model from sprawling planning to quality planning. Even so, governments pay more and more attentions in advocating governance, stimulating social self-regulation and active interaction to support social vitality. From May 2016 on, the "Walking in Shanghai 2016: Micro-renovation Program for Community" was officially launched in Shanghai and the exploration of innovative methods for urban micro-renovation has become a hot topic.

This paper takes an example of the Lilong community micro-renovation, Yifengli of Hongkou District, in Shanghai in 2018. The Lilong is typical cultural heritage of residential townhouse with the combination of Chinese and Western architecture styles. With participatory action research methodology, the authors were engaged in the project, working as members of the design team on the one hand and as observers on the other hand to explore the link between knowledge and action through critical reflection (Carr and Kemmis, 1986). The project could be divided into three stages of initiation, implementation and perfection. Stakeholders were engaged in the whole process, including the local residents, the local government and the university consultant team which takes the leading role. Through the interesting and inclusive involvement at every stage, stakeholders had gathered together in identifying the problems, discussing the choices, evaluating the planning and design, taking action and reflecting for constant modification.

From urban renewal to urban micro-renovation

The term "urban renovation" was presented in the first urban renewal seminar held in the Netherlands in August 1858. Since then, it has been discussed for more than a century. Scholars categorize it into the four stages since the second world war (Carmon, 1997; Ng, 1998; Ng & Tang, 2002a): Stage one, erased reconstruction from the Second World War to early 1960s; stage two,

neighborhood restoration from 1960s to late 1970s; stage three, economic recovery and public-private partnerships from 1980s to early 1990s; and stage four, Multi-partnership since the 1990s. Since the second stage, the idea of citizen participation in the urban renovation was gradually adopted. When it reached the third stage, the government began to encourage private developers to increase investment in urban reconstruction. However, just relying on market mechanisms could not achieve the desired effect of urban renovation because profit-seeking developers often considered less demands of local residents. Therefore, the new trend of urban renovation had gradually formed since 1990, encouraging the cooperation among “public, private, and community” (Zhai and Ng, 2009). The residents played a role from the passive to the active in public participation (Hughes & Carmichael, 1998).

Compared with the West countries, China starts urban renovation relatively late. China's urban 's renovation can be divided into four stages since 1978. In the first stage, the mode of large-scale demolition and reconstruction aimed at pursuing the largest return; In the second stage, the environmental aspect had been stressed but it still took the approach of the government-led and profit maximization; In the third stage, the “bottom-up” model had been emerging since 2000 while China had entered a period of the rapid urbanization and diversification of urban transformation. In the fourth phase, from 2010 to the present, urban renovation has been shifted to the “people centered” approach, improving the sustainability of urban development, upgrading the livability as a strategic direction, and creating a governance pattern of sharing and co-governing. (Liu and Xu, 2018). The "urban micro-renovation" is one of the key features in the fourth stage. A departure from past urban renewal, the word “micro” presents a rejection of the large-scale and massive production of the built space. Instead, it encourages the designer to engage with the community more deeply. As a “tiny” intervention, community micro-renovation can have a certain catalytic effect on urban development, and optimize urban space spontaneously and slowly (MA and YING, 2016). The urban micro-renovation advocates that residents should be the main driving force, and cultivates residents' sense of self-governing as the ultimate goal. As a result, residents should still have the capacity to maintain the community vibrancy even without the assistance of the government and the design team, in order to ensure the sustainable development of the community.

Community participatory praxis

Community participation is often asserted in theory as an important quality criterion for the intervention, but in practice it appears to be less well understood in China (Chiu, 2008). One of the reasons is that participating is a time-consuming and labor-intensive process. In many practical projects, both time and labor are costly for the “participatory transformation”, which makes it look like an illusory concept. Fortunately, the "community micro-renovation" proposal would change the situation. Planners and architects in China start to explore the new renovative model catering the transformation of the “run-down” community.

The community micro-renovation of the Lilong, “Yifengli”, is an attempt. From the beginning, both the government department and the design team have the aim of multi-party collaboration and deep participation. In order to put this aim into reality, we used participatory action research (PAR) as the research method. This methodology aims at making researchers as agents of transformation in the community. It has to be of immediate interest to the people in the studied community, involving them

in formulating the study problems and in finding solutions. It gives the local people opportunities for learning from the researchers. At the same time researchers learned a lot from the local people because people talk freely with people acquainted (Swantz, 2008).

The participants

- *Community residents.* There are 32 households, among which 13 are indigenous ones and 18 tenant ones. 73% indigenous residents are about 50 to 80 years old. They grew up in "Yifengli" from their birth and have deep feelings for this narrow alley. However, due to the aging of structures and facilities, some richer households who lived here in the past have moved out of the alley and rent the house to rural migrant workers. Some tenants have been living here for more than ten years.
- *The subdistrict office.* They are the dispatched officials with its jurisdiction in the area administrated by the street level government. In the "Yifengli" project, the role of the subdistrict officials is to provide supports as representatives of the government.
- *Neighborhood committee.* It is a grassroot mass "autonomous" organization in urban areas of mainland China, but it is still under the leadership of a higher-level government (The subdistrict government) and does not have the power to handle community affairs independently. In the "Yifengli" project, the neighborhood committee mainly takes the lead in project, organizing and coordinating, and applying for the renovation fund.
- *Design team,* it consists of professors and students from the College of Architecture and Urban Planning of Tongji University, as well as other universities. The members include an urban planning professor (China), a sociological professor (Canada) and an assistant professor of geography and architecture (Germany), and Chinese and foreign master students and undergraduates. In the "Yifengli" project, the main task of the design team is to stimulate the participation enthusiasm of residents, coordinate multi-party conflicts of interests, cultivate residents' sense of self-governance, organize workshops, and work with residents in transformation of the Lilong.

The process of participation

The project can be divided into three stages. Stakeholders are engaged in the whole process.

3.2.1 The stage of initiation

With the help of the local neighborhood committee had negotiated, the design team decided to use this project as a pilot for residents' participation, and then the model could be extended to the neighboring Lilong if it was successful. The subdistrict government could cooperate with other stakeholders, but play with no dominant role. In order to stimulate the enthusiasm of residents for the project, the design team organized three workshops. After each workshop, the team evaluated and reflected on the methods implemented and the gains in the process, and strived to improve them in the next workshop.

Workshop 1. Before the first workshop, the research team carried out the meeting including the representatives of the all stakeholders, and got the basic information of the requirement of deferent stakeholders. Based on the collections of the requirements, the team launched the workshop, and asked residents a series of questions, such as “Where do you feel the most needed to upgrade?”, “What kind of space do you want to live in?”, “Where are you inclined to retain?” and so on. Most of the residents’ answers are “No matter what transformation will be, they will accept it” or “No idea.” or “Reconstruction is useless. We are waiting for demolition (in order to get high compensation).” Residents' responses reflected that local residents did not have the awareness to protect their rights and were used to following government decisions.

In order to change the negative attitude of the residents, the design team initiated two small discussions. The first one was to let the residents choose the pictures they liked most for the vision of the renovation in their narrow lane. The team took out some of the pictures we had prepared, which depicted the future visions of the small neighborhood. The pictures were displayed in front of the residents, and our German professor, Ms. Iris, explained the intention to the residents in Chinese. Driven by curiosity and freshness, many residents came to watch. After the inspiration of the pictures, residents began to express their opinions, such as "I like the scene of this picture. It makes people feel happy.", "The scene of this picture is not suitable for our Lilong."(figure 1, 2) When their opinions were not the same or when a certain opinion conflicted with the others, they would debate and discuss till reached a consensus. After the discussion, we put pictures of the façade of Yifengli on the wall and encouraged residents to pin up their favorite pictures to the corresponding place of the façade on the wall. In this process, the designer simply recorded the opinions and ideas of the residents and did not interfere with their choices and preferences of the residents.

The second discussion was called ‘PARK’, which means P-preserve, A-add, R-remove, K-keep. The discussion was organized by the sociology professor of our team. The rule was for residents to write down their own opinions on the sticky notes and paste them to the corresponding positions of “P, A, R, K”. Unexpectedly, the activity did not go well because the residents did not will to pick up the pen and write their own ideas and paste them on the wall.

Figure 1, 2 Inspiration of the pictures in the first workshop Source: Made by the author

After the end of workshop 1, we evaluated both discussions. The first discussion was successful to inspire residents' interest and gained a high level of participation. Using pictures to convey intent is more easily. Through the discussions of residents, the demands and conflicts among stakeholder were more stressed, and in fact, residents themselves actively sought solutions. Its shortcoming was that it could not be systematically responded, and key issues might be overlooked in free discussions. Due to

the influence of the pictures, the imaginative space was limited and the residents' suggestions were limited to what they saw. The second discussion failed. The reason should be that this method is more suitable for experts, elites, or groups with higher education levels and professional knowledge. Most of the participants in this workshop are elderly people aged 50 or 60, and they were not sure to make decision by themselves.

To summarize this experience, in the next workshop, the design team should consider the followings. (1) Activities with mutual discussion will be easier to attract residents to participate; (2) The professional team should create some guides for residents to discuss; (3) the acceptant degree of knowledge by the residents will be considered in advance.

Workshop 2. In order to encourage more residents to participate in the inter-activity, the second workshop was held on the site of Yifengli three weeks later. The team brought the paperboard and plastic model of “Yifengli”, the drawings of the design based on the opinions collected in the first workshop and the projector equipment on site. The drawings were posted on the wall which depicted the blueprint of the lilong for the future. Attracted by these interesting stuffs, the residents brought small chairs from home to join in the “strange” workshop. When the residents saw their ideas appearing on the plan, they were so excited. And they had a strong sense that their community would change better because of them. At the moment, the residents had more new ideas. As the priority of the actions were discussed (figure 3, 4), the residents raised more new suggestions and problems related to their daily life, such as the drainage, the night lighting, and the public space occupation by the scooters. Residents ranked the priority in terms of the intensity of their willingness to solve the specific issues. This method could inspire the local residents who know the space most personally to tell the design team what they really needed.

Figure 3, 4 Checking the design and ranking the priority by the local residents

Source: Made by the author

For the evaluation of the second workshop, the authors believe that it is an effective improvement of workshop 1. The reasons are as follows: (1) Holding workshops in the Lilong has greatly promoted the enthusiasm of residents to participate and interact. It is an inclusive way, regardless of gender, age, affiliation and local or migrant tenant, that all can participate in it; (2) The method of sorting problems is effective, especially the key issues are obviously picked out. It helps designers having a clear direction and focus as they prepare the subsequent design decisions; (3) The sense of autonomy has increased. It can be proved by the enthusiasm and participation extent of the residents. Residents' sense of self-governance is not absent. Instead, it can be gradually cultivated; (4) But in this workshop, the authors also found a problem that the tenants did not participate. There are distinct attitudes between the local residents and the tenants. The indigenous residents believe that tenants will never

care the environment as they do. Tenants think that they are not part of the local (due to the difference of the household registrations). Therefore, they do not have the right of decision. So, they voluntarily withdraw from the participating groups.

Workshop 3. It held a month later. This workshop was divided into a meeting with the government and a joint meeting with residents in Lilong. It was interesting that the feedbacks for the transformation plan from the two groups were quite different. The government stressed to beautify the decoration of the space of Yifengli and not support the renovation of the water sinks located in the small lane. Because the sinks “misappropriated” the public space, it should not be encouraged. In the joint meeting with the residents, they preferred to renovate the water sinks because they needed to use it every day and the “kitchen” was too small to put the sink inside. Also, the beautification part is not the most important. To coordinate the issue, the design team took a mid-way after discussing with the two groups again, which means not to replace the water sinks with brand-new ones, but refurbish them based on the current situation (figure 5, 6). And many issues had been solved by the coordination.

It is luck for the design team that most of the various contradictions among stakeholders had been exposed before implementation. Although the interests of the two parties are different, their visions is unified. The participatory renovation method provides a platform for communicating between different parties and a suitable way to find solutions to problems.

Figure 5, 6 The image of the sink before and after Source: Made by the author

The stage of implementation

Another one month later, the construction phase was initiated with a symbolic ceremony, in which the honors were given to the active participants to thank their work, especially to the students from Tongji university. The job of the implementation consisted of two parts. One part was the repair work by construction workers, encompassing repairing underground drainage ditches, replacing the dilapidated canopies, renovating water sinks, reorganizing the crisscross electric wire and so on. The other was mainly the facade beautification, done by residents and designers.

In order to achieve the effect of the universal participation among residents, the design team usually held small events on weekends to attract residents to participate. The most important was the graffiti. No matter the children or the elderly, all aged people participated in making the graffiti on the wall. That was a really enjoyable moment. Some of the elderly ladies were scared to brush the wall because they were afraid to ruined the graffiti. After the design team encouraged and taught them repeatedly, they finally made it and were thrilled. One of the residents who was good at drawing took the leading

role in the color preparation, the outlines of the figures drawn on the wall and the filling inside of the outlines with colors for the graffiti. During the period, the residents served the students dinners if they stayed there later for the refurbishing work. Since the figures of the graffiti were chosen by the residents and reflected their past life and a common memory (figure 8), the residents liked them very much. These graffiti are portrayals of the scenes of residents playing in Yifengli in 1960~1990, embedded the stories of Yifengli for near half a century.

Figure 7, 8 The image of the graffiti during the painting and after source:7.made by Yifengli resident CHEN Debao; 8. made by the author

Through the public participation, the talents of the residents were stimulated on the one hand and the cost of renovation were reduced on the other hand. What is more, it makes the results more meaningful for the psychological aspect and the future maintenance aspect. Residents will be more careful of taking their new “living room”. Besides, the communication and trust among residents, the design team and government were promoted, and naturally community cohesion is stronger than before.

The stage of perfection

After the completion of the construction, the renovation project came to an end. In order to empower the residents to be more self-dependent, including maintaining the Lilong, making minor new improvements, after the design team and the government withdrew, the design team taught the skills to the residents in fixing the graffiti and repairing the newly renovated sink and so on. The “Longtang Convention” was also formulated with each household signing on it, and was written and pasted on the walls to encourage the residents to protect their neighborhood.

After four months of the frequent interaction, designers and residents have established good emotional relationship. The young students and the elderly residents become good friends.

Conclusion

Though the thesis just briefed the process of the renovation of Yifengli, the dilemmas and contradictions encountered in the renovation reflect that participation in practice is far more complicated than that discussed in the theoretical world. However, in the process of construction,

through continuous evaluation of the participative effect and self-reflection of the designers themselves, the experience gained is conducive to the next step. The project has gone relatively smoothly although the different stakeholders presented divergent interests. The outcome is desirable beyond the expectation of inhabitants. A higher level of work efficiency can be achieved through a deeper understanding of residents' neighborhood relationships, their knowledge background, and the living conditions and demands. Finding a capable person in the community is an important gene for maintaining the sustainable development of the community and promoting residents' autonomy. It is necessary for designers to reach out to the community and take some roots in the community, thereby building trust between designers and residents. During the cooperation, designers and residents could be able to learn from each other. The study argues that the participatory action research methodology is a meaningful tool, not only for bringing out the positive change in urban built area renovation, but also for spurring the social cohesion. Participatory action research also has political connotations. It makes invisible people visible so that there is a chance to solve their problems. It increases awareness and makes authority conscious of the people's right (Swantz, 2008). Due to the co-existing between success and conflict, happiness and dilemmas, more research is needed for exploring the potential and limitations of community micro-renovation practice.

The role of activist researchers in urban and regional planning.

Analysing and comparing international case studies of social change.

Abstract: Activist researchers in urban planning place an emphasis on facilitating social change through innovation and empowerment. The research explores the definitions of action research, how these different dimensions of activism in urban planning can be identified and redesigned as new situations and challenges arise. In defining action research, the paper also introduces the roles that activist researchers play in contributing to practice and theory through their research. Considering the research carried out by the authors, the paper compares the different approaches adopted by the researchers analysing international cases of social change. The authors argue that the research activist positions in urban and regional planning can affect the long-term change of a place by contributing in theory and practice, defining new models and procedures. Through these examples, the research affirms that the methods applied in action research, can be constructive or critical of existing urban planning processes and can contribute to the production of knowledge for both theory and practice. However, the main concern for activist researchers will always remain the long-term impact of their research and its benefit to society.

Keywords: action research; activist researchers; social change; urban and regional development.

1. Introduction

The paper is focused on the analysis of the use of action research in urban and regional planning, and the roles and positions of the researchers. The paper contributes case studies to contemporary literature by providing an analyse on the different positions taken on by the authors in their own research investigations. The concept of action research is connected to other theories and themes (Figure 1) regarding social change, community involvement, social benefits assessment etc. For example, the concept of bottom-up processes as inclusive methods necessary to create an open spatial planning; or collaborative economy as innovative life-style based on sharing and cooperation (Botsam & Rogers, 2010; Gruszka, 2016). A related topic, social impact assessment (SIA), is used to verify the consequences of the processes in the social dimension or the social innovation theory that aims to create new solutions in order to affect the socio-economic fields and create a social change fixed over time (Moulaert et al., 2005; Phills et al., 2008; Caulier-Grice et. al., 2012). The aim of this paper is to analyse the meaning and the definitions discussed about action research, and to compare methods adopted and the different positions and roles undertook by the activist researchers in urban and regional development¹. It will form an epistemological basis for using action research in infrastructure, institutions, housing, grassroots movements and re-cycling processes.

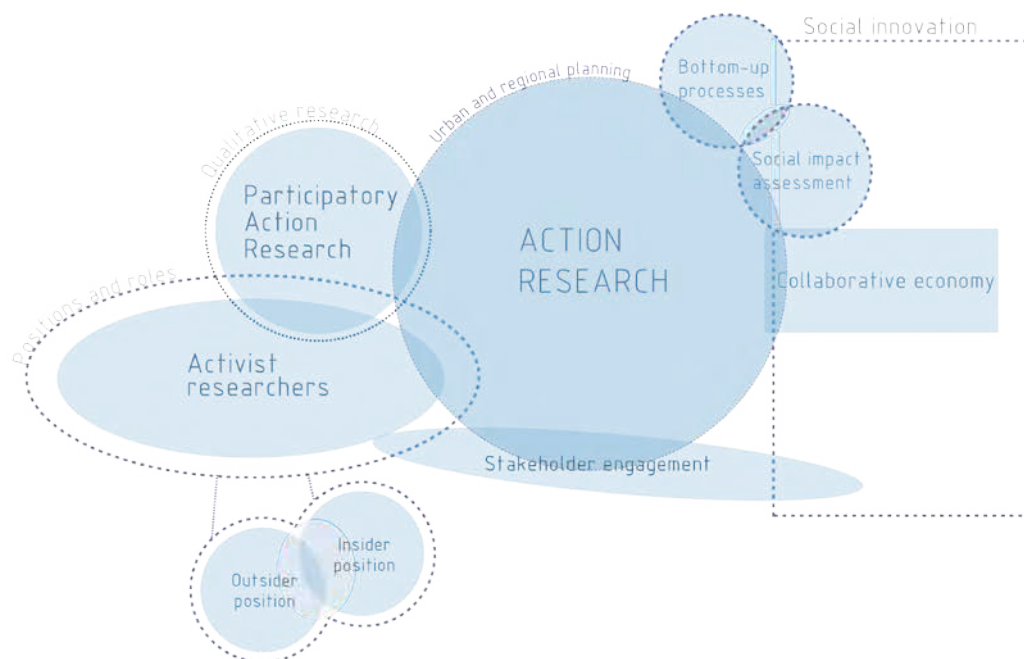

Figure 1. Themes scheme. Graphic elaboration by Federica Scaffidi.

¹ The paper analyses the authors positions and roles in their research.

2. Methodology

The paper is developed using a critical, qualitative, and structured approach. The main objective is to analyse in a critical way the researcher positioning in scientific investigations and understand the resulting consequences for theory and practice. Therefore, the methodology allows for analysing the theoretical and empirical scenario with reference to action research and researchers' positions.

In summary, the methodology was developed in the following steps (Figure 2):

1. **Literature review** – with the main intention to study and classify the different lines of thought about action research, the literature review is dedicated to the analysis of the state-of-the-art focusing on the analysis of action research, the roles and positions of researchers, and their relation to the spatial and social transformation. This part, therefore, is focused on the identification of specific models of action research.
2. **Empirical analysis** – description of the empirical activities developed in international case studies of social initiatives in urban and regional development. The researches mainly adopt a qualitative approach. This analysis shows the different roles of activist researchers and their implementation of specific models/procedures for the empirical scenario.
3. **Data analysis and comparison** – considering the different data and examples analysed, a comparison among the lines of thoughts and international cases is developed through tables and matrix.
4. **Identification of researchers' positions** – considering the identified activist researchers' positions described by the theoretical framework, an identification process was adopted to verify and select the activist researchers' positions used by the researchers in the empirical framework.
5. **Identification of researchers' roles** – description of the roles of activist researchers and how they affect and influence urban and regional development processes in theory and practice.

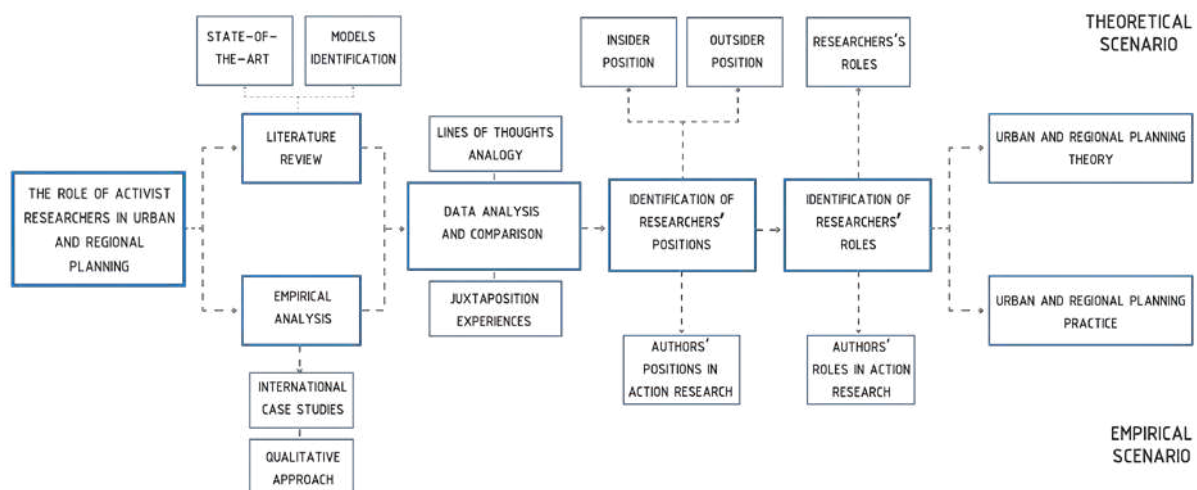

Figure 2. Methodological structure. Graphic elaboration by Federica Scaffidi.

The action research is analysed from two main points of view in order to understand its meaning and the role of activist researchers in urban and regional planning processes. The paper is developed in a structured way based on the two main following parts:

- the theoretical scenario;
- the empirical scenario.

The first scenario is focused on the analysis of contemporary literature and the definition of main researcher's positionality in action research. The method used to study the concept of activist research was oriented to discover the meaning and definitions presented in the state-of-the-art and classify the different theories and scientific positions developed. This part is necessary to understand the main theoretical lines of thought regarding action research and analyse more in depth the elaborated models. The theoretical analysis is also oriented to the examination of the different positions and roles that activist researchers can undertake during their scientific investigation. This step is focused on the evaluation of the typology of relations and connections that the researchers use to interface with the place. Therefore, according to Herr and Anderson (2005), the analysis is oriented around two main positions (insider and outsider) in relation to the entity of collaboration developed. The second scenario is focused on the analysis of the research activities developed by the authors in order to understand the real connection with the action research. This analysis, furthermore, is oriented to the assessment of the typology of action research and the analysis of the methodology adopted. Starting from the researches developed, the paper is concentrated into the evaluation of the characteristic of researches' positions and their role in action research.

2.1 Action research and participatory action research: meaning and definitions

Action research has a varied history within its academic applications tracing back to the 1940's researching the effects social democracy and organization change. However participatory forms of enquiry have existed throughout human history (Reason and Bradbury, 2003). Therefore, action research can be seen less as a methodology and more as an approach to research that utilizes multiple methodologies to achieve its participatory nature, being called 'promiscuous in its sources of theoretical inspiration' (Reason and Bradbury, 2003; Herr and Anderson, 2005). Education and health research fields have been the primary users of action research to understand how practices can be improved, and to a lesser extent how theory could be enhanced by action research's approach. Activist researchers are morally committed and are considered participants (Dick, 2015; McNiff, 2013; McNiff & Whitehead, 2011). Action research proponents note the need to be free from theory, be apolitical, and allow participants to guide research (Adelman, 1993; K. Lewin, 1946; Foote Whyte et al., 1991). However action research is inherently political (Jordan & Kapoor, 2016). Action research's political orientation stems from its understanding of power and hierarchies within society inherent in capitalism and urban planning (Jordan & Kapoor, 2016). Burawoy constructive critique highlights the need for a theory to allow interpretation of the world outside of your AR site (Burawoy, 2013). Action research methodology aims to be disciplined, systematic process that includes a reflexive process that occurs in cycles, see figure 3 (McNiff, 2013; McNiff & Whitehead, 2010, 2011; Foote Whyte et al., 1991). Action research process steps:

1. Observe, take stock of what is going on
2. Identify a concern, issue
3. Think of a possible way forward, develop actions around this way forward
4. Try it out, perform the action steps developed
5. Monitor the action by gathering data to show what is happening
6. Evaluate progress by establishing procedures for making judgements about what is happening
7. Reflect on those learnings personally, in relation to theory, and with the group
8. Test the validity of these reflections
9. Modify practice in the light of the evaluation
10. Repeat steps 1 - 9

Figure 3. Action Research Cycles (Bradbury & Reason, 2003; McNiff & Whitehead, 2010, 2011).

Participatory action research (PAR) varies slightly. PAR provides greater control between practitioners and researchers and makes no claims that thoughts about an action must be felt prior to that action (Foote Whyte, 1991). A critique is that participatory action research is too ‘common-sense’ which can cause dismissal by mainstream social sciences (Jordan & Kapoor, 2016), and relying too much on the case studies with too specific findings that ‘do not lead to defensible generalisation’ (Miller & Brewer, 2003). Critiques of participatory action research note that the co-option by neoliberalism (and governance institutions) masks true unbiased participation; or only provides a value-add to that institution rather than effecting real social change (Jordan & Kapoor, 2016; Foote Whyte et al., 1991). Issues can also arise in the reporting of research about power relationships between the researchers and participants (McNiff, 2013; McNiff & Whitehead, 2010, 2011; Foote Whyte et al., 1991). Power relations can be addressed through a few ways. In particular the idea of “I” and “we”. In much action research the objective of enquiry is the “I” (Bradbury & Reason, 2003; McNiff & Whitehead, 2010; Reason & Bradbury, 2001). This can be problematic in the relationship with the ‘we’ (the participants or partners), but the ‘we’ and ‘I’ can reduce this by being bonded in values or goals (McNiff & Whitehead, 2010). Being bonded in values and goals, whereby it is not a co-opting of a process, but an equal alignment between researcher and participant.

There are two ultimate goals as they relate to practice and theory of action research, urban cities, and systemic change. In practice, the goal of activist research is transformation of practice towards sustainable and resilient urban planning. For example, focus on the outcomes of social impact in housing, infrastructures, grassroots movement and brownfields re-cycling. In theory, it links the learnings of the activist research with relevant field theories, thus taking Burawoy’s criticism of need to maintain an understanding of the outside influences on your action research site. Action research’s ability to drive real change could break free of theory and critical analysis if it deals with the underpinning epistemological issues discussed. What is real? It is in the use of methods to drive action research or activist research where it has the potential to grow and combine theory and practice (Gustavsen, 2003). Under the action research paradigm, activist research engages with the immediate struggles of grassroots movements challenging institutions power and organization (Choudry & Kuyek, 2012; Jordan & Kapoor, 2016).

2.2 Activist researchers: roles and positions

Two main types of action researcher exists, the insider (or practitioner) action researcher and the external action researcher. The insider works within the company, as a member of that specific field (for example, a nurse working with patients or teacher working with students) or organisation they are performing the action research on (Herr & Anderson, 2005; McNiff, 2013; McNiff & Whitehead, 2010, 2011). The outsider collaborates with the organization studying its insiders or supporting them as equal partners. There is a continuum and implications of the insider to outsider researcher whether the insider is studying its own self or the outsider studying the insider without collaboration (Herr & Anderson, 2005; McNiff & Whitehead, 2011). Drawing on practices of participatory action research, the outsider collaboration with insider can contribute to knowledge base, organization transformation and radical change within communities (Day, 2016; Herr & Anderson, 2005). The research participation mode will not be co-opted where by the relationship of research and action to the local people is on them, compliance whereby the relation of the research and action to the local people is for them, or collective action whereby the local people set agenda and carry out research without the researcher, e.g. it is by them and I am only an observer (Herr & Anderson, 2005). Other modes of participation include consultation whereby it is a for/with relationship, cooperation where it is a with relationship, or co-learning where it is a with/by relationship (Herr & Anderson, 2005). In contrast to participatory action research, the activist researcher is interested in co-creation. Co-creation is key for driving transformations and real time learning about transitions in the moment. In non-academia, communicative planning theory and smart technology of both practitioners and institutions is changing the way they engage communities on a wider scale (Head, 2007). Though the effects of this type engagement are still seen in many cases as superficial and ticking of the box, the main issue may be the expectations of engagement (Legacy et al., 2017; McAndrews & Marcus, 2015; Silverman et al., 2008). The grassroots movement and the institutions may have different expectations regarding the outcomes of engagement. Combining citizen participation with action research principles can enhance community involvement with the planning process and develop new approaches to community driven planning by being reflexive throughout the process (Silverman et al., 2008). Barriers to citizenship participation even with the use of action research remained primarily because of expectations. This included not setting up the contract with the client (local government) to ensure that more action researcher principles were able to be achieved, for example the attendance of meetings by the community (Silverman et al., 2008). The researcher becomes an activist researcher engages with the groups studied in order to improve the area and achieve a social change.

3. Discussion

This section of the paper is focused on the analysis, description and comparison of the researches developed by the authors (Table 1). The different thematic fields analysed are related to the urban and regional development through social initiatives.

The main topics analysed are the following:

1. Railway infrastructures and urban development;
2. Urban sustainability and grassroots movements;
3. Socially innovative re-cycling and spatial development;

4. Housing regeneration in historic centres.

The authors' researches are oriented on the analysis of social benefits, the evaluation of stakeholder involvement processes and social impact assessment. The international cases here exposed are different in typology and geographic location. The international framework of the case studies is very huge. It is related to Australian and Dutch examples of public participation in infrastructure development, the bottom-up-community-led grassroots movement in London, the social reactivation of brownfields in Italy, Spain and Germany, and the housing strategies in Mexican historical centres regeneration. The wide empirical scenarios analysed have in common a qualitative research approach with exploratory and dialogic surveys and qualitative interviews (structured, semi-structured and unstructured). All these researchers had the ambition to be active, to involve different kind of stakeholders and local actors, and to promote a social and spatial development of the place. The purpose of the paper is the analysis of these many developed experiences as action research and the positions and roles of researchers.

Cases	1	2	3	4
Research topics	Public participation in high impact projects	Bottom-up-community-led movement	Social innovation in re-cycling processes	Housing regeneration
Research objects	Railway infrastructures	Grassroots	Neglected resources (brownfields)	Historic centers
Location	Australia The Netherlands	United Kingdom (London)	Italy Spain Germany	Mexico
Research approach	Qualitative research	Qualitative and quantitative research	Qualitative and quantitative research	Qualitative research
Methods	Exploratory surveys, semi-structured interviews and focus groups	Dialogic surveys, semi-structured interviews, strategy development workshops.	Demographic analysis, exploratory and dialogic surveys, structured, semi-structured and unstructured interviews	Exploratory surveys, semi-structured interviews
Stakeholders	Local institutions and community	Local institutions, volunteers, associations	Public administrations, social enterprises, local community, experts	Local institutions and community
Objectives	Social impact assessment and management processes for regional development	Bottom-up processes for sustainable urban development	Socially innovative re-cycling procedures for urban and regional development	Assess method to assist urban development of historic centers

Table 1. Action researches matrix. Graphic elaboration by Federica Scaffidi.

3.1. Railway infrastructure in Australia and the Netherlands

This research focuses on the implementation of social impact assessment and management processes in railway infrastructure projects. The research aims to contribute theory in the discipline of Social Impact Assessment (SIA) and strengthen its role in urban transport planning (Vanclay, 2003; Esteves & Vanclay, 2012; Vanclay et al. 2015). A key aim is to contribute towards improved positive social change outcomes from rail infrastructure projects.

The empirical part of the research focuses on some specific international case studies of infrastructure projects. In particular, the three case studies selected are:

1. Parramatta Rail Link in Sydney (Australia);
2. South-West Rail Link in Sydney (Australia);
3. North-South Metro Line in Amsterdam (the Netherlands).

The research adopts a multi-method qualitative approach to share lessons learned in practice from three case studies, as well as, Impact Assessment (IA) practitioners and academic experts internationally. The methods adopted included: grey and academic literature review, field investigations, semi-structured interviews and focus groups with varied stakeholders involved in decision-making processes for transport planning. The primary methods of semi-structured interviews and focus groups were used to obtain in-depth knowledge about the inclusion of social considerations in project implementation processes, including. This knowledge includes experiences by participants (project managers, construction personnel, IA practitioners, government staff, politicians, alderman) as key elements to understand fundamental lessons from each case.

The research highlights the need for greater accountability in urban governance and raises awareness of the value of SIA practice in decision-making result in significant positive consequences for the project's delivery (Mottee & Howitt, 2018). It contributes to existing SIA theory through an improved understanding of the assessment and management of social impacts in the making of urban transport projects in both Amsterdam and Sydney. This also demonstrates a practical contribution value of SIA by including social impacts in decision making in practice. Through implementing improved processes in SIA, including good practice public participation, the potential for long-term positive social change is facilitated.

The researcher is an outsider with access to inside understandings and processes to produce an assessment which will in turn inform future understandings and processes. Thus, the researcher here participates in two ways. First, as an observant and critic of the development of processes which in this case entail the implementation of practitioner knowledge into existing urban structures. Second, as a passive insider with sufficient knowledge to assess and potentially change future practice decision-making processes. The activist role of the researcher in this study is constructive as it aims to contribute both with theoretical and practical knowledge to existing practice but also critical as it proves current practice decision making processes fail to deliver consistent positive results.

3.2. Urban Sustainability Transitions and Grassroots movements

The research focuses on the bottom-up community-led grassroots movement's role in urban sustainable transition processes. The research objective is to understand barriers to grassroots movements promoting urban infrastructure changes to attain more resilient and sustainable cities.

In order to examine these connections, an action research framework has been used that fully embeds the author within cycling movements within London (three local grassroots' volunteer cycling groups and a regional charity, London Cycling Campaign). The partnership is over a 12 to 18 month period (beginning in August 2018 and April 2018 respectively). The community groups goals are the initial focal point of the transitions analysis and influence the qualitative and quantitative research methods used.

The researcher provided a template to groups which linked systems thinking and socio-technical analysis approaches (Turnheim 2015). It used a variety of methods for observation and engagement. These methods included local council meetings with the groups, discussions, qualitative interviews, strategy development workshops, etc, seeing interactions of groups, meetings with the local institutions, policy documents and other materials that are related to these processes. Working alongside the grassroots movements can provide resources and additional information with which to make decisions. This is most similar to initiative based learning such as co-design (Turnheim 2015). They are building knowledge capacity whilst the researcher is learning. It is a reflexive process whereby they can utilise the research information in the action research process and understand if those projections will positively create tipping points. It links quantitative and qualitative analysis through a socio-technical analysis examining the regime and landscape with qualitative data. Quantitative data is used to analyse the costs, time, and distance factors to examine rates of change.

The researcher functions as an insider that is also producing outsider-oriented knowledge. Following this methodology, which entails doing action research with a grassroots group (Reason & Bradbury, 2001), the researcher becomes an active member of the change. The changes are also analysed and assessed through the research, a process and product that happens outside grassroots developments. It may be considered that both roles at once are adopted through this bridging method, which are iterative and add to the outlook of the research results. It is because of this, that the researcher here acquires the position of activist in practice, with input placed as a constructive method that draws from critical thinking processes.

3.3. Socially innovative re-cycling of brownfields in Italy, Germany and Spain

The research focuses on the analysis of contemporary literature about social innovation and re-cycling processes with the main intention to understand the impact on urban and regional development. It critically analyses and interprets the re-cycle theory developed by the Italian Research "Re-cycle Italy" (PRIN) focusing on its social innovative aspects. Starting from the definition of re-cycling as the operation of reactivation of new life cycles that generate new economies and self-feed its own development (Marini and Bocchi 2014; Carta 2014). The research illustrates its relations to the social innovation concept. This is considered as a novel solution to a social problem that brings measurable improvements for the local community (Phills et al., 2008; Caulier-Grice et. al., 2012) and includes many stakeholders (associations, public and private institutions, and local community) in order to create new social values (Maiolini, 2015; Moulaert et. al., 2005). The connection of these two dimensions fosters the local development processes affecting socio-economic and spatial development. The research, therefore, aims to understand in which ways socially innovative re-cycling initiatives can interfere in the planning policies (Scaffidi, 2018). To answer to this question eleven

empirical references² have been selected from the European scenario (Italy, Germany and Spain) in which the research activity has been carried out.

These international experiences have been analysed and compared in a matrix. A quantitative and a qualitative approach has been adopted with demographic analysis, explorative and dialogic inspections, semi-structured, and structured and unstructured interviews to some social actors and privileged observers (Corbetta, 1999). All these examples are socially innovative experiences that have defined positive effects to the local site, promoting cultural initiatives, social involvement, urban regeneration processes and new economic, demographic and touristic flows. During the action research, the author developed quantitative analysis to understand the demographic trend and interviewed many local actors, inhabitants, social enterprises and local institutions in order to analyse the context in depth and to assess the effects of the social change.

The research focus is the investigation of social and spatial change in empirical references of brownfield re-cycling. In the ones analysed, the theoretical characteristics of the concept of activism were highlighted, combining the community involvement with the principles of action research (Silverman et al., 2008). All the examples analysed are activating socially inclusive processes that define positive effects to the local area. A relevant role in the social change is taken on by the social enterprise, that encourages the creation of cultural initiatives, creating the conditions for urban regeneration processes and new territorial flows. This is the case of the social enterprise of the former silk factory of Perosa Argentina, which has generated new cultural and tourist itineraries on the municipality, encouraging the enhancement of the industrial heritage of the area, the participation of the local community and the creation of new socio-cultural activities. This is the case of the association of the Arnao coalmine or Periferica in Mazara del Vallo, which periodically contribute to the redevelopment of some urban areas and the development of initiatives based on cooperation. Another example is the Fundación Valle Salado in Salinas de Añana in Spain, where thanks to the social enterprise and the recognized value of the resource, it has given rise to an economic and tourist development of the town. The reactivation process lead the local institutions to draw up the Plan de Embellecimiento and the Plan de Ordenación Urbana to guarantee a parallel development between the productive landscape and the urban landscape. In other cases, social enterprises took place within brownfield reactivation initiatives and urban planning processes promoted by local governments, thanks to which the resource revives over time (e.g. Matadero of Madrid, Cantieri Culturali della Zisa of Palermo, ExFadda of San Vito dei Normanni or ZecheZollverein).

The research focuses on the promotion of locally developed processes of knowledge and practice through evidence of social benefits effects that enable positive urban development. The aim of this

² The selected cases are the following: Spinnerei cotton mill of Leipzig (Germany); Cantieri Culturali della Zisa of Palermo (Italy); Perosa Argentina silk factory (Italy); ExFadda of San Vito dei Normanni (Italy); Manifatture Knos of Lecce (Italy); Matadero of Madrid (Spain); the coalmine of Arnao (Spain); Periferica of Mazara del Vallo (Italy); the asbestos mine of Balangero (Italia); the saltworks of Salinas de Añana (Spain); ZecheZollverein of Essen (Germany).

research is to affirm the influence of social innovative practices in urban and regional development processes. It argues that active interaction between local institutions, residents and social enterprises of an area can define and create new local development strategies for social and territorial development. The research contributes to contemporary discussion about reactivation of neglected and disused resources analysing the social benefits and the local development. The theoretical and empirical contributions of this research are the socially innovative re-cycling theoretical model and new empirical guidelines for local community, social enterprises and local administrations. In this research, the researcher functions as an outsider with wide access to observe, understand, assess and disseminate a wide array of spatial development process experiences through the analysis of socially re-cycling initiatives. Ultimately participating in two ways as well. In the first, as an insider with access to insider information to develop well-informed understanding of contextual-based experiences. In the second, as an outsider who observes and assesses socio-economic change within and throughout the urban processes to produce information that will bring light to practices which should or should not be replicated in similar initiatives. The activist role of the researcher is constructive as it seeks to build on existing academic knowledge and practice-based processes. It is also critical as it provides in-depth portrayal of elements which can hinder or enhance projects of this nature.

3.4. Housing in regeneration of historic centres in Mexico

This research focuses on developing an assessment of housing regulations and strategies in regeneration approaches for Mexican historic centres of Guadalajara and Mexico City. Acknowledging international influence (UNESCO, UN-Habitat) in the conception and implementation of national and local planning for conservation and housing.

The aim of this research is to assess current housing planning regulations and strategies within historic centres' conservation and urban development strategies. It is being done to develop an assessment and produce knowledge to assist change in the different aspects relating to social justice in the conservation and housing development in the regeneration of historic centres. It is based on an explorative qualitative methodology through semi-structured interviews with official bodies, academic sector and community representatives to assess local processes of urban development. One of the preliminary findings of this research relates to the processes of appropriation of the urban environment by local groups, effectively putting pressure on projects' strategies and development. This research contributes to existing literature on urban regeneration as well as to conservation and housing literature and policy. This research, ongoing until 2020, hopes to provide an assessment method to assist urban development processes in historic centres and other inner areas under regeneration schemes. Looking to position this research beyond its case studies to contribute to wider ongoing discussions on the role of housing in heritage conservation and urban regeneration processes.

The researcher here functions as an outsider with access to inside conceptual and practical construction processes to both observe and understand development and implementation processes. Additionally, the researcher here participates in two ways that relate to her inherent position as an outsider. In the first, the researcher will be an outsider with temporary and partial insider access, as she connects with actors who will direct to other actors through a snow-balling process. In the second, she is as an outsider who will understand and assess processes of which she is not an active part in creating or receiving. The activist's role of this researcher is constructive as it aims to provide relevant assessment of use in the future to local communities and policy makers. Yet, it is also inherently

critical as she objectively gains knowledge of and evaluates processes from which to identify gaps that help or hinder key aspects which are partially or not contemplated by these processes.

4. Results

This section is focused on the analysis of the research results and the identification of researches' roles and positions according to the theoretical framework analysed. It aims to assess which kind of position is adopted by the researchers in their own investigations' (between insider and outsider positions) and their roles for the theoretical and empirical improvement in the urban and regional development field. According to Dick (2015) and McNiff (2013) who affirm that action research is primarily value-laden and researchers are participants in the investigations, thus cases here are examples of action research. From the action researches analysis is possible to observe two main positions undertook by the researchers. It has been chosen to evaluate the degree of involvement into the research considering a range that consists in low, average and high level. The image below (Figure 4) shows the researchers' positions as insider and outsider in the three ranges selected. The "case 1_railway infrastructure in Australia and the Netherlands" mainly adopts a high outsider position with a low insider approach. The "case 2_urban sustainability transitions and grassroots movements in UK", on the contrary, adopts primarily a high insider approach, forming research from an active insider point of view. The "case 3_socially innovative re-cycling of brownfields in Italy, Germany and Spain" adopts a mixed position, with a mainly outsider approach based on the analysis of theory and empiric examples, and an insider position undertaken in qualitative analysis. The "case 4_Housing in regeneration of historic centres in Mexico" primarily adopts a high outsider position in collaboration with insider activists of Mexican context and a medium insider position during the field survey and qualitative researches.

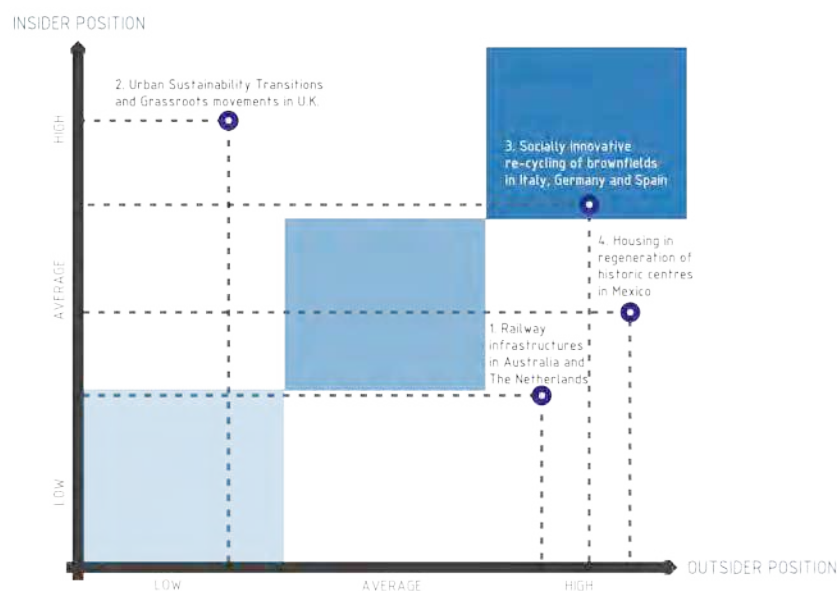

Figure 4. Activist researches positions. Graphic elaboration by Federica Scaffidi.

The graph above illustrates a research approach in the field of urban and regional planning more active and highly connected to the area of investigation - whether as insider or outsider - with the objective to interact with the place and study it in-depth. The findings show a changing role of the urban planner,

strictly related to the local site, its social transformations, economic and cultural effects of the urban interventions. This led to the need to define a novel theoretical and empirical approach aimed at assessing the action research implications on urban and regional development. This paper represents the starting phase of this approach. These contributions aim to produce specific models and procedures in urban and regional development, based on the themes, problems and thesis argued in the specific research fields. The following graph (Figure 5) illustrates the activist research outcomes. Case 1 aims to develop improved social impact assessment and management practices, which includes good practice of public participation. Therefore, its contribution is highly related to the elaboration of a model of social participation for the regional development by local infrastructures. Case 2 focuses on grassroots movements, a bottom-up approach for socio-technical transitions. Case 3 contributes in theory processing a specific socially innovative model and in practice by defining new guidelines for local administrations, social enterprises and local community. Case 4 contributes in theory and practice by elaborating an operative tool to reduce social inequality in housing policies.

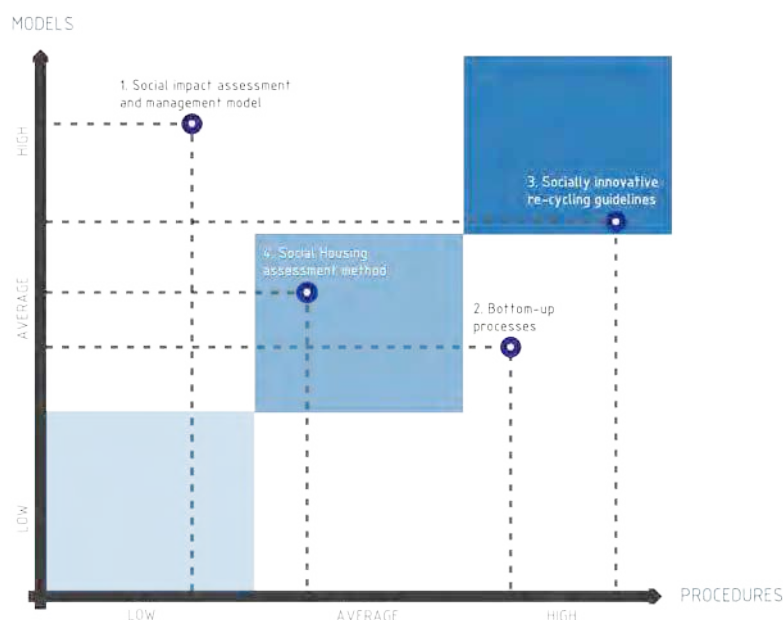

Figure 5. Activist researches outcomes. Graphic elaboration by Federica Scaffidi.

Considering the personal active research contributions, the paper focuses on the comparison of these approaches aiming to collect several experiences and define future proposals and new perspectives of active research in urban and regional planning.

4.1. Comparing action research approaches in urban planning theory and practice

This section is focused on the analysis of the action research approaches used within the framework of urban and regional planning in theory and practice. Figure 6 shows the four dimensions and the roles adopted by the authors in their own researches. This can be seen more easily in the graph which showcases the four dimensions and the positions of each researcher. In the 'x' axis the theoretical and practical roles are placed, while in the 'y' axis the contribution levels are added. Here the constructive or critical contribution to theory and practice are separated, positioning the different levels and scopes of each research's assessed contribution.

The image shows different approaches for what concern the practice dimension, it is possible to observe that case 4 is located in a low position and in the quarter of “constructive approach”. This case is represented by the creation of a specific model of social housing assessment for distance centres regeneration. On the contrary, in the same position but in the quarter of critical approach it is possible to observe case 1, where the author’s role is more critical in practice than in theory promoting methodologies for equitable social participation in urban projects. With regard to cases 2 and 3, the graph illustrates a high-level position in practice with high constructive approaches represented by the objective to be constructive in the empirical context by creating models and procedures (Image 4) for urban development. Case 3, furthermore, adopts a medium-high critical approach in theoretical analysis by observing in a critical way the social innovation and re-cycling theories. On the contrary, case 4 adopts a low approach as critical theory analysing the concept of social housing and contributing with operative tools to reduce social inequality. Case 2 is the only case that adopts a constructive approach promoting new methodologies in socio-technical transition. The literature discussed may imply that there is only one type of activist researcher role and that this role can be compartmentalised. Such as, the researcher is only truly critical if a participatory action research approach is adopted and for the researcher to be constructive, then they can no longer function as an activist researcher. However, the authors argue that the collective experience shows there is no single understanding of an activist researcher. Contending that many roles can be adopted from within (as an insider) or external to practice and process, to effectively gather information and enable participation towards generating positive social change. However, in making a contribution to theory and practice, there lies a challenge in moving from research findings, from our examples, to recommendations for positive and practical changes for implementation. The investigations here exposed to understand existing environments, plans, programs and contexts, and in drawing lessons from cases, empowers researchers with knowledge and experience to make informed recommendations. However, how does this influence extend beyond authors’ researches? How can researches turn into real social change? The researchers adopted a critical approach to analysing theory and processes, then provide constructive and practical feedback in order to facilitate change. To answer these questions the researchers’ aimed to produce specific models and procedures (Figure 6) to make a positive impact into the urban and regional development processes. These are questions and challenges that the urban planning discipline must consider for the activist researcher’s recommendations to have a positive long-lasting influence on society.

Figure 6. Activist researches approaches. Graphic elaboration by Megan Sharkey.

5. Conclusions

In conclusion, starting from the contemporary literature analysis, this paper illustrates the meaning and definitions of action research and activist researchers by doing an in-depth analysis on the current research. Description and comparison of the international cases of social change focused on the analysis of the researchers' positions to show different opportunities for engagement with other people (insider and outsider). The examples analysed activist researcher roles contributing in theory and practice in urban and regional planning.

This paper aimed to present positive and practical changes in social, economic and cultural development in contemporary territories (Figure 7). This analysis is made by an activist point of view, with an insider or outsider position, through qualitative methods from interviews, collaborations with local actors to workshops. We argue against the criticism that action research lacks the methodological rigour and technical validity that is the gold standard of much academic research (Greenwood and Levin, 1998). The authors argue that the researcher activist positions are necessary, relevant and required. For this reason, the researcher's role is to elaborate new models and procedures in order to facilitate that change and improve the urban and regional development creating social benefits and a positive social impact to the area.

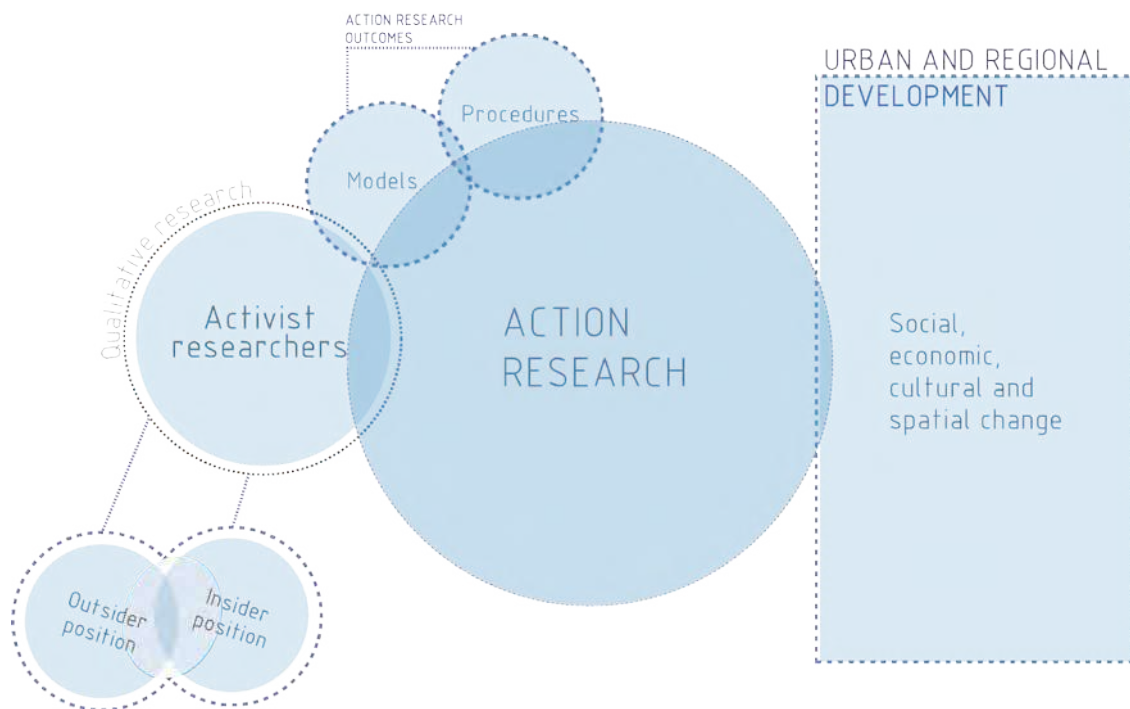

Figure 7. Action research role in urban and regional development. Graphic elaboration by Federica Scaffidi.

Acknowledgment

Within the unitary work, the first author, Federica Scaffidi, developed the following paragraphs: “1. Introduction”, “2. Methodology”, “3. Discussion”, “3.3 Socially innovative re-cycling of brownfields in Italy, Germany and Spain” and “4. Results”). The second author, Monica Lopez Franco, developed the following paragraphs: “3.4 Housing in regeneration of historic centre in Mexico”, “2.2 Activist researches: roles and positions” and “5. Conclusions”. The third author, Laura Mottee developed the following paragraphs: “3.1 railway infrastructures in Australia and the Netherlands” and “4.1. Action research approaches in urban planning theory and practice”. The final author, Megan Sharkey developed the following paragraphs “2.1 Action research and participatory action research: meaning and definition” and “3.2 Urban sustainability Transition and Grassroots movements”. All authors contributed to the editing of the paper.

Networking collective knowledge to foster change. The case of Sansheroes network (San Siro, Milan)

Elena Maranghi

Politecnico of Milan, elena.maranghi@polimi.it

Abstract: The aim of the following paper is to offer a reflection on the role that the co-production of knowledge assumed in the development of a local network of rooted social actors in the context of San Siro neighbourhood, one of the biggest Milanese public housing complexes. The paper will analyse the different phases of the development of the network, underlining the main strengths and the critical aspects related to the role that it assumed in promoting a new vision for the transformation of the neighbourhood. It will especially focus on the role that Mapping San Siro - Politecnico of Milan action-research group - played in the creation and progression of the network, particularly in relation to the involvement of the institutional actors and in the governance of the network. The contribution will set up some reflections regarding the role that governance, time, spatiality and planning play in this kind of processes.

Keywords: local knowledge, knowledge co-production, local network, community of practice

Setting the scene: Mapping San Siro finds its place in the neighbourhood

In November 2016 Mapping San Siro (Department of Architecture and Urban Studies - Politecnico of Milan) – the interdisciplinary action-research group which I take part in as a researcher – gathered around the same table a number of social actors (both formal and informal, yet organized, ones) active in San Siro neighbourhood (Milan), one of the largest and most problematic public housing districts in the city¹, to discuss about its future.

The convocation was the result of a long process of engagement, started by the research group in 2013, the year of the realization of Mapping San Siro workshop. Promoted by Francesca Cognetti and Beatrice De Carli, Mapping San Siro was first conceived as a residential workshop aiming at studying

¹ Located in the North-West part of the city, not far from the city center, San Siro is composed of about 6.000 housing units and with a population of about 10.000 inhabitants, the neighbourhood is characterized by the presence of fragile populations and by strong socio-spatial inequalities and intercultural/intergenerational conflicts (around 50% of the population are immigrants, with about 85 nationalities represented). Despite being also characterized by the presence of diverse and strongly committed local actors (associations, cooperatives, groups of inhabitants), San Siro has always been heavily stigmatized in public discourses with the effect of worsening its exclusion from urban dynamics. More information on the website: www.sansirostories.it, developed by Master in Journalism of Università Cattolica of Milan together with Mapping San Siro; www.mappingsansiro.polimi.it

and representing the complex dynamics that characterize the neighbourhood, challenging its stereotyped and negative image (usually promoted by the media discourse). One of the main objectives - but also one of the assumptions of the workshop - was the involvement of local actors in the co-construction of shared and *usable* knowledge that could effectively tackle local change. Considering the conditions of the workshop (which was organized as an intensive, yet short, work in the field), local actors were assumed as the main sources of knowledge, able to ease the relationship with dwellers but also to introduce themselves local perspectives and understanding to the group.

At the end of the period of intensive work, a mixed group of students, teachers and researchers decided to *stay* in the neighbourhood; first of all, precisely because challenged by the responsibility of multiple issues and demands that emerged from the local dimension. After a year being hosted by several associations, in 2014, Mapping San Siro obtained from Aler – the Regional Agency for Public Housing of the Lombardy Region, which owns and manages the public housing stock – the possibility to re-open a vacant shop, located on the street level in via Abbiati, which became the headquarter of the group and was named Trentametriquadri – 30 square meters – in virtue of its size².

In the absence of a definite commissioning for the research (at the very beginning the majority of the group was composed by people who were volunteers and there wasn't any stable fund available), Mapping San Siro identified the local actors as the main clients of the research, with whom to try to develop a co-designed research path, on the basis of continuous exchanges and interactions, and to whom to return the outcomes of the fieldwork. When the group established itself in the neighbourhood, there was no real network of local entities. On the contrary, the situation was highly polarized because of the existence of two local committees of residents: one composed by the elderly, mainly Italian, dwellers, disoriented by the changes occurred in their environment, and the other one referring to a right-to-housing activist movement, *legitimizing* squatting practices in the neighbourhood for people in need. For its very nature, the research group decided not to take anyone's side, but to place itself in a *third* position, building a solid relationship with the different actors. A central element was the intention of the group of becoming a local actor, interested in building a rooted knowledge, capable to produce some kind of change. We as a group had the understanding that – facing the distrust in changes or either in participation policies (the neighbourhood was part of a Neighborhood Contract which wasn't considered successful) shown by dwellers and local groups – there was a pressing need, on one hand, to show that transformation was possible, on the other hand, to get the institutions closer to the neighbourhood, since there was a widespread sense of abandonment (Grassi, 2018) which nourished distrust and social tension that tended to pour out in everyday relationships. In this sense, we were aware that we could play a role as planners and as researchers, not in projecting and proposing new *solutions* for urban regeneration – even in a participatory way – but first of all in activating ourselves locally, building open and accessible

² It was the beginning of a new phase: inhabiting a space and *becoming* a locally rooted actor, on one hand developing embedded research and teaching activities on three main topics – home and dwelling conditions; courtyards and public spaces, non-residential vacant spaces – and, on the other hand, trying to tackle the urgent issue of promoting participated local change, in a neighbourhood characterized by abandonment, exclusion, dis-trust and inertia. See Cognetti and Padovani, 2017.

knowledge frameworks, promoting planning platforms capable to involve both local and institutional levels. Our perspective was engaged and rooted (I refer here to the concept of *situating*, elaborated to describe Mapping San Siro methodology, see Castelnuevo and Cognetti, 2019), but at the same time as part ourselves of an institution (University) we were playing a key role. On one hand, because we were somehow *neutral* in relation to local conflicts and – being there – capable of building meaningful local relationships: dwellers and associations were positively struck by the fact that *the University was going to the city and staying*; on the other hand, because we were in the condition of interacting with other institutions: we were conscious in this sense that we would have needed time but we could have been able to become a local reference for them to interact with, in an easier way.

Sansheroes: the origin and the development of a local network based on the collective knowledge

Made possible by the relational capital built and nurtured in the previous years, the convocation which took place in November 2016 was the result of a shared frustration in seeing how the neighbourhood was once more excluded by public policies addressing urban peripheries in the city (Piano Periferie, promoted by the Municipality). As Mapping San Siro, we interpreted this shared feeling among local actors as a favourable condition to try to overcome, not denying their existence, local conflicts and giving a significant impulse to the possible co-design of a shared vision of the neighbourhood and of its possible transformations (physically, socially, culturally speaking). We considered the field ready for experimentation of collective design of possible regeneration strategies, able to enhance local competencies and resources and to recall for a significant investment from the institutional level. The efforts made by projects promoted by the third sector organizations and NGOs were not enough, indeed, to tackle structural problems of the neighbourhood, especially the ones regarding the quality and uses of different spaces (vacant spaces, public spaces, dwellings, etc.). Moreover, there was also a matter of involving different – and sometimes conflictive among themselves – public institutions: Municipality of Milan (with different departments), local administration (Municipio), Aler, Lombardy Region).

The first step of this possible path had to be, to our opinion, the one of building a collective understanding of the context which, from different fields of actions and perspectives, we were all working in. Together with the participants – at first representatives of around ten entities active in the neighbourhood³ – to the roundtable, held in Trentametriquadri, we decided to structure a sequence of meeting to discuss different topics: social and demographic situation, housing and spatial issues, existing bottom-up policies and practices, previous policies promoted and their macro-effects etc. The aim was to build a common framework in which everyone could be able to identify himself and the same time going deeper in the understanding of emerging or either structural phenomena, of which different entities were *experts* in virtue of their different roles in the neighbourhood. The entities involved were very heterogeneous: a local school (represented by the parents' association), social cooperatives, little associations, a church, micro-local social services (managed by social

³ In January 2017 this was the list of the twelve entities participating to the meetings: Mapping San Siro - Dastu Politecnico di Milano; Associazione Alfabeti Onlus; Associazione La Banda dei Pirati Onlus; Centro di Ascolto Parrocchia Beata Vergine Addolorata; Comitato Abitanti San Siro; Commissione Intercultura Istituto Cadorna; Cooperativa Sociale Tuttinsieme; Emergency Onlus – Programma Italia – Politruck; Servizio di Custodia Sociale del Comune di Milano (Cooperativa Sociale Genera Onlus together with Cooperativa Tuttinsieme, Azione Solidale e Comunità Progetto), Sindacato As.i.a. Milano - Associazione Inquilini e Abitanti; Progetto “Velo’ce mente”; Comitato di quartiere San Siro.

cooperatives), tenants' committees, etc., and it was exactly the added value of the process of delving into local knowledge.

After a few months, in January 2017, the group, which was meeting once a month, decided to informally structure itself into a local network, giving itself the name of Sansheroes.

Looking back to the development of the local network from then on, we have identified four different phases, characterized by the milestones achieved:

1. Collective understanding of the neighbourhood (November 2016 - December 2017)

Through five meetings and a following elaboration of the contents emerged, the local network elaborates a first *sketch* of the neighbourhood in the form of a document. The objective of this phase is to bring out a collective latent capital of knowledge, emerging from everyone's daily activities in the context. The document also includes a first set of statements on possible actions that could foster a positive change. The result of this step is the publication online, in December 2017, of *Fotografia del quartiere* (Picture of San Siro neighbourhood)⁴.

2. Sharing the path (January 2018 - June 2018)

The local network organizes a series of focus groups and dialogues aimed at sharing the document with some target-groups, representative of relevant populations in the neighbourhood (women with a foreign origin, elderly, youngers, etc.). Several observations, suggestions and critics enrich the *picture*. Aim of this phase is to verify whether the understanding of the neighbourhood could be validated by inhabitants or not. The decision is to structure this phase in a qualitative way to be able to gather deeper perspectives. The result of this step is an extended version of the previous document. During this period, the network expands itself⁵.

3. Planning together (June 2018 - December 2018)

The network works together to co-design a vision for the future of San Siro, outlining possible policy-areas to foster. It identifies five areas: Intercultural development, Education, Local skills, Housing and support for social vulnerabilities, Quality of the lived environment. The development of these fields declined in possible strategic actions integrates a new version of the document, which also takes a new name: *Istantanee di San Siro. Presente e futuro del quartiere* (Snapshots from San Siro. Present and future of the neighbourhood)⁶ and is published online in December 2018. The document is furnished by maps, elaborated by Mapping San Siro, showing the existing situation and the possible future one.

4. Involving the city (January 2019 - March 2019)

⁴ https://issuu.com/52340/docs/fotografia_del_quartiere_san_siro_2

⁵ Six more enties join Sansheroes network: Associazione Itama Onlus; Associazione Punto.it Onlus; Associazione La Fenice; Associazione Mamme a Scuola Onlus; Associazione Il Telaio delle Arti, Cooperativa Sociale Comunità Progetto.

⁶ https://issuu.com/52340/docs/istantanee_2019

The network decides to share the process and its results with the city and with the institutional level, in order to recall responsible entities to their role of taking care of emerging and pressing issues concerning the neighbourhood, but also letting them aware of the existing resources and the capabilities of local actors working in the field. Meanwhile, indeed, Sansheroes becomes also a network able to project together and to attract resources locally. Three relevant projects (financed by private institutions but also by public calls) are developed or started between the end of 2018 and the beginning of 2019 (one on education, one on intercultural development and the third one on social services are developed within the network, directly involving different actors and supported by Sansheroes as a whole). In order to share the result of its work, Sansheroes organizes a public presentation at Triennale di Milano (an important cultural institution in the city), inviting public institutions (Municipality, Region, Aler, local administration, etc.) but also private ones (Fondazione Cariplo, Casa della carità) to intervene. The presentation is a success in terms of inhabitants (of San Siro neighbourhood) and citizens involved, but, at least at first, it doesn't seem to raise the awaited awareness of public institutions. After the presentation, the local network decides to continue to work together in order to reinforce the strategic actions to foster local change and to find possible partnerships to promote additional projects. The network furtherly expands itself⁷.

Nevertheless, in the following months, due also to the involvement of the Municipality in a pilot project on public space⁸, taking place in San Siro and promoted by Mapping San Siro with the collaboration of other local actors, Mayor Giuseppe Sala publicly declares his will to open up a working table on the neighbourhood together with Lombardy Region (also as responsible for Aler) with the participation of Politecnico di Milano, as an actor able to guarantee a sort of scientific and technical but also local perspective.

The statement⁹ is positively received by Sansheroes, even though the local network will not be formally included in the announced working table. However, Mapping San Siro group involves the local network in the writing of a brief document, identifying priorities and possible roles for responsible institutions, which is sent both to the Region and the Municipality. The document also identifies possible spaces to develop pilot actions within the neighbourhood.

Collective knowledge as an elaboration of relational and active capital

As could be noticed, the process is still ongoing and, actually, undergoing a crucial point. Even though, as part of Mapping San Siro group, I would like to propose some reflections here, moving from this experience which on one hand could be useful to discuss this very experience with the local

⁷ Two more entities join: Fondazione Soleterre and Associazione Zucche Ribelli. Laboratorio di quartiere, the neighbourhood lab which is actually a public service provided by the Municipality, starts to join the meetings, even though it doesn't become part of the network.

⁸ GreenLivingLab San Siro and its related Collaborative Pact. <http://www.mappingsansiro.polimi.it/3-progetti/3-1-spazio-pubblico-e-rigenerazione-urbana>

⁹ While the author is writing this paper, the Municipality and the Lombardy Region have publicly stated their commitment on a shared project on San Siro, to develop in the following months. https://www.comune.milano.it/-/quartiere-san-siro-milano-incontro-tra-presidente-regione-e-sindaco-lavoriamo-per-migliorare-la-qualita-della-vita-dei-cittadini?fbclid=IwAR2USNJGpg1knXFBQWVzYl0P1IXIH8V_-GzcyrvhkevNLXnxLRZe3wEUZp8

network itself, and on the other hand could inspire a broader discussion on the role of actionable knowledge, collective learning (among so-called experts and non-experts) and the role of planning research and practice rooted in local communities.

To do so, I will briefly introduce some reflections regarding the learning process that involved both our group and the network itself and the role assumed by Mapping San Siro *in* the local network.

First of all, it could be stated that Sansheroes network could be somehow identified as a community of practice (Wenger, 1998; 2010). A community of practice is, first of all, a learning context, characterized by the belonging to a certain community identified by a given field of practice. In this case *the practice* could be recognized as the field of local welfare production, in which the different entities of the network are involved. Like other similar cases (Ranzini, 2018), Sansheroes network is a particularly rich one in this sense since it is composed by very heterogeneous entities which are active in diverse fields of the welfare sector, with different competencies, but also with diverse roles: volunteers, professionals, researchers, activists. The element that profoundly links them is a common aim: to collaborate for the local development of a marginalized neighbourhood. The fact that welfare policies and practices are more and more rooted in a territorial perspective (Vitale, 2007) made it possible for some professionals to tie to certain specific territories, while at the same time the withdraw of public policies opened up the field to local activation (which has overcome participation), both in volunteering activities and political activist practices (Pellizzoni, 2008).

The beginning of an empowering process in the case of Sansheroes network was generated by the misrepresentation of the neighbourhood (as already mentioned, more and more stigmatized in media and public discourse) and, at the same time, the inertia of responsible institutions in activating structural policies. These aspects directly struck local actors, which were not seeing an adequate acknowledgement of their work and their daily struggles in the field; on the contrary, their voice, claiming urgent and substantial interventions, seemed not to be heard. So, at a certain point, they were ready to react.

I will deal in a while with the role of Mapping San Siro group in facilitating a common and organized *reaction*, but before I would like to point out an aspect that made the difference in terms of empowering, cohesion and duration in time of the network. Social networks are investments of time and resources: to be successful and to last, they must be sustainable and useful (Conte and Laffi, 2019) for the ones who participate. The element that has kept the network together is precisely the process of co-construction of knowledge and the ability of the community of practice, as a learning context, to convert itself in a community of planning. The co-construction of an actionable knowledge and the process of mutual and collective learning has played a key role since on one hand, it was a factor of mutual acknowledgement of local actors – even the ones that have different or opposite positions regarding certain issues such as squatting – which recognized one to the other the fact that they all belonged to a local community of practitioners with complementary competencies; on the other hand actionable knowledge is the basis to promote projects with a higher quality, more aware of the complexity of local need and of the potentiality of integrating competencies and perspectives. So, more *competitive* and effective. As stated by Barbier when referring to action-research, changes start only when action and discourse are complementary and when the actors involved in a common path carry out a concrete action together (Barbier, 1998). In the case of Sansheroes, these actions were, on one hand, the projects that the network was able to start and promote and on the other hand the public

presentation of the work produced (at Triennale di Milano). These were fundamental steps that allowed the network to recognize itself collective identity and a set of expertise. In other words, to recognize itself as a *competent community* (Iscoe, 1974).

Showing a strong internal cohesion and the ability to plan and develop projects collectively was a key aspect also in relation to institutions and their involvement. As partially underlined above, it was precisely the development of pilot projects that contributed in creating a sort of trust of public institutions towards the local network and that brought them into the neighbourhood.

This aspect leads to talk about our role as Mapping San Siro in the whole process. Even if, from the very beginning, we assumed an inclusive, open, collective position, the propulsive role of Mapping San Siro has been fundamental – and still is – for the endurance and progress of the network and for its governance. And it poses an issue in terms of possibility to emancipate from a leadership.

More specifically, Mapping San Siro, in virtue of its research role, played a crucial role on the one hand in proposing the construction of knowledge as a *common ground* from which each actor was able to recognize as part of a collective subject, despite or rather in virtue of the existing differences. Secondly, it played a decisive role in the governance of the process through a lead role based on: giving a constant rhythm to the meetings, calling the shots of the different phases (also through the constant production of reports and updates through mailing lists), promote an active role for the participants, enhancing their skills and promoting a vision of knowledge oriented to give value to a mix between expert and non-expert (yet rooted) knowledge. It also carried out the production of materials (collective documents and maps), coordinating the different phases of the process, without forgetting to include the other actors in the decision-making phases.

It was a quite hard and awkward task that, nevertheless, resulted in the establishment of a social climate based on trust in the group, which, for instance, has allowed, even the most *extreme* actors to accept a dialogue with institutions that in the past had never recognized their value or existence.

Mapping San Siro also had the role of promoting a strategic and complex vision of the transformation of the neighbourhood, starting from the transfer of *spatial (analytical) skills* (beyond technical skills related to the ability to structure projects, which were mostly relevant in the case of little associations) and a planning vision to local actors. This proved to be another key aspect, not only because it showed the ability of local actors to converge beyond their individual interests and fields of action, but also because it was the crucial point for the engagement of institutions, through their more local branches. Mapping San Siro in fact, contextually to the work with the local network, developed a series of micro pilot projects in the framework of SoHoLab project. These projects (especially one related to the regeneration of public spaces and the other one to the reactivation of vacant shops) were the chance to start little collaborations with the main public institutions (on the one hand, the Municipality of Milan and the local municipality, on the other hand, Aler and Lombardy Region). These experiences were able to progressively *lead* institutions into the neighbourhood since Mapping San Siro acted as a sort of guarantor and mediator of a certain kind of relationship with the context. In the next months, we will see if and how this relationship will develop and where it will lead the neighbourhood and the local network itself.

Open issues: three main open questions to investigate

To conclude, I would like to outline three critical points that I intend as open issues I would like to further explore and discuss.

1. The development of a local network based on collective knowledge requires time. But how much?

As can be noticed, this experience has required a serious investment of resources made by several actors, first of all in terms of time. On the one hand, Mapping San Siro has spent years in developing its role of locally rooted actor, able to gather together heterogeneous entities. On the other hand, the development of the local network has required years to obtain a partial and not yet clear commitment from public institutions and to start to develop projects together. More generally speaking, an approach that has the aim of tackling structural transformations through a local and bottom-up empowerment process requires the possibility to invest time and social resources. As Mapping San Siro, we didn't link our stay in the neighbourhood to specific project duration, nor our role of governance of the local network and mediation with institution to a specific time. However, we question ourselves on the investment of time a process like this requires, first of all, because we were not able until now, to promote shared governance which goes beyond shared decision-making and includes a sharing of organizational tasks and duties. Secondly, because we more broadly question the possibility to transfer this process elsewhere, with certain restrictions in terms of time and investment. Moreover, this case is peculiar in terms of leadership because it involves a University, which is rarely conceived as a local actor. This characteristic has potentiality in terms of acknowledgement of the leadership role of an actor which is not seen as a *competitor* by other organizations or by institutions. Is this condition however sustainable in a long perspective?

2. We act as a third-party mediator. But is our mediation-role always a good choice?

At the beginning of our work with and in the local network, we were able to act as mediators in order to gather together different actors. More recently, in the process of engagement of public institutions, we were able to benefit of our position of researchers belonging to an institution as a sort of warranty for their involvement. But is mediation always a good choice? We question ourselves if in some cases a more conflictive and disruptive position could lead to more effective changes. In this sense, we would like to investigate how different roles in the network could be more effectively employed to interact more strategically with certain actors. We also wonder how we should position ourselves, as well as part of an institution, towards the broad area of social conflicts: to what extent does our institution allow us to assume a conflictive position?

3. We criticize participation and promote activation. But how could we guarantee inclusion?

At the very beginning of our work, we implicitly avoid to mention the concept of participation or participatory planning: there were too much frustration in the local community and, in many cases, not enough resources to effectively take part of certain processes. We decided to access the field by inhabiting a space in the neighbourhood (ours headquarter and the portion of the street just in front of it), interacting on an everyday level and to work with practitioners and more or less structured local actors: it was our first tool to gather knowledge of the context and doing research. Later, as a local network, we founded our discourse on the fact that we were not representing inhabitants, but we were speaking as people who inhabited the neighbourhood in a different way and who have stable and deep

relationships with certain groups or populations. Even if specifying these issue, we are aware of the risk of being identified (even on purpose) with the voice of the so-called *inhabitants*. And at the same time, we are conscious of the necessity (and the complexity) to guarantee their inclusion in future development projects (if they will take place). So, the issue of *real* participation is still open. I will conclude this reflection with a provocation: is the production of responsible knowledge on a specific context enough to ensure the recognition of certain populations?

Let's meet at the urban courtyard! The role of the community participation in micro-scale urban regeneration in Krakow.

Magdalena Miśkowiec¹

¹*Institute of Geography and Spatial Management, Jagiellonian University, Krakow, Poland,
magda.miskowiec@doctoral.uj.edu.pl*

Abstract: According to the recent urban regeneration policy shift, interventions are required at local-scale development. That approach aims at integrated micro-projects promoting spontaneous regeneration and social integration with the local community involvement. In particular, within Urban Regeneration policies public participation is introduced as a tool to reflect public concerns and to guide the urban space transformation. In recent years, studies regarding regeneration were spatially focused on city centers, main public spaces, historical sites, and post-industrial land uses. However, not much attention was paid to the renewal of semi-public spaces reserved particularly for local residents. At the same time, urban courtyard areas become one of the significant sites within the latest Regeneration Programmes. Therefore, the aim of this study was to determine the behaviors and social attitudes towards participatory planning in semi-public spaces regeneration. The research was conducted based on the “Centrum D” urban courtyard case study in the Nowa Huta, the city of Krakow. The study was carried out using in-depth interviews with three groups of stakeholders: 1) local community leaders, 2) municipal officials, and 3) participatory practitioners. The findings are expected to add insights into the discussion on the community participation within micro-scale regeneration inside cities urban setting.

Keywords: public participation, urban regeneration, semi-public spaces, urban courtyards

Introduction

Currently, more and more attention is paid to the community participation within urban regeneration policy (Lawless and Pearson 2012). The communication and participation processes are viewed as a key factors responsible for creating better urban spaces. The participation term is understood as a ‘voluntary process by which people, including the disadvantaged (in income, gender, caste, or education), influence or control the decisions that affect them’ (Saxena, 1998, p. 111). The community engagement in planning may facilitate understanding of the local needs and interests, support the interventions efficiency and provide the empowerment of those who are affected by urban policy (Innes and Boher, 2004, Taylor, 2007). Thus, it is

required to acknowledge the multidimensional complexity of problems affecting local areas to enhance community members quality of life. It corresponds with urban regeneration term defined as a ‘comprehensive and integrated vision and action that leads to the resolution of urban problems and which seeks to bring about a lasting improvement in the economic, physical, social and environmental condition of an area that has been, or is, subject to change’ (Roberts, Sykes, 2000, p.17). The new public management approach regards to public governance promoting more local micro-projects in terms of spontaneous regeneration and neighborhood integration (Elwood and Leitner, 1998, Dargan, 2009). It is due to previous experience with urban regeneration interventions concerns mainly public spaces, cultural heritage sites and postindustrial areas (Domański and Gwosdz 2010, Lorens 2010, Kazimierczak 2014). Although, these regeneration’ interventions contribute to positive benefits, there were focused on more spatial outcomes and broaden group of stakeholders. As a result, there is a gap in studies related to regeneration renewal targeted the improvement of local scale housing conditions. Particularly, it seems significant since the regeneration policies aim problems and concerns of the local community members as a neglected stakeholder. Therefore, the semi-public spaces promoting greenery activities are worth considering as the research areas. There are several studies proved the multi beneficial outcomes of the urban green spaces, such as foster air quality, urban temperatures and climate change (Nowak *et al.* 2013, Baró *et al.* 2014). In spite of greenery environmental benefits, there is a great potential in creating green spaces in order to promote spontaneous social life, socializing, rest and restitution (Baur and Tynon, 2010). Particularly, community green spaces facilitate bringing neighbors together in ways that increase social integration and interactions (Gehl, 2011). In this research, urban courtyards redevelopment is recently identified as a significant part of the latest Regeneration Programmes and City programme aiming the greenery and community engagement. Urban courtyards are defined as the spaces between residential buildings and require renewal interventions (Gidlöf-Gunnarsson, Öhrström, 2010). These areas are often used to pass by, park a car or collect garbage. In regard to urban planning assumptions, urban courtyard as a local urban green space should provide environment for outdoor recreation and social integration. However, the question is how to redevelop and create the local environment that collects neighbors together and enhances the development of a strong, resilient and healthy community that also improves safety, builds life-long relationships and is resilient in social changes?

It has been proven that place-related thoughts, beliefs and attitudes about our local environment impact the behaviors towards places. Studies have shown that spaces strengthen social bonds and promote the feeling of being attached to the place and community affect residents’ overall well-being (Theodori, 2001). There is a particularly, great potential in fostering place attachment and sense of community in regard to neighborhood regeneration process (Brown *et al.* 2003). Therefore, the understanding of people’s perceptions and attitudes toward their environment may enrich the planning process. Moreover, the community relationships to place influence whether and how they may participate in local planning efforts (Manzo and Perkins, 2006). However, the stakeholders are not a homogenized subject and have various concerns and interests within participatory planning process. According to studies, communities from disadvantaged areas struggled with poverty, unemployment, crime and social exclusion are less willing to engage (Atkinson, 2003). It is due to experienced low level of self-efficacy and isolation among residents and therefore it is more difficult to promote participatory planning. However, there are studies proven that the positive effects were achieved by regeneration projects where the engagement and partnership between local community and local officials occurred (Bassett *et al.* 2002, Coaffee and Healey, 2003). Providing participatory mechanisms in disadvantaged areas is viewed as a way to reinforce residents’ confidence and understanding of their contribution (Jones, 2003, Gullino, 2009). Not many studies provided empirical research in order to investigate multidimensional relationships between semi-public spaces and its local communities. In this context, the main aim of this study was to verify the social attitudes towards participatory planning within urban regeneration. Using the case study of the Centrum D urban courtyard, allow to investigate the relationships between different stakeholder’s attitudes towards the following aspects:

1. problematics of the case study area

2. the local community role within participatory process
3. challenges within participatory process

The context of Nowa Huta district

Nowa Huta was formed in 1949 as a satellite city. In its function, it referred to the reality of socialist realism and the period of industrialisation. The main idea was to create a city where the Lenin Steelworks would be opened. Initially, the city was supposed to have 100,000 inhabitants, but in the subsequent years the assumed value increased more than twice (Komorowski, 2005). It was a place offering a high standard of living and accessibility due to the fact that Lenin Steelworks provided a large amount of social and cultural services for employees and their families. Thus, its inhabitants had free access to medical care, schools, community centres, sports clubs, theatres and cinemas (Domański, 1997). The uniqueness of Nowa Huta results from its preserved historical, urban and architectural heritage. In terms of architectural values and spatial planning, Nowa Huta is one of the most interesting examples of socialist realist urban layout on a European scale. Housing estates blocks were equipped with access to internal semi-public spaces in the form of courtyards. The idea was to provide easy access to green areas for the local communities. Additionally, access to Nowa Huta Meadows surrounding the area makes Nowa Huta one of the districts of Kraków that is often referred to as the Green City (Halicka, 2014).

Since the transformation and collapse of the Steelworks, the district has experienced economic and social changes in its functioning. Currently, the district of Nowa Huta is inhabited by 52,332 inhabitants registered as permanent residents, which constitutes approximately 13% of the residents of the city of Kraków (Report on the status of the city from 2017). The problem of losing a permanent job led to an accumulation of problems of unemployment and poverty in the district. What is more, in the consciousness of the inhabitants of Kraków, Nowa Huta received a label of a dangerous district to which no one goes unless necessary. According to research in this regard, the media and the local press had a great influence on the creation of a negative image of the district (Guzik, 2000). However, the statistics contained in the periodical surveys clearly indicate that the number of crimes committed in Nowa Huta is lower in relation to those committed in the centre of Kraków's district I (Update of the Municipal Regeneration Programme for the city of Kraków, 2017). The regeneration process is seen as a means of changing the image of Nowa Huta. The area of the "old" part of Nowa Huta together with Nowa Huta Meadows with a total area of 399 ha has been designated as one of the regeneration areas in the current Municipal Regeneration Programme for the city of Kraków. The concentration of negative social phenomena, such as unemployment, poverty, population decline and the process of community ageing, was indicated as one of the reasons (Update of the Municipal Regeneration Programme for the city of Krakow, 2017).

In order to counteract negative social phenomena, works have been launched on the project called "Spotkajmy się na podwórku" [in English: "Let's meet in the courtyard"] aimed at revitalising the central spaces of housing estate blocks in the old part of Nowa Huta. The total area covered by the project is inhabited by 16,702 people. The project responds to one of the problems identified by the inhabitants during the public consultation, namely, bad condition of the courtyards. In the opinion of the inhabitants, courtyards are now a no-man's-land that is neglected and dirty. At the same time, they highlighted the fact of disappearance of relations between neighbours and the lack of spaces where people could interact with each other (Report from public consultations to AMPRK, 2016). Therefore, one of the key directions of the current regeneration programme are activities related to the development of the Nowa Huta courtyards and ensuring social interventions. During the public consultations, residents may identify problems occurring in the space and discuss solutions. Workshops, field walks and open meetings were used as part of the participatory mechanisms. The research took into account the results of a case study of a courtyard located in Centrum D housing estate (Figure.1).

Methods

The general methodology approach of this research is embedded in between the social sciences and human geography. Therefore, the qualitative approach was utilized to capture deeper insight into the behaviors in space and with reference to space from the perspective of the stakeholders' individual perception (Yang, 2014). Hence, in regard to socio-ethnographic point of view, we carried out selected in-depth interviews (IDI) to identify stakeholders' attitudes towards participatory planning within urban courtyards regeneration. The findings due to the practitioners and participants perceptions give a multidimensional understanding of the participatory processes. The interviews were performed with three different groups of stakeholders representing local, social and political environment; 1) local community leaders from the urban courtyard area, 2) municipal officials, 3) participatory practitioners. In winter 2019 we conducted 8 interviews in total. We carried out individual interviews with each stakeholder. Local leaders (communities' members, activists, NGOs, informal groups, local officials) were those who are active and recognizable in the life of local community. Selection of respondents from the municipal officials (Municipal Greenspace Authority in Krakow; Zarząd Zieleni Miejskiej w Krakowie) and participatory practitioners was carried out through judgment sampling. For interviewees' identification, the mailing lists and snow-balling technique was used, starting with municipal officials. The interviews concerned the following issues: 1. the urban courtyards' problematics, 2. the participants' role within public participation, and 3. the challenges and difficulties in public participation. The interviews data was then analyzed to identify common themes among responses and to verify the relationships between groups statements. The qualitative analysis' outcomes were combined with the survey of sources and field research. We carried out several visit observations during different day time, with lasting approximately 20 min each time.

Results

Description of the research area

For the purposes of this research, the case study of the urban courtyard located within the housing estate block in Centrum D in Nowa Huta district has been chosen. The courtyard located in Centrum D is situated on the western side of the Reagan Central Square in the central part of the Old Nowa Huta area. It was founded in the years 1950-1956. The surface of the courtyard is 0,03 km² and the real estate has a communal status (the City of Krakow is its owner). The field studies within Centrum D courtyard make it possible to explore the complexity of local problems and relationships related to this example of a semi-public space. The western part of the courtyard area within 5-6 blocks is called “ogródek jordanowski”. The founder of these gardens’ idea was a polish doctor Henryk Jordan who believed in physical, mental and social benefits for kids and youth (Smoleński 1961). Since the end of 19th century, these gardens have been providing space particularly for recreation and outdoor activities, being equipped with a playground, basketball court and open-air gym. Throughout the day, open-air playground constitutes a crucial space for kids and older youth to play and spent time with peers.

Problematics of the Centrum D courtyard

The insight formulated due to in-depth interviews and field research revealed crucial spatial and social problems that the Centrum D courtyard area struggles with in terms of the following aspects:

- 1) Greenery
- 2) Shared space

In the interviews, the respondents from Centrum D highlighted not only their current views on the urban courtyard but also how they would ideally see its development in the future. While the answers were diverse, most respondents perceived the area redevelopment as a catalyst for change. The case of greenery was one of

the significant themes regarding the obtained IDI results. Nevertheless, all stakeholders were altogether mentioning the concern regarding the greenery redevelopment. Each group has a different approach to management. As mentioned by the practitioner, there were two opposing points of view during the consultation process. Some residents claimed that cutting trees and mowing lawns is necessary. The reasons for that include allergic reactions and the sense of disorder in the area. The second group of participants wanted more greenery for outside activities and local recreation. On the other hand, the problem of greenery is linked with the existing parking system. The individual interviews emphasised the unresolved territorial dispute over the relations between green areas and parking spots. It was particularly related to the green field area in the eastern part of the Centrum D courtyard. That area is often used by dog owners and elderly people. It is a quiet and well-shaded part of the courtyard with trees and benches where one may rest during a walk.

We will certainly put this space in order because now the cars that stand there cause an extraordinary chaos. So we're working on hardening the surface for those cars. The locals wanted it too. Of course, we are not hardening it as much as they would like, which means we do not want to pave it over thus creating something more like 'let's meet in the parking lot'. [municipal official]

During the interviews, most of the local leaders mentioned the problem with safety and noise around the courtyard due to overwhelming role of cars and chaotic system of parking.

Cars should be removed from the urban courtyards in Nowa Huta. Thanks to that, those spaces would regain new life. If we start to replace green spaces with parking spots, the number of such spots will never be enough. [local leader]

In the area, there are too many cars in comparison with available parking spots. From the interviewed pedestrians' point of view, it causes the unsafe environment and concerns among parents who let their kids play outside. Apart from that, it contributes to making it difficult for the elder or disabled people to pass due to the fact that the pavements are often occupied by cars. Currently, there is an on-going battle for urban space between the two opposite groups of actors: pedestrians and cyclists versus car owners. The problem is much more complex because the areas of urban courtyards in Nowa Huta have never been redeveloped since their foundation. Their function has remained the same for the last 70 years, regardless of a rapid growth in the number of cars in the urban centres.

The aim of the redevelopment was also to create a shared space, in particular for the local community in order to enable interaction and strengthen neighbourhood ties. In addition to the visual and physical benefits, it is expected that there will occur social changes in terms of social capital, attachment to the place and civic involvement.

This project was called "Spotkajmy się na podwórku" ["Let's meet in the courtyard"]. That is why we tried to take these functionalities into account so that the inhabitants could meet each other. When I proposed it and asked: 'listen, the project is about meeting each other in the courtyard, but we didn't design any bench'. In response, I heard that those benches would only serve bums who would drink alcohol there and that there is no point in taking it into consideration. The same person who raised the subject did not know that there were also elderly people in that courtyard who had no place to sit. [participatory practitioner]

Collectively, those opinions refer to a concern related to the greater number of shared spaces within the area, which may lead to an increase in the number of acts of hooliganism. There were a few interviewees among the local leaders who mentioned the sense of unsafe environment and acts disturbing silence. According to the respondents, it is due to the local group of youth and men drinking alcohol while sitting on the benches in the evenings. As it was suggested, one side of the problem results from the presence of liquor stores that are located nearby and open for 24 hours. On the other hand, there is a lack of street lighting system within the area, which could provide a sense of surveillance.

The role of the local community in the participatory planning process

The second part of the interview scenario aimed at verifying the stakeholders' understanding of the local community role in the participatory planning process. The social consultations involved three meetings with the local community. The first participatory mechanism was the field walk aimed at analysing the issue of courtyards and becoming familiarised with functioning of such spaces as a whole.

It was cool that those residents, who had never participated in such a field walk, could walk around the courtyard with such a focus, through those parking spaces, and see that place and discuss it with specialists. We were also keeping in mind the conservation officer all the time. [local leader]

During the second meeting, the residents participated in workshops aimed at identifying and highlighting key problems, as well as discussing tangible solutions. The meeting was also attended by a person representing the municipal conservation officer's office whose task was to take a position on the proposed changes concerning development in accordance with the regulations on restoration. At the third meeting, preliminary concepts for the development of the courtyard were presented. The residents were acquainted with them and could express their comments.

From the perspective of a practitioner running the consultation process, the resident acted as an expert in moving around in space.

We raised the role of residents to the role of experts. We started with a white sheet of paper with nothing on it. And we said it openly: Ladies and Gentlemen, we are not present in this area, you are its users and experts. Experts who transmit knowledge about what works well in a given courtyard and what does not, and users because they use this courtyard every day. [participatory practitioner]

Local leaders themselves saw the role of the resident as a conscious user who, through participation, rediscovers the space of the courtyard and receives new information and knowledge about the existing relationships in that space.

For me, this role of the residents was crucial [...]. I have learned a lot. Apart from the fact that there are front yards, the conservation officer's concern is to preserve as many of these original elements as possible because we have a temptation to change everything. But we are in such a historical context that we must remember that such were the original assumptions. [local leader]

This awareness also applies to the rules governing the joint decision-making process. In the opinion of leaders, there are usually two dominant groups of participants in consultations. One is represented by active residents who are aware of the conditions resulting from participation in urban projects. The second group is composed of residents participating somewhat by accident who are not experienced in having public dialogue yet.

This meeting was attended by people who have already somehow dealt with social participation in various projects and know a little bit about what can be changed, what can be achieved and what cannot really be changed already at the concept stage, as there are things that are impossible to change. There were also people who probably thought that when one comes and asks what they want, it will be done, but it is also so impossible to achieve. In fact, if anyone has had contact with a social dialogue, they know that this is really a clash and search for a compromise. [local leader]

Challenges for the participatory planning process

Information and representativeness

The last part of the questions in the interviews concerned the most important thoughts on participatory planning. One of the observed difficulties is related to the organisational conditions, i.e. how the participation process was communicated and, as a result, what level of attendance was achieved. The place and time of the meetings were announced by means of posters hung on the doors of staircases, leaflets, websites and on the Kraków local radio station. The problem emerged at the stage of discussion whether the information about the meetings actually reached the residents.

In my opinion, ordering roll-ups for the community centres informing about the time and place of consultations did not work at all. I do not want to even analyse the content of this information and whether it encouraged to come or not. There was not a single article in Głos (local newspaper - Tygodnik Nowohucki) while this part of the residents reads the traditional press. [local leader]

Both consultation meetings were attended by about 10 individuals from among the residents of the housing estate. There was a voice on the part of the leaders that the achieved attendance results from individual motivation to participate rather than proper notification.

The fact that the attendance at the meetings is like this does not depend only on the Management Board. Information about the meetings was communicated in various forms. The easiest way to get it was via the Internet, but there were also information sheets hanged on the staircases. The fact that someone hasn't read it or does not care about it is a problem of society and not the good or bad will of the organiser. [local leader]

The experience gained in participating in the social dialogue results in the fact that active inhabitants are usually those who are representatives at the meetings.

I think that people were also a bit unprepared for such a form of invitation that someone asked them to express their opinions and participate in the meetings. Someone may have come there out of pure curiosity. Those neighbours were encouraged by me so that's why they appeared. The neighbour who drinks was caught just like that, Iwona came deliberately because it is 9, Zbychu also came deliberately because it is 5 and he was also very interested. These are the people who are rather active and their willingness to act was already noticed before in our activities. Ladies who take care of the front yards were also very interested in what will it look like from the point of view of care for greenery. However, they were rather listening than actively participating. [local leader]

Based on the comments given by the interviewees living in that area for more than 20 years, the Centrum D courtyard used to function differently in the past. Neighbours were spending more time outside. There were frequent bottom-up initiatives taking place around that area, such as barbecues, ice rink, art exhibition showing the works created by the local artist Marian Kruczek. One could hear groups of kids playing outside from the early morning till late evening each day. Neighbours knew each other very well and often shared food or equipment they had without any hesitation. It was also connected with the previous communist system that had impact on the lack of goods and resources on the market. Therefore, neighbours had to rely on each other. Nowadays, after 30 years of democracy, our market provides goods that are needed and thus introduces more self-reliance. Getting used to the previous political system partially means that older people in particular are not involved in participatory activities. On the one hand, the interviews show that they still have this habit that decisions were made on the top.

Besides, there is a group of 'quickly to the store, quickly to the church, quickly home' people. They do not talk to anyone. Sometimes they just stand there and complain about diseases. But when they are asked to come because we want to organise something, they say that they are too busy. There are also those shy people, who hide themselves behind their curtain and do not have enough courage to go out. In the old days, if a manager gave an order, everything was done. Nowadays, there is no one to give an order. [local leader]

On the other hand, there is a group of residents that has already taken too many hopeless actions in terms of involvement. The negative experience of unsolved issues in terms of a dialogue between residents and municipal officials results in people feeling discouragement and lack of self-efficacy. Therefore, this group of residents gives up on any actions requiring involvement right at the beginning.

Bottom-up initiatives vs top-down regulations

Regardless of organisational challenges, another key difficulty was observed within the decision making-process. It is related to the top-down manner of public management and the need for spontaneous and bottom-up initiatives at the same time. The area of the “old part” of Nowa Huta is inscribed on the List of Kraków monuments. As a result, it is subject to the main historic buildings conservation officer’s management. Therefore, the flexibility of urban design is very limited, as it must always be considered by the historic buildings’ conservation officer. In consequence, the residents’ motions during consultations, such as underground garbage collection, fences and garden for the community, were rejected.

At the meetings, there was a person representing the municipal historic buildings conservation officer. It went very well, but that person was attacked quite clearly. Unfortunately, this is an area that is entered in the register of monuments and we cannot accept here parking lots made of openwork panels even if we would like to because despite the fact that it is some kind of permeable surface, it does not fit the place and is not accepted by the conservation officer. So that person said immediately what cannot be introduced for sure and the confrontations were quite serious in this respect. [municipal official]

However, there is a noticeable need for more creativity and uniqueness with regard to the redevelopment of the courtyard area based on the local leader’s perspective.

For me, the reason for participation was a desire to discuss the possibility of having something unique inside this space and to emphasise our local identity. When I look at my people who participate in our various actions, I think they deserve some cool space. [local leader]

From the official’s point of view, the problem with more spontaneous initiatives is related also to the ownership status. The real estate is communal, therefore, the city of Kraków is responsible for spatial management, so any ideas coming from the locals require a top-down permission. According to the urban development policy, all initiatives need to be consistent with the Master Plan and the opinion of the historic buildings conservation officer.

However, there are still active residents among the Centrum D community who are willing to carry out collaborative initiatives. In order to create neighbourhood ties and interactions, they organised bottom-up picnic meetings together with Jędrus housing estate club (Klub Osiedlowy Jędrus). Another initiative aimed at removing the graffiti was organised by the residents in the form of a collaborative painting action together with a bottom-up organisation called Scrawl Busters (Pogromcy Bazgrołów). They collected painting equipment and together created a mural with aquarium theme. This mural shows a cat called Włodek (Kotek Włodek), a well-known character from a book for kids. The aim was to create a positive and local identity in order to bring Nowa Huta legacy closer to kids and other residents.

Ultimately, the concept plan provides a shared space in the central part of the green area between blocks number 1 and 9. It is meant to function as a part of the space for meetings and social interaction with neighbours. The plan envisages a decorative greenery area and a green belt protecting from the road traffic and reducing the noise level. Taking into account residents’ responses concerning the lack of safety, the concept plan envisages a street lighting system. During the social consultations, participants mentioned the idea of a unique and artistic concept for the Centrum D area to strengthen the local identity. The concept plan involves an artistic installation corresponding to the style of the local artist Marian Kruczek.

should participate in it as partners who understand the need for their own involvement and the need to delegate power (Taylor, 2012). Based on studies, Poles have little experience in active engagement in public participation initiatives. *'They do not know how to act because they do not take action and they do not take action because they do not know how to do it'* (Czapiński, 2015, p.348).

– in the opinion of practitioners, residents during the consultation acted as experts and conscious users of space. However, the difficulty consists in the fact that the creativity of the residents clashed with top-down regulations and authoritarian decisions of the representatives of the authorities, e.g. historic buildings conservation officer. It is a mechanism consistent with the theory of post-socialist cities, where the authorities make decisions without consulting the inhabitants or beyond negotiation. From the perspective of the residents, the officials themselves are seen as an inaccessible elite and not as discussion partners. As a result, such a relationship creates a distance between the two parties and its long-term existence makes it difficult to change the approach to cooperation (Kotus 2006). In such a situation, it is very difficult to maintain the involvement of the residents, i.e. active initiators of activities. On the other hand, covering the old part of Nowa Huta with protection of the conservation office allowed to maintain the unchanged shape of the urban assumptions that make this district unique.

– reaching the residents with information on public consultations and the representativeness aspect still remain a challenge. In the opinion of the local leaders, failure to publish information in places usually chosen by the local community, e.g. store or local newspaper, automatically makes it impossible to reach a significant part of the population. Elements related to the date, place and form of information have a significant impact on the number of people participating in the consultations. On the other hand, there is a noticeable lack of interest and a sense of lack of responsibility for the process of social participation.

– statements of the local leaders contained a motivation to implement bottom-up initiatives aimed at integration of neighbours. According to Gądecki's research (2012), in Nowa Huta we first encounter a basic bond between residents of the same block of flats, and then at the level of the community of the entire housing estate functioning within the space of the courtyard. There are four basic elements that influence the sense of community, such as affiliation, interaction, satisfaction of needs and sharing of emotional connection (McMillan, Chavis, 1986). According to the interpretation of other authors, building a sense of community requires attachment to the place, local identity and social interactions (Kim, Kaplan 2004). Designing green spaces together and then contributing to their creation is intended to act as a means to build or strengthen these factors. The result of a collaborative organisation of green spaces, e.g. planting plants, may also be an increase in the sense of ownership and responsibility for the space. In this manner, in the face of acts of vandalism and uninvited users, residents will react and notify the relevant bodies.

- in the case of the courtyard located in Centrum D, local leaders go one step further and feel the need to restore the uniqueness of this place by making a reference to the local history (e.g. artist Marian Kruczek, book character Kotek Włodek). Such motivation may result from the desire to emphasise the local identity in relation to the significant character of the Nowa Huta district itself. Artistic and social initiatives based on local history and identity can increase the number of courtyard users. The growing popularity of the place may lead to the phenomenon of touristification, and consequently gradual gentrification (Gotham, 2005). This creates a threat of the green gentrification phenomenon, which occurs when the new green space becomes so popular that it attracts new users and thus new investments and commercial services (Gould, Lewis 2012). Such a phenomenon may lead to an increase in property prices and, consequently, to the expulsion of current residents. At the same time, top-down regeneration activities may accelerate the process leading to the above situation, which may result in a risk of losing the status of "our space" dedicated primarily to the current residents of the Centrum D housing estate.

Lost or found in translation? Translating innovative forms of participation into formal decision making

Toril Ringholm, UiT The Arctic University of Norway

Tel: +47 77645591/+47 99155137

Abstract

The theme of this paper is the impact of new and expressive forms of participation on policy decisions. Over the last 5-10 years, we note that some of the new initiatives in planning participation are characterised by the use of expressive and art based forms, like exhibitions, theatre, music, gatherings and various forms of installations. Sometimes these are initiated by the citizens, in order to gain attention to a place or a planning issue. Other times, the local planning authorities orchestrate them, for much the same reasons. Social innovation and urban transformation are often the core motivations behind these, in many cases, rather informal forms of participation.

At the same time, the planning system – the legal and procedural arrangements for decision making – remains unchanged, meaning that the input that is gathered from the various arenas needs to be translated into a language that works in the more bureaucratic settings that otherwise characterise the planning process. We have little knowledge of this translation process in terms of what elements that are being channelled into the decision making and what is left out. In this paper, I ask the question of how this process of translation take place.

1 Introduction: translating innovative participation

Participation has been a core element in planning theory and practice for decades. Over the years, a multitude of forms of participation has developed, and a well-stocked menu of techniques is at hand. It varies from hearing procedures and traditional public meetings, to workshops, digitally based participation and the use of different creative techniques. New issues, along with the recognition of new groups of citizens as important in different planning contexts, calls for expanding the scope of perspectives and knowledge that are channelled into the planning process (Fung, 2015; Nyseth, Ringholm & Agger, 2019). With widening the perspectives and the notion of what knowledge that should be considered relevant, comes increased diversity in the forms of participation. We want to hear the voices of children, of the elderly, of those not familiar with formal meetings, of the passers-by, of the not-the-usual-suspects, and therefore innovative practices are employed in order to record those voices.

The Innovative practices come in many shapes and it seems like neither the formal processes nor the research has actually kept track with much of the new and sometimes “untidy” participation practices, in Norway as well as in other countries (Ringholm, Nyseth and Hanssen, 2018). They can have the form of gatherings and events, and also appear as creative and expressive uses of an area (Sim, 2016). Both planning and development authorities and citizens initiate such events. They are for example known from the type of processes that are often labelled “City-lab” (Evans et al., 2017; . Smas et al., 2016) In a recent survey to all municipalities concerning the evaluation of the Norwegian Planning and Building Act from 2008, the response to the following statement: “Local politicians

participate in open arrangements that includes creative inputs” was more than 55% who confirmed that this had been the case in the spatial plan, and 38% in the masterplan (Ringholm & Nyseth, 2018). The survey, alas, tell nothing of how the politicians, or other participants conceive of their experiences from these settings, or how they use them in the decision making. Such questions are interesting and important, firstly, because they can produce insight into what impact these forms of participation have on the decisions. Secondly, because they can shed light on the compatibility between the innovative participation and the formal framework of the decision making process. On the one hand, the innovative participation practices have the potential to be acknowledged as conveyors of really new and useful insights, that are activated in the decision making. On the other, they may be regarded as the “icing on the cake” of an otherwise traditional and not-so-innovative planning process. Or, to use Arnsteins terms, as “therapy” (Arnstein, 1969). Research indicate that the more open and informal participation initiatives may have more of an advisory function, and that it can be difficult to trace whether they have an impact (Nyseth, Ringholm and Agger, 2019)

It should be noted, though, that a situation close to the latter need not be the result of deliberate strategies from the authorities. The motivation for the less formal forms of participation could be a genuine wish from the planners, the politicians, or both, to bring in new voices and gather new knowledge and viewpoints. However, the tools that are at hand for the bureaucracy, may be less sufficient for conveying the voices and insights into the process of decision making, or that the connections between the specific forms of participation and the decision making is vague or lacking (Nyseth, 2011). To a great degree, this can be connected to the question of *how the knowledge, experiences and ideas that are generated at the innovative participation arenas is framed and translated in a way that is recognized by the decision makers in the planning process*. What capacity is available for doing this, and what considerations are being made in the process? Who are the “translators”? Does the translation vary with regard to the type of actors that are involved? Are there elements that are in fact impossible to translate? Innovative participation, like more traditional participation, has a democratic anchorage. In a broader view, the questions regarding the translation mechanisms and capacity are important also in order to position an assess democracy aspects of the innovative forms of participation.

These questions will be discussed in the paper, through the development of a theoretical approach, and by the analysis of a case study of a city-lab process in a small Norwegian city. Section 2 contains a short introduction to relevant aspects of the Norwegian Planning and building Act, and section 3 presents the analytical approach, which is anchored in an institutional logic perspective and a translation perspective. In section 4, the method is presented, and section 5 and 6 contains the analysis and tentative conclusions of the case of innovative methods of participation.

2 Requirements and performance of participation in Norwegian, municipal planning

Participation is mandatory in public planning in Norway, and is enshrined in the Planning and Building Act (PBA). The requirement is stated as follows (my translation):

§5.1

Anyone who puts forward a planning proposition shall facilitate participation. The municipality shall make sure that this requirement is fulfilled in planning processes carried out by other public or private actors.

The municipality has a particular responsibility to ensure active participation from groups that require special facilitation, including children and youth. Groups and interests that are not able to participate directly shall be offered good possibilities for participation in other ways.

The PBA, thus, gives the citizens rights as legitimate actors in planning. The local authorities have to a large degree been delegated the task of defining and deciding who should be included in the participation, and in what way. However, after a revision of the PBA, carried out in 2008, *groups in need of particular facilitation*, such as children, people with foreign or indigenous backgrounds and disabled people, are especially mentioned.

The mandatory requirements of the PBA are *information and consultation*. Information is stated by the requirements for *advertising the establishment of the planning process*. It is required that the municipal planning strategy is made public 30 days prior to political consideration. To make the plan available for public inspection in a way that gives everyone access and a possibility to provide feedback, the use of electronic media is an option. The time frame for hearings is six weeks, extended from 30 days in the 2008 revision.

The PBA also require consultation. A plan proposal should be sent to those regarded as affected by the plan, and from whom feedback is required. The PBA also contain new rules for presenting comments on plan proposals. For both municipal plans (§11–14) and detailed zoning plans (§12–12), the legal preparation is required to make explicit how the comments received in the hearings have been considered, and whether they have been assigned any impact on the output.

Those are the minimum requirements of participation, stated by the law, and in general they follow the rules (Ringholm & Nyseth, 2018). This gives the municipalities a great deal of freedom to decide what form of participation they should employ, as the law does not pose any limitations, only the minimum requirements. Also, the local authorities are encouraged by the ministry to employ an extended menu of participation. A survey carried out in 2017 show that the municipalities in general do more than they are required to. Around 72% answers that they arrange public meetings, more than 50% carry out workshops or similar methods of participation, and there are also the small percentage of 7 who make use of creative techniques and expressions (Ringholm and Nyseth, 2018).

The percentages mentioned above present an overview, but have their limitations when it comes to presenting a picture of how different forms of participation is combined, over time or with regard to the type of planning process. We do not have aggregated research data on the scope and form of this, thus the research based knowledge basically stems from case studies (ref...). However, an impression that arises from those, from search on the Internet and from conversations with planners in different professional settings, is that there is at least an ambition, and possibly also a trend, among the municipalities to widen the scope of participation, and of combining the more traditional and the expressive forms. One reason is that many of the planning actors?

3 A three-dimensional theoretical approach

The theoretical approach of the analysis is based on three strands of theory. Firstly, that of democratic innovation, which has become an increasingly hot topic in the trail of the more overarching debate on public innovation. A particular dimension of this discussion is related to aspects of participation, which has, of course been a topic in planning and democracy theory since long before the public innovation debate gained momentum. The analysis is, thus, inspired by old as well as more recent contributions to the participation discussion. Lastly, since the core question of the paper is about how experiences from innovative participation is translated into the decision

making, what is generally known as translation theory will be an important part of the theoretical background.

3.1 Democratic innovation

As one main ambition with the innovative forms of participation is to contribute to democratic renewal and policy making, there is a need to clarify what the innovative aspects are in terms of democracy. The debate on democratic innovation has to a large extent been connected with the logics and dynamics of participative and communicative democracy. Significant contributions have been made in order to evaluate participative innovations, based on criteria that go beyond the democratic institutions and identify democratic values (Agger & Löfgren 2008; Smith 2009; Michels, 2012; Geissel, 2013). The evaluations contribute with concepts of democratic goods such as inclusiveness, popular control, considered judgement, transparency, efficiency, transferability, meaningfulness, improvement of legitimacy, quality of deliberation, improvement of effectiveness and enlightenment of citizens.

The approach that this paper take in order to analysing the democratic potential of the innovative approaches, is to dig into the process of translating the inputs that in particular the less formalised participative actions provide, into the more formal decision making. On a general level, one can expect *democratic tensions* to emerge when new practices meet existing practices. This is well known from earlier and ongoing discussions on democratic goods, such as the question of representativeness and accountability in contexts of governance and collaboration (Behn 2001, Sørensen 2012). Experimentation and improvising will sometimes take place as a process with a very limited and handpicked selection of participants. These features may cause shortcomings in terms of democratic legitimacy. On the other side we have open gatherings, social media and events, where it is difficult for the initiating authorities to know who the participants are, and to assess and interpret the type of knowledge and opinions that are distributed among them, and the expressions that are displayed. Recent studies show that such tensions are certainly present in local politicians' considerations regarding innovative participation (Røiseland, 2019; Sønderskov, 2019). On the one hand, they are sympathetic to the idea of a closer and possibly less formal interaction between the citizens and the politicians, while on the other, they are reluctant to it because of the risk of jeopardising institutionalised values of representation.

'Creative experimentation' is one label that planning theory offer to some of the innovative participative practices. Experiments are speculative methods of knowing, working with doubts and uncertainty (Hillier, 2007:76). The label has been put on performative practices characterised by a situational openness and fluidity (Hillier, 2008). The task is to move from "what is" to "what if", and make planning practice a process of "becoming" rather than of fixing. Hillier emphasises the organising of "good encounters, or of constructing assemblages (social, political, artistic) in which powers of acting and the active affects that follow from them, are increased." (Hillier, 2008: 230). She argues for a planning that is a more inclusive, open and creative imagination of the past-present-future, and collaborative, critical discussion of potential consequences.

As with all forms of participation, the well known as well as the new and innovative, it is important to ask questions of what their impact is in the process, and possibly on the planning decisions. How can they be described with regard to important dimensions, and how are the innovative activities perceived by the decision makers of the planning authorities?

3.2 Dimensions of participation

Archon Fung (2006) introduces three dimensions that create the variation in participation: who participates, how communication and decision making take place and the degree of authority and power..

Fig. 1: The Democratic cube (Source: Fung, 2006)

The dimensions also have a relationship with the distinction between invited and invented spaces of citizenship (Miraftab, 2009). *Invited* spaces refer to the formal processes of participation initiated, organized and orchestrated by local governments, like formal hearings in a planning process. *Invented* spaces refer to collective actions that confront the authorities and challenge the status quo. As the ByLab-process is initiated and organised by the planning authorities, all the activities place themselves in the category of invited space. The process did, however, take place over a time-span of approximately a year and a half, and consisted of several occasions of participation (see presentation below). The participants entered the process in different ways. Some of the gatherings were workshops with individually invited citizens and correspond with Fung's categories of 'professional stakeholders' or 'lay stakeholders' (Fig.1). Other workshops were arranged by an open invitation, and the participants were 'randomly selected'. Other occasions again were of a nature that put them barely within the frame of the cube, in the 'open, self selected' and also possibly just on the outside – in the 'diffuse public sphere/everyone'. Invited spaces are often, but not always orchestrated events. Many of the new and innovative developments in participation seem to be characterised by a low degree of directing and formalising from the planning authorities' side (Nyseth, Ringholm & Agger, 2019). As planning is generally a policy process that is framed by rather formal arrangements, one can sometimes wonder what position the participation that happen in the outskirts of the formalities actually take in the planning process. What degree of power and authority is connected with it, and how does it place itself in terms of communication and decision mode? One way of finding out more about this, is to investigate how the input from the participation is brought into the further process of decision making. Since the innovative forms of participation we are dealing with here, are of a rather different nature than that of public bureaucracy, one way of shedding light on the issue is to ask questions of whether the experiences from participation in the outskirts of the cube are being translated into a form that corresponds with the general framing of the planning process.

3.3 A translation perspective

Innovations do by nature represent a challenge to established ways of thinking and acting. Sometimes, the innovation is meant as a full replacement of an existing service or practice, other times the intention is to “fill in the gap” between existing, institutionalised practices. In the latter case, however, the existing practices are not likely to proceed unchanged, as long as there are activities that connects the old and the new practices. On the other hand, the new ideas, when put into practice, could also undergo a certain degree of change in the meeting with the institutionalised practices (Thornton, Ocasio & Lounsbury, 2012; Holmen & Ringholm, 2019). There is, in other words, reason to expect a certain degree of reflexivity between the established system and the new ideas and practices.

3.3.1 Translation in theory

One way to understand the journey of a new idea or practice into an established, institutionalised system, is in terms of translation. The translation perspective has developed within public management theory, mainly in order to understand how new ideas travel and are transformed from one context to another (Czarniawska & Jorges, 1996; Røvik, 2016; Wæraas & Nielsen, 2016). The perspective is less, if at all, applied in planning studies. I believe, however, that it can be a fruitful approach to understanding how new participative developments are received by planning institutions. By applying a translation perspective, one recognises that even if practices origin from the same idea, and are applied in organisations that apparently have much in common, they can display a considerable degree of diversity when put into practice. Such differences can be explained by several factors that contribute to embed the new practice, such as differences in institutionalised values, different power relations, varying degrees of enthusiasm for the idea and differences in the competence that is put into realising the idea. Implementing innovative ideas into existing institutions and practices is, thus, a process that several researchers label “the translation process” (Czarniawska & Jorges, 1996; Røvik, 2016; Wæraas & Nielsen, 2016). In this perspective, the introduction of an idea, and the process of transforming the idea into practices is; *“... a complex process of negotiation during which meanings, claims and interests change and gain ground.”* (Wæraas & Nielsen, 2016:237). In other words, it is a process where factors such as competence, power and negotiating skills could be activated, factors that are likely to vary between organisations, localities and the actual problem context). Hence, we should not be surprised if innovative forms of participation that origin from a common body of ideas and ambitions, are received in different ways by different municipalities.

There are different perspectives on translation, and O’Maloney presents us with what he calls four ‘archetypes’: Diffusion, Actor-network theory (ANT), Scandinavian institutionalism and Organisational boundaries (O’Maloney, 2016). I will not elaborate on the relation between the perspectives here, other than argue that they may all have something to offer in terms of understanding how innovative participation as an idea and as practice is introduced in public planning.

The translation perspective underlines the unpredictability connected with the output – and outcome – of the process of introducing a new policy of participation. There are different forms of changes, and Thornton, Ocasio and Lounsbury (2012) suggest two main categories: Transformational change and developmental change. In transformational change one institutional logic replaces another, though possibly with some modifications (blending, segregation). Developmental change is a concept used in order to describe a situation where the existing institutional logic is not replaced, but where it to some degree could be influenced by the new idea. The question that researchers on

participative planning and planning authorities alike need to ask is to what degree the innovative, experimental forms of participation are able to shift institutionalised understandings of what participation should be.

3.3.2 Translation in practice

Like with other social phenomena, there are several ways of studying translation. In a review article, O'Mahoney shows how different perspectives, 'archetypes', tend to attract different methodological preferences. While the diffusion perspective most often seems to be operationalised by quantitative methods, the more intensive, qualitative methods characterise the other three perspectives.

The aim of this study is to gain insight into how actors that are important for bringing the insights from the innovative practices into the decision making, perceive of the participative arenas. Innovative participation has the potential to turn the course of action through powerful narratives. It may also just be an easily forgotten occasion – the icing on an otherwise entirely tidy planning process. How should one explore the mediators' way into the policy-making process and is it possible to identify their impact on policy-making?

The decision making system, the bureaucracy, is strongly characterised by text based presentations – preparatory works, reports, minutes and so on. However, the decision makers who took part in the new arenas, or those who have heard from others who have participated, the practical experiences and the impressions that are conveyed from other participants, will bring these with them into the considerations that are made. In other words, the translation will happen both 'by text' and 'by memories' or 'by stories'. As innovative practices do by nature challenge existing practices, one needs to ask if the existing practices for conveying impressions from participative arenas are sufficient for the new forms of participation. Or is it possible that the innovative forms demand other tools for translation than the traditional, formal forms?

3.4 Innovation in participative planning in a translation perspective

4 Data

The data is gathered by a mixed methods approach, consisting of a document analysis and interviews.

The documents that are included in the analysis are five reports from the whole strategy process: Report from youth workshop, report from the business workshop, report from the citizens workshop, report from ByLab, Report from the ByLab workshops, summing up of the ByLab

The interviews with 7 municipal actors were carried out in the spring of 2019 – one year and nine months after the strategy was decided upon by the local council. The actors had different roles in the strategy process, and also in the ByLab arenas. Four of the interviewees are politicians, one is a planner, one is head of department with responsibility for societal development and planning and one is the leader of the board for the local organisation for business and town development. The interview guide is enclosed (App. 1)

5 The Case: CityLab in a medium sized town

The CityLab in was carried out in a town of approximately 15.000 inhabitants. The process was spurred by a need for transport planning in the area of the city and its surroundings, which was linked to a city development process. The aim was a development strategy for the city area. Such

strategies are not mandatory by the Planning and building Act, but are often used in order to make the strategic choices visible and to. The problem situation can be summarised into three factors: firstly, the general idea of compact city, urging new ways of thinking, both with regard to the built environment and with regard to transport. Secondly, an ageing population, which made the municipality take measures to inspire young people to participate. Thirdly, the desire of the municipality to bring new life into the city centre, in particular in order to attract young people. A broad set of participatory efforts was therefore decided on.

5.1 The process summarised

The whole planning process was carried out in the period from autumn 2015 to winter 2017. The activities and meetings during the process were initiated in a collaboration between the municipality, the county authorities, the national road authorities, and a network organisation open to business actors, organisations, and individuals, that advocates for activity in the city.

The methods for citizen involvement included: 1) In-house preparatory work and a start-up conference focusing on everyday experiences from different parts of the city. 2) Three workshops were carried out in 2015/2016, namely the Youth Workshop with the youth council, the Business Workshop with business actors and the City Seminar which included a broader spectre of citizens. The workshops took place as group discussions. Each group then summed up their inputs in a document that they submitted to the planning committee. Later, a 'Future Workshop' and a public meeting was instigated, which both included a diverse set of citizens. The most innovative form in this context, was the CityLab, ByLab in Norwegian. This lasted one week and was the final part of the participatory process. A CityLab had not been carried out in this municipality before, and the purpose of it was to gather insight in less formal ways, for shaping future images and concept development. ByLab combined meetings that were held in new arenas, politicians' lunch in the pedestrian street, politicians' sofa, visits to different workplaces, collecting of written suggestions from the citizens in the form of short statements by the thumbs up or down, citizens' photos of important places. Children and young people were deliberately involved, along with citizens of all ages. As one can see, the arenas were set up not only in order to engage the citizens, but also with the purpose of facilitating direct contact between the politicians and the citizens. People from the administration were also present in all the arenas.

The participants of the varying invited spaces fall into different categories, and below I have listed them according to the categorisation of participants developed by Fung (2006).

Table 1: types of participation and arenas in the process

Participation arena	Participants	Type of invited space
Start-up conference		Indoor meeting/formal
Youth workshop	Professional stakeholders, invited	Indoor meeting/formal
Business workshop	Professional stakeholders, invited	Indoor meeting/formal
City Seminar	Open, self-selected	Indoor meeting/formal
Public meeting	Open, self-selected	Indoor meeting/formal
<i>ByLab: Politicians' lunch in the pedestrian area</i>	Open, self-selected/diffuse public sphere	Outdoor moving/informal

<i>ByLab: Meeting people in the shopping centre</i>	Open, self-selected	Indoor, informal
<i>ByLab: Politicians' sofa at the city hall</i>	Open, self-selected	Indoor, informal
<i>ByLab: Walking with young parents out rolling with the babies in prams</i>	Semi-open, self-selected	Outdoor, moving/informal
<i>ByLab: Visit to workplaces</i>	Semi-open, self-selected	Indoor meeting/semi-formal
<i>ByLab: Visits to schools</i>		
<i>ByLab: Thumbs up/thumbs down at various places in the town</i>	Open, self-selected	Outdoor, informal, expressive
<i>ByLab: Citizens' photos of important places at the town hall and the schools</i>	Open, self-selected	Outdoor/indoor, informal, expressive

Among all these invited spaces, it is in particular the informal and semi-formal forms that were organised as part of the ByLab process, that are of interest to this paper, since these are the innovative ones. In defining what innovation is, I will lean heavily on Schumpeters contextualised definition, later adopted by a multitude of scholars (Schumpeter,). The municipality had previous experiences with using workshops as a participative arena, but the informal ways described above were new in this context.

5.2 Translation by text: gathering inputs into documents

How is the input, the knowledge and viewpoints that are generated by innovative, informal participation framed when they are conveyed into the formal decision making process? One way of looking into this question, is to ask what capacity, in the form of knowledge/skill and time resources, that are available for doing this. Another question is in what form the input is presented.

A team was set up for processing the input from the different participation arenas. The team consisted of one person from the municipality, one from the regional authorities, one from the road authorities, one from the town network organisation and one from the consultant agency. The practical job with was mainly carried out by the hired consultants.

The inputs from all the arenas, the workshops and the ByLab arenas, were summed up in altogether five reports. All the documents were made accessible on a designated homepage for the project. This homepage also enabled responses. The responses, however, have not been saved after the policy document was presented.

One of the reports contained the summing up of the ByLab part of the process. The report also contain an overview of how many participated in the different arenas that the citizens were invited to. The overview (table 2) is rather semi-detailed, as it does not separate between the different occasions at the city hall.

Table 2: Number of people that the politicians/planners have had a dialogue with during the ByLab

Visits to the city hall	Workplace visits (6)	School visits (4)	Workshop and public meeting	City talk at shopping mall/young parents	Sum
163	88	252	70	80	653

Source: Report on the ByLab, retrieved from the municipality's webpage

The inputs that were put forward by the citizens on these occasions were carefully noted by the representatives from the municipal administration who were present at the different arenas. These are also listed in the report. They are presented in a rather short form, and listed according to the respective arenas where they were put forward. Below is an example of the form, gathered from the city talk in the shopping mall (my translation):

- Positive to development and densifying
- [name of town] can take tall houses
- Yes to more residential houses in the town centre
- We are ready for densifying
- Important to take care of the old things
- Thumbs up for development of the station area
- Wants small houses in the town centre, not tall houses

From this particular event, 34 bullet points are listed, filling one whole page. Altogether, the bullet points from the different arenas fill nine pages of the report.

The report also contains some photos, five from the school visits and four thumbs up/thumbs down. The photos from the school visits show where the students have put red and green pins on a map of the town centre, in order to express an opinion of this particular spot. These photos are, however, not accompanied by much explain text. The reader is not oriented of what the exact purpose of the pins is, or if the color has a particular meaning – though it is close at hand to assume that red means something bad and green something good. Under each of these photos some statements are referred, and one gets the impression that they must be uttered by some of those that the visitors from the municipality met at the schools. One example: one of the photos display a section of the town map that show the railway and bus station area, including a pedestrian area. On this photo, 75 pins can be counted. Under the photo, we find the following three statements (my translation):

- The station should be renovated
- It is not nice to stay here
- The pedestrian street is dilapidated and has little to offer the youth

The three text points are probably the essence of the opinions that were made on this particular area of the town in school meetings. However, the reader is not informed of whether these are the opinions from one school in particular or of whether there are variations of any significance.

The photos of the thumbs up/thumbs down show these placed in different places of the town, and an opinion of the particular location written on each of them. Altogether ten thumbs (6 with an up and 4 with a down) are displayed on the photos. Of the ten, the text is readable in three or four. On the other photos the text is blurred due to lack of sharpness of the photo.

'Future pictures' (my translation) is a document that were developed by the project team and presented in the policy documents that were prepared for the business and city development committee. 'Future pictures' to a certain degree sums up the input from the different arenas. However, the composition of the text is such that it is difficult to trace the particular viewpoints to one or more arena and stage of the process. The process as a whole is referred to in general terms, and the document is short (....pages). The formal arenas, the workshops and the meetings that have

a formalised character, are to a greater degree possible to identify in the documents than the informal ones. Arenas like the politicians' lunch and the thumbs up/thumbs down, are more or less invisible. They are not referred to explicitly in the way that the input from some of the formal arenas are.

As we can see, the summing up of the input has not undergone an editorial work apart from the listing that is partly referred above. If exchanges of viewpoints or heated discussions occurred, they do not protrude from the documentation. In that respect, the documentation appear as somewhat "clinical", even if different viewpoints can be read from at least some of the listings.

New arenas were established by the ByLab, and some of the people who are generally absent from municipal planning were engaged. In particular that goes for children, youth and people who are members of organised interests that are tend to engage in planning issues. It is, however, fairly easy to map the arenas, while getting a comprehensive picture of who the participants on the arenas were, is more of a challenge. Also, it is not easy to detect what kind of person that is behind the viewpoints. Of course, to a certain extent, some are possible to guess. The school visits gathered pupils and teachers, the workplace visits gathered employees at the respective workplaces. Nevertheless, the reports give the readers little to go by in terms of putting faces to the inputs.

When asked about the challenges with presenting the experiences from the ByLab arenas in a written form, the people I interviewed had varying opinions. Some, and in particular the administration, are of the opinion that the form that they are presented in is good and meticulous – that they wrote down everything that was being said, and that is can be found in in the documents that are referred to above. Others, and especially one of the politicians who was present at all types of arenas, emphasise that a lot of what was being said and discussed in the arenas is not necessarily written down, (my translation): *"But then there is all these small discussion that have occurred. They are not documented.... They are something that the politicians perhaps have brought into the political processes."*

5.3 Translation by memories: the municipal actors' impressions

All the interviewees agree that the ByLab process as a whole was interesting and worthwhile, and that it is vivid in the memory of the participants. They do, however, have different opinions on what was the most rewarding or interesting arenas, and what purposes that were fulfilled by the process.

The process as a whole

When asked about the process as a whole, the general impression is that the interviewees think it was useful and interesting. Two of the interviewees did only participate in one of the workshops, the City seminar, which was an open workshop for anyone to attend. The enthusiasm seems to rise with the number of arenas they attended, as those who were present at all or at least several types of arenas, express their opinion on the usefulness and relevance more strongly than those who only participated once. Only two of the informants had only participated in one single arena, and one from the administration had been present in all of them. The others had taken part in all the different types of arenas, however not inn each and every one of them – not all the workplace and school visits, for instance, but at least one of each.

A part of the enthusiasm is connected to the multitude of forms and arenas that were set up, and the fact that they could meet people in different ways, both in informal and more formal settings. Those who participated in different forms of arenas, express that it is precisely the combination of arenas that contribute to give a more comprehensive picture of the citizens' opinions. In addition, the fact that they process was quite "compact", as it was carried out during a time span of three weeks. It

made them keep up the energy and concentration on the theme, and one describes it as an aspect that made them more receptive to the inputs they gathered from the citizens.

The intensity of the process and the many arenas that they attended is likely to be an important reason why the process and the strategy that was developed on the bases of it, was still vivid in the informants' memory more than two years after the ByLab was conducted, and a year and a half after the strategy was decided on by the local council. In addition, this was the most extensive participation process that the municipality had carried out, and with several elements that were innovative to the context, which probably contribute to the general enthusiasm. They describe it as a new and very energising experience. The positive attitude to the innovative participation was also confirmed by their opinions on whether arenas such as those in the ByLab process should be employed in other planning context. On this question, the agreement was unison among the interviewees. This also goes for those who only attended one of the workshops, and not the ByLab arenas. Their positivity stems largely from what they have heard from others who participated, both politicians and citizens, and from observing that the process and the strategy is actually being referred to in discussions both in the local council, the committees and in the social media.

It should be noted, though, that when asked if these forms of participation should be used more frequently, they people I interviewed are aware of the fact that the process as a whole was time consuming and resource demanding, and the whole apparatus cannot be activated for any small detail zoning plan. However, they agree that the experiences have opened new paths into participation, and that elements from the process should be applied more often. Especially, they point to the work place- and school-visits, and the informal meetings they had with the citizens in for instance the shopping centre and in town. One also mentions that in such arenas the politicians are to a certain extent "freed" from party politics, and speak more openly and with another attitude with the citizens. From the informant, this is meant as a positive feature.

What was the most important experiences of the process?

While there is a general agreement that the process as a whole was good and useful, the people I interviewed display more variety with regard to what the most important, interesting and useful aspects and arenas of the process were.

From the preparatory document, and from the town centre strategy, the process is described as a participative process: *"... a process with active and broad participation from politicians, business actors, citizens and public sector actors."* (Town centre strategy: 9, (my translation)). The importance of the input they got from the citizens in new and innovative ways, was emphasised by all the informants. It is no doubt that one main aim of the process was to gain insight into people's images of their town in the future. The workplace and school visits and the city talks (shopping centre, politicians' lunch, parents with prams) were often mentioned as good arenas for getting new knowledge of people's viewpoints and their reasons for acting as they do. The all connected this to the informality of the arenas, and that they got to talk with other people than those that usually turn up at meetings and other, more formal occasions. As one of the politicians put it (my translation): *"As politicians we often meet people with strong interests. More seldom do we meet 'the silent majority'. In the shopping centre we met some of them."*

The other experience that all the interviewees emphasise, was that the process was important for anchoring the town-centre strategy. This is in particular expressed with regard to anchoring among the politicians, but also with regard to the citizens and the business actors. When asked about what they mean with "anchoring", they give elaborations that fall into two main categories. Firstly, it is about anchoring the new ideas of city development that is connected to the challenges of reducing

the use of fossil energy and enhancing public health, which among other lead into the path of densification and motivating people to use collective transport, cycle and walk, rather than private, fossil driven transport. Though many embrace these thoughts, there is certainly also a significant degree of resistance to them. Much of the residential areas in the town centre, consist of detached houses with gardens around them, and people in general tend to use their car a lot, and to a great degree on short trips, such as going to a shop or visiting a service just a few hundred metres away. It was reported in the interviews that much of the discussions and inputs were related to these topics. From the interviews one can see that anchoring these overarching ideas of city planning and development is directed both towards the citizens and the politicians. The politicians that attended the different participative arenas felt obliged to be well prepared for the possible discussions with the citizens, and had made more effort than they usually would do in connection with a planning process, to obtain knowledge of the ideas and what the implementation of them would lead to for their town and citizens. Participating was voluntary for the politicians, but altogether many more than was usual in for example a public meeting, took part in the ByLab. The engagement from the politicians' side brings us to the other important perception of anchoring that is emphasised in almost all the interviews.

The process was deliberately designed in order to anchor the strategy among the politicians. Generally, many municipalities experience that their politicians do not engage much, neither in planning nor in strategy processes (Ringholm & Nyseth, 2018; Kvalvik, 2018). In the committee that prepared the process, the importance of engaging the politicians was agreed upon, both by the administrators and the politicians. This idea got few, if any, objections when the process plan was presented to the politicians. Since participation was voluntary, those who could not or did not want to attend, were free to do so.

In other words, anchoring was, firstly, a question of making both citizens and politicians, familiar with the overarching ideas and thoughts that framed the strategy, and which the strategy document would need to recognise and give a local direction. Secondly, the ambition of anchoring also meant that the politicians should gain ownership to the strategy document, because this was meant as a platform for the further planning exercises of the municipality, among other the spatial plan that was going to be developed shortly after the strategy document was decided on.

In the interviews, the anchoring of the framing ideas and the strategy document among the politicians were pointed to as an important achievement of the process. That such a large proportion of the politicians actually turned up at the arenas, the debates they engaged in and the new knowledge they gained from this, was regarded as very valuable by both politicians and administrators. The following quote from one of the administrators is illustrative for the general opinion that I registered (my translation): *"The fact that all the important politicians have participated, has given them such an ownership to it [the strategy document] and that they speak positively about it."* Another administrator put it like this (my translation): *"Now they [the politicians] have got it "drip-wise" in several rounds. Then it is easier to get a large plan."*

The anchoring and ownership of the framing ideas and the strategy document was, however, not the only output, in terms of experiences, that the interviewees thought of as important. The meetings and conversations with the citizens had also given new knowledge and a certain shift regarding how the ideas of a vivid and dense town centre could be developed. Both administrators and politicians say that they would have to think again about the cars and parking facilities, about the height of new buildings, and about how to deal with the existing green areas in and around the town centre. They connect this directly to inputs that they got from the citizens in the ByLab process. Since the process was connected to a strategy, and not a legally binding plan, some of the interviewees emphasise that

the knowledge that was gained will present itself on different future occasions when particular plans are being decided upon. Nevertheless, they all say that some of opinions of the citizens that were mapped in the ByLab arenas, have been embedded in the strategy document. It is, however, impossible, they say, to follow the trace from the particular arena and into the strategy. One has to look at the process as a whole and consider the inputs in light of the editorial work done by the administration.

Lost or found?

The issue that this paper discuss is the question of *how the knowledge, experiences and ideas that are generated at the innovative arenas of participation is framed and translated in a way that is recognized by the decision makers in the planning process*. The question is important in order to assess the democratic value of the new participative initiatives that are made by both planning authorities and the citizens. They seem to become more and more popular, and there can be several reasons for that. On the one side, they could be really useful for gaining insight in the citizens' opinions and experiences. On the other, they could be "the icing on the cake" – a happening with no real impact on the decision or other feature that makes them meaningful.

The presentation in the previous chapter show that the ByLab- process served more than one purpose. It also show that the input from the arenas was translated in more than one way. These experiences can in short be summarized into the following points:

- A main purpose of the process was both to get a broad picture of the citizens' ideas and viewpoints on the development of the town center, and to anchor the overall framing – the new ideas of city development, with the citizens and the politicians.
- Another main purpose was to enhance the politicians' ownership to the strategy and its framing ideas.
- The translation of the inputs from the innovative arenas are presented as unedited lists of utterances in the reports, sorted by arena, whereas in the strategy document viewpoints are not referred to different arenas.
- Small talk and discussions that politicians and administrators engaged in at the arenas are not referred in the reports.

There are, of course, good reasons why not all of the inputs were being referred. It is very time consuming and would demand more manpower than was made available for carrying out the process. Capacity limits is surely one explanation. The findings also indicate others explanations. One is that that the administrators found this way of referring a good and thorough one, and in line with what one could expect – well within the standards that is applied by the planning organization. Another explanation could be that the mixed purposes of the process – of embedding the framework of ideas for city development among the citizens and the politicians – has had an impact on the efforts that are put into the presentation of the input. It could also be that the framing has had an impact on how the inputs are sorted, in the way that it has colored the lenses of the translators. In this case, the translators from the administration that was responsible for summing up and preparing the written output from the process. One of them have been thinking a bit in terms of the administrators' impact on the final document, and formulates this as a question: *"Is it so that because the process has been so large and wide spanning, then it has become an even more professional product?"* In a way, this administrator questions the whole rationale of the innovative participation arenas. The quote also show that even if you have been at the core of the process, you do not know the answer.

Even more untraceable are the stories that the process form in the heads of the participants, and which are shaped by the meetings with people and the conversations that take place in the arenas. These are probably important vehicles, the “good encounters” in moving from “what is” to “what if”, and make planning practice a process of “becoming” rather than of fixing (Hillier, 2008). Would it be a good idea to write them down or record them and put them on the municipality’s homepage for the public to see and learn? This is a lengthy discussion, that involves the consideration of factors such as a possible loss of spontaneity and the informality that the participants obviously value up against the transparency dimension of the representative democratic system.

More traceable is the underlying story of the informal arenas as a way to go forward in future planning processes. Both the politicians and the administrators express a great enthusiasm about them, and are positive to institutionalizing them. If this is a development that gains weight, not only in this municipality, the questions regarding mechanisms for translation are likely to be more outspoken. The participants of the open and informal arenas place themselves in the outskirts of Fung’s democratic cube (Fung, 2006), and it is a question of translation capacity and skills whether we are able to detect where they are to be placed in terms of communication mode and possibly of authority.

It is also possible that a process like this contains elements that are in fact impossible to translate into the known practices of the planning system. The enthusiasm or heatedness of a certain situation, the mutual understandings that can suddenly occur, the experience of being part of a meaningful conversation, or the complete opposite. Such experiences protrude from the interviews, but are not made explicit in any of the documents. The strategy documents’ sober description is (my translation): *“The strategy is the result of a process with active and broad participation from politicians, business sector, citizens and public sector actors. This has been important in order to ensure a good product with a solid ownership to the project.”*

All in all, the ByLab seems to have played a role in creating a new story, or new stories, about the town. It has become a point of reference for subsequent political discussions and planning projects, first and foremost among the political actors, but to some extent also among other actors. Some of the story, one version, is in the documents, other parts are in the heads of the participants, and can only be revealed by following the issues that are brought up in connection to town development.

Appendix 1: Interview guide

- 1 What are your experiences with the ByLab process?
- 2 What experiences are conveyed to you from others who participated in other parts of the process than yourself?
- 3 Is this way of designing participation useful for the planning and development work in the municipality?
- 4 Do you think the presentation of the process and the experiences from it, as it appears in the documents, is in accordance with your impressions from participating in the process?
- 5 Was the discussion in the local council different from discussions that you have experience from, regarding other planning contexts. If so, in what way?
- 6 Do you see any limitations or disadvantages with these forms of participation?
- 7 Do you have thoughts or ideas of other, new forms of participation?
- 8 Concluding remarks

Transformation of Grown City Centers

Elisabeth Schaumann¹, Christina Simon-Philipp²

¹*University of Applied Science, Stuttgart, elisabeth.schaumann@hft-stuttgart.de*

²*University of Applied Science, Stuttgart, christina.simon@hft-stuttgart.de*

Abstract: Urban district centers are key in supporting community life in European cities. The vitality of these centers is essential for the functionality not only of the districts but indeed the entire city. Many established city centers suffer a high adjustment pressure; formerly vital centers experience a loss of importance. In order to explore the hypothesis that the required transformation of those centers can only be positively affected by strategies of different actors, especially local actors, researchers conducted four case studies in German cities. The city centers examined throughout the study offer various challenges and opportunities, specific constellations of actors and different development options. The article analyses the role of transformation research, real-world laboratories and social innovations in the transformation of urban district centers.

Keywords: Transformation, Social Innovation, Transformation Research, Real-World Laboratories

Introduction

Established district centers bear an important meaning for community life in European cities. The vitality of these centers is of essential relevance concerning the functioning of the entire city. Grown city centers suffer a high adjustment pressure, former dynamic centers experience a loss of importance. There are various reasons for these developments: structural changes in retail, digitalization and e-commerce, changed mobility behavior of consumers, demographic change and so on. The consequences of these developments are for example underused commercial properties, high vacancy rates, and underused and neglected public spaces.

Principle thesis of the research project TransZ, Transformation of Urban District Centers (2017-2020), is that the required transformation of those centers can only be positively affected by strategies of different actors, especially local actors. In order to explore the hypothesis, the research is based on different case studies in German cities. The city centers examined throughout the study offer various challenges and opportunities, specific constellations of actors and therefore different development options. The article will discuss the different interests and opportunities of action the actors in urban district centers have and in how far urban real-world laboratories can help to initiate social

innovations. These are in this case, broadly speaking, understood as new solutions, which meet social needs, improve capabilities, relationships, and optimize the use of resources.

Research Project TransZ

In the research project TransZ (cf. www.transz.de), different real-world laboratories were set up to test alternative methods of center development and to possibly initiate social innovations. The project is funded by the Federal Ministry of Education and Research (BMBF) as part of the flagship initiative “Zukunftsstadt” under the funding stream “Sustainable Transformation of Urban Spaces”. As part of the project 4 institutions (HafenCity University Hamburg and University of Applied Science Hamburg, University of Applied Science Hildesheim / Holzminden/ Göttingen and University of Applied Science Stuttgart) collaborated over a 3-year period of time (2017-2020) to identify and strengthen transformative forces in the city centers. Specific approaches to accompany transformation processes positively and to improve the situation in the centers sustainably have been developed with local actors. The universities have been deepening their work in the project areas themselves as well as in thematic research areas such as public space and planning processes or self- organization and governance in center development.

Importance of Grown City Centers

Not all cities and districts profit from the spatial processes of urban development such as growing population or rising real estate prices. Grown city centers for example suffer a high adjustment pressure, former dynamic centers experience a loss of importance. Especially local supply centers, urban district centers and outskirts of central positions suffer a high loss of function. There are various reasons for these developments: structural changes in retail, digitalization and e-commerce, changed mobility behavior, demographic change and so on. However, urban district centers bear an important meaning for community life in cities. The vitality of these centers is of essential relevance concerning the functioning of the entire city.

As place for identification in the daily life of residents and community, district centers fulfil multiple functions. They are places of social cohesion, economic viability and cultural innovations (Bundesministerium des Innern, für Bau und Heimat (BMI), n.d.). Structural change adversely affects centers resulting in multidimensional challenges. City centers are a focus of scientific, technical, economic and social development, but they are also the place of social and ecological problems and structural changes (Frauns and Scheuven, 2010, p. 10). Challenges resulting from changes in economic structure reach far. Many commercial spaces no longer appear interesting for investors under the current requirements of building structure and location. Extensive concentration processes, the growth of retail floor area and a simultaneous thinning of the shop network makes small units unattractive for investors. As a result, they remain vacant and may be converted into flats. Another reason for structural change is the expansion of discounters and large chains with which smaller, locally owned shops are often unable to compete. Large-scale retailers are located at the outskirts of cities, are easy to reach by car and offer free parking. E-Commerce is putting owner-managed commerce under pressure as well, while e-commerce turnover in 2008 was 12.6 billion euros, it rose

4fold to 53.4 billion euros in 2018 (Frauns and Scheuvens, 2010, p.10, Bundesministerium für Wirtschaft und Energie (BMWi), 2017, p. 2, Handelsverband Deutschland (HDE), 2019). Many centers are in danger of becoming deserted (BMWi, 2017, p. 2). Shop vacancies lead to a loss of attractiveness, a reduction in turnover and frequency and soon to a loss of image. This results in a loss of customers and a loss of value of the property. Vacancies are therefore a major problem for centers (Greipl, 2007, p. 16f).

Another challenge is the urban space. Pedestrian precincts are for example an important part of urban space, they are economically very important but the aesthetics are not meeting today's expectations anymore. Public space is central in European cities, new concepts are required to meet the needs of all generations. Contemporary solutions are important; the diversity of the European city is endangered if urban planning solely keeps to traditional top-down planning processes. It is an important space for example for social needs and integration; therefore, it is for example important that public space allows encounters (Frauns and Scheuvens, 2010, p. 13f). Some of these challenges can end up in trading-down effects if nothing happens. Trading-down effects result in a reduction of company costs in order to be able to survive in the local market. Consulting services are reduced, the staff is reduced, and pound stores set up. This can also happen due to a mismatch between supply and demand. Productivity per unit area has fallen; an oversupply of sales areas that are no longer marketable emerges. This often leads to a downward spiral outside the prime locations (Achten, 2017, p. 66f). Secondary centers are the big losers of these developments. Centers with an extensive business area and a lack of space for larger units are particularly at risk. Customers are switching to other options. This also weakens the secondary center as a residential location. Occasional purchases are not enough to let retail trade survive. A loss of significance and function, "erosion processes" in smaller cities, decentralized secondary locations, or even in suburban areas are the result (Fischer *et al.* 2011, p. 26, Oswalt *et al.* 2014, p. 10). Urban development policies can strengthen the diversity of land use in these centers using investment and non-investment measures, but the success is not always permanent. In Germany, urban development funding is very important for urban development in general, but especially for urban district development. There are various support programs, which aim to address a variety of difficulties - structural, functional and social. The federal government grants financial assistance in accordance with article 104b of the constitutional law, which is supplemented by funds from the federal provinces and the municipalities (Städtebauförderung, 2019).

Transformation Research

Sustainable development is a challenge for the entire society. Research has been trying to find new options and solutions for sustainability problems in fields of, for example, economy, consumption, mobility or energy. The awareness of transformation processes in sustainability research has grown. New concepts are being developed to get scientific findings as well as socially robust information to initiate concrete solutions. Exemplary research fields dealing with the transformational processes are sustainability science (e.g. Kates et al 2001), transition studies (e.g. Markard et al 2012), resilience research (e.g. Olsson et al. 2014), social innovation sociology (e.g. Westlex et al. 2013), political science, future studies, and psychology (e.g. Haum and Pilardeaux 2014, Heyen and Brohmann 2017, Patterson *et al.* 2015). Scientists work together with practical actors to integrate their concerns, knowledge, and competencies in research processes (Schneidewind, 2014, p. 1, Wittmayer and Hölscher, 2017, p. 13, Rose *et al.* 2018, p. 2). In international context "sustainable transition

management” (e.g. Grin *et al.* 2010) has become more popular, in national context, talking about Germany, transformation processes and corresponding research was promoted through the main research report by the scientific advisory board of government global environmental changes (WBGU) about “great transformation” (Schneidewind, 2014, p. 1, Wittmayer and Hölscher, 2017, p. 13). Transformation research can be understood as a research perspective that studies complex and pervasive societal problems. Fundamental societal change processes and dynamics are supported towards sustainability. Wittmayer and Hölscher (2017, p. 15) define transformation research as follows: “Transformation research studies and supports fundamental change processes of societal systems towards sustainability from a scientific perspective. These research goals require both, descriptive-analytical as well as transformative research approaches, which yield conceptual and actionable knowledge through trustworthy, transparent and reflexive research processes. The complementary research foci of transformation research include the objects of transformation (what changes over the course of a transformation), the change dynamics of transformation processes and emerging transformation pathways (how do transformation processes occur), and the drivers of transformation processes (by whom/how are transformation processes supported). “(Wittmayer and Hölscher, 2017, p.15)

Apparently, appropriate research is a challenge. It has to be organized transdisciplinary, as the design of transformation processes asks for a combination of system knowledge, target knowledge and contextual- and actor specific knowledge. There is an active debate about the right usage of research methods for studying and supporting sustainability transformations (Schneidewind, 2014, p. 1f, Wittmayer and Hölscher, 2017, p. 13f). At this point, classical methods of observation and modulation reach their limits, as the examined processes ask for knowledge about specific transformations (Schneidewind, 2014, p. 2). For this reason, social- and economic sciences experience an experimental turn. New ways of research help to improve classical observation and model-based approaches (Schneidewind, 2014, p. 2, Schöpke *et al.* 2017, p. 1.). In transformation research, different methods like research diaries, system analysis, hackathons, knowledge hubs, real-world laboratories or participatory action research are used, to just name a few of them. Each method has the potential to contribute to transformational research, yet a combination of methods enables the integration of different research topics (Wittmayer and Hölscher, 2017, p. 21ff). Moreover, the knowledge about social transformation is simultaneously affecting the community, as scientific knowledge influences the processes. A classical observation-system-division is not possible anymore. Transformation researchers are part of the explored transformation processes (Schneidewind, 2014, p. 2).

Transformation research wants to trigger a change; it is about developing creative and reflexive skills in dealing with transformation processes both in science and in society as a whole. The so-called “transformative literacy”, describing the enabling of civil, political and economic actors to promote circumstances for sustainable oriented changes, is still at the beginning. These circumstances arise, for example, when people learn from each other within the framework of the research process or also from the input / intervention of the researchers (Schneidewind, 2013, p. 82, Schneidewind, 2014, p. 1, Parodi *et al.* 2016, p.17). Regardless of scientific research, transformation processes are not giving satisfactory evidence about mechanisms of successful transformation processes. One possibility to improve the understanding of causal links in these systems are scientific guided interventions in a real political, social and societal context (Schneidewind, 2013, p. 82 ff, Schneidewind, 2014, p. 2).

Real-World Laboratories

To improve the understanding of transformation processes, real-world laboratories are part of the research project TransZ.

In general, the usage of real-world laboratories in transformation research is in vogue. Still, real-world laboratories and the connected research “are new concepts, and therefore not yet clearly defined” (Parodi et al. 2016, p. 9). According to the frequently used and very popular definition of real-world laboratories in Germany by Schneidewind (2014, p. 3). They are based on the idea of real-world experiments and are a hybrid kind of experiment, lodged in between knowledge production and knowledge application as well as controlled and situation-specific conditions (Schneidewind, 2014, pp. 2 f, 6, Beecroft and Parodi, 2016, p.4, Schöpke et al. 2017, p. 1). Real-world laboratories form the context for real-world experiments; their aim is an improvement of knowledge about sustainable oriented transformation processes and the initiation of sustainable oriented transformation processes. Participatory methods like real-world laboratories generate conceptual and actionable knowledge (Schneidewind, 2014, p. 2f, Schöpke et al. 2017, p. 1f, Wittmayer and Hölscher, 2017, p. 25). Urban real-world laboratories are very important to study social change processes. It is easier to study social processes of change on the city level, as all technical structures can be found and the area is still not as big as entire countries. Besides that, cities are an easier reference object than entire countries. The complexity of cities is still manageable, socio-technical dynamics can be observed easier. Furthermore, cities are the origin of cultural changes, changing lifestyles and therefore an appropriate place for experiments. Macrosocial developments can be observed and be scaled to higher layers (Schneidewind, 2014, p. 3, Schöpke et al. 2017, p. 4). Urban real-world laboratories on district level study process happening in the districts more closely. Thereby effects of cultural identities and social diffusion processes can be observed. By a worldwide comparable substructure of cities in districts of comparable size, results from district related real-world laboratories enjoy a high degree of comparability (Schneidewind, 2014, p. 4).

Real-world laboratories have to fulfill some criteria: First, they have to be oriented towards civil society. The co-design and co-production of the research process have to happen with the civil society and societal actors, whereby all actors have to understand the (in real-world laboratories indispensable) transdisciplinarity of the process. Furthermore, the real-world laboratory research design has to have long-term support and orientation, must be continuously methodically reflected, and the research support has to be coordinated by institutions with experience in transdisciplinary processes. The process has to have laboratory character, which means that the required physical and personal research infrastructure of the transdisciplinary experiments is guaranteed. If these characteristics are fulfilled, real-world laboratories are more likely to generate value and innovation for the society (Schneidewind, 2014, p. 3, Parodi *et al.* 2016, p. 7 f, Schöpke *et al.* 2017, p.3).

The characteristics of real laboratories already described make clear how time-consuming the process is and how high the flexibility requirements are (Parodi *et al.* 2016, p.6). Real-world laboratory research is just at the beginning and there are many questions and challenges (Beecroft and Parodi, 2016, p. 5). One of them is context dependency and the limit of controllability of boundary conditions. The fundamental difference between a real-world laboratory and a classical laboratory is the partial controllability of boundary conditions. The higher the context- and situation dependency of real-world experiments are, the lower is the transferability of findings. A rebalancing of research

interest and situation dependent transformation profits of practical actors is necessary (Schneidewind, 2014, p. 4). Another challenge is the transferability of outcomes; they differ from classical quantitative empirical social research (Schneidewind, 2014, p. 4). Furthermore, the appropriate integration of actors is difficult. Research in real-world laboratories needs cooperation with practical actors in the transdisciplinary processes, meaning discussions between practical actors and researchers on an equal footing. It is important that practical actors do not feel like the object of research (Schneidewind, 2014, p. 4). Lastly, the terminology is quite important. The usage of the word real-world laboratory is subject of a controversial debate. Classical laboratory research rejects the term, as real-world laboratories do not fulfill the constitutional conditions of a laboratory – that is controllability. Despite the status of development and the justified concerns about the approach, real-world laboratories are an interesting methodical extension to improve the understanding of complex transformational processes in society. More experiments with real-world laboratories are needed (Schneidewind, 2014, p. 5, Parodi *et al.* 2016, pp. 6-9).

Social Innovations

To understand, in how far real-world laboratories can help to initiate social innovations, a short glance at social innovations is indispensable.

Social innovations can be very diverse; and there is no universally agreed definition (Rückert-John *et al.* 2014, p. 9). The social innovation academy (www.socialinnovationacademy.eu) hosts a blog which provides eight different definitions; the approaches differ by their ways of consideration. That is how it happens that for example the meeting of social needs, a change in daily routines, the generation of value primarily for society or empowerment /political mobilization are the focus of the definitions. The Young Foundation (2012) used a general approach for their definition of social innovation: “New solutions [...] that simultaneously meet a social need (more effectively than existing solutions) and lead to new or improved capabilities and relationships and better use of assets and resources.” They also emphasize that “social innovations are both good for society and also enhance the society’s capacity to act.” Wigboldus (2016) made a very clear definition, it includes innovations, which emerge in the social realm of experienced reality, innovations which are “about new ways in which people interact and about new ways in which people interact with their environment” (Wigboldus, 2016, Balamatsias, 2018).

So the variety of different initiatives, projects or new production and consumption practices calling themselves social innovations or being called social innovations are emerging out of recent trends as sharing economy, collaborative consumption, DIY and Upcycling. These attempts have in common that they take action against the rising number of European societal challenges like throwaway mentality, anonymity, alienation, energy- and resource waste, refugee crisis or unemployment, which are all problems of our society (Rückert-John *et al.* 2014, p.6f, Max Weber Institut für Soziologie, 2015, Balamatsias, 2018). However, as a big social transformation is just possible if everyone in society is involved and willing to change habits and mindsets, everyone has to get involved. As social innovations develop out of the community as reactions to existing problems, they are likely to spread fast and get a high acceptance throughout the community. For this reason, politics is very interested in social innovations as well; social innovations became for example central points in the political program of the EU. The research program “TEPSIE – The Theoretical, Empirical and Policy Foundations for Building Social Innovation in Europe” for example has been focusing on strategies to

promote innovative solutions for social challenges in the EU since 2012 (Max Weber Institut für Soziologie, 2015, Rückert-John *et al.* 2015, p. 25).

Categorizations of social innovations are as diverse as the individual definitions. Socio-juridical, socio-political, socio-economic, etc. are categories describing the thematic background of social innovation (Wigboldus, 2016). A typology is also imaginable based on the “internal characteristics” of the single innovations – for example., the level of self-initiative, sense of community, level of innovation, formality or prevalence. Depending on these “internal characteristics”, the procedures to initiate, develop and promote social innovations are different (Rückert-John *et al.* 2014, p. 9ff). And, of course, different social innovations can bring about different degrees of change. A social innovation could be about a slight change, for example a new management process, but others might be about new ways of for example doing research and therefore involve a radical change (Wigboldus, 2016).

To further develop, some innovations need seed capital, others need strategical support, for example contact to companies or assistance with the removal of impediments, for example obtain permits from the administration. Support in public relations helps all of the innovations; in this case, it is just important to figure out which target group wants to be reached. Nevertheless, as all innovations are very different, they all need different foci and combinations of foci; this also depends on actor constellations in the project (Rückert-John *et al.* 2014, p. 11, Rückert-John *et al.* 2015, p. 80).

In the real-world laboratories in TransZ, different kinds of social innovations developed out of the needs of the inhabitants. To actually activate existing potentials and to focus on existing problems in the urban district centers, the process was designed very openly.

Real-World Laboratories and Social Innovation in the Project TransZ

The University of Applied Science Stuttgart (HFT) initiated real-world laboratories in two different centers in the greater Stuttgart area. After introductory talks with representatives of the city administration, interviews with key personalities in the urban districts were conducted by which further motivated multipliers were identified. People with different backgrounds and perspectives could be won for the process: Residents, retailers, restaurant owners, representatives of social institutions, artists, etc. got involved in the process. They were invited to so-called "steering groups" to exchange ideas about the future of their district center, to develop actual ideas they could realize on their own and to initiate projects. Invitations to official meetings were sent by mail and e-mail, were published on the project website, in the local newspaper and communicated by the already existing participants.

The role of the city administration is very important. In the real-world laboratory, Stuttgart Wangen (S-Wangen) the University of Applied Science Stuttgart invited interested people to the first meeting, but from the very beginning, the city administration assured support in the process. They offered a room for the meetings, attended the meetings without making demands and even organized an information session about the planned real-world laboratory process. Still, the real-world laboratory process was clearly connected with the University of Applied Science Stuttgart, the city administration was in the background. The University of Applied Science Stuttgart set up the communication structure, invited to interviews, designed the real-world laboratory process, etc. This

trust of the city administration in the University of Applied Science Stuttgart led to the fact that new committed people in the urban district were reached due to the changed communication structure.

In Fellbach, the location of the second real-world laboratory of the University of Applied Science Stuttgart, the city administration did not support the real-world laboratory process as strongly as for Stuttgart-Wangen. There were no rooms offered, no attendance on meetings without clear communication about the importance of the attendance, no extra information about the real-world laboratory process. Nevertheless, the people in Fellbach were still interested in the real-world laboratory and attended the first meetings.

During the meetings, it became obvious, that the majority of those involved were willing to play an active role in the real-world laboratory process. In both real-world laboratories, the first self-organized processes already developed during an initial “idea development phase”. The ideas in the real-world laboratories are very different; they have been developing in the course of the process.

In S-Wangen for example, a homepage was created to improve the presentation of the district's potential, a city game for networking and education was initiated, a building workshop for the redesign and revitalization of a central square was carried out and a non-commercial flea market was organized. In addition, various temporary interventions were carried out in one of the real-world laboratories under the title "Talking Streets". An international and interdisciplinary team of students made "city stories" visible, pointed at deficiencies and articulated wishes of the residents. The interventions were an important part of the debate about the future of the center, which is developing from a former village center to a place of intercultural coexistence. For example, lunch was taken together on temporary furniture, several creatively designed "communication boards" in the district were used to ask about the district's potential in different languages, an oversized local newspaper was used to stimulate conversation or a temporary "blasting device" was used to draw attention to a disturbing fence. It was noticeable that the acceptance of the interventions decreased over age. There was little understanding on the part of many elderly in the district, whereas children participated in the different actions, were not too shy to write their thoughts on communication boards, etc.

The focus in Fellbach was different; participants there designed a new logo and developed a shopping guide for the area. Furthermore, the group discussed some ideas about a better connection between different actors in the area but did not develop them further.

If one compares the two districts, the different spectrum of the ideas becomes visible. The social innovations developed in the real-world laboratory S-Wangen did not need much support from the University of Applied Science Stuttgart, the mixed group focused on many different aspects including history, education, urban design, etc. In Fellbach the group was mixed as well in the beginning but changed to a single retail-oriented group throughout the process. As a result, the actually developed projects focus solely on retail issues. In contrast, the district S-Wangen is not just about retail, it is a mixed district next to an industrial area where people live, work, go to school. The examined part of Fellbach is a mixed district as well, but the persons working in retail relate most to the street itself. Surrounding inhabitants, cultural or educational institutions rather relate to the entire city and not to the examined district center. Therefore the sense of responsibility for the street of the retailers is much bigger than from other, for example, institutions or inhabitants.

Conclusion

During the process, a number of findings could be ascertained.

It was important to trust in the ideas of the participants and to transparently communicate with all participants. The municipality (city administration and local city policy) has a central role to play. Without the trusting atmosphere created by the city administration in Wangen throughout the years, the various interested people would certainly not have been so motivated to participate in their center in the long term. In Fellbach the sustainability of the developed ideas is in jeopardy, there is not such a trusting atmosphere as in S-Wangen; it is rather an atmosphere of mistrust. Especially if the sense of responsibility for the area is rather limited, as it is in Fellbach, the role of the municipality is even more important. The neutral role of the University of Applied Science enabled a positive real-world laboratory to start in both areas. However it is not possible for a University of Applied Science to reorganize retail in a shopping street, social innovations would have to happen on a different level in this case. This is also not possible for retailers on their own; in this case, the municipality plays the most important role. Therefore, besides seed capital, strategic support, removal of impediments or support in public relations, sustainable social innovations need support and trust on the part of the city administration.

Of course, it must also be discussed how the individual people were addressed and which type of activation seems to be the best to motivate people to become part of the transformation process. The direct contact to first multipliers and the further contacts developing out of the interviews were very good to get an overview and the trust of the participants. This personal atmosphere motivated both sides, the University of Applied Science Stuttgart and the participants. On the other hand, the anonymous communication boards also activated many people to write down their opinion. The mix of methods – in this case, classical interviews and different kinds of urban interventions – could reach a wide mass. A mix of methods is recommendable for every project, only in this way numerous opinions can be captured and thus a greater acceptance in the population be generated.

The small administrative structures in the Stuttgart area further facilitate social innovations in urban district centers. Every urban district has its own district governor, thus it is easier for the citizens to talk to a responsible person. Moreover, it is easier for the district governors to “care” for their district and stay on top of things as the size of the area is manageable. These district governors have in turn better contact with the town hall than citizens have and therefore can achieve support for the social innovations in the district more easily. Nevertheless, this does not mean, that real-world laboratories are suitable and effective only on district/quarter level. It depends on the topic the real-world laboratory aims at, some topics (e.g. socio-technical dynamics) need the real-world laboratories on city level and for other topics (e.g. cultural identities), district level is enough (Schneidewind, 2014, p. 4).

Social innovations are highly dependent on diverse interests in the group. The different actor constellations, of course, led to different social innovations in the districts. Different professions, different ages, etc. result in different interests, lead to, for example, different abilities, and different amounts of time for the project. In the end, the thematically mixed oriented group in S-Wangen was very productive, as different interests met each other and therefore ideas could grow. Of course, there are also inconsistencies in this process, but they have to be accepted as part of the process

(Wigboldus, 2016). The participants developed social innovations that have value for a large part in society, not just for one group. In Fellbach the thematically one-sided discussion led to a potentially possible solution of one problem, but not to social innovations. Different opinions have to be discussed, different people have to find a problem or potential in common – this is what social innovation is about - not the generation of profit for retailers by designing a new logo or shopping guide.

The research project will continue to focus on these issues; there is more need for research.

Social innovations have the potential to support a sustainable transformation in urban district centers. Within the framework of a real-world laboratory process, the advantage of external support is added. An institution like the University of Applied Science Stuttgart can bring different people together, make them discuss their needs and the potentials of the urban district and thereby function as a catalyst for social innovations. Especially in urban district centers, it is important to support social innovations, they are places of daily routine, places where people live and not just go to work to, and therefore places for social innovations to happen. Many challenges can be solved best on the urban district level, but they have to be discussed with many different persons and need support and trust from the city administration. Top-down and bottom-up urban development are no opposites anymore but should be used to complement each other.

Co-creating collective imagination. How to produce thought-images for urban reframing?

Jan Schreurs¹

¹*University of Leuven, jan.schreurs@kuleuven.be*

Abstract: This paper situates epistemological challenges of community-based practices and social innovation research within the perspective of urban transitions. It explores characteristics of innovative, contextualized and generative planning stories. Insights about transformative imaginaries are distilled from an explorative case of reframing urban challenges by thought-images. Planning – as a critical discipline co-creating and supporting explorative paths towards a sustainable future – cares about approaches that can deal with community building for change. This implies an expanded language of planning. Decisive dimensions and characteristics of such a language, and how to build it, can be learned from ‘concept grants’ serving urban policy in Flanders. These grants serve multidisciplinary teams to reframe inchoate situations conceptually, to root those concepts into ongoing and new local processes, and to prepare for implementation. Collective re-framing makes stakeholders ‘see’ the potentials of a unique situation. They can feel how new collaborative coalitions can lead to effective change. They can imagine a different future and the capacities needed to bring it into reach. They incorporate imaging a thought-image while collectively creating, testing, refining and actualizing it.

Keywords: Co-creation, urban policy, reframing, thought-image

Introduction

This paper situates epistemological challenges of community-based practices and social innovation research within the perspective of urban transitions. It explores characteristics of innovative, contextualized and generative planning stories. Insights about transformative imaginaries can be taken from an explorative case of reframing by thought-images.

On transforming the language of planning

Community development versus challenges

Actual challenges demand substantial transitions. All over the world climate change, migration, uneven development and many related issues are put on the agenda tenaciously. Pressure from scientific and grassroots communities are increasing. Although political will to change is expressed discursively, it is hardly found in action mode. Finding effective answers to all those challenges is a complicated endeavor. The interplay amongst physical, social and mental dimensions is of a complex nature. Climate, eco-systemic, and socio-economic challenges need to be tackled in a systematic and integrated way. Ambitions and programs ought to be global; actions and interventions need to be local in order to effectively change, show and ‘sell’ the ideas behind. To realize this, many social and economic sectors, policy domains and disciplines have to be involved and interrelated. In Flanders, a recently created, expert-based Panel for Climate Change and Sustainability (*Panel*

voor klimaat en duurzaamheid) listed ingredients for the urgently needed systemic transition in order to tackle climate change and ecosystem crisis. These ingredients cover multi-level governance, nature and open space, industry, housing and spatial planning, mobility, energy, food, production and consumption, science and innovation, integrative and transversely, community building (Klimaatpanel, 2019). Worldwide it is only one out of many reports, declarations, programs and agreements for a drastic transition. But it serves the purpose to stress a crucial aspect in terms of activation and success: active community development. In the report this is framed as a combination of citizenship, coproduction, and deliberation. It implies mental shifts, empowering communication, deliberative and co-productive democracy. Although listed in the report as the last ingredient in a cocktail of actions and interventions, it should be considered to be the keystone: the one stone of an arch, which finishes the construction, consolidates its strength and symbolizes its meaning.

Re-conceptualizing planning language

Today, active community development is an opportunity and a task for planners. We know that spatial planners are able to identify and articulate multi-faced challenges within a complex socio-spatial context. We expect that they are prepared to articulate socio-spatial transformations dealing with such challenges, to the benefit of concrete people and places. This implies involving stakeholders within processes of collective learning, defining together combinations of goals and means for the implementation of priority transformations. This means working for and with people and places as components of an integrated socio-ecological system (Segers, 2016). As a critical discipline, co-creating and supporting explorative paths towards a sustainable future, planning cares about community development/engagement for change. To that end, planning is building up an expanding body of approaches (ideas, practices, attitudes), taking into account physical, social and temporal contexts. These approaches are evidently change-oriented.

Leonie Sandercock stresses that stories are of essential nature in planning, and qualifies crucial factors: organizing hope, negotiating fear and mediating memories (Sandercock, 2003). Indeed, the challenges ahead of us demand drastic changes. No-one knows their precise nature and impact. Such changes of existing socio-spatial regimes inevitably will meet resistance, inspired by fear for (drastic) change. Overcoming this resistance implies an expanded language of planning (Sandercock, 2003: 221). Evidently this language should acknowledge not only knowledge, but also emotions such as desire, anxiety, relief, etcetera. Stakeholders need to be convinced that improvement is possible. Moreover, they have to believe that their engagement matters and will contribute to change. Thus stories need to be able to express rational as well as imaginative dimensions.

A language for collective imagination

Like a language, stories need to be shared in order to be productive. Effecting complicated changes, such as building cities and developing regions, asks for an adherence to shared myths (Harari, 2018). Such shared stories enable large groups to plan and implement complex tasks, by collaborating in a flexible way, adapting to circumstances (Harari, 2018: 46). Collective imagination, as a concept, encompasses all this. “In every community or group of people exists a *collective imagination*, i.e. a set of symbols, customs or memories that have specific meaning to it and common to all the people who are part of it.” (Wiki Didactic, 2015). Examples are dominant religions, their holy stories, values, symbols and history to the extent they are well known.

Imagination is essential. In order to initiate change, planning stories need to allow actors to create a world that looks different from the world that exists. *Imagination* is often linked to creativity. It is the capacity to represent (an image of) something which is not present (Arendt, 2016: 242). Scholarly articulations of Arendt’s conception of imagination include: “the capacity to represent the perspectives of other people in our mind, the capacity to represent in our mind an object that is not present, and the capacity to imagine a new reality in place of the one that exists” (Tyner, 2017: 523). ‘*To imagine*’ thus stands for the process of (re)calling impressions and experiences of objects, persons or situations, and of creating new ones in the mind’s eye. We use the term ‘*imagining*’ for the act of creating mental ‘*images*’. The term ‘*imaging*’ stands for ‘idea formation’, the “actual

durational experience of mapping, drawing, modeling, and making as a generative sequence in creative thinking” (Corner, 1999: 246). The resulting constructed concrete objects or representations can be called ‘pictures’. Creating and representing new futures, as essential processes of innovative urban renewal projects, thus are very much depending on imagination.

While imagination is essential, a collective dimension is crucial. Transition thrives on effective changes of behavior by many actors. Urban transformation is city-making, which always implies interventions of many actors in public spaces. To push for a mental and behavioral shift of local actors is one thing; to redirect their different perspectives along a similar line of flight is much more difficult a commission. Whenever their imagination is a collective imagination, it will perform better in the service of urban transformation. Co-oriented imaginations and imaging will contribute to the coherence of interventions. The way we imagine our environment is decisive for the way we see it, conceptualize it and make it (Corner, 1999). Therefore this collective dimension of imagination is crucial, and needs to be taken care of. According to Arendt (political) judgment and action rely on a collective dimension. Imagination is instrumental in mobilizing the capacity of *sensus communis*. This sense – the effect of reflection on the mind – links an actor’s judgment to opinions of others (Arendt, 2016), by subjecting his ideas to the possible judgment of others (Tyner, 2017: 523). Reflecting on the imagination of other actors’ opinions is called ‘enlarged thinking’. Arendt’s *sensus communis* enables such ‘enlarged thinking’ which is the condition for a just judgment, constructed relatively unbiased via imagination and reflection (Schreurs, 2019).

In any real process of urban transformation, three questions are on the collective agenda: What do we want? What can we want? What will we do? These questions imply the need for a three-fold capacity: cultural imagination, designerly research and political decision-making (Brugmans, 2016). Those capacities energize innovative, reframing ideas, produced by imaginations of many and diverse actors. ‘*Imaginaries*’ – imagined representations of the future (Hajer, 2016: 78) – play a decisive role in reframing as a prerequisite for potential transformations. Maarten Hajer coins such a transformative vision as ‘*thought-image*’: a shared perspective on the world, which enables common practices, together with a commonly supported feeling of justice and goal-orientation (Hajer, 2016: 78). Similar to ‘eidetic operations’ (Corner, 1999), thought-images share the aim to create a connecting dimension by means of a collective imagination covering thinking, feeling and making.

Explorative research into thought-images

Summarizing: making community development the corner stone of a transformative planning approach, implies the need for constructing an expanded language, mobilizing stories that serve and (re-)produce a collective imagination of thought-images as imaginaries of an alternative world. We now understand what collective imagination is and why it is of crucial importance. The next question is: how can it be produced or stimulated? This raises new questions: Which kinds of thought-images are able to express clearly the meaning and ambitions of transformations aimed-at? Which actors can imagine such alternatives? Which imagining and imaging can help to translate thought-images of change into effective implementation?

We consider these as guiding questions in our explorative research for the characteristics of transformative thought-images, as well as for their meaning and importance. This research will be approached by analyzing a case. An illustrative demonstration can be found in cases of ‘concept grant’, used as an instrument of Flanders’ Urban Policy. Why? As will become clear in the next section, there are three important arguments. Processes initiated by Urban Policy administration are oriented to urban change (Loeckx, 2009). More specifically, concept grants have urban reframing as a main goal. Finally such reframing is combining triple characteristic: innovative concepts, action and implementation-oriented, anchorage in local processes (Schreurs, 2018). A transformative ambition, a conceptual focus and implementation at the horizon seem to be excellent starting points for an exploration into transformative thought-images. We first explain the approach of concept grants and its context. Next we focus on one specific good practice in order to learn how collective imagination is

coproduced in practice. The final section concludes on characteristics of structure and sharing of thought-images.

Learning from Urban Policy concept grants

Urban renewal as capacity building

Announced as ‘White Paper’, as a visionary document preceding concrete goals and actions, the book *The Century of the City; City republics and grid cities* (Boudry *et al.*, 2005) marked a decisive turn in Flanders’ urban renewal. The new approach can be marked as project-based co-production. Renewal of the city hardware was thought of as an alternative for direct support for soft interventions within deprived neighborhoods. As such it was controversial. Years after the start of this new urban policy, critical voices were still being raised, but concrete results and shifts in focus made discussions gradually more nuanced and productive. Amongst the most important shifts we consider: more attention being paid to social aspects of sustainability and development, and a more explicit focus on citizen participation. The responsible administration in Flanders, the then newly founded Team Urban Policy (part of the Agency of Home Affairs of the Flemish Government), was inspired by multidisciplinary reflection. This led to amending a pure project-based approach (Loeckx, 2009). A multidisciplinary jury judged, using clear and coherent criteria for ambitious qualities. Co-production had to involve not only local government and private developers, but also a broad scope of stakeholders and designers. An important goal of the new approach was to use co-production of urban renewal projects for local capacity-building in favor of directing complex projects. One can argue that this succeeded quite well, as can be judged from a growing number of speech-making projects and processes (Loeckx, 2009; Cherroud) (one of which will be discussed at length).

Urban Policy instruments

An appealing instrument, created by the Urban Policy Team is the *project subsidy*. It can be awarded to 35 Flemish cities if the following conditions are met: socio-spatial qualities, co-creation and direction by the local government. This subsidy is meant to contribute decisively to investments in innovative urban renewal projects, which have to function as a lever for a neighborhood’s potential and to increase its living qualities in a meaningful way (VLAAMS STEDENBELEID). Key-aspects that need attention are: a sharp project-definition, capacities needed to translate this into effective realization, relevant development-coalitions and processes (Loeckx, 2009).

Apart from this project-subsidy, a concept grant is made available by the Team Urban Policy. The subsidy is meant for hiring expert assistance from a multidisciplinary professional team. The award includes support from a Direction Team of experienced professionals and academics. The main goals are similar to those of the project-subsidy: to contribute to community-shared innovative and sustainable answers to crucial challenges, seen from an urban perspective. A specific goal is to stimulate capacity building on how local governments can play a directing role when the situation (conditions and opportunities) for renewal are still unclear or even inchoate. Such conditions need innovative (re-)framing. Therefor the instrument is geared to develop concepts which help to simultaneously diagnose, test and discuss alternative futures and means for implementation. Concepts result in new perspectives on possible and feasible change-trajectories. Depending on case and context, the contours of these concepts can be an inspiring project-definition, a visionary brief, a program for a civic debate, a set of urban manuals... The history of the tool concept grant displays an evolution from designerly exploring possible spatial interventions, towards primarily socio-spatial inquiring into possible answers to social challenges, starting from concrete places and crucial coalitions. Concept grants thus play a double role: locus for conceptualizing local urban transformations, and breeding-ground for continuous re-conceptualizing urban renewal. These are favorable prerequisites for analyzing a case of transformative thought-images produced co-creatively.

Learning from a case: from coal track to multi-productive trajectory

With Peter Murphy's endeavor to explore the social foundations of imagination and its collective expressions (Murphy, 2012) in mind, this section analyzes a case, illuminating problem and context, conceptual re-framing by innovative metaphors, and the co-creative process.

Need, demand, desire

Two years ago a concept grant labelled 'Multi-productive coal track' ('*Multiproductief Kolenspoor*') reported on its hope-giving results (plusofficearchitects *et al.*, 2016). The study starts from an *objet trouvé*: an old railway track formerly interconnecting three mining sites and a harbor. The railway track is used-up and still functioning only very partly. Thus futures-to-be-found for that infrastructure, should be useful and concrete. Most important however, the re-conceptualized track should serve as a catalyst for the future of the whole city of Genk. This former coalmining city is in need of new development perspectives urgently. Indeed, after the closing down of its coalmines in 1987, its next major economic motor, a huge FORD-automobile company plant, also left the local scene in 2014. A multi-disciplinary team of urban designers (Plusoffice), landscape architects (DELVA), and socio-spatial experts (Social Spaces - University of Hasselt) was invited to figure out how this mono-functional infrastructure could function as a multi-productive network. This resulted in an inquiry of the potentialities of diverse productive scenarios, as well as their transduction into concrete coalitions, prepared for realizations. Its explicit ambition was to build upon existing initiatives and actors, and to scale those up towards an innovative multi-productive socio-economic model.

At the moment the process of the concept grant started, it was impossible to clearly articulate the question 'which future suits Genk-in-crisis best?' The majority of the population still fell rather at ease due to an active branding by the city government, as a creative hub with a shared spirit, driven by an imaginative verb: 'to Genk'. The important underlying question – How can we think, develop and secure Genk's future? – was rather formulated as hope by the local council: 'The coal track together with the adjacent old mining sites seems to have capacities to function as a structural basis for future urban developments' (CITY OF GENK, 2014). Hope expresses desires; desire is the result of a 'lack', originated from the imploded mining industry and the empty FORD-factories. As we know, it is quite hard to articulate desires clearly. Expecting that an imaging_concept study would meaningfully contribute to such an articulation – content-wise and in terms of process – was not farfetched.

Moving, connecting, collecting

In line with these expectations, the multidisciplinary task-force tried to reframe the 'space' of the old coal track. The physical space is a linear trace through the landscape, sometimes a cut-through, sometimes elevated, filled with remnants of the former use, limited by expanding adjacent occupations, heavily fragmenting the landscape. Although out of sight and out of heart for most inhabitants, this space is also a mental trace connecting the industrial past, the present-in-crisis and the hopeful future. Research, reflections and discussions with stakeholders (city councilors, administrations, civil society, economic actors, experts) were synthesized in three scenarios for 'thematic trajectories': Experiential Green Belt (*Landschapsbelevingspark*), Production Loop (*Productielus*) and Recycle-machine (*Kringloopmachine*) (as represented in Figure 1). Partly inspired by historical and contextual opportunities, but soaked with a 'next economy' philosophy (Ruimte Vlaanderen *et al.*, 2016), these verbal images for a multi-faceted re-use of the track-space, express how the decrepit track could strengthen local resilience. It could enable recreational access to a beautiful undulating landscape of small creek valleys. Inner- and intercity connectivity for innovative modes of transport could be improved, thus helping to reduce the now excessive regional car-mobility. Alternative energy-concepts, based on circularity instead of (the former) extraction, could strengthen the weakened economic tissue. The capacity of these verbal images to tell a

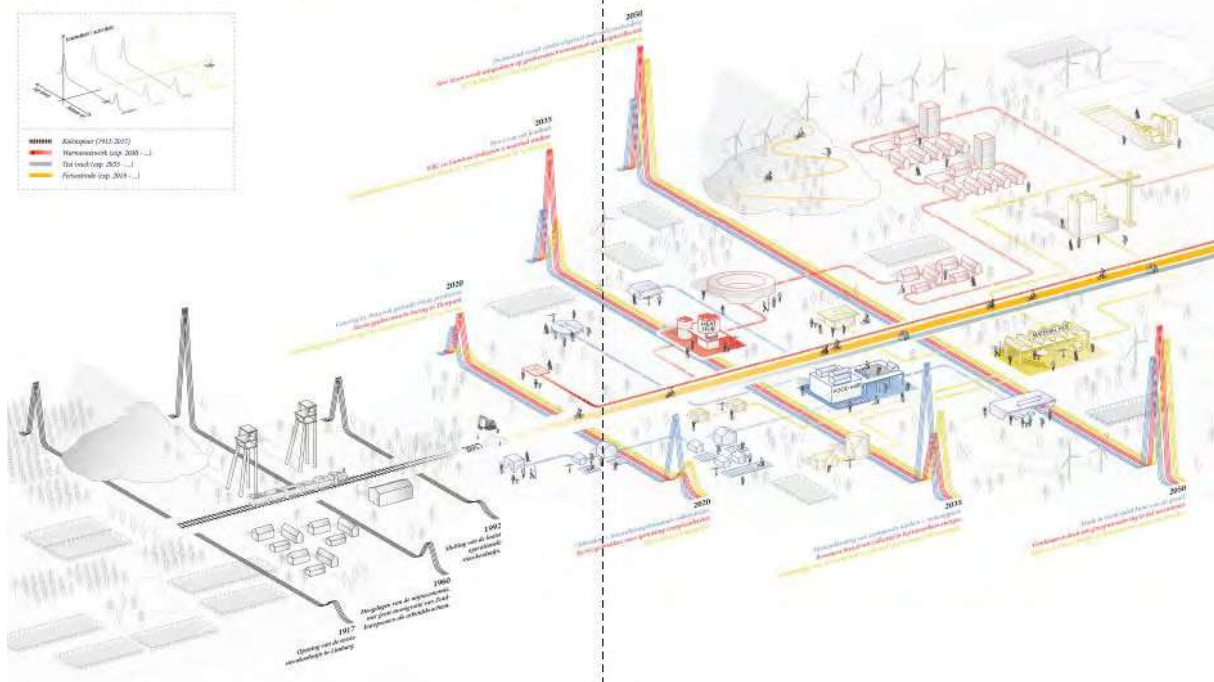

Figure 2: Idealized possible evolution of three coinciding trajectories and workstations, projected on the space of the former coal track, being instrumental to an evolving metabolism which is fed by formal and informal activities, becoming more intensive over time.

Imagine, develop, test

The process of the inquiry is structured into three phases (as schematized in Figure 3). ‘Processing’ (*Verwerken*) of multi-various data collected by fieldwork and desk-top research, means analyzing inventories (of study reports, plans, projects, actors), data-mining focusing on productive structures, mapping of physical and social phenomena, and experiences from an existing living lab exploring local capacities. ‘Projecting’ (*Projecteren*) synthesized six preliminary hypotheses concerning the future of the coal track into three trajectories (as thematic scenarios for the future) and three workstations (as building blocks for those scenarios). Finally an ‘entrepreneurial’ phase (*Ondernemen*) brought these concepts to the level of live tests and action plans, performed by preliminary coalitions.

Figure 3: Three phases of the concept grant process (processing, projecting, undertaking) interrelated by two sets of test-labs.

These three stages are interrelated by two sets of test-labs (*Toetsingslabo's*). These serve to bring the hypotheses together – conceptually in trajectories and workstations, literally by stitching patches into a quilt (as can be seen in Figure 4) – discuss and reformulate these, in order to be tested with and by already engaged and interested stakeholders. The first test-labs resulted in the thematic trajectories already mentioned. As ‘what if’-scenario’s they were appreciated for their capacity to link and to integrate. Imagining the future coal track as workstations on a multi-productive trajectory worked as an invitation to project diverse initiatives onto and nearby the track space. As such many actors could be identified and stimulated to participate and meet, to think collectively and to design collaboratively. The second set of test-labs developed the workstations as concrete emanations of alternative socio-spatial futures of the coal track. Stakeholders from the urban productive community collectively re-conceptualized, developed and tested the hypotheses about the workstations against possible and feasible coalitions (mixture of small and large players), territorial distribution (concentrated or dispersed connectivity), intensity of connectedness to the track (adjacent or as window of a distant company seat). Combinations of diversities were always an important and explicit goal, because aiming at a robust platform for concrete initiatives. Actions were considered as a route towards governance of the coal track, but even more to excite and to inspire local entrepreneurs.

Co-creation for co-orientation

The imaging structure of a thought-image

The collective imaging of three trajectories and their workstations results in a complicated but productive thought-image. The catchy titles (the themes) attract attention. They imagine a possible future, dealing with present issues, building on assets from the past. The given labels (Experiential Green Belt, Production Loop, Recycle-machine) sound strangely familiar: common language uncommonly used. As such, these offer holds for specific ideas and reactions, but also invite (re-)interpretation. Thus they open an arena for suggestions, reflections, discussions, considerations... and organize group discussions.

Graphically the content of the themes is suggested by means of multiple small schemes and diagrams. Those schemes are imaging different sectors and related aspects. The Experiential Green Belt is for instance elaborated into six drawings (Figure 5). Each can be read as a story which adds meaning to the theme, c.q. the larger story. This helps to imagine one trajectory as multiple possible trajectories. Thus the drawings actualize the multi-productive aspect of the trajectory once more. Additionally, the drawings play with similarity and dissimilarity. Within the six stories of the Experiential Green Belt, functionally and affectively a cluster can be discerned composed of ‘small-scale’, ‘recreation’, ‘bicycle culture’, ‘green belt’, ‘landscape’, ‘ecology’, while ‘attraction pole’, ‘food-project’, ‘cycle infrastructure’ rather seem to belong to different sectoral domains. At the same time these more technical terms prepare the soft green belt to couple with the two other trajectories/themes, thus reinforcing the multi-productive mission.

Figure 5: Six schemes imaging the rich content of the trajectory Experiential Green Belt.

Together, the three trajectories and their work stations produce a multiplicity of imaginative ideas. The combination of catchy but intriguing titles, rather simple schemes and diagrams, as well as concise phrases offers a thought-image which is accessible and recallable, and thus easy to share and to distribute. This format of ‘thought-image’, combining *inscriptio* (titles), *pictura* (pictures) and *subscriptio* (captions), is well suited for

conveying critical, transformative content (Richter, 2007), in this case an alternative socio-economic model for the city (cfr. Figure 6). This format also helps to grasp essential meanings, without the need to name those explicitly (and thus reducing the meaning more often than not). The ideas produced and the way of representing those is similar to what James Corner calls “an aesthetics of invisibility, a perception of essences. Speech, verbal description, gestures, and other rhetorical figures conjure up such otherwise invisible images, allowing one to see an idea.” (Corner, 1999: 247). Paraphrasing Corner, we state that “imaging, understood as idea formation” is integral to the conception and practice of the thought-image produced. The ‘multi-productive coal track’ is a crucial imagination for a transformational turn. This ‘multi-productive coal track’ is also a collective imagination. The focus on the coal track as connecting and collecting public domain, is appealing to many and diverse stakeholders. The overlap of several trajectories on one track adds arguments such as efficiency, feasibility, cooperation, intensity... which are valuable for different city-makers. Moreover, thematic associations with the bucolic regional landscape, the heroic historical production-capacity, and the promising new recycling machine touch affective registers and thus the readiness to act.

Figure 6: Three schemes representing the search for alternative socio-economic model, underlying the collective story of imaging a transformative thought-image for the coal track.

Sharing thought-images

While thought-images are crucial instruments to change a regime (Hajer, 2016), they need to be shared in order to be productive in a context of spatial planning. The concepts developed to frame the coal track as a multi-productive network, possess characteristics that will help: articulated representation, appealing to ratio and affect, and a critical attitude inspire many stakeholders. This seems to be confirmed by the number of stakeholders and more importantly by their participatory intensity. The fact that the mayor asked the multidisciplinary team to produce a note which could explain the thought-image during a talk in an elevator, is a strong indication that the local government is strongly supporting the idea of sharing. The idea of a multi-productive network also helps imagining the concept of ‘grid city’ (*Rasterstad*) which is the shared dominant socio-spatial concept for the future development of the whole city. This confrontation of a general, city-wide concept and a pre-proposal for projects invites citizen to debate these views of the future.

Institutional links between the concept grant and broader planning initiatives result in even more occasions to help share this thought-image. The timing was for instance perfectly attuned to a sub-process of the Spatial Policy Plan Flanders (*Beleidsplan Ruimte Vlaanderen – BRV*), which started in 2014, and to which the concept study contributes concreteness, tangible scale and assessments of stakeholders. Next, as a follow-up, of this *relance* of the BRV, a regional strategic project was mounted and approved for funding, while the city of Genk and the province of Limburg activate and co-coordinate its work. The results of the concept study were also

displayed at the International Architecture Biennale Rotterdam (IABR 2016), primarily reaching peers. On top of this, most of these initiatives connect in one way or another to a so-called territorial development project (T.OP) for the province of Limburg, which researches the assets of space in terms of regional socio-economic development.

The most concrete occasions to share opinions are structurally linked to the co-creation process of the concept grant. The imaging-process and the twofold intermittent design and deliberation in ‘test-labs’ happened in collaboration with the living lab ‘The Other Market’ (*De Andere Markt*). Already functioning before the concept-study, this organization is networked well locally. Thus it could, and still can, identify, activate and connect diverse groups, over a longer period of time. During the concept study, the living lab opened up this network, amongst other things by the collective making of a tapestry, imaging the three thematic trajectories and workstations, and using this as a medium of collective participatory design (as seen in Figure 4).

Coda

It would be arrogant to state that choices for new futures of the coal track are secured and that necessary changes of behavior are guaranteed. They are not. Nevertheless one can observe many signs of sympathy and interest of inhabitants and stakeholders: the mayor asking for a promotion-note which can help sharing the thought-image; the aldermen engaging in inter-sectoral deliberations during the process; stakeholders already exploring potential coalitions during the test-labs and the making of an action program; new contacts being established and routes for cooperation being explored; coalitions becoming already active, e.g. in launching a food-cooperative; effective coproduction of collective mock-ups that pre-figure future workstations. It is clear that this imaginative process of concept grant is hitting the imagination of many. The collective re-framing makes stakeholders ‘see’ the potentials of a unique new public space. They can feel how new collaborative coalitions can lead to effective change. They can imagine a different future and the capacities needed to bring it into reach. They incorporate imaging a thought-image while collectively creating, testing, refining and actualizing it.

Whether this thought-image will be able to generate more and more enthusiasm, whether more stakeholders will be prepared to share their engagement, whether all will be or stay motivated to evolve into the same direction, whether inspiration will stay ahead of transpiration... is not certain at all. But without doubt, the contours of the desire to act became imaginable. Behavioral change obtained a lively line of flight.

Acknowledgements

As a member of the ‘direction team’ installed by Flanders’ Urban Policy Administration, I like to express my gratitude to my colleagues of the Team and to the multidisciplinary team of experts who have been working on the concepts study *Multiproductief Kolenspoor Genk*. Our many discussions have contributed in a significant way to the ideas in this paper.

Street-Level Democracy?

Urban professionals as participatory innovators in neighbourhood planning processes

Jelle van Aanholt, Gideon Spanjar*, Karin de Nijs, Frank Suurenbroek and Stan Majoor¹

Amsterdam University of Applied Sciences (AUAS),

Research Program Urban Management

Abstract: In 2017 the municipality of Amsterdam launched a programme to combat a housing shortage and realise ambitious societal goals for 32 of its most deprived neighbourhoods. After decades of urban renewal projects, these areas still scored poorly on most socio-economic indicators. The programme aims to develop more affordable housing for low- and middle-income households, to revitalise the existing public spaces of these neighbourhoods and to improve the residents' socio-economic position. In addition, the progressive municipal council installed in 2018 intends to democratise urban renewal processes with the aim of increasing community involvement.

The first phases of the urban renewal programme have now been completed and the 'street-level bureaucrats' involved adopted the democratization agenda. The focus has shifted to the challenges these bureaucrats face. To identify the key challenges confronting them during the participation process, 30 qualitative interviews were conducted. In partnership with the municipality, the AUAS also developed a community of learning with street-level bureaucrats who work in the designated neighbourhoods by organising monthly learning sessions. These

street-level bureaucrats work at the nexus of new participatory ambitions and ossified municipal bureaucracies. They are constantly searching for shortcuts within planning procedures to ensure that citizens' needs and ideas are incorporated in the plans they develop. Their disruptive interventions potentially reveal effective pathways for democratic community-based development.

Keywords: street-level bureaucrats, deprived neighbourhood, disruptive interventions, urban renewal

Introduction

In 2008, a national urban renewal programme was launched in the Netherlands, aimed at revitalising the most deprived neighbourhoods across the country. The programme included seventeen neighbourhoods located in Amsterdam. In line with the planning paradigm of that time, project-based planning was used to combat socio-economic and spatial problems. These redevelopment projects were systematically monitored between 2008 and 2012, and this showed that the expected improvements had not played out as intended (Permentier, Kullberg and Van Noije, 2013; Koster and Van Ommeren, 2018).

In line with a decentralizing trend, a new national coalition government stopped national funding for local regeneration programmes in 2012. However, as most deprived neighbourhoods in Amsterdam were still suffering from socio-economic problems, the capital city presented its own local programme of urban renewal in 2017. This time, 32 deprived neighbourhoods in the city were designated as Developing Neighbourhoods ('Ontwikkelbuurten'). They are located in the districts of New-West, South-East and North ('Nieuw-West', 'Zuid-Oost' and 'Noord'), and also include the 17 neighbourhoods selected for

the national round of urban renewal in 2008. Four interbellum neighbourhoods within the city's ringways that were included in 2008 were excluded from the current programme. Consequently, the new programme mainly focuses on post-war neighbourhoods in the city's periphery (see figure 1).

Figure 1 The 32 'Developing neighbourhoods' in Amsterdam.

In 2018, with the arrival of a new progressive municipal council, the Developing Neighbourhood policy was coupled with the city's new Democratization Agenda. It became an official policy goal to 'develop a new way of working in which Amsterdam's residents are involved in making and implementing policies (Gemeente Amsterdam, 2019). This new focus on 'democratization' is not unique to Amsterdam. Cities in the Netherlands and abroad increasingly aim to develop new forms of citizen participation via more direct forms of democracy. This can be seen both as a response to perceived public hostility and existing

representative policy-making as well as an attempt to mobilize citizens' perspectives and local knowledge, ideas and initiatives in creating more responsive policies (Tonkens et al. 2015).

This paper analyzes the intersection between the policy ambitions for more democratic planning and the practice of urban renewal processes. The shift towards more democratic planning is challenging for two main reasons. First, involving citizens with a weak socio-economic position is traditionally complex (Tonkens and Verhoeven, 2018; Oude Vrielink 2017, Bovens and Wille, 2017). Second, the democratization of existing (and strongly criticized) 'consultation' practices poses new challenges to local government officials (van Stokkom, 2006). It is unclear to what extent the intricate bureaucratic machinery can, and is willing to, open up to and implement politicians' ambitions in these complex neighbourhoods.

In this paper, we focus on the challenges facing local government officials involved in implementing the ambitions for democratic urban renewal. They are street-level bureaucrats, operating at the nexus between ambitious policy goals and practical day-to-day reality. Based on their experiences, we investigate the current (im-)possibilities for democratic innovation in the practices of neighbourhood renewal.

Street-level Bureaucrats

Coined by Michael Lipsky in 1980, street-level bureaucrats (SLB) refers to (local) government officials who are in direct contact with citizens, working at the crossroads between government and the public (Lipsky, 1980; Brodtkin, 2012). Lipsky's work highlights government officials as actors making tough choices, instead of portraying them as involuntary cogs in a bureaucratic machine. Viewing government officials as dynamic actors sheds new light on policy implementation. Lipsky and others have shown that SLBs often have a significant amount of

discretionary power when implementing policy, especially when that policy is both ambitious and vague (Brodkin, 2012, 2). Therefore, ‘the decisions of street-level bureaucrats, the routines they establish, and the devices they invent to cope with uncertainties and work pressures, effectively become the public policies they carry out (Lipsky, 1980, xiii). The effect that policy has on the street, is in effect, a compromise between policy-as-planned and the complexities of society. Using their discretionary power, SLBs constantly negotiate and re-negotiate that compromise.

When the ambitions for democratic urban renewal are viewed through the lens of street-level bureaucracy, it seems likely that the operationalization of these ambitions falls to the ‘street-level planners’ – the local government officials who engage with citizens to inform them of and improve plan-making. What does this mean for the intended transition towards democratic planning? We offer two hypotheses: one pessimistic, the other optimistic.

Lipsky demonstrates that SLBs often lack the time and resources to systematically implement policies as they were intended. Instead, they tend to develop so-called *coping strategies*, reducing policy ambitions to box-checking exercises. This effect is familiar to scholars of interactive and democratic planning (van Stokkom, 2006). However, transition theory suggests that discretion can also work differently. A more optimistic hypothesis is that the discretionary space resulting from the vagueness of democratization ambitions offers street-level planners new *niches* to experiment in: together with citizens, they can find *new ways of planning* that better fit with the changing landscape. These experiments with street-level planning might, in turn, disrupt and change the existing planning regime (Geels and Schot, 2007).

We will investigate both hypotheses in the context of planning practices in Amsterdam. The experiences of two ‘street-level planners’ are used to demonstrate the challenges SLBs face when they attempt to implement democratic planning policies in their urban renewal projects. What kind of strategies do they use to navigate the complexities of citizen-centred planning, and to translate citizens’ ideas and interests into professional, sequential and hierarchical municipal planning processes? Are they only *coping* mechanisms that turn democratic planning into box-checking exercises, or do they carve out *niches* of innovative planning practice?

Method

Building on our empirical action research we reflect on the current urban renewal planning processes. Since 2017 the AUAS has collaborated closely with the municipality of Amsterdam to evaluate and innovate the participation processes of the ‘Developing Neighbourhoods’ programme. Initially, 30 qualitative interviews were conducted with practitioners who were active in 10 of the 32 Development Neighbourhoods. Using these interviews, we identified key challenges facing the practitioners from the three district of South-East, North and New-West Amsterdam (van Aanholt et al. 2019 and Spanjar 2019 et al.).

In the middle of 2018, the AUAS developed a community of learning to address these challenges. At least 15 civil servants participate in monthly thematic sessions. Most of them are street-level bureaucrats in the sense that they work directly with citizens. Based on these thematic sessions, the case studies for researching democratic planning are identified for further investigation. Using ethnographic methods, an in-depth analysis has been conducted in four projects. In these cases, AUAS researchers participated in the street-level planners’ daily routine, for example, by attending participation meetings with residents, joining SLBs in the

daily round through their neighbourhood, and attending internal team meetings. Two of these case studies are presented here: the renewal of a public space in the Venserpolder neighbourhood in Amsterdam South-East, and the redesign of a park in the Eendrachtshuurt neighbourhood in Amsterdam New-West (see figure 1 for their locations).

In both cases, the study's limitation in terms of scope and time makes it impossible to reach a definitive conclusion in relation to the hypotheses posited above. Yet the case studies can serve as a first exploration of these hypotheses. They can be considered as extreme cases for the democratization of planning: the redevelopment of existing neighbourhoods is complicated and is always accompanied by competing interests and positions, both between residents and other groups and between the municipality and citizens. Moreover, democratic redevelopment plans for deprived neighbourhoods are even more complex because they have to deal with a population that is notoriously difficult to reach and involve. Below, practitioners' names have been changed to protect their privacy.

Learning by doing: two practitioners' stories

Case: Venserpolder

James is an assistant project manager for the Venserpolder neighbourhood in Amsterdam's South-East district (see figure 1). This district is dominated by Bijlmermeer, which was first conceived in the 1930s as a new, fully planned district that complied with the CIAM's Modernist principles. Bijlmermeer was constructed between 1963 and 1975 and consisted at the time of high-rise flats organized in a characteristic hexagonal grid (Van Beveren, 2014). However, the high-rise dwellings proved to be less popular than expected. Even before the construction of all the planned flats had been completed, residents complained about the monotonous architecture, the eerie emptiness of the public space, and the lack of amenities.

Many of the new dwellings were left vacant. The promised metro line connecting Bijlmermeer to Amsterdam was not completed until 1977. By then, crime, drug use and poverty had risen dramatically. In response to the disappointment of Bijlmermeer, later parts of the South-East district were constructed according to a different planning philosophy. Venserpolder, constructed in the 1980s, is situated to the north of Bijlmermeer and is characterized by 5,000 low-rise apartments surrounding green courtyards and a mix of residential, traffic and work functions. In 2018, when the case study was carried out, it had 9,656 residents, one-third of whom were unemployed and live on benefits (compared to 18 per cent in Amsterdam, OIS, 2019). Venserpolder is one of the 32 neighbourhoods designated for urban renewal in the 'Developing neighbourhoods' programme.

In 2018, prior to making major investments in public housing renewal, Amsterdam invested in improving public spaces in the Developing Neighbourhoods. James is employed by an external project management agency and he was contracted by the municipality to manage the urban renewal programme in this area. His task was to design easily implemented interventions in public spaces together with the residents of Venserpolder and the H-neighbourhood. The municipality emphasised that residents' involvement was essential, and that the interventions should be completed by the end of 2018. Faced with time constraints, James was unable to carry out all the essential participative processes with residents himself. Furthermore, he was unsure of the best approach for involving residents in quick-fire neighbourhood renewal. James decided to work together with two different partner organizations within his two designated neighbourhoods.

In Venserpolder, James decided to work with social design startup Plygrnd.city. Plygrnd.city takes an unorthodox, informal approach to participation, with roots in advertising, social work and street art. Instead of inviting residents to participation evenings, they placed a shipping container in a central location in the neighbourhood. Plygrnd.city offered passers-by a lounge

chair and a drink, and engaged them in conversation. In addition, design games and neighbourhood walks were organised from the container. In total, after one month, an estimated 400 residents were involved. The process resulted in a booklet containing 12 sketch designs based on residents' ideas for 'quick win' interventions in public spaces in Venserpolder. Because of the container's central location, the project reached residents whose challenging socio-economic status meant they probably would not have attended scheduled consultation meetings about urban renewal.

The project leader was satisfied with the pace and reach of participation. However, the unorthodox nature of the process also meant that the local government officials who are normally tasked with designing and maintaining public spaces were only marginally involved in the participation process. They were confronted with the fixed outcomes and not open to supporting the ideas developed by residents. Yet it was they who had to approve and develop the residents' ideas. James found that several of the ideas conflicted with sector-specific standardized regulations. For example, one of the ideas involved using street art to make a bicycle path safer. However, the municipal transport authority does not allow street art on bicycle paths and their expert pointed to reports that showed the negative effects of street art on traffic safety.

Another example is the placement of wooden picnic tables in a public space to facilitate spontaneous meetings between residents. This did not sit well with officials in the city's maintenance department, who objected that wood is a high-maintenance material and that the tables could be burned or stolen: 'they only wanted stainless steel'. James spent the next month in a series of meetings with local government officials to discuss the feasibility of the plans: he in effect became an advocate for the residents' ideas within the municipal organization. At this stage, residents themselves were no longer involved. Partly due to James's effective internal lobbying, most of the ideas were eventually approved, albeit in trimmed-down versions.

Reflecting on the process, the project leader remarks that it felt like a ‘battle against the system’: ‘We have organized an alternative form of working with citizens – that was our mission. But for this way of working to become the new standard, the internal systems of the municipality also have to change. We need a way of working that isn’t based on reluctance.’ However, this example also points to the essential efforts of planners to align citizens’ ideas at an early stage of the process with standardized rules and legislation.

Case: Eendrachtspark

Eendrachtspark is situated in Geuzenveld-Slotermeer, a neighbourhood that is part of Amsterdam’s New-West district (see figure 1). Like Bijlmermeer, Geuzenveld-Slotermeer was first planned in the 1930s and constructed in the 1950s. Unlike Bijlmermeer, Geuzenveld is based on a ‘garden city’ plan: self-contained units of low-rise portico flats surrounding green courtyards, separated by green belts. The urban plan was a response to the chaotic, polluted and dense working-class residential areas in the city centre and it was the dominant planning paradigm at the time. Workers needed dwellings with daylight, (fresh) air, and space. As part of this philosophy, every neighbourhood in the new district needed its own park.

Similar to Bijlmermeer, the popularity of Geuzenveld-Slotermeer steadily declined in the decades after its construction. In 2018, it contained many of Amsterdam’s poorest neighbourhoods - 14 of the 32 neighbourhoods designated as ‘Developing Neighbourhoods’ are situated in Geuzenveld-Slotermeer. Eendrachtspark borders on the Van Deyssel neighbourhood, which in 2018 had the lowest quality-of-life ranking in Amsterdam (OIS, 2018).

Peter is an Area Support worker for Geuzenveld’s Area Support Team. The Area Support Team is the municipality’s first point of contact for neighbourhood residents. Peter’s tasks include

supporting citizen initiatives. Before he became an Area Support worker, he worked for the municipality's project management agency for two years. In early 2018, he was contacted by a resident who had a plan to renovate Eendrachtspark. The resident launched a campaign on a website intended for the aggregation of citizen initiatives: 'de Stem van Nieuw-West' (the voice of New-West). On this website, residents can propose ideas for their neighbourhood and vote on ideas submitted by others. The Nieuw-West district council is committed to discussing the most popular plan every month. The plan for the renewal of Eendrachtspark received 1,032, and the resident pitched his ideas to the district council in March 2018.

The council responded positively to the resident's plan and tasked Peter with investigating its feasibility. The 'Stem van Nieuw-West' website does not have its own budget. Peter therefore linked the plan to the Developing Neighbourhood's budget for improving public spaces: the same budget that paid for the interventions in Venserpolder mentioned above. This meant that funding was now available for the renovation of the park. However, the funding came with conditions: the park had to be redesigned in cooperation with local residents, and it had to be finished in 2018. Peter quickly discovered that no one at the city's planning department had time to work on the park at short notice. Their response, in Peter's own words, was: 'No request for capacity has been made in advance, so we cannot help you. We could help you in 2019'.

Instead, Peter decided to hire a local landscape designer, who was also a resident of the Eendrachtspark neighbourhood. Officially, this was not permitted: external design work must be assigned in open tenders. However, the park had to be finished in 2018, which left no time to put out a tender. Peter framed the assignment as 'participation advice' instead of as 'design'. This meant he could circumvent procedures and pay the designer from the Developing Neighbourhoods participation budget. The park re-design started in June 2018.

Peter and the local landscape designer quickly assembled a group of 18 'park ambassadors': residents who would take part in the park's renovation. The designer invited the park

ambassadors to his parkside apartment for three rounds of iterative feedback on his designs. Between rounds, Peter sent the plan to the municipality to check if it complied with regulations, and was advised that it did. Within two months, the designer submitted his definitive design to the municipal government. Peter noted that ‘partly because he could do both participation and the design [the landscape designer] was able to work much faster than our own designers would have’. However, the scope of participation was limited by time constraints: only a small group of residents was involved and, although they provided feedback, their creative involvement in the design was limited.

In compliance with the municipality’s planning procedures, the plan’s final design, maintenance plan and total costs had to undergo a final check by several experts from the municipality. None of these experts was available at the time, which delayed the project by several weeks. When the results of the checks became available, they showed that several elements of the plan would be difficult to construct. Without informing and involving residents or the local designer, the plans were adjusted to comply with the regulations. The redesign of the park was completed in early 2019.

Discussion and Conclusion

Amsterdam initiated an ambitious urban renewal programme for 32 of its deprived neighbourhoods. The municipality also has high ambitions for more democratic forms of planning. However, these ambitions are mostly undefined, leading to different implementations at street level. This in turn forces the civil servants 'on the ground' to deviate from their usual roles and procedures and act like ‘street-level planners’. We hypothesised that local government officials in the front line might respond in two different ways. On the one hand, they might use *coping mechanisms* to formally meet the new participatory demands while

clinging to their usual role and, thus, to the existing institutional norms and procedures. On the other hand, we see early indications that they used the discretionary space resulting from the ambition for increased participation as a niche, where they could experiment with new roles and pathways.

James, assistant project manager for Venserpolder, successfully worked with a company to invent new ways for residents to participate. Due to his lobbying skills, he managed to make other professionals from the municipality participate or at least cooperate. James reinvented and extended his role from only *facilitating* the participation process with residents to that of an all-round participatory process facilitator, mediating between the interests of citizens and those of other civil servants.

Peter, the Area Support worker for the Eendrachtspark renewal, also worked around the current planning regime. First, he enterprisingly linked the park plan to the Developing Neighbourhood's budget and funding, and he had to work within a narrow timeframe as spending had to be approved by the end of 2018. He combined acceleration and participatory planning by involving a local landscape designer, thus bypassing the tender procedures. Peter coped with institutional boundaries by inventing short cuts and bypassing some elements of normal procedure altogether.

The two cases discussed here, Venserpolder and Eendrachtspark, show that these street-level bureaucrats for the most part acted in line with the second hypothesis, aiming to use the discretionary space to invent new solutions. Yet their actions tend to work *around* existing institutional regimes, rather than trying to innovate them from within. For them, bypassing procedures proved to be an effective way to deal with the combination of time constraints and

pressure for democratic planning. The question arises as to whether this type of disruptive behaviour by street-level bureaucrats typifies a larger number of cases and, if so, whether it exerts enough pressure on the current planning regime to have a transitional impact. In other words, how can the SLBs' innovative short-cuts contribute towards democratic planning? Answering this question will require further research. The literature on transition could prove useful. According to Geels and Schot (2007), transitions may be understood as the outcome of interaction between the three levels:

- the landscape - exogenous macro-trends
- the regimes - dominant institutions and practices
- the niches - places of innovative practice

Viewed within this framework, street-level bureaucrats' niche innovations put pressure on the current regime; they may cause destabilization and in turn, create a window of opportunity for niches to grow and disruptive practices to emerge (Geels and Schot, 2007). The decentralization of the urban planning programmes described, as well as the national policy trend towards 'do-democracy' (Nota 'Doe-democratie', Ministry of General Affairs, 2013) and the increased focus on bottom-up initiatives and civic society can be perceived as important landscape trends. The upcoming 'Omgevingswet' further increases the pressure ('Environment and Planning Act', Ministry of Infrastructure and Water Management, 2017): it entails the combination and integration of 23 environmental and planning laws and emphasizes participation as a mandatory element in planning processes. However, one of the major challenges, as the cases demonstrated, is the disconnect between 'SMART-defined' municipal planning processes and local planning practices with their unpredictable timeframes and requirements, which is characteristic of democratic deliberations with the community.

In the second half of 2019, we will continue to analyze the activities of street-level bureaucrats in different cases in the Developing Neighbourhoods and conduct more interviews to analyze whether their pressure on the current planning regime will amount to a substantial transition towards more democratic planning.

Acknowledgements

Amsterdam University of Applied Sciences, Research Program Urban Management collaborates with the Municipality of Amsterdam in evaluating the planning processes for the Developing Neighbourhoods, *in action*. This research project started in November 2017 and will continue until at least 2020. There are three lines of research: 1) embedded research into the planning processes in four selected neighbourhoods; 2) monthly ‘confrontation’ learning sessions with the professionals involved, from street-level bureaucrats to management; and 3) frontier experiments. Max van Engen, director of housing at the Municipality of Amsterdam, has final responsibility for the processes, which are managed by Henriette Rombouts, the deputy director of the Amsterdam Projectmanagementbureau. We are particularly grateful to the street-level bureaucrats for their cooperation.

Planning for transition and the multiple perspectives on democratic legitimacy

Almut Wolff¹

¹*Jade University of Applied Sciences; almut.wolff@jade-hs.de*

Abstract: Connecting transition processes to participation and community planning implies the search for possibilities to reconcile the knowledge driven transition goals with democratic legitimacy. If we understand planning processes as multilateral communication processes we discover multiple interactions of diverse actors, which do not necessarily belong to a definable local community. The actors create a complex network of interdependencies with symmetric and asymmetric power relations.

This paper shows in reference to a case study the different approaches and expectations involved actors have towards planning outcomes and decision-making in a planning process. Within complex actors constellations the legitimacy of representing public interest is claimed by various actors in a field of conflict. These claims are related to diverging conceptions of democracy that co-exist in daily political practice. Besides of turning legitimacy into a negotiable aspect the claim on legitimacy interferes also into conflict about the contents of planning. Referring on case study results this paper shows how several actors promote divergent goals claiming to defend public interests and the needed interventions for a future transition.

Complexity of transition needs lead to the integration of phases for collective learning and qualification into planning processes in order to facilitate an adequate debate on desired planning outcomes. Nevertheless expert knowledge remains a controversial field when it comes to define the type or place of an intervention. This paper reflects on the role of different actors' perspectives for rationalizations about planning outcomes within the discourse of transition.

Keywords: legitimacy; actors' perspectives; planning conflicts; planning for transition

Introduction

Transition and the implementation of related planning goals becomes a disputed issue in planning processes. The increasing role of public participation and communication in planning turns the legitimacy of planning interventions and the actors promoting them into an essential base to facilitate the implementation of planning.

Planning projects that aim on envisioning transition goals are mostly driven by expert knowledge. But this knowledge does not generate a democratic legitimacy for planning outcomes or the processes to define them. Opposing actors dispute on planning goals and claim to defend the public well. They refer on divergent aspects of legitimacy to claim their own or to put into the others legitimacy. This entwining of goals and legitimacy happens on base of divergent actors' perspectives on democratic legitimacy.

This paper will revise these issues on base of a case study in Bremen (Germany) studied in parallel to the planning process. Rationalisations of the involved actors' within a conflict about mobility issues is analysed.

The arguments of actors generate an own narrative about relevance and interdependence of specific planning goals. Actors refer on divergent guiding principles for planning.

The article illustrates on base of the case study how the narratives of actors relate the conflict on planning goals to legitimacy of the actors' themselves. Legitimacy is negotiated along the conflicts about planning. In the course of debate actors refer on divergent sources of legitimacy and balance them to paths of decision-making and planning goals. Throughout the paper it becomes visible which are the sources of legitimacy that are applied to foster transition oriented planning goals and how they relate to other sources of legitimacy.

The conclusions reflect on the relation of these negotiations of legitimacy towards transition oriented planning. Planning for transition in many cases suggests an urgency to prioritize certain planning goals. Depending on who defends these goals - citizen, politicians or planners - the paths to generate legitimacy in the discourse about planning decisions vary.

Neues Hulsbergviertel and its planning conflicts

The case study is about a new neighbourhood, Neues Hulsbergviertel; in Bremen (Germany) created by conversion of a former hospital into a mixed neighbourhood.

The project is considered a model case in terms of planning goals and process design. The Bremen Parliament defined that the project had to aim on sustainability (in terms of construction, transport, energy and environment), a mix of uses, the promotion of varied types of property and dwelling (such as cooperative housing), and an intense citizens' participation within the planning process (Bremische Bürgerschaft, 2010, p.2).

These planning goals can be considered key issues of currently formulated goals of urban transition to face climate change, challenges of social inclusion and citizens' engagement.

As the planning goals were determined by the Bremen Parliament they are backed by representative democracy. At the same time the aim to create an extended process of citizens' participation longs to acquire additional legitimacy by consulting citizens and fostering deliberative processes.

As the 14 ha sized plot is now in use for a hospital and has no current inhabitants there is no 'natural' community to be consulted. The citizens who engaged in the process were dwellers from adjacent neighbourhoods, persons and groups interested in a future living on the area, groups willing to promote certain urban developments, and some other individuals interested in planning process and outcomes.

The current owner of the plot is the public hospital company (Gesundheit Nord, hereinafter: GeNo) who expects to refund part of their deficit by the sales revenues of the plot.

Main stakeholders in the political arena are the senator for finances (A senator in Bremen is equivalent to a minister.); the senator for environment, building and transport; Bremen Parliament (Bremer Bürgerschaft) and its planning commission (Baudeputation); and as well the borough council (Beirat).

The planning process is handled by the local planning department (SUBV). In charge for the development of the area is the state owned property development company (hereinafter: GEG). These both actors jointly coordinate the public participation events.

From the beginning there was a high proximity between the actors concerning the general planning goals formulated in the prior political decision. This fact distinguished the Neues Hulsbergviertel from several other planning projects. For example in projects for new neighbourhoods on inner-urban voids or in projects concerning the implantation of highways, high-voltage lines, etc. the conflict often begins from scratch in questioning the plausibility of a need for the proposed planning project.

Nevertheless balancing conflictive goals and detailing plans led to evident conflicts within the planning process for the Neues Hulsbergviertel. These conflicts show elements that can be seen as characteristic for planning for transition. When transition becomes a motor of planning it is justified by expert knowledge perspectives, such as knowledge about causes and effects of climate change. Expert knowledge gives legitimacy to planning. On the other hand transition towards a more inclusive society requires legitimacy by democracy. This involves a scope of divergent concepts of democracy, fostering participative elements or highlighting the values of representative democracy.

The case study in Bremen was analysed on base of Interviews with several actors, participant observation and document analysis. Within this material it becomes obvious that actors' discourses about planning contents are set into rationalizations that refer on different guiding principles.

Based on the results of political decisions, several public assemblies and previous expert evaluations the award documents for an urban planning competition were defined. According to the award- winning plan the new neighbourhood would be built around a central green area, the buildings would be organized in city blocks, and the most emblematic of the existing buildings would be preserved.

The planning department elaborated consequently a binding land-use-plan. It was developed on base of the previous decisions and due to further political debate, citizens' claims in public assemblies and internal processes of balancing and negotiation between planning department and other actors. Key issues were:

A portion of 25% of housing is planned to be social housing and an additional 20% is foreseen for joint building ventures and cooperatives.

A mobility concept was developed in order to reduce drastically the motorised private transport and accordingly the space reserved for parking. Walking, cycling and car sharing should be fostered in change. The number of required parking spaces was reduced to 0.4 spots per housing unit, instead of 0.8 as it is the common local legacy. These parking spaces should be located in the perimeter of the neighbourhood in order to reduce internal car circulation.

While the planning department was elaborating the legal-land-use plan and an additional urban development contract the debates between the several actors on detailing regulations continued.

Constructing argumentations

This article illustrates an entwined discourse between content related rationalizations and legitimacy. As mobility was a largely discussed topic during the planning process I will pick the debate on parking garages to show how several actors promote divergent goals claiming to defend public interests and the needed interventions for a future transition.

In the original urban plan there were no underground parking spaces beneath the building blocks instead there were only collective parking spaces in multi-storey car parks. During the revision process the planning department decided to insert three underground parking car parks. The debate about the underground parking spaces and the impacts for the neighbourhood and its mobility concept took place in public assemblies, direct actors negotiations and in meetings of political boards. The narratives of the different actors about the issues could be found in interviews, on the projects websites, in press releases and other published statements of citizens' groups, and of proceeding and documents of political boards.

The arguments on the issue are conducted very differently by the different actors, and each actor treats the issue associated to other thematic contexts.

The arguments about mobility can be assigned to five different contexts:

1. Planning approach
2. Expectation on sales revenues upon the plots
3. Creating a socially mixed neighbourhood (social inclusion and justice)
4. Quality of urban design
5. Ecological sustainability

Based on this, on these topics two basic argumentative groups can be identified (see also Table 1). The decisive key issue is the planning approach that defines the guiding principle of each argument:

Balanced Approach (Argument A): The balanced approach sets as a guiding principle the argument of a balanced sound planning that accomplishes to carry out all aspects of the original political decision. The goal of reducing the motorized private transport must be balanced against another with complementary considerations and goals to develop a more down-to-earth option referring to the mobility concept. The key argument is **BALANCING DIVERGENT PLANNING GOALS (1A)**. This argumentation is applied to the question of underground car parks. Above all, the maximization of sales revenue (2A) and the quality of urban design (4A) determine the patterns of this argumentation. A common reference to support these arguments are the planning goals defined by the Bremen Parliament in 2010, especially referring on the needed sales revenues.

Committed Approach (Argument B): The guiding principle in the committed approach is to assure that planning is envisioning the future, especially focusing on ecological sustainability and social justice. The commitment is to foster the transition oriented aspects of the original political decision and to preserve the outcomes of the first phase of public participation. The key argument is the **COMMITMENT TO ECOLOGICAL SUSTAINABILITY AND SOCIAL PLANNING GOALS (1B)**. This argument is also applied to the question of underground car parks. While the parking space key itself represents a tolerable compromise, the aims of mobility concept are frustrated by the construction of underground car parks. Assuring a socially mixed neighbourhood (3B) and preventing negative effects on ecological sustainability (5B) determine the patterns of argumentation. In addition, it is argued that reducing car traffic significantly increases the attractiveness of public spaces (5B). A common reference to support these arguments is the Bremen Parliament resolution of 2010, assigning the status of a model case to the planning for the Neues Hulsbergviertel and highlighting in particular the aspects of ecological sustainability and social mix. In addition, the argument refers on political resolutions of a Bremen Alliance for Housing and subsequent policy guideline on social housing.

In the synopsis, the arguments are not only thematically linked to different contexts but also the references that support and justify the argument vary. These references are used as an argumentative background to underpin one's own position.

Four such types of references can be identified:

- Compliance with the political decisions (documents)
- Compliance with the results of public participation
- Commitment to political goals / transition (social justice, ecological sustainability)
- Professional criteria (based on professional experience): sales revenues for certain types of housing, quality of urban design, sound transport planning

Table 1: ARGUMENTATIONS

A. BALANCED APPROACH (accomplishing equally all political demands)

	STATEMENT	SUPPOSED EFFECTS	REFERENCES
1 A	Planning for Neues Hulsbergviertel has to be sound and all criteria of the prior political decisions on planning goals have to be balanced and accomplished equally.	Balancing all planning goals allows to accomplish all criteria equally.	Resolutions of Senate and Bremen Parliament (2010)
2A	Housing with assigned underground parking spaces is a standardised product on real-estate market and fosters successful sales of apartments.	Generates increased sales revenues on assigned plots.	Resolutions of Senate (2010) claims maximisation of sales revenues. Supported by expert statements of real-estates professionals
2/4A	Multi storey car parks in the perimeter reduce the attractiveness of the neighbourhood. The underground car parks could substitute some of them.	Generates increased sales revenues for the entire neighbourhood.	Resolutions of Senate (2010) claims maximisation of sales revenues. Supported by expert statements of real-estates professionals
3A	To offer apartments with assigned underground parking spaces attracts clients with an affinity to car use.	Creates a neighbourhood for everybody according to the existence of diverse demands within society.	Fits in with resolution of Bremen Parliament (2010) that claim diversity of types of dwelling. Covered by the documented results of participation.
4A	The underground car parks could substitute some of the multi storey car parks in the perimeter.	Improves quality of urban design and attractiveness.	Supported by expert statements of planning professionals.

Lower ranking aspect: ecological sustainability (5)

The referenced political resolutions are: Senate in June 2010, Bremen Parliament (Bürgerschaft) in December 2010; Bremen Alliance for Housing (Bündnis für Wohnen) and subsequently the housing programme (Wohnraumförderprogramm) in 2012/13, and the policy guideline on 25% social housing for areas with new land-use plans in 2013.

B. COMMITTED APPROACH (ecological sustainability, social justice)

	STATEMENT	SUPPOSED EFFECTS	REFERENCES
1 B	Planning for Neues Hulsbergviertel has to be a model case.	Ecological sustainability, social justice and public participation are fostered.	Bremen Parliament resolution (2010) ; Bremen Alliance for Housing, housing programme (2012/13) and the policy guideline on 25% social housing for areas with new land-use (2013) Needed to accomplish the results of public participation.
3B	To offer apartments with assigned underground parking spaces attracts wealthy citizens who “expect to have their SUV next to their apartment”.	The social mix of the neighbourhood shifts. Because of the currently high prices on real estate market even a slight shift could cause the exclusion of citizen with lower or middle incomes.	Endangers goals of resolution of Bremen Parliament (2010) which claims diversity of types of property and dwelling, including cooperative dwelling projects and innovative housing types. Conflicts goals of Bremen Alliance for Housing that aims to foster affordable housing. Endangers the results of public participation. Contradicts committed approach (social justice)
5B	To offer apartments with assigned underground parking spaces attracts wealthy citizens who “expect to have their SUV next to their apartment”.	Accessibility of a car so close to the apartment will increase the use of cars. Property on cars contradicts intentions of ecological sustainability. Entrances of underground car parks will boost car traffic within the neighbourhood and affect the attractiveness of public spaces.	Endangers goals of resolution of Bremen Parliament (2010) which claims ecological sustainability also in terms of transport. Contradicts expert statements of planning professionals. Endangers the results of public participation. Contradicts committed approach (ecological sustainability)
5B	Underground car parks can't be eliminated easily when not needed anymore due to future reduction of individual car use. Multi storey car parks can be demolished more easily to open up space for other uses in a future.	Construction of underground car parks does not open up possibilities for an adaption to future developments.	Endangers goals of resolution of Bremen Parliament (2010) which claims ecological sustainability also in terms of transport. Endangers the results of public participation. Contradicts committed approach (ecological sustainability)

Lower ranking aspects: Maximising sales revenues (2) and Quality of Urban Design (4)

During debates on planning goals on the Neues Hulsbergviertel actors have formed varied issue related alliances. These alliances vary even within this limited field of conflict about the underground car parks. But in general terms, the two Arguments (A and B) can be assigned to the different actors.

The balanced approach can be assigned to the property development company (GEG) and the Planning administration (SUBV) claiming that balancing planning goals is part of taking care of the common well. This approach is (in the background of public debates) also supported by the hospital company (GeNo) and the senator of finance, showing a clear inclination of giving the balance an inclination towards the maximisation of sales revenues. As well in conflict between GEG and SUBV the GEG tends to incline argument toward sales revenues.

The committed approach can be assigned to the citizens' action group (BIA) whose members defend ecological sustainability and social justice as commitments that derive from common well and the compromise for transition. In these concerns they get support of NGOs that are engaging for environmental issues or affordable housing. Furthermore, the BIA claims on defending the results of the first phase of public participation. This aspect is used by planners in public administration (SUBV) in conflicts with GEG to support their professional convictions about transition oriented planning.

Political boards as Senate, Bremen Parliament and its commissions took decisions according to a balanced approach referring on the compromise to public well. Nevertheless, clear inclinations to one or the other side of the balance could be observed according to political affiliation or political charge. The borough council, despite of some internal political differences, inclined their decisions more towards the committed approach. But they began to balance when these goals seemed to conflict other issues they felt compromised to. Like as considering the possibility that an extreme reduction of parking spaces in the new neighbourhood could possibly affect the surrounding neighbourhoods, or the aspect that financial difficulties of the hospital company (GeNo) could endanger employment. Thus, being the elected political representatives of the neighbourhood and its particular interests took a clear influence on the political decisions taken.

Simplifying the arguments it can be stated that the expectation on sales revenues upon the plots is opposing the commitment to foster the ecological sustainability of cities and to create a socially mixed neighbourhood that facilitates social inclusion and justice.

Bremen's permanent budget deficit is known by all actors. So in a certain way the need for sales revenues is accepted by everybody involved. Nevertheless, defenders of argument A accept it as a dictum while the defenders of argument B see the commitment for transition the prominent aspect to envision the future.

Legitimacy

All involved actors claim legitimacy by relating their argument to public well. But during the debate they question each other's legitimacy and alter reasons for their own legitimacy.

The legitimacy refers to divergent dimensions which depending on context support or contradict each other. The legitimacy of government in representative democracy is based on input legitimacy assured by constitutionally guaranteed free elections that define political boards. Scharpf (Scharpf, 1998, p. 3) calls this input-oriented legitimacy the "government by the people" referring on Abraham Lincoln's Gettysburg Address. He concludes that "Government, in other words, is meant to be self-government, and compliance can be expected because the laws are self-determined, rather than imposed by an exogenous will" (Scharpf, 1998, p. 3).

The output-oriented legitimacy he describes in change as "government for the people" referring to consequences of decisions to assure issues of common interest. In this case legitimacy is given "because collective fate control is increased when the powers of government can be employed to deal with those problems that the members of

the collectivity cannot solve either individually, or through market interactions, or through voluntary cooperation” (Scharpf, 1998, p. 3).

Within this output-oriented concept of legitimacy knowledge has an important role. Accessibility of expert analysis generates a knowledge base that allows a projection about the effects of planning.

These two forms to acquire legitimacy focus on the persons that are legitimized and on the type of decision that can be considered legitimized. But as well the process of decision-making itself generates democratic legitimacy: Through-put oriented legitimacy refers on the quality of governance processes and can be understood as “government with the people” (Schmidt, 2013, p. 3).

[In an] ideational and discursive construction (...) throughput legitimacy involves the ideas and deliberative interactions of the agents involved in the wide range of governance processes [...], and how these promote efficacy, accountability, transparency, inclusiveness and access to civil society (Schmidt, 2013, p. 7).

The concept of throughput-oriented legitimacy shows that legitimacy does not only result from institutional attributes of government. Being based on democratic decision making processes and fostering public well does not lead automatically to citizens’ approval or obedience. Decision making processes are object of discourses that influence on citizens’ confidence on legitimacy and lead to corresponding attitudes. (Schneider, 2012, p. 188)

These discourses can be found in the debates on planning processes where claims and doubts about legitimacy become a relevant aspect of actors’ rationalizations. “Legitimacy claims and assessments establish a link between regimes and their institutions on the one hand, and normative benchmarks on the other” (Haunss and Schneider, 2013, p. 1).

Analysing the case study of the planning process for the Neues Hulsbergviertel we can observe how the rationalizations about planning contents in debates about the planning issues become entwined with legitimacy. Actors claim legitimacy for themselves or put into doubt the legitimacy of others. This does not mean that any of the actors would not accept the input legitimacy of political bodies in general but it shows how legitimacy is reassured and negotiated as strategic part of discourse.

The local planning department (SUBV) earns its task from the decisions of political boards. So the planners acquire the input legitimacy. At the same time the involved planners at SUBV claim output legitimacy justified by their professional knowledge. They interact and negotiate directly with all other actors and balance the input of these actors’ claims. The rationalizations about possible planning decisions given in the debates with other actors acquire relevance by the professional expertise of the planners. Nevertheless, in case of conflict they refer additionally on the citizens’ demands that are registered as results of public participation to claim a throughput legitimacy for planning decisions that fit to their professional approach. This applies in special to the conflict with GEG about maximising the sales revenues by inserting underground parking spaces and additional densification. But as soon as agreements are found and presented to the political boards GEG and SUBV suggest a lack of legitimacy to certain demands of the citizens’ action group (BIA). This argument is sustained by the assumption that BIA would establish their legitimacy only on base of representativeness for the citizen of Bremen. This is supposed of not to apply to the group as is not a huge movement or represents an average citizens opinion.

The property development company (GEG) claims legitimacy by the political mission of the company to develop and sell the plot ensuring appropriate sales revenues. So GEG supposes that the input legitimacy of representative democracy is transferred to the company in order to implement the political decisions. The GEG also interacts and negotiates to all other actors. GEG aims on the development of a positive urban development balancing the diverse goals but showing a strong compromise to real-estate issues. This fact leads other actors -

like planners and citizens - to questions the extent of legitimacy given to the property development company. As GEG contracted a project developer as sub-agent they also claim a professional expertise to support their legitimacy.

The citizens' action group (BIA) claims the throughput legitimacy for defending the results of public participation. And they claim on an output legitimacy for defending efficient policies for social justice and ecological sustainability as aims of public well that are needed to face transition and to envision the future. The demand of political boards to take these guiding principles as a base of political decisions. They suppose that those politicians in charge who give value to these principles would need the support of citizen groups to defend their legitimacy.

The borough council claims the input legitimacy for being the elected representatives. On this base they defend the interest of citizen' on affordable housing and a vivid mixed neighbourhood against the interests of profit. Thus, on the same base they object on supporting BIA with their claim for a further reduction of parking spaces. They refer on defending the interests of the adjacent neighbourhoods which would possibly invaded by visitors of the new neighbourhood and hospital. Towards the citywide political boards the borough council claims a throughput legitimacy as a favourable vote of the council gives legitimacy to the further decision on Bremen Parliament.

This variance of legitimacy claims show the complexity within the negotiation of legitimacy for planning. The different sources of legitimacy complement each other or compete on priority. Planning processes are multilateral communication processes within a complex network of interdependencies with symmetric and asymmetric power relations. These actors' relations interfere with the perceived legitimacy of planning. Neither can we identify a definable local community that becomes a legitimate subject of planning decisions nor can we argue that planners' knowledge or political decisions guarantee legitimate planning outcomes.

Conclusions

The claims and doubts about legitimacy become a relevant part of planning processes since planning is seen as a communicative process. When it comes to planning for transition the balance of transition goals with other divergent planning goals are an inevitable part of debate. So if planning goals have to be balanced one could reconsider the need for a deliberative discourse based on principles of free speech and rational argument (Healey, 1997; Fischer and Forester, 1996; Forester, 1999). But of course the weight of rationalizations within the debate is connected to power (Flyvbjerg, 2012; Forester, 2010).

On one hand rationalizations about planning for transition are connected to the experts' knowledge. So if this knowledge is allied to the planning institutions and political boards the rationalizations might lead to the intended planning outcomes. Depending on the course of debates this can be understood as a legitimate planning intervention or be questioned for a lack of throughput legitimacy.

Richardson in his article about environmental assessment concludes that revealing authorship of the evaluations relevant for statements about planning and making explicit the paths of decision-making would contribute to solve conflicts on planning. He states that in times of extended public debates a story-telling is needed, right as making visible the ethical nature of the judgements may help to build legitimacy (2005, pp. 362–363).

But what if the argument prioritizing transition goals is maintained by citizens' groups? This is the case in the Neues Hulsbergviertel but can also be observed in other contexts. Lately the students' movement 'Fridays for Future' has been claiming to prioritize the ecological transition goals. So despite they can be considered a type of citizens' movement they claim on the output legitimacy for future policies that prevent climate-change. They base their demands on scientific research results but apparently their position against established political forces

is weak. This relationship can be described referring on Flyvberg (1998) by saying that the less power an actor has the more rationality has to be applied in arguments.

What can be learnt is that legitimacy of planning is built in discourse and connects to the intended goals of planning. In the best case the complexity of transition needs lead to the integration of phases for collective learning and qualification into planning processes in order to facilitate an adequate debate on desired planning outcomes.

Cultural Staking: Transition of the Core Public Space of Rural Settlements

Guiqing YANG¹, Yinghe XIAO²

¹Tongji University, yguiqing@163.com

² Tongji University, 669224456@qq.com

Abstract: Abundant culture have been accumulated in the historical evolution of rural settlements in China, with organic corresponding relationships among cultural, social and spatial attributes. In these certain relationships, the most significant cultural spirit and social relationships are usually presented as the core public space. However, accompanied with the transition of the rural traditional social structure and cultural life, the core public space of rural settlements has been gradually forgotten and its physical environment has been abandoned by degrees because of the change of productivity and production relations. This research points out that with the approach called cultural staking, starting from the core public space of rural settlements as an acupoint can be an effective way to the village revitalization planning. Combined with the author's practice experience in Shatan Village, Yutou Township, Huangyan District, Zhejiang Province, this research shows the effect of a creative spatial restoration and regeneration of the core public space with the cultural staking approach as a key.

Keywords: cultural staking; rural communities; core public space; transition

1. Introduction

There are a large number of rural settlements in China that carry the excellent Chinese traditional culture accumulated over thousands of years. Because rural settlements are formed in different historical and geographical conditions, the rural culture contained in them is therefore diverse and with regional characteristic.

With rapid economic development of China in recent years, rural society has undergone tremendous changes. With the change of productivity and production relations, the collapse of traditional social structure and the decline of space is common in rural settlements. The core public space once was committed to the core function and has important social connotations and cultural value in the traditional rural settlements. Nowadays, most is gradually ruined and dismantled because it is difficult to adapt to the new needs of the rural society in the new era. Besides, rural planning and construction lacking local cultural characteristics is also a universal phenomenon, and there is even “constructive destruction” caused by limited theoretical understanding and improper planning strategies. The local cultural diversity contained in Chinese rural settlements is rapidly disappearing in the rapidly changing socio-economic process.

The Chinese government proposed to implement the rural revitalization strategy in 2018, in which cultural revitalization is the soul. Then, national strategic planning documents also propose to flourish rural culture. Hoping to pass on the great traditional culture of rural settlements through protection and reutilization, theoretical research and practical explorations on rural revitalization has been

carried out in China recently. On the whole, theoretical research needs to be further explored, and the practical paradigm needs to be summarized. So, how to know the relationship within the cultural, social and spatial aspects of rural settlements? How to understand the cultural and social evolution characteristics of the core public space in rural settlements? How to adapt to the new rural social changes through the planning and transformation of the core public space with the soul of cultural revitalization, in order to achieve rural revitalization? This paper will study the above problems theoretically, and discuss the practical results of the method of cultural staking in combination with the rural revitalization practice in Huangyan District, Zhejiang Province. It is hoped that this study will provide theoretical guidance for similar planning practices.

2. The organic relationships among cultural, social and spatial attributes in rural settlements

2.1 The cultural characteristics and contemporary significance of rural settlements

The formation and evolution of rural settlements were influenced by many factors such as politics, economy, culture and military defense in different periods. With low level of productivity, “depending on the sky” reflects the dependence on nature and the fear of natural disasters. This creates awe and worship of nature, so worships and blesses become the spiritual pillar of the original people (SUN Dazhang, 2004). Nature worship has gradually become an important component of the cultural content of rural settlements. In order to resist the threat of natural disasters, aggression and war, people need to be closely united and support each other in a settlement. With the advocacy of the clan system in feudal society, villages are usually inhabited by consanguinity. Collective identity in these rural settlements is stronger. On the one hand, it is due to the resource allocation within consanguineal network, on the other hand, it comes from the inner respect for the ancestors and the goodwill of the ethnic groups (LIU Senlin, 2011).

Nowadays, productivity and production relations has undergone tremendous changes. The traditional rural social structure has been replaced by urban-rural dual social structure. A large amount of labors and other resources in rural area have flowed out to cities. The population in villages, especially the young and middle-aged population, has rapidly decreased. Many “hollow villages” are springing up. The agrarian society and the rural social structure formed under the agricultural economy are gradually disintegrated under the influence of the modern market economic system. As a result, the traditional cultural characteristics of rural settlements are losing.

The rural settlements with the goal of survival and reproduction have formed rich culture in the process of evolution, such as family culture, local belief culture, folk culture and physical culture. Traditional culture still plays an important role in promoting rural civilization and maintaining social harmony and stability. The cultural characteristics formed during the evolution of rural settlements are diverse and special. They are valuable to the reconstruction of rural social relations that are in transition. Therefore, the contemporary creative transformation and innovative development of the cultural characteristics of rural settlements has become an important mission of rural revitalization.

2.2 The relationship among cultural, social and spatial attributes of rural settlements

The culture of rural settlements does not exist in isolation. According to study of cultural connotations, social structures and spatial forms in rural settlements, it is found that cultural, social and spatial attributes of rural settlements have an organic correspondence (Figure 1). Rural settlements develop

from the background of survival and reproduction to the goal of the clan developing. This process is accompanied by continuous construction of the organic relationship among the three parts. Changes in rural social structure affect villagers' way of producing and living. Production and lifestyle also play a role in the formation of culture, which in turn will change the structure of society. The relationship between culture and society is presented through space, which in turn consolidates the culture and social structure of rural settlements.

The spatial form of villages and the interior layout of buildings are generally determined by social structure. The correspondence between social structure and spatial structure is also the basis for social culture and architectural culture. According to the family culture, the space presenting the concept of clan is the ancestral temple in the settlement or the ancestral hall in the residence. It is a place for ancestor worship, family council and family activities. The scale of the residences is determined by the way in which the family live. The distribution of the ancestral hall as well as residences in the settlement and the symmetrical interior layout of the residence reflect the family hierarchical concept. The Ho Family residence in Nanhai Village is a typical reflection of the feudal society living together (Figure 2), fully demonstrating the hierarchical order of the Ho Family. The ritual promoted in the family culture can be reflected through the memorial arches to commemorate the people who made outstanding contributions. For example, according to “Loyalty, Filial Piety, Propriety and Justice”, seven memorial arches stand in line at the entrance to Tangyue Village in Yi County, Anhui Province. The Wenchang Pavilion, Wenfeng Tower or other religious buildings, as well as the traditional academy and the Cultural Temple, are the products of the idea of “the one who excels in study can follow an official career” (SUN Dazhang, 2004). It demonstrates the advocacy of culture education. These spaces reflecting social relationships and public values are usually core public spaces in villages or residential buildings.

Figure 1. The Relationship within Cultural, Social and Spatial Aspects of Rural Settlements

Figure 2. Floor Plan of the Ho Family Residence in Nanhai Village, Guangdong Province, China (SUN Dazhang, 2004)

The local belief culture of rural settlements can be represented by some buildings such as temples, bell towers and Buddhist temples. The bell tower, the altar, the land temple and so on are the symbols of reverence for nature. The Guangong Temple and the Guanyin Temple are the places to pray for blessing from the mythical figures. There are also some miscellaneous temples, dedicated to the local sages. The local belief place reflects the local belief culture by carrying belief activities, mainly providing space for worship during daily life and festivals. The spatial type and distribution of local

belief buildings are related to their functions and service scope. For example, large-scale yard-typed or single-temple belief buildings is usually dedicated to gods who pray people in wide range, and these buildings are mostly located in the center of the protection range; The small-scale free-style belief place is for the gods with a small range of protection. It may be a small house or an altar embedded in building wall, which is closer to living place of the residents (HE Shaoying *et al.* 2016). These local belief places are also important public spaces in the rural settlements.

Folk culture is usually derived from family culture and local belief culture. Spatial presentation is mainly public space carrying folk activities. Architectural culture is manifested on the one hand by ordinary dwellings, and on the other hand by public buildings or structures that reflect core values and social structures in rural settlements. It can be seen from the above that the social structure and cultural spirit in rural settlements are interdependent and are stored in the physical space together, with public space as the main carrier (Figure 3, Figure 4).

Figure 3. Cultural Manifestation of the Core Public Space in Rural Settlements

Figure 4. The Core Public Space in Shatan Village, Zhejiang Province, China (Provided by Li Shuaijun)

3. The evolution of cultural and social attributes of the core public space in rural settlements

The public space reflects social and political relations in rural settlements, and also contains cultural meanings (MEI Ceying, 2008). The core public space reflects the main characteristics of social relations, represents the core public spirit of the society, carries important cultural connotations. It is the main spatial expression of the social and cultural attributes of rural settlements.

3.1 Physical presentation of core public space

As an important part of the overall spatial structure, the core public space is usually in an important position, such as the geometric center of the rural settlement, or the edge of the settlement with higher altitude. The buildings there are usually larger or higher than others, usually with a large square. Therefore, the core public space is highly recognizable. At the same time, as the layout center of settlement, the core public space has high accessibility which is important to public activity.

Following are the typical cases. In most instances, the core public space of the Dai village in Yunnan is the Buddhist temple with surroundings located in the center of village. However, there are some exceptions. One is that the Buddhist temple is built on the edge of the village (Figure 5) or on the hill

to be the commanding height of the whole village (Figure 6) when the village is located in the mountainous areas. Or some is built at the entrance to the village for easy identification in the distance. Similarly, the Drum Tower with its surroundings in the Dai village is the core public space of the village. The other residences are built around it. The Drum Tower is also located in the center of the village (Figure 7), and the height is definitely higher than the surrounding houses. The core public space with particularities in terms of location, spatial volume and layout has obvious centrality and leading position in space.

Figure 5. Plan of Manting Village in Ganlan Dam, Yunnan Province, China (SUN Dazhang, 2004)

Figure 6. Aerial View of Jinghong Dai Village in Yunnan Province, China (SUN Dazhang, 2004)

3.2 Cultural and social attributes of the core public space

The particularity of the spatial layout of the core public space corresponds to its dominant and controlling role in the society and culture of the field. The identification of the core public space in the rural settlement embodies the core value of social control (YANG Guiqing, 2014), and is the concentrated expression of the social structure, public value and spirit of the settlement. The core public space is usually based on buildings that have profound significations, such as ancestral hall, temple and drum tower. There may be square, opera stage or other affiliated facilities around. It is a psychological cognitive place in the daily life of the villagers.

The core public space with ancestral temple as the main body reflects the family community with kinship as the link, focusing on the strength and honor of the collective. Tulous or Weiwus are defense-oriented residential buildings built after the settlement of some war immigrants in history. Usually there is just one family group in Tulou or Weiwu. From the overall layout of the village, there is no obvious central space, but the central public places enclosed is the core public spaces for the information exchange and public activities. The location reflects the importance of uniting the family and jointly resisting external violations to ensure that the family can survive and develop. (Figure 8)

Figure 7. Aerial View of Congjiang Dong Village in Guizhou Province, China (SUN Dazhang, 2004)

Figure 8. Plan of Tianluokeng Village in Nanjing County, Fujian Province, China (SUN Dazhang, 2004)

Belief place as the core public space in rural settlements, is an important "acupoint" of traditional culture and spiritual life in areas where local beliefs and culture flourish. For example, the Dai people believe in Southern Buddhism, so Buddhist temples are the center of the spiritual and cultural life for villagers. Its remarkable spatial layout also confirms the prominent position of Buddhism in the spirit of the Dai villagers. The Drum Towers in the Dong villages are mostly public buildings for collective use funded by the same region or family name. It is an important place for villagers to step on the temple, worship the ancestors, gather, discuss, and entertain, combined with the surrounding ground for drying grain (SUN Dazhang, 2004). The Drum Tower also has the function of preaching ethical codes to build a harmonious society with moral principles. It can be seen that the Drum Tower has a leading position in the social and cultural aspects of rural settlements, and is also organically corresponding to its central location in physical space.

In some areas where the family concept or the local belief culture is relatively weak, the core public space of the settlement is mostly adapted to the actual needs of the villagers. For example, the core public space of ancient commercial town Luocheng Town in Sichuan Province is the main street with shape similar to the boat. The boat-shaped main street symbolizes "crossing a river in the same boat", which means pulling together in times of trouble. Although the residents are mostly Cantonese immigrants, and the family culture or religious culture is not strong, the boat-shaped street reflects the homesickness culture indirectly (SUN Dazhang, 2004). Except cultural connotations, the main street also meet usage need. It is a commercial street with a stage, a memorial hall and a step-like theater space in the center. It can be seen that the function of the core public space of the settlement is mainly commercial and leisure, with a focus on practicality. The Lingguan Temple at the end of the main street is relatively high but with weaker centrality, reflecting that religious culture does not occupy the dominant place in the settlement (Figure 9).

Figure 9. Aerial View (a), Plan (b), Profile (c) of Core Public Space in Luocheng Town, Sichuan Province, China (SUN Dazhang, 2004)

Therefore, the cultural, social and spatial attributes of rural settlements correspond organically. The inheritance and development of cultural traits cannot be separated from the social structure and spatial form. In the spatial form, the core public space is the physical space carrier of the main social structure and the core spiritual culture. The rural cultural revitalization should use the core public space as the catalyst to carry out the creative transformation and innovative development of culture.

3.3 Dialectical views on the transition of the core public space in rural settlements

The cultural and social attributes of the core public space is not static, but is constantly changing with the development. For example, in the long-term agricultural civilization era, the core public space is mostly a place that symbolizes the family spirit or the local belief culture. In the period of China's planned economy in the last century, it was the collective production space such as the supply-marketing cooperatives and the drying field. After the reform and opening up, the centrality of the traditional core public space in rural settlements was weakened and replaced by administrative cultural place. Nowadays, the commercial and entertainment activity squares are the main form. The core public space in different periods adapted to the economic system, social structure, production methods and life style at that time, reflecting the cultural and social attributes of a particular period.

The development requires that we should treat the cultural value of the core public space during different periods in a dialectical way. Take the essence, throw its dregs. Protect, pass on and update the culture that adapts to contemporary development. Nowadays, the production methods and social relations have changed. The reshaping of the core public space should adapt to the new production relations, social background and development prospects, rather than the simple restoration and reconstruction of the traditional core public space. On the one hand, we respect the diversity of the rural culture developing types, and at the same time adopt the advancing and suitable methods to inherit and develop. For instance, the design for regeneration of Lai clan settlement fully considered three different civilizations of Changhe Ancient Town during three development periods. This design advocated that the primary goal of regenerative design is to integrate the old and new spatial elements of the settlement under the premise of maintaining the recognizability of different civilizations. Thereby, maintain the continuity of the local civilization and integrate it into the process of modern urban life evolution (CHANG Qing, 2016). Therefore, the cultural characteristics of rural settlements are changing with the historical evolution. The inheritance of culture should adapt to the contemporary rural life and derive the rural culture with the contemporary characteristics.

4. Cultural staking with the core public space as the "acupoint" in rural revitalization

In the context of implementing the rural revitalization strategy, many parties are exploring the revitalization of the countryside. The practice of rural revitalization in Huangyan District, Taizhou City, Zhejiang Province has obtained some achievements. Recently, the experience of the practice is summarized in the "Working Methods for Rural Revitalization" (WU Liang *et al.* 2018), in which cultural staking takes the first place. Cultural staking means take culture as the priority to stake the village revitalization. The reconstruction and reuse of the core public space is the implementation of the method cultural staking in rural settlements.

4.1 Cultural staking

The Shatan village is located in Yutou Township, Huangyan District. It is a provincial historical and cultural village with profound cultural heritage, such as, Taoist culture represented by Taiwei Temple, the Confucian culture represented by Rouchuan Academy, the farming culture, the traditional Chinese medicine culture and the modern architectural culture. However, it is remarkable that cultural revitalization is not a simple excavation and protection, but a protective use of cultural elements in the context of productivity and production relations transitioning. In this way, the new needs of villagers and tourists can be meet. Because the cultural, social and spatial attributes of rural settlements is inseparable, cultural staking should be organically combined with industry, society and space to implement a function of "hematopoiesis".

Cultural revitalization should be carried out regionally, taking full account of the difference in diverse regional ranges. Which village should be revitalized and how to revitalize should be determined on the base of the systematical plan. In this case, new villages and towns are built on the east side of the old Shatan village. The new township government and commercial facilities are added in the new village, while buildings and street in the old village gradually declined due to their inadaptability to new needs (Figure 10). Therefore, the old village of the Shatan should be considered with the township, that is, regarding it as the cultural block in the township master planning based on its rich cultural elements.

After the direction is clear, a series of methods can be used to revitalize culture, including: First, finding the cultural identification of the villagers, such as the ancestral temples, ancestral halls, customs, traditional crafts, etc. Second, repairing, reconstructing or building the cultural identification recognized by local villagers. Third, planning and constructing different cultural facilities combined with local customs. Fourth, building a public cultural architecture, publicizing culture and morality in the new era. In the Shatan village, there are two major cultural buildings, named Taiwei Temple and Rouchuan Academy, as well as public buildings built during the period of the People's Commune, such as township office, veterinary station, health center and grain stations (Figure 10). These are cultural identifications of villagers in different periods. However, most of them has been abandoned because it cannot meet the new needs of villagers. To releasing the contradiction between supply and demand of public service facilities, the historical cultural identifications were repaired and transformed. Finally, the protection and reconstruction of the buildings with cultural connotations in the old village is realized, and the adaptive function transformation is carried out in combination with the needs of living and travelling (Figure 11). Thus, the cultural context of the old village is continuing and the cultural atmosphere of the Shatan village is restoring. For instance, the Rouchuan

Academy has been returned to an excellent traditional cultural education base, and at the same time the Rural Revitalization Institute. Some other buildings of the People's Commune period are adaptively transformed into information center, cultural activity center, and homestays according to their location and interior space.

Figure 10. Present Land Use and Distribution of Public Facilities in Shatan Village (YANG Guiqing *et al.* 2015)

Figure 11. Land Use Planning and Distribution of Public Facilities in Shatan Village (YANG Guiqing *et al.* 2015)

4.2 Practice of core public space

Cultural staking is first aimed at the declining buildings and space environment in rural settlements, especially the core public spaces with cultural connotations. The core public space generally has a good physical space foundation carrying the traditional culture of the settlement, and also is the cultural identification of the villagers. Therefore, it is an important and primary “acupoint” for cultural revitalization, also rural revitalization. Focusing on the core public space to implement cultural staking, it is easy to put the village planning into effect under limited capital conditions, in other words, it has strong operability. The overall village planning can be promoted from the most important “acupoint”, that is, core public space. The combination of cultural staking and starting from acupoint is suitable for rural areas with limited financial and labor conditions to promote cultural revitalization.

The planning and construction of the Shatan village originated from the excavation of the unique cultural connotations of the village, and finally positioned on the Taiwei Temple with the southern opera square. The Taiwei Temple has a history of more than 800 years. The origin of its construction is to commemorate the local villager Huang Xidan who died of saving the people from fire. He was honored by emperor and esteemed by villagers and generations. So far, the temple has a strong incense. The villagers still express their respect for the ancestor by organizing social activities. “Respecting heroes” and “cultivating virtue” are the roots of the culture of the Shatan village and the cornerstone of the cultural revitalization. The Taiwei Temple is the cultural identification of the villagers.

After the excavation of the culture of the Shatan village, the core public space is planned and designed. The original Taiwei Temple was damaged, and the space in front of it was messy. In order to improve the condition of ancestor worship and promote the culture of the Shatan village, a series of planning and construction have been adopted, such as removing latrines and garbage in front of the temple, instead setting up a clean public toilet, building the opera stage and the corridors and so on. All of these make up a core public space with the Taiwei Temple as the center, composed of the opera stage,

the opera square and supporting facilities. So, the core public space, as the cultural identification of the villagers, is reshaped (Figure 12 to 15).

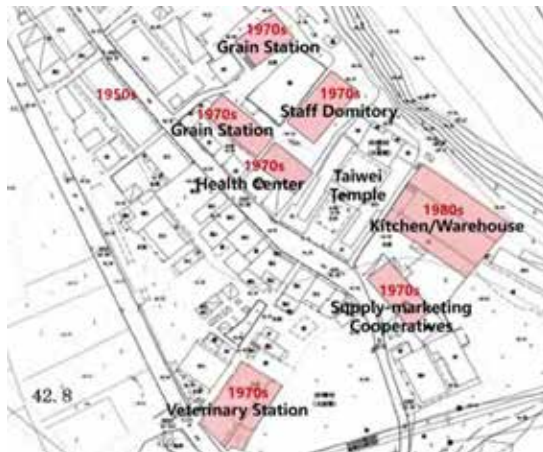

Figure 12. Present Layout of Core District in Shatan Village (YANG Guiqing *et al.* 2015)

Figure 13. Planning of Core District in Shatan Village (YANG Guiqing *et al.* 2015)

Figure 14. Planning of Core Public Space in Shatan Village (YANG Guiqing *et al.* 2015)

Figure 15. Model of Core Public Space in Shatan Village (YANG Guiqing *et al.* 2015)

The space is meaningful owing to its being used. As the old physical space of the village, the core public space needs to adapt to new social structure and redefine new functions, so that the physical environment can gain new development connotations and motivation (YANG Guiqing *et al.* 2016). The core public space of the Shatan village is not only the local belief space all the time, but also the venue for the family activities. At the same time, it can meet the new spatial needs of villagers for rest, communication, entertainment and exercise (Figure 16 to 19). The construction of the core public space has promoted the creative transformation and innovative development of other public space nearby. The repair and reconstruction of the old Shatan village centered on the core public space will be gradually promoted on the basis of respecting traditional culture.

(Provided by Ningxi Township Government)

Figure 18. Village Opera Performance in Shatan Village
(Provided by Ningxi Township Government)

Figure 19. Huang Clan Celebration in Shatan Village
(Provided by Ningxi Township Government)

The construction of the core public space in Shatan village provides a place for the Huang clan worshipping activities and local belief activities, which not only contributes to the inheritance of the traditional family culture and local belief culture, but also enhances the villagers' sense of identity and pride on local culture. Moreover, it also satisfies the needs of locals. Further, helps to build a new type of rural social structure, and enhances social harmony and stability. In addition, in the context of urban-rural factors flowing, the core public space is also a place for tourists and villagers to interact, so that it promotes the integration of urban and rural areas.

5 Conclusion

With the constant changes in productivity and production relations, the social structure of rural settlements in China is also changing. In the process, the cultural characteristics of rural settlements have gradually formed, especially family culture and local belief culture. Nowadays, these traditional cultures are losing due to the inability to adapt to current society, but they still have social significance in contemporary rural settlements and should be passed down.

Culture has an organic correspondence with social structure and space. The organic correspondence among social structure, cultural connotations and spatial forms of different settlements is similar. Therefore, the cultural revitalization in rural revitalization should fully consider the changes in social relations and spiritual culture, and plan to create suitable spaces to carry. The core public space is the

main carrier of the core of the social and cultural connotations of the rural settlement, so it is chosen as a catalyst for cultural staking. Based on the organic correspondence among the three attributes, integrate all the actors and make the transition of the core public space. It is not only the inheritance of traditional culture, but also the spatial embodiment of rural culture and local civilization in the new era.

In the context of new era, with cultural revitalization as the soul, creative transformation and innovative development of the core public space will eventually realize rural revitalization. The theory and working methods of cultural staking have universal guiding significance for protecting and reutilizing historical and cultural traditional villages. However, localities should carry out cultural revitalization according to their own conditions, that is, respecting and protecting rural cultural diversity and local characteristics.

Acknowledgements

The beautiful village planning and rural revitalization of the Shatan village benefited from the support of many parties. The authors would like to acknowledge the support offered by the participants of the local government of Huangyan District and Yutou Township in Taizhou, Zhejiang Province, as well as the teachers and students of Tongji University.

Theorizing urban change:
complexity and ethics

Rebuilding the planning system: The transition towards professional antagonism in the uphill battle of Madrid Nuevo Norte

Ángel Aparicio¹, Félix Arias²

¹*Universidad Politécnica de Madrid, Spain, angel.aparicio@upm.es*

²*Architect, Plataforma Zona Norte, Madrid, Spain, farias28016@gmail.com*

Abstract: This paper takes as a case study Madrid Nuevo Norte (MNN), a redevelopment scheme launched in 1993 by the national railways in association with a private developer, and that remained inactive for many years, until an agreement with the local government was publicly disclosed in 2017. The agreement got wide political support from most of the city councillors, but faced sharp criticism from residents and some influential local planners. These planners pointed out that the agreement would do little to address the residents' concerns about the massive construction of office space and its associated risks for gentrification and displacement, and would further accelerate the spatial and social segregation between the north and the south of the city. They called for strengthening the much weakened legal planning framework in Madrid, and for making better use of technical expertise in the decision-making process. The approach of these planners is to empower the public to participate at the public debate through the provision of factual evidence and legal advice. These planners do not seek centrality or hegemony in public deliberation. In this sense, they would exemplify a particular neo-pragmatic turn in planning.

Keywords: Planning ethics; planning theory; complexity; antagonism

Introduction

Planning theory debates can be of interest beyond the academic community. They can provide useful tools to analyse complex processes and decisions in cities. This is illustrated by the case of Madrid Nuevo Norte (MNN), the main development scheme currently under discussion in Madrid. MNN illustrates how stakeholders navigate the under-regulated, antagonistic environment of urban development in Madrid; it shows the limits and traps of the agonistic approach privileged by the progressive local government in office between 2015 and 2019, and provides some evidence on the revival of activism among planners critical with the planning process and its outcomes.

The central hypothesis in this paper is that, under certain conditions, understanding planning as an agonistic process can lead to further weakening the prospects for a better, long-term future. And that the answer of some critical planners is to reaffirm the need of a normative framework in planning that can refocus public deliberation on the public interest. In the absence of this, the agonistic deliberation in planning risks to substitute the maximisation of the financial value created for the common good, and to exclude from public deliberations those critical voices that do not accept such replacement. As a reaction to the deliberative principle requesting participants to abide to the “best argument”, the

agonistic understanding of deliberation does not put particular conditions to the contents of the arguments to be exchanged, and in this way, tends to put feelings, beliefs and reasons on the same level. While this may provide a more realistic picture of public deliberation in our cities, it also tends to downplay the value of technical knowledge, and to open the door to the legitimisation of purely traded or bargained planning, in which stakeholders merely impose their power above others. On the other hand, the focus of agonistic planning on the *present* may diminish the relevance for planners of a strategic, long-term vision, and underestimate the capacity of the normative framework to produce long-term changes. If norms are merely seen as flexible rules of the game that can be changed by the participants in order to facilitate the achievement of tactical agreements among adversaries, it is difficult to see how non-hegemonic agents and visions incompatible with the interests of hegemonic stakeholders can be preserved.

This potential bias of agonistic planning can be illustrated by recent developments in the MNN scheme, which help to understand why a local government deeply committed with radical democracy principles could ratify a planning option based on the maximisation of financial value creation and the dubious vision of a business centre for a globalised metropolis. There seems to be a lack of alternative, strategic vision on behalf of a municipal action dominated by short-sighted tactics, and an inability to define the public interest beyond the utilitarian realm of financial costs and benefits.

This potential contradiction can be explored by analysing the similarities and differences between the competing influences of agonism (Laclau & Mouffe, 1985) and deliberation (Habermas, 2000; Rawls, 1973) in planning. There are key similarities between both: respect for some common rules, the centrality of citizenship; there are also key differences: the consideration of rationalism, the value of consensus, interaction among stakeholders understood as deliberation or bargaining, and the consideration of the public interest. These dimensions were already developed by John Dewey (1927) in the first third of the XX century, and were recently revisited at the end of the century by so-called neo-pragmatists such as Richard Rorty (2000).

The position of some of the critical voices to the NMM scheme in Madrid can be qualified as neo-pragmatist, in the sense that, following the Deweyan tradition, they (1) focus public deliberation on the concept of the common good, (2) they consider education and information provision as a key instrument to empower the public (and particularly the residents and those with poor access to the public space), and (3) they ask for rebuilding the system of checks and regulations in the planning system as a way to level the playing field in the city.

This paper is structured in three sections, besides this introduction. The next section reviews some deliberative, agonistic and pragmatic considerations that have influenced current planning practice. The third section provides a description of the MNN scheme in Madrid, and analyses the limited relevance of technical considerations, the role left to the residents in the process and the weakening of the legal planning system on behalf of a particular vision of the city aligned with the needs of global financial investors. The final section provides some conclusions of how to avoid the “agonistic trap” the local government of Madrid fell into by reclaiming some virtues of the planning tradition like the robustness of the legal framework, minimum quality standards for technical studies, and the right scale and size of

the development area under discussion, avoiding too large, rigid schemes that neglect both the urgent social needs in the city and the concerns of residents.

Agonism, deliberation and pragmatism in planning

The philosophical framework: the task of democracy

It is well known that planning theory has been strongly influenced since the 1980 by the broader political discussion on democracy. Two elements of this political discussion can be useful for the purpose of this paper: on the one hand, the discussion on the foundations of democracy; on the other hand, the discussion on the role of conflict in democratic societies.

In the liberal tradition, the recognition of value pluralism does not impede to look for a link between democracy and rationalism. Liberalism is regarded as resting on a belief in certain universal values and fundamental human rights. It is the case of those liberal thinkers, like Isaiah Berlin, more interested in negative liberty, i.e., in preserving the freedom of the individual from undue restrictions; this pluralism does not take Berlin to outright relativism: there are actions that are to be considered as unacceptable, and Berlin (1988) could not accept to sacrifice individual freedom for the sake of abstract, uncertain political goals, as a certain sense of *human decency* should remain as a common ground at the basis of pluralism. In the liberal tradition of John Rawls (1973) or Jürgen Habermas (2000), positive liberty, i.e. freedom to act politically to achieve certain goals, is central, and political deliberation becomes crucial to agree on the goals to be achieved. As political deliberation is grounded on reason, the ideal conditions for reason-based deliberation are explored by both thinkers. For Rawls, these conditions are met under the veil of ignorance, when the participants in the deliberation cannot anticipate the personal consequences of the options at hand; for Habermas, these conditions are met under a discourse ethics to which rational participants adhere, abiding to the best argument, as the core nature of democracy is deliberative.

The necessary link between rationalism and deliberative democracy has been challenged on different grounds. Building upon Derrida's concept of the radical singularity of the other, and upon Carl Schmitt's focus on antagonism, Laclau and Mouffe developed their concept of agonistic pluralism: Political deliberation takes place between antagonistic participants, who do not aim at reaching consensus, but at gaining hegemony (Mouffe, 2000). Passions are as relevant as rational arguments in this interaction. Instead of Schmitt's authoritarian solution, it is possible to redirect antagonism among enemies towards agonism among adversaries through a democratic process respecting some rules; the agonistic process does not moves towards consensus, but towards the provisional hegemony of a certain group of participants, at the expense of the others; however, this hegemony is provisional and contingent, so that other participants can provisionally accept the results, in the hope of gaining hegemony in the future to impose their preferences.

The grounds, contents and purposes of political deliberation become central in this discussion. It cannot be a surprise that this discussion spills beyond the realm of political philosophy to reach the more practical areas of public policies, and in particular, planning.

The anti-foundational trend that rejects the necessary link between rationalism and democracy looks for alternative, softer commonalities to avoid to fall into plain relativism and to try to keep together the individuals within a democratic community: Isaiah Berlin referred loosely to some sense of "human decency"; Richard Rorty (1989) refers to the avoidance of all forms of cruelty; John Dewey referred occasionally to some empathy as a basis for the political community; for Derrida, the field of politics offers an alternative to the risk of structural lack of determination or chaos that results from the

singularity of the individual that is irreducible to politics (Mouffe 1996). Pragmatists such as Dewey or Rorty would avoid these metaphysical waters in their navigation, even at the price of getting into trouble to explain how the political debate should take place: whereas accepting rationality as the basis for democracy facilitates the trip towards the acceptance of rational arguments as the contents of deliberation, losing the rational foundations implies the additional burden of rethinking what deliberation consists of.

One inspiring path to follow is Laclau's and Mouffe's discourse theory, building upon their idea of politics as "decision taken on an ungrounded terrain". Under these premises, the role of conflict in democratic societies becomes paramount. Conflict is mostly avoided by those considering liberty from a negative perspective (as in Berlin): when liberty is understood with a focus on the individual, the opportunities for conflict are reduced, and individual freedom is protected by the state. For those understanding liberty from a positive perspective (liberty to undertake action in society), conflict is managed through rational-based discussion (as in Habermas).

Another inspiring contribution in Mouffe's and Laclau's (1985) understanding of political deliberation is their consideration of the relevance of passions/feelings in social relations. They pay more attention to the differences at the base of conflicts (stressing their inevitability and constitutional character, following Derrida's deconstructionism), thinking of politics as a way to negotiate differences, rather than to overcome conflicts (and reach consensus). From what they claim to be a real-life, non-foundational perspective (following Gramsci), conflict is negotiated through hegemonic relations, in which certain positions prevail.

It is worth to remind that this philosophical construction is developed around the concept of national states, and could be referred to as the "constitutional level". Planners have had a stubborn tendency to transfer these constitutional discussions to their particular realm of public policy, i.e. spatial planning. Obviously, planning discussions do not take place at the constitutional level, but in the context of concrete public policies; they do not have a foundational character, but rather aim at identifying useful tools to deal with normative, analytical and practical questions. For example, Mouffe (2014) makes it clear that her agonistic project is thinking at the national state level. However, she admits that it could provide some clues if applied in an analogic manner to the local level. Moroni (2019) considers that planning problems should be analysed sequentially "from the basic structure of society to the development and subsequent implementation of increasingly focused principles, laws and policies", moving from the constitutional to the post-constitutional levels and identifying the appropriate principles and criteria suited at each step.

Seen from this post-constitutional level, Laclau's and Mouffe's agonism has been useful in planning to balance the deliberative focus on consensus-building with recognition of the pervasive conflicts among social groups in planning practice, and to consider how conflicts can be negotiated in the absence (or beyond the limits) of rational deliberation. It enriches, rather than replaces, the paradigm of collaborative planning with a conflictual dimension and an expansion of deliberation to complement reason with passion.

Three questions can be relevant to planners from the agonistic revision of the deliberative paradigm: (1) the relevance of the normative framework defining the participants and the limits of deliberation; (2) the identification of the public interest; (3) the contents of the deliberation, and the comparative relevance of rationality and emotional positions from the participants. The relevance of these questions grow as we move down to the post-constitutional level of public policies, and in particular to planning discussions. At a time in which agonistic deliberation seems to dominate planning processes, to the benefit of the most powerful stakeholders and to the weakening of local governments and the dilution

of the public interest, it can be useful to look for a fresh way to revisit these three questions. Neo-pragmatism provides some valuable elements for this: On the one hand, neo-pragmatism avoids the foundational character associated to the critical tradition; on the other hand, neo-pragmatism replaces deliberation by the more flexible concept of persuasion: whereas keeping the exchange of reasons and arguments at the heart of the public debate, it leaves room for non-rational exchanges, putting empathy in the middle of the scene (see e.g. Rorty, 1998). Furthermore, the neo-pragmatic consideration of democracy as an on-going project in which regular citizens must be engaged offers a strong argument to pay careful consideration to the normative framework in which planning operates. Finally, it is also useful to recall Rorty's insistence in the relevance of the vocabulary that is chosen for the framing of questions: This can be a major contribution of planners (Wicks, 1993), beyond the discussion on the public-private split: the need to create the appropriate language to deal with the problems at stake. The conflictual nature of public deliberation in a democracy can be accepted without renouncing to the search for a definition of the public interest. Furthermore, utilitarian rationality can be rejected as the sole basis of deliberation and even a non-foundational concept of democracy can be embraced, without being compelled to enter a deliberation based mostly on emotions and fantasy: fact-based knowledge can save deliberation from the Scylla of utilitarian value-creation and the Charybdis of the global metropolis phantasies.

MNN: The facts and why this development is relevant for our discussion

In some cases, participation and decision-making in planning have significantly deviated from democratic practice. Beyond the constitutional, ontological discussion on what democratic practice is about, certain minimum conditions are generally accepted. In this section, the key facts and figures are presented together with the critical views of some planners, highlighting whether some minimum conditions concerning normativity, the concept of public interest and the deliberation process are respected in MNN. These critical views can be characterised as a particular case of professional activism, making use of technical knowledge that, contrary to any technocratic position, tries to build up a more democratic view of urban development policies in Madrid.

Chamartin railway station is based on railway plans developed in the 1930s, although the station was not opened until 1967. It was expanded in 1970-1975 to include commercial and leisure space, reserving the surroundings of the station for future expansions, that the subsequent decline in long-distance rail traffic made unnecessary, resulting in the blight of the area, owned by RENFE, the public rail company (to be split into two organisations, RENFE and ADIF, in 2004).

In the 1990s, new plans to expand the high speed rail network and the suburban rail services called for the expansion of the railway station. This expansion would need only a fraction of the land owned by RENFE, and RENFE saw an opportunity to intervene as an urban developer with the remaining land, dedicating the expected benefits to its plans to expand the suburban rail network in Madrid. RENFE considers that it needs a financial partner to secure the development plan, and launches the process leading to the MNN scheme in 1993, as summarised in Table 1.

Table 1: Key dates in the development of Chamartin Railway Station in Madrid

1993-1994	A public call is made and DUCH (Desarrollo Urbanístico de Chamartin) is selected as financial partner. DUCH is owned by a public-owned bank, with a minority share owned by a medium-size real estate developer. The contract is signed in 1994.
1997	The Local Plan of Madrid is approved, including the general guidelines for the area (300 ha).
1994-2004	DUCH lobbies to increase the built-up density of the area, and the municipality approves to raise it from 0.6 to 1.05 m ² /m ² . A development plan is subsequently prepared by it fails to get the support of the national government, which changes hands in 2004, on the basis of not taking sufficiently into account the needs of the railway system.
2009-2015	A new agreement is reached among ADIF, DUCH and the municipality in 2009, but the subsequent development plan is partially cancelled by the Court in 2013. A revised development plan is prepared, but cannot be approved before the local elections gives way to a different party.
2016	Based on public consultations, the local government publishes a draft document with the guidelines for the development of the area. It substantially modifies the scheme that failed to be approved in 2015. DUCH and ADIF are initially opposed to the document, but they agree to enter a negotiation process with the local government, outside the public participatory process.
2017-2019	A new agreement is reached in July 2017, raising the built density of the area. Grassroots organisations are critical to the concept; a low-profile public consultation procedure is completed in December 2018. The development plan is challenged at the Court by grassroots organisations, and the local government cannot get it approved before new local elections take place in May 2019.

The main stakeholder in MNN is ADIF, the public rail infrastructure manager, under the control of the national government through the Ministry of Transport. ADIF's objectives are to enlarge and modernise the rail station, and to obtain a net profit of some € 1 billion, to be dedicated to rail investments in Madrid. For this, it joined a partnership with DUCH, a private developer, since 1994. DUCH's strategy is to increase the area dedicated to high-quality office space as much as possible, and to keep the control of all development stages.

The objectives of the local government have fluctuated following the changes at the local elections. Relevant objectives have included (1) developing a modern downtown to compete internationally; (2) to improve the urban motorway network in the area; (3) to obtain a fair share of the benefits, through the mechanisms established in the law. Although these mechanisms were envisaged to facilitate an affordable housing policy, they have been used by municipalities to finance many other actions.

The profile of residents and businesses in the area is far from uniform, but they share some common concerns regarding the reduction of the barriers created by railway and motorway infrastructures, and the expansion of green open space and public facilities. They are backed by a variety of NGOs and local associations, sharing a "smart growth/ low growth" attitude. Their requests include (1) the preservation of most of the open space; (2) a substantial increase in social housing; (3) rejection of what they consider unnecessary infrastructures, such as the cover-up of the railway tracks and motorway capacity expansion; (4) substantial reduction in the provision of new office space.

Some professional planners have engaged in this debate, either individually or supporting grassroots associations, particularly since the 2015 local elections took a progressive coalition to the local government. They question the legitimacy of the positions taken by the key stakeholders: (1) ADIF's role as a developer and its naked search for profit, (2) the involvement of DUCH in the scheme as a purely financing partner, (3) the mild commitment of the municipality with affordable housing. They also question the distribution of charges and benefits, noting that the financial partner has not undertaken any investments in the area yet, and that those investments more relevant for the residents

will be subordinated to the progress of the development process, materialising only in the long term. Another key criticism refers to the office market studies provided by DUCH and backed by the municipality. Finally, they point out to several technical shortcomings in the development scheme: the operational restraints the slab covering the railways will impose on rail operations, the scarce appeal of the green zone that can be established on the slab, and the unsustainable transport options retained to provide access to the area. Therefore, the core of the criticism of these planning activists refer to the speculative strategy of ADIF and the municipality, their subordination to the financial partner, and the dubious quality of the documents provided. This activism is of a particular nature: rather than following an agonistic character, it aims at improving the quality of the public debate, and to preserve and reinforce the legal framework that should protect the public interest.

To understand the approach of these activists, it is useful to recall the particular evolution of the legal planning framework in Spain in the last decades. Although urbanisation schemes can be implemented by the public sector, the system has increasingly relied on the figure of the private developer, who is expected to produce the planning scheme (*plan parcial*), to self-organise implementation through urbanisation boards (*Juntas de Compensación*) with the participation of land owners and the developer, and to transfer to the municipality a percentage of the urbanised land or a monetary compensation.

The potential wrongdoings of this urbanisation procedure were well illustrated in the report discussed at the European Parliament in 2009 (Auken, 2009). The core concept at the basis of the urbanisation scheme is the central figure of the developer in the capture of the value created through the urbanisation process, and the distribution of this value among the developer, the land owners and the municipality, in an excellent example of a process of “self-organisation of the powerful” (Eizenberg, 2019).

Several points are made by planning activists: first, that the existing legal framework, though weakened, does not prevent local governments from leading the urbanisation process, and this is what should be expected, whenever a large impact on the city is likely. Second, that the legal planning framework, is not built around the idea of maximising the financial benefits of urbanisation, but about attaining a “sustainable, competitive and efficient urban development”. Third, that the law also encourages the participation of the public at the preparation and approval of planning schemes, and at its environmental assessment. All these principles are at odds with the opaque negotiated process undertaken among ADIF, DUCH, and the local government: A negotiated planning process that cannot be justified on the grounds of encouraging private participation in urban development or attaining a more competitive scheme yielding higher financial benefits. By doing so, urban planning ceases to be an activity grounded on the definition and materialisation of the public-interest, to become an instrumental, profit-generating activity focusing on the capital gain created through urban development and to its distribution among the agents controlling it.

The bargaining process opens the door to twist the rules: this is illustrated in this case by the all-too-original inclusion of the land occupied by the rail tracks in the computation of building rights, and in the consideration of the slab covering them as a green zone in order to meet the minimum legal standards.

Activists point out that the bargaining approach has implied the abandonment of some of the key local government’s legal obligations: (1) accepting the framing of the problem established by the financial sector, i.e. capital gain maximisation; (2) artificially restraining the number of alternatives at hand for the development of the area (as other alternatives would merit consideration if housing, environmental quality or neighbourhood regeneration would have been included as objectives, and (3) lack of interest

on a knowledge-based, fact-founded rational deliberation, to the benefit of purely utilitarian considerations.

The understanding of the public interest in the MNN scheme by ADIF and the local government is dismayingly shallow. In the case of ADIF, the public interest is identified with the enlargement of the railway station, in order to accommodate the growing long-distance high speed rail traffic. The costs of this reform is estimated at more than € 800 million. Additionally, new headquarters for the public railway companies (ADIF and RENFE) are envisaged, as well as new suburban railway stations serving the new developments and further improvements in the suburban rail network.

ADIF takes it for granted that any railway investments are made in the public interest. Little justification, and even less scrutiny can be found on the need for the additional platforms, the soundness of the substantial new commercial space to be developed in the new terminal or the rationale for the future headquarters. The same can be said about some of the suburban rail improvement projects anticipated, like a high speed connection with the airport, on top of the already existing one. In ADIF's logic, it seems that the public interest consists of maximising the capital-gains from the urban development scheme, in order to dedicate it in the railway system. This position raises two questions: first, whether the public interest can be better served with an alternative urban development scheme, in which capital returns for ADIF diminishes while other outcomes- be it social housing, open spaces or social cohesion- increase; second, whether all the railway investments envisaged are duly justified or, on the contrary, rail operations could be provided in the future with lower investments.

The local government has repeatedly declared that the development scheme is good "for the future of the city". This claim is supported, mainly, by market studies that consider that (1) there is a global demand for premium office space that Madrid has not addressed so far, (2) investors in the new office space will bring with them additional economic activity and jobs. The economic analysis makes the basic assumption that there is a potential demand of office-based activities that cannot materialise in Madrid due to the lack of adequate office space. This assumption is not consistent, however, with the facts of the significant rates in Madrid of both, unemployment and vacant office space. In other words: the local government is gratuitously assuming that the creation of additional office space magically generates the activities to occupy it. In doing so, the local government also fails to explore economic development alternatives that could better fit the characteristics of the economic system and the job market in Madrid.

Another argument advanced by the local government refers to the creation of new social housing. However, compared with the size of the area, the number of social housing units is strikingly low: 2,100 or just 20% of the 10,474 units envisaged. Furthermore, the surface dedicated to housing is merely one third of the total envisaged by the scheme. It can be concluded that, as ADIF, the local government has made a narrow and biased interpretation of the scope of the public interest.

In the absence of a consistent identification of the public interest, the choice of the public stakeholders is to mimic the financial logic of private developers. Interestingly, financial prospects can hardly be sustained by factual evidence. They are merely expectations, more related to passions and feelings than to rational arguments. Furthermore, the significant risks associated are transferred from private to public agents: Financial investors deal with this uncertainty by securing their position and delaying actual investments; public agents, on the contrary, have to advance their assets and investments to push the scheme forward.

Public deliberation is formally requested by planning legislation in Madrid for both, the development scheme concept and its environmental impacts. Obviously, negotiation process among the key agents that is taking place in MNN is not envisaged within the legislation, and is not subject to any conditions

regarding participation. As it is usual in these cases, the process has included long negotiations behind closed doors, followed by a well-publicised public relations campaign once the key agents reached an agreement. It is at this final stage, once the key decisions had been taken, that the developer approached residents and invited them to discuss minor suggestions regarding the design of the public space and facilities included in the scheme.

Two issues are relevant in the deliberation process: which are the participants included or excluded from it (the “adversaries” and the “enemies” in the agonistic jargon), and which is the “knowledge” (i.e. the facts and arguments) considered and dismissed in the conversation.

In the absence of more stringent rules, the map of participants has varied along the process, with three key players controlling it: ADIF, DUCH and the local government. ADIF and DUCH signed its first agreement in 1994, followed by subsequent amendments never made public until a recent (2019) Court decision requested to release them. Similarly, negotiations between DUCH and the local government were made public at the time of its formal approval, when the legal requirements for public information had to be met.

Interestingly, the new local government opened for the first time the deliberation to those critical with the previous scheme (the one that failed to be approved in 2015) when they took office in mid-2015. At that time, its strategy was to de-legitimise the agreement reached by its predecessor. Once ADIF and DUCH abode to the new situation, the local government changed its strategy, excluding the critical voices and coming back to the traditional practice of entering opaque negotiations with them.

This experience indicates the insufficiency of the current legal framework, as it provides powerful stakeholders with the ability to redefine the boundaries of participation and to identify enemies to be excluded, in accordance with their changing particular interests.

The local government and other powerful stakeholders enjoy a similar discretionary capacity for deciding the considerations to be included in public deliberation. Instead of abiding to facts and knowledge-based arguments, the local municipality sets up a deliberation scene based on a fancy future of global investments and glamorous jobs. Those unwilling to share this imposed vision are excluded from the deliberation as guilty of ideological bias, incapacity to cooperate with the private sector and unrealistic visions. What is interesting in this particular framing of public deliberation is that passion and feelings dominate: the ambition of the hegemonic stakeholders to “put Madrid on the global map” is undeterred by the facts and knowledge provided by the critics regarding the public and social costs involved, the functional unbalance, the extremely long delays to those hypothetical benefits for residents to materialise, or the dubious need of some of the costly transport infrastructure investment foreseen.

Conclusions: Avoiding the agonistic trap?

Agonism is about recognising the differences among groups in a democracy and assuming that these can be negotiated through the respect of agreed-upon rules. The case of MNN illustrates how, in urban planning, agonism can easily degrade into plain legitimisation of negotiated planning *to get things done*, even for progressive local governments. This can have been the agonistic trap the local government fell into in Madrid: starting by a poor identification of the public interest, and considering planning as an agonistic process in which hegemony has to be built up, it labelled as *enemies* to be excluded from the debate those that could not share the developers’ vision of fancy office towers and that were asking for a prior re-definition of the public interest. By wrongly accepting to frame the discussion on the basis of capital-gain and value-creation, the local government got trapped in a process in which facts and

knowledge became irrelevant, a process that it could no longer control: The strategic discussion was dominated by capital-gain expectations and global competitiveness promises, not by social and spatial unbalances or poor living conditions.

This case study illustrates that an agonistic approach to planning by a local government risks to be blind to the calls of rationality (including knowledge- and fact- based considerations on infrastructure functionalities, the reasonability of future expectations or the relevance of competing city challenges) to the benefit of a purely “bargaining” process dominated by capital gains and distribution. More fundamentally, such an agonistic approach is likely to be biased while identifying the stakeholders that deserve to join the process. It risks, finally, to privilege decision and action over fairness and rationality. The reluctance of agonism towards transcendental concepts such as the public interests also facilitates for the local government to fall into a deliberation focused on capital gains and their distribution. One of the sources of these shortcomings in agonistic planning can be the result of a hurried application of concepts from the constitutional level of political philosophy to the post-constitutional level of practical public policies.

The reaction of some professional planners in Madrid, becoming enlightened activists, is not too distant from the positions of some post-Marxist planners. They (1) try to re-focus the public deliberation on structural issues (the metropolitan unbalance, lack of affordable housing, easy to implement opportunities to improve the residents’ environment, accessibility and sustainable transport concerns...); (2) they aim at changing the criteria set to establish the boundaries for the participation of agents in the debate, basing their legitimation on the public interest at stake rather than on their capacity to set up a hegemonic position; (3) they adopt a pragmatic approach in urban development, one coping with urgent needs rather than overcomplicating the scheme to maximise cash flows. A novel profile of planning activism emerges from this experience, partly taking us back to the radical democracy discussions privileged in pragmatic and neo-pragmatic thinking: based on the rule of law, good reasons, and focus on transitional processes. From this perspective, more careful attention in planning is due to laws, codes, regulations and technical savviness. Not to claim a technocratic turn, but to state that technical reasoning can be a worth alternative to pseudo-technical thinking, loosely based on utilitarian reason.

Sex (Roles) and the City

Chiara Belingardi¹

¹DiCEA, chiara.belingardi@uniroma1.it

Abstract: In the last years a new wave of feminism arise, showing how the violence against women is still present in contemporary society. Violence against can be intended both as direct (domestic violence, harassment, ...) or structural (pay gap, less opportunity, less listening in the public arenas). The paper aim to show different aspects of structural violence affecting women, coming from urban environment. They can be recognized in more difficult in access to houses, to public spaces, to spaces of self-organization; in the preference given to private transports than to public ones in the mobility management of the cities; in the difficult to conciliate productive and reproductive activities; the lack of representativeness of women in the design and planning disciplines. The last issue is object of different international research in recent years, and can be one of the causes of the little attention payed by planners to gender issue.

Keywords: gender issues, violence on women, city of difference, wellbeing

Introduction

In recent years the debate about the violence against women arise internationally, spreading at institutional and grassroots level. Researchers in various disciplines (both social science - humanities and STEM) started to rethink about their way to do scientific investigations and the role of women in the professions.

In 2011 it was held by the Council of Europe an international conference in Istanbul about violence against women. The charter emerging from the debate was ratified in most country of Europe. The *Convention on preventing and combating violence against women and domestic violence*, known as *Istanbul Convention* is a point of reference in the debate. In the Preamble some definitions of different forms of Violence against women are provided. Beside the blame of any form of direct and domestic violence against women, it is written: *Violence against women is a manifestation of historically unequal power relations between women and men, which have led to domination over, and discrimination against, women by men and to the prevention of the full advancement of women; it has to be recognised the structural nature of violence against women as gender-based violence, and that violence against women is one of the crucial social mechanisms by which women are forced into a subordinate position compared with men* (Council of Europe, 2011).

In 2015 starting from Argentina a new feminist wave arise. *Ni una menos* is a *collective scream against the violence against women*. Starting from Latin America the scream spread all over the world. In Italy in the same year many women unite themselves in NonUnaDiMeno, a feminist movement. The first acts of the movement were the organization of a big march and the collective writing of a *Feminist plan against male violence against women and gender-based violence* (Piano femminista contro la violenza maschile sulle donne). Also this document deal with the concept of *Structural violence*, meaning all the direct and indirect forms of violence: *When we affirm that violence is systemic, we mean that its forms of expression are multiple and transversal: in fact, they touch all the areas of our lives, constantly weaving between them*. (NonUnadiMeno, 2017).

This paper deals with some of the forms of structural violence against women emerging by the urban environment. Since many years it has been underlined that urban environment is not neutral, but it is instead designed under the exigences of a certain type of user: male, white, adult (Sandercock, 1998). This has been claimed in several scripts, as *Making space: women and the man-made environment*, wrote by the collective Matrix in 1984 (Matrix, 1984), or the seminal text *What Would a Non-Sexist City Be Like? Speculations on Housing, Urban Design, and Human Work* wrote by Dolores Hayden (1980), and in some international documents, as the *European Charter for Women in the City* (1994). These documents denounce the invisibility of women in urban environment both as user and producer.

The paper will deal with both forms of invisibility (violence) and is structured as follow: the first part is about the professional gap among men and women in the design professions (architects, planners); the second part is about the demand of women as city users; the conclusions will provide some suggestion on how planners and policymakers could act against violence against women.

Room (of one's own) at the top

The title of this chapter is the mesh of two title of texts: one is the renown *A room of one's own* (Woolf, 1929), the other is *Room at the top? Sexism and the Star System in Architecture* (Scott-Brown, 1989). The text of Virginia Wolf deal with feminine creativity: the author wrote that the creativity need room (in physical and metaphorical meaning) in which the creator can be alone for all the time needed for the creative activity. This kind of space is traditionally denied to women, as they could be constantly distracted by demands and exigences of husbands and children. Actually the problem of the conciliation of time to be dedicated to family and professional work is at the centre of feminist debate since the first women started to work out of home. The lack of room and time is one of obstacles for women professionals, but not the only one.

The roots of the problem are to be looked first in the denial for women to access the professional education and to the profession. It was not possible to women going to university, especially the technical ones. The first schools opened to women were in the United States (1873 Illinois School of Architecture; 1888 American Institute of Architects). In Europe the first graduate was Signe Hornborg in 1890 a Helsinki (Mattogno, 2013). In Italy the first graduate in Engineering was Emma Strada in 1908 at Turin Polytechnic (Galbani, 2001). In Rome, it was possible to access the faculty of Engineering in 1910. The first was Elena Sadowska, who after her degree went back in Russia. The second one, Bice Crova, had a long professional and scientific life, but notwithstanding the long enrolment as “free lecturer” in the Faculty, she never achieved a permanent position, neither was appointed as professor.

After the graduation the second obstacle were (are) the prejudices conscious or unconscious women face. To many people once they get their graduation, still don't have the capacity to going larger than interior design (Mattogno, 2013; Rodano, 2010). Mostly they design with their husbands, fathers, brothers or colleagues, and they don't sign the projects. For this reason a lot of the projects women did in the last century is forgotten, unknown, overshadowed or credited to the male partner. Also this is one of the reason the Architectural world is a male world: because women architects are mostly unknown. In 1989 Denise Scott-Brown, partner and spouse of Bruno Venturi, wrote *Room at the Top? Sexism and the Star System in Architecture* (Scott-Brown, 1989). It took 15 years to decide to publish it. A sentence is exemplary: *I watched as he was manufactured into an architectural guru before my eyes, and, to some extent, on the basis of our work* (Ivi: 237). The work architect Scott-Brown did was so little recognized that only he, of the design couple, received the prestigious Pritzker price in 1991.

In 2013 Ines Sanchez De Madariaga and Marion Roberts edited a book about gender and city planning (Sanchez de Madariaga, Roberts, 2013). In her introduction Marion Robert indicated the lack of women in design and planning professions as one of the main problem in the conquer of a *fair shared city* (Roberts, 2013). The topic was reprised by Ines Sanchez de Madariaga (2013), who in her contribution to the book presented the problem

more in deepen: *Contemporary research tends to see the processes of professionalisation as a form of control of occupations through which carefully designed jurisdictions and privileges guarantee the autonomy of a few, masked under a rhetorical discourse of objectivity and political disinterest* (Layne, 2009). *In this way overwhelmingly male elites have ensured their place in the hierarchy through patterns of homo-social reproduction* (ivi, 156).

However gender inequality in the design disciplines means not only the number of successful women architects, engineers or planners. It means the predominance of a “male” way of designing and planning, which is less sensitive to daily problems and challenges of being women (as it will demonstrated in the next paragraph). Male problems are considered as universal, while feminine once are considered as partial. So women designers should adapt themselves to male professional and design practice, with only few space for thinking on their own feminine practice and problems. Encourage and empowering women design means to encourage a different way of thinking urban spaces and citizens wellbeing.

Basing on the scripts left by women architects on their own way of designing (see Belingardi, forthcoming), it is possible to affirm that the way of being a women architects comprehend: adopting a situated looking and questioning traditional rules; starting from oneself, recognizing one's problems as collectives and designing the solution; designing in a not hierarchical way, enhancing different knowledges (see Dwyer J., Thorne A., 2007); focusing on listening, the relationship, the human (see Lonzi, 1982 and 2006). There could be more aspects, but starting to using and teaching these tools could start a revolution in the design professions.

Women's place is at home

Thus women are not intended as city users.

Thinking about violence against women in city, generally means to deal with physical violence perpetrated by unknown men in public space. This is why public policies generally address the prevention of this risk through policies of public order (increasing police, exclusion of populations considered as indecorous, order). These policies have the effect of limiting women's freedom of movement and increasing the perception of risk. For this reason, in the face of a non-increase in the number of crimes, the autonomy of movement in urban environment of the categories at risk or of weak street users: children, elderly and even women in part have decreased. Policies and projects made to act against this kind of violence comprehend: maps of risk (even made through app), manuals to go on the streets, “rape-prevention tips”, and so on. These kind of devices have the main effect of giving to women the responsibility of the violence act and enforcing victim blaming.

Focusing on the statistics, it appears that the less safe place for women is their home, and that women have more possibility to be harassed or beaten by their husbands or man they know. Just to delivery an example, in Italy in 2016 149 women have been killed, 109 of them have been killed by their partner, ex-partner or relative (Alleva, 2018). It is safer for a women stay in public or collective space then at home, even thinking about the possibility of being helped by anyone (friends, strangers, police). So one of the challenges for planners to acting against violence against women should focusing on domestic violence.

Moreover, thinking about violence against women in cities it is important to shifting the focus also on structural violence. That means that cities are designed and planned for white, adult men (Sandercock 1998). That means that are planned to ease the problem of productive work, instead of reproductive one. Most of women in the contemporary ages still face the problem of conciliate the productive work with the reproductive one (Macchi, 2006): they have the charge of their job and also of cleaning home, providing meals, caring of children or elderly. Planners cannot deal with family agreements, but they can do something about public services and facilities and their locations in the city, about paths people have to cover (in terms of difficult and length/duration), about collective spaces.

Lack of safety and wellbeing in public spaces and in the streets can also affect women's daily life, not for their being weak users, but for their task of accompanying truly weak users (children, elderly, ...). About the mobility in the city, Silvia Macchi defined women's mobility way like "costal navigation": not long travel as commuters, but many little transfers (Macchi, 2006). This kind of mobility is considered as irregular, unexpected by current mobility design and technics, but for most women correspond to their daily path, due to the different duties to be completed during the day.

Also public space are designed with men as parameters, as it has been demonstrated by the case of Einsiedlerpark in Vienna (see Irschick, Kail, 2013). The park had facilities geared to interests of boys and male adolescents, with the results that girls and female adolescents didn't use it. Or: girls and female adolescents had less possibilities in using the park even if it was a public space in a neighbourhood densely built up, due to the male made design of the park. As a result of two workshops involving specifically girls it emerged that girls, for example, had problems in using an enclosed cage playground to play with the ball due to the predominance of boys and overall to the presence of only a door to in-going and out-going. Also sports facilities were made for male-preferred sports. So the city organized a competition to re-design Einsiedlerpark and another park, named Saint Johann by taking in account what emerged in the participatory workshops. Moreover the city offices wrote the *Guidelines for Gender-sensitive Park Design*. Since 2007 these recommendations, together with the general Park Design Guidelines, constitute the planning basis for all new project (ivi).

Conclusion: a planners' plan against violence against women

In the first two parts of the paper, gender - inequality was shown in the planning and design of cities. it has been said that this is primarily due to the minoritization of women in the project disciplines, to the greater difficulty they face in the construction of their careers and to the lack of recognition of their work. So one of the first actions to do to build a fair shared city, or to take action against violence against women in urban environment, is to reduce this gap, not only in terms of the number of women architects and planners, but above all in terms of how to design. It means to let female designers formulate projects starting by their own experience and point of view.

With regard to urban environment it has been said that women suffer direct violence (especially in the domestic environment) and indirect violence, due to the fact that cities are built only for others (male).

About the domestic violence, it appears urgent to design some policies to facilitate the access to social housing, or housing at low price for women (and children) at risk to suffer violence. In this way women, who generally are the economically poorest part of a couple, could be facilitated to move in safer space and to conquer their independence. It appears also useful to increase places in which women can meet and stay together, intertwining relationships of sisterhood among themselves (this is useful also for fighting against structural violence).

About public spaces, it should be important to stop using the image of women as potential victim in public spaces, also to justify security interventions. It is instead important to create safe and pleasant places in which women (and men) feel good. In this way people could use public spaces and create the sense of wellness and neighbourhood safeness of which spoke Jane Jacobs (1961). To create comfortable public spaces also for girls and women (public space, parks and playground), it is important to incorporate their point of view in the design, basing of their real participation and not in stereotype. As it was shown by the example of Einsiedlerpark in Vienna, this point of view is rarely taken in account, as it is assumed the male one as universal.

About urban mobility is seems important to care for and encourage short travel path made by foot, bike and public transport or mixing the way of moving. In this way they would be ease the routes made in the neighbourhood, and children and youngsters autonomous mobility. Positive consequences of these decisions would concern environment and people wellness.

Finally is important to create collective spaces: a women's home in every neighbourhood. Born as separate spaces of feminist movement, at present women's home opened their activities also to queer persons, children and men. These these places are not spaces of service, in which to go in the moment of need, or to solve some problems, but places "of desire", in which it is possible for every woman to realize the desire she has for herself and for her environment (social and physical) of life.

Acknowledgements

What is wrote in this paper has been deepen through common research and thought shared with Federica Castelli and Serena Olcuire (Atelier Città, Iaph Italia), Claudia Mattogno (DICEA Sapienza), and Le Pantegane.

Managing religious mega-event in a mundane urban community: the case of Muslim Eid al-fitr in Huxi Mosque, Shanghai

Tong Cai ¹, Ze Zhang²

¹ *Tongji university, tong.cai@qq.com*

² *Tongji university, zhangze47@qq.com@qq.com*

Abstract: Accompanying Shanghai's opening-up and rising-up as a global city, both internal and international Muslim immigrants are rapidly increasing. With a large proportion of the irreligious population, the Chinese government's attitude to religion is neutral. As religious mega-events would require extended open space, the Muslim immigrants have to occupy some public spaces around the mosque to hold religious events, confronting the everyday life of the local residents in the surrounding community. Taking the Eid al-Fitr 2017 in Shanghai Huxi Mosque as an example, we investigated the religious mega-event when it took up the whole streets for a whole day, and interviewed 56 Muslims, 89 locals, and 9 administrators. The results show that the rigid top-down government-enforced management model cannot resolve contradictions between the two groups because different social groups (the Muslims and the local residents) have completely different spatial demands. Based on the interview with key informants and survey, preliminary findings suggest that a bottom-up model, for example, a street-based community comprised by residents, Muslims and neighborhood committees, may work better to manage this religious mega-event in a self-organized fashion. First, more channels should be created to express the Muslims' opinions regarding the planning and formulation of both mega-events and daily life. Second, a harmonious cultural atmosphere could be created for the Muslims group by organizing some unique local activities and cultural festivals or temporary markets to enhance mutual understanding between local residents and Muslims. Finally, establishing Muslim cultural community may play an important role in strengthening the understanding of religious culture to the surrounding communities and mitigate the misunderstanding and alienation between locals and Muslims. These findings will generate implications for policy-makers to manage religious mega-events more effectively in a mundane urban community in Shanghai, and other global cities with diverse ethnic groups.

Keywords: religious mega-event, community, social group, self-organization

Introduction

With the rapid development of urbanization, more and more minority groups are flooding into cities, which brings many problems worth thinking about for the development of urban society. Among them, how to properly deal with large religious gathering places in high-density cities has always been a main topic in urban studies. Through reading relevant literatures, it is found that in the traditional settlements, Muslims mainly live in "adjacent temples", "due to temples" or "homologous temples", with characteristics of taking their own religious beliefs as the platform of social relations. However, in metropolis of Shanghai, most Muslims come to Shanghai by ways of immigration, the activity space is still very limited. At the same time, Muslims are

restricted by work restrictions, residence isolation, language barriers, communication limitations and communication methods, which further deepen their appeal for religious life.

In recent years, during the eid al-fitr and eid al-adha, many news media reported that thousands of muslims would occupy the whole road in Changde Road, Putuo district, Shanghai. The swats, public security and traffic policemen in Shanghai would "open the road" for believers to make pilgrimage. The international media was taken aback, lamenting as "Muslim occupation of the streets of Shanghai". The "pilgrimage on the road" of the eid al-fitr in the west mosque of Shanghai has aroused great controversy, which directly conflicts with the interest demands of other groups. Shanghai has always held an inclusive attitude towards ethnic groups and religions, and has adopted a series of management measures, but contradictions still exist and even become more and more controversial. So why do muslims "make pilgrimage"? What is the social impact? Why the controversy was happening?

Methods

This paper covers the area of Huxi Mosque, No. 3, 1328 Lane, Changde Road, Putuo District, Shanghai. It is adjacent to Line 7/13, and has convenient public transportation. Muslims worship in Shanghai for many years. Shanghai West Mosque, also known as Yaoshuilong Mosque, is the first rebuilt mosque in Shanghai after liberation. The whole building is exquisite, magnificent and full of modern Arab Islamic architectural features. The mosque is located between the residential area of Changshou New Village, a kindergarten and a further education institute. It also has a main entrance and exit on Changde Road, the city's sub-main road, and a secondary entrance and exit in the adjacent Changshou New Village.

We hope that by understanding and understanding the religious spatial organization in high-density cities, we will pay more attention to the contradiction between religion and urban mainstream groups and ethnic minority religious groups behind urban life. This paper focuses on the "Occupied Road worship" incident of the Shanghai West Mosque, investigates and analyses its process and social impact, understands the real ideas of interest groups and the causes of "Occupied Road worship", analyses the causes of disputes from a relatively fair point of view, and puts forward some suggestions for mitigating the impact and optimizing related management in the future.

This social survey adopts the methods of field observation, interview, questionnaire survey, literature review, software analysis and so on. The subjects were mainly Muslim worshippers, residents and managers. Fifty-six questionnaires were interviewed with Muslims and 89 questionnaires were interviewed with Muslims of different types, including 23 Muslims, 32 residents and 9 managers.

Analysis of the results

Limited religious space for muslims

According to the data of the Fifth and Sixth Census, there were 60,000 registered Muslims and 78,000 Muslims in Shanghai in 2000 and 2010 respectively, while there were 30,000 and 120,000 foreign Muslims in the same period. Although they accounted for a small proportion of the total number, they grew rapidly. The average annual growth rate of registered Muslims was 2.6%, which was 4.7 times the growth rate of registered population, while the average annual growth rate of foreign Muslims was 14.8%. On the one hand, local Muslims continue to grow, on the other hand, a large number of foreign Muslims continue to pour in, resulting in increasing demand for Muslim religion in Shanghai.

In addition, it was found that Muslims who attended the Eid al-Fitr came from various districts and counties in Shanghai, exceeding the service radius of the Mosque itself. On the one hand, the number of mosques in Shanghai has not changed for a long time. In 2004, there were 8 mosques in Shanghai. Each mosque

corresponds to 8,479 Muslims with household registration. It ranks second among provinces, autonomous regions and municipalities directly under the Central Government, far exceeding the number of believers that a normal mosque can do. By 2010, this figure has risen to an average of 9,700. The monasteries are unevenly distributed, overlapping service areas, and generally occupy a small area with limited accommodation. The number of Muslims is increasing and the demand is increasing, while the number and space of mosques are not increasing. It is the imbalance between supply and demand in this space that leads to the occurrence of the incidents of the occupation of public space by the pilgrimage of Eid al-Fitr.

Lack of jurisdiction and feedback among relevant groups and departments

The administrative administrators of the Eid al-Fitr worship in Shanghai West Mosque are mainly divided into three departments: Street residents committee - Changshou Road Street residents committee, traffic control Brigade - traffic police detachment of Putuo Public Security Bureau, Public Security Department - Putuo Branch of Shanghai Public Security Bureau and its subordinate police stations. In the organization and management, the district government takes the lead, jointly with the above departments, as well as urban management departments and religious offices, to coordinate various work and feedback from interest groups.

The mosque lacks the consciousness of communicating with the residents actively, and the opinions and consideration of the surrounding residents are insufficient. It does not assume the responsibility of informing and explaining actively. Their lack of initiative also increases the difficulty of other management departments. Relevant departments failed to establish effective communication channels. Due to the sensitivity of religion, it is difficult to establish effective communication channels due to the passivity and delay in dealing with problems and the complexity of relevant departments. Due to the lack of communication and feedback between the departments and residents, residents do not attach importance to the universality of religious assemblies, and only publicize the results of administrative management. The public lacks the basis for understanding religious assemblies, thus increasing misunderstanding and dissatisfaction.

Comments and feedback between residents and Muslim because involves the religious and ethnic problems, management style is more complicated, making comprehensive management department is difficult to deal with both sides, both sides communication channels, combined with the traffic police are required for large religious gatherings, urban management, public security, such to maintain order, to strengthen the residents of the Muslim sense of distance, make growing estrangement together.

Discussion

Through the semantic difference, it is found that residents and muslims have different attitudes towards eid al-fitr, residents generally do not understand and feel monotonous, while muslims think it has a happy festive atmosphere. The difference in values and culture behind this event is the reason for the controversy caused by the road using. Objectively, muslims are different from ordinary people in dress, language communication, eating habits and even lifestyle. This cultural difference will inevitably lead to the exclusion of the two sides in the contact, which is further reflected in the values. Residents generally feel the influence of road worship, while muslims are accustomed to it.

The communication between muslims shows a ranking characteristics of religious identity, local identity, identity, community identity and professional identity. After arriving in Shanghai, due to the differences in cultural customs, community relations gradually weakened along with their identity, occupation and community identity, and continuously strengthened their religious and local identity. This kind of self-identity of muslims habitually constructs the social circle according to the traditional way. They lack a sense of belonging to the local people and have a strong "pass-by mentality". As a result, their identity is blurred and "inner circle". The original dogma of not supporting intermarriage limits the communication of muslims. 70% of muslims show a negative attitude towards non-muslim communication and have no strong subjective will for communication.

This has led to "inner circle" social networks, in which muslims are mostly of the same ethnicity and religion and rarely interact with non-muslims. Due to the residents' lack of willingness to take the initiative to learn about muslims, the frequent occurrence of international violence and the excessive exaggeration by the media, the residents generally form stereotypes about the Muslim community, such as "extreme" and "restless". Even their religion, culture and some negative events are associated to form a label. The formation of such a cultural label is also the cause of the growing estrangement between the two sides. The cultural differences between the minority groups and the urban mainstream groups make the two sides in the process of cultural contact, integration and adaptation, have alienated and discordant towards other cultures, and even subjectively have negative attitudes, such as cultural separation, cultural isolation, and cultural disidentity. Islam belongs to the minority group culture, so the residents will feel superior to the mainstream culture when they come into contact with it, resulting in different cultural acceptance attitudes of the two sides. Through the questionnaire, it is found that the residents generally believe that muslims should follow the local customs and learn and understand the local culture, but they do not think that they should also take the initiative to understand the Muslim culture. Such an imbalance in attitude makes muslims have been alienated from the mainstream culture rather than integrated.

To sum up, the objective cultural difference makes the Muslim community more inclined to ethnic identity, and intensifies its social "inner circle". The labeling of religious culture and the difference in cultural acceptance attitude make the relationship between muslims and residents more alienated. This kind of space, the cultural difference behind the behavior and even the social identity, is the main cause of the controversy of this pilgrimage.

5 Conclusion

This paper covers the area of Huxi Mosque, No. 3, 1328 Lane, Changde Road, Putuo District, Shanghai. It is adjacent to Line To sum up, the objective cultural difference makes the Muslim community more inclined to ethnic identity, and intensifies its social "inner circle". The labeling of religious culture and the difference in cultural acceptance attitude make the relationship between muslims and residents more alienated. This kind of space, the cultural difference behind the behavior and even the social identity, is the main cause of the controversy of this pilgrimage.

In the process of in-depth analysis, the author found that "occupying the road to worship" is not a horrible problem. The essence of the dispute is mainly caused by spatial imbalance and cultural differences. According to the statistical analysis of the number of Muslims coming from various districts, mainly living in the northern suburbs, considering the radius of the mosque service, it is recommended to build a new mosque or relocate the Huxi mosque to the northern suburbs, and appropriately expand the scale to meet the religious activities of Muslims.

In the case where the current space is limited, the following measures can be taken. First, focusing more on national cultural exchanges. Relevant departments or the media should strengthen the science of national culture. Residents can have a way to understand Muslim religious beliefs and customs, thus narrowing the sense of distance and strangeness between different cultures, changing the stereotypes of the people and removing cultural labels. Fully mobilize the enthusiasm of the Muslim community mechanism, promote mutual understanding, thereby enhancing the sense of identity and creating a harmonious and good cultural atmosphere for different groups. Second, enhancing the effectiveness of communication channels. In view of the shortcomings of timeliness, communication effectiveness and information transparency in the management mechanism, the proposal to establish a permanent body of the Standing Committee is proposed. It consists of representatives of residents, management departments, and mosques, allowing residents to participate in and understand the development of the activity process to compensate for the feedback from residents to the communication channels between departments. Through self-governing institutions, we will establish long-term

exchange channels between residents and mosques to resolve misunderstandings and alienation caused by lack of communication throughout the year. Third, promoting creations of religious activities. In order to shorten the social distance between religious culture and secular society, some “innovative” religious festival patterns can also bring us some inspiration: turning religious festivals into local festivals and secular festivals, including unique localities. Activities, non-religious recreational breaks and market events can be naturally integrated into it. If Eid al-Fitr is not only a religious activity, but also a secularized local national cultural festival, it will be conducive to the harmony of national culture.

Life is still going on with times changing. Shanghai's pressure on population growth, environmental resources constraints, cultural complexity and diversity is increasingly prominent. Shanghai must break through the development bottleneck and realize the transformation of urban development model. As mentioned as Shanghai 2035, “in a future society with a more diverse demographic structure, Shanghai will strive to become a humanistic city with successful cultural governance, outstanding global influence, and high public recognition through its unremitting pursuit of urban quality”. As a remarkable global city, religious groups and religious activities will be treated in a more inclusive manner. Even if it is not the same faith, everyone can still find a space in the city, can be recognized and looking forward to know each other.

The right to housing: from occupation to transitory collective housing in Turin. The case of via La Salette

Abstract: The case of "La Salette" transitory collective housing (Turin, Italy) problematises the relationship between conformative planning systems and urban practices. Since the occupation of an abandoned space for housing purpose in 2014 by around 90 migrants, the housing use "legalization" of an abandoned private building, was reached in 2018. Urban stakeholders have been involved and activated, the space has been regenerated with a multidisciplinary approach and housing co-management and small informal economic activities have been set. It was possible by the simultaneous presence of inhabitants and works and by people's self-maintenance. Specific pieces of rules were identified and articulated in a sort of technical and legal tool consistent with the current legal framework. The Italian planning system is defined as urbanism (EC, 1997) and conformative (Janin Rivolin, 2008, 2017): in response to a local community social need, not foreseen by the existing plan, the proponent of an eventual response to that need could not propose a solution, not included in the existing plan, although responding to a territorial development objective. The concept of interventions' predetermination within conformative systems does not include the promotion of voluntary territorial development proposals, approved because of their contribution to development objectives. Predetermined interventions prevail on development objectives, so if territorial needs are not foreseen by the plan, responding by parts is necessary. In this case, the intervention was divided into parts attributable to preordained determinations, assembling a technical and juridical construct, resulting in an overlap of normative fragments belonging to the existing legislative apparatus. Nevertheless, this ad-hoc juxtaposition cannot ensure the automatic realization of further interventions on the same site. In conclusion, although the inflexibility of conformative urbanism, the production of a sort of new rule, has permitted the realization of an "unexpected" project.

Keywords: temporary collective housing, legalization, self-production, co-management

Introduction

This work is based on project reports, elaborated for the commissioning and for the Compagnia di San Paolo, one of the donors, and on technical reports for professionals. In particular, reference was made to Guiglia e Sordo (2018). This work was presented in June 2019 in: XXII Conferenza Nazionale SIU. L'urbanistica italiana di fronte all'agenda 2030 per lo sviluppo sostenibile. Portare territori e comunità sulla strada della sostenibilità e della resilienza Bari - Matera, 5-7 Giugno 2019

The initiative called “Collective Transitory Housing of La Salette” in Turin was carried out by members of the civil society and the Church organizations to provide a response to housing emergency and social segregation. In particular, the project regarded a building constructed in 1958, initially used as boarding-school, then as a home for elderly, finally decommissioned in 2008¹. In 2014, it was illegally occupied by a group of 90 refugees arrived by the immigration wave in 2011. In 2014 the Turin Diocese, Pastoral Office for Migrants and the Diocesan Caritas activated a complex work programme, in accordance with the owner and occupants of the building and with the “Solidary Committee Refugees and Migrants”², aimed at:

- sharing the progressive housing regularization process,
- supporting people in becoming independent in housing, labour and social terms,
- improving housing conditions throughout the physical refurbishment of the building,
- defining and realizing, even in a med-and-long-term perspective, a new transitory and self-managed housing solution, specifically addressed to vulnerable people (Guiglia & Sordo, 2018).

In May 2015 the no-profit association “Insieme per accogliere”³ was tailor-made, with the participation of the Pastoral Office for Migrants, the Diocesan Caritas and the Missionaries of Nostra Signora de la Salette. This association - since the agreement for the loan-for-use of the building, granted by the Order of La Salette - instructed Cecilia Guiglia e Paola Sacco, professionals belonging to “Luoghi Possibili”⁴ to coordinate the technical and participatory architectural interventions, and instructed the Cooperativa Orso⁵ to carry out the social support. The first level of participation consisted in building a sort of “collective commissioning”⁶, composed of owners, inhabitants, representatives of the Diocese, Solidary Committee Refugees and Migrants and social workers.

After that, other technicians were involved to solve specific problems, selected by the specific competencies, experience and attitudes, firstly Architettura Senza Frontiere Piemonte⁷. They composed the project team⁸.

³ The association was created in May 2015 in order to regularize the residency of the occupants.

⁴ It is a group of interdisciplinary projects, born in 2004, expert on housing and urban regeneration. It coordinates the technical and social aspects of architectural intervention.

⁵ The Cooperative was born in 1987 and usually works in Torino, Cuneo, Asti on the labour, migration, integration and youth policies. From 2009 it works also with refugees.

⁶ “Collective commissioning”: aspiration to share with other actors project key elements, according to a feedback-loop approach.

⁷ Architettura senza Frontiere Piemonte ONLUS is a no-profit association, located in Turin, funded in 2006, belonging to the international network Architecture sans Frontière International, inspired by the principle of the Chart of Hasselt, on the basis of which intervenes with cooperation and local development project in the South and in Italy, in presence of social, urban and territorial emergency. It proposes the architecture as an inclusive and interdisciplinary practise addressed to participatory architecture with the local communities.

Since the mid-2015, the team started the works in parallel to the social support of inhabitants and supported to the labour and social integration. The total value of the intervention was approximately euro 880.000, reached thanks to private financings by donations and calls.

Figure 3 Graphics of the final uses Fonte: elaboration by Paola Sacco and Andrea Sassano.

⁸ The project team is composed of Cecilia Guiglia, Paola Sacco (Luoghi Possibili) Valeria Cottino, Veronica Gai, Annalisa Mosetto (ASFP), and the free-lances Mario Alessio, Ivan Castagno, Daniele Filippa, Daniela Re.

The part of the building for residential use was functionally divided by floors into rooms and common services, on the basis of the observation of occupants' behaviour in this structure and in other experience: limited size of the common spaces, number of inhabitants per area and natural tendency to gather by nationality. The team of the project expressed the need to build good neighbours' relationship – even throughout the use of the garden – and identifying spaces able to economically contribute to the management of the building. In the observation of the spontaneous practices of use of these spaces by the occupants, one of the most relevant and complex issues – particularly in case of self-management, regards the right to accommodate friends in their own rooms. Because of that, a part of the basement could be used as guest-rooms.

Figure 5 View of the garden, after the intervention. Source: Architettura senza Frontiere Piemonte.

The realization of this collective housing was not obvious at all, because the national and local regulations do not foresee this type of final use, nor the realization of building works in an already inhabited space, although with the objective of social inclusion, in a logic of self-construction. Therefore, it was necessary to identify every single legal reference, and unifying all of them in a technical-legal device, acceptable by the current urban planning system. Indeed, in Italy, the planning system is conformational and urbanism (EC, 1997; Janin Rivolin, 2008, 2017). Because of that, it is necessary to identify the existing planning rules which are valid to justify the proposed intervention, in order to conform it to the regulatory system in force.

This implies various operational difficulties: with respect to the real social need expressed by a part of the local community, but not previously defined by the plan, the promoter of a project is not allowed to propose solutions that, even responding to territorial development objectives, are not foreseen by the previously established rules.

Because of the rigidity of the rules in force, the first problem was the temporariness of the migrants' reception and integration process determined by the features of social housing⁹. The reception would be considered as equivalent to the touristic activity, not permitting to certify the legal residency, that is necessary to obtain the resident permit for migrants. Because of that, the residential final use was selected and connoted as "collective", thanks to "Insieme per Accogliere" who nominated a head of the building among its members. To do so, the municipal offices made use of an existing agreement on these issues between Turin Diocese and Municipality of Torino, that permitted to go ahead, maintaining the same designated use. In fact, the change of designated use would have taken two years and would have been too expensive.

According to the Turin Municipal General Master Plan, the area is designated to be used for private services of public interest (art. 3 comma 15 & art. 8 comma 68) and the building was used as a care home for elderly. Keeping the use classified in the same macro-category, it was possible to convert the final use into "reception" (art. 3 comma 15), avoiding the payment of the land occupation fee and limiting the necessary adaptation. In order to respect the legal parameters as private service of public interest, it was necessary to add some sleeping places available for the public authority.

Further, the guidelines for projects of university residences were consulted (All. A al D.M. n. 27/2011)¹⁰, so that the dimensional standards were coherent with the existing practice of use, designing space to respond to the inhabitants who were more interested into the number of sleeping places than into available private rooms. Even regarding functions and standards, the university residence was taken as a reference. So, the compresence of the residential functions and related services must be ensured, in order that the need for both privacy and social life is satisfied.

Regarding the sizing of rooms and technical rooms, the traditional residence regulation was taken as a reference, adapting spaces to the hygienic requirements, demanded by the regulation for the living quarters (D.M. Sanità 5 luglio 1975)¹¹. Also, the fire regulation does not imply the option of "collective housing": after considering the hygienic residence regulation, the hotels' regulation was used and a fire-escape was installed, not required for the traditional block of flats, but compulsory for the touristic ones (D.P.R. n. 151/2011)¹².

⁹ The permitted permanence is maximum 18 months, according to "Linee Guida per il Social Housing in Piemonte", Delibera Giunta Regionale 5 novembre 2007 n. 27-7346.

¹⁰ Allegato A. Decreto Ministeriale 7 febbraio 2011 n. 27. Pubblicato nella Gazzetta Ufficiale del 28 aprile 2011 n. 97

"Standard minimi dimensionali e qualitativi e linee guida relative ai parametri tecnici ed economici concernenti la realizzazione di alloggi e residenze per studenti universitari, di cui alla legge 14 novembre 2000, n. 338".

¹¹ Decreto Ministeriale Sanità 5 luglio 1975. Pubblicato nella Gazzetta Ufficiale del 18 luglio 1975 n. 190 "Modificazioni alle istruzioni ministeriali 20 giugno 1896, relativamente all'altezza minima ed ai requisiti igienico-sanitari principali dei locali di abitazione".

¹² D.P.R. 1 agosto 2011 n. 151. Pubblicato nella Gazzetta Ufficiale del 22 settembre 2011 n. 221. "Regolamento recante semplificazione della disciplina dei procedimenti relativi alla prevenzione degli incendi, a norma dell'articolo 49, comma 4-quater, del decreto-legge 31 maggio 2010, n. 78, convertito, con modificazioni, dalla legge 30 luglio 2010, n. 122".

Although the complex regulatory framework, the self-construction was taken into consideration, with the purpose of actively involving the occupants, making them responsible in the maintenance and management of the good, and offering them an opportunity of professional training. Nevertheless, there is no national, nor local regulation for the self-construction and it emerged that in Italy there is a regulatory gap for the self-construction that is actually experimental. Even if this practice is mentioned in different normative and project proposals, this practice, implying the active participation of not qualified people in a building site, has not a defined application field. The only authorized person, even if with limitations, to access the building site without being a technician or a worker, is the owner or the tenant. Further, the voluntary work and the no-profit associationism are not foreseen and regulated in a building site and the self-construction is not promoted at the political level. Thus, it was necessary to convert the concept of self-construction in self-refurbishment and self-maintenance.

Since the dialogue with the Ministry of Work, it has been understood that it was necessary to identify labour contracts in the self-refurbishment, throughout an association, the internship, apprenticeship, in a cooperative or in a company, with all the related obligation, but they were complicated options, that would have demanded the involved companies a professional training oriented to the recruitment.

Therefore, a tenure title was provided to the occupants who had to become members of a voluntary association as to ensure insurance cover, even when the building-site is open. Because of the critical points illustrated so far, it was not possible a global involvement of inhabitants, and just some works were self-realized, with the support of traineeship. The project options, driven by money saving criterion, foresaw that 50% of the works for completion were realized by inhabitants as volunteers and the 30% as workers. In particular, some occupants attended a carpentry course at Scuole Tecniche San Carlo in Turin, and some of them were assisted by voluntary craftsmen. All the occupants got involved in the works of his related floor, throughout precise planning of works. Since it was not possible to transfer the inhabitants during the whole period of intervention, the work was divided by floors. The work in each floor lasted 5 weeks and was then suspended for ten days each time, to make possible the works of completion and the moving with the help of volunteers. Given the presence of the inhabitants in the structure, the security plan was studied in detail to ensure a net division between working areas and living areas.¹³

Figure 6 View of the roof, before the intervention. Source: Architettura senza Frontiere Piemonte.

¹³ The spaces of the building site were as more as possible independent on the living spaces, to avoid interferences. The underground floor was refurbished and temporarily used to lodge inhabitants during the works in their respective floor.

Figure 7 View of the roof, after the intervention. Source: Architettura senza Frontiere Piemonte.

In architectural and plant engineering terms, the project foresaw some distributive modifications to improve the functionality of the building and respect the current regulation (among the others: Legge 13 del 1989 e s.m.i.¹⁴ for the elimination of architectural barriers), with the remake of the bathrooms and the access-ramp to the ground floor for disabled people and the reactivation and testing of the elevator.

Besides, after an analysis of consumptions and dispersions, taking into account the relationship costs/benefits of the fire regulation, but also the typology of building and of users, interventions to improve the building energy performance were identified. The proposed solutions are divided into two typologies: the ones on the building envelop and the ones on thermal and electric plants.

From the experience in La Salette, it emerged that housing practices and policies in Italy framed the social precarious conditions within temporariness, but these conditions cannot be solved in periods of time predetermined by a general legal provision and, because of that, the concept of temporariness was replaced by transitoriness. Indeed, in the Piemonte Region, the social housing model foresaw a residential time limited to only 18 months, even if it can be renovated in some cases by leaving and entering again the house. It is also true that it was expressed by the inhabitants the need not to respect a predefined period of time, as usually imposed by the traditional reception institutional projects because the social and economic inhabitants' problems did not allow at all how long it takes them to become independent. Further, the building management expenditure should have been compatible with the solutions, mostly informal, of the self-sufficiency economy. It meant to operate outside of the tradition current legal and practical framework, already set for the formalization of social housing.

The participation to the process permitted to observe from inside some dynamics: not predefined periods of time and informal economies are not compatible with the current categories regarding residence, workplaces and use of economic resources. In fact, migrants tend to send almost all the gained resources to countries of origin and many of them are not able, if not supported, to save money to invest in their future in Italy.

The cooperation among the above-mentioned private actors permitted the housing self-management. For example, activities inside the structure able to ensure small income to support the house expenditures, especially for whom was not continuously autonomous. Further, it was possible to observe the regional, national and European trajectories followed by migrants, strictly connected to their work activities.

¹⁴ Legge 9 gennaio 1989, n. 13 “Disposizioni per favorire il superamento e l'eliminazione delle barriere architettoniche negli edifici privati”.

It was clear that the answer to the housing need must consider the feature of the seasonal work, the opportunities that are activated by their networks, that are available even in an uncertain and sudden way. For example, a compatriot from another country calls for a short period another “brother” or “cousin” and he expects not to lose their right to live in the house that partially built as well while going the visit his compatriot. Therefore, the answer has to be extremely flexible, without giving up having a shelter, as ensured by the collective residence.

Initially, a self-managed approach was assumed, regarding the house management, but when works ended, it was clear that the inhabitants would have not been able to continue the “collective housing” experience all by themselves. There were no relevant conflicts, but certainly defining a shared decision on the economic criteria for the sustainability of the house was taking more and more time. Consumption, maintenance and caring of the “housing space” were the object of the daily debate. Since that point, it was changed the way to organize the floor assemblies. With the efforts of the social workers and the *Comitato Migranti*, it was possible to convince all the inhabitants to subscribe to a “Housing Pact” on the shared rules for living the house. After that, self-management and accompanying were replaced by co-management and coaching.

The process, especially regarding the economic aspects, which will be gradually modulated towards a higher management capacity of the housing expenditure, is still on-going and needs further time to reach the independence of individuals.

It is evident that for some of them, it will not be possible in a short time, but the long-term objective remains the independence on the external economic support, for the conviction that the dignity of people is firstly based on having the autonomous right to choose.

In conclusion, this experience represents a bottom-up policy for the social and urban inclusion in response to the large movement of people, based on a new kind of social and spatial organization – the “collective housing” – as a result of an urban community.

It does not consist only of refugees’ reception, but migration trajectories overlapping existing physical and social structure, with new lifestyles, new needs, generating innovative spaces and new urban functions, negotiating with the urban government a new social legitimation and housing legalization. This intervention emerged for the listening skills of the actors’ mutual needs – representing the basis to elaborate proposals – for a social and political approach, by the composition of the sensitiveness and competencies, always with a multi-disciplinary perspective.

In conclusion, given the results in social and organizational terms, and the limited conflicts during the realization process, this experience questions the rigidity of the conformational urbanism and show that, throughout a strategic mix of the current rules, it is possible to create a new rule that allows the realization of unforeseen interventions.

Acknowledgements

The authors of the current article thanks all the ones who have made possible the realization of the “transitory collective housing of La Salette”. In particular, they thank the promoters: Diocese of Turin, throughout the Pastoral Office for Migrants and Caritas Turin, the occupants and the “Comitato di Solidarietà Rifugiati e Migranti”; the supporters: Diocese of Turin, Compagnia di San Paolo, IREN, network of parishes (Unità pastorale 10) and Unicredit spa; the makers of the intervention: the project and coaching team, composed of the Cooperativa Orso, Luoghi Possibili, Ufficio Pastorale Migranti, Architettura Senza Frontiere Piemonte Onlus, “Comitato di solidarietà rifugiati e migranti”; the collaboration of the associations Casematte and ConMOI.

They also thank the companies and the high-qualified craftsmen, who took part in works, accepting the experimental dimension of the intervention, that required an additional effort, in terms of ideas and energies.

Urban agriculture and the social role of urbanism: Planning and ethics for communities and territories

Abstract: UN Habitat III and the 2030 Agenda for Sustainable Development have challenged scholars to reappraise the urban environment from the sustainability perspective. The study of urban form (urban morphology), as well as of resources and materials needed for cities to function (urban metabolism) are two specific areas which have potential to assess the urban environment and their projected development. Departing from such contributions this presentation, focus on the contributions of an ongoing research Project (SPLACH – Spatial Planning for Change), which aims to promote a sustainable urban transition of Lisbon Metropolitan Area (LMA), informed on a desirable food-based urbanism, with impact on the improvement of environmental conditions and people's lives. LMA concentrates about 3 million inhabitants, whom mostly occupy its peripheral residential areas, mostly developed throughout 20th century. Many of these areas gave rise to relevant problems including social isolation and car dependency, while others have witnessed a number of municipal and private initiatives to counteract such issues, including the promotion of urban agriculture. SPLACH Project has surveyed a number of case studies which aim to theorize planning and housing dynamics occurred in LMA while identifying their impacts on territorializing ethical principles grounded on urban agriculture initiatives. Specifically, we will question what specific issues have been identified in SPLACH case studies which deem to provide opportunities to rethink urban planning and urban form towards a more sustainable environment and promote the social role of urban planning.

Keywords: urban agriculture; urban planning; ethics; Lisbon Metropolitan Area

Introduction

Urban planning has always questioned what constitutes a 'good city' and a 'good life' which it will promote. Yet, how to define 'good'? Aristotle, for example, believed theory and action tended towards 'a certain good', but conceded that 'good' meant different things for different people in different contexts. That modern democracies have barely managed to tackle these differences proves the everlasting importance of ethics.

Ideas and structures shaping our notions of how to live, good and bad, acceptable and unacceptable, our relations to others and behaviour standards is the terrain of ethics (Blackburn, 2001). Even when ethical dimensions are

not directly referenced, creative and critical acts are imbued in them, since we exist in what Blackburn (2001) calls an ‘ethical environment’ even when unaware of it.

Although ethics usually comprises a consideration of relations between human beings, sustainability, as it has been conceived since the publication of the ‘Brundtland Report’ (UN, 1987) challenges this traditional understanding of ethics. The official title of the report itself, ‘Our common future’, points this rather clearly – sustainability must envision the relation of our current practices and behaviors with life conditions which future generations will inherit from us (UN, 1987). As such, our unsustainable behaviors towards nature will inevitably compromise not only nature itself, but the survival of generations to come. These concerns led a great number of scholars to accept and research the emergence of the Anthropocene or Capitalocene, a proposed new geological age marked by deep alterations on the Earth by human action, particularly under the guise of capitalist development (Sagan, 2019). That alone makes sustainability an important ethical question.

As urban populations are expected to double until 2050 (UN, 2017), the impact of cities in social and ecological sustainability is a crucial area of study, to which many scholars in vastly different areas have already contributed. That is the case of urban morphology which studies the physical form of cities and the processes that form it in time (Oliveira, 2018), and also of urban metabolism, which identifies stocks and flows of materials and energy necessary for human activities (Fischer-Kowalski and Weisz, 2016).

Resarchers in urban morphology and metabolism have contributed greatly to the understanding of the formal, morphological, political and environmental aspects of the city. However, we believe that alongside these more or less ‘tangible’ aspects of cities, the processes and consequences of their change over time and their variance across space must also be interpreted in the context of relationships between present and future generations, but also between human entities and ecosystems they explore. These can be included in the field of ethics, and it is an ethical reading that we aim to sketch here.

To do so, we first seek to establish an operative concept of ethics, which we will then confront with specific examples of planned neighbourhoods and the way they have been transformed, either through new planning or through their use by communities. Our ethical reading will include both top-down and bottom-up initiatives, and will mostly focus on processes of change as they represent important contributions for sustainability (Scoffham and Marat-Mendes, 2000) and ethics. We draw from preliminary results of ‘SPLACH – Spatial Planning for Change’, an ongoing research aiming to promote a sustainable transition of the Lisbon Metropolitan Area (LMA), by understanding links between urban form and socio-metabolism, particularly through the food system.

Urban agriculture emerges as one of the most outstanding themes in this context, in the LMA as in other world cities. As Purdy (2015) points out, food, treatment of animals and climate change, the paradigmatic Anthropocene problems, leave people uncertain of what to make of their key encounters with the natural world. As will be demonstrated, urban agriculture is not always born out of this conscious need to reconnect with nature, and in some respects, it may have adverse political results

Theoretical framework and literature review

A unique perspective on ethics is that of Austrian philosopher Ludwig Wittgenstein (1889-1951), who. defined ethics as *the inquiry into the meaning of life, or into what makes life worth living, or into the right way of living* (Wittgenstein, 1965, 4).

In his first book the ‘Tractatus Logico-Philosophicus’ (1921), Wittgenstein conceived ethics as the discourse category that allows the possibility of thinking of good and evil, and states it is individually established through specific acts. However, Christensen’s (2004) reading of Wittgenstein’s posthumous ‘Philosophical

Investigations' (written from the 1940s to 1951) and 'On Certainty' (written 1950-1951) suggests a change in this understanding. In these later works, Wittgenstein's epistemological concepts had changed: he no longer believed the world could be described by pre-established categories, but rather by endless patterns in which these categories intertwined in use, which for Wittgenstein is always public. In this context, for something to constitute an ethical norm, it must be publicly assessable as such (Christensen, 2004).

When discussing an ethical dimension to sustainability and urbanism, this is extremely helpful, since it would be impossible to think of them as individually defined. They are not acts, but result from specific acts involving individuals. Acts including choices by an architect or urban designer on a plan, citizen use of public space, decisions by municipalities on construction or demolition, preferences of urban developers – acts with a public impact.

Surveying 20th century urbanism, Nielsen (2004) identifies ethical paradigms in urban models attempting to materialize specific relations between socio-political values and built environments. However, Nielsen (2004, 42) rightly observes even revolutionary ideas have been cannibalized by the market and devoid of meaning, concluding that *an ethical urbanism can only be created retroactively by theory*, that is, through ulterior interpretation. Although Nielsen's arguments are convincing and there may be some truth to his conclusion, we maintain that certain approaches to ethics remain useful not just in historiographical criticism, but in informing current and future planning practices, as is the ambition of the SPLACH Project.

Sustainability – unaccounted in Nielsen's survey – demands rethinking our ethical environment. Such is the approach of Kopnina (2018), who extends ethics to nature, namely plants, aiming at a sustainability-based ethics. Purdy (2015) also identifies a shift in notions of sustainable land-use, from wilderness preservation to food-production, from 'unaltered' landscapes to landscapes transformed by labour which connects people with land and with nature in general.

Indeed, changes in urbanization changed social attitudes between society and nature (Gandy, 2014). Tibbs (2011) suggests that culture is shifting towards greater concerns for ecology, while we have elsewhere discussed how sustainability is a structuring socio-cultural force in the present (Marat-Mendes and Borges, 2019). What is generically known as the food movement, which suggests a new picture of people and nature, where food production and preparation is a source of satisfaction and knowledge, which preserves, rather than exhausts, natural processes (Purdy, 2015).

Kopnina's review of environmental ethics around two different lines shows that if the inclusion of nature in our ethical ideas is a logical response to resource overexploitation and climatic change, it is a complex matter – while land ethics acknowledges intrinsic value to ecological collectives (like ecosystems), deep ecology attributes it to individual living organisms. This ecocentrism vs. biocentrism debate – echoing early 20th century sociology debates between methodological holism (Marx, Durkheim, Radcliffe-Brown) and individualism (Weber, Malinowski) – has its implications, but we accept Kopnina's suggestion that the fundamental goal is a re-orientation of our world-view, in which limitless exploration of nature becomes unacceptable.

In Kopnina's proposition, different forms of describing the world – ecology, urbanism, economics and ethics – interplay in specific patterns, like Wittgenstein suggested in his later writings (Christensen, 2004).

Nielsen's (2004) ethical reading of Keynesian 1960s politics of redistribution identifies the construction of a modern industrial society as a driving force, controlling urbanization and forming a large middle-class to consume produced goods. We would add massive land-use conversions that eliminated rural soils to allow urban growth and the increasing segregation of urban and rural activities and territories. The latter, marking inequalities between city and countryside (Weaver, 1983), may have contributed to the collapse of the 'Keynesian consensus' in the 1970s, when its ethical principles of equality and justice were perceived as

limiting individual freedom (Nielsen, 2004), while the former exposes that only human entities were included in this ethical paradigm. With the later publication of the ‘Brundtland Report’ (UN, 1987) it became clear that, if not in ethics, in economics and planning, sustainability would have to become a touchstone.

One sign of change can be found in the growth of urban agriculture. It has been discussed for its historical role (Barthel and Isendahl, 2012), but also its advantages in creating social bonds (Parham, 2015), improving territorial metabolism (Ibañez and Katsikis, 2014; Faraut, 2017), changing patterns of human occupation (Viljoen et al, 2005; Napawan, 2016) and increased political participation (Lyons *et al*, 2013; Purcell and Tyman, 2015; Reynolds, 2016).

In the case of the LMA, urban agriculture has been noticed for its potential for economic development (Delgado, 2018), its role in establishing social relations and political participation (Cabannes and Raposo, 2013) as well as the changes in its planning (Oliveira and Morgado, 2016; Marat-Mendes *et al*, 2018). Dias (2018) has furthermore studied municipal urban agriculture case-studies in Lisbon and Cascais from a morphological perspective.

Here, we start by confronting this literature review with two examples of neighbourhoods from two LMA municipalities, namely the Lisbon neighbourhood of Chelas and the Amadora neighbourhood of Alto do Zambujal. After a description of each, a comparative reading will be presented and discussed against the background of ethics. The conclusion will draw suggestions for improving urban gardens and optimizing urban agriculture in Greater Lisbon.

Case studies from the Lisbon Metropolitan Area

In this section, we present two case-studies of the role of urban agriculture in planned urban areas. Thus, we selected two neighbourhoods planned between the 1960s and the 1970s, when several legal programs led to the planning of several council housing neighbourhoods, allowing an observation of residential space as planned by municipalities themselves. We present a brief overview of their current state and what forms of urban agriculture have emerged since their construction, as none of the original urbanization Plans proposed any space for agricultural activities.

Figure 1 – Case-studies location: 1 – Chelas Valley; 2 – Alto do Zambujal

The Chelas Valley

Until the 1960s, Chelas was a large extension of agricultural land. It remained practically untouched by urbanization, aside from small extensions of slums and some industrial facilities in the fringe closer to the Tagus river. The GTH – Gabinete Técnico de Habitação (Technical Office for Housing), a municipal planning office, was created to draw plans for Lisbon's Eastern end, starting with Olivais Norte and Olivais Sul, also former agrarian properties expropriated by the municipality for the development of high-density council housing, inspired by the principles of modern urbanism (Gonçalves *et al*, 2016).

Architects José Rafael Botelho (b.1923) and Francisco Silva Dias (b.1930) were charged with the Chelas Urbanization Plan in 1960. In 1962, Silva Dias started its final version (GTH, 1966). Zones or estates were developed afterwards, all with specific compositions of high-density housing and public areas that included green parks and equipment. New elements of urban form were added to the urban landscape, including several high-rise slabs (in the Amendoeiras and Olival Estates), a city-building (the Condado Estate) and continuous sequences of buildings (the Lóios Estate). Many of the estates in Chelas can be considered megastructures as they came to be defined later by architectural critic Reyner Banham (1976), showing great creativity in the articulation of different urban elements into massive structures countered by large extensions of green space. The original plan was dismissed in the later developments, particularly after Silva Dias left the GTH in 1973, and corresponding zones have more conventional urban form solutions, namely tower-blocks.

Figure 2 – Lóios Estate, seen from the Municipal Horticultural Park

Figure 3 – Guerrilla Garden and Salgadas Estate on the background

Figure 4 – Guerrilla Garden and Flamenga Estate on the right

Figure 5 – Guerrilla Garden and Flamenga Estate on the background

The morose development of Chelas was hardened by the fact that planned equipment and infrastructures were only partially or never implemented. Particularly with mobility infrastructure, this translated into a relative segregation of Chelas from the remainder of the city. Furthermore, the whole neighbourhood has become isolated from the rest of the city, suffering from social exclusion, poverty, unemployment and criminality (Heitor, 2001). In 1998, a film by Leonel Vieira, 'Zona J' displayed the general negative perception Lisbon society had of Chelas. This led extensive demolitions in the Condado Estate in 2009, a solution whose positive impact remains unconfirmed. Another initiative of the municipality to tackle the problems of Chelas was the creation, in 2010, of an horticultural park between four estates – Zone O, Amendoeiras, Lóios and Flamengo. Significantly, these include some of the most impoverished areas of the Valley (Cabannes and Raposo, 2013).

However, despite its success, the horticultural park occupies only a parcel of overall land available for it. It has grown since its original layout, and all of its plots are currently occupied and profusely cultivated. Moreover, they add a luscious element to the urban landscape, contrasting with the That popular interest is greater than the park currently allows is testified by the nearby guerrilla garden, larger than the municipal park. These informal gardens – in which planted species are not significantly different from the ones in the municipal park – occupy an area never developed for urbanization. It is the leftover space between the Flamengo Estate, a council estate planned by the GTH, and the Olaias Slope, a facing urbanization for the middle-class privately developed in the 1980s. Standing between these two planned areas, the guerrilla garden is only one of several elements that are somewhat unarticulated – some housing rows, storage spaces, a motorway and a railway, as well as ruins of premodern houses. As we have defended elsewhere (Marat-Mendes and Borges, 2019), this neighbourhood seems to be returning to Lisbon's agrarian roots, which, in the undeveloped areas, proves to have never disappeared.

Alto do Zambujal

Alto do Zambujal is located on the borderline between the Lisbon and the Amadora municipalities. The latter is the smallest municipality of LMA, but also the most densely populated. With a large population and a relatively small territory, Amadora is still revising its Municipal Masterplan, which still dates from 1994 (Marat-Mendes *et al.*, 2018).

The Alto do Zambujal Integrated Plan was started in 1973 and its implementation in 1974. Rising over a slope, the planned neighbourhood includes two significant estates, the Alto do Moínho, designed by Francisco Silva Dias, António Pinto Gomes and Ana Salta; and Zambujal, designed by Vítor Figueiredo and Duarte Cabral de Mello. Alto do Moínho is a low-density housing estate located on the lower end of the slope, with two- and three-storey semidetached houses, separated by small patios and flowerbeds. The green space surrounding the ruins of a windmill was left unoccupied and remains so today, with the exception of some small agricultural plots.

Zambujal is a high-density complex on the hilltop. It presents several rows of multi-storey slabs, although its lowest slab is a row of two-storey single-family houses. There is a generous amount of public space with large urban gardens, several underpasses, cafés and public benches. After the 1980s, the Zambujal estate was redeveloped to increase its density, and many other slabs, of a considerably poor design by architects other than Figueiredo and Cabral de Mello were added, sacrificing some of the originally planned green public area.

However, between the lower slab of the Zambujal Estate and the CRIL highway – which divides the Amadora and Lisbon municipalities – an extensive guerrilla garden has been created by locals. Additionally, some individual plots can also be found in the nearby urban park, at the centre of Alto do Moínho and even in the fringe of the Industrial Zone in the southwest of the neighbourhood. Urban farmers themselves designed plots, selected species and agricultural techniques and often recycle objects and materials to suit needs such as rainwater harvest, irrigation and storage.

Discussion

Both Chelas and the Alto do Zambujal belong to the ethical paradigm of Welfare States, as described by Nielsen (2004). However, in Portugal, a social-democratic welfare system did not start until 1974, when a military coup ended nearly 40 years of a conservative ruralist dictatorship. However, previous urbanization processes had shown Portuguese architects and planners were indeed aware of international urban debates, and managed to incorporate this knowledge in their practices.

The principles behind the 1964 Chelas Plan, designed to provide quality housing for poor populations are not unlike principles guiding other 1960s council housing in democratic countries (Borges and Marat-Mendes, 2019), showing a great capacity of GTH planners to overcome adverse political conditions. The vast green areas, supposed to provide leisure spaces between estates, as well as the extensive use of deck-access are both associated with the Doorn Manifesto and with the debates kickstarted by Team 10 (Heitor, 2001), a collective of architects whose most relevant projects were dependent on the construction of the city for the Welfare State (Risselada and Van Den Heuvel, 2005). In social housing, this *pas-de-deux* has proved sour, as several neighbourhoods planned under these principles have been systematically demolished (Hatherley, 2010). Chelas shares the same difficult outcome. Refurbishing and demolition work in some of the areas have tackled the social problems of some of the areas through changes in design. However, an observation of the urban agricultural practices in Chelas are a positive sign which has not been fully acknowledged. The appropriation of vacant space for food-production was not planned by the GTH, but the plan still had both conditions and space for it to happen, confirming the suggestion of Scoffham and Marat-Mendes (2000) that space is the asset allowing urban change to succeed. Indeed, if our age is one of uncertainty on how to reconnect with nature, experiments like in these neighbourhoods undoubtedly have an ethical dimension, insofar as they propose a necessary change in relations between humans and their environment (Purdy, 2015, 230).

In the Alto do Zambujal Plan, the commitment to ethical principles of justice, equality and dignity are clearer, as both Alto do Moinho and Zambujal were built after 1974. The former was even integrated in SAAL (Serviço de Apoio Ambulatório Local), a social housing program started by the First Interine Government. SAAL functioned in three key areas, Greater Lisbon, Greater Porto and Algarve and was only finished in Algarve when it was suspended in 1976 (Bandeirinha, 2007).

Despite their intended emphasis on public space, neighbourhood life and decent accommodation for all, these plans faced implementation difficulties and were for a long time left to neglect and social exclusion. Nowadays, they stand close to later mass-housing developments for the middle-class – namely the Olaias and the Alfragide developments, in Lisbon and Amadora respectively – but most estates in Chelas and Alto do Zambujal have had trouble being integrated in their specific areas. In many places within these neighbourhoods, public spaces are poorly kept, littered and underused, and sometimes were not even implemented as designed in the plans. In Alto do Moinho and the Amendoeiras Estate, this is not so, as residents' associations have been involved in maintenance and refurbishing processes.

These examples show that the ethical critiques to the Welfare State pointed out by Nielsen (2004) arrived to Portugal, only later. From the 1980s to the 2000s, Portugal saw tremendous increases in construction, mostly led by the private-sector, and the territory was urbanized at an unprecedented rate (Mourão and Marat-Mendes, 2016). Meanwhile, the key public policy for housing for most governments was easier access to bank loans (Drago, 2018). The State no longer ensures or programs housing conditions, but rather manages urban development and encourages people to individually borrow money and get housing for themselves. Thus, the 'welfare or freedom' critique of 1960s ethics identified by Nielsen (2004) can be confirmed in Portugal.

But what would Kopnina's (2018) suggestion of a nature-inclusive ethics tell us? Both Plans reserve generous amounts of green soil to counter urbanization, although also confirm 'urban parks' as non-productive. On the

other hand, these urbanizations displaced large agricultural explorations: activities changed in these areas, but so did land-cover patterns and ecosystems. Arguably, this was necessary, given the severe housing crisis at the time of design. Very different is the case of the largely unregulated urban growth in the 1980s and 1990s which advanced through massive land-use changes and resulting in a housing surplus (Mourão and Marat-Mendes, 2016). Besides ecosystem destruction, this process implies further damages to the environment since it runs parallel changes in Portuguese agriculture motivated by the EU Common Agricultural Policy (DGAGRI, 2003) and large public investment in car infrastructures.

Despite the eradication of productive green areas, in both Chelas and Alto do Zambujal, there is a strong emphasis on community spaces. These too have ethical importance – they echo the 1960s obsession with high-density neighbourhoods that maintained strong convivial bonds (Borges and Marat-Mendes, 2019). More recent developments, even in areas surrounding these two neighbourhoods, were arguably less focused in creating such public spaces and opted for more conventional solutions, with tower-blocks separated by leisure gardens and parking space. In a sense, it is the ambiguity of the urban forms employed in Chelas and in Alto do Zambujal that left enough space for unplanned initiatives to emerge.

Once we observe the same neighbourhoods as they stand today, we see further opportunities for ethical consideration. The return or resistance of urban agriculture is particularly telling. Although it is widely understood that allotment garden agriculture peaked in Western cities in crisis associated with the World Wars (Whitehand, 2019), the phenomenon is renewing, not least in Lisbon (Cabannes and Raposo, 2013; Delgado, 2017; Delgado, 2018; Dias, 2018; Marat-Mendes and Borges, 2019). Since cultivated species are mostly edibles, one wonders if informal agriculture spawns from the impact of the 2007 Financial Crisis on the food security of the urban poor (Delgado, 2017).

All these changes question the growing schism between urban and rural activities and territories. The rise in industrialization and urbanization seemed like a logical option for a country where the agrarian socio-metabolic regime (Krausmann *et al.*, 2016) lingered until the 1960s. However, sustainability forces us to reequat these developments. The food system allows us to link the food security of urban population and corresponding patterns of land-use. Cabannes and Raposo (2013) and Delgado (2018) observed that urban agriculture both formal and informal is important for self-consumption, particularly for impoverished communities within the LMA. However, Dias (2018) and Marat-Mendes *et al.* (2018) noticed that most municipal agriculture allotments are clearly meant for leisure purposes, with a particular emphasis on activities for the elderly with secondary productive value. Although recent Municipal Masterplans envision environmental strategies and emphasize the role of green areas, ethical and sustainable appreciation of plants within ecosystems as defended by Kopnina (2018) are generally lacking.

In the Chelas Valley, where the planned municipal horticultural park has failed to grow to its full potential, the lack of a clear strategy aimed at food security, productive land or ecosystem management is visible, especially when compared to the much larger guerrilla garden nearby. The latter seems more directly linked to the needs of local communities, not least because every aspect – from plot design to cultivated species – is ensured by farmers themselves away from top-down regulations. In Alto do Zambujal, where no municipal initiative exists, the guerrilla garden also shows tremendous initiative from local communities to vacant space in the neighbourhood. No less than expressing the will of farmers to improve their own food-security, this shows that local communities understand neighbourhood space as their own, a principle that was common to many social housing developments in the 1960s and 1970s (Borges, 2017; Borges and Marat-Mendes, 2019).

If guerrilla gardens constitute conscious use of public space, what ethical dimensions can be highlighted? As examples of ‘do-it-yourself’ attitudes, they represent a grassroots appropriation of vacant areas with tremendous sustainability potential – for soil and ecosystem maintenance, but also for recycling practices and increased food security.

However, it is important to stress that many of these urban farmers come from neglected communities, whose particularities seem to have fallen outside the reach of Portuguese public policies on housing. As confirmed by Nielsen (2004), the neoliberal paradigm that followed the collapse of Keynesian redistribution politics barely managed to ensure equity or opportunities for all – perhaps not even food for all.

Furthermore, what can we see in municipal attitudes? In Lisbon, whose Masterplan dates back to 2012, land is wholly classified as urban, and its system of green corridors does not have non-aedificandi status. In Chelas, the horticultural park has not grown, despite the existence of long waiting-lists in most municipal allotments surveyed by Dias (2018). As for the guerrilla garden, one may imagine that municipal intervention would eventually be unhelpful, since nothing indicates a commitment of the municipality to strengthen or protect its urban farms (Marat-Mendes *et al*, 2018). The case of Amadora is harder to assess, considering its conditions, but also its outdated Masterplan. There are no particular signs of interest for the green areas of Alto do Zambujal, although the municipality has recently created some horticultural parks in impoverished neighbourhoods like Falagueira. Yet, the lack of an updated Masterplan makes it difficult to understand whether this is included in a larger territorial or social strategy.

Conclusion

In 1943, Portuguese architect Francisco Keil do Amaral published a booklet with his notes from a trip to the Netherlands, where he went to survey local modern architecture. Among his descriptions of Dutch buildings and historical episodes, Amaral reflects upon the importance of architecture being assimilated by society and culture, inspired by an occasional conversation with two Dutch non-architects who advised him on buildings he should visit (Amaral, 1943, 32-34). This encounter with common citizens with informed opinions on architecture leads Amaral (1943, 35) to a very interesting definition of urbanism: *the science charged with the collective discipline of the interests and needs of urban settlements*. In treating the interests and needs of cities as a collective discipline, Amaral is definitely posing an ethical program for urbanism. The conversation with two informed citizens reveals to the architect that the city is not his concern alone, it is also the concern of inhabitants, who perceive space, and relate to it and may even transform it by themselves.

Such an ethical program for urbanism is not necessarily the same thing as identifying specific ethical inclinations within specific urban projects. Quite the contrary, it is a statement on the very nature of urbanism as a practice. If we accept Amaral's proposal, urbanism is always ethical, insofar as it designs and implements elements which will deeply impact people's lives. This can be interpreted as a challenge to rethink the actions and decisions of planning authorities and professionals.

In this context, municipalities could have an important role in shaping the future of the case-studies analysed here, particularly in the guerrilla gardens. This role could include improving informal gardens, contributing to education of farmers in sustainable agriculture and even creating strategies for professionalizing farmers, improving their financial and food security. However, Dias' (2018) research suggests there may be incompatibilities. Municipal allotments stick to limited morphological solutions – mostly rectangular grids – which does not happen in these guerrilla gardens, where plots are irregular in shape and size, prioritizing production needs instead of leisure opportunities. Thus, different designs show different understandings of the same phenomenon. Moreover, negotiations between needs of farmers for food and the municipal emphasis on leisure is not balanced, since farmers have no property rights over occupied land.

Indeed, Purdy (2015, 232-233) presents the ethical problems associated with the food movement – which must include urban agriculture – rather well: for him, it can either suggest an environmental ethic that melds its values to practices already in place, or it can suggest a new practice and identity, in which the relations of oneself with nature are redefined. In the surveyed case-studies, it would seem as though the latter has already come to pass. Sometimes without the encouragement or help of any municipal or public authority, communities have managed

to establish a new practice in the way they use public space, thus reshaping that space. However, if we assume these are practices already in existence, the question remains: will municipalities acknowledge them and seek to optimize them?

The ‘laissez-faire-laissez-passer’ attitude of municipalities (Cabannes and Raposo, 2013) poses more ethical challenges yet. Other than the lack of consideration for urban ecosystems in their real complexity, it may resemble a Victorian attitude in which the problems of the poor are of the poor themselves (Malpass, 2005). One must also remember that the surveyed neighbourhoods were planned as council housing, showing a State – first dictatorial and then democratic – which contributed directly to ensure quality urban space, including in residential schemes. In face of sustainability challenges, we must re-learn how to assess and conceive ‘quality’ urban space, which must necessarily encapsulate sustainability, but also validate forms of community appropriation of space if these represent an environmental improvement.

The food system and urban agriculture offer unique opportunities for observing urban planning decisions and attitudes ethically. In Chelas and Alto do Zambujal, large guerrilla gardens reveal a schism between priorities established by municipalities and by communities. This schism must also be understood by architects and urban designers, who must find creative ways to respond to societal demands. If Contal and Revedin (2011, 12) state that, being one of the oldest professions in the world, architecture is also one which regularly sells out to market forces, in the context of sustainable transitions, this must be understood as a challenge for architects and urbanists to redefine their priorities, also in ethical terms.

The interest clearly expressed by populations has not found echo in spatial planning and no legal framework concedes protection for informal gardens. Further study of the goals and needs of guerrilla gardeners in these areas is fundamental for any reassessment of the importance of their gardens, but this must also include a serious consideration on the positive impacts of agriculture on soils and its importance in counterbalancing urbanization and even the recycling of waste and materials.

These two case-studies are particularly suggestive when imagining a requalification, particularly considering their integration in urban plans of the 1960s and 1970s which deserve themselves further study. Interest in the work of architects like Silva Dias and Vítor Figueiredo has also increased recently (Ribeiro and Canelas, 2006; Maldonado and Borges, 2015). These two aspects suggest that both the green productive spaces and the built estates in these neighbourhoods can provide an integrated strategy for intervention in Chelas and in Alto do Zambujal. Such a change would have great potential, from an ethical and a sustainability point of view.

Finally, although ethical principles behind an urban or architectural design do not keep it from being used differently, specific uses do point out ethical rules. Even if these council housing neighbourhoods failed in some of their goals, their collectivist structures and their strong emphasis on public space may have played a role in creating communities capable of appropriating such spaces. Perhaps some ethical rules are indeed possible to express in urban or architectural forms, and if these can extend to the territory, including its ecosystems, they must certainly be studied and protected. Such an approach to urban planning, necessarily more inclusive, would help bring back more ethically-committed notions of urbanism, towards the ‘collective discipline’ identified by Amaral (1943), to which it is evermore pressing to return.

Towards Post-Human Urbanism

kimmo.lapintie@aalto.fi

Abstract

“Post-human” is, of course, a provocative concept in the context of architecture and urbanism, which have essentially based their ethos on designing and planning a “human-centred” environment. However, the concept is actually not as radical as it might seem: although it does question some of the taken-for-granted assumption of classical humanism, particularly the universality and a-historicity of human nature and the legitimacy of needs justified by this universalism, it is not a doctrine against human beings. Against the ideology of “cities for people” (Gehl 2010), post-human critique highlights the fluidity, the diversity and the contested nature of human identities.

What makes this theoretical perspective relevant in today’s urbanism is the fact that the universalist human being is rapidly dissolving. The growth of multiculturalism is an unavoidable phenomenon in European cities as the result of immigration and increasing mobility of work. However, its perception in urban planning is by no means self-evident. Contemporary planning discourse is rather characterized by an almost systematic avoidance in this respect. It is this silence that will be studied in this paper, by using the method of archaeology of knowledge introduced by Foucault in his books *Words and Things* and *Archaeology of Knowledge*.

An attempt is made to explain this observation with reference to the strong functionalistic tradition in the Nordic planning agenda and the tacitly adopted biopolitical definition of legitimate needs of the urban citizens. The Utopian ideology of a class-less planning for the ‘human being’, with its biopolitical undertones of biologically determined features of the population, will necessarily clash with new demands for culturally oriented, specialized services and spatial practices that multiculturalism necessarily entails. This is confronted with the seemingly ‘transparent’ and generalizable planning ethos that has remained unquestioned, hidden by the emphasis of physical planning along with social and cultural ‘soft’ policies.

This study is part of a multidisciplinary project BEMINE: Beyond MALPE Coordination, Integrative Envisioning, carried out at the Department of Architecture, Aalto University School of Arts, Design and Architecture.

1. Introduction

The presence of citizens from various cultural backgrounds, with the corresponding needs and values, is a growing and unavoidable feature of European urbanizations. The European population is getting older, and the average fertility rate of 1.58 will not allow sustainable growth or even reproduction. The lowest total fertility rates are in Southern European countries, but also in Northern Europe they are well below the reproduction minimum of 2.1. Finland has seen a rapid decline in the yearly number of births for seven years in a row, reaching an all-time low number of 50 321 and a total fertility rate of 1.49 in 2017 (Statistics Finland). The logical result is that population growth is already totally based on immigration: while the net migration was 3 273, the natural growth was negative with 2 695 less births than deaths. Paradoxically – though understandably – this development has aroused political opposition among the populist parties, in Finland as well as in other European countries.

In this paper, however, I am not addressing this phenomenon as such, but rather its consequences and challenges for urban planning. One would assume that the rising phenomenon of cultural diversity would be addressed in one way or another by planners, even in countries where the proportion of residents with different ethnic and cultural backgrounds is still rather small, like in Finland. But, as we shall see, this is not actually the case: contemporary planning discourse is rather characterized by an almost systematic silence in this respect. It is this silence that I want to study in this paper, by using the method of archaeology of knowledge introduced by Foucault in his books *Words and Things* and *Archaeology of Knowledge*. Since this method was famously criticised by Dreyfus and Rabinow, we need to dwell for a while in the theoretical underpinnings of the methodology. I agree with Tiisala (2015) that archaeology can be given an interpretation (following Foucault's own 'pragmatic turn') that avoids the problems discussed by Dreyfus and Rabinow. I am particularly interested in the possibility of an 'archaeology of silence', the concept originally coined by Foucault in his *Madness and Civilization*.

The paper is structured in an unorthodox way. After discussing the methodological framework (in Chapter 2) the contemporary planning discourse in Helsinki and the surrounding Uusimaa region is

analysed (in Chapter 3). The result, as we shall see, is almost a total lack of discursive statements addressing the emergent cultural diversity. Finally, directions for theoretical ways for explaining this phenomenon are discussed (Chapter 4).

2. *The Archaeology of Silence*

Foucault's archaeology of knowledge is a methodology developed in his books *Madness and Civilization* (1973, orig. 1961), *The Birth of The Clinic* (1973, orig. 1963), *The Order of Things* (1985, orig. 1966), and *The Archaeology of Knowledge* (1985, orig. 1969). It is based on an analysis of historical discursive formations, where statements are taken as events, and the relationships of these statements is studied inside the discourses. This does not mean that they would be unrelated to non-discursive elements, but the way they are formed is not based on a reference to transcendental objects (AK p. 49) or the experience or meaning-giving of the subject (AK p. 54). Thus, Foucault is using double-bracketing: without denying the existence (or even the relevance) of non-discursive events, he is searching for the rules that determine the formation of statements within the group of serious speakers. Unlike language (*langue*) that allows an infinite set of possible sentences, the discursive formations are characterized by rarity (AK p. 118): not anybody has the authority to speak seriously (about medicine, about economics, about science, etc.), and there is a rarity of what they can say.

"This authority also involves *the rules and processes of appropriation* of discourse: for in our societies (and no doubt in many others) the property of discourse – in the sense of right to speak, ability to understand, licit and immediate access to the corpus of already formulated statements, and the capacity to invest this discourse in decisions, institutions, or practices – is in fact confined (sometimes with the addition of legal sanctions) to a particular group of individuals; in the bourgeois societies that we have known since the sixteenth century, economic discourse has never been a common discourse (no more than medical or literary discourse, though in a different way)." (AK p. 68, italics in the original).

In their famous critique of the archaeology of knowledge, however, Hubert Dreyfus and Paul Rabinow argued that this double-bracketing is a problem for Foucault, since there will not be any

consistent way of grounding the rules of formation that are so essential to archaeology (Dreyfus & Rabinow 1983). “The discursive practices analyzed by the archaeologist are motivated by the speakers’ conviction that they are uttering serious truths about man and society, or that they are helping to make explicit the implicit thoughts of those who were in possession of such truths. The analysis, however, substitutes for this “naive” conviction as its condition of occurrence a set of meaningless strict rules.” (Dreyfus & Rabinow 1983, p. 93-94). This critique has been taken for granted by many scholars, which is a pity, according to Tuomo Tiisala (2015), since it has prevented research in the humanities and social sciences – including planning – to develop archaeology as a fruitful methodology. For instance, as Maarten Hajer was developing his discourse analysis, he was led to the later Foucault of discipline and governmentality instead of the ‘discredited’ earlier works (Hajer 1997, p. 47).

Tiisala argues that Dreyfus and Rabinow have not understood the pragmatic turn in Foucault’s thinking, which makes it possible to assume strict rules of discourse formation that are not accessible to the speaker’s consciousness, nor are based on the validity of these statements, but which they learn through practice. He refers to the unpublished manuscript of the *Archaeology of Knowledge*, where Foucault still defined the rules of discourse formation as statements, which would indeed have undermined his idea of unconscious rules that are followed (but not known) by the speakers (Tiisala 2015, p. 659). In the published version of the *Archaeology of Knowledge*, however, Foucault clearly states that the rules are part of the discursive practices:

“By system of formation, then, I mean a complex group of relations that function as a rule: it lays down what must be related, in a particular discursive practice, for such and such an enunciation to be made, for such and such a concept to be used, for such and such a strategy to be organized. To define a system of formation in its specific individuality is therefore to characterize a discourse or a group of statements by the regularity of a practice.” (AK, p. 74).

Archaeology of knowledge is also suitable for analysing planning discourse, even though the early Foucault did not discuss it while he was interested in the archaeology of the human sciences. But how can one analyse – by using the archaeological method – that which is not said? In *Madness and Civilization*, Foucault clearly had this ambition: “The language of psychiatry, which is a monologue of reason *about* madness, has been established only on the basis of such a silence. I

have not tried to write the history of that language, but rather the archaeology of that silence.” (MC, p. xi, emphasis original) In the *Archaeology of Knowledge*, however, he seems to be saying almost the exact opposite:

“We are studying statements at the limit that separates them from what is not said, in the occurrence that allows them to emerge to the exclusion of all others. Our task is not to give voice to the silence that surrounds them, nor to discover all that, in them and beside them, had remained silent or had been reduced to silence. Nor is it to study the obstacles that have prevented a particular discovery, held back a particular formulation, repressed a particular form of enunciation, a particular unconscious meaning, or a particular rationality in the course of development; but to define a limited system of presences. The discursive formation is not therefore a developing totality, with its own dynamism of inertia, carrying with it, in an unformulated discourse, what it does not say, what it has not yet said, or what contradicts it at that moment; it is not a rich, difficult germination, it is a distribution of gaps, voids, absences, limits, divisions.” (AK p. 119).

But how can you define the limits of discursive formation without going to the ‘other side’ and describe it? Does this in the end mean giving a voice to the silence? This difficulty reminds us of the famous observation by Wittgenstein that seeing the limits of your world and language (which are the same limits) is not possible, since you would in a way need to ‘measure’ them from the outside (Wittgenstein 1961, 5.61). But the limits that Foucault means are less all-encompassing; they are the limits of the group of experts that have the authority (at a certain historical time and place) to speak seriously about madness, the economy, science, planning, etc.

Foucault himself had the benefit of following the longer span of history to find the gaps and absences. In the *Madness and Civilization*, he pointed out the lost dialogue between the men of reason and the men of unreason (folie) that still existed during the time of Cervantes’ *Don Quixote* and Shakespeare’s *Macbeth*; this ‘silence’ we can still read from their texts. In *The Order of Things*, on the other hand, he used Aldrovandi’s *History of Serpents and Dragons* as an example of the time (in the sixteenth century), when the observed facts and fiction were not yet separated, and compared it to Jonston’s *Natural History of Quadrupeds*, in which the semantic dimension was simply left out (OT p. 128). This did not mean that Jonston would have known more (actually he

knew less), but he became the landmark of the transition from unity to separation (or from similarity to representation) that is still with us. A biologist of today – or any serious speaker for that matter – could never write a book on serpents *and* dragons. Also in this case the absence could be seen in the historical change in the scientific discourses.

But if we want to use the archaeological method to study contemporary formation of statements, we need to construct the ‘dragons’ to see where the limits of the professional discourse are. In this paper, the ‘dragon’ is multiculturalism (or the diversity of people with different ethnic and cultural backgrounds and the diversity of their needs, values, habits, religions, etc.). I will not simply say that Finnish planners don’t talk much about multiculturalism (they don’t), or that they *should* do that; rather I want to understand why the contemporary planning discourse in Finland is like it is, why the limits of discourse are drawn in this particular way, creating this particular rarity. Thus, the analysis must concentrate on the rules inside the discourse, revealing its hidden logic. The presence of something is, however, the absence of something else; even if the discourses themselves would not hide or repress alternative discourses, planning research can try to measure the limits of the discourses of practice also by looking at them from the outside.

It is interesting to compare the ‘silence’ of multiculturalism to the human-centered discourse in planning. For instance, Gehl’s ideas of planning for the ‘human being’ of *homo sapiens* (the erect mammal walking 5 km/h, frontally oriented and fond of other people) has no difficulty in embedding itself in the professional discourse of architects and planners, although the idea would not stand closer scrutiny. There is no way that we could distinguish a *homo sapiens* without technology (actually the making of tools started already with the *homo erectus*). Foucault’s critique of the existence of such a creature (that would give justification to planning solutions) is thus a very promising perspective to understand the formation of the planning discourses.

3. The Regularity of a Practice

The Finnish planning practice is regulated by the Land-use and Building Act (132/1999) that has been in force since 2000, with several amendments. The planning system is hierarchical: the statutory plans and regulations include national land-use objectives prepared and approved by the

council of state, the regional plans approved by 19 regional councils, and local master plans and detailed plans approved by municipal councils. In addition, there are several non-statutory national and local policy documents on architecture, nature conservation, environmental health etc.

The general objectives of the Act are to “create preconditions for a favourable living environment and promote ecologically, economically, socially and culturally sustainable development.” (Chapter 1, section 1). The word “cultural sustainability” is thus mentioned, but it is not given any formulation later in the Act. Citizen participation and transparency are also included in the general objectives: “The Act also aims to ensure that everyone has the right to participate in the preparation process, and that planning is of high quality and interactive, that expertise is comprehensive and that there is open provision of information on matters being processed.” (Chapter 1, section 1). The Act thus uses the abstract term “everyone” that logically implies also ethnic and cultural minorities. Language is not mentioned, however, which implies that “everyone” is supposed to have proficiency in the national languages (Finnish or Swedish). In the more detailed objectives, the “everyone” is, however, categorized: Land-use planning should promote “a safe, healthy, pleasant, socially functional living and working environment which provides for the needs of various population groups, such as *children, the elderly* and the *handicapped*” (Section 5, item 1, my italics). The categories are clearly biological; age and physical performance are recognized, but not cultural or social features, such as customs and different cultural values, religion, ethnicity, sexual orientation or wealth. Biology rules: diversity is understood only as biological diversity (section 5, item 5).

In Finland, architects are the dominant professional group in land-use planning. Recently, the profession has been active in preparing architectural policy programs at national, regional and local levels. According to the Uusimaa architectural policy program from 2009 titled “Our Common Metropolis”, the text reads that “with the help of architectural policy, common objectives for the culture of building will be created, to express what residents, decision makers and planners and designers want from the built environment of high quality.” (p. 5). It also highlights that “It is important for the whole that different neighbourhoods recognize their local identity and respect it.” (p. 7). The program thus constructed the idea of community and also *commonness*: there are

common objectives among residents, decision makers and planners, and even the different neighbourhoods can recognize their *common identity* (in singular).

In the ongoing preparation of the Uusimaa regional plan for 2050, one of the strategic focuses is “a *healthy and skilled human being*”. Immigration is recognized, but only in quantitative terms: it is assumed that 2/3 of the growth of the population will come from immigration. But how is this reflected in the plan? Not in any way; the biological and educational features of the population (health and skills) seem to be the only ‘human’ categories at the regional level. The same is true at the municipal and local levels. The recent comprehensive City Plan 2050 of Helsinki is based on an assumption of rapid growth of population by 250 000. As mentioned above, the population growth of the whole country is already totally based on immigration. The situation in Helsinki is somewhat different, around three quarters of the population growth is coming from immigration, reaching 94 888 or 14,9% of the city’s population in 2017. In the planning documents, however, immigration is not mentioned; the city aims to densify its urban structure, expand the city centre, change motorway-like thoroughfares into boulevards, and also build more housing on greenfields. As the basic ideology behind the plan is New Urbanism, one would expect to find something about cultural diversity. Urban culture, however, means cultural events: “Helsinki is already a fascinating stage of urban culture. A wide variety of events take place in Helsinki’s districts.” Or it is typical New Urbanist aesthetics: “A more urban Helsinki means more street-level shops in blocks of flats, bicycle lanes, the clatter of trams, coffee at the market place, international flavour, urban productivity, seaside saunas and district festivals.” Not a word on multiculturalism, if the word is not “international flavour”.

The same can be seen in detailed plans also. One of the new centrally located neighbourhoods on a former harbour area, Jätkäsaari (at the moment under construction), was planned to be “an urban and cosy seaside neighbourhood”. The objective was to create “an identity of an urban neighbourhood, with unique quarters. All of them are united by a dense urban structure, where the streets are enclosed by buildings.” The dominant role of physical planning is clearly visible in the documents of the detailed plans.

4. From Functionalism to Biopolitics

This short review of the Finnish planning discourses clearly reveals that, if the planning discourse is approached from the outside, the limits of the discourse formation are clearly visible, as far as multiculturalism is concerned. If one wants to find out how multiculturalism, ethnicity, or culture in a wider sense (i.e. not just cultural events) are dealt with in planning legislation, policy programs, or regional and local plans, one will find mainly silence. This is despite the fact that all statistics tell that the city of Helsinki and the region of Uusimaa – as well as the whole nation – are in front of a major change in their history: the end of the homogenous Finnish culture. This cannot be a coincidence, but it clearly reflects the rules of the discourse formation that planners are unaware but need to follow. This is obviously a very complex system, as Foucault warned us: “...complex group of relations that function as a rule: it lays down what must be related, in a particular discursive practice, for such and such an enunciation to be made, for such and such a concept to be used, for such and such a strategy to be organized...” (AK, p. 74).

What, then, can the archaeologist uncover? My intention in this paper is not to provide any comprehensive analysis of this system, only to point out some directions where answers could be found. Two structural features seem to be repeating themselves in the planning and policy documents: functionalism and biopolitics. The former is obviously an important tradition and ideology well known by architects and planners, but its structural closure in the planning discourse is not so easy to see. The latter is less well known in planning, being a theoretical concept coined by Foucault, but it has an interesting connection to functionalism.

Functionalism still forms the main structural grid behind land-use planning; the mere division of land into housing, industries, recreational areas, public and private services and transportation seems to be unavoidable, even if mixed functions and multifunctionality are gaining ground (Di Marino & Lapintie 2018). The main ethos of functionalism is that since areas, buildings and things are supposed to satisfy human needs, they need to be functional: glasses need to be suitable for drinking, houses for living, roads for driving, schools for learning, etc. But if we go further in our reflection to more complex things, the ethic is not so evident. Suppose that I live in the city but travel weekly to my villa in the archipelago for teleworking and recreation, which is made possible

by the highway and the local road between the two locations, the car and the internet connection. Can we say that this complex 'thing' (my apartment in the city, the motorway and road between the two locations, my car, the villa in the archipelago, and the internet) is functional – for what? Or should we rather say that these things have made it possible for me to adopt a multi-local lifestyle that has its cultural history from bourgeois summer villas and later summer cottages to third-agers' multi-local living? Function (multi-local lifestyle) thus follows the form (the apartment, the motorway, the local road, the car, the villa, the internet), not the other way around as functionalism would make us believe. But if we study contemporary planning discourses, it seems evident that this last question (and its cultural underpinnings) is never asked. The environment is supposed to follow functions, period. We have clearly found the limit that planners are not supposed to cross. "Whereof one cannot speak, thereof one must be silent", as Wittgenstein so aptly put it in his *Tractatus* (No 7).

The second theme that arises out of our analysis is the role of biology. For Foucault, biopolitics meant the modern use of power by managing the health and productivity of the population, in addition to direct disciplining of the individual bodies (Foucault 2004). It is actually stunning to see these exact features as a strategic focus of the new Uusimaa regional plan: "a healthy and skilled human being". But the biopolitical emphasis goes through the whole spectrum: from the age and disabilities of the legislation to design-for-all (but not for the cultural minorities) of mainstream planning.

Finland is of course different from many other countries where immigration and multiculturalism already have a longer history. But – partly because of this – it is also an interesting case to experiment with the methodology of Foucauldian archaeology of knowledge, to better understand the systems of discourse formation in planning practice where the homogeneous culture is challenged.

COMMUNICATION THROUGH VISUALIZATION: THE PURPOSE, ROLE AND STYLE OF VISUALIZATIONS IN URBAN PLANNING

Burcu Mikulcik

Technical University of Vienna, burcu.mikulcik@gmail.com

Abstract: Visualization is used to convey information to communicate a message and in its all different forms they help us to understand our cities and make it available for analysis. They increase our capacity of comprehension by making useful conceptual shortcuts in our understanding to have a glimpse of “what’s happening” in our cities. The article analyses the use of visualization in planning discipline, how it was used and perceived throughout the planning tradition. The objective is to analyse the role of visualizations, how they are used to establish dialog, at what stage it is useful and effective to introduce them into the dialog. It further investigates the style of visualizations by analysing the basic design principles and as well as visual perception and cognition fundamentals to clarify what effects the efficacy of the visualization in traditional and digital visualization.

Keywords: visualization, planning, digital visualization

Planning with Images

We all experience cities differently. When we think of Paris, New York, Istanbul, Tokyo, distinctive images or narratives comes to mind. One of the most natural characteristics of the cities is being very diverse. They are capable of accommodating so many possibilities of both creative and destructive forces all together. This diverse nature makes our understanding of a city or a region almost impossible, a utopia. We need to make useful conceptual shortcuts in our thinking in order to have a glimpse on “what is really happening” in the city.

Cities must be understood as processes of constant change. While accommodating multi-layered character and increasing diversity makes it an ever more complex subject of active transformation in material terms. Finding meaning in complexity which is in constant change is not yet an easy task. However, planning needs to engage in cooperative action to maintain the power to act in a context of uncertainty and complex challenges.

Throughout the planning history, planning discipline has looked at visual representations in various different ways, sometimes paying no particular attention at all (Jarvis 1994; Neuman 1996, 2000; Faludi 1996; Dühr 2007) Since the notion of “planning through debate” (Healey, 1992) they are accepted as powerful communication tools. They help us to shape our attention, hence shaping the dialog (Forester 1988; Kunzmann 1996; Healey 1997, 2006; Forester 1999).

Collaborative planning made planning communicative and negotiable. While governments still hold the decision-making power, it requires cross disciplinary collaboration to support the process of meaning-making.

Discourse can produce meaning and challenge previously unquestioned knowledge. Therefore, any medium that supports the discourse must be interpreted as powerful tools to steer urban development.

There is no doubt that visualization in planning are powerful instruments, because often it conveys more clearly than a text would do. However, this may also result in manipulating the truth by focusing on certain parts while inevitably neglecting others. According to some theorists (Pickels 1992; Harvey 1996; Neuman 1996; Shields, 1996), this considered as treacherous, because the process of meaning-making via visuals are results of partial perspectives, reflecting one of several possibilities.

To investigate the role of the visualization in planning theories, rational planning theory would be an appropriate starting point. According to rational model in planning theory, planning is rather a technical process and there is a clear distinction between the planner, who has the objective expert statues and the politician who sets values and defines overall strategy (Dühr, 2007). The model also assumed that the planner has the sufficient autonomy and the authority to develop and design plans with rational decision-making skills and in the end, he holds the power to implement these as well.

This planning theory is mainly criticized that it is essentially focused on science and technology and being ignorant to societal values and norms, most importantly politics. Many theorists (Lindblom, 1959; Mandelbaum et al. 1996; Simon, 2013) have tried to point out the obvious delusions of the rational planning model, and some tried to enhance its capabilities by introducing modifications to make it more fitting for the real-life conditions.

However, this general belief on objectivity has changed when we realized that the planning is highly political and therefore open to manipulations (Forester, 1999). Recognizing planning as political has had important implications for the perception of the role of visualization in planning process. If planning viewed as a fundamentally political activity, ‘values’ become essentially important.

Over recent decades, planning theories strongly influenced by contemporary social and political theories, particularly Habermas’s theory of communicative action (1984). According to Habermas, the “truth” cannot be produced through science. Rather, science is an instrument which can be easily manipulated by the power relations in society. The science or the scientifically informed expert may produce the truth, however it might fail by being ignorant to societal values and norms. Therefore, the superiority of the expert knowledge become no longer valid, the local knowledge is recognized as important as the expert knowledge. Habermas’s theoretical approach has been highly influential in shaping contemporary planning theory which supports planning through debate. Healey (1997) describes it as collaborative planning which is basically about reaching consensus through dialog. And till consensus is reached all communication is the exercise of power.

The collaborative planning model accepts the limits to power and the ‘subjective’ selective process of decision-making of policies. It acknowledges that any planning institution has values, opinions, views on certain issues and therefore leads to particular planning objectives.

We created images and used them to convey meaning thousands of years before the first languages were recorded. The reason why we are focusing on visuals is obvious. Drawn images are used to support verbal statements of policy, enriches the discussions and the result is debated informed decision. While planning theorists are still sceptical of its deceits and difficulties, one does not have to wonder about the role of visuals in the creation of modern era city plans and the development of the planning profession.

After having a deeper look in the use of visuals and its role in urban planning, it became clear that not only the reason why we are using them (or why we are not using them), but how we are using them needed an investigation.

The role of visual representation was not only limited due to previously mentioned obstacles but also the perception according to different countries, cultures and planning traditions. Many countries look at urban representations in different ways, and that different view had a significant influence on the debates that took place. When in some countries a map is a plan, a blueprint of how things should be, in other countries they are more indicative, and abstract in nature.

Otto Neurath, a member of Vienna circle, already in the 1930s had realized the importance of the use of visualization (Neurath *et al.*, 2013). Although during his time, the dominant view on visualization was more on the traditional side, he already knew that the co-operation between different disciplines is essential to achieve the best for public good. An essential task for him was to inform the Viennese about their city. The aim was to “represent social facts pictorially” and to bring “dead statistics” to life by making them visually attractive and memorable.

In urban planning, images can be considered as expert’s viewpoint, a subjective one, which is one of several possibilities. As a consequence, visualization can support the transfer of the key themes of urban planning, which can be understood not only by the experts in planning, but also by the audience of non-experts. As a matter of fact, this is one of the main objectives of the contemporary planning theories, name it as collaborative planning, communicative planning or participatory planning. The local knowledge and the collaboration of the very audience itself, the ones who are directly affected by the actions taken by the planners, has become essential.

Furthermore, in order to be able to bring the lay people into the dialogue, the planning needs to be more attractive and appealing to the audience. Therefore, representing urban data visually to an ever-wider audience of experts and non-experts, in an attractive way becomes very important. On the other hand, how can we make planning interesting to a wider audience without using visuals (Zech, 2013)?

Communication through Visualization

The very notion of representing the city or rural areas has led to questions which requires interdisciplinary cooperation. Especially the ones on “how” we are creating those visuals. Due to the fact that urban planning has transformed into an open and cross-disciplinary process, dialog has become a vital part of the decision-making process, therefore the use of visualization as well. Through the process of decision-making in which a solution is negotiated amongst various interest groups, creation of the visuals becomes an important task, which is potentially challenged by power relations and ethical dilemmas. However, they may be used to manipulate or lead the discussion in a particular desired direction, but they may also give voice to disadvantaged parts of society.

A good visualization is the one that communicates effectively and efficiently. In other words, it should do, what it supposed to do and in most cases with minimum amount of resources. As Kosslyn (2006) puts it, a good visualization forces the reader to see the information the designer wanted to convey. It can be solely used to analyse certain group of information or to communicate a certain message with the help of the relevant dataset. Making a visual display attractive and visually appealing is the task of the creator mostly, whose talent and visual sense give a certain visual appeal.

Visual displays of information can be considered as cognitive artefacts (Bertin, 1983; Card et al., 1999; Tversky, 2001; Ware, 2012; Meirelles, 2013; Norman, 2014), in that they can strengthen our mental abilities to facilitate understanding and meaning-making. Ware (2012) argues that effective design should support quick and accurate processing of visual queries; thus, better understanding of the basic principles can lead to better design. However, in the information visualization literature there has been some concerns (Arnheim, 1969; Kosslyn, 1994, 2006; MacEachren, 2004; Ware, 2012) on how do we create them so that they can communicate effectively.

The efficacy of the visualization is pretty much dependent on two factors: (1) internal factors which are affected by the creation process of the visualization; and the (2) external factors which are relevant to the audience and their environment on how they receive this information. Effective design should facilitate both factors; thus, better understanding of the basic principles can lead to better design and effective delivery of the message that it carries. In regards to external factors, there is not much we can do other than trying to boost the cognitive capabilities of the human mind to facilitate effective communication.

The creation phase is mainly considering the basic design principles, which are focusing on different attributes ranging from contrast, colour, shape, size, figure-ground to recognizing patterns in two-dimensional space and three-dimensional patterns. The organization of seeing objects, so called Gestalt principles, are one of the main attributes that we have to keep in mind while designing. Gestalt principles refer to theories of visual perception that investigate how people tend to organize visuals, for instance according to their proximity, similarity, closure and symmetry. The Gestalt principles are effective not only in drawing attention and enhancing perceptual reading but also in facilitating problem solving and thinking processes.

When a visual is constructed, the relevant information is encoded (creation phase), basically through position, shape, size, colour, etc. When a person looks at a graph, the information is visually decoded (perception phase) by the person's visual system. A visualization is only successful if the decoding is effective. No matter how the informed decisions are made cleverly and how technologically impressive the encoding was, it would eventually fail if the decoding process fails (Cleveland, 1984). Therefore, understanding the constraints and capabilities of visual perception and cognition is essential for the creation of the effective visualizations. From information visualization to cartography to statistics, skills and the know-how on design principles are closely related with the visual perception and cognition principles.

Kahneman (2011) suggest that it is entirely legitimate to enlist cognitive basics (or outline cognitive biases) to work in our favour, and based on the studies of truth illusions this provides specific suggestions that may help us achieve this goal. The general principle is that anything you can do to reduce cognitive strain will help for our advantage.

“Know your audience” is an important step for the efficacy of the visualization. To communicate effectively, the intended audience need to be familiar with the content, background knowledge and the concept as much as possible. If the visualization is done with the presence of heavy jargon and technical or scientific terms, then the chances are quite high that the lay people who are non-experts in the area are going to lose interest or have difficulties to understand the image with minimal effort.

How decisions are made, what should and should not be visualized is solely dependent on subjective however informed decisions made by the creators and their experience on how the message is intended to be received in general. Clearly, we cannot eliminate the fact that the subjectivity of the creator due to his/her skills and ability to visualize or the cultural surrounding that he/she has experienced, this will inherent in any human artefact. Nonetheless, this does not give us the license to ignore the practical consequences of our decisions in designing that artefact. The realization that any profession contains similar limitations of skills and cultural baggage, does not reduce the significance of works such as Lynch's (1960) work on the image of the city.

Digital Visualization

Before the personal computer became as a commonly used tool, we were faced with a labour-intensive process to present data graphically, involving the use of a T-square, draftsmen's triangles, and a collection of special pencils and pens (Few, 2009). The process itself took a lot of time and effort, and the graphical communication skills of the people who are responsible for this work usually took longer to develop.

Today, we can create visualizations much easier and faster. Thanks to the ubiquity of programs to create visualizations easily and the availability of massive, dynamic data sets which are easily accessible (Dunne *et al.*, 2016). Data visualization, born from the marriage of classical charts and powerful computer graphics, is a way to discover meaning out of all these available data sets. But given that our modern chart forms such as the pie, line, and bar chart, which were originally invented to show dozens of data points only, today they need to adapt to showing thousands of those data points. Probably, William Playfair did not have this in mind when he first created the line chart in 1785.

The design guidelines for web-based contemporary visualizations are different. They can be in nature dynamic and interactive. Interactive visualizations can pack in much more information by separating the amount of information in different segments and making them available to the user which can be accessible on demand. This kind of segmentation helps to avoid frustration and allows the user to interactively get engaged in case he needs more details into certain specifics. Meirelles (2005) explains that in a dynamic environment, as in the web, the attributes such as shape, position, color, etc. are no longer enough, now they have properties in spatial and temporal dimensions that cannot be isolated anymore.

Over the years we have developed an intuition about what makes data visualization interfaces work well, there are valuable resources which provides resourceful guidelines (Kirk, 2012; Meirelles, 2013; Cleveland, 1984, 1993; Few, 2009, 2013; Ware, 2012) although we don't have a strict formula for a successful interface, we know that some basic principles do help.

The computer graphics revolution, which began in the 1960's and has intensified during the past years, stimulated the invention of graphical methods types of visualizations and types of quantitative information to be digitally visualized. It has grown so fast; the number of visualization techniques and styles makes it hard to follow and only time will show if they can stand longer or if new methods are going to replace them.

It is crucial that the web-visualization give users immediate and informative feedback at every step along the way. This means that the web-interface must not be too complex or confusing as to discourage users, nor so simplistic as to make them bored.

Open Data and its Impact on Visualization

Apart from the creation factors which are essential in affecting our cognitive capabilities and enabling us to perceive the desired message, there is the data factor. We are producing an enormous diversity of data, from governments to city councils to institutions they all try to make meaning out of this data. From real time GPS data to national development statistics, digital data visualization enables us to use hundreds and thousands of points instantly and to let readers "see through" points which has potentially meaningful outcomes.

The growing volume of open data makes cities more inclusive, enabling its citizen and different organizations to actively take part in it. Open data initiatives and institutions are actively encouraging their 'smart' citizens to use the data and make meaning out of it. This led us to think on more fundamental issues on how information is collected, structured, represented and communicated.

It is important to point that the open data, in and of itself, is not the same thing as open information. An open information policy would imply the further duty to provide data in citizen-accessible and citizen-intelligible form, and to provide for public access to the information used by experts, decision-makers, and service providers acting on urban systems. Despite the great accomplishment that the open data initiatives, in general, achieved, using this data with the help of visualizations tools that are available and turning it into public information works is quite labour intensive. However, this doesn't reduce its significance and achievements.

The planning discipline have been slow to adapt to the new advancements of data visualization. Connecting the available data sets is greatly valuable, but it is only part of the solution. For planning and design purposes, “hard” data is much more useful when properly fragmented and correlated with qualitative information and associated with geo-spatial attributes.

Creation of Urban Change in Time (UCIT)

UCIT (<http://www.ucit.or.at>) is created as an open source web-application consisting of open source solutions. The application brings together and shows the extent of development in Vienna from 1600s till today. It allows navigation through historical maps of Vienna from different times and different scales. Additionally, it lets you to explore the existing built fabric, by grouping the age of the buildings according to their built year and/or built period.

The making of UCIT showed that even though the willingness to have such visualization exist, the availability of the public information infrastructure was the main obstacle for the realization. The goal of integrating qualitative with quantitative dimensions of urban data to communicate a growth story, was already ambitious (although nothing new). In the beginning it seemed quite easy, to create such an application, the data should somehow exist. Find the data, use a fitting open source visualization technique and there you have it. However, the most cumbersome and exhausting part was to “find” the appropriate data (if even exists) and then “clean” it and structure it properly so that it can be used with the selected open source solutions that are available for use.

The central objective to the empirical research was whether it is possible to create such a visualization and by doing that to interact public and media attention by solely displaying the urban information interesting and easily available for public access. I believe UCIT has achieved a satisfactory response from public and the media (60k unique visitors, 8 publications), by creating a ‘simple’ web-application which led people talk, make critical analysis about the transformation and the age of the urban fabric of Vienna. The debate was not only focusing on what application has provided itself, but also the availability of the open data was one of the focal points of the critical discussion. Despite the fact that most of the data was provided as open source, some were still needed to be funded.

Conclusions

This article investigated the different aspects of visualization, first with an emphasis on its use and role in planning discipline, how it is used and the great potential that it contains in bringing the stakeholders into dialog. Secondly, the design aspects of visualization to clarify and enhance how we organize and encode information visually to establish an effective communication. It is my hope that this article (and eventually the thesis that it originates from) will help broaden the dialogue on creating visualizations both on static or dynamic terms, which can help foster skills in designing for information communication. This study is created with the planning discipline, its students and scholars in mind however the scope was not only limited to them.

The study of the visualization showed that having the attributes that are listed below results in successful communication:

- Communication-centred: Created with both experts and non-expert stakeholders in mind. Here it is important to break down the conventional distinction between user-friendliness (pretty) and expert-friendliness (functional).
- Collaboration-minded: Designed to support stakeholders interacting on the analysis or the investigation before, during or after the visualization.
- Know your audience: To communicate effectively, the intended audience need to be familiar with the content, background knowledge and the concept as much as possible.
- Convey a 'clear' message: Having a clear message or slogan in general is important for establishing effective communication. Provide a clear overview of the model, as well as the possibility to drill down into details, if necessary.
- Design basics in-mind: Better understanding of the basic design principles can lead to better design, eventually better communication.
- Perception and cognition basics in-mind: Enlisting perceptual or cognitional basics to work in our favour will help. The general principle is that anything you can do to reduce cognitive strain is helpful.
- Adaptability in-time: Available data will change over time and the new visualization techniques may replace existing ones; the adaptability is the key here.

We need to re-examine the city and its attributes within, keep it open to further critical analysis. Especially with the new possibilities that the web allows us, effective visualizations have the potential to lead to interesting discoveries and collaborative creations.

Design in the Anthropocene: an opening to the *other*

Micol Rispoli

Ph.D candidate in Philosophical Sciences, University Federico II of Naples, micolrispoli@gmail.com

Abstract: Nowadays, more than ever, the acquired awareness of man's responsibility towards the compound planetary crisis we face is stressing the need of a change in perspective. Against the modernist anthropocentrism, some emerging theories are suggesting that coexistence is not only a human issue, but it rather concerns all the entities (animate or inanimate, material or immaterial) that compose the world. This is not seen anymore as a passive background, but rather as a system of relationships, made of different actors - human and non-human - all provided with a political voice and agency. The idea behind this assumption is that reclaiming ground that has been previously purified of too many missing voices and actors might spur the cultivation of a more responsible, ecologically sound politics. Such change of perspective is, clearly, shaking the foundations of all disciplinary fields and also affecting the very idea and practice of design.

What kind of approach to design are these perspectives contributing to shape?

Keywords: anti-anthropocentrism, ontological pluralism, (cosmo)politics, prototyping

Introduction

This contribution seeks to address the complex relationship between design and the increasing concern over planetary conditions. A growing number of scholars think we have entered a new geological era, the Anthropocene, ever since the atmospheric chemist and Nobel Prize winner Paul Crutzen popularized the term in 2000. The main argument behind this assumption is that humans - the major force in the current geological epoch - have irreversibly altered the planet, which is reacting with global climate upheavals. The acquired awareness of man's responsibility for similar phenomena is shaking the foundations and boundaries of all disciplinary fields and stressing the need of a change in perspective. Peter Sloterdijk's Spherology, Science Technology Studies, Latour's Actor Network Theory, together with New Materialism in philosophy - pioneered by political theorists such as Jane Bennett - are emerging trends in 21st century thought. By abolishing the traditional dualities of Modernity, such as the nature and culture divide, they are suggesting new ways to understand the world we live in and to address the compound crisis we face. Against the modernist anthropocentric perspective, the surrounding world is not seen anymore as a passive background, but rather as a system of relationships, made of actors or *actants* - «something that acts, or to which activity is granted by another» (Latour, 1996) - human and non-human, both provided with an agency which is also political.

This perspective implies going beyond the traditional, restrictive notion of politics as "the give and take in an exclusive human club", towards what Stengers and Latour defined *cosmopolitics*, i.e., politics seen from the viewpoint of an "ontological pluralism" as a continuous negotiation, a practice of coexistence

to which all the living and non-living entities participate (Stengers, 2005). The boundaries between nature and culture, *inside* and *outside*, entities and agencies traditionally seen as oppositional (human/animal, life/matter, organic/inorganic) are called into question, as well as those defining traditionally autonomous fields of knowledge, that begin to cross-fertilize each other.

Such change of perspective has, clearly, a profound impact also on the very idea and practice of design. Indeed, design practices can unveil and re-shape the co-existence of different entities, agencies and interweavings that constitute the political sphere.

1. Design and Politics

Martín Tironi, Chilean sociologist interested in interdisciplinary research on design, argues that «while politics must deal with the governing of human interests for the sake of common good, design, instead, would be focused on form, the aesthetic and functional arrangement of the things that populate the world. (...) on transforming, creatively and sensitively, the materialities into useful, usable or decorative products.» He suggests moving beyond these restrictive boundaries which see design as a tool or equipment *outside* the political (Tironi, 2017).

The sociologist Domínguez Rubio and the architect Foguè argue that until now the usual way to explore the relation between design and politics has been focused around what we can call design's capacity to *enfold* the political. That is its *prescriptive attitude*, its ability to inscribe political programs into materials, spaces or bodies, and to create silent forms of power and influence: design, thus conceived, turns out to be a form of doing politics through things. The rendering of power would work at a sub-political level by controlling the physical and technological elements that silently shape our actions and thoughts (Domínguez Rubio and Foguè, 2017). This means - using sociologist Akrich's words - that politics works through inscribing a certain «*vision* (prediction or scenario) of the world in the technical content of the new object» (Akrich, 1992). These *scripts* or scenarios constitute attempts to predetermine certain settings, defining a framework of action.

However, even if design's capability to create silent forms of power is and remain undisputed, it is equally important not to overestimate it. Predetermined inscriptions «tend to create a sort of performative illusion» (Domínguez Rubio and Foguè, 2017), according to which the effects of intentions and programs are some sort of inevitable result of the original design. Design objects, instead, are continually changing as people creatively transform them according to their need. Unpredictable and unexpected events come to disturb the *script*, letting the *otherness* in. To support this argument, Domínguez Rubio and Foguè mention the fate of those project that aimed to use architecture to enfold different visions of a new society, such as Le Corbusier's project to modernize Chandigarh, which has «turned into a flea-market and a place to hang clothes» (Domínguez Rubio and Foguè, 2017).

The unexpected and miserable fate of examples like this could be seen as an ironical commentary on the *enfolding* capacities of architectural design and leads us to realize the limits of the traditional way of considering its political capacities. It is therefore important to introduce a different way of thinking about how design can become a political matter.

2. The disappearance of the outside

In order to do so, we need to gain an insight into the complexity of the contemporary world. The process of *disappearance of the outside*, as Latour explains, «is certainly the defining trait of our epoch» (Latour, 2009), a phenomenon with great architectural and urban impacts whose relevance cannot be ignored. The compound crisis we face and the emerging of resilience issues are spurring a change in perspective.

Latour's Actor-Network Theory argues that rather than conceiving any subject or object as isolated, we should consider it as an entity enmeshed in a complex web of relationships, in which other human and non-human actors interact. A web that is always contingent, as it changes according to each specific condition. He radically questions traditional approaches to scientific issues, by referring to what he calls *collective experiments* (Latour, 2006). Science was once practiced *inside* laboratories, confined workplaces for experts only, leaving *outside* the pure *empirical experience*. Nowadays the laboratory has in most cases dramatically broadened its boundaries, and we are now all involved in the same

collective experiments mixing humans and non-humans together. Stressing the fact that the distinction between the inside and the outside of the laboratory has disappeared, Latour refers to what have been called *hybrid forums*. So far only two types of forums have existed: one that was in charge of representing *things of nature* and another one which was in charge of representing society. One simple way to characterise our times is to say that the two meanings of representation have now merged into one: to define the new politics, Latour introduces the expression *Parliament of Things*.

«The global warming controversy is just one of those many new hybrid forums: around the table, some of those spokespersons represents the high atmosphere, others the lobbies of oil and gas, still others non-governmental organisations, still others represents, in the classical sense, their electors (with President Bush able to represent simultaneously his electors and the energy lobbies who have bought him up!). The sharp difference that seemed so important between those who represented things and those who represented people has simply vanished. What counts is that all those spokesperson are in the same room, engaged in the same collective experiment, talking at once about imbroglios of people and things.» (Latour, 2001)

This shift implies a different attitude towards the traditional relationship between the *outside* and the *inside* and a philosophy of space aimed at making the *outside* disappear.

In order to better understand the meaning of this theoretical model and how it could be linked to design, it's necessary to draw attention to Peter Sloterdijk, one of Latour's main references, who first grasped the depth and extension of the concept of *design*.

«When we say that “Dasein is in the world” we usually pass very quickly on the little preposition “in”. Not Sloterdijk. In what? he asks, and in where? Are you in a room? In an air conditioned amphitheatre? And if so what sort of air pumps and energy sources keep it up? Are you outside? There is no outside: outside is another inside with another climate control, another thermostat, another air conditioning system.» (Latour, 2008)

Historically the personal sphere has always been formed at the expense of the *foreign*, the *not-belonging*. Nowadays, according to Sloterdijk, this short-sighted attitude has reached its constitutive limit.

«Because “global society” has reached its limit, however, and shown once for all that the earth, with its fragile atmospheric and biospheric systems is the limited shared site of human operations, the praxis of externalization comes up against an absolute boundary. From there on, a protectionism of the whole becomes the directive of immunitary reason. (...) Thus, the classical distinctions of friend and foe collapse. Whoever continues along the line of previous separations between the own and the foreign produces immune losses not only for others, but also for themselves.» (Sloterdijk, 2013)

In developing his theory, Sloterdijk signals the need to break down the partition wall between the *personal sphere* and the *foreign sphere*. He calls on us to think about the human subject, and the supra-individual subjects that we call *society* and *civilization*, together with objects, things, nature, animals, plants and the environment. These *things*, this *foreign sphere* so far has always been objectified, looted, taken for granted, exploited. (Sloterdijk 1998, 1999, 2004). By using the term *co-immunity*, Sloterdijk thinks of an unprecedented coupling between the personal and the foreign sphere: between human and non-human, as well as between human beings, to preserve themselves and the biosphere as an entity capable of guaranteeing their survival.

3. A political ecology of things

Within these reflections, Remo Bodei, in his analysis of the term *object* points out that the term object

«seems to derive theoretically from the Greek term *problema*, where “problem” is understood as an obstacle put forward as a form of defense, an impediment that blocks the way and causes something to stop. In Latin, more precisely, *obicere* means to throw against or place before. The idea of *objectum* (or, in German, *Gegenstand*, what is before or against me) implies a challenge, a contraposition that prevents the subject’s immediate affirmation precisely because it “objects” to the subject’s pretensions to dominance. It presupposes a confrontation that concludes with a definitive overpowering of the object, which, after the struggle between subject and object, is made available to be possessed and manipulated by the subject. A thing, in contrast, is not an object, an indeterminate obstacle that I find before me and that I have to conquer or circumvent – rather, it is a cluster of relationships in which I feel and know that I am implicated and of which I do not want to have exclusive control.» (Bodei, 2009)

For his part, Latour, opposing to the modernist attitude towards the material world, argues that:

«To think of artifacts in terms of design means conceiving of them less and less as modernist objects, and (...) more and more as “things”. To use my language artifacts are becoming conceivable as complex assemblies of contradictory issues (...). When things are taken as having been well or badly designed then they no longer appear as matters of fact. So as their appearance as matters of fact weakens, their place among the many matters of concern that are at issue is strengthened.» (Latour, 2009)

By reimagining ostensibly settled *matters of fact* as contested and constructed *matters of concern*, he argues that we could reveal the configurations of interest and agency that connect human and non-human actors and which give particular social realities their weight. Thinking of the social in terms of complex assemblies, in fact, leads us to consider the political field from a completely different perspective. Jane Bennett, referring to Dewey’s idea of the *public*, claims that «there is no action that is *not* conjoint, that does not, in other words, immediately become enmeshed in a web of connections.» (Bennett, 2010)

Focusing on this assumption Bennett questions the positivist and antropocentric perspective - according to which the human understanding is the source of the general laws of nature - and argues that political theory needs to do a better job of recognizing the active participation of nonhuman forces in events. Nowadays, more than ever, climate change and its effects show that coexistence is not only a *human* issue, but it rather concerns all the entities (animate or inanimate, material or immaterial) that compose the world. Bennett suggests to abolish the traditional dualities of Modernity, such as human/animal, life/matter, organic/inorganic: oppositional pairs that establish separating lines and excluding boundaries. The surrounding world is not seen anymore as a passive background, but rather as a system of relationships, made of agents that condition each other, revealing their political role, their *agency*. Bennett - who refers to Deleuze’s assemblage as a term of choice for describing reality as a multiple object - aims to demonstrate that non-humans have an effective political *agency*. She suggests that recognizing that *agency* is distributed this way, and is not solely the province of humans, might spur the cultivation of a more responsible, ecologically sound politics and a new awareness of the new climatic, political and social urgencies. (Bennett 2010)

4. The (cosmo)political capacities of design

Laura Lieto and Robert Beauregard argue that «thinking of the social as a matter of associations and not as an entity pre-existing the process of assembling is a path-breaking ontological position that questions enduring social theories deeply embedded in design theory and practice. With similar subversive force, the idea of extending agency to entities other than humans – objects, material things, technologies, natural elements – poses new questions to all scholars and practitioners engaged with urban and architectural issues, not just to social scientists». (Lieto, Beauregard, 2015). The restrictive notion of politics therefore extends beyond its traditional boundaries, making design practices a particularly useful space to reflect on the multiplicity of entities, agencies and interweavings that constitute the political sphere.

Domínguez Rubio and Uriel Fogué, besides their analysis of design's prescriptive attitude, introduce a different way of thinking about how the project can become a political matter. Moving away from a technocratic approach, aimed at setting the rules, the *script*, and its boundaries, they use the verb *unfold*, to rather signal an *opening* (Domínguez Rubio and Fogué, 2017). This means the possibility of events occurring without having been previously predetermined by the designer, but as a result of the free interplay of multiple actors (not only human) involved in a contingent situation.

This *unfolding* ability, this letting the *otherness* in, can be defined as a *cosmopolitical* activity, i.e. a continuous negotiation, a practice of coexistence in which all the other living beings and non-living entities - to which we usually refer as *resources* - participate¹ (Stengers, 2005). It means to leave open the possibility of agency of the non-expected, surprising and unlikely *other*.

As Latour points out, speaking for Isabelle Stengers:

«For her, the strength of one element checks any dulling in the strength of the other. The presence of *cosmos* in *cosmopolitics* resists the tendency of politics to mean the give-and-take in an exclusive human club. The presence of *politics* in *cosmopolitics* resists the tendency of *cosmos* to mean a finite list of entities that must be taken into account. *Cosmos* protects against the premature closure of *politics*, and *politics* against the premature closure of *cosmos*.» (Latour, 2004)

Nature is no longer seen as unified, is not just *out there*, a simple backdrop for human activities: it has to be done, created, instigated, and *composed* (Yaneva, Zaera-Polo, 2015). The ethical role that design can take in the composition and perception of these heterogeneous assemblies is fundamental.

«cosmopolitics as a matter of design is an invitation to recognise the boundaries and extents of the design methods centred around humans, and to explore forms of de-centralisation through operations of co-designing that allow the inclusion of other, invisibilised entities.» (Tironi, 2017)

From the perspective of the Anthropocene «architecture has lost its fixity, along with its presumed modern purity». In fact it cannot be seen anymore as a self-contained, autonomous object set against the background of cities or landscapes. It is bound «to humans and non-humans, to material and immaterial entities, (...) to discursive and representational practices, to socio-economic and symbolic systems.» The shared awareness of its ontological instability and heterogeneity is «subverting concepts, unsettling binaries, questioning received notions of agency and authorship, as well as troubling the discipline's authority» (da Costa Meyer, 2016).

How can design be an effective tool in dealing with this acquired awareness?

Cosmopolitics, rather than working by means of a *totalizing prefiguration* - which adheres to the modernist determinism - proposes actions capable of producing results in terms of an *opening* of the present, by embracing the logics of openness and *prototyping*. As Martín Tironi argues, «prototyping does not impose or reconfigure, but its reason to be is to allow realities based on its successive failures and malfunctions to emerge, forcing to reconsider other paths and questions.» (Tironi, 2017) It doesn't refer to neither utopian nor heterotopic spaces, but requires an action to be performed in a contingent situation, installing «a notion of politics open to the potential, a relation with the present based on the speculative: it can make present, performatively, political worlds and possibilities that are still absent. (...) the political issues, problems and interests start to co-emerge in the process of testing.»

¹ However, a clear distinction needs to be made between *cosmopolitics* and *cosmopolitanism*. *Cosmopolitan* is a very old term which comes to us from Kant, referring to anyone who is a citizen of the cosmos. In this sense, it refers to the possible unification of all people - only humans, who have different perspectives on the world - through universal laws, while nature, the *cosmos*, is simply there, a fixed background. *Cosmopolitics* instead, refers to the politics of a *cosmos*, which includes all the many natural and material entities that make humans act. Whereas for cosmopolitans there is one unified nature, in cosmopolitics nature is multiplied, is a Multiverse. It is no longer seen as a simple backdrop for human activities: it has to be done, created, instigated, and composed. While cosmopolitanism stands for politics *in the cosmos*, cosmopolitics instead refers to the *politics of the cosmos*.

A cosmopolitical approach therefore opposes an idea of assemblage and *bricolage* to any totalizing vision.

«The ‘bricoleur’ is adept at performing a large number of diverse tasks; but, unlike the engineer, he does not subordinate each of them to the availability of raw materials and tools conceived and procured for the purpose of the project. His universe of instruments is closed and the rules of his game are always to make do with “whatever is at hand,” that is to say with a set of tools and materials which is always finite and is also heterogeneous because what it contains bears no relation to the current project, or indeed to any particular project, but is the contingent result of all the occasions there have been to renew or enrich the stock or to maintain it with the remains of previous constructions or destructions.» (Lévi-Strauss 1962)

In contrast to a *problem solving* logic-based approach, a political understanding of design, adopting *prototyping*, also turns into a sort of *problem-making* practice, intended as way to introduce innovative ways of exploring and becoming sensitive to the contingency. By also questioning traditional disciplinary fields, it suggests a new way of looking at the social life, considering the multiple agents involved in it and unveiling *other* realities.

These perspectives clearly abandon the idea of prefiguring an *elsewhere* to *converge*, to rather promote open and situated activities of questioning and altering. According to them, future is not so much what has to be imagined or planned, but rather the *openness* emerging from an experimental and continuous alteration.

In this frame, it is worth mentioning a number of recent and not-so-recent attempts that try to activate and unfold different possibilities for political action and imagination.

Díaz Moreno and García Grinda, founders of AMID.cero9, in Madrid, let the interaction between different agents emerge in their work. In the 2002 project named *Magic Mountain* (Figure 1), in Ames (Iowa, U.S.) they transformed a massive urban power station into a piece of landscape inside the city. Challenging established instruments they proposed to deploy a local gardener’s ancestral techniques of genetic selection and covered its volumes with a membrane of roses, lights, and honeysuckle. Like a real mountain, the membrane provides a resting place for the largest species of North American butterflies on their migratory route. At the same time, an enormous variety of bird species can nest, since in recent years many of the area’s forests and wetlands have disappeared. The power station provides an alternative habitat and a living laboratory where the university can test new varieties of species adapted to this climate.

Figure 1

Lacaton & Vassal, in France, make intelligent reuse of the existing, and avoid recurring to demolition, regardless of how green the replacement building may be. Their desire is to find *what is essential in each situation* and to create a language of architecture based on an economy of means. Moving against

the anthropocentric tendency to reduce and define, they choose the option of altering and remodelling the dysfunctional buildings from the inside out, letting the needs of the users dictate the final form and look. They see their role as extending far beyond just building, creatively engaging with and also challenging traditional urban planning policy, which is too often destructive in its approach. In the social housing project in Mulhouse (Figure 2, Figure 3), in 2005, they provided any user with twice the normal area by reducing costs through a clever handling of the construction program and by using unusual and low-cost construction methods.

Figure 2

Figure 3

La Borda Cooperative, in Barcelona, together with LaCol Arquitectura, promotes more accessible and fairer homes, with a non-speculative regime. The project (Figure 4, Figure 5), which began in 2012 and foresees the construction of 32 apartments (the “co-habiting units”) in the district of Sants is based on the following guidelines: tenant participation in the entire process, the creation of a flexible structure re-adaptable in future, the introduction of neighbourhood initiatives in order to favour community life.

Figure 4

Figure 5

In their work, the Rotterdam-based group 2012 Architecten (now Superuse studios), starting from questioning the notion of re-cycle - whose decomposition and recombination processes require enormous amounts of energy to be applied - propose the concept of *superuse*, which uses materials, components and objects in the form that they are found. In their project named *Wikado* (Figure 6), in 2007, they managed to renovate an existing playground by using discarded wind turbine parts.

Figure 6

In his *OS (OpenStructures)* project (Figure 7), the Belgian designer Thomas Lommée explores the possibility of a modular construction model where everyone designs for everyone on the basis of one shared geometrical grid. The intention is to initiate a kind of collaborative Meccano to which everybody can contribute, in order to stimulate re-use cycles of various parts and components and enable collaborative (and thus exponential) innovation within an hardware construction.

«When that product is discarded, enormous amounts of energy have to be applied to make the waste product break-down into smaller quantities. Often toxic by-products, energy and material-resource are used in the deconstruction process. The production of most products in our western, consumption-based society still run off this linear cradle to grave process.» (Lommée, 2009)

Figure 7

In 2013, Eindhoven-based designer Weilun Tseng has produced a system of open and modular electronic components, *Open E-Components* (Figure 8), that allows users to build their own electronic devices, lowering unnecessary consumption and blind buying action (i.e. planned obsolescence main effects). Each module can function independently, enabling the users to expand and adapt the electronic appliances to their personal needs.

Figure 8

5. A space for hesitation and care

The attempts listed - although differing in scale and context - share the same approach: they aim to question, interrupt, modify or subvert processes, practices and logics. They analyze certain realities in depth and highlight the agency of different material and immaterial entities. Against an unquestionable technocratic approach, they deploy and allow *slow reasoning*, *negotiation* and *re-interpretation*. Broadening the range of possibilities, they openly embrace change, and let the *otherness* in.

More than ever, the complexity and uncertainty we are dealing with at the present time compells us to slow down, deeply reflect, dig into the consensual way a situation is presented and create a *space for hesitation* (Stengers, 2005) where one can express concerns and disagreement. «We need to slow down, not to consider ourselves experts, authorized to believe we possess the meaning of what we know»

(Stengers, 2005). This requires adopting what Latour defines the *precautionary principle*, «a call for experimentation, invention, exploration, and of course risk taking» (Latour, 2006) and an attitude to *thinking with care*, (Puig de la Bellacasa, 2017), as a radically transformative political project that encourages intervention in what things *could be*.

«Words seen through care accentuate a sense of interdependency and involvement. What challenges are posed to critical thinking by increased acute awareness of its material consequences? What happens when thinking about and with others is understood as *living with them*? When the effects of caring, or not, are brought closer? Here, knowledge that fosters caring for neglected things enters in tension between a critical stance against neglect and the fostering of speculative commitment to think how things could be different.» (Puig de la Bellacasa, 2017)

Transition paths
and urban futures

Landing

The need for a renewed urban vocabulary for hospitality (and the city)

Martina Bovo¹

¹*Politecnico di Milano, DASTU, martina.bovo@polimi.it*

Abstract: Within the framework of recent socio-demographic changes, migratory flows have gained a crucial role in the European context, challenging territories and cities, opening up renewed questions for urban governance. Along the migrant trajectory, the paper focuses on migrants' *first arrival* in the city and on first reception dynamics, addressing a phase preceding settlement and rather regarding populations with a temporary perspective in the relation to the territory. The work considers the case of Milan, which in Italy has particularly experienced the temporary dimension of first arrival, being until 2015 a transit area and then quickly turning into an arrival city. Assuming the background of existing policies, the work draws on a qualitative observation of Milanese first reception, with specific attention to hospitality "practices", broadly defined. The observed scenarios show an oversimplified answer to the conditions of temporary populations, often translated in "exceptional" reception spaces and emergency-based policies. The work argues the urgency of a renewed and more complex definition of arriving migrants' condition and the relevance of existing practices as a powerful mean to challenge ordinary urban governance tools. Questioning the common understanding of arrival may be the first move to imagine the transition towards alternative urban futures and structurally receptive cities.

Keywords: migrants' first arrival; first reception; temporary vs permanent; Milan

Introduction

The relation among migratory flows and urban environments has deep roots, often strongly bonded to the birth and growth of contemporary cities or parts of them. Recent fluxes around the Mediterranean Sea have once again strengthen the link between migrant trajectories and cities, often redefining the role of certain centers in an international network, but also transforming diverse urban areas and introducing "new populations". Recent migrations make us reflect on the capacity of the city to offer plural ways of inhabiting its spaces and in general to support the presence of these populations, instead of simply opposing and resisting to them. Such considerations and the structural nature of the migratory phenomenon force to consider migration within a contemporary urban question and to conceive migrants' arrival and reception as more and more ordinary and structural functions of our cities.

The work aims at investigating the conditions of intersection between migratory flows and the city, particularly reflecting on the short temporality of the firsts and the longer temporality of the second. At this aim, the contribution chooses as point of observation the dimension of first arrival, or landing¹, and first reception of migrant populations within the city, conceiving it as the moment preceding settlement. Such choice is based on two considerations: on the one hand, the nature of recent migration policies has stretched the dimension of first arrival, enhancing the figure of the “asylum seeker”, as almost the only way to access Europe; on the other hand, the dimension of first arrival seems to be representative of further urban phenomena, opposing their short temporality to the longer one of the city. Thus, looking at first arrival is intended as a chance to challenge the urban vocabulary of hospitality, but also, more broadly, that of certain urban spaces, services and policies.

The paper draws on the work of a Master Thesis in Architecture, at Politecnico di Milano, which explores the case of institutional first reception centers in Milan between 2015 and 2016 and starting from a closer observation of the spaces tries to investigate the relation between first arriving migrants and practices of first reception². The contribution is organized as follows: the first two sections outline the main reasons why it seems relevant to look at the moment of first arrival and the key points of the used methodology, it follows an introduction to the Milanese context of incoming flows and a summary of the main observations and results of the work, finally some conclusions are drawn.

The territorial dimension of first arrival

Background

Addressing the migration question within the urban realm leads to deal with an extremely complex and necessarily interdisciplinary topic; among the possible study fields, the contribution chooses to look at the territorial dimension and to investigate the intersection between migratory flows and the city starting from spatial practices and spaces of arrival and reception.

Literature dealing with the relation between migration and the territory identifies two parallel paths: on the one hand, global networks, flows and national policies, and on the other, a rather *local* scale, where municipalities, inhabitants and local policies (re)act, developing everyday experiences of hospitality. The crucial scale to understand tools and processes of territorialization appears to be the local one, which looks both at the dynamics occurring in city districts and in smaller towns (Balbo, ed., 2015; Caponio, 2006). Urban studies have further built a rich framework around the territorial dimension of migration, focusing on immigrants and populations who are settling (or already settled) in urban areas. Within this long-term perspective, literature describes the processes of territorialization of immigrants (Tosi, 1998; Lanzani and Vitali, 2003; Blockland and Savage, 2008)

¹ The term *landing* is used to refer to the first phase of arrival on a territory ("primo arrivo e prima accoglienza" in Italian), and to differentiate it from the following settlement processes. In the following pages will be regarded simply as “first arrival”.

² The term practice here is broadly defined, as unexpected uses of space, non-institutional actions, and unplanned answers by the Municipality.

and discusses the tools of urban policies towards the multiethnic city (Crosta, 2010; Lo Piccolo, 2013; Briata, 2014).

In a different way, the will to focus on the temporary dimension of first arrival implies to assume the mentioned studies as a background, and to shift the gaze from the notion of *im*-migrants to that of migrants, who interact with the territory in a clear perspective of mobility (Tarrius, 1993). The theme of first arrival, regarded as a temporary condition that migrants undergo before settling down, raises diverse questions: the French anthropologist Agier started the ‘Babels Research Program’, revolving around the concept of the city as a border and investigating “what migrants do to the city and what cities do to migrants” (Agier, 2016); more recently, the issue of first arrival has been addressed within studies of social policies related to first reception systems. But, while different research fields (anthropology, sociology, law) on migration start addressing this temporary dimension, urban studies still struggle in considering it as a subject by itself, so that the territorialization processes and tools of first landing still remain a rather unexplored field. A consideration may make more evident the reason of this gap: urban studies and policy are asked to deal with populations who are not (yet) territorialized and settled, but already using intensively urban spaces (Pasqui, 2008).

In this sense, the dimension of first arrival triggers a wider issue: the contradiction between the short temporality of some contemporary urban phenomena and the strength, of resistance and inertia, of urban territories, both in terms of planning and regulation and in terms of physical transformations. Among other temporary populations, migrants express an extreme condition of mobility, intensively involving urban areas.

Mapping first reception

Methodology

Within the given framework the contribution carries out a qualitative observation of the institutional first reception centers in the city of Milan, between 2015 and 2016. The choice to look at the case of Milan is based on the fact that in those years the city undergoes a crucial transition, having been a transit place since 2013, in 2015 it quickly turns into an arrival and destination city. The will to focus on the institutional answer to first arrival is based on the belief that in a long-term perspective hospitality should more and more be seen as an institutional and ordinary urban function, relying less on informal solutions. In this sense, it appears significant to investigate the answer and outline the main characters of the reception system, planned at a formalized and institutional level.

In order to carry out the qualitative observation of the reception system and to build a knowledge framework of the Milanese system, it has been chosen the tool of a *qualitative and multilayered mapping* (Figure 1). The map allows to maintain throughout the work the reference to the spatial dimension, while the multiple layers help building a richer framework able to include not only information on space, but also on time, actors etc. Within a specific timeframe (April 2015 - November 2016), the observation has been carried out on three main levels: collection of newspaper articles and reports to draw a map of existing reception centers in Milan, in depth interviews with various actors involved in the system and direct observations and insights on the spaces and life in the centers. The use of the news to detect the opening and closing of reception centers allows to overcome

the static information often provided by institutional documents and to rather express the dynamic nature of the geography of reception; the visits to the centers are “windows” on realities where often unexpected environments are outlined beyond very introvert spaces; the interviews give voice to a broad set of actors, from the Municipality to the third sector institutions managing the centers, to their hosts, passing through the associations more lightly involved in the hospitality of newcomers. The three maps have been drawn at the same time, always considering the crossed-relations between them.

Milan, from transit to destination city

Context

The system of reception in Italy considers three main steps: First Aid and Identification, First Reception, and Second Reception and Integration; each moment is meant to represent a specific phase of the reception path, and it should correspond to a stage of the legal procedures for the achievement of a recognized status and to a set of services and spaces provided. Soon after accessing the country and being identified, migrants should present their request for asylum; while waiting for a temporary staying permit, they are hosted in the so-called Hotspots, i.e. centers of first aid and assistance mainly placed in the border areas of the country. When - and if - having obtained a temporary staying permit as asylum seekers³, migrants wait to be called by territorial commissions; during this period they should be distributed among centers of first reception (Centri di Accoglienza per Richiedenti Asilo [CARA]), or Hubs across the country, big structures where basic services are provided. After being called by the commission and while waiting for a definitive response, asylum seekers are supposed to undergo the phase of Second Reception and Integration, spending their time in smaller centers distributed among different municipalities where both primary and complementary services for integration are delivered (Sistema di Protezione per Richiedenti Asilo e Rifugiati, SPRAR). Such structured system very rarely develops according to the expected and planned steps, both in terms of time and space; in the case of first reception spaces for instance the duration of staying should not exceed one month, but people often end up spending in the centers up to two years, similarly the transfer from first to second reception facilities is often based on the availability of spaces rather than on the correspondence to a certain stage of the legal procedures. In 2014, moreover, due to the increasing crisis of reception management, Italy introduced a further typology of reception facility with a clear “extra-ordinary” nature and with lower managerial and spatial requirements (Centro di Accoglienza Straordinaria [CAS]), which soon became the most common center across the country, used both for first and second reception (Bovo and Lippi, 2017).

Among the Italian regions, Lombardy is between the firsts for the role it plays in the reception system, it counts 13% of the country reception, and Milan also plays a central role in the regional context. The most recent migratory fluxes start involving the city during August 2013, when the first Syrians arrive

3 When the asylum request is not accepted, migrants are rejected and destined to repatriation centers (originally, Centri di Identificazione e espulsione [CIE], from 2017 Centri di Permanenza per il Rimpatrio [CPR]), often very similar to detention structures, where people are supposed to be waiting to go back to their home country.

at Milan Central Station; for the two following years the Municipality hosts 74500 people, of which less than 1% asks for asylum in the city, but only spend there from five to eight days, before continuing the journey towards other European countries. Milanese reception in these years is shaped around the figure of the transiting migrant and the city grows as a transit place. The situation dramatically changes in autumn 2015 due to the enclosure of the Italian Northern borders, so that in April 2017 the amount of asylum seekers is set around 99% and Milan is no more a city of transit but of destination (Municipality of Milan, 2017).

Temporary populations and spaces of first reception

Observations and results

Within this context, the work of mapping tries to investigate the conditions of intersection between new arriving populations and the city, conceiving it as an interaction, or dialogue, among the claims and needs of the firsts and the tentative answer of the second, particularly explored in its territorial and spatial dimension, i.e. starting from the observation of first reception facilities.

Populations at first arrival experience very different interactions with the urban environment, often depending also on their personal background, networks, and in general terms, “capital of use” of the territory. It seems reasonable to address their presence in the city as expressed by their needs. The claims of arriving migrants in their first period - months - of staying certainly compose a quite complex mosaic of different situations, nevertheless some common traits outline the importance of considering the variable of time when dealing with such populations. Within the first days of arrival, migrants who enter the reception system seek very basic services, such as a night shelter, medical and legal assistance, nutrition and acquisition of certain information; the essential nature of such demands makes it easily sharable by a wide target. Even if still deeply uncertain of the possibility to settle in the city, migrants often express some further, and complementary, needs, regarding education and information, recreational activities, worship, food’s and clothes’ purchase and transport. If the essential claims could (mis)lead to an interpretation of migrants’ way of inhabiting the city as a mere presence “at low intensity”, the consideration of the complementary needs clearly outlines the complexity of such presence, in a phase which is instead often concerned as merely and continuously “of emergency”. Whereas the mentioned definition of needs may appear easy to outline, their complexity lays in the consideration of their extreme variability in time, the same service or space may be oversized or undersized depending on the amount of people arriving, on their origin or family composition. In other words, transitory migrants may be defined as special inhabitants, “dwellers with an individual impermanence and a collective permanence” (La Cecla, 1999). Thus, in a perspective of spatial answer to these needs, the factor of time not only becomes an essential element to consider but it is also what makes the answer more complex. In other words, the observation of the claims of arriving populations outlines the need for reception spaces not only able to provide specific services, but also able to adapt in time to their dynamic nature.

With the aim to respond to such temporary populations, the institutional system of first reception opens, between 2015 and 2016, seventeen facilities in the Municipality of Milan, some managed by the Municipality and some others by the Prefecture. The work maps them in a moment of transition from spaces mainly devoted to transiting migrants to structures hosting for several months asylum

seekers willing to stay in Milan. The location of the centers depends on the real estate availabilities of the management institutions, since in most cases the call regards the service and the space of reception; therefore, the distribution obtained does not respond to any lodging criteria and could vary in time. Based on the great number of transiting people in the previous years, in 2015 the Municipality decides to open a filter space, the Hub, very close to the station, where people could spend few hours or days before continuing the journey or being relocated in the city. Once gone through this first filter, asylum seekers are displaced in more traditional structures, mainly functioning as dormitories. The kind of spaces may be grouped in five typologies: former barracks, disused schools, reception facilities, big-sized structures and small-sized spaces normally devoted to other services. The barracks, accommodating on average three hundred people, maintain a military character and result extremely fixed and evidently close to the surrounding, often with high walls preventing to look through. The schools host averagely two hundred migrants at time, they provide more welcoming spaces often surrounded by small gardens or sport halls, but the organization of the space makes them hardly usable, often the beds also cover the common spaces. The third case is that of buildings already functioning as reception facilities, both for homeless or as previous hostels; these spaces are much more suitable, thanks to the way space is organized and to the size of each room, the number of hosts is usually lower. Reception facilities are also big-sized structures originally conceived for other uses, such as sport halls or former warehouses, where the reception function rarely fits the space; the most evident case is the one of a sport arena, where migrants are accommodated in foldable beds, asked to free the space during the daily hours and on Fridays, when Milanese Muslims use the structure for collective worship. Finally, there is also the interesting case of smaller buildings, which normally have different functions and that try to host a limited number of migrants while keeping on their activities; this is the case of Cascina Cuccagna, the Shoah Memorial and the San Marco library. Besides the centers, should be briefly mentioned a network of further spaces, also used by migrants: i.e. daily services. These spaces include day-care centers, canteens and public showers; only few of them are originally thought for refugees and asylum seekers, but their nature allows also migrants at their first arrival to access them.

Looking back at the relation between quickly changing needs and the answers in terms of reception spaces, at least three main issues arise. Firstly, the fact that the geography of first reception does not follow any localization criteria, but largely depends on the real estate availability of the managing institutions; such consideration showcases how, similarly to other welfare fields, also in the case of reception the public actor currently does not play a role of complete control on the system, but rather of overall coordination, in this case worsened by the emergency-based approach towards migrations. The second observation refers to the way the services are provided within the mentioned structures; first reception facilities provide the hosts with dormitories and canteens and only in some cases further services are offered, in most cases anyways all services are concentrated within the reception centers, such polarization leads to a strong isolation of the structure from the rest of the neighborhood, limiting the need and the opportunity of any kind of interaction between migrants and local residents. Thirdly, the physical features of first reception facilities should also be taken into account; the most used building typologies are indeed characterized by a strong rigidity, which prevents any kind of adaptation to the changing needs described above, and are therefore often implemented with rather temporary solutions, such as tents, indoor and outdoor.

In conclusion, the mentioned dialogue between arriving populations and spaces appears to be a *mute* dialogue, where the spatial answer to the structural presence of temporary populations struggles in building an effective reaction to migrants' arrival and rather opposes a certain degree of inertia.

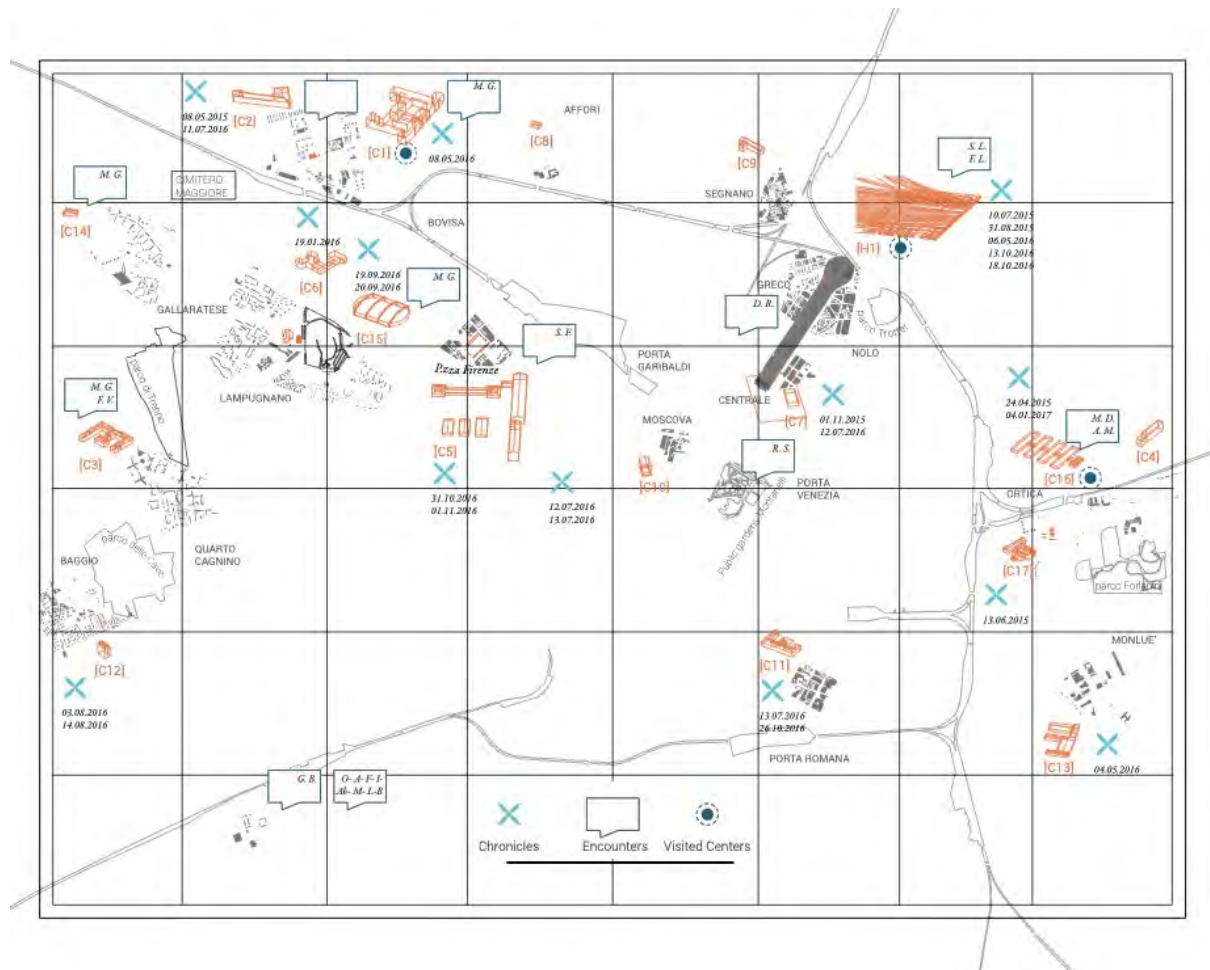

Figure 1. Map of Milanese First Reception, between 2015 and 2016 (Bovo and Lippi, 2017)

Towards a renewed urban vocabulary for hospitality

Conclusions

The structural nature of migrations and the clear impact they have on cities underline the urgency of considering reception as an ordinary urban function. Exploring the less ordinarily-managed part of reception, i.e. first reception, in this perspective, reveals different issues, and focusing on the spatial dimension outlines at least one main theme.

As seen, the lack of any localization criteria, the polarization of reception services within single facilities and their rigid physical character hint at the incapacity of the space to deal in a not temporary way with populations that are only individually temporary, but collectively permanent. Investigating the intersection between the short temporality of the latter and the longer temporality of the physical city opens up a broader question, i.e. the contradiction between *temporary and permanent*

and the apparent impossibility to combine the two within a spatial answer to reception. Interestingly, the same theme has been developed by professor Mehrotra in his work on Ephemeral Urbanism; by looking through very different cases of temporary settlements, Mehrotra argues that the arising distinction between permanent and temporary should not be conceived as a binary but should rather activate a broader understanding of permanence. In this sense, one of the clearest example refers to the Hindu festivity of Kumbh Mela, which every three years gathers millions of people - in 2007 they were 16 million - for only 45 days; here what makes such temporary settlement successful is the fact of being organized, in terms of management and space, as if it were permanent, i.e. by following rules very similar to those of long-term settlements (Mehrotra, 2016). Such theme opens up the question how the design of spaces of reception could build a structural answer to populations even at their first arrival. In this perspective some of the crucial characters of first reception structures are very much challenged: on the one hand, the notion of reception space as confined within single centers prevents hospitality to be combined with other urban functions and to build any interaction with the rest of the city, thus it could be interesting to shift from the existing single structures to a system of spaces, scattered in the territory and combined, when possible, to existing services; on the other hand, the physical inertia of reception centers introduces the theme of *plural spaces*, broadly addressed in the debate on the design of contemporary (welfare) facilities (Crosta, 2010; Oosterlynck *et al.*, 2015; Bricocoli and Sabatinelli, 2017).

In conclusion, the developed map of Milanese first reception certainly represents a partial picture of reality, in terms of space and time, but it seems to reveal both the specificity of the dimension of first arrival and some crucial issues emerging from that. In other words, looking at the intersection between migratory flows and the answer of the city through the spatial dimension of first reception outlines the urgency of working on a renewed urban vocabulary for hospitality.

Looking through first arrival to the city

Open questions

The choice to consider first arrival as a privileged point of observation does not aim at defining it as a predetermined and fixed condition of precariousness, but it is rather based on its understanding as an interesting lens to discuss the relation between certain populations and the territory.

As seen, the dimension of first arrival outlines issues around the vocabulary of reception, but it also opens up questions that more broadly deal with the city. In the first place, the definition of arriving migrants as temporary populations with a structural presence suggests a comparison with other temporary populations (Pasqui, 2008), crossing our cities that - with the due differences - also build with the urban environment a relation limited in space and time; thus the question arises how does and might the city support their presence. Secondly, the spatial dimension of reception reveals the contradiction between temporary and permanent, which is crucial in the case of first reception spaces but is also very relevant in the current debate on Ephemeral Urbanism. Similarly, the dimension of

first arrival seems to be able to trigger broader and relevant debates also when seen from the perspective of services, actors and policies⁴.

In conclusion, the mentioned considerations certainly still remain as open questions, but the fact of being raised starting from the investigation on first arrival and of going beyond the realm of first reception, might be an evidence of their relevance. In this sense, the dimension of migrants' first arrival seems to be an interesting starting point to address *also* broader dynamics challenging the contemporary city.

Abstract: Peri-urban area is the transitional territory between rural and urban areas and the most diverse area that the ecosystem confronts the urban development. It is probably one of the fastest growing areas across the world, especially in developing countries, among which China is recognized as one of the most important contributors. Extant research document peri-urban area not only as the most dynamic and growing territories, but also the territories haunted by urban sprawl, environmental pollution, social segregation, etc. Based on the particularity of the ecosystem in the peri-urbanized area, this paper proposes a human-centered analytical framework for assessing ecosystem functions based on the original ecological service value assessment method. First assess the performance of ecosystems (ES), including cultural services, supporting services, regulating services and provisioning services to meet the diverse needs of urban dwellers, rather than equal value or biomass carbon. Further, instead of simply superimposing the four types of ES, clustering analysis is used to classify the ES types of each analysis unit because they differ in the four dimensions of the ES, and finally some scenario predictions were made through the classification results.

Keywords: peri-urban; ecosystem service; people-oriented; developing countries

1 Introduction

Ecosystem services play an indispensable role in the human environment, including supply of food and fresh water, climate and temperature regulation, soil diversity maintenance, spiritual culture and entertainment value (Costanza *et al.* 1997; Ma and M. E. A., 2005). Ecosystem services not only play a decision-making tool in the growing urban population and social system, but also an important tool for maintaining human health (Gomez-Baggethun and Barton, 2013). Currently ecosystem system services are still one of the priorities of multidisciplinary research (Seppelt *et al.* 2011, Fisher *et al.* 2009), and the demand for urbanization and other practical applications is becoming more and more obvious (Daily *et al.* 2009, Burkhard *et al.* 2010).

With the rapid urbanization process, urban population expansion and land expansion are also ubiquitous, resulting in rapid and disorderly changes in land use (Haas and Ban, 2014), which gradually destroys natural ecosystems, especially the decline of ecosystem services. At the same time, in the rapid development stage of urbanization, the rapid growth of the built environment and social capital has replaced the natural capital which centered on the value of ecosystem services and become a mainstream value orientation, and the contribution of the ecosystem network to human well-being has been greatly underestimated (Costanza *et al.* 2014a; Costanza *et al.* 2014b). This phenomenon is particularly remarkable in the circle-type and regionalized “peri-urban areas” in the suburbs of megacities.

The peri-urban area is not only one of the most economically active areas (Zhang *et al.* 2008), but also the frontier areas where the urban built environment and the natural environment face each other. The composition of ecosystem service functions is more diverse and complex, and more Urban planning is urgently needed (Hudalah *et al.* 2007; Webster, 2011; Wu *et al.* 2008; Tian *et al.* 2013). Studies have shown that urban land use management affects changes in natural ecosystems directly or indirectly, and management policies and planning decisions also largely influence land management practices (Carpenter *et al.* 2009; Maring and Blauw, 2018; Bai *et al.* 2004). Therefore, spatial planning may effectively control the negative effects of semi-urbanized development (LeGates *et al.* 2014; Zhao, 2013; Huang *et al.* 2009). But the planning system itself also needs to make profound changes (Hudalah *et al.* 2007)

Judging from the service value assessment of ecosystems, the traditional performance research is mostly based on the economic value judgments measured in the form of currency, carbon sink or land change, and does not fully consider the real ecological needs of people. In this paper, an ecosystem service evaluation framework is proposed for the peri-urban areas, which based on township streets and human needs. This framework will help bridge the gap between the scientific assessment of the value of ecosystem services and the administrative management of urban ecological functions, and provide decision support for ecologically oriented planning interventions.

2 Particularity of ecosystems in peri-urban areas

2.1 Prominent contradictions between construction and ecological land

Peri-urban area refers to the progressive, fragmented and transitional regional type of rural areas that are gradually transforming into urban areas in the economic, social and spatial attributes out of the urban core built-up area (Webster, 2011). In the process of rapid urbanization, the peri-urban areas are in dynamic spatial reconstruction and social economic transformation. Industrialization and urbanization

erode the original ecological landscape, lifestyle and production mode. The coupling of various forces such as the disorderly spread of urban space, the urbanized standardization of landscapes, the deprivation of capital and power through space reconstruction, and the destruction of ecological base by industrialization lead to acute contradiction of land use in peri-urban areas, and the evolution is particularly complicated. It also makes the land in the peri-urban areas completely different from the cities and villages (Cheng *et al.* 2017).

Land use in peri-urban areas is characterized by a mix of industrial, commercial, residential and agricultural uses, of which a large amount of land is still used for agricultural purposes. Industrial land is scattered and spreads rapidly along major traffic routes, intertwined with rural settlements and agricultural land (Tian and Ge, 2011). From the perspective of eco-environmental effects, the expansion of construction land in peri-urban areas has had a strong impact on the land ecosystem, and economic growth is followed by a higher environmental cost.

From this point of view, the peri-urbanization process itself will have a greater impact on the human settlements. The land use in peri-urban areas changes drastically. It is the region where the contradiction between construction land and ecological land is the strongest, which has a great impact on the service of ecosystem. The problems such as human-land conflict, land shortage and environmental pollution are very prominent in the peri-urban areas, which become the focus of land remediation and transformation development. It is necessary to formulate corresponding land use and eco-environment policies for different ecological background characteristics of different regions, optimize land use patterns in peri-urban areas and ease the contradiction between construction land and ecological environment (Pan and Tian, 2018).

2.2 Diversified ecosystem services

The ecosystem services in peri-urban areas are highly diversified. In the central area of the city, the ecosystem is relatively simple, mainly as a leisure place for urban residents, so its cultural (touring) service is the most significant; in rural areas, the ecosystem is also relatively single, mainly responsible for supply, regulation and support services. When it comes to the peri-urban areas, based on the original ecological background, the ecosystem service is more complicated and diversified. It not only undertakes food supply, climate regulation and diversity maintenance, but also maintains certain spiritual culture and entertainment value.

The ecological service of peri-urban areas is closely related to the urbanization process. With the expansion of cities, the ecological land such as farmland and woodland in peri-urban areas will inevitably be transformed into urban construction land, which will be a threaten to the ecosystem and cause a series of social and environmental problems (Simon, 2008; Buxton *et al.* 2006; Liu *et al.* 2003).

Studies have shown that the value of ecosystem supply, regulation, and support services is closely related to the area of ecosystems that provide these services, but rarely have studied the value of ecosystem services from the perspective of “human needs”. In the process of urbanization, due to the expansion of urban built-up areas and reclamation from the sea, the area of cultivated land, offshore waters and tidal flats has been declining, resulting in the reduction and inhibitory effect on the supply, regulation and support services of the ecosystem. Therefore, with the continuous advancement of urbanization, the land use type has been rapidly transformed, and the urban construction land has increased significantly, which has led to a downward trend in ecosystem services on supply, support and regulation. At the same time, the continuously improvement of urban infrastructure and

development of tourism and cultural undertakings have promoted the cultural services of urban ecosystem (Huang *et al.* 2012).

3 Methods and Limitations of Traditional Ecosystem Service Assessment

3.1 Two traditional assessment methods for ecosystem services

The assessment of the value of ecosystem services has long been challenging (Wallace, 2007). There are mainly two types of methods for assessing: one is monetary methods based on cost-benefit analysis, value assessment or payment willingness, and another is based on supply-demand analysis of ecosystem services, carbon sinks, carbon footprints, and ecological integrity.

The first category is a monetary approach based on cost-benefit analysis, value assessment or payment willingness. Innovative approaches to monetary methods such as cost-benefit analysis, value assessment or payment willingness assessment (Costanza *et al.* 1997; Farber *et al.* 2002; Xie *et al.* 2008; Xiao *et al.* 2016), measured the value of ecosystem services quantitatively. The above methods can usually perform spatial simulation and feature calibration, so that ecosystem service assessment can be achieved through map drawing. Existing research is generally based on the estimation of the land classification, and the ecosystem service of the urban area is judged by obtaining a specific economic value. With the advancement of technology, ecosystem evaluation software, such as GIS, InVEST, FUTURES, CA-markov, CLUE-S, SPANs, etc., has been gradually developed, and it is inevitable to modify it into an operational and visual tool for natural resource management (Kienast *et al.* 2009; Burkhard *et al.* 2012; Stürck *et al.* 2014; Wolff *et al.* 2017; Nikodinoska *et al.* 2018; Chen *et al.* 2019; Dang *et al.* 2019). These methods are generally recognized theoretically (Ma, 2005), but due to the complexity and diversity of the ecosystem, the selection of research fields and calibration methods is often “completely integrated”, resulting problems in accuracy and consistency (Ludwig, 2000; Spangenberg and Settele, 2010).

The second category is the methods based on ecosystem service supply and demand analysis, carbon footprint, carbon sinks and ecological integrity assessment. Ecosystem service assessment based on ecosystem service supply and demand analysis has several core methods including carbon footprint, carbon sink and ecological integrity assessment (Wackernagel and Rees 1996; Costanza *et al.* 1997; Ma, 2005; Müller, 2005). For example, Paetzold *et al.* (2010) pointed out that the status of ecosystem services is not only affected by itself, but also by human needs and the needs of society. The relationship between supply and demand of social systems and ecosystem services is inseparable. Syrbe and Walz (2012) propose that there is a service connection area between the supply unit and the use unit area of ecosystem services, which is a common space for the supply and use of ecosystem services, where the transmission and conversion of services takes place. Kroll *et al.* (2012) used data on land use, climate, population, energy consumption, etc. to evaluate the supply and demand of ecosystem services in rural-urban areas of Germany, and to analyze the law of spatial change. Burkhard *et al.* (2012) proposed the concept of ecosystem service supply and demand quantification and related spatial visualization, and pointed out that as time and space change, human activity patterns are different, ecosystem service capabilities and land use will also change. Based on the application practice of land use management, Chen (2019) identified the thresholds of land use ratios required for different services in the ecosystem services to fill the deficit and balance supply and demand.

3.2 Limitations of existing ecosystem service assessment methods

A large number of ecosystem services researches aim to the well-being of human beings. Deriving the extent of human well-being only from the ecosystem service cannot fully consider the real ecological needs of people. Few studies focus on the value of ecological services from the perspective of human needs systematically.

The value of ecosystem services is usually measured by monetary value, carbon sinks, land changes, etc. (As seen in Figure 1). For example: (1) GDP accounting, usually select one element as the benchmark and the rest are derived through simple calculation. It is widely used in explaining the relevant large-scale ecological service mainly in agriculture and forestry. However, there are obvious scale differences in space and time of the ecosystem service in the city, which leads to the planning management department not being able to obtain the judgment information accurately; (2) the GEP accounting, usually calculates the ecological service of the factor as carbon and judges it through carbon storage. In current urban development, people's needs are developing rapidly and the carbon is rapidly consumed, which contradict with the nature of carbon sequestration, so it is difficult to advance decision-making. (3) LUCC land change accounting, usually plots the changes of various factors over the years and reflects the future development trend of the city by superimposing the change of land use. Based on the level of social and economic development, people are more sensitive to changes in the process of urban development, amplifying their own needs and neglecting the needs of others, just like the choice of neighboring facilities. Thus, it is also difficult to put forward decision-making.

Figure 1 Schematic diagram of the research process of ecosystem service value

Source: Author self-painting

These assessments have certain limitations in supporting urban ecological planning at the application level. Urban ecosystem services are considered as an important basis for decision-making support for decision makers (Bai, 2018), and the integration of demand-side into ecosystem services assessments, ecological processes that focus on time and space are also generally considered to be very important. However, as the spatial characteristics of ecosystem services change by time and usage, the research on ecosystem services is relatively lagging, which makes the correction methods for obtaining human well-being relatively simple, thus affecting the judgment of decision makers. With the aim of ecosystem protection, combined with the land use scenario dynamic-city (LUSD-city) model, looking for key ecosystem service areas and conducting graded protection, the natural resources can be effectively planned, developed and used, which also provide important decision-making basis for urban decision makers. (Knight *et al.* 2008, Lv *et al.* 2013, Lv *et al.* 2017, Orsi and Geneletti, 2010). Rapid and efficient clustering, integration of complex information such as time changes, spatial characteristics and distribution patterns of ecosystem services, and the formation of visual display tools will enable decision makers (such as land managers) to conduct sustainability assessments effectively (Swetnam *et al.* 2010).

4 Construction of ecosystem service assessment method for diversified human needs

4.1 Overall framework

At present, traditional ecological service assessments usually target abstract human well-being, but there are few ways to deal with the relationship between local needs and ecosystem services provided elsewhere (Seppelt *et al.* 2011). The author believes that the value of urban ecosystem services should be measured from the single natural resource supply to the diversified human demand. Relevant scholars believe that in the process of rapid urban development, we should still follow the guidelines of equality and guide the overall balanced development of cities through the changes in the supply and demand relationships of urban land-use unit ecosystem services. Finding acceptable and equitable levels of ecosystem services and properly balancing the supply and demand for local ecosystem services is an important step towards sustainability (Burkhard, 2012). Therefore, we need to follow the overall framework of ecosystem services assessment. According to the study of Costanza (1997), MA (2005), Müller (2007), Burkhard *et al.* (2009, 2012), Groot *et al.* (2010), based on the actual conditions in China, an overall assessment framework for cultural, supporting, regulating and provisioning services of the ecosystem is obtained, meeting the existing data conditions. (As seen in Table 1)

Further, certain human needs may generate a large number of negative ecological effects and should be included in the overall accounting. In the process of urbanization, the ecosystem aims to improve service functions, but the goal of this improvement is not always consistent with the needs of urban development. The diverse needs of human production and life often affect the ecological space directly and destroy the logic of ecological service value optimization, leading to the assessment of ecosystem service far from diversified human needs, which affects the judgment of decision makers.

Based on the content conversion of ecosystem service assessment, this paper considers that the function of ecosystem service in the evaluation unit is a comprehensive process, that is, supporting, provisioning, regulating and cultural services. Although some scholars have proved that the dominant order of human needs is regulation, provision, support and culture, the author believes that rather than the ecosystem of the unit be analyzed separately, it should be considered as a whole. One of the important consideration is that if it cannot be closely related to the needs of urban development, then the research on the value of ecological services can optimize the ecological environment, but it is difficult to meet the diversified

Table 1 Indicators of ecosystem service value assessment revised by author

classification	Ecosystem services	Function of ecosystem services
supporting services	Biodiversity	Whether there is a selected species, (functional) population, habitat composition or species composition
	Abiotic heterogeneity	Providing suitable habitats for different species, species functional groups and processes is critical to the functioning of ecosystems.
	Biological water flow	Balance of the operation of the inter-aquatic water system
	Metabolic efficiency	Refers to the energy required to maintain a specific biomass and is also used as a pressure indicator for the system
	Nutritional loss	Irreversible loss of elements in the ecosystem
regulating services	Storage	Store the system's nutrients, energy and water, etc. and release them when needed
	Climate monitoring	Land cover changes will locally affect temperature, wind, radiation and precipitation
	Global climate regulation	Ecosystems play an important role in the climate by isolating or emitting greenhouse gases
	Flood control	Suppress flooding
	Groundwater supply	Surface runoff, changes in system water storage potential, such as wetland conversion or replacement of forests. Farmland or farmland in urban areas
	Air quality regulation	The ability of ecosystems to remove harmful substances and other elements from the atmosphere
	Erosion regulation	Soil conservation, prevention and control of wind and sand, mountain protection
	Nutritional regulation	The ability of the ecosystem to perform (re)cycles, such as N, P or others.
	Clean water	Ability to purify water
provisioning services	Pollination	Pollination distribution, abundance and effectiveness
	Crop	Grain production
	Livestock	Feeding animal
	Vegetables	Amount of edible vegetables
	Fishery	Capture commercially interesting fish that fishermen can enter.
	Aquaculture	Animals are raised in terrestrial or marine aquaculture.
	Wood	A tree or plant used in wood.
	Wild food	Wild animals, plants
	Combustion consumption	Area used for combustion consumption
	Energy (biomass)	fossil fuel
	Biochemistry and medicine	Production of biochemicals, pharmaceuticals.
	freshwater	Fresh water volume
cultural services	Entertainment and aesthetic value	Landscape and visual quality. Capacity and number of arrivals
	Intrinsic value of biodiversity	Native species, endangered species

Source: According to the study of Costanza (1997); MA (2005).; Müller (2007); Burkhard et al. (2009, 2012); Groot et al. (2010), conforming to Chinese Computable Logic and meeting existing data conditions.

4.2 Indicator selection

This study quantifies the service value of ecosystems from the perspective of people's needs, explores the spatial mismatch between land use and the supply and demand of ecological service related to urbanization, and feeds them back to land management and urban development decisions. Therefore, we select assessment indicators as criteria that are quantifiable, can be quickly mapped and fed back into land management, and can be directly related to human needs. In this way, carbon storage, food production, PM2.5, and entertainment are four important indicators for urban areas, mainly because most urban areas face local pollution (such as polluted air), natural resource waste (such as carbon emissions exceeding the standard), mismatch between supply and demand of living conditions (such as food shortage) and the need for leisure space.

Specifically, 1) Supply: Select the grain crop yield as the core indicator and compare it with the per capita consumption. Food supply capacity can benefit urban residents; 2) Support: Select carbon storage capacity as the core indicator to compare adult per capita use with demand, which helps to improve residents' understanding of global carbon emissions and atmosphere changes; 3) Regulation: Selecting the PM2.5 concentration of climate monitoring as the core indicator, which is helpful to improve residents' awareness and maintain a clean and safe living environment by comparing with the damage of urban population; 4) Culture: Select entertainment as the core indicator to compare the real-time population activity with the land capacity. Cultural and recreational services can help residents maintain a good mental state and enjoy a high quality of life (Bai *et al.* 2018; Chen *et al.* 2019).

4.3 Clustering of ecological service value

This study believes that the township and streets can be used as a unit to cluster and analyze the four types of ecological service values: provision, regulation, support and culture. The functions of ecosystem service of peri-urban areas are classified according to the leading functions of each analysis unit ecosystem. The resulting ecosystem classification may be, but is not limited to, the results shown in the table below (As seen in Table 2) :

Suspended territories and windows of opportunity after the 2016 earthquake in Central Italy.

Marco Emanuel Francucci

Università degli Studi di Palermo, marcoemanuel.francucci@unipa.it

Abstract: While globalization is promoting strong economic concentrations in a few urban centres, peripheral regions are negatively affected by decreasing population and increasing impoverishment, due to the lack of policies and the failure to develop and maintain rural economies. Although natural disasters accelerate these trends, the shock created by unexpected events may generate a window of opportunity, linked both to risk-reduction processes and to transition paths towards more desirable futures. This review aims to discuss tendencies in post-disaster management in the central Apennines after the 2016 earthquake, since this shrinking rural region is slowly concluding the emergency phase and starting to plan reconstruction in the medium-long term. According to the UNISDR Sendai Framework for Disaster Risk Reduction, the reconstruction phase is a critical opportunity for Building Back Better. In order to achieve this primary objective, this paper suggests new scenarios based on a multi-scalar approach and on rural-urban interactions. This is a new opportunity for the rural areas in question to re-evaluate the role of the landscape and the environment and act accordingly. The creation of clusters of highly efficient multifunctional agricultural and infrastructure projects is seen here as an opportunity to create future ecosystems and new approaches to land and landscape management.

Keywords: Earthquake, Landscape, Valley Section, Urban Bioregion.

Introduction

We live in a world where it is becoming more and more difficult to distinguish between the urban and the non-urban; in the current age of Anthropocene, all the earth is urbanized and the environment is transformed by profound human interactions. A number of scholars have offered new conceptualizations to inform on the role of humans in shaping the environment; among them, Neil Brenner and Christian Schmid have attempted to describe the ubiquity of the “urban condition” and radically to rethink the epistemic enclosure of “the urban” as a category. They put the urban age under discussion and suggest innovative interpretations for “the creation of new scales of urbanization” (Brenner, 2013), proposing a shift from an urbanization made up of agglomerations and settlement types to the planetary urban fabric of operational landscapes. Operational landscapes support human agglomerations by transforming resources and energy and describing the planetary dimension of contemporary metabolic processes (Brenner *et al.*, 2014). This analytical construct helps us to understand the complex spatial relations of cities, political regionalism and the rescaling of state intervention to intermediate levels such as the city-region.

Figure 1. The Valley Section by Patrick Geddes.

Patrick Geddes was the first to stress the dependency of urban areas on the territorial configuration of society within its hinterland. In 1909 he drew The Valley Section (Figure 1), which depicts an ideal regional-urban condition. This is a topographic section, which begins in the mountains and then follows the course of a river down through a plain towards its estuary; where different forms of human occupation were related to specific geographic features.

“The valley section does not comprise a single valley, but a number of valleys. Seen from a bird’s-eye perspective, the diagram depicts a fan-shaped region of valleys focusing on the river’s estuary. Into this region, Geddes inscribed different meanings. Along the bottom of the diagram, he notes the so-called natural, i.e. best adapted, occupations represented by tools of different trades and crafts. [...] Higher up in the mountains one finds isolated huts and small villages, further down these settlements increase gradually in size until they culminate in a metropolis at the coast. This large metropolis is the one settlement which is not matched with one particular natural occupation. Ultimately, the large city was created by the united efforts of all the other natural occupations and smaller settlements. [...] Geddes does not refer to the obvious fact that a geographical hinterland might support a coastal metropolis. Instead, he expresses in The Valley Region that Enlightenment theory of social evolution that describes mankind’s development through the four stages of hunting, pastoral, and agriculture toward commercial societies. [...] It is important to note that the Valley Region was for Geddes not primarily a planning suggestion but first of all a depiction of an ideal type of city which could be found time and again throughout mankind’s evolution (Welter, 2001)”

These “occupations” and the use of natural resources through extensive agro-silvo-pastoral activities have been the driving force which has shaped landscape structures, and created functioning “cultural landscapes” (Antrop, 2005). Globalization has expanded the close sectional relationships described by Geddes “as it began to transcend the local (Masoud, 2013). Furthermore, the deep socio-economic changes that arise from industrialization, mechanization of agriculture and intensive farming have generated the abandonment of rural and mountain areas after centuries of human presence (Bracchetti *et al.*, 2012). These evolutions have dramatically transformed land use, as highlighted by the EEA report “Landscapes in transition: an account of 25 years of land cover change in Europe”; there are three emerging trends (EEA, 2017):

- expansion of urban areas (roads, rail, industrial parks, housing, commercial zones);
- decrease of agricultural land continues at an average rate of 1,000 km² per year;
- the area of European forests has increased since the 1960s.

Beside this, the Valley section remembers the morphology of Italian territory, where the Apennine Mountains divide the Adriatic coast from the Tyrrhenian: as in the Geddesian section, medium-large cities are mainly

located along coastal areas while networks of minor towns, villages and rural areas are located in hilly or mountainous zones. In recent decades, a combination of globalization, contemporary capitalism and technological change have accentuated the agglomeration and the density of many large metropolitan areas, leading to spatial and economic inequalities. Major urban systems host primary services and are a spatial concentration of innovative activities and knowledge, making them the major driving force of economic growth (Iammarino *et al.*, 2018). Major cities are becoming more important as concentration of economic activity, whereas marginal regions and centres of small and medium-sized manufacturing cities are affected by trends of demographic and economic decline. This current development path, characterized by unequal distribution of resources and opportunities, increases the vulnerability of peripheral regions, and produces differential risks (Collins, 2008). Furthermore diverse studies, in the field of *Disaster Research* and *Environmental Justice*, have observed how “hazard exposure, structural characteristics, and socioeconomic characteristics are significant predictors of structural damage” (Highfield *et al.*, 2014) and how pre-existing vulnerabilities influence the quality of the recovery process (Finch *et al.*, 2010).

This paper focuses specifically on the case of the 2016 earthquake in Central Italy to look at short- and long-term consequences on marginal territories affected by a natural disaster. The main question addressed here is the following: can catastrophes generate a window of opportunity to rethink the future of the territory? This contribution has been divided into three sections. The first offers a background of the pre-existing context; the second deals with the emergency management phases, with reconstruction after the impact of natural hazards and with tendencies in mid-term reconstruction; finally, in the last section a scenario is suggested on the regional scale.

Pre-existing context

Starting from 24 August 2016, several earthquakes struck the Central Appenine region, producing casualties and damage on structures and infrastructures. Those disasters involved a very large territory including several Regions (Abruzzo, Lazio, Marche and Umbria,) and 140 Municipalities; creating a new geography, the so called “Seismic Crater” (Figure 2). The crater area covers nearly 8,000 square kilometres (2.6% of the national territory), of which 2,000 square kilometres are located in protected areas or natural parks. Most of the municipalities in the earthquake area are located in the hilly and mountainous areas of the regions involved (more than 50% located at an altitude of over 900 meters asl). The Municipalities involved in the disaster are composed of small and very small settlements, 130 of which with fewer than 10,000 inhabitants and 56 with fewer than 1000; the total population amounts to almost 600 thousand. 25% of the inhabitants are seniors over 65, while 12% are children under 14, 2 percentage points below the national average. In 107 of the 140 Municipalities the population is decreasing, with rates of decrease up to 30%.

Figure 2. The Seismic Crater (Credits: Protezione Civile)

The economic sector is fragmented and diversified, the productive activities are almost exclusively limited to the sectors of agriculture, zootechnics and tourism, without, however, the presence of strong productive vocations and with a very low entrepreneurial density (the number of local units per sq km is equal to 5.9 against 15.6 at the average national level). There are about 25,000 farms for an average of 4 per 100 inhabitants, compared to a national density of 2.7 per 100 inhabitants. Almost all the farms are family-run (96.5%), often dedicated to small breeding and related activities such as the management of holiday farms, while the cooperatives are few and malfunctioning. Moreover, alongside the registered activities, there are many others that survive in the world of the informal economy, mostly managed by the elderly and voted to the exchange market or self-subsistence. Because of these, agricultural activity must therefore be considered an integral part of the culture and identity of the resident population, since it assumes not only economic but also social importance. While there are many shared aspects that can describe the crater as a whole, it is necessary to consider the areas affected by the earthquake as diversified from a socio-economic point of view. Indeed, it is possible to distinguish between the poorer inland areas most severely affected by depopulation dynamics and others, that before the disaster went through a phase of considerable recovery, placed at the centre of agro-food systems of excellence and dedicated to export (Olori *et al.*, 2017).

However, depopulation and cessation of traditional farming in the central Apennines is causing the disappearance of local cultural landscapes, which are the result of the millenarian integration between land use and natural processes.

Emergency management and reconstruction

The Presidency of the Council of Ministers, in reaction to the seismic events, provided a government structure in which the emergency and reconstruction activities were divided. On one hand, the emergency management phase was assigned to the Italian Civil Protection Department, through the establishment of the operational centre DICOMAC (Direzione di Comando e Controllo); on the other, the recovery and reconstruction management phase was delegated to an Extraordinary Government Commissioner. The Italian Civil Protection Department administrated the aspects connected with immediate support to the population and to the productive activities, in particular the recognition of damage to buildings and infrastructures, the management of

emergency housing solutions, support for zootechnics activities and collection and transport of rubble. A useful tool for supporting decision-making processes, rescue and aid delivery activities was provided by the European Space Agency, through the Copernicus Emergency Management Service activated for Earthquake in Central Italy. Real-time satellite images were used to make immediate broad assessments of damage, to calculate requirements for temporary accommodation, and, in general, to take stock of an evolving situation over large areas (Figure 3).

While the DICOMAC continued to manage the emergency phase, the Extraordinary Government Commissioner started the reconstruction phase. According to the Decree Law 189/2016 the Commissioner had the following tasks: to work in agreement with the Civil Protection, to coordinate the reconstruction and restoration of buildings and infrastructures, to support economic activities, and to monitor and supervise the funds, assisting the local authorities in planning the interventions. The Decree Law 189/2016 described a strongly centralized governance structure, in which the Extraordinary Commissioner acted as the pivot of the system and connected the Presidency of the Council of Ministers, the individual Ministries involved, and the Presidents of the four Regions who assumed the role of Vice Commissioners.

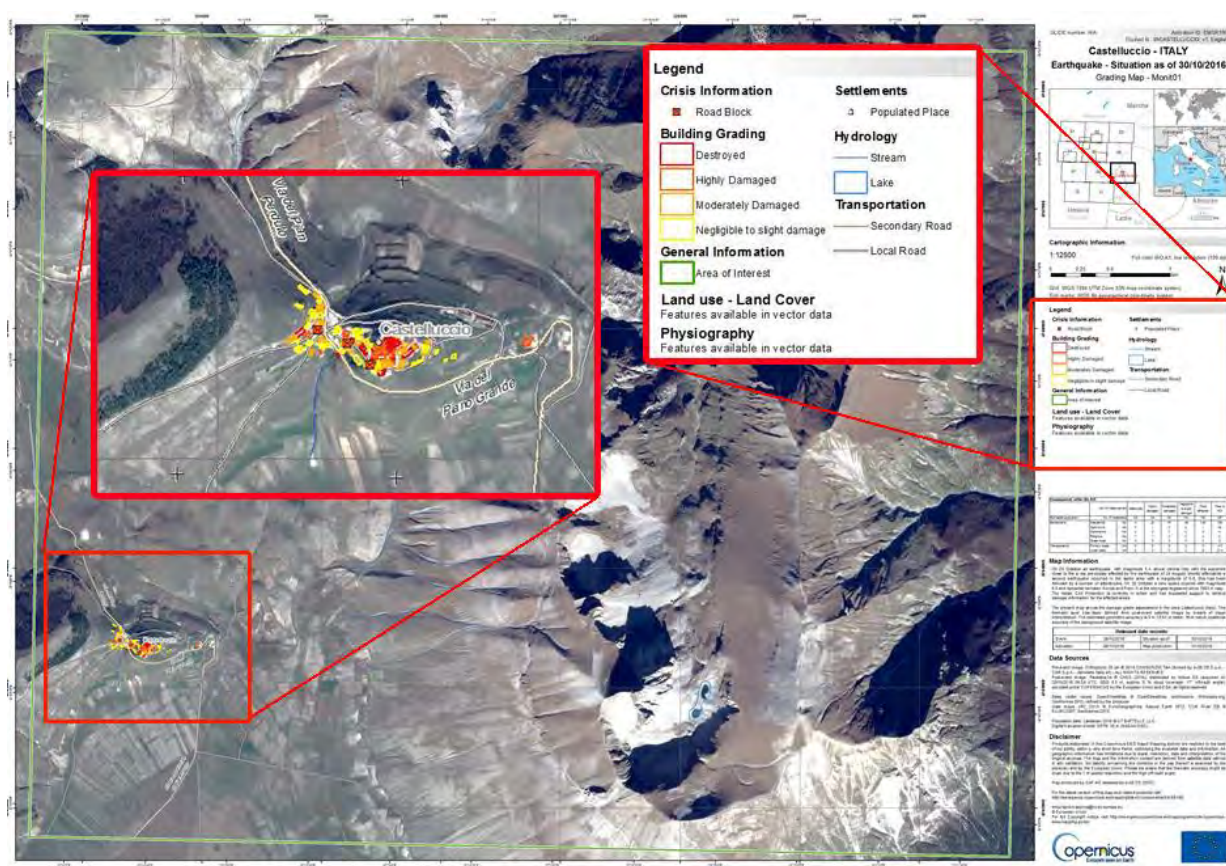

Figure 3. Copernicus EMS Grading Map of Castelluccio di Norcia, Italy (Credits: Copernicus Emergency Management Service).

This structure was organized on several institutional levels, where each institution was accountable for the matters of its competence, and, in some cases, even overlapping in order to define the strategic elements of the reconstruction. Furthermore, the reconstruction plan designed with the D.L. 189 was based on some fundamental elements, which established in particular:

- special reconstruction offices, set up by each Region together with the local administrations, with the task of managing the reconstruction;

- a reconstruction fund, established by the Ministry of the Economy and Finance, whose resources were allocated to the special accounting of the Extraordinary Commissioner;
 - a central commissioner structure to assist the activities of the special offices for reconstruction and to implement the decisions of the Extraordinary Commissioner.
- (Bertelli *et al.*, 2017).

Today, two and a half years after the first earthquake, three different Commissioners have followed one another in close succession and the general situation is incredibly precarious, while reconstruction and recovery proceed at a slow pace. There is still work to be done to clear away all the rubble: in November 2018 only 50% of the public debris produced by the earthquake's destruction had been removed. In March 2019 some prefabricated post-disaster transitional dwellings were still lacking. Another issue concerning these transitional settlements relates to the question of how long people must stay there: experience from past disasters has shown how this temporality will last for at least ten years. Such delays are the result of a whole host of factors: on the one hand the considerable scale of the disaster and the different earthquakes that have taken place over time; on the other significant problems with the Italian Government's strategy for managing the aftermath of the disaster. This is because of a fatalistic attitude to disasters and "a pervasive lack of planning and a corresponding inability to set strategic priorities for resilience" (Alexander, 2013).

Furthermore, as pointed out in the investigation led by the independent research collective Emidio di Treviri, special post-earthquake legislation is characterized by a lack of social participation, indeed the involvement of the earthquake affected populations in crucial choices for their territory is at present completely absent (Barra *et al.* 2017). Furthermore, the current political approach on the national, regional and local scales indicates that no proper longer-term strategy is being developed.

Future scenario

Although the disaster has accelerated pre-existing conditions of marginalisation, post-earthquake reconstruction and related funds offer uncommon resources that may generate a window of opportunity, linked both to risk-reduction processes and to the possibility "to intervene on the wider and longer-term socio-spatial trajectory of a certain territory" (Coppola, 2016). Natural disasters serve as focusing events that generate policy windows (Solecki *et al.*, 1994) "they dramatize interdependencies between different scales, spatialities and temporalities creating a sort of augmented territorial condition" (Coppola, 2016). Evidence from past disasters indicates that policy windows are transitory opportunities: they may close quickly and do not ensure the adoption of transition paths towards more desirable futures. Before this window closes, there is a strong need to design participative settings aimed at involving a variety of local actors to outline transformative patterns of development, cooperation and innovation, in the search for a transition from current states of socio-economic decline to states of affairs considered more socially desirable.

Looking at the seismic crater through the lens of regional approaches offers valuable potentials for imagining new spatial outcomes related to the concept of operational landscapes "for the creation of selective regional closures of the regional economy and productive structure in relation to the global system" (Fanfani, 2018). Moreover "integrated multiscale design and planning can address the consequences of development at the regional level while creating a context for designing on progressively smaller scales. [...] If regional design is the action that brings intelligence from the overall vision to the everyday detail, it also integrates disciplines such as economics, ecology and social policy as well as design and planning (Wall, 2008)." In this perspective, the re-appropriation of the Valley Section becomes relevant, as an exploration tool and as "a fundamental relational diagram between project and geography"; and also as a "design and planning tool, to recalibrate our understanding of regionalism and employ it as a substantial device in developing a contemporary attitude towards urbanism" (Masoud, 2013). The true potential of such investigation relates to the development of a contemporary conception of environmental and systemic thinking, which is leading to the design of alternative

relationships between places, communities and nature. Another important condition to develop new scenarios is the "new cooperation between urban and rural areas, conceived as basic tool of territorial innovation and local development" (Fanfani, 2018) linked with the dimension of the urban bioregion. This refers to geophysically and ecologically coherent area of territory (Atkinson, 1992) "defined by its natural physical characteristics, not by man-made political boundaries" (Tonn *et al.*, 2006) and characterized by a polycentric settlement model. An urban bioregional approach aims to achieve a balanced co-evolution between human settlements and the surrounding environment (Magnaghi, 2014), through the introduction of place-based development concepts "enabling especially local production/consumer clusters such as regional food-sheds or local food systems, local energy systems, districts of fair economics" (Fanfani, 2018). Moreover, the reconnection of urban and rural ecosystems, reinvented in an age of social innovation and networks, offers space for cooperation between alternative food networks, food businesses, education, research and policy-making. These may contribute to the "design of social infrastructures that enable the emergence of new enterprises, and the deployment of technology" (Thackara, 2019).

Indicators of the pre-earthquake statistics show that the agricultural system of the crater area, which now requires to be strengthened, has a development potential that is still largely unexpressed. These indications suggest a path of qualitative enhancement of local production, the reinforcement of the innovation processes of small companies also through the modernization of production structures and cooperation between producers in a supply chain logic (Arzeni *et al.*, 2017). To this end, it is necessary to invest in processes of institutional and social innovation to create alternative systems of food production, based on a framework of small-scale agro-ecological production, that are environmentally sustainable, economically viable, and socially fair. Furthermore, there is need for an urgent change in attitudes in the policy of recovery, in order to reverse the trends outlined herein. A more locally based, socially inclusive public governance is required, capable of dealing with multidisciplinary matters and delivering original and shared visions of development.

Abstract: For the past decades, Lithuania has been facing various challenges, including a massive emigration, shrinking towns and cities as well as a rapidly changing demographic, social and economic structure of the society. Inevitably, such dynamics produced a ‘spatial imprint’ in both, urban and rural areas. At the same time, different levels of governance attempt to catch up with such an accelerated development, lacking alignment, values and collectively agreed directions. Due to these pressing and complex challenges, a very recent process has been initiated by the Ministry of the Environment, aiming to move the existing national strategic planning approach to the next level and to develop an active, inclusive Comprehensive Spatial Plan of the Republic of Lithuania (CSPRL). The plan and the process behind it, are expected to set a new, transformative and innovative direction, addressing the future of the entire territory of the Lithuanian Republic and bringing all sectoral strategies into alignment. At the spotlight of the ongoing discussions are the definition of the nation-wide values, ambitions and vision, determining the future roles of existing urban centers and potentially redefining their relationship with suburban and rural ‘backlands’.

Keywords: transformation, value, vision, integrative development

Introduction

This contribution reflects upon the overall approach, process and methodology of the ongoing national Comprehensive Spatial Plan development in Lithuania. The transformational nature of the current events in the Lithuanian spatial planning scene shapes the core of the content and discussions in this article. The aspiration of the planning experts and political actors presently driving the development of the Comprehensive Spatial Plan of the Republic of Lithuania (thereafter - CSPRL) reaches beyond the established planning routines and aims to create a ‘living’ spatial planning framework capable to overarch and align all other national strategies and plans as an umbrella framework.

Following the collapse of Soviet Union, Lithuania went through remarkable shifts and in the ways, how national spatial organisation, policy making, stakeholder involvement and implementation have been approached: starting off with heavily centralized, top-down controlled spatial planning system on all levels and rapidly transitioning into market driven, neoliberal planning practice, based on the Anglo-Saxon planning traditions. This transformation has taken place in the relatively short time of nearly thirty years, facing challenges in the establishment of a mature and democratic planning culture.

The current spatial planning practice in Lithuania contains characteristics of two quite contradictory mindsets and approaches in addressing the spatial distribution and allocation of the economic, cultural, environmental and social interests and priorities and related negotiation between the public and private interests. The top-down, national planning and policy setting, still featuring remaining traces of the centralized planning inheritance of the past, collides with the neoliberal local spatial development dynamics, driven predominantly by the private and sectoral interests, controlled using zoning and land-use instruments. This situation generates a variety of conflicting interests and fragmented approaches, exposing an urgent need for the definition of collectively agreed values and priorities, joint vision, alignment, assessment, and cross-sectoral integration of development directions, followed by the consistent and effective implementation on the local level.

At the heart of the described issues are the numerous general misperceptions concerning the role that space takes up in the context of political and economic development priorities and debates. The understanding of space as a key asset, resource and catalyst for the cultural, environmental, economic and social transformation, shaping the identity of a country, has not yet been sufficiently anchored in the collective consciousness of the population, political actors and the key stakeholders which drive the process and direction of the national development.

For the most part, the focus of this paper lies on the elements of fundamental transformation, process and methodologies enveloping the spatial development dynamics in Lithuania. However, some specific contents (such as sustainability principles and two alternative development schemes) will be touched upon, to convey and illustrate significant moments and the nature of development dynamics and changes.

CSPRL development stages and structure

Following the national law and regulations of Lithuania, National Spatial Plans are developed for a period of at least twenty years (concept), while the related detailed local plans (solutions) are valid for ten years. Since the Restoration of Independence of the Republic of Lithuania, it is the second time that a National Spatial Plan is being prepared. The CSPRL - currently under development - is in the hands of the Ministry of the Environment of the Republic of Lithuania (thereafter – MoE) and is scheduled for official approval by the Seimas of the Republic of Lithuania in autumn 2019. Assuming a successful approval, it will be valid until 2050, the related detailed local plans (solutions)– until 2030.

The MoE initiated a four-stage tendering process targeting the development of a ‘New Generation’ CSPRL, which is expected to outline a clear vision and values as well as set the direction for the national development. The four tendering stages entail: 1) the assessment of the existing situation (completed in 2018); 2) conceptual development of the CSPRL (tendering completed, development ongoing); 3) Strategic Environmental Impact Assessment (tendering completed, development started) 4) development of detailed local concepts (solutions).

At present, the winning expert team is engaged in the second stage: conceptual development of the CSRLP, which is set for completion in autumn 2019. Two of the authors: Kristina Gaučė and Giedrė Ratkutė-Skačkauskienė are the leaders of the Lithuanian expert-team; the two remaining authors: Daiva Jakutyte-Walangitang and Nikolas Neubert served the Lithuanian team in the process as

external, international advisors. Thus, the collectively generated experience and knowledge, reflected in this contribution, compiles the outcomes derived from an almost a year long transdisciplinary collaboration.

Expectations towards the CSPRL development

According to numerous comparative analyses by different authors from a variety of EU countries (Reimer et al 2014), the nature of Lithuanian spatial planning system and practice (this also applies to the majority of post-Soviet countries and the UK (Cullingworth, Nadin 2001)) tends to be rather “land use planning” than “comprehensive planning” due to the lack of spatial, regional and economic planning traditions and integrated, multi-sectoral approach. Thus, turning to a comprehensive spatial planning approach that aims for the development of a clear, integrative and flexible spatial document, backed and owned by the key actors and stakeholders, communicated, discussed and agreed across different layers of governance is a new and promising direction that Lithuanian planning culture has taken up. However, such transformation naturally encounters challenges and conflicting interests on its way, especially bearing in mind its ambitious aims, pushing the existing sectoral as well as collaborative boundaries and expectations. The key objectives of the CSPRL contain, but are not limited to:

- Enabling a more effective implementation of all national sectoral long-term strategies and actions by exposing their spatial relevance and alignment, minimizing conflicting spatial functions and use.
- Aligning and guiding the national economic, environmental and social development by the means of budgetary distribution, based and in accordance with the guiding principles compiled in CSPRL.
- Finding an adequate and meaningful path and format for the establishment of sustainable spatial development principles, capable to accommodate, align and guide all sectoral national strategies in one direction while being sufficiently flexible and assimilative concerning future (long-term) trends, changes and adjustments.
- Establishing a robust foundation for an effective decision-making process, based on well informed anticipation, forecasting and appropriately planned actions, avoiding the ramifications of delayed and fragmented reactions to existing and arising challenges.
- Identifying the key principles and best-practice examples for an effective integration of European and international sustainability aims and goals (e.g. SDG's).
- Defining and applying most suitable methodologies enabling a coherent, consistent and integrated approach to the development of an agile Comprehensive Spatial Plan.
- Deriving the key principles from such European national spatial planning examples that have proven successful across numerous European cases. Discerning the main elements potentially relevant and useful in the context of Lithuanian national spatial planning from identified examples while taking in to account the diverse and locally specific processes behind national planning experiences, cultures and perspectives.

- Addressing the question, how the present planning process can enable, open up and encourage adequate forms and formats of the key local actor and stakeholder engagement as well as public participation (vs. information), turning the shaping of the future of Lithuania into an authentic and collective effort reflected in the equally collective ownership of the plan.

All the points outlined above aim to further, connect and maximise the integration of already existing processes, knowledge, data, and debates in the portfolio of the Government of the Republic of Lithuania.

The CSPRL development steps

To ensure an extensive consultation and adequate integration of experts, representatives of different political and governing bodies as well as to create a platform for discussion among the general public, the content of the CSPRL conception (second tender stage) has been gradually elaborated in four steps:

- First – setting up a consistent methodology and approach for the development of CSPRL;
- Second - identification of the key nation-wide values, ambitions and vision for an aligned and congruent development of Lithuania;
- Third– spatial assessment and allocation of the main attributes of the vision and related functional priorities. Elaborating two alternative spatial development paths;
- Fourth – definition of respective recommendations related to the upcoming development of detailed local concepts (solutions), national sectoral strategies and related legal acts.

The conception of the CSPRL in the format of specifically focused steps has enabled the core development team, comprised of 13 transdisciplinary expert groups, to engage in a broader discussion, including transdisciplinary perspectives in each of the development steps. Most particularly, the Public Forums, organized approximately every two months, enabled the carrying on of discussion, ‘anchoring’ the main topics and raising awareness beyond the involvement of experts.

Understanding development priorities – exploring national values, ambition and vision

This section briefly touches on the key CSPRL content related elements, principles and discussions. The core principles of CSPRL development are based on the universally recognised triple bottom line for sustainable development (Figure 1). The overall concept rests upon the interlinking of the triple bottom line and core values (specified and governed by the Constitution of the Republic of Lithuania), ambitions and vision for the next 30 years of national development.

Figure 1 Foundation, underlying sustainable development of the Republic of Lithuania

High level of complexity that understanding of sustainability entails, raises the question, how it can be broken down and made ‘actionable’? How will the application of sustainability principles affect different sectors and systems of Lithuania? What are the concrete implications that these development goals and aims will have on cities, regions, rural areas, etc.? What are the specific roles that different spatial agglomerations will play in the overall context? What are the best means for an effective distribution of national resources in alignment with different regionally specific development settings? In search for answers to these questions, three main dimensions have been elaborated and defined, aiming to create a matrix (Figure 2), which identifies more specific structure and steps for further development of CSPRL:

1. Definition of the main systems of national importance:

- Urban system
- Economic system
- Connectivity - infrastructure
- Engineering systems - infrastructure
- Ecosystem
- Ressources

2. The differentiation of national territorial typologies

- Urban centers and towns
- Rural and agricultural areas
- Sea and coastline
- Natural landscapes

3. Special priority themes:

- Strong identity
- Competitiveness
- Objects of national importance

The elements outlined above have been interlinked in the form of a matrix (Figure 2), which enabled the experts to assess different degrees of interdependency on a variety of layers and to link the outcomes with the two alternative development scenarios (Figures 4 and 5).

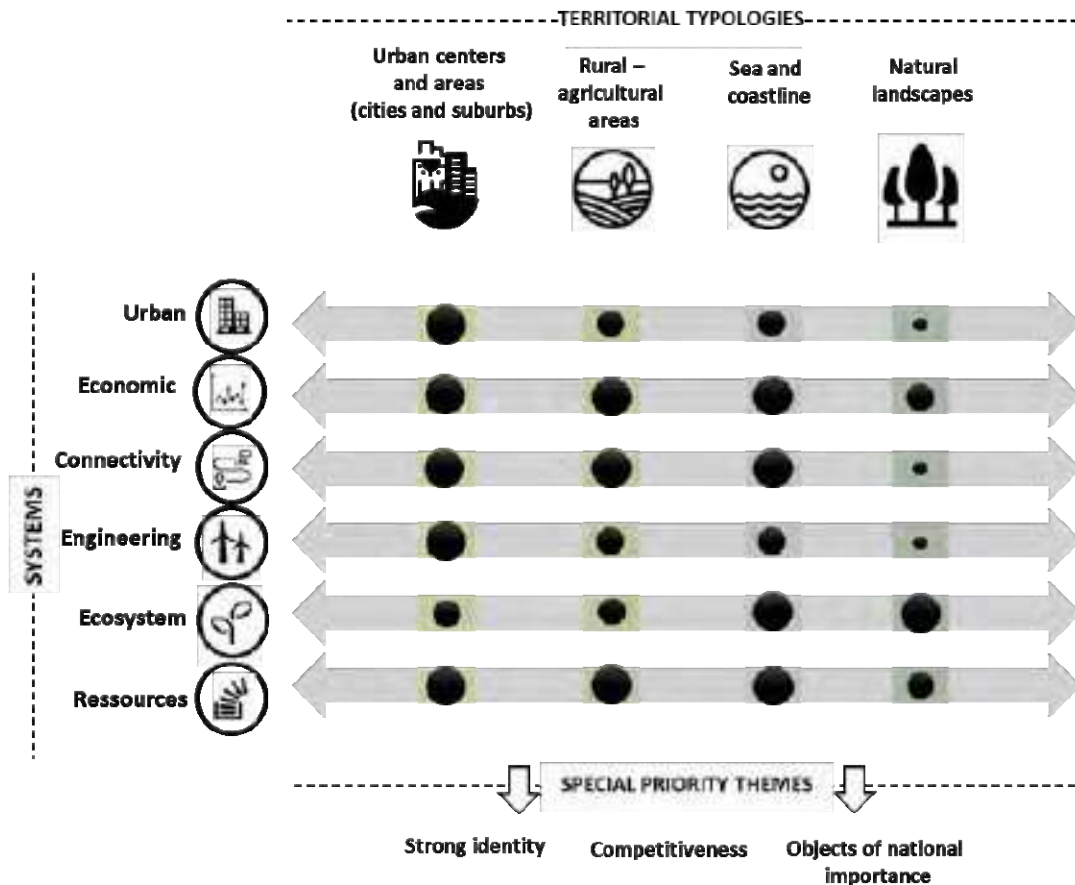

Figure 2 Systemic matrix: correlation between different domains and their spatial relevance

Two alternatives for the spatial development of Lithuania

In the past decades Lithuania has been facing a substantial decline in population mainly due to high and consistent emigration, causing many regions to rapidly shrink and loose population. Most European (Cities of Tomorrow, 2011) countries are familiar with this challenge, exposing rapidly changing development dynamics between growing and shrinking regions. The approaches in addressing this situation vary greatly from country to country, depending on the local planning culture and related legal framework conditions.

In the process of current CSPRL development, this topic lies at the bottom of ongoing most controversial debates concerning the roles of different regions, facing limitations in their capacity to sustain the local quality of life and supply of public services in the short, medium and long terms. To date, the discussion among the experts, politicians and population in Lithuania is concentrated on two main alternative approaches, which are at the core of the CSPRL development.

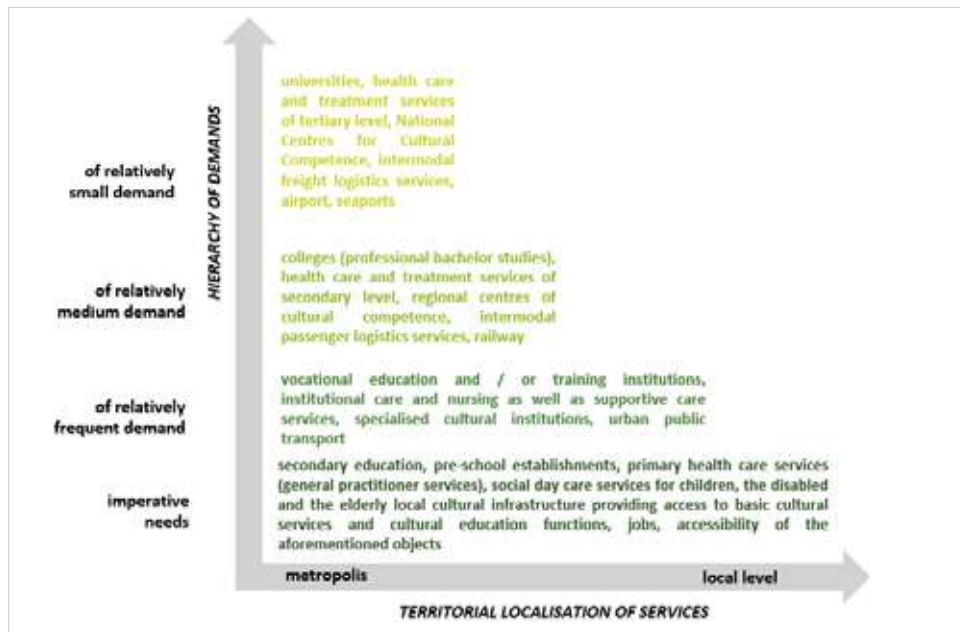

Figure 3 Distribution of needs and services by the level of urban centres

Most controversial points of discussion concerning the future development options are centered around the distribution of the national budget, resources and provision of the public services in correlation with the local spatial, social, cultural and economic development characteristics and features in specific regions and their urban centers. Multidisciplinary experts, politicians, key stakeholders, local administration and wider public are engaged in continuous debates and the decision for the final direction will likely be made by the end of this year. However, going into depths of this topic would overstretch the boundaries and the purpose of this paper, therefore the two alternatives being elaborated and discussed currently, are described in a brief comparison, conveying the essential points and differences only.

The **first alternative** (Figure 4) contains the proposition to sustain and further develop ten regions, driven by the respective urban centers, namely: Vilnius, Kaunas, Klaipėda, Šiauliai, Panevėžys, Alytus, Marijampolė, Utena, Telšiai and Tauragė. This alternative gives priority to the principle of autonomy of equitable regions, whereby public investment is distributed as evenly as possible and a wide range of basic services is equally concentrated in each region. It distinguishes the following categories of urban centers (Figure 3):

- **Metropolitan** – internationally active system of urban centers, containing a range of services and operating as national economic engines: Vilnius- national Capital, Kaunas - cross border center and Klaipėda – port city.
- **Regional centers** – concentrating a wide range of regional services and amenities, intense level of regional economic activities and playing a key regional role in maintaining and improving quality of life in the given region. The cities in this category are further subdivided in the regional development driving centers: Šiauliai and Panevėžys and regional development supplementing centers, such as Alytus, Marijampolė, Utena, Telšiai, Tauragė.
- **Local centers** – towns with the primary objective of maintaining the viability of the regions by working with regional centres and providing some services.

Figure 4 Development Alternative I - Regions, urban centers and connectivity network

The main East-West and North-South transportation corridors connect and further strengthen the network of named urban centers. The first alternative maintains the existing administrative structure and distribution of agricultural land-use, natural landscapes and resources as well as protected structures and objects of national importance.

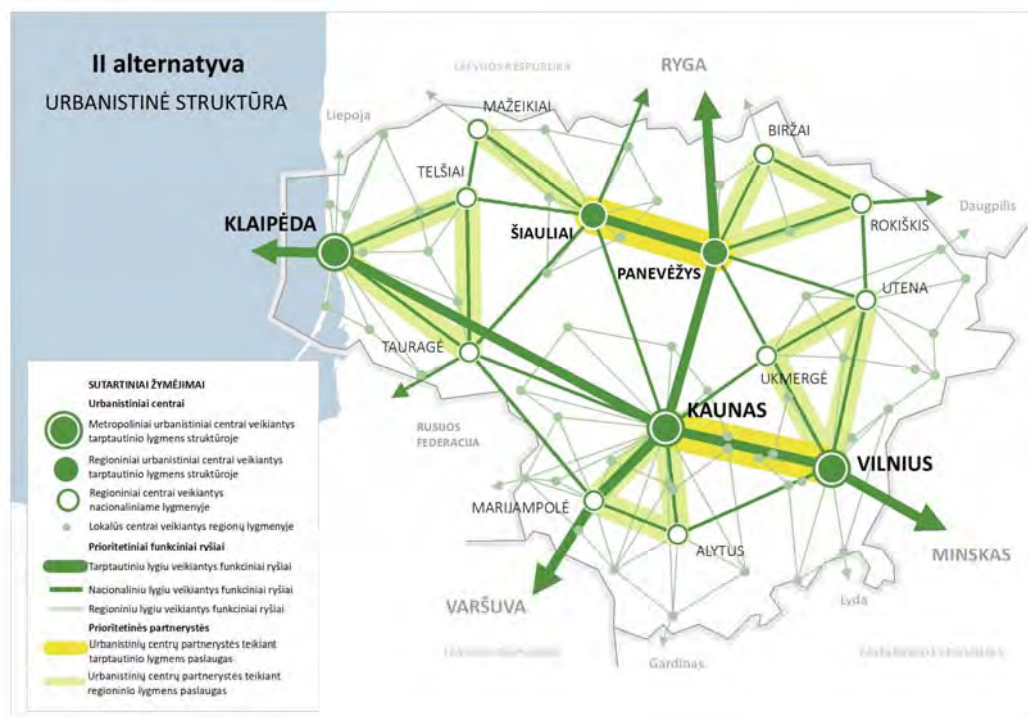

Figure 5 Development Alternative II – Regions, urban centers and connectivity network

The **second alternative** (Figure 5) proposes a greater degree of differentiation between the regions and their urban centers, consequentially followed by an adequate allocation of national budget, resources and public services, depending on the more specific local characteristics and development typologies. This alternative expands the understanding of the future development potentials beyond the existing administrative and institutional boundaries, aiming for a greater integration between functional, natural (environmental) and economical features that specific areas contain. This approach aims to identify synergies and common potentials that different territorial units expose, including the integration of geographical-morphological characteristics (planes, hills, water bodies, etc.); potentials for specific functional use (e.g. agricultural, recreational, tourism, etc.); economic features (based on 'Invest Lithuania' data); connectivity (including different types of connectivity); proximity between different urban centers, towns and rural settlements (Figure 6).

The hierarchical distribution of the internationally and nationally important urban centers of Lithuania, as well as their regional and local roles differ slightly from the first alternative. The core difference lies in the focus on different city- region relations and the long-term intention to stabilize shrinking regions (mostly in the Northern and North-Eastern areas of Lithuania, adjacent to the Latvian boarder) by strengthening their collaboration with the strongest adjacent regional center. Main regional centers in this alternative are grouped along three tiers: 1) Šiauliai and Panevėžys, 2) Alytus and Utena and 3) Marijampolė, Telšiai, Tauragė, Mažeikiai, Ukmergė, Rokiškis, Biržai. Vilnius, Kaunas and Klaipėda contain the same categorization and importance as in the first alternative.

Figure 6 A scheme for the identification of common territorial potentials and synergies

Both alternatives outline the same development direction concerning the sustainable development of agricultural land-use, protection of natural resources, large scale open spaces, objects of national importance, sustainable treatment and development of the coastal areas and the strengthening of

transportation infrastructure and key corridors ensuring the sustaining and improvement of connectivity between urban centers.

The process of the CSPRL conceptual development and stakeholder involvement

The CSPRL development is an ambitious undertaking and a widely discussed document. The overall aim is to engage a broad audience into the planning process, starting with political representatives and going all the way to students who are very likely to be involved in the actual implementation and further adjustment of this document in the future. There are several dozens of actors in the project, who are driving the entire process and are involved in different formats and roles:

1. Direct participants, containing clear responsibilities throughout the project, working on the project and informing other participants about certain results:
 - decision-makers (e.g. coordination of the working group);
 - experts (e.g. core development team).
2. Indirect participants providing feedback on the interim results:
 - containing the right to veto decisions (e.g. politicians);
 - involved directly in the consecutive implementation of the CSPRL (e. g. the Ministry of Environment of the Republic of Lithuania);
 - likely to be involved in the development of certain parts of the project in the future (e.g. academic community);
 - regional and local administration, which will be implementing and integrating the plan on the regional and local level (e.g. regional representatives).

The main structure and connections between the key parties involved in the development of the CSPRL are depicted in the Figure 7. The scheme illustrates the process of interaction between the participants. Two main roles: 1) the owner and initiator of the plan development process – the Ministry of the Environment of the Republic of Lithuania and 2) and the expert-development team, implementing the actual development of the plan. The strategic and methodical core of the project (in the oval section of the scheme) consists of the project owner/organiser and related consultants, the coordinator of the project preparation, the methodical project preparation manager, and a range of topic managers. The project structure shows that the generated outcomes are controlled and dependent on the expectations and competence of the project owner, government working group and official project consultants.

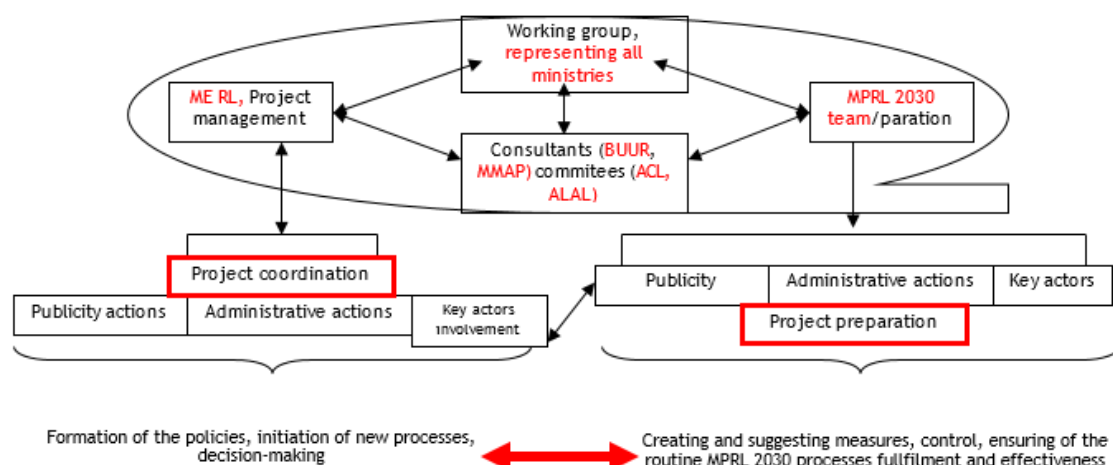

Figure 7 Organisational structure and overall management of the CSPRL development process

The team of local experts consists of over 20 professionals: urbanists, architects, engineers, geographers, environmentalists, sociologists, anthropologists, economists, geologists, heritage and cultural specialists. The project marketing team contains geographic - information systems professionals and communication experts and graphic designers.

Key elements of the multi-level stakeholders involved in the planning process:

1. Political level. The concept of the plan (MPLR 2050) will be approved by the Seimas of the Republic of Lithuania, the detailed solutions (MPLR 2030) – by the Government, therefore, from the very beginning of project initiation, political institutions are actively informed and included in the discussion, MoE RL periodically reports on project's progress and content updates.
2. Governing bodies:
 - Central government. All 14 Ministries of the Republic of Lithuania are part of the CPRL 2030 coordination working group. Responsible deputy ministers, their advisers and business professionals of the ministry participate in the activities of the Group. The activities of the group are coordinated by representatives of the organiser of the plan (deputy minister of MP LR with a team of advisers). The authors of the plan also organise meetings, discussions and workshops to discuss ministerial / business issues.
 - Regional Development Councils. Lithuania is administratively divided into 10 regions that unite 4–8 municipalities each. By way of rotation, the organiser of the plan participates in the Regional Development Councils meetings providing the latest CPRL material presentations, responds to issues relevant to politicians / municipal leaders, documents and expresses their expectations to the organisers.
 - Municipalities. 60 Lithuanian municipalities are represented by the Association of Local Authorities in Lithuania, however most productive work with representatives of municipalities takes place through the Architectural Chamber of Lithuania (ACL). Representatives of both, the plan organiser and the developer, through their reports and intermediary material, involve the Community of Lithuanian Architects (almost 1500 professionals in the field, including municipal architects) in the preparation of the CPRL 2030.
 - Associations: a variety of associated structures is involved in the CSPRL development process (e.g. academic community, business association), non-governmental organisations (e.g. cyclists' community, geographers' union), as well as companies operating under the Ministry: Lithuanian Railways, Lithuanian NGDO Platform, etc.

Content development and management process

The project process map (Figure 8) is subject to regular updates throughout the duration of the entire project. Its complexity and patterns are easier to explain through the scheme of achieving any intermediate result (Figure 9).

Figure 8 CPRL 2030 Process Map

The ongoing work on the conceptual development of the CSPRL (any segment of it) is organised in stages that contain the following pattern:

- Methodological tasks (a) are formulated, their scope and expected results are checked by the organiser of the plan (b);
- The team of experts is informed on individual or team-specific business and related tasks. Based on a schedule of activities, the work is performed by and *in cloud-based* principle using a variety of technological solutions remotely and/or in the format of thematic creative workshops among the experts (c). Thus, the ongoing discussion between the organisers, the compatibility between the specific elements of the project and a sense of authorship and community is ensured.
- The intermediate progress and outcomes are communicated to the organiser of the plan (d).
- The organiser of the plan, together with the expert team, ensures that the results (e) are presented to the government representatives (deputy ministers, interinstitutional meetings), cross-sectoral discussions (creative workshops with experts from different fields are organised to discuss interim results) (f), expert society and the public (open forums / conferences, 9 forums during preparation period (g) are planned).
- The obtained outcomes are carefully documented, ensuring that the result of all discussions as well as new insights are integrated accordingly into the final interim report(h).
- The process diagram depicting the generation of an intermediate outcome is depicted in the Figure 9.

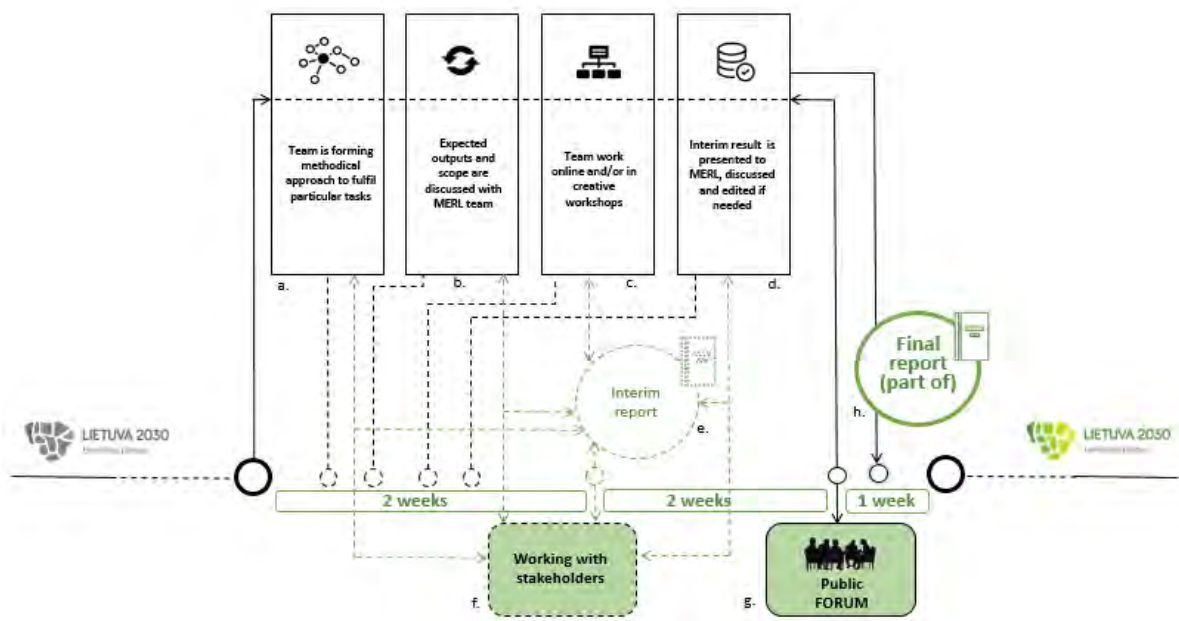

Figure 9 Intermediate outcome - process diagram

Encountering the benefits as well as challenges in the process of CSPRL development

Along with the new approach towards the spatial development and importance of the CSPRL in the overall agenda of Lithuania's strategic goals and decision-making processes, a number of common and specific challenges as well as benefits were encountered by the expert team, in charge of the plan development:

- Organisation of the CSPRL development – new groups of experts are involved in each stage of the CSPRL development, making it challenging to ensure continuity and consistency of the overall development format.
- The development process requires adequate allocation of time linked to specific tasks. The development intensity and the overall frequency of the events in the relatively short total development period creates a conflict between different priorities at the peak times, in which case the quality of the focus on the contents often suffers.
- Integration of the new development methodologies – great focus is being placed on the clarification of the planning methodologies, in some cases placing the experience and competence of the local expert team in a disadvantaged position.
- Application of the new stakeholder and public engagement methods – great focus is placed on the process, publicity and the integration of public opinion.
- Application of new tools and formats, including indicators, interactive platform and Public Forums are beneficiary and enriching to the overall process and outcomes.

Summary and Conclusions

Shaping the national spatial development direction is a demanding and challenging task. The conceptual development phase of the CSPRL is nearing the finish line and the present transdisciplinary expert team has entered the end-phase of the task completion and the finalisation of the outcomes accomplished to date. However, the next stages of the CSPRL development will continue until the year 2020. The new CSPRL will unfold its impact and effectiveness in the years 2020-2050 guiding the overall spatial development dynamics of Lithuania and serving local municipalities and authorities as well as sectoral strategies by outlining and allocating clear principles and development objectives.

The process of the past two years, since the onset of the CSPRL development has been a transformative experience on multiple levels:

- The degree of vertical (between different levels of governing bodies and administration) and horizontal (among experts from different disciplines, academic community and the wider public) integration, understanding and communication has grown consistently throughout the process, allowing the quality and the effectiveness of the debates to mature and progress; This is an important achievement, considering that the democratic planning culture in Lithuania is relatively young.
- The extent to which the general awareness and acceptance of the need for spatial planning is increasing, exposing a generally growing interest in this topic.
- The capacity to work in an integrative, open and discursive environment is developing and increasing continuously, shifting from the sectoral-silo mentality and exposing more and more interest and willingness for a synergetic, discursive and interconnected generation of outcomes.
- Different levels of national governance and local administration continue to narrow down the existing gap between the national strategic planning and local capacity to implement comprehensively managed local plans through the increasing levels of transparent, inclusive and productive communication and consultation.

This reflection upon the experience gathered in the process and context of CSPRL development to date captures a fragment of time, that encapsulates only a relatively short phase of the overall expected 'lifespan' of this significant undertaking and document. The promising implications and effects will expose and prove their transformational potential in the years to come. The outlook however, is encouraging!

Acknowledgements

The authors of the paper wish to acknowledge the team of the Ministry of the Environment of the Republic of Lithuania as well as the Urban Planning office BUUR for the discussions and knowledge exchange throughout the process of CSPRL development.

Brex City: Current and Future Urbanities of the United Kingdom/Republic of Ireland Border

Tom Jefferies¹

¹*Manchester School of Architecture, Manchester Metropolitan University, t.jefferies@mmu.ac.uk*

Abstract: The political crisis produced by the UK's June 2016 referendum decision to leave the European Union, 'Brexit', has brought focus on the UK/Republic of Ireland (RoI) border as a microcosm of the renegotiation of the territorial relationship between the EU and UK. The location of the UK/RoI border results from the internationalisation of former county boundaries. Its status reflects shifts in connectivity across a border created from within what was historically a single territory. Settlement around this border reveals spatial utilisation, type, and patterns that are particular to this place. A dispersed urbanism has emerged, actively embodying difference; between legal structures, tax regulations, building and urban codes, currency fluctuations and cultural values, united by freedom of movement. Building types, settlements and localities where access and egress is only possible by passing through another state reflect a relationship with the border that objectively embodies the lived reality of territorial difference. Through a process of critically reviewing the current border condition, identifying latencies and potentialities through enquiry by design, this paper proposes possible futures for this place. Brex City is a unique urbanism embodying a range of possible futures, mirroring the challenges, absolutes, ambiguities, paradoxes and tensions established by Brexit.

Keywords: Brexit; Borders; Frictionless/Seamless; Urbanism

Introduction: Data Mapping the UK/RoI border

One unintended outcome of the 23 June 2016 EU Referendum vote was to place the status of the UK-Republic of Ireland (RoI) border into sharp focus. In the situation of the UK leaving the EU, this border, historically existing as a set of county boundaries before its formalisation with the creation of the Republic of Ireland and the UK province of Northern Ireland, will become the only international land border between the UK, now a third state, and the EU, massively increasing its international importance and status.

The complexity and interconnectedness across this border reflect its historical origins and the reality of the border region acting as an interconnected whole. The historic interdependencies across the border line have been interrupted by periods of military hardening as seen during the establishment of the Irish Republic and the Troubles 1968-98. Since the 1998 Good Friday Agreement the border has reverted to an entirely porous boundary, barely noticeable when it is crossed.

The complexity of the border is often discussed in abstract through news reportage and the border has been mentioned by the UK media on an almost daily basis since the referendum result, but detailed understanding of its spatiality and use is elusive, partly the result of this single place being split between two states. This raises questions around how the border actually operated, how it has informed

communities on either side of it and what is the operational and societal spatiality of the border as seen in Figures 1 and 2.

Figure 1: The Gates of the United Kingdom, near Crossmaglen, looking into the UK from the Republic of Ireland 2018 (photo author's own)

Figure 2: Gateway to the European Union, Killea, looking from the UK into the Republic of Ireland 2018 (photo author's own)

The Data Mapping Method and Research Through Design

This research has two primary goals:

1. To use data mapping as a methodological approach to explore, identify and reveal crosscutting insights into the operation and performance of space and place in the UK-RoI border and its wider regions.

2. To use the findings of these spatial explorations to explore novel approaches to design which tackle multi-dimensional problems in relation to services, physical and invisible infrastructure, and the role of built form.

This work originates from a starting point that considers the UK-RoI border as a form of dispersed urban space, developing an exploration of new and emergent forms of contemporary urbanism undertaken by the Infrastructure Space Research Group at the Manchester School of Architecture since 2015.

Initial desk-based analysis was followed up by immersive fieldwork. This analysis produced exploratory mappings that compare and give spatial context to publicly available, existing data sets to identify contemporary and historical patterns of occupation across the border region, and from this frame opportunities and challenges for the region. The analysis explored thematic approaches to physical and invisible networks and patterns of use and occupation.

With an overarching goal to understand the context and infrastructure that supports activity around and across the border, the study investigated four key themes within the context of the border:

- Health and Lifestyle
- Energy and Power
- Demographics and Economy
- Networks and Connectivity

This enabled patterns of use to be clearly represented, and through this process of representation to establish questions and gaps in knowledge within which further actions can be located.

Mapping Border Settlement

Preliminary data mapping and spatial analysis undertaken between September 2018-January 2019 mapped extant data from publicly available sources, including census and local authority data, against the UK/RoI border and its wider geography. This involved academic staff and postgraduate architecture students from Manchester School of Architecture working with a range of stakeholders and sources. The approach allows the cross-thematic referencing of data sets to give an overview of the border condition which provides initial insights into the way in which spaces along the border are populated, inhabited and occupied on a day-to-day basis. Desk work was tested and developed through extensive fieldwork undertaken October-November 2018 that followed the full length of the 499 km border from Muff in the Northwest to Warren Point in the Southeast and also included a number of N-S and E-W transects through key areas of the border to understand them in more detail, including Derry/Londonderry-Muff, Lifford-Strabane, Armagh-Monaghan and the A1-N1 corridor between Newry-Dundalk. This work has provided a basis for the development of spatial (architectural and urban) proposals which serve as exploratory tools to evaluate the socio-spatial effectiveness of technological and policy mechanisms that have so far arisen from the Brexit negotiations. The process of spatialisation

and visualisation is key to accessible and meaningful communication to a wide range of audiences, to support a better understanding of ‘place’. This work builds on previous data mapping studies undertaken in the Highlands of Scotland and Cornwall in Southwest England between 2015-2018 (Jefferies, Coucill et al 2017). The Data Mapping method affords:

- the engagement of diverse audiences in place-specific data;
- the representation of place-specific, multi-level and cross-cutting spatial and socio-economic relationships;
- the recognition of new and emerging spatial conditions and characteristics.

The preliminary research project exposed many questions about the effect of the border, the spatial integration of technologies and their social and community implications, raising further questions in terms of understanding the effects of potential changes in border demarcation and operations. Evaluation of this data through architectural design methodology based cross-disciplinarily engaged workshops involving stakeholders and academics allowed the understanding of this place to be substantially advanced through the form of the critical design project.

Turning Latency into Opportunity: Research Through Design

A complex understanding of a place through data mapping enables the identification of latency within a situation. This may be the result of types of either realised or potential surplus or the result of two or more factors creating synergies. The examples of proposals discussed below demonstrate that through a focus on maximising the potential of place physical and systemic infrastructural solutions can act as drivers for creating inhabitable and beneficial places that are measurably good. We recognise that technological obsolescence is faster than cultural change, and that society’s view of what is good or bad built form also shifts over time. Consequently, new infrastructures that support the development of culture must be able to both accept redundancy as an inevitable part of their lifecycle, and embody the potential to support culture as future heritage components and spaces in often radically redefined contexts.

The purpose of research through design is to critically test and extend ideas and situations that are identified through the initial Data Mapping phase of the work. The outcome of this are proposals that can be used as mechanisms to explore potential futures of the region and ask questions of current decisions, processes and spatial operational models.

A number of key themes emerged from the data mapping phase, ranging in scope from tightly defined built or policy based proposals, through to significant and potentially radical co-created geopolitical changes, all framed by the reality of Brexit.

- Built infrastructure interventions
- Harmonised cross-border activities
- New spatial, territorial and temporal entities

Built Infrastructure Interventions: Designing the Frictionless Border

Upon completion of the Data Mapping phase of the work, between December 2018-June 2019 design proposals that developed infrastructural approaches to the Border were developed. These were partially triggered from the findings that certain key infrastructures were missing, raising questions about what should be in place. These included a limited rail network, incomplete motorway network, no domestic gas supply network, patchy digital communication coverage and service delivery models that engaged with cross border cooperation on a sector by sector basis. It became apparent that an approach to infrastructure that both acknowledged the border and sought technological advantage would potentially be productive. It was also clear that the costs of developing coherent infrastructural approaches to the Island of Ireland either required significant politically driven prioritisation or a longer-term perspective to justify the cost of implementation.

The Consolidated Solution and Customs Fulfilment Centre. The discussions around the ‘Irish Backstop’ have hinged on the possibility of developing a technological solution to frictionless cross border condition. The spatiality of what such a condition might entail has been left open but is currently seen as a technologically led solution. This is a flawed approach and ignores the necessary interplay between spatial scales and technological provision that could provide the basis for a frictionless border.

This proposal shown in Figure 3 envisages seamless and efficient cross-border logistics through a systematic arrangement of policies, procedures, workflow and technology, coupling architectural typology and scanning technology at both macro and micro scales through designed spatial and technological infrastructure. This design proposes a feasible and proveable alternative to the Irish Backstop proposal by the UK government, thus providing a potential spatio-technical solution to the Brexit conundrum.

Figure 3: Designing the Frictionless Border: The Consolidated Solution Customs Fulfilment Centre (Tan, J supervised by Jefferies, T and Morton, R)

The work was underpinned by an investigation of the present value, nature, demographics, volume and condition of cross-border trade and logistics. Existing customs policy, regulations, border procedures, import and export arrangements, infrastructure and technology adopted by the Republic of Ireland and the UK were analysed, with particular focus on third country trade conditions in preparation for post-Brexit scenario. Scenario-testing reviewed the Kent Resilience Forum Contingency Plan for Dover

Straits Ports as a precedent to anticipate potential disruption at the UK/RoI border. The in-depth understanding and findings informed the proposal of the All-Island Customs & Logistics Network, a series of key macro networks and strategically placed consolidation/distribution nodes that facilitate the possibility of a frictionless border condition for cross-border goods logistics. The macro spatial framework is developed around logistics demand, type and capacity, supported at micro level by buildings and facilities that are crucial to frictionless border operation through the typology of the Customs Fulfilment Centre (CFC).

This is the architectural component enabling the transition from macro to micro scales of the Consolidated Solution. CFCs provide a network of goods consolidation facilities central to future cross-border logistics on the Island of Ireland. The potential handling capacity of these CFCs are established by analysis of cross-border goods trade figures, thereby determining the infrastructural capacity and spatial requirements. This defines a typology that can be applied across the network of CFCs designed to embody scalability to different capacity (i.e. volume and type of goods and freight traffic).

Learning from the innovative retail distribution model of Amazon, the proposed establishment of a network of CFCs throughout the island streamlines customs logistic traffic through designated border crossings as well as distributing customs processes throughout the island. Legislative control of the border is expanded to these CFCs, which receive, check and inspect goods from regional traders. Goods are then consolidated and dispatched across the border via the designated crossings to fulfilment centres on the other side of the border, before being received by private traders to be distributed to the final destination. These CFCs are equivalent to a port for ground logistics and can be nationally or privately owned as representative of the relevant customs authorities just as all sea ports in UK are currently privately owned and operated.

Harmonised Cross-border Activities

The Border Farm. Agricultural production is a key activity of the Border Region. Figure 4 shows this design proposal that envisages a series of spatial interventions along the entire length of the UK-RoI border to form a 499 km long continuous farming region that can prosper irrespective of the hard or soft status of the border. This has material, historical and societal implications in how this situation is addressed at a settlement and architectural scale.

Figure 4: The Border Farm (Moloney, J supervised by Jefferies, T, Morton , R and Brook, B)

The Border Farm design is based on research conducted into identity and the value of agriculture in Northern Ireland and the Republic of Ireland. In a post-Brexit world where there would likely be calls for a form of physical border that is monitored, the new border interventions form a secure barrier, designed to contribute to the physical, social and cultural landscape. The formation of a Border Farm appeals to the common agricultural heritage between the nations either side of the border and the mutually shared identity of caring for the land. The proposal also forms an economic model for continued seamless trade in a post-Brexit landscape, reinforcing the agricultural jobs market and enhancement of the border regions social infrastructure and connecting to the wider landscape through the mechanism of the marketplace and distribution hub.

Tax Free Living. In the context of the U.K/Irish Border Condition and, by Extension, Brexit, What Does a Tax-Free Lifestyle Look like? Fieldwork identified dwellings that can only be accessed by crossing an international border, raising questions of the *raison d'être* for such buildings. What draws houses to be built directly onto the border and what are the benefits that could be developed from this particular situation?

The Tax-Free Living project strategically attempts to identify loopholes and exploit the two jurisdictional tax systems of the RoI and the UK across their border.

Figure 5: Built Strategies for Tax-Free Living, (Hykin, M supervised by Jefferies, T and Morton, R)

It asks the question, is it possible to construct the physical environment for a tax-free lifestyle as explored in Figure 5? Through the inspection of the spatiality of UK and Irish Tax laws, legislative definitions became design parameters. These designs offer architectural and urban typologies that side-steps tax liability definitions from each jurisdiction through exploiting the immediate border condition. The proposal builds on research of the secretive world of tax avoidance and proposes a strategy and theoretical framework to avoid tax liability.

The research identified definitions in tax legislation of both the U.K and Ireland to provide parameters for spatial design of these laws. This identifies loopholes and contextualises the development of new architectural typologies that build out tax avoidance in their realisation. This strategy exploits the two tax jurisdictions of the U.K and Ireland across an immediate border that sits between the two to test and explore the typologies that allow a tax-free lifestyle. An architectural taxonomy of tax avoidance emerges, one that defies the defining laws on tax, and enables lifestyles directly engaged with the border condition.

New Spatial, Territorial and Temporal Entities

Tibos: The Irish Border State. The departure of the UK from the EU, Brexit, has been recently postponed to October 2019. The issue of the UK-RoI border persists and raises questions, such as national identity, sovereignty, citizenship and migration. This project shown in Figure 6 seeks to redefine the notion of borders and propose an alternative solution to the Brexit stalemate, one that is neither 'Hard' nor 'Soft', but both.

Tibos is a new citizen-led sovereign and buffer state, that acts as a mediator following Brexit where current deals and agreements between the UK and the EU cease to exist and be valid. Tibos is formed by the declaration of independence of neglected and generally deprived villages and smaller settlements that are located alongside the border region, on either side of the border. This new state does not approach the border as a two-dimensional line a map, but as a complex and dynamic three-dimensional region. Each village located within the state's territory gains control of the border everything that moves through it. The project investigates what is required across the newly established territory to control and mediate all cross-country movements and flows. It embraces different levels of border control friction and proposes a situation where users have the freedom to decide the speed at which they travel through the new state, and most importantly the level of border control friction they would like to go through.

The journey from the UK to the RoI and vice versa, through Tibos, is used as a focal point. All objects, scenes, landscapes and components witnessed across this journey are compiled as spatial experiences across each village. These spatial interventions range in type, scale, timespan and level of friction, all creating a collective experience-led architectural language that belongs and is governed by its people. By challenging traditional notions of national identity where belonging derives from physical locality and proximity, the project explores and questions the meaning and existence of borders in an age of identity saturation, mass migration and large-scale political upheaval. Tibos demonstrates that to be citizens of virtual space, we need to understand our physical space, and particularly our frontiers, challenging pre-conceived norms of territorial division at political and social scales.

Throughout the 2 years of Brexit negotiations, the Irish border has been a key topic of concern and contention by all parties involved. The UK and therefore Northern Ireland's exit from the EU has severe social and economic implications, particularly in the event of a no-deal scenario triggering a hard border condition. Apart from contributing to the peace process within the region, current border conditions exemplify significant economic cooperations between UK and the Republic of Ireland, through strong supply chain activity and trade, particularly in the agri-food sector. Therefore, finding a solution to prevent a potential disruption to current frictionless cross-border trade, businesses and operations, is paramount.

However, so far, the UK government in negotiation with the EU has yet to arrive at a plausible solution. Proposals include the highly controversial 'Irish Backstop', as well as the customs partnership and maximum facilitation 'frictionless' proposals. However, none of these have fully addressed the demands of the border, especially in the event of a hard Brexit.

Figure 6: Tibos, The Irish Border State (Leonidou, A supervised by Jefferies, T, Morton , R and Brook, B)

Unity and the Archaeology of Sport. Northern Ireland's religious and political identities have affected migration, housing and education. Although religious segregation can be seen in sport too, certain sports such rugby union and association football are loved and enjoyed by both communities. The project shown in Figure 7 both surrounds and is at the heart of Belcoo (NI) and Blacklion (RoI), twin villages located across the Belcoo River. The design embodies sport and ancient structures common to the whole island of Ireland, preceding contemporary political structures, to directly mirror shared historical memories through the medium of the large-scale earthwork, a form that will outlast contemporary history, producing a future archaeology and urban shape that directly engages with the moment of Brexit.

Figure 7: The Future Archaeology of Sport, Belcoo (NI) and Black Lion (RoI) (Kipic, I supervised by Jefferies, T, Morton , R and Brook, B)

Conclusion

The initial process of data mapping, developed as a basis for testable design proposals has identified the reality of the UK-RoI border as a complex dispersed urban space. In some areas there are clear interdependencies between settlements across the border, with some places straddling the border itself. Muff, Lifford-Strabane, Pettigo, Belcoo-Black Lion, Belleek, Monaghan-Armagh, Jonesborough-Dromad, Newry-Dundalk. This reflects the historic settlement patterns that preceded the creation of the border and that have persisted despite changes to the border's status in the past century. It is also clear, from both data mapping and fieldwork, that economic and social activity freely engages with and

crosses the border to maximise the locational advantages of the extended border region and the status of the two adjoining states.

The mapping and fieldwork process identified significant gaps in infrastructural provision across and along the border, this includes infrastructures that have been removed as a result of policy decisions, e.g. railways and through direct removal e.g. bridges across the border demolished during the Troubles. These physical absences can be considered alongside gaps between data sets produced by governmental methods used to assess produce and capture data in the UK and RoI. This ability of the border to both create ellipsis as a form of space *and* data allows activity and settlement types to emerge that are unique and point towards potential modes of occupation that overtly engage with the quality of ‘borderness’ as a distinctive spatial and societal condition.

The Brexit vote and subsequent negotiations have established the basis to explore the many unintended consequences of the UK leaving the EU. Design research enables the development of testable proposals that engage with both the found condition and possible future trajectories of the UK-RoI border, triggered by the potential status shift of the relationship between the UK, Ireland and the EU. The changes across the border may be significant or imperceptible depending on the final outcome of the Brexit process. Proposals above range from concrete physical interventions to engaging with invisibles such as tax regimes between two neighbouring states. The proposals also establish the rationale for significant regional identities to be recognised as new territories with their own distinct identity, in the case of Tibos as a means of radically resolving the relationship between the EU and a third state. Proposal also exist and can be mapped through time, both in the near term and as future archaeology. Borders are recognised as being places themselves, rather than the edge of two adjoining territories.

The methods discussed above can be applied to numerous contexts, enabling complex locations to be understood both as factual entities and as new places of inhabitation and potential.

Building urban futures through an exploratory project: how can innovative design approaches be used to regenerate urban planning routines?

Abstract: Technological change and emerging social concerns signal the advent of new economic innovations and social inclusion challenges for cities, in addition to the transition to an ecological and smart society. These changes raise questions about urban planners' routines, which may need to be reviewed. They clearly call for a review of planning processes, especially in urban projects, in order to explore the potential of new paradigms. Some private and public companies have responded to this challenge, with convincing results, by developing tools based on innovative design theories. One of these methodological tools, Definition-Knowledge-Concept-Proposition (DKCP), was used to regenerate the range of planning options of an urban district in Montreal, Canada. Elected officials wanted to adopt a planning vision for the next 20 years. Some observations emerge from the use of the DKCP method: 1) the introduction of a necessary "deterritorialization" at the beginning of the process (failing this, spatial constraints act as cognitive fixations, limiting expansive thinking); 2) disciplinary decompartmentalization, in order to integrate a diverse range of knowledge and disciplines (engineering, health sciences, arts, agribusiness, etc.), to rethink the identity of projects and develop new routines among planners.

Keywords: Urban futures, routines, rule-based design, innovative design

Introduction: the necessary paradigm shift in urban planning as a design activity

In the coming years, most Western cities will face increasingly complex challenges related to the emergence of many social, environmental, economic and technological changes. In particular, this is reflected in a new view of traditional urban activities:

- In many cities, inequalities in access to housing become critical, which calls for a reinvention of urban density. Housing will be marked by flexibility and affordability, the search for a "enjoyable density", the reinvention of the family unit and nomadism. This transformation of housing may heighten tensions between permanent and temporary residents of neighborhoods, or create social, economic and even environmental disparities between central and peripheral neighborhoods;

- The world of work will face strong mutations: it will be influenced by an explosion of forms of work and workplaces, open innovation and the emergence of a community of innovations, robotics and experiential work. However, our cities are structured under a logic of daily home-work commuting and highly segregated activities. The redevelopment of activities in the city is also likely to create tensions between The reorganization of activities in the city may also create tensions between mobile, multi-purpose and urban youth compared to older, sedentary, off-centre youth who holds a single job that fully satisfies them;
- Leisure time faces the challenge of social inclusion and sustainability, while having to resist the pressure of algorithmic standardization. Entertainment will need to be redesigned to take into account the individualization of leisure, the bursting of “urban rhythms”, but without increasing inequalities. The frenzied development of digital and immersive technologies may lead to new experiences for which no organization (city, museum, theaters) is currently capable of hosting the content.
- Finally, the current environmental crisis (climate, local atmospheric pollution) requires cities to urgently reinvent their mobility system. Proximity could be redeployed by the desire for experiential mobility, the offshoring of all activities, mobile internet, ubiquity. The changes in the nature of the activities set out here should bring about new forms of mobility that are more flexible and experiential, but also less predictable.

Many cities are translating these challenges into policy statements that take the form of concrete utopias: the carbon-neutral city, the circular city, the smart city. In addition, cities must ensure that the necessary living conditions are in place to ensure the social integration of all populations, as well as economic prosperity.

These challenges and the complexity of implementing effective responses to them thus raises questions about the practices, tools, and methods of intervention in urban planning. They raise questions about traditional instruments, such as urban planning, zoning, financial tools and other policies, as to their ability to properly equip upstream public policies (Ascher, 2006). The practice of urban planning thus takes the form of a "rule-based design activity¹": it frames collective action to make it effective in a given context, according to rules that ensure predictability. However, it is less convincing as a way to guide change in the long run.

In recent years municipal organizations have tried some new practices or approaches to renew their processes and instruments. For example, in terms of processes, the City of Copenhagen has encouraged the networking of contributions by urban planners, citizens and designers. Its "Create Your City" project has helped shift the city planner's perspective towards the less technical and more humane aspects of planning (Munthe-Kaas, 2014). For example, on instruments, several North American and Canadian cities have formalized new urban planning tools and reworked the zoning with a form-based code to integrate the user experience (installation of benches and landscaping, display and other visual cues, etc.) (Duany and Talen, 2007). This enriched conception of rule-based urban design may propose new directions for the work of the town planners, but it remains, however, insufficient to reinforce the capacity of urban planners to innovate. It avoids revisiting the identity of design objects (what is

¹ According to this formulation, which draws on ideas proposed by Schön (1980, 1993) and Simon (1969), town planning constitutes a “design discipline”. The goal of urban planning and the work of the urban planner is to "conceive" of the right sequence of problem solving, exploration, informed decisions and experimentation to guide the organization of a geographic area in order to produce, in the long term, the greatest collective satisfaction.

a public square, urban density, or smart and sustainable mobility?) and, in its place, seeks to capitalize on and disseminate good practices.

In spite of the obvious interest of these developments, there remains a gap between the scale of contemporary challenges and the capacity of these tuned instruments of design - even those that are enriched - to respond appropriately. The urban planner still has difficulty reconciling the disparities that exist, for example, between an abundant supply of active and collective transport in urban centers and the outskirts of the city, areas where car ownership is essential.

To ensure that urban planning is fully able to respond to these challenges, we propose focusing on the practices, references and paradigms that structure the routines of urban planners. This concept of “routine” has been used in organizational theory to characterize activities and to think about a genealogy of productive models, associated learning dynamics and possible performance (Brem 2017, Coriat and Weinstein 1995, Nelson and Winter 1982). The interest of this work lies in being able to closely analyze professional practices in order to understand what makes innovation possible and to emphasize their framing effects.

One of the challenges is how an innovative design culture can take hold in municipal organizations. A first reading of the legal and educational framework suggests that this has not yet occurred in the practices of urban planners in Canada in general and in Quebec in particular. Legal and regulatory tools favor normative or prescriptive considerations and ignore the activity of design. On the professional development side, university urban planning programs focus on learning and applying a variety of regulatory audit tools. Except for a few exceptions (Scherrer *et al.*, 2017), there is no training in Québec in how to innovate, as there is in most architectural or design training programs.

However, such methods that make it possible to revisit the identity of routines can be found in private organizations that are facing rapidly changing technological or social contexts (Arnoux and Béjean, 2015, Potier, *et al.* 2015). To anticipate these changes and force adaptation, they intentionally introduce elements of rupture. For example, they will create new roles for the actors, explore new identities for objects, and enable the regeneration of tasks and jobs (Le Masson *et al.*, 2017). The transposition of these methods to the public sector is currently limited to a few organizations with specific missions (moving people in urban Paris (Amar and Michaud, 2009) or between urban areas with the French railway company (Laousse and Hooge, 2015)). However, by associating them with forward-looking methods (Durance 2010, Durance and Godet 2010), they could probably be applied in municipal organizations.

Given this increasingly complex context for cities, what would these future professional planners' routines look like? We hypothesize that an existing set of innovative routines developed in business companies could inspire public urban organizations. This set of innovative design routines is understood as four successive activities called DKCP (where "D" is a common definition of desired explorations, "K" is an assessment of known and unknown knowledge, "C" is the generation of concepts and "P" is their transformation in proposals or projects) (David and Scheffer, 2017, Hatchuel *et al.*, 2009, Le Masson *et al.*, 2011). Can this set of routines can be transposed into the urban public organization? If so, will the routines be identical or take other, specific forms?

These innovative design routines in private enterprise and their transposition to urban public organizations have been the subject of some research (Georg *et al.*, 2011; Croisel, 2014). These routines are yet far from being systematized. We intend to contribute to this discussion. First, we will propose the value of routines as a way to better understand the design activity in urban planning. We will then explain the usefulness of intervention research as a methodology for framing the necessary scientific approach in urban planning when exploring the unknown. Third, we will present a specific case of experimentation that took place in a Montreal organization. Finally, we

will present a sketch of a set of routines in the four phases (D-K-C-P). We will conclude by specifying the usefulness of these steps to the future of the practice of town planning.

1. Professional routines at the service of creativity

Let us return to this notion of a professional routine. In our opinion, it possesses indispensable virtues for the members of organizations, both private and public, who wish to implement responses to social and technological change. It is also useful for understanding the work of urban planners. In particular, we will present a theoretical model that proposes moving from the current paradigm to an innovative design paradigm, thereby revising the identity of the routines.

1.1 Professional routines to formalize organizational learning

In general, the notion of a routine refers to its comforting dimension: a series of habits which, repeated daily, structure the life of each and every one of us, as is the case in our daily travel to and from the workplace. In organizations, individual habits are transposed into routines that formalize behaviors shared by colleagues, forging standardized behaviors (Hodgson, 2008). The most effective of these behaviors eventually become rules to be followed by all. The word “routine” also refers to the repetitiveness, disenchantment and lack of surprise in day-to-day life. This can even become enslavement and alienation from individual desires (Juan, 2015) by preventing workers from trying out new tasks or services. Finally, “routine” may refer to favoring ready-made solutions that are not always adapted to the changing social or environmental context (Knudsen, 2008).

Routines can also be something positive. The most ordinary gestures and processes are easily transmitted within an organization. A new employee will quickly be able to rely on these skills, methods and tools shared by public or private companies to quickly carry out their tasks. Nelson and Winter (1982) pointed to the particular evolutionary context of organizations, in which they must constantly take into account social and technological changes. How these organizations respond becomes part of their particular identity, a formula of codified language that defines the organization’s personality. It is compared to the role played by genes for human, in that the manner of formulating this response determines the behavior of the firm’s employees. The strength of an organization then becomes its ability to continually adapt and regenerate its routines to threats that could undermine the organization. It must learn from the inside, letting its employees question the methods, tools and processes so that they can be constantly improved.

1.2 Turning Design Routines into Innovative Design Routines in Municipal Planning

Thus, one should not see professional routines as ways to freeze an organization in an immutable space-time. Routines adapt and evolve in response to the new tools, methods or processes that employees adopt (Coriat and Weinstein, 1995). They also help support a learning dynamic within organizations by empowering employees, allowing them to see problems from different angles that otherwise might not have emerged (Miner *et al.*, 2008). At the same time, in large public organizations such as cities, routines can create path dependencies (Teece *et al.*, 1997). Routines optimize past structures rather than favoring disruption and demanding changes in how they are implemented. Conversely, Labatut *et al.* (2012) have shown that the techniques and methods used can produce unsuspected generative effects that completely change the practices of organizations and produce a new range of actors. The effects of innovations are not only felt on the objects themselves, but also on those who produce them.

It is our opinion that the above discussion of professional routines highlights the particular challenges faced by urban planners’ practices in municipal organizations. On the one hand, the empowerment dimension of urban planners highlights the rigor with which they use their various instruments to solve the problems presented to them, without being given the time or the opportunity to question the ins and outs. On the other hand, the dimension

of path dependencies is illustrated by planners' reflex to reproduce in new projects or approaches what may have worked well in the past, without enriching it in any particular way. The long lives of public administrations and the sequence established to avoid displeasing one or another of the stakeholders, which applies to the two previous dimensions, makes it difficult to effect a change in direction once a process has started. However, to obtain the disruptive effects of innovation, it becomes useful to place planners from the outset in a position to generate unsuspected effects.

1.3 Exploring an original model for conceptualizing urban planners' routines

Thus, it is also necessary to question the professional identity of urban planners by having them ask themselves how to regenerate regulated routines (professional routines that support their work, new ways of conceiving and doing, their repertoire of knowledge and tacit actions, the ability to act and learn). Rampa *et al.* (2017) formulated another set of criteria in a study conducted in a public administration (an energy producer and supplier in Québec): the ability to identify the missing knowledge in the dominant design of an object; the ability to produce knowledge expansions that enhance the initial functions of the dominant design; and enthusiasm and excitement about the creative process.

To characterize the design regimes of municipal organizations and their attempts at enrichment, we propose an original model of analysis. The model (as seen in Figure 1 and detailed in Table 1) combines the relation to the objects under design and the type of professional routines:

Figure 1

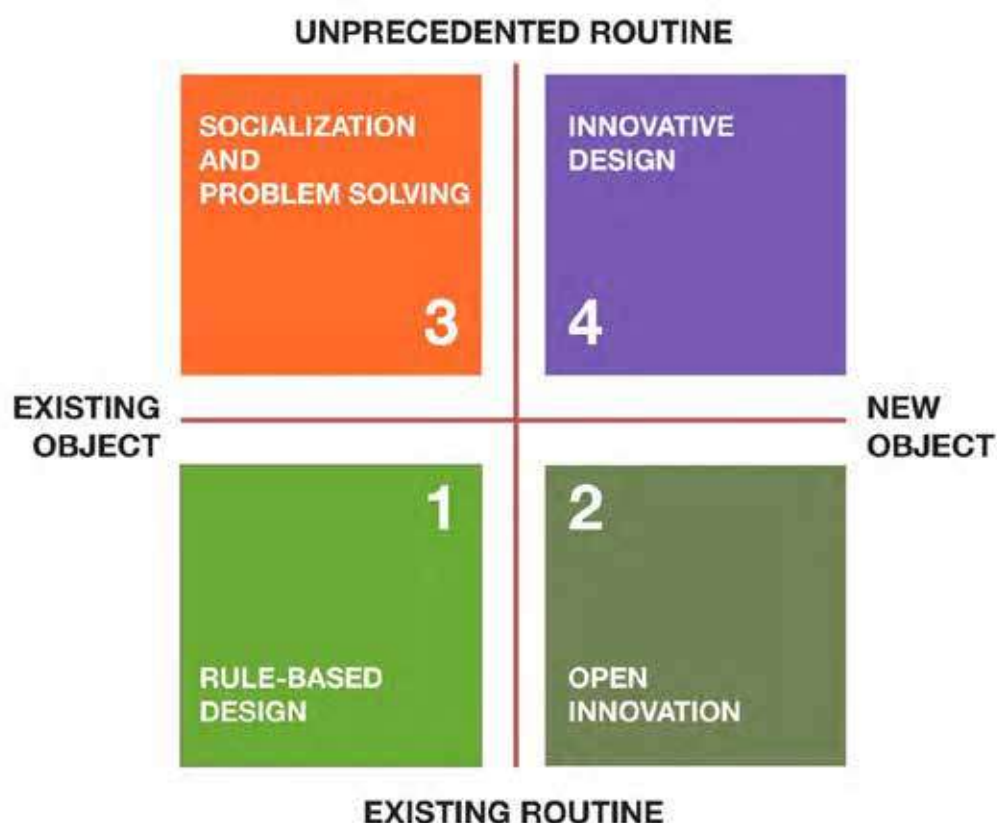

Table 1

	Combination	Description	Benefits	Limits
Quadrant 1	Existing routine, existing object	Includes the well-known, traditional practices of urban planners, strongly marked by detailed knowledge of objects and past learning, but also by tools from the regulatory, legal or legislative framework, budgets, and best practices.	Makes it possible to ensure consistency and common identity in the profession	There is a danger of not being up to the challenges that will arise. The possibility of limiting ourselves to path dependencies is also present.
Quadrant 2	Existing routine, new object	Consisting of open innovation practices. This is often carried out by a consultant who has a method that is applied consistently, regardless of the context. Standardized activities (architectural or design competitions) to encourage urban innovation, for example in eco-neighborhood projects (Susse <i>et al.</i> , 2011), also belong in this category. In France, the exploration study agreement is an excellent example of enriching the traditional call for tenders. However, these approaches do not allow the municipal organizations to learn about the innovation process, since they rely on the invisible routines of others (those who compete).	Makes it possible to recognize a quick contribution of new knowledge.	Learning ability may be low. The municipal organization may also be able to steer the content. Finally, there is a danger of the “black box” effect, i.e. participants only share part of their content.
Quadrant 3	Unprecedented routine, existing object	Creative tools to play with the (re)organization of forms, activities, actors. Typically, these are knowledge-sharing activities (Lehman, <i>et al.</i> , 2015),	This is an enriched public participation formula. It encourages better contributions from	Generally proposes an original reorganization of the existing routine, but one that is

		that foster new routines such as hackathons or brainstorming. On the other hand, these positions remain in the existing paradigm. They favor the sharing of existing ideas, without raising questions about their foundations (Agogu�� <i>et al.</i> , 2014).	everyone in involved in the thinking process.	thought about and discussed under the same parameters.
Quadrant 4	Unprecedented routine, new object	Composed of tools or methods to facilitate the process of disruption in the design of urban referents, to call into question the identities of objects or actors. The challenge lies in whether these innovative ideas can be reintroduced in projects. Examples of these kinds of products are more common in private companies (Arnoux <i>et al.</i> , 2015) and parastatal organizations in France (Hooge, <i>et al.</i> , 2018).	Opportunity to identify new spaces of values, new actors and the resulting practices.	May be very creative, but this approach can neglect the important task of returning to transform the current organization. One can also stay too close to the design brief frame and limit the expansion of knowledge.

Currently, urban planning routines are essentially confined to the first quadrant of the diagram, with some attempts to move to quadrant 2 and 3 to enrich them. On the other hand, what is learned remains the property of the designers, and the participants remain confined to their usual practices. However, it is only in the fourth quadrant that the planner can truly attribute new identities to objects, which will eventually condition creative professional routines (Le Masson *et al.*, 2017). The fourth quadrant therefore represents a new space which deserves to focus on it. Our hypothesis is that this innovative design routine can be generated by a set of four phases and their interrelationships.

2. Methodological relevance of the intervention study and its DKCP formalization tool

To illustrate this model, we will now present a real case that took place in Montreal. This section presents the method used to make innovation take root in a municipal organization.

Our proposal to generate unprecedented routines for urban planners requires the identification of new forms of reasoning, to describe and explain new realities (new routines, new urban objects, and the relationships that are established between them). Since we are in the field of manufacturing the city of the future, these new reasonings must be based on observations of real situations.

In this context, the data must be produced within organizations with real urban problems. This requires strong and consistent investigative methods that position the researcher in a position of listening to practitioners. For all these reasons, we believe that methodologies inspired by action research and its derivatives, particularly research-intervention or research-experimentation, deserve our full attention.

2.1 Intervention research as a mode of knowledge production

Two points of similarity between the approaches used in action research and in intervention research may be summed up by the fact that the search for solutions and the validation of these solutions by the actors constitute mutually supportive and self-sustaining operations. Although action research and intervention research both come from "field" analysis, intervention research is unique in that it establishes a space for collaboration between actors and a researcher who jointly seek solutions that will allow them to both contextualize the problem, but also test possible solutions with the actors (David, 2002).

On the other hand, intervention research is not only about producing knowledge for potential action, it is also about producing knowledge through action (Hatchuel, 2000). Like action research, actors adopt a variety of strategies designed to produce consequences, each of which is weighed and analyzed. On the other hand, from this perspective and more specifically than in action research, intervention research implies the involvement of the researcher-intervenor in the production of the action. This is not only intended to guide the reflections of stakeholders, but also to have stakeholders actively involved in the process of defining this (collective) action.

Intervention research is therefore not compatible with observing participants detached from stakeholder analysis in action. The "laboratory" model - in which the actions of the participants are scrutinized - gives way to a field study in which it is possible to interact with real actors defending legitimate personal or collective issues (David and Hatchuel, 2014). The researcher-intervenor will need to respond to stakeholders' questions. The answers can and will have to take into account the particular context experienced by these stakeholders.

2.2 Mobilization of a tool for an innovative design process: DKCP

To clarify the nature of these innovative design routines, we took this model as our hypothesis. To identify the richness of this disruptivity, we used a methodological tool inspired by the theory of innovative design (Hatchuel and Weil, 2003). This tool, called "DKCP" (Amar and Michaud 2009, Hatchuel *et al.*, 2009), therefore favors the formalization of creative ideas in response to a particular problem formulated in neutral terms. The tool takes its name from the four main phases of its reasoning (Abramovici *et al.*, 2016):

1. A definition and initial framing of possible innovation fields (phase D);
2. A pooling of knowledge useful for reflection, with important work to identify out-of-the-box knowledge (phase K)
3. An expansion of the knowledge, translated into new concepts with high disruptive potential (phase C);
4. The translation of these disruptive scenarios into concrete projects (phase P).

This reasoning relies on the formulation of stimulating briefs². By adding new attributes, drawn from a knowledge disjunction, it is possible to partition this brief, thereby opening new avenues of exploration from a bold (re)

² A brief is a bold formulation of a problem, an original description of a way to solve it. At first glance, it does not have a logical status (Hatchuel and Weil, 2002), so it is considered *prima facie* neither true nor false. An example

formulation of the problem (imagine, for example a retractable public square rather than simply a comfortable public square) (Le Masson *et al.*, 2010). The process of expanding knowledge and concepts leads, after a few steps, to the creation of a tree of new functions, uses and designs, unexpectedly leading to one or more unprecedented prototypes.

3. Results: An application of DKCP to the Montréal territory

The first experiment conducted with the DKCP method was carried out in the *Rosemont-La Petite-Patrie* Borough, one of the 19 boroughs of Montréal³. This municipal organization asked the team at “Lab Ville prospective” to initiate a reflection to develop original approaches to land use planning (Abrassart *et al.*, 2018). The borough expressed its initial vision in the following terms: “Live, Work and Play within Walking Distance in 2037” (more simply called P37). It was aware that, in the next twenty years, it will be strongly transformed by the many social, economic and technological changes mentioned at the beginning of this text. These changes will have an impact on the routines practiced by urban planners. It was therefore particularly stimulating to investigate these changes by thinking about the future. These changes could also generate new needs, inspire new lifestyles or generate a new form of governance, more responsive and forward-looking. This municipal entity wanted to better identify these developments, which will have consequences on its provision of services. The four DKCP phases were applied continuously over a period of about five months (as shown in Table 2).

Table 2

	Phase	Description	
Pre-project		Conducted by the Université de Montréal team in close collaboration with a "project team" made up of professionals and executives (half of whom came from the planning world).	Seminar ⁴
	D	This phase ended with the establishment of a schedule of exploration activities. Deliverables: a calendar of activities and a roadmap specifying the desired learning	
	K	This knowledge was produced by the University of Montreal team in close collaboration with three speakers. Their presentations focused on experiential mobility, the city and aging, as well as “third places” ⁵ . The	

of a brief: design a boat that flies. In appearance, a boat floats but does not fly. By applying principles specific to aviation, it was possible to design the hydrofoil (Agogué *et al.*, 2014)

³ Montréal, along the St. Lawrence River, is the second largest city in Canada in terms of population (3.4 million) and is a metropolitan area and an island (2 million inhabitants) composed of 16 cities, including Montréal (1.8 million inhabitants), itself divided into administrative units called "boroughs" whose size and area vary.

⁴ This seminar took the form of eight meetings spread over five months, with meetings every three weeks. It was punctuated with preparatory exercises for the discussions, creative exercises, conferences, and disruptive activities.

⁵ Oldenburg (1989) has proposed the concept of third places to identify those spaces that are neither places of work nor places of employment (cafes, bars, restaurants), where one goes for entertainment or to work. These places may, however, become new friendly spaces as found in all urban fabrics.

Pre-project and projects		<p>exploration of current trends and their extrapolation into the future allowed the team to imagine four evolution scenarios by variables, called in this case "evolution hypotheses". Each of these hypotheses was briefly described to the project team in order to transparently share the thinking behind the development of these so-called "evolution hypotheses". These trends have relied on identifying "non-knowledge" that would potentially be crucial to innovation.</p> <p>This phase concluded with the formulation of projector concepts (which can be understood as new spaces of values) or triggers (which prepare the design activity of the next phase).</p> <p>Deliverable: disruptive projector concepts</p>	
	C	<p>This phase began with the organization and holding of a prospective codesign workshop with borough stakeholders. The codesign workshop encouraged reflection on the transformations expected by the borough over the coming years in order to better address them.</p> <p>This phase ended with the formulation of a new prospective scenario, a narrative of fictitious characters in 2037 and the illustration of these scenarios by cartoonists.</p> <p>Deliverables: enriched scenarios and generative concepts rooted in the territory, and suggestions of possible action plans.</p>	
	P	<p>Some suggestions were made during the course of the codeign workshop. This pre-project stage would make it possible to propose a variety of projects that the Borough can propose in the coming years as a way to respond to the new issues identified at the outset.</p> <p>This phase produced a report outlining ten (10) possible paths to carry out the ideas generated.</p> <p>Deliverable: an action plan to transform the municipal organization</p>	

Four 2037 briefs were proposed to planners with the municipal organization and to various stakeholders. Among the various formulated projectors revisiting the initial problems of the district (live, work, entertain, proximity (250 m)), two foresight scenarios were particularly full of unknowns.

- Circular environments with positive energy:** This first scenario proposes dividing the borough into 26 sustainable living environments (or ecovillages) where citizens can engage in most of their activities: working, living, entertaining and shopping, and all within walking distance. These living environments generate "positive social energy" because the inhabitants would be encouraged to participate in the social life of the community through daily service. Two ways of living tend to collide. On the one hand, there is collaborative private housing (with grandparents, children, etc.) where one wants to stay in one's house for life. On the other hand, as access to housing has become expensive, "the micro-habitat" (as seen in Japan) becomes a solution for residents of 20

years in 2037. They live in intimate spaces small dimensions, basically intended for sleeping. They live their urban life out of their homes. In this scenario, people do several jobs in a day or a week and they participate through their productive "hobbies" in the production of goods and services: it is the era of multi-work-leisure. Entertainment is serious, residents want to become performing being, and games/competitions between communities are regularly organized. In addition, residents are invited to travel, staying in Rosemont, another village.

- **E-care zones with companion robots:** In this scenario, inhabitants live away from their "homes". During the day, they are separated from their loved ones because they work elsewhere, but with the help of the Internet of Things and companion robots, it is possible to provide support and care to loved ones remotely. The borough has set up 12 pilot "e-care zones" (screens, gardens equipped with the Internet of Things, "companion robots" that can be activated remotely, etc.) around places where their loved one are fragile or have less autonomy (schools, nursing homes). The habitat is individualized, digital (with home automation, controlled remotely) and the inhabitant can stay in this house, if possible, for life. To include all inhabitants in these accelerated technological changes, the borough has set up ongoing training for citizens ("robotic literacy") in public libraries. Permanent commercial entertainment dominates, and the robots are the good facilitators of "e-care" in public spaces. They are also companions who let inhabitants travel in their minds by telling them stories from around the world.

The participants were then invited to participate in a working group led by facilitators previously trained by the research team. Three activities were proposed to them:

- In the first exercise, participants were asked to present the elements of the scenario and comment on their interest (membership) or disinterest (dissent).
- The second exercise was aimed at enriching the triggering scenarios presented in the introduction. The participants were asked to imagine a logic of starting the scenario, through a day in the life of a family in 2037 (agenda, living experiences, work and entertainment).
- The last exercise, backcasting, was to develop possible strategies and routes for guiding between 2017 and 2037 the borough towards the desirable futures.

The approach was built by going in new directions, moving away from local or current problems. The proposals also ventured well beyond the confines of traditional planning tools. Ideas emerged for how to better integrate the activities of certain institutions into the urban fabric. In many respects, travel in the city was more understood as an activity unto itself, a source of fortuitous encounters, a constraint experienced with difficulty by citizens. Some concrete ideas were formulated:

- Recognize and value social involvement in living environments: most people contribute to their community by taking daily actions to help their fellow citizens. Inspired by the idea of the "Carbon Pass" and local currency proposals, this "Social Pass" draws on good actions taken by citizens in the neighborhood in terms of social and community investment. In exchange for good actions, points are accumulated, and could become marketable at the borough level since they contribute to its influence and to improving living conditions for the citizens. Value would be attributed to the points to motivate good actions.

- Consider the proliferation of "circular" third places; inspired by the concept of the circular economy as a principle of local economic development, circular third places could be developed to encourage the development of innovative entrepreneurial initiatives in every living environment (e.g. repair cafes, tool libraries, textile micro-enterprises and urban agriculture). Some of these circular economy activities could be grouped into third places of various sizes to allow for economies of scale and greater capacity for investment in specialized equipment (e.g. specialized Fab-Labs with 3D printing of spare parts, but also highly productive and sustainable urban farms). In addition, these third places registered in the urban area could be part of a network of specialized skills at the metropolitan level.
- Talk in terms of "movement in the city" and experiential mobility, rather than transport or displacement: following Amar (2010, 2015), the "speed-distance" paradigm, in which the journey between origin and destination is considered lost time, was discussed and criticized throughout the process. It was then picked up and supported by stakeholders during the codesign. The discussions often returned to the idea of promoting "time-substance", i.e. to take advantage of the fact that we are in movement in the city to fill our travel time with rich and varied moments of life (the pleasure of a walk, to meet with other people, to stop along a route to work or play). This idea recognizes the emergence of a population that seeks this connecting and experiential mobility, a form of everyday nomadism within the city. This drift is supported, even encouraged, by new technologies (and defines a way of thinking about "intelligent mobility"). This trend could bring vitality to the living environment (new passers-by creating surprises, an opening, meetings, bringing customers and users to the economic activities of communities). It could also cause tension in case of conflicts of use, a new form of NIMBY (e.g. ephemeral nomadic gatherings occur in a living environment at a late hour or on weekends).

4. Discussion: tackling future urban issues from the perspective of a set of routines

For the majority of municipal organizations, formulating creative ideas only focus on one step in the process, represented by phase "C". This is a much more complex activity. Innovative design in large organizations (the 4th quadrant of Figure 1) is more of a succession of phases that predispose planners to discovering a new set of routines. This new innovation process consists in turn of routines intertwined with each other, as represented by the DKCP steps. They must be well coordinated to avoid the pitfalls that would prevent discovery or cause participants to move into the other boxes too quickly.

The first routine is that of definition, "D". This is a necessary first step in order to fully understand the opportunities available and imagine new spinoffs. It was at this stage that the team of researchers met with borough planners to identify various paths for exploring ideas.

The second routine is that of knowledge, "K". Disciplinary decompartmentalization is used to bring a diversity of knowledge and disciplines (engineering, health sciences, arts, agribusiness, etc.) into the process in order to re-imagine the identity of the planners' routines. This routine is also about identifying where a particular municipal organization lacks knowledge. More specifically, it involves seeing how other knowledge can help reopen the pockets of knowledge that have been identified. It is in this sense that the concept of mobility has been re-imagined in terms of temporality (promote the notion of time-substance (choosing which mode of transport to choose for a displacement of a certain duration) rather than of time-distance (250 m) (Amar, 2010)). The notion of ubiquity (being two places at the same time) also opened up great possibilities. Finally we find in this routine "K", the need to involve non-experts and to imagine the future users of the city.

The third routine is a design activity, “C”. This is a delicate and complex step. The urban planners were both surprised by the formulations of these scenarios and somewhat confused - they did not imagine being able to formulate them with *such* originality. Projector concepts must be formulated in terms sufficiently open to allow for the expansion of knowledge, and use relevant approaches for communication: scenario writing, maps representation, illustration in comics. In the Montreal project, imagining the “e-care zone” was a completely disruptive new idea to urban planners and citizens (although several participants disagreed with the scenario). Projector concepts must also be described in understandable terms, failing which citizen participation will be ineffective. Moreover, the casting of the participants becomes a crucial question. The time required to complete a prospective territorial project requires participants setting aside their short-term expectations. So they must also be chosen according to their ability to “expand” the knowledge mobilized in the urban project, not only according to their representativeness.

These first three routines, D-K-C, also have a particular dimension specific to urban planning. Indeed, from the definition phase, there is a need to deterritorialize knowledge (Scherrer *et al.*, 2017). This does not suggest that we should ignore the spatial or technical constraints, but rather that we move away from them temporarily, to better explore the “field of breaks and possibilities” (Debarbieux, 2009, Klauser, 2012, Raffestin and Butler, 2012). Otherwise, when spatial constraints act as cognitive fixations (Hatchuel *et al.*, 2011), they limit expansive thinking. These ideas will later be recontextualized. In the case of the Rosemont project, this recontextualization step was an important step in the codesign project, but only occurred once the participants had responded to the initial scenarios.

The fourth step is therefore the routine of the propositions, “P”. This is possibly the most important, most underrated, forgotten and most complex step for urban planners. This is when we determine the actions to be taken and their sequence, in order to ensure that the most desirable scenario can be realized. This step of backcasting can, however, impede important changes that may occur along the way. In the Rosemont project, participants had a mandate to imagine a major and potential event in 10 years’ time that could require the reorientation of the scenario.

The last routine could be considered as a binding routine, since it turns out to be transversal to the process. It took the form of a seminar (several successive sessions, each time enhancing the knowledge generated earlier), during which the members of the project team built their own knowledge. They learned to let themselves get caught up in this search for the unknown, even if it raises doubts about the predictability of their methods. The fact of documenting this step, punctuated by disruptivity, in an iterative way, made them feel less destabilized.

Conclusion

Urban planning is a social science discipline in constant turmoil. This boiling point is driven by social and technological changes that now punctuate the activities of municipal organizations, and by the same token, those of their territorial planning teams. Municipal organizations and urban planning departments must therefore renew their methods and develop their organizational functions: will it be by the creation of municipal Innovation Labs ?

Since Weber, municipal organizations have often been encouraged to assimilate instruments and methods used in private companies into their processes (Lascoumes and Le Galès, 2004). This contributes to the interest in innovative design approaches used in the industry.

The example presented here is only an experiment established in a particular context. It has proven its usefulness in generating ideas that are at odds with the way urban planners approach urban planning. While the DKCP set of routines has proven its usefulness in regenerating urban planners’ practices, it has yet to demonstrate the real ability

of urban planners to implement each of the steps. Routines for defining innovation fields are an easy process to implement. Establishing a routine interested in new knowledge. On the other hand, it is difficult to formulate projector concepts and so much for the transformation of disruptive scenarios inspired by these projector concepts into concrete projects.

Any municipal organization, unlike private companies, must demonstrate public accountability for the time and resources invested in innovation activities. The difficulty of taking risks, the rigidity of organizations, the difficulty of controlling long time, are all obstacles that must be overcome. The most effective way to act would be for a municipal organization, through its urban planners in particular, to promote innovative design approaches. Project P37 is a first step.

We must now move on to the next step. And dare to implement disruptive processes. And to accept that these projects are invaluable sources of learning to prepare for current and future urban challenges. In this way, it would be possible to design the innovative design of tomorrow's urban planning.

Abstract: The following contribution aims to explore the projective qualities of the metaphor, with a specific focus on the organic metaphor, and its potential applications within the milieu of climate change. Firstly, the paper will concentrate on the understanding of the metaphor as a tool for the construction of referential images and imaginary projects, taking into consideration some of the projects that have been generated through this powerful, cognitive means. Secondly, analyzing the term *adaptation* and the whole of its spatial connotations, an investigation will be proposed, which will identify this very concept as the vector for the modification of cities and areas that are – or soon will be – facing the impact of current and prospective climate transformations.

Keywords: climate change, urban theory, anthropology, adaptation.

1 | The orienting potentiality of the image.

Over the course of his professional career, Franco Farinelli demonstrated that the construction of the map, far from being an objective gesture of graphic translation, always inherently implies a certain degree of representational bias, be it conscious or unconscious. (Farinelli, 1992). At the dawn of the modern age, the shift from celebrative cartographical models to denotative models, marked by the «the disappearance of the paradise of the map»[2], (Farinelli, 2009 p.22) inevitably corresponded to the epochal shift from an otherworldly legitimation of power to a system based on its worldly distribution (Cfr. Heidegger, 1927). «Grasping the analogy between the cartographic representation and the market, which is its very implementation, the natural form becomes value-form [...] In other words, space and money are all the same, in the sense that cartographic symbols and money function, the former in the map and the latter in the market, exactly in the same way [...] The organization of reality dovetails with its geographical manifestation, namely, cartography»[3]. (Farinelli, 2009, 28-28) This very shift, whether conscious or not, transforms the role of cartography, from celebrating the Earth as a metaphor of the divine power – that is embodied in the worldly power – to employing it as the site (and metaphor) of human power. Thus, the renowned philosophers of natural law postulated the existence of the Social contract – a concept that referred to the transposition of the primary source of power from God's will to the collective being. Michel Foucault, similarly to what Farinelli proposed in his definition of the map, describes how the first change is the economic-political change, which is then followed by the

justification. In other words, we can say that the descriptive metaphor is a product of the context and not vice versa. (Cfr. Foucault, 1961)

With regard to the field of urban planning, we might trace back this process to the very shift from the city of God – such as Plotinus' Platonopolis, More's Utopia, (Mumford, 1922, 45-61), and Campanella's City of the Sun – to the novel understanding of the town planner as a social physician, bearing in mind the notion of the corrective machine, introduced by Bentham's Panopticum and Haussman's *artiste démolisseur* (Cfr. Foucault, 1975). Together with the turn from an otherworldly to a worldly power attribution, the very focus of urban development shifted from the divine field to the earthly one.

Thus, this archetypally orienting value resides in an understanding of the image as an «act of territorialization, whereby it becomes possible to take up the definition of a relational system, connecting physical territory, built environment, and anthropic space»[4] (Guida, 2011); this had been previously described by Giuseppe Guida in his *Immaginare Città*, and, in turn, inspired by the work of Pasqui (2004) and Bruzzese (2001).

«The construction of images is, essentially, a cognitive act that unfolds according to a precise set of mental proceedings, apt to explore new areas of knowledge, by taking up a known context as the starting point of the map. In dealing with these overlapping interpretational layers, imagination can function as a complex and ambitious space, located in between rhetoric, poetry and speculation» [5] that is defining of the metaphor. (Guida, 2011). Thus, Guida understands the metaphorical structure of the image as an operation «in between the layer of scientific knowledge and that of a mere opinion», (*Ivi*, p.45) which aims at the alteration of a specific research as well as at the production of space and institutions. According to Guida, the act of generating the metaphorical image is at once interpretational and orientational. In other words, the image is able to give substance to a description not only via comprehension, but also through a dimensional quality of the productive thought. «According to what has been previously stated, when it comes to territorial sciences and urban planning, a figurative approach can facilitate a horizontal and vertical dialogue among the actors involved in the practices of planning, thereby structuring a *shared vision* that is necessary in order to describe and act upon complex realities»[6]. (*Ibidem*)

If this is the case, that is, if «description is to urban planning not only a sort of reconstruction of reality, but also a generative notion, implicitly introducing a projective stance»[7], (*Ivi*, p.46) we might be able to ask ourselves, with a certain degree of both malice and awareness, which metaphorical images can be orientational towards the desired projects and models. Specifically, we might wonder which class of images has the capacity to take over the very role of the *paradise of the map* – or of the leviathan – in guiding urban planners and citizens towards a pertinent collective response to the challenges posed by the contemporary tendencies in urban planning. Having said that, the critical question regarding the relationship between risk management and its actual concrete implementation, posited by Gilber White, Robert Kates, and Ian Burton in *Knowing better and losing even more*, remains unsolved (White et al., 2001). In their work – which was proved solid by the reiteration of their experiments in the following decade – it was argued that the progressive improvement of risk and emergency management techniques did not result in an increase in the number of cases where these very techniques could have been applied to tackle local issues.

Our essay is intended as an analysis of the relationship between risk-management techniques and the metaphors that are currently adopted in the field of urban planning, with specific interest paid to the management of the risks brought about by climate change. Moreover, it will question the actual efficacy of these metaphors as tools for the production of imaginary scenarios and local problem solving.

The main focus is put on *adaptation*, which here will be analyzed against the backdrop of the long

lasting tradition of organic metaphors it originates in, as well as within the context of its current potentiality to foster a transformative change in the approach towards the city – which is needed in tackling climate change.

2| Climate change and the city. A new organic metaphor.

With regard to his own definition of *hyperobjects* – entities that question the very notion of the object due to their ambiguous positioning within the fields of time and space – philosopher Timothy Morton [8] argues that climate change has rendered climate a substance rather than an accident. This is a tendency that permeates every aspect of contemporary life. Opposing it requires urban planners, politicians, and citizens to rethink their approach towards the city and the territory, as a response to extreme natural phenomena such as flooding and rising temperatures – be they temporary or permanent.[9] «This challenge will lead buildings, cities, and wider areas to shape our lives and our environmental footprint. Aside from the transition to clean energy, urban planning will play a critical role in facing the intertwined menaces. As a matter of fact, it will be impossible to provide a successful answer to climate change and to our energy challenge without a more sustainable form of urban planning» (Calthrope, 2009). Accordingly, the future of urban planning will reside in a global understanding of the urban territory, as well as in coming to terms with the consequences of its unprecedented growth and expansion. [fig. 1]

Figure 1 – Judy Natal, Future Perfect 2040, Solar Panel and Steam Portrait Woman With Helmet. Judy Natal is a contemporary artist who explores the future of the anthropocene between science, philosophy and climate change.

This essay will question, firstly, the efficacy of the organic metaphor of *adaptation* as a tool for fostering human agency within the context of «a world of planetary disasters, emerging pandemics, tectonic shifts, strange weather, oil-drenched seascapes, and the furtive, always-looming threat of extinction» (Thacker, 2018). Secondly, in a more pragmatic fashion, it will ask whether the notion of adaptation [10] is able to serve as useful conceptual framework for the study of the urban form, its morphological features, and its potential development.

3 | Some key points on organicism.

In the last two centuries of the brief history of urban planning, organic metaphors have provided a fundamental basis for theories and projects concerning the city and the territory. In parallel with the development of science and biology, we can observe that *organicism* [11] has progressively broadened its field of action. It first emerged as a discipline based on the sole quest for formal harmony, and then evolved to one focused on the imitation of the biological processes. Since the beginning of the 20th Century, it started to incorporate the models offered by machines, technological networks and social relationships.

It is possible to observe some trace of organicism as early as in the writings of Vitruvio and Alberti, (van Eck; 1997) wherein the notion of harmony was employed to draw comparisons between the human body and the shape of the Corinthian and Doric columns. This ideal was bound to change as a consequence of Galileo's scientific method as well as of the advent of natural sciences. In Piccinato's *La progettazione Urbanistica. La città come organismo*, an organic viewpoint was understood as necessary to both the explanation of the evolutionary patterns that led to the transformation of the medieval city, and to the grasping of their resemblance of an anthropomorphic organism, wherein brain, heart and muscles can be metaphorically discerned [12] (Piccinato; 1941). «In 1628 William Harvey explained how the human heart causes blood to circulate mechanically through arteries and veins. [...] A century later Harvey's discovery about the circulatory system became a model for urban planning; the French urbanist Christian Patte used the imagery of arteries and veins to invent the system of one-way streets we know today. Enlightenment planners imagined that if motion through the city became blocked at any major point, the collective body would be prone to a crisis of circulation like that an individual body suffers during a heart attack». (Sennet, 2018)

According to Benedikte Zitouni, since the beginning of the XIX Century, the School of Edinburgh developed an ecosystemic understanding of the urban dynamics, which was useful for the analysis of the historical evolution of the city, and best epitomized in the writings of Scottish sociologist and urbanist Patrick Geddes. In *Cities in evolution* (Geddes, 1915), observing the origination of the English cities following the industrial revolution, Geddes detected – with regard to their birth, development, expansion, and contraction – a precise correlation between the location of the residential areas and that of potential mining sites. An organic approach becomes further explicit in his infamous concept of the *valley section*, which – in reference to the relationship between plants, animals, and biotopes included in Von Humbolt's *Geographie des plantes equinoxiales* – pins down the strong link between the potential productivity of a specific territory and the process of settling. In *Garden Cities of Tomorrow*, Ebenezer Howard established that the foundational aspects of a city are one central node and the set of smaller satellite nodes connected to it, thereby proposing a model wherein the well-being of the citizens is granted by a close connection to the countryside, to avoid the congestion of the big city.

At the beginning of the 20th Century, the School of Chicago made a similar use of the organic metaphor. However, a new set of concepts was introduced, which also included the organic features embedded in machines and new technologies, and characterized the city as an indefinite entity, inherently devoid of

any physical and conceptual threshold. In this context, Frank Lloyd Wright's *Broadacre City* was able to bring this very mutability to the forefront. In support of the ideals of democracy and individual freedom, a *Jeffersonian grid* established a new set of spatial relations directly tailored on the individual, thereby assuming the organic metaphor as a fundamental interpretative framework – based on living in harmony with nature. In keeping with this no longer anthropomorphic perspective, it is worth to mention the *Inflation der Gross-Städte* (Gloeden, 1923), a model according to which an understanding of the city as a multicellular living organism is theorized. Its form is indefinite, and capable to comply with the whole of the urban necessities, by dint of a process of functional specialization of the individual cells, which is governed by the logics of production, habitation, and mobility. [fig. 2]

Figure 2 – The model proposed by Gloeden applied to the central Veneto area according to a principle of cellular duplication according to purely settlement parameters (left) and according to metabolic parameters (right). Author's processing.

In the same period, Le Corbusier fostered a shift in the interpretation of what had been generally described with the notion of organicism. In the context of his *machine à habiter*, we can observe that the machine, far from being biological per se, begins to be understood as such, insofar as its inner functioning reproduces the same dynamics as those of an organism [13].

In Japan, over the course of the 1960s, the aforementioned understanding of the machine as an organism morphs into an even more radical acceptance – which results into the project for the Tokyo bay [14], the Osaka Expo, and the *Nakagin Capsule tower* [15]. «Metabolism [16] [...] regards human society as a vital process – a continuous development from atom to nebula. The reason why we use such a biological word, the metabolism, is that we believe design and technology should be a denotation of human vitality». (Kurokawa, 1977) The result is a cyborg architecture, or capsule, wherein man, space and machines are all part of a unique organic entity.

Thus, the capsule becomes a tool for social differentiation, namely a shelter protecting the cell as the minimum unit in the potentially infinite process of growth of the Japanese city.

In the last decades, the theoretical discourse around the organic metaphor has evolved further and sharpened the focus on the social drivers underpinning the construction of space. This tendency is best epitomized in the project for MVRDV's *Almere Osterworld*, where it is implied that «both the passing of time and the new residents are (f)actors influencing the future design of the district» (Schilders, 2010). The metaphor here becomes the ideal support of a *bottom-up* approach, understood as the concrete manifestation of a natural process of self-organization, whereby spontaneous actions fuel the main vectors of the process of planning. Given the relevance the organic metaphor maintained in urban planning over the course of the last centuries, it is timely to reflect upon the potentialities of such powerful cognitive tool – in relation to the transformations brought about by climate change. A useful reading might be found in the words of Zitouni, who argued that «The city needs breadth of vision [...], there has been a need for sidetracking into biology or life sciences in order to describe intricate action patterns. The organic metaphor gives us a sense of what causality may be like in a complex urban system. Causality, then, is the way in which action travels inside a system or set of interactions». (Ivi)

4| Adaptation: a metaphor for urbanism in the age of climate change.

As previously stated, a set of terms borrowed from biology – such as *evolution*, *metabolism* and *resilience* [17] – has come to be, over course of the last two centuries, a source of inspiration for the development of organic metaphors in the field of urban planning. Specifically, with regard to the last decades, evolutionary biologists' notion of *adaptation* [18] has become a shared frame of reference for ecological thinkers (Morton, 2017), architects, and urban planners alike.

The employment of this very metaphor, which has been transposed from biology and ecology to urban planning, helped architects and urban planners to focus on new features – *anatomical* (shape, orientation, local specificities, fixed capital), *physiological* (flows, metabolism, territorial capital), and *behavioral* (modes of use, lifestyles, cultural capital). It further allowed for an analysis of society, environment, and urban territory, based on a continuously evolving system of interconnected implications. According to this interpretation, which sheds new light on the *modification theory* [19] developed in Italy over the course of the '90s, *adaptation* introduces a soft approach to planning, which is oriented towards progressive, continuous and non-traumatic transformations of the build space – whose effects can be measured in the long term. In radicalizing these concepts – in order to foster a pertinent response to the shifting environmental conditions – it might be useful to turn to the four variants of adaptation recently identified by French biologist and evolutionist Guillaume Lecointre: *préadaptation*, *exaptation*, *transaptation*, *adaptation* [20].

In the context of Lecointre's own distinction between primitive and derivative structures and functions, *préadaptation* and *exaptation* describe the process whereby the fully-evolved character of a specific function is repurposed into a new one (e.g. theropods' plumage, which was critical to their evolving into flying species, was originally meant to carry out a set of thermoregulatory functions). On the other hand, according to *transadaptation* and *adaptation*, the evolutionary process resides in the global function of a particular element, which can be identified as *anatomical*, *physiological*, or *behavioral*. [fig. 3]

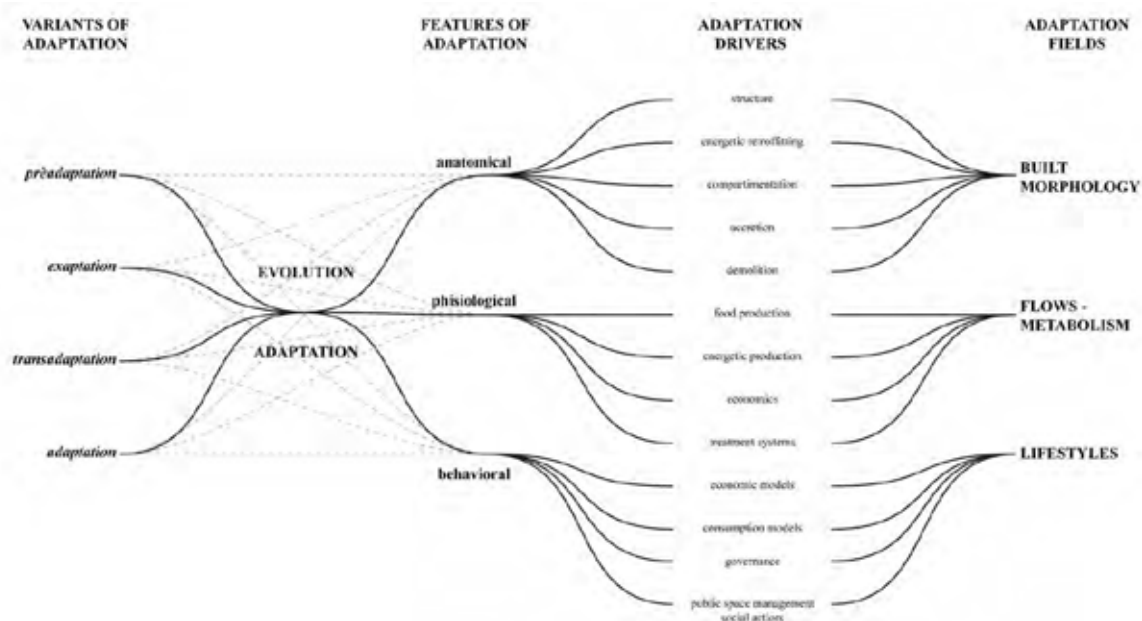

Figure 3 – Adaptation process diagram. Author's processing.

Hence, acting upon the variants of adaptation of the *anatomical* features of the territory – such as the building stock, the road system, the water distribution system, and the energy and technology networks – it is possible to build a set of evolutionary scenarios that simulate the potential progressive transformations of the fixed capital. For instance, adapting the construction stock in conformity with the consumption patterns (by dint of operations such as building compartmentation, infill, accretion, structural adjustment, volumetric extension, and energy *retrofitting*) allows for a sustainable implementation of the urban density, which does away with additional land consumption (*transadaptation–adaptation*). Another example might be the process of river adaptation (based on operations such as the transformation of the streambeds and the redesign of the riverbanks), which allows to acquire a new series of specialized sites for the controlled water infiltration in the soil, and, at the same time, to obtain – as a derivative function (*exaptation*) – a series of infrastructures that might couple the solution of hydraulic problems with the safeguarding of the environmental biodiversity as well as with the leisure related requirements of the communities.

Furthermore, the adaptation of the energy networks (via the redistribution of the systems of accumulation, the employment of *off-grid* systems, and so forth) allows for the progressive transition from a centralized system to one based on the distributed and decentralized generation of energy.

On the other hand, acting upon *physiological* features such as density, *mixité*, energy, water, and food, it becomes possible to revise the metabolic flows powering the city, as part of a process of optimization of the pre-existing peculiarities (*transadaptation – adaptation*), which is realized via operations of recycling and waste reduction – inspired by *circularity* as well as by a *systemic design*. (Berger 2009).

Finally, the adaptation of the *behavioral* features requires a gradual valorization of the territorial capital – which is understood as the totality of the socio-cultural and environmental skills of the citizens (Camagni 2009) – on the basis of the potential behavioral shifts in the context of an evolutionary scenario, wherein individual action can still be considered useful for global scale transformations.

It is this very process of adaptation, which lays the grounds for «a world where everyone designs», that prompts an understanding of the urban planner as a designer, who facilitates the ongoing process of social innovation by fostering new collaborative economies, everyday politics, and life projects that concretely change the world (Manzini 2015; 2018).

Given the wide range of the observational methods making use of the organic metaphor in the past century, it is not hard to imagine how *adaptation* can become a unifying force in the reconciliation of the different natures of the notion of the project, as well as in the definition of a fruitful combination of urban space and architectural possibilities.

However, despite the manifest potentiality of the concept of *adaptation*, it is equally important to keep in mind that this soft approach does not take into consideration the radical revolutionary processes that are necessarily required by the most pressing and catastrophic issues caused by climate change. If the role of the image as a territorial metaphor is that of acting descriptively not only in the process of understanding, but also in the prospective thinking concerning the production of space, it becomes necessary to investigate the limits and the opportunities of *adaptation*, when applied to the relation between climate change and built environment.

It becomes necessary – in observing the city and its development from an organic standpoint – to hermeneutically anticipate the effects of *adaptation* in all its spatial implications, thereby focusing on the modalities through which the adaptive model can productively affect the metabolic understanding of the city.

Assuming the efficacy of this metaphor in favoring the resilience of a given territory, we must fully understand the potential of its specific features (anatomical, physiological, behavioral) and of its biological variants of adaptation (*préadaptation*, *exaptation*, *transaptation*, *adaptation*). Doing so fosters concrete and useful developments, capable of both tackling short-term emergencies and building a robust set of long-term derivative structures. In other words, we need adaptation – and its variants – to lay the foundations for ambitious projects capable of nurturing an effective and meaningful evolution of the settlements.

Abstract: Current geographies of hydrological risk are rooted in deep inequalities. Every year more than 100 million people are stricken by hydrological extremes, which disproportionally affect low-income and marginalized groups. The severity and the frequency of floods and droughts have often increased as a result of climate and socio-economic changes. In addition to the impacts produced by the event, hydrological extremes also compromise the future of affected communities. The production and distribution of hydrological risk thus raises important questions of justice. Although critical studies have developed different conceptual tools to define and capture how power manifest through unjust water flows, there remains a gap in understanding how this power intersects with hydrosocial extremes and results in disproportionate experiences of drought and flood events. Drawing on different perspectives of justice, this paper reflects on what justice entails in the context of hydrological risk. It argues that understanding injustices in hydrological extremes requires unravelling the dynamics of risk emerging from the mutual shaping of hydrological extremes and society. Finally, the review stresses the need for an inter-disciplinary approach to holistically address the uneven production and distribution of hydrological risks.

Keywords: hydrological extremes, justice, water, vulnerabilities

Introduction: Hydrosocial extremes

Sustainable development of different societal groups hinges on its continuous interactions with risks and losses caused by severe floods or prolonged droughts (Fraser et al. 2017). Every year, these hydrological extremes affect more than 100 million people (Di Baldassarre et al. 2017a). The expansion of the human pressure on water resources, together with other anthropogenic changes, can increase the severity and frequency of hydrological extremes and in turn, affect the environmental and societal systems (Rockström, et al. 2014; Vorosmarty et al. 2013). As a result, in the Anthropocene, floods and droughts do not solely result from atmospheric and hydrological processes, but also continuously re-shaped and triggered by socio-economic processes. These continuous interactions between water and society render floods and droughts hydrosocial rather than solely hydrological extremes.

Socio-economic processes do not merely incubate environmental crises, but also magnify their uneven impacts. If on the one hand, they trigger hydrosocial extremes intensifying the magnitude and frequency of the hazard, on

the other socio-economic processes influence and exacerbate the vulnerability of the systems affected by the hazard (Verchick 2012). In light of this, hydrological risk is best described with the term hydro-social to fairly account for responsibilities and impacts in the production and distribution of floods and droughts risk. We thus define hydrosocial risk as the combination of the probability of occurrence of a hydrosocial extreme and the potential negative consequences it entails. The first component of risk reflects the flood or drought hazard and very much depends on the materiality of water and its continuous interactions with socio-natural systems. The second component instead, reveals the vulnerabilities of the systems exposed to the hazard.

Considering drought and floods hydrosocial extremes means recognizing that they occur within certain political spaces and result from prevailing power structures (Douglass et al. 2018). While water and society co-evolve, they produce uneven geographies of risk. And this co-evolution is marked with power, class, religion, gender and ethnicity (Zwarteveen et al. 2017). As Sanderson (2018) presents it, water flows unevenly, because humans and their social structures are also stratified and unequal. In turn, uneven water flows often result in uneven distribution of hydrosocial risks (Zwarteveen et al. 2017). Current geographies of hydrosocial risk are thus rooted in deep inequalities, which further exacerbate as water and society co-evolve (Fraser et al. 2017).

For this reason, floods and droughts solicit a claim for justice, for the way they unevenly materialize and distribute across nature and society (Douglass et al. 2018; Sultana 2018; Zwartveen et al. 2017). Driven by this call, this paper aims to create a better understanding of the injustices that produce or are produced by hydrosocial extremes. Although justice debates have long existed within environmental, water and climate studies, they have not entirely retraced the co-evolution of human-water systems, nor have they accounted for the complex facets and manifestations of hydrosocial risk in an integrated form.

This paper develops the concept of hydrosocial justice to capture its dimensions of inequalities and their relations to hydrological risk. Section 2 briefly reviews analyses of justice in relation to water and environment to elaborate on the different dimensions of hydrosocial justice. Section 3 integrates these definitions with an analysis of the relationship between power and vulnerability in hydrological extremes. Section 4 and 5 advocate for an inter-disciplinary approach, which makes allowance for the manifold factors producing hydrosocial injustices. By dialectically engaging socio-hydrology with critical studies, scholars could comprehensively explain the ways hydrosocial injustices are produced and truly experienced.

What Justice for hydrosocial extremes?

Concepts of justice, equity and fairness have a long history in academic debates. Yet it was only a few decades ago, when environmental and climate concerns started to raise scholarly and public attention, that justice debates interweaved also with water and environmental concerns (Lele et al. 2018).

Environmental justice for instance, provided a deep critique of the uneven distribution of costs and benefits of environmental degradation across different societal groups (Holifield 2001; Schlosberg 2013). More recently, global debates on climate mitigation and adaptation, have raised specific questions around climate justice, focusing on equity implications of climate change and its responses (Steele et al. 2015). While the water justice movement questioned how to fairly distribute water access rights and political water decision-making (Zwarteveen et al. 2014; Sultana 2018; Perreault 2014). Lately, disaster justice became concerned with how issues of socioecological justice follow moments of crisis, rupture, and displacement (Douglass et al. 2018; Williamson 2018). The injustice theorized by those scholars, manifests for instance, in the release of pollutants into a river affecting marginalized areas or in the over pumping of groundwater sources which mostly deprive less powerful water users. Injustice materializes as well in government resettlement plans that exacerbate floods' impacts mostly in resettled areas.

Whilst departing from different standpoints (climate, water, and the environment), this scholarship places much attention on distributional justice, which focuses on the outcomes of distribution mainly in economic and material terms (Schlosberg 2013; Perreault 2014; Zwarteven et al. 2017; Zwarteven et al. 2014). The procedural and recognition justice instead, emphasise the ways in which decisions are taken and who is involved (Zwarteven et al. 2014). These concepts have also been expanded to include intergenerational justice, which appeals with ideas of fairness and obligations among different generations (Weiss 1990). Moreover, understanding that distribution, procedure and recognition are necessary but not sufficient conditions, Schlosberg (2013) adds the dimension of capability to better understand and eventually achieve justice. When capabilities are opposed to idealized rights, justice becomes the actual possibility of an individual to fully function and maximize its potential (Schlosberg 2013). Lately, most of these scholars, emphasising the integrity of socio-natural systems, aim to expand the arena of struggle also to non-human species (Schlosberg 2013; Zwarteven et al. 2014; Strang 2016).

From the dimensions through which these scholarships dissect justice, it becomes clear how justice closely relates to questions of power and how analysis of power structure and power imbalances are essential for understanding injustices (Cook et al. 1986). These many dimensions of justice are all equally relevant and significant when it comes to justice in hydrosocial extremes. Overlooking these aspects would mean to ignore how certain disparities originate and manifest (Klinsky 2017). However, these wide-ranging characterizations of justice give little help to scholars, which seek to recognize the injustices entangled with hydrosocial extremes. Any claim for hydrosocial justice should make allowance for and understand how floods or droughts risk is produced and distributed across nature and society. Particularly, scholars should examine the two components of hydrosocial risk for understanding how hydrosocial extremes can become unjust.

Here, the evolving fields of the political ecology of water, human geography, hazard and vulnerabilities studies or disasters studies, are particularly relevant. These scholars have fundamentally retraced how power reshape the water regime and (unevenly) redistribute water flows. Similarly, they have also illustrated how such power generates differential vulnerability to floods and droughts. The following paragraph recasts major critical studies, with an attempt to describe and define injustices that produce, or are produced, by hydrological extremes.

Unravelling power and injustices in hydrosocial extremes

Injustice in hydrosocial extremes manifests in the disproportionate vulnerability to floods and droughts of certain social groups in relation to others. These inequalities (in risk and opportunity) are largely a function of the power relations operating in every society (Bankoff, 2003). The following paragraphs illustrate how hydrosocial injustices deeply relate with power when it materializes in uneven water flows or when it produces disproportionate vulnerabilities to hydrosocial extremes. This section finally recommend not to discount the materiality of the water systems, and look at the ways power intertwines in the production of extreme hydrological conditions and their uneven experiences.

About power that produces disproportionate vulnerabilities

‘Vulnerability’ (Adger 2006) is defined as the ‘state of susceptibility to harm, powerlessness, and marginality of both physical and social systems’ exposed to stresses (Adger 2006). Therefore, different vulnerabilities imply different hydrosocial risks and result in unequal experiences of hydrosocial extremes.

Vulnerability studies have often guided normative analysis of interventions necessary to reduce risk and subsequently enhance well-being (Adger 2006; Pelling 1999; O'Brien et al. 2004). The many methods and

epistemologies developed in vulnerability research (e.g. Entitlements studies, Human ecology, Natural hazard, Pressure and release model or Vulnerability, adaptation and resilience of social-ecological systems) reflect the divergent objectives of the research and the phenomena studied (Adger 2006). However, Adger (2006) identifies common features among the conceptual tools used for assessing vulnerability. He mentions among them, the resources available to cope with risk exposure or their distribution across space, and the institutions that facilitate the access to these resources and other coping strategies (Adger 2006). In particular, those studies describe vulnerability and its manifold manifestations, as the result of social and economic processes of marginalization and inequalities (O'Brien et al. 2004). Pelling (1999) has been exemplary in following these processes when studying the political ecology of Urban Guyana. There, he showed how the vulnerability to flood hazard, represented by the local conditions of coastal areas, was the result of the global political economy which influence the society-nature relations and therefore the experiences of hazard (Pelling 1999). The reduced access to economic assets, the inadequacy of infrastructure, and underdeveloped civil society for instance, they all contributed to expose Guyana's urban and peri-urban households to floods.

Critical geographers like Mustafa and Collins, use the hazardscape concept (Mustafa 2005; Collins 2010; Huber 2019) to further illustrate the way power through discourses and ideologies, influences vulnerability to hazard at multiple geographical scales. Mustafa (2005), in his work *The Production of an Urban Hazardscape in Pakistan*, unpacks the politics that shape the geography of hazard in the Lai floodplain, Pakistan. He analyses the vulnerability and response to floods with reference to the material and discursive context influencing those factors. In this way, hazardous places become function of multiple and diverse variables across different scales, i.e. the global political economy (Mustafa 2005). The vulnerability of the Lai floodplain residents is thereby view as the result of policies and projects biased toward engineering solutions. The technical and engineering bias of policy makers and consultants do not entirely reflect the river's hydrology nor the social reality of power imbalances and capitalist structures. As a result, certain residents inevitably end up in harm's way. Mustafa (2005) goes further by arguing that the vulnerability to floods in the Lai floodplain is the consequence of a social structure that systematically excludes the poor from the management of their living spaces, gives power to a bureaucracy hostile to the civil society, and facilitates alliances between that bureaucracy and the land mafias. Similarly, Collins (2010) describes the unequal distribution of flood risk in the 2006 El Paso (USA)-Ciudad Juárez (Mexico) flood disaster. He compares the two areas of El Paso and Ciudad Juárez, to show how their distinct urbanization has influenced differential vulnerabilities to hazard and created different flood-prone landscapes. Through a marginalization/facilitation framework, he further illustrates how USA and Mexican urbanization processes amplified unequal vulnerabilities and reshaped the 2006 flood disaster. In this uneven hazardous landscape, only the elite can expose themselves to hazard in pursuit of environmental amenities and charming locations. Those benefits accessed by the elite are mostly the result of unjust socio-economic processes (Collins 2010).

Also disaster studies scholars emphasize the socio-political production of disasters and their unjust experiences (Douglass et al. 2018; Williamson 2018; Huang 2018; Parthasarathy 2018; Bankoff 2003; Verchick 2012). These scholars refuse to consider disasters merely natural events, as this would obscure and flatten the political space where they unfold and eventually stop any quest for justice. Moreover, framing of such disasters as natural or divine, could refrain from attributing responsibilities to governance processes or uneven development. Each one of these works usually focuses on a specific context and a singular disaster where scholars analyse the anthropogenic sources of uneven vulnerabilities to hazard. Fiona Williamson (2018) for instance, attributes to the political decision to resettle the Paya Lebar farming community into a flood prone site, the exacerbated scale and cascading impacts of the Singapore extreme flood in 1954. She argues that the framing of the flood as an 'Act of God' was a linguistic and legalistic way for Government and responsible authorities to avoid culpability (Williamson 2018). Accordingly, vulnerability to flood (and drought) starts from the political process that produce unsafe conditions and often determine the highest vulnerability among the marginalized and disadvantaged populations (Douglass et al. 2018).

About power that shapes uneven water flows

Following water flows and the manifold ways this flows distribute in space, political ecologists and critical human geographers have unravelled the choreographies of power, structural processes and hydraulic relations that mark water-human interactions (Ahlers et al. 2009; Swyngedouw 2009; Loftus 2009; Budds 2016). By refusing a-political ecologies this scholarship foregrounds the role of power in shaping the water flow and producing uneven geographies of hydrosocial risk.

Loftus (2009) conceptualisation of (in)justice starts from the injustice of water poverty (Loftus 2009). Throughout his research, he identifies the power relationships through which water is produced and distributed thereby exposing the related injustices. In his 'Rethinking Political Ecologies of Water', Loftus (2009) shows how Durban Water provision becomes an "accumulation strategy" because of broader political economic processes. Durban residents do not freely access to drinking water because water distribution needs to ensure profit and return on investment. As a result, Durban system differentiates among people with free access to their means of production and those who can only sale their labour power to get access to water. Using Loftus words "water is divorced from the majority for the profit of the few" (Loftus 2009). While mobilizing the concept of hydrosocial cycle, waterscapes or hydrosocial territories, other critical scholars have conceptualized water as inherently social and political (Linton et al. 2014; Swyngedouw 2009; Boelens et al. 2016; Swyngedouw 1999). This explains how every instance of the hydrologic cycle is shaped by particular social structures and geometries of power (Linton et al. 2014; Swyngedouw 2009). In turn, it also shows how the social or natural induced variations of the water flow change existing social linkages and reshape social spaces and territories (Boelens et al., 2016). While enhancing environmental quality in some places and reducing them in others, those hydrosocial circulations result in processes of inclusion-exclusion, development and marginalization, and distribution of benefits and burdens that differently affect the concerned social groups (Boelens et al., 2016). So far, their theorizations of human-water interplays have not yet explored the way power manifests in extremes conditions of water scarcity or water flooding which are produced by particular human-water dynamics and which inevitably cause different socio-natural responses.

Swyngedouw uses the Spanish and Ecuadorian waterscapes, to demonstrate how water and power are mutually constitutive (Swyngedouw 1997, 1999). In the city of Guadalquivir, he shows that more than a third of the population remains excluded from supplies of potable water. This injustice for Swyngedouw is the result of an urbanisation which is simultaneously a political economic and a political ecological process (Swyngedouw 1997; Loftus 2009). Through the Spanish waterscape, he illustrates the role that water plays in shaping relations of power. In a way that Franco's fascist project for Spain was produced and reproduced through transforming the hydraulic engineering of the country (Swyngedouw 1999). Boelens (2014) employs the hydrosocial cycle to disclose how Andean cultural beliefs were and are still used to reinforce certain power strategies and therefore legitimize uneven reconfigurations of the water flow (Boelens 2014). Budds (2016) adopts the same conceptual framework to discuss a conflict over water resources for agriculture in Chile. Finally, Rusca et al. (2018) explain the Mozambican State projects (the colonial era, the socialist post-independence state and the neo-liberal state) as a "material re-patterning of hydrosocial territories". As if at different stages in history, water infrastructure helped consolidating the state power by materializing its discursive ideologies (Rusca et al. 2018).

Other scholars, as Rusca et al. (2019), have also tried to materialize political ecology in order to show the role infrastructure has in affecting hydrosocial configurations. By means of redirecting ecological flows and harnessing resources, infrastructure does regulate water and society interplays (Slinger et al. 2011). Water infrastructure reshapes hydro-social systems not only by changing the water flow yet also by reordering societies institutionally, politically, economically and culturally (Rusca et al. 2018; Ahlers et al. 2017; Tiwale et al. 2018; Slinger et al. 2011). While Ahlers et al. (2017) for instance, present Dams as agents in dynamic and

contested spatial strategies; Tiwale et al. (2017) employs water pipelines or storage reservoirs to trace uneven water flows across the City of Lilongwe, Malawi and understand how inequity perpetuates throughout the water supply network.

Overall, those studies unravelled hidden human-water dynamics, retraced invisible flows, and revealed how social inequalities materialize throughout water flows. While focusing on politics and power, they also become useful instruments for promoting equitable hydrosocial relations (Linton et al. 2014). However, this same perspective often overlooks the materiality of hydrological flows and risks missing the co-evolution of human-water systems. In fact, those studies rarely retrace how politics and power can lead from normal to extremes hydrological conditions of floods and droughts. Giving to water anthropogenic traits should not obscure its biophysical characteristics and its continuous interactions with the atmosphere, the land surface and the ecosystem. As the climate and the hydrological cycle, strongly relate between each other as well as with land surface and ecosystem processes. As a result, they influence the production of hazard and the resulting geographies of risk.

How does power exacerbate hydrosocial extremes?

The critical studies examined in this review, comprehensively address the role of power in creating inequalities and struggles for justice at different scales. On one hand, vulnerability, hazard and disaster studies describe how powerful interests assimilated by discourses and policies, influence the decision-making process and in turn, the production of disproportional vulnerabilities to hydrosocial extremes (Adger 2006; Mustafa 2005; Douglass et al. 2018). On the other hand, critical water studies show how power intertwines with water. By uncovering powerful voices, authorities, knowledge and expertise of water, these scholars foreground the role of power and politics in shaping water and society dynamics and creating uneven hydrosocial configuration (Ahlers et al. 2009; Swyngedouw 2009; Loftus 2009; Budds 2016; Zwarteveen et al. 2017).

What remains less explored instead, is the way this power, by creating certain hydrosocial configurations exacerbates into hydrosocial extremes and results in disproportionate experiences of drought and flood events. To explore these processes it is important to recognize the materiality of water and the co-evolution of human and water systems (Linton et al., 2014). Water should therefore remain an active co-agent in the production of hydrosocial risks both for its biophysical characteristics, and for its continuous interactions with atmospheric, land surface, ecological and social processes. A short-sighted focus on human processes already had and will continue to have on the long-term detrimental impacts on human and nature (Strang 2016). The following section reflects on the potential of engaging with socio-hydrology to re-materialise the production of hydrological extremes and to account for both physical and social processes in the production of injustice in hydrological extremes.

Materializing the production of hydrosocial extremes

Conceptualizing hydrosocial extremes as the result of human-water interactions, hydrology started to introduce humans and society in the production of hydrosocial risks and expanded his field of study to Socio-Hydrology (Sivapalan et al. 2012). This research strand is thus a major breakthrough in understanding human-nature interactions and describing how hydrosocial risk materializes throughout history. Socio-hydrology stresses the importance of accounting for the mutual feedback between water and society and posits that ill conceptions and poor understanding of those dynamics might lead to counterintuitive and dramatic consequences (e.g. levee effects, supply-demand cycle etc.). While addressing current societal challenges represented by hydrological extremes, this theory stresses the relevance of a more holistic understanding of human and water systems dynamics.

Sivapalan et al. (2012) introduce socio-hydrology as the science of people and water by presenting the case of the Murrumbidgee River Basin in Australia. With this example, he argues that traditional hydrologists cannot entirely predict neither human induced changes on the water system nor their impacts on water cycle dynamics: *“The common history of hydrology and the societal changes seen in the Murrumbidgee is an example of unexpected process dynamics. Prediction of water cycle dynamics over long timescales is not feasible without including the interactions and feedbacks with human systems (Sivapalan et al. 2012, p. 1271)”*

Socio-hydrologists posit that society and nature change interdependently as well as in connection with each other and that their mutual reshaping continues and evolves over time (Di Baldassarre et al. 2018a; Kallis 2010). On the one hand, society importantly alters the hydrological regime. It modifies the frequency and severity of floods and droughts through continuous water abstraction, dams and reservoirs construction, flood protection measures, urbanization, etc. In turn, hydrological extremes shape societies which respond and adapt to the impacts of floods and droughts spontaneously or through collective strategies (Di Baldassarre et al. 2018a).

Di Baldassarre et al. (2018) elaborate on those human-water interactions explaining the relevance of coupling socio- with hydrology and highlighting that these elements do not merely interact but actually co-evolve and reshape each other over time. In fact, neglecting nature and society interaction and co-evolution might lead to unintended and often counterintuitive consequences. Unforeseeable feedbacks within human-water systems could be i.e. increased flood risk and fatalities due to human settlement in flood prone areas and increased vulnerability due to non-occurrence of flooding or to over-reliance on reservoirs (Di Baldassarre et al. 2018b; Di Baldassarre et al. 2017b; Di Baldassarre et al. 2014; Sivapalan et al. 2015). Di Baldassarre et al. (2017) use the case of Rome to demonstrate how the construction of levees meant to limit future flooding of the Tiber River, by reshaping the socio-economic development of the city has also increased the vulnerability of the people living on the riverbanks (Di Baldassarre et al. 2017b). Through Las Vegas and Athens, Di Baldassarre et al. (2018) demonstrate instead how the construction of complex storage systems by altering the water regime and water availability can increase water demand and people vulnerability to droughts (Di Baldassarre et al. 2018b).

In general, Socio-hydrology should draw on different disciplines and include historical studies, comparative analysis and process based modelling to explain the co-evolution of human and water systems (Sivapalan et al. 2012; Di Baldassarre et al. 2013). Most of the socio-hydrological efforts to date have focused on investigating recurring social behaviour and societal development resulting from their coevolution with hydrological systems (Pande et al. 2017). The majority of these studies have explained coupled human and water systems through quantitative approaches and dedicated efforts to capture human-water interactions and feedback through mathematical model, mostly as non-linear differential equations (Wesselink et al. 2017).

Accounting for both water and nature interactions, socio-hydrology re-establishes an equilibrium that anthropocentric perspectives have so far unbalanced. They have explained and conceptualized the production and of floods and drought risks as the result of human and water interactions. Fewer examples to date explore instead the way those risks unevenly distributes across space. Xi Chen et al. (2016) propose a socio-hydrologic model of the Kissimmee River Basin (Florida, US). This river underwent a channelization in the 1960s and a subsequent restoration in the 1990s for a shift in emphasis from flood protection to ecosystem health policies. Defining this shift as the result of changed human values and preferences, Xi Chen et al. (2016) develop a conceptual model to simulate the interactions between community interests and hydrology. In this model, they are able to account for the power imbalances between the more numerous and wealthy upstream urban residents (in favour of wetland restoration) and the downstream rural residents (in favour of flood protection). Similarly, O'Bannon et al. (2014) are able to expose how the externalization of pollution is disproportionately borne by few countries. They assess the impact of agricultural pollution based on international trade records and nation

specific grey water footprints. By so doing they first show how international trade co-produces and unevenly redistributes pollution. Secondly, they explain how social development status also contributes to such inequality.

So far, socio-hydrologist have mostly formalized hypotheses about generic socio-economic patterns and formulated explicit assumptions about the interactions and feedbacks between human and water systems. Significant aspects that influence the production of hydrological risk as well as shape responses to environmental changes remain unexplored. Except fewer studies similar to the ones presented above, socio-hydrologist did not extensively elaborated on the uneven distribution of risks across nature and society. Also, most of their conceptual tools do not account for the plurality of human values, different human agencies and path dependency of societal power relationships (Massuel et al. 2018). Neglecting power imbalances in hydrosocial extremes can conceal the unfair production of risk and flatten its uneven distribution. As a result, there will remain questions of justice not properly addressed.

Addressing injustices in hydro-social extremes

This reveals how hydrosocial injustices are intertwined with the manifold ways hydrosocial risk is unfairly produced, distributed across, and experienced by those who have power and those who do not. Power materializes in the production of uneven hydrosocial configuration, manifests in disproportional vulnerabilities to hydrosocial extremes and results in unjust experiences of floods and droughts. Together with risk, hydrosocial (in)justice emerges and unfolds within society and nature continuous interactions. As a result, ensuring socially-just governance of hydrological extremes entails unravelling the dynamics of risk emerging from the mutual shaping of hydrological extremes and society. From here, this review leaves three major recommendations to scholars that engage in justice in hydrosocial extremes.

First of all, considering the complexities uncovered throughout this paper, analyses of hydrosocial justice entail moving beyond addressing simple or singular aspect and widening the analysis to broader recognitions of ecological, political and social issues. In other words, this justice requires combining geo-hydrological and climatological insights with understandings of the socio-technical and legal-cultural determinants of water flows. These observations demand an inter-disciplinary approach that combines different disciplines and as a result, is able to make allowance for the manifold factors producing hydrosocial injustices (Massuel et al. 2018). This paper suggests to dialectically engage socio-hydrology with critical studies in order to comprehensively explain the ways hydrosocial injustices are produced and truly experienced.

Second, and more as a philosophical reflection, this review stresses the need to equally appreciate society and nature in the production of hydrosocial extremes. If critical theories have attempted it by insisting on the inseparability of the social and the physical; socio-hydrologists instead, did it by theorizing the co-evolution of social and water systems. This conceptualization should on one hand, help avoid anthropocentric perspectives, which prioritize human needs and gives insufficient significance to the needs of the non-human (Strang 2016). On the other hand, it must also account for the human interventions and consider how existing power structures reshape water flows and related risks (Douglass et al. 2018; Verchick 2012). This conceptual but also practical effort, is crucial when the objective is to ensure a justice for all, which avoids long-term detrimental impacts on human and non-human species (Strang 2016).

Third, questions of justice are scale sensitive as their appreciation also depends on the unit of time and space that are considered. Scale matters when considering those relations and phenomena that are spatially or temporally distant but still contribute to the production of injustice. As a result, justice research should not constrain itself to fixed or predetermined scales but rather maintain time and space scale flexible. In this way any analysis can account for relations and phenomena that may be spatially or temporally distant (Perreault 2014). Studies on justice should explicitly assess the way scales are constructed and how they relate to

hydrosocial dynamics (Zwarteveen et al. 2014). In particular Zwarteveen et al. (2014) suggest to pay attention to terms such as ‘local’ and ‘global’, because so-called ‘local’ phenomena are often manifestations of supra-local processes and powers.

The strategic dilemma of an open and closed approach of transitional change. Comparing three transition paths to sustainability in the Netherlands.

Ries van der Wouden

PBL Netherlands Environmental Assessment Agency, ries.vanderwouden@pbl.nl

Abstract: The paper aims to make two contributions to the literature on planning and transitions. First, it analyses transitional change as an open and closed process. The policy challenges are ‘wicked problems’ with unforeseen uncertainties, multiplicity of political values, and complex institutional systems. Dealing with these kind of challenges requires an open approach. Yet, in spite of the wickedness of the issues at stake, policymakers tend to treat transitional change as a closed process: as a large project with fixed goals, road-maps, time-tables, and strategies to reduce uncertainty. The paper argues that this is not a matter of ignorance but the result of institutional mechanisms that push policymakers towards a closed approach. Second, the paper analyses how a closed approach leads to the exclusion of crucial aspects of transitional change, in particular the matter of social justice. It argues that, whereas some transition processes exclude social justice issues, it is better to include them in order to design an open and viable transition strategy. These issues are demonstrated by a comparative analysis of three transition paths to sustainability in the Netherlands: climate and energy, agriculture and food, circular economy.

Keywords: Sustainability; long term planning; the Netherlands; comparative analysis

Introduction

The political debate on climate change has triggered a renewed interest in long term policy. The downfall of the Berlin Wall and the following two decades of ‘less state, more market’ had given long term policy and planning in general a bad reputation, albeit less so in continental Europe than in the USA and UK. But the urgency of a transition to a more sustainable society has changed this. Long term policy is back on the political agenda, but in a different way than during the 1960s and 1970s. The ‘rationalistic’, ‘blue-print character’ and the ‘central-rule approach’ of former long term policies have been effectively criticized by political scientists and economists (Simon 1957, Rittel and Webber 1973, Van Gunsteren 1976, Pressman and Wildavsky 1979, Rhodes 1996). The times of modernist, rationalistic planning are behind us. Long term policy nowadays has a more reflexive character:

rationality is bounded by principal uncertainties of long term processes, the long and complex road from plan to action is recognized, and the central government rule is replaced by the concept of governance. But this new, more reflexive context of long term policy produces its strategic dilemma's. One of them is the dilemma between an 'open' and a 'closed' approach: the recognition of uncertainties and multiplicity of political values, multi-actor processes, adaptive strategies and learning processes versus policy as a large project with fixed goals, road-maps, time-tables, and strategies to reduce uncertainty. This dilemma is at the heart of long term transition policies to a more sustainable society.

The transition to sustainability is not the first long term transition policy in the Netherlands. During the first decades after the Second World War, the transition to a modern economic system was a big issue in Dutch politics. The industrial sector was to be modernized, rationalization of the agricultural sector was thought to be necessary to rise food production and to keep prices low, and new relations between labor and capital should prevent economic conflicts in the future. Central government and its institutions played a big part in this transition. The result was a rise in economic production, not only in the industrial sector but also in agriculture (Luiten van Zanden 1997: 171). A number of new institutions came into being: knowledge institutes for the economy and agriculture; corporative structures for consultation between government, capital and labor; organizations to rationalize and coordinate different economic sectors. They formed a sound institutional base for the future Dutch welfare state.

During the 1960s and 1970s it became clear that economic growth caused a lot of environmental problems: pollution of water and soil, smog, reduction of biodiversity by the use of pesticides. Environmental policy gained importance, at the national as well as the local level. Environmental policy led to a reduction of some of these problems. It took some years before it was evident that long-term transitions were needed in order to create a sustainable economy for the future generations, and that some problems could only be tackled on a global level. In the Netherlands, the National Environmental Policy Document 4 (NMP 4, 2001), was an important starting point for transition policies. The document named three essential transitions: of the energy system, of the agricultural system, and towards sustainable use of raw materials. These transitions still are dominating Dutch long term policy, albeit with somewhat different names. Energy transition was related to climate policy, sustainable use of raw materials became circular economy, and agriculture now includes the food system.

The paper is structured as follows. The next section discusses the central theoretical concepts of this paper: open and closed approaches, the role of uncertainties and multiple values, institutions and transitional change. Next, three long term transition policies to sustainability in the Netherlands will be discussed: climate and energy, agriculture and food, and circular economy. In the last section of this paper the transitions will be compared, and some conclusions will be formulated.

Transitions, cognitive systems and institutions: open and closed strategies

Transitions to sustainability differ from day-to-day policies. Whereas the latter usually stay within the borders of the existing policy system, transition policy deliberately aims to change the policy system itself. The existing policy system has to be replaced by a new policy system, embedded within political values reflecting sustainability, with new goals and instruments. Therefore, transition policy is long term policy almost by definition, and involves reflection on political values and the knowledge structure of the policy system. Geels and Schot (2010: 11-12) defined the main characteristics of transitions, which can be summarized as follows.

Transitions are:

- Co-evolution processes that require multiple changes in socio-technical systems or their configurations, including technologies, markets, regulations, infrastructures, cultural symbols.
- Multi-actor processes, usually with interactions between groups from the private sector, public sector, and civil society.
- Radical shifts from one system or configuration to another. ‘Radical’ refers to the scope of change, not to its speed.
- Long term processes, very often 40-50 years.
- Macroscopic. The level of analysis is that of ‘organizational fields’.

This definition refers to transitions as socio-technical systems. In this paper we will concentrate upon the policy systems, connected with those socio-technical systems. The distinction between socio-technical systems and policy systems is important, because policy systems are connected to other policy systems and the political system as a whole. Economic policy, social policy, environmental policy, spatial policy, agricultural policy, they all have developed their own core values, goals, instruments and institutions. They interfere on the level of political choice. Sometimes their core values conflict, leading to political debate and struggle. The last century showed a lot of conflicts between maximizing economic growth and social justice, asking for a more equal distribution of welfare. And during the last decades, conflicts between the values of economic growth and protection of the environment. These value conflicts lead to a shift from the daily routines within the policy systems to the field of political deliberation, political choice, and the search for compromises. It is a shift from a ‘closed’ to an ‘open’ policy context: from a context of policy making as a rather technical set of routines with well-defined risks and no debate on core values to a context with multiple values, unknown risks and shifting institutional structures. The balance between ‘closed’ and ‘open’ contexts within policy systems changes in the course of time, and so does the need for ‘closed’ and ‘open’ policy strategies.

This is also true for transitions to sustainability. Although they often start within the borders of an existing policy system, in the course of time they are confronted with the need to change the policy system and to challenge its core values. But they do so within different contexts, the context of different policy systems and their core values. A transition path to sustainability of the agricultural policy system may be different from the energy system or transport infrastructure. This makes a comparison between transitions to sustainability within different policy systems interesting. It learns us more about which factors matter and which not, and which policy strategies can be transferred to other policy systems and which not. Therefore, this paper compares three transition paths to sustainability in their policy systems: climate and energy, agricultural and food, and circular economy.

The policy systems and their transitions will be compared on following two aspects.

- The cognitive structure of the policy system/transition (knowledge, values)
- The institutional structure of the policy system/transition, including its political, economic and social contexts.

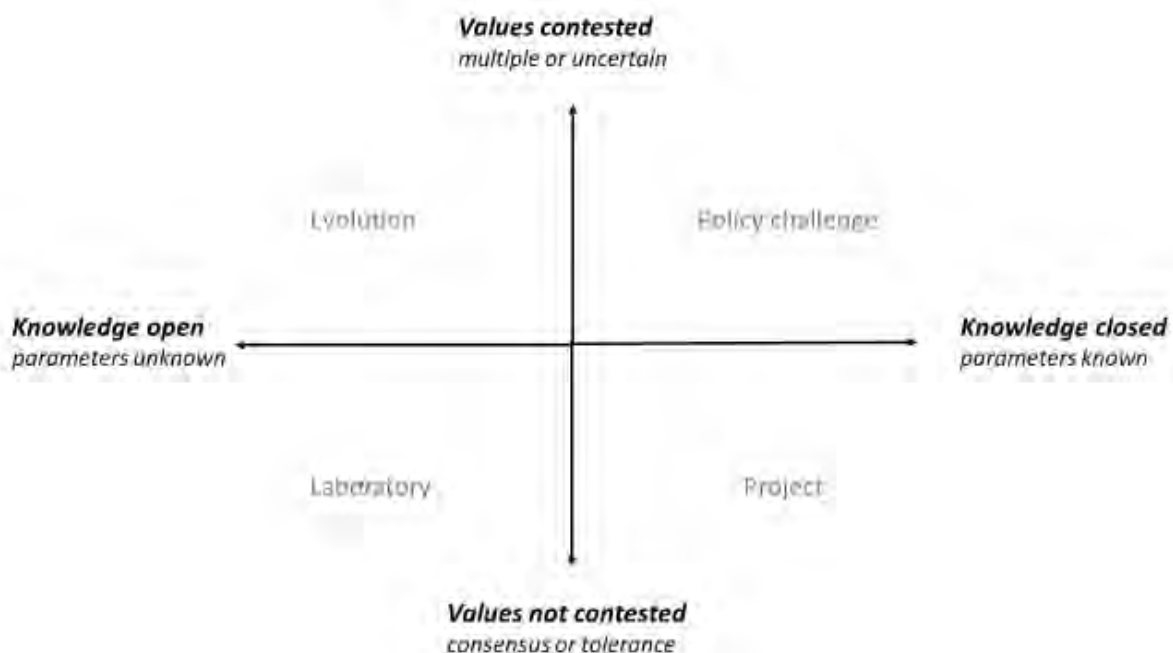

The cognitive structure of the policy system/transition

Policy systems are problem solving machines, among other things. Social, economic or environmental problems enter the policy system through interaction between (parts of) the society and public institutions (problem finding and defining), these problems are ‘structured’, translated into policies (‘solutions’), and matched with the set of available policy instruments, thus leading to bureaucratic action. This is a brief description of the policy making process as a cognitive activity. It is slightly idealized, because very often the policy making process goes the other way around: the existing policies and instruments are matched with a set of policy problems. But either way, it is important to notice that this cognitive dimension of policy making involves both knowledge and values. Sometimes the values seem to be hidden, but they always are there, because policy problems define the gap between an existing situation and a more desirable situation, between ‘is’ and ‘ought’. No ‘ought’ without values, not even in day-to-day policies. But the more ‘fundamental’ the policy problems, the higher the change that the underlying values are debated and contested.

There is a growing collection of scientific literature on the cognitive dimensions of the policy process, especially on the structure and structuring of policy problems. In 1973, Rittel and Webber published their seminal article on ‘tamed’ and ‘wicked’ problems, followed by the publications of many others (Rittel and Webber 1973, Levin et al 2012, Crowley and Head 2017). Others discern ‘structured’, ‘moderately structured’ and ‘unstructured’ problems, referring more or less to the same characteristics as Rittel and Webber did (Dunn 1981: 103-104, Hoppe 2010: 72-75). For ‘tamed’ or ‘structured’ problems, a solution can be found through careful analysis, for ‘wicked’ or ‘unstructured’ problems this strategy does not work. For wicked problems there is no definitive formulation, let alone a ‘best’ solution. Wicked problems are always connected with other problems and therefore lack a final and verifiable knowledge base (there are always ‘unknown unknowns’), and are often situated in a multi-value environment. Environmental policy problems very often belong to the category of wicked problems (Crowley and Head 2017: 533-534), and this is even more true for the long term policies for transitions to sustainability, Levin et al. (2012) even labelled them ‘super-wicked’.

How to connect this cognitive dimensions of transitions to sustainability with ‘open’ and ‘closed’ policy strategies? *Figure 1* shows a typology.

Figure 1. Structure of transitions

The horizontal axis shows the knowledge system, at left side the ‘open’ system (parameters unknown), at the right side the ‘closed’ system (parameters known). The vertical axis shows the value dimension, on top the ‘open’ value situation (values contested or uncertain), on the bottom the ‘closed’ value situation (consensus or tolerance of differences). This results in four quadrants with different policy strategies. The two extremes are Evolution and Project. Evolution means finding your way while constantly dealing with wicked and changing problems definitions and multiple values, with uncertain time-paths and instruments. Core values of policy systems (sustainability) sometimes conflict with others (social justice), often resulting in compromises but without final solutions. This is the most ‘open’ strategy. Projects deal with a tamed problem, consensus over values/goals, optimal instruments, and the possibility to make a fixed time-table. This is the most ‘closed’ strategy. Policy challenge and Laboratory are in between these extremes.

Transitions to sustainability seem to fit into the Evolution strategy. But as we stated before, the structures of policy problems are not ‘fixed’, problem structuring is a cognitive and political activity that sometimes results in a move to another category. An example is the transition of the energy system in the Netherlands. The ‘cutting up’ of the policy problem into several smaller problems resulted in a move from Evolution to Policy Challenge, at least temporally. This will be discussed in the next section. However, there is a constant pressure within policy systems to move from ‘open’ to more ‘closed’ strategies, not only because the necessity to operationalize of policies demands this, but also for reasons of political accountability (‘what results can be expected and when?’). All forms of reflexive long term policies face the dilemma between an open and a more closed approach, according to Voss, Smith and Grin:

‘On the one hand, the requirement is not to suppress diversity, but to nurture bottom-up spontaneous developments that are open to ambivalence and contestation, and to retain adaptability towards the complex dynamics of change. On the other hand, there remains a requirement to achieve coordination, to take a synoptic view on broader developments, to close contingency, to fix long-term goals for orientation and mobilization.’ (Voss, Smith, Grin, 2009: 281).

The institutional structure of the policy system/transition

Policy systems do not only have a cognitive structure, the institutional structure is equally important. Most of the ‘mature’ policy systems have complex institutional structures. Usually, they consist of central and local governments, private organizations, pressure groups, knowledge institutes, etc. The institutional structures of those mature policy systems are multi-actor and multi-level, and they have uncertain border-areas with other policy systems. Whereas some of the policy outcomes are the result of the actions of one governmental organization, the more often are not. Other actors from the organizational field are ‘co-producers’ of the policy outcomes. This reflects the shift from ‘government’ to ‘governance’ (Rhodes 1996, 2017; Hajer 2009), from central-rule to network policies (Castells 1997).

Transition policies have to deal with this complex ‘organizational fields’. Sometimes, they cut through different policy systems, with different institutional structures. Complex institutional structures are not easy to change, they create their own path-dependence. The complexity of institutional structures is influenced by:

- The combination of public, private, and civil actors
- The number of government layers involved (international, national, regional, local)
- The number of policy systems involved

These policy systems and organizational fields function within the broader institutional contexts, both national and international. Political factors: the legitimacy of the national political system, the role of international organizations and agreements, the level of political consensus and conflict. Economic factors: the preferences of consumers, the role of the international markets, the consequences of the digitalization of the economy. Social factors: national and international pressure groups, the level of trust in a society, the role of civil society (see Geels *et al* 2016, comparing transitions of the electricity systems in Germany and the UK). This varied set of factors is hard to categorize, and their effects differ from policy system to policy system. For example, the globalization of food markets has strengthened the lock-ins in the agricultural sector, and has reduced the capacity of farmers to change their ways of farming. But on the other hand, the 2015 Paris Agreement on Climate Change has enhanced the national capacity for the energy transition. We will discuss the influence of the most relevant external factors in the next section.

Transition policies can move through this institutional and organizational fields with different strategies, again ranging from more ‘open’ to more ‘closed’. The governance-based strategies are more open (collaboration between actors, collective responsibility), the government-based strategies are more closed (public organization responsible). Here, the political pressure comes from both sides. There are pressures towards an open strategy, because of the necessity of a broader public support. But there are also pressures towards a closed strategy, because of political accountability and the need to develop clear ‘guidelines’ for transition policy.

Analyzing transitions to sustainability in the Netherlands

Climate change and energy

The energy system has gone through many transitions in history: from wood to coal, and to oil, gas and nuclear energy. Nowadays, the transition of the energy system is connected with the political discourse on climate change. In order to reduce global warming, there is a growing sense of urgency to switch from fossil energy to more sustainable sources of energy. The 2015 Paris Agreement on Climate change underlined this urgency, and its goals were adopted in the national climate and energy policy in the Netherlands. There is a national Climate Agreement in the making, and a new Climate Law has already passed the Second Chamber of Parliament. The energy transition is the most important, but not the only policy issue in climate policy. There are also policy programs to tackle the consequences of rising sea-level and changes in the river system because of climate change. Recently, political debate on climate policy has flamed up again, because of the rising prices of energy for households.

Its global character and its relation with other political issues has made climate change into a ‘super-wicked’ problem. These are the most important reasons: 1. despite the Paris Agreement, there is no central authority to coordinate and enforce policies; 2. those who are willing to solve the problem are also causing it; 3. time is important and running out, delay enhances the risk of passing a point of no return in global warming; 4. politics discounts the future irrationality (Levin *et al* 2012, 126-130). And we can add one more reason: 5. in the political arena the core value of climate policy (towards a sustainable world order) potentially conflicts with other political values. With these characteristics, climate policy seems to be firmly rooted in the Evolution quadrant of *Figure 1*. But the combination of the Paris Agreement and its translation in national goals with the energy system offered the opportunity to structure the climate change problem into policy programs for energy transition. Policy makers used the strategy of ‘cutting up’ the energy transition into different parts, in order to develop more viable policy programs (PBL 2017). Some of these programs are connected with innovations in the field of energy production. Whereas the energy transition as a whole cuts through a number of policy systems, the ‘cutting up’ in different policy programs connected each program more or less one-to-one to an existing policy system (industrial policy, agricultural policy, housing and built environment, production of electricity, mobility and transport). By this strategy, the energy transition moved from the Evolution quadrant of *Figure 1* to the Policy Challenge quadrant.

The ‘cutting up’ strategy has its strengths and its weaknesses. It has made the implementation of the energy transition easier. Policy makers could concentrate themselves upon their own policy programs and projects. For example, the energy transition in housing and the built environment has been translated into many projects on the level of urban residential areas, very often in cooperation between public and private actors. The possibility to translate abstract goals into action is one of the strengths of this strategy. But it also made the energy transition more ‘closed’, in two ways. First, the different parts of the energy transition had to be ‘fitted into’ existing policy systems: housing, mobility and transport, agriculture, economic policy. Thus, these parts of the energy transition had to adapt themselves to the dominant rules and institutions in the policy system. Second, public and private actors concentrate upon their own part of the energy transition, and lose sight upon the broader context. And this broader context is the source of conflicting values, as became clear in the course of 2018 and 2019. The prices of energy for households did rise more than predicted, whereas the industrial companies with much CO₂ pollution did not seem to pay their just part of the costs of the energy transition. Thus, the energy transition came into conflict with social justice as one of the core values of tax- and income policy. All of a sudden, the

energy transition seemed to be back in the Evolution quadrant. Both the core values and the knowledge base (uncertainty on the income effects and the feasibility of some programs) were contested again. But at the same time, most of the policy programs and projects continue. The energy transition may be situated in both the Evolution and the Policy Challenge quadrants at the same time. The outcome of this balancing act is uncertain, and partly depending on political forces. On hindsight, it would have been wiser to have kept the energy transition more 'open' in order to include social justice issues.

The institutional structure of the climate policy and energy transition ranges from international (Paris Agreement) to regional and local. On the national level, the development of a National Climate Agreement includes many actors, ranging from public to private and civil society, including NGO's. On the regional level, provinces, municipalities and water boards cooperate in the design of regional energy strategies. Here, the shift is made from a government to a governance system, from a closed to an open institutional system. But the balance between government and governance in climate and energy policies is still a dilemma that comes to the surface of the political debate from time to time. On the one hand, more government actions and choices can create more certainty for investments from the private sector and citizens (electric cars, sustainable houses), on the other hand an inclusive governance structure enhances the legitimacy of the climate policy and energy transition and makes room for innovative initiatives.

Agriculture and food

Agriculture has a long history of transitions and a strongly institutionalized policy sector. National agricultural policy started after the crisis in food prices at the end of the nineteenth century. Farmers formed cooperative organizations for the purchase of seeds and fertilizers as well as for the production of dairy products. The government started with information services for farmers, research institutes and an educational system, ranging from basic vocational training to the Wageningen agricultural university. After the Second World War the institutionalization of the agricultural policy sector became stronger. The Ministry of Agriculture was established, as well as a number of corporative structures and a new research institute, the Agricultural economic institute LEI (Keulen 2014: 24-71). This institutionalized cooperation between government and the agricultural sector became very effective in defending the interests of the agricultural sector, and was known as 'the green front' or even the 'iron triangle'. A modernization program started, including rationalization of production methods, a more efficient use of land, and the enlargement of farming companies. As a result of these actions, there was a strong growth of agricultural production and export of agricultural products. A successful transition to modernity (Grin 2010). There was broad consensus on the core values of agricultural policy: efficient production methods and land use, food security, and secure incomes for farmers. These values formed a rather closed policy system. The wicked problem of fluctuating food prices and food shortages seemed to be tamed. Agricultural policies were firmly situated in the quadrants of Policy challenges and Projects of *Figure 1*. Technological innovations were framed by the search for rationalization and efficiency of agricultural production.

But the economic success had its downside. During the 1960s and 1970s it resulted in the overproduction of dairy products, and the first environmental problems became visible. There were concerns on the effects of pesticides on human health, on the degradation of the landscapes by the agricultural companies, and on animal welfare. The spatial impact of the modernization of agricultural sector was huge: agricultural land use covered about two-third of the Netherlands, and changes were visible everywhere in the countryside. The societal image of the agricultural sector became more and

more negative: from successful economic sector to 'bio-industrial complex'. A strong environmental counter-discourse against modern agricultural production came into existence, and soon gained much social support. This critical current existed of two branches: a 'eco-fundamentalist' and a 'eco-efficient' branch. The first branch based itself upon counter-values against the dominant agricultural practice: small-scale and biological production methods, living in harmony with the earth, less or no meat consumption. It promoted an alternative agricultural and food system. The second branch tried to reconcile ecological values with economic values, promoting more efficiency in order to reduce the environmental effects of agricultural production while preserving the economic vitality of the sector. And more efficiency implies large scale rather than small scale farming. From the 1990s onward, the globalization of food markets and the decrease of national government subsidies led to a downward pressure on food prices, and the 'eco-efficient' branch became dominant, in production as well as in the policy system (Schoorman 2013). This resulted in a 'lock-in' of agricultural production. Farmers have to rise their production levels and to invest in new technologies (often with borrowed capital) in order to survive. Alternative ways of production become more and more difficult, if not impossible. And the changes in the institutional system have enhanced this. There is less government influence, but instead the farmers have become more and more dependent upon the big supermarket-companies, the most powerful actors in the food system. The 'lock-in' of agricultural production itself is related with this institutional 'lock-in'. Compared to the two other transitions discussed in this paper, the agricultural policy system does not have to deal with many other policy systems, but is by far the most institutionalized policy sector, thus creating its own path-dependencies. The complexity of the institutional arrangements was enlarged by the growing influence of EU-policies, not only in agricultural policy, but also in environmental and nature policy.

But at the same time, a number of crises (BSE, Q-fever, animal welfare issues, reduced biodiversity, and degradation of nature close to agricultural areas) shows that the eco-efficient approach has reached its limits. Some environmental goals have been absorbed into the rather closed approach of eco-efficiency, but a transition to a more sustainable agricultural and food system asks for more changes (PBL 2018b). A more 'open approach' is wanted, to combine the value of efficient food production with sustainability values. However, there is consensus that the negative environmental effects of agriculture should be reduced, but far less on the transition itself. What values must prevail: animal welfare, reducing the effects on biodiversity and climate change, protecting landscape and nature? And can these values be combined with protecting the economic vitality of the agricultural sector, with affordable food prices, or with feeding a growing world population? What to expect from technological innovations, and how to prevent more dependency of farmers from banks and supermarkets? How can the policy system influence agricultural production and consumption? These are the fundamental issues in the transition of the agricultural and food system in the Netherlands nowadays.

Answering these fundamental questions for a future transition policy asks for an open approach, including and confronting the different values in a public debate. And an open approach on the institutional level: including producers, governments, consumer organizations, supermarkets and NGO's. The need to take this essential step towards a transition to a more sustainable agriculture and food system is now recognized by the Dutch government (LNV 2018). In 2019 further steps in the debate and the design of a transition policy will be taken.

Circular economy

Compared to the two other transitions to sustainability discussed in this paper, the transition policy from a 'linear' to a 'circular' economy is quite recent. However, the transition policy was preceded by a policy program aiming at recycling waste, from the end of the 1980s onward. In the course of the years, the policy program also focused upon the reducing the use of raw materials, as a stepping stone towards attending the circular economy as a whole. Since 2016 the government of the Netherlands adopted a National Program Circular Economy, with an even stronger focus upon raw materials (I&M and EZ 2016). The program developed a policy goal: a reduction of 50% in 2030 in the use of raw abiotic materials (minerals, metals, fossil energy sources). In 2018, five priorities were formulated: biomass and food, synthetic materials, industrial production, building industry, and consumption goods. There is a strong link with the priorities in the EU-policy on promoting a circular economy.

The transition policy is based upon a ranking order of strategies, ranging from refuse, rethink, reduce, reuse, repair, to recycle and recover energy (PBL 2018c: 11). The ranking order starts with the most fundamental strategy. Refusal, rethinking and reducing the need for raw materials is more fundamental than recycling or using waste for energy purposes. But the most fundamental strategies also demand the most fundamental changes in the economic system, the innovation of products and the process of production. In the Netherlands, the majority of policy actions have been aiming at bringing more efficiency in the process of production, and the recycling of waste in the process of consumption. Here, the situation is comparable to the agriculture and food system: policies are directed at maximizing the eco-efficiency of the existing economic system, not at transforming the system itself. There is no operationalized transition strategy, the strategy is still in the phase of translating concepts into policies. In this respect, it lags behind the Climate change and energy transition program.

A more fundamental transition strategy also demands innovation, in products and in processes. In 2019, PBL published the results of a research project monitoring circular activities in Dutch society (PBL 2019). This study had two important conclusions. First, not all circular activities are new. The majority of activities is rooted in the traditional economy, such as the repair of bicycles and cars, and reselling used furniture. Second, only a minority of the activities have an innovative character, in the sense that they are aimed at the change of products and processes of production. Many of these innovative activities are 'recycling' initiatives, experimenting with new ways of reusing materials. This innovative initiatives situates the transition policy towards a circular economy in the Laboratory quadrant of *Figure 1*: trying to find out what works and what not. The PBL report advises the government to give more support to innovative initiatives outside the recycling category, in order to develop a more fundamental transition strategy. This strategy could bridge the gap between policy concepts and practice. It is also a strategy to postpone fundamental debates on the core values of the transition, and its potential conflicts with other political values. The approach is 'open' in its experimental search for new knowledge, but 'closed' towards the debate on core values, at least temporally.

The institutional context of the transition to a circular economy is potentially complex. It connects activities on many levels, from the global markets of raw materials to local activities. And it at aimed at changing the most fundamental social system, the economy as a whole. Therefore, it involves many policy systems, and many public and private actors. But in this phase of the transition, much of the institutional complexity is still hidden. There are some initiatives to coordinate activities towards a circular economy, such as the national Raw Material Agreement. But compared to the Climate and energy transition, this 'open' approach is still in its starting phase, and it misses the urgency of

internationally agreed goals like the ones in the Paris Agreement on climate change. But on the other hand, the transition policy toward a circular economy can learn from the successes and failures of the other transitions to sustainable development. And recently, the Minister of Agriculture adopted a circular approach to promote more fundamental change in the agriculture and food system. This could give a boost to the circular economy transition.

Comparison of transitions and conclusions

In the preceding section the three transitions are analyzed separately, in this section the transitions will be compared in relation to the cognitive and institutional aspects discussed in the previous section. The results are summarized in *Table 1*.

Table 1 Three transitions compared

Aspect	Climate/energy	Agriculture/food	Circular economy
<i>Wicked/structured</i>			
Knowledge	Structured by partial policy programs, innovation	Partly structured by research and knowledge	Not much structured, growing innovation
Values	Urgency, from consensus to re-politicization	Urgency but no consensus, Different core values	Medium consensus and urgency
<i>Institutional structure</i>			
Role private sector	Mixed: some policy issues low, others large	Large	Mixed: some policy issues low, others large
Policy systems involved	Many	One dominating policy system	Many
Layers of governance involved	Global (Paris Agreement) to regional/municipal	European and national dominating	European to municipal
<i>Open and closed approaches</i>			
	Closed on policy programs, opening on (conflicting) core values; governance mixed	Open on core values, tendency to more open governance under social pressure	Open towards innovation processes, fuzzy governance

Some conclusions can be drawn from this comparison:

- There are many similarities between the climate/energy transition and circular economy, especially in their institutional characteristics. Both transitions involve many policy systems, both have a mixed public-private structure. Their governance structure is a bit different, because

of the existence of the global agreement on climate change. A similar agreement is absent in the transition to a circular economy. This is an explanation for differences in both the urgency and the development and implementation of policy programs. The process of transition for climate and energy seems some steps ahead of the transition to a circular economy. This implicates that some lessons can be drawn from the climate/energy transition process for the circular economy transition.

- At the same time, the climate/energy case clearly shows that this large transition is not a linear process. The process of structuration of the initially wicked problem through the creation of partial policy programs was confronted with a renewed political debate on the consequences of the transitions for the incomes of households in the Netherlands. Thus, the core value of the transition, i.e. sustainability, came into conflict with the political value of social justice. The transition process was forced to 'open up' for this political debate. This did not mean that the process of structuration in the partial policy programs stopped, both processes have parallel lives. But it creates an uneasy balance, which can be disrupted by political shifts. On hindsight, it would have been wiser to have kept the energy transition more 'open' in order to include social justice issues.
- The situation of the agriculture and food transition is completely different from the other two, to begin with the institutional structure. Whereas the two other transitions have relatively new policy programs that 'cut through' various policy systems, agriculture has a longstanding policy tradition, resulting in a strongly institutionalized policy system. During the last century, the prime goal of this policy system has been the modernization of the agricultural sector, supported by the rationalization of the production of food. From the 1980s onward, there were two major changes. First, worries about the environmental effects of agriculture became an important policy issue. The 'eco-modernist' strategy tried to combine environmental goals with the modernization program. This strategy has reached its boundaries. Second, the agricultural system has moved from a 'policy ruled' to a 'market-ruled' system, with price-based competition. This creates lock-in situations for farmers, making it difficult to change their ways of production. Most of the actors involved agree that it is necessary to move towards a more sustainable system, but there is much debate about the core values, including the economic vitality of the agricultural sector. But apart from an already initiated open debate on these core values, it is clear that this transition cannot do without a strong program for institutional change.
- What about open and closed approaches? At the level of core values, it is clear that a more open approach is emerging in some transitions. It has the advantage of the possibility to identify potentially conflicting values in an early stage, especially social justice values. Energy prices and food prices are crucial for most households, and lower income households spend a relatively large part of the incomes to food and energy. Social justice values are strongly institutionalized in Dutch society, and therefore it is better to include them in the transition strategy by an open approach (Van der Wouden 2017). This is less clear at the operational and institutional levels. Sometimes a more closed approach can create an operational 'fast lane' for the development of policy programs with clear goals, a transition path with certainty for investors, and accountability towards politics and society. But this strategy comes with some risks. The 'cutting up' of both the energy transition and the transition towards a circular economy into different policy programs implied that these transitions had to adapt themselves to existing policy systems (for the energy transition: housing, mobility and transport,

agriculture, economic policy). At least, the closed approach may be combined with a more open approach at the project level: bottom-up, experiments and trying out innovation. And at the institutional level there is an essential tension between the more open governance strategy and the more closed government strategy. A governance strategy will facilitate economic and social support (and sometimes resistance) and also the use of the creativity of private co-producers of transition policy. But for some types of institutional change, especially when laws and rules are involved, a more closed approach is suitable. Decisions on these issues are the legitimate domain of government.

- The transitions to sustainability will have consequences for land use, especially at the regional and local level. Wind energy, solar panels, combining nature and agriculture, electric cars, water retention because of climate change, new ways of urbanization, they all imply changes in land use. This is where the urban and regional spatial planning comes in, because land-use planning is its core business. The default strategy at this level is an open approach, because the land-use claims of different transitions often have to be combined in the context of scarcity of available land. Involvement of different policy sectors and actors is crucial for success. On top of this, an open approach can facilitate creative innovation in the combination of functions in land-use.

Urban Resilience to Disasters: A Policy Case from Turkey

Selin Adikutlu¹, Meltem Şenol Balaban²,

¹Middle East Technical University, selin.adikutlu@metu.edu.tr

²Middle East Technical University, mbalaban@metu.edu.tr

Abstract: Due to continuous increase of world urban population and urbanization rates, cities are confronting many challenges and problems as over-consumption of the resources, the impacts of global warming, climate change and natural disasters. With the increased concentrations of people and commodities in cities, risks and vulnerabilities are also increasing. This has resulted in the development of new visions for cities to overcome the adverse impacts like achieving disaster resilience or becoming a resilient city. Resilience notion, by covering coping and adapting capacities in multiple aspects of ecological, social, economic, community and governance, also help to connect disaster risk management and envisioning sustainability within cities with several public policies and community-based movements. Disaster resilience is described as a set of actions for preventing the possible losses and reducing risks while increasing the capacity to recover when facing any disturbances like disasters. In this respect, resilience thinking in urban planning helps to understand the capacities, vulnerabilities, risks, to connect multiple aspects with each other and to build or enhance capacity in a systematic way. This paper that is based on the MSc research study seeks to identify the relationship between urban regeneration policies and disaster resilience by using the Turkish Law no.6306 “Transformation of Areas Under Disaster Risk”. For this reason, the law and its regulations were analyzed by using urban resilience to disasters framework. Based on the findings of the study it could be asserted that the Turkish urban regeneration experiences reflect that the policy instruments of the Law like “risky areas, risky buildings and reserve areas” are as a way of disaster risk mitigation including protective, preventive and transformative measures which contributes to the reduction of vulnerabilities, addressing different dimension of resilience yet with several limitations and challenges.

Keywords: Resilience; Disaster Resilience; Urban Regeneration; Turkish Law no.6306

Introduction

World’s urban population has been rising day by day resulting in a continuous increase in urbanization rates. Due to increased rates of urbanization cities are now facing variety of problems and challenges, like over consumption of the resources, the impacts of global warming and climate change. It is widely accepted that natural disasters are results of human activities so that the risks and vulnerabilities in cities are increasing because of increased concentration of people and commodities. In this respect along with the sustainable development goals, several universal targets are set as achieving disaster resilience or becoming a resilient city (UNISDR, 2012). In this respect, originated from the ecological studies, resilience is now a notion used across many other disciplines varying from social sciences, engineering to development studies. The principal characteristic of resilience is, it is a concept for describing the adapting, coping and transforming capacities of

complex systems when facing disturbances, shocks or changes (Brand and Jax, 2007). With the evolution of the concept, some argued that resilience thinking includes the ‘learning’ capacity as well as coping and adaptive capacities in systems. So, one way of defining resilience is, developing the capacities through learning to sustaining development when come up against unexpected or wonted changes and disturbances (Folke, 2016). This concept is adapted to the new challenges in cities like disaster risk management. As highlighted by Cutter (2014), resilience thinking help connecting disaster risk management, disaster risk reduction and envisioning sustainability within cities with several public policies and community-based movements. Resilience notion in disasters research stands for set of actions for preventing the possible losses and reducing risks while increasing the capacity to recover when facing any disturbances like disasters (Johnson and Blackburn, 2014; UNISDR, 2017).

On the other hand, with the economic restructure in cities beginning in 1980s, urban regeneration policies became one of the core urban policy of local governments as a solution to the challenges and problems occurred in urban areas. Even though the main purpose of the urban regeneration concept was commonly accepted as to develop new urban spaces within the deindustrialized cities, the policy and its instruments used in solving many other urban problems such as regeneration of illegal settlements (Roberts, Sykes and Granger, 2016). Lately, the policy is also used as a way of disaster risk management, a mitigation or a recovery tool in facing disaster risks in cities. A variety of urban regeneration cases from world, show that urban regeneration help addressing the urban problems in multiple dimensions in cities. Yet there is no clear description about the ways of developing urban regeneration policies in the context of disaster resilience in cities.

From this point, this research seeks for finding answers to the question of “in what ways urban regeneration policies connected to the disaster resilience?”. With this aim, the Turkish Law no.6306 Transformation of Areas under Disaster Risk (hereafter the Law no.6306) is analyzed in this research.

Research Methodology

This study was designed based on the major research question and finding answers and evidences from Turkish Case with analyzing the Law No. 6306 Regeneration of Areas Under Disaster Risks in Turkey. Although the research covers 3 steps of analysis which were policy, institutional and sample implementation project analysis, within the theme and track of the AESOP 2019 Conference, the focus of this paper is policy analysis based on the Turkish Case.

Main reason for selecting this case from Turkey is because the author herself has experience in the practice of decision-making and implementations of this law. Even so, the literature was reviewed to identify other cases to study where urban regeneration policies and/or projects were developed in the context of disaster risk management. However, there is very limited information about other examples in the literature.

On the other hand, the Turkish Case of Law no. 6306, was used as an evidence because the law is enforced since 2012, which provide six years of practice experience to be analyzed. And also, this law is covering the whole country and is implemented in many different cities which provides the wide range of implementations for analysis and discussion rather than a project-based analysis.

To allow a comprehensive analysis of the law with the policies defined this study includes a secondary data collection. The statistical data about the implementations of the law, urban development plans were collected from the Ministry of Environment and Urbanization. The secondary data resources that were used in this research were mainly the academic articles and researches, theses and official reports both about the theoretical background of the study and for the analysis of the urban regeneration policy case of Law no.6306.

Disaster Resilience and Urban Regeneration

This section would like to draw theoretical framework of this research which is about the urban regeneration policies in the context of disaster resilience. For this purpose, firstly the resilience concept is evaluated with respect to the evolution of the concept, the components and its system. It is emphasized by several researches that the main elements of resilience are adaptive, coping and transformative capacity of complex systems (Figure-1) (Brand and Jax, 2007; Béné *et al.*, 2012; Eraydin and Taşan-Kok, 2013). And the resilience is “a way of thinking” which aims to not only have the capacities but also improve these capacities by learning while facing sudden or expected disturbances (Folke, 2016).

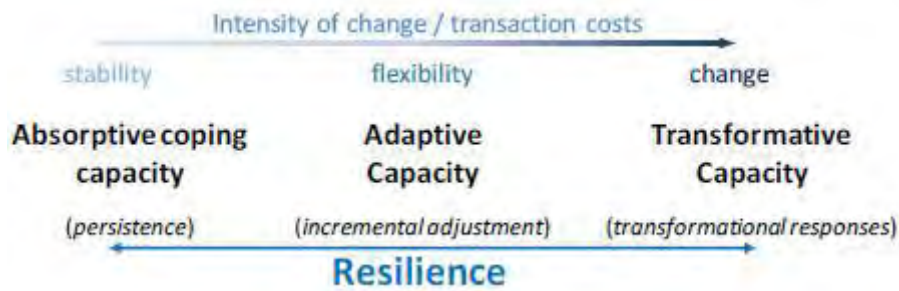

Figure-1: Resilience Framework (Bene et al., 2012)

Based on this research about resilience, before drawing the connections between resilience and disasters, first, it is essential to explain the urban resilience concept and its four dimensions about metabolic flows, governance networks, social dynamics and built environment (Figure-2) (Resilience Alliance, 2007; Chelleri, 2012). In this respect, urban resilience is defined as the capabilities in all dimensions within the urban system to keep up or restore the functions after facing any kind of disturbances for providing adaptation to change and building transformation capacity to enhancing future adaptive capacity (Resilience Alliance, 2007; Chelleri, 2012; Meerow, Newell and Stults, 2016).

Figure-2: Conceptualizing Urban Resilience (Chelleri, 2012; Resilience Alliance, 2007)

For revealing the framework of disasters and urban resilience, the literature regarding the disaster risk management, was also reviewed. This review shows, there exist different disaster management approaches and the literature about disaster risk management evolves with the help of international conferences such as World Conferences on Disaster Reduction took place in Yokohama in 1994 and 10 years after in Kobe Hyogo Framework and the Sendai Framework for Disaster Risk Reduction (DRR) (2015-2030). The development of disaster risk management reflects the emerging concepts such as disaster risk reduction and mitigation planning and other measures targeting not only post disaster actions but also pre-disaster approaches to achieve disaster resilience and sustainable development. As can be seen in Figure-3, after 2015 with a paradigm shift from managing the disasters to management of risks, the 2030 Agenda, the Paris Agreement on climate change, the New Urban Agenda (NUA), the Addis Ababa Action Agenda (AAAA), cover Disaster Risk Reduction and resilience measures, parallel with the goals and targets of Sendai Framework and accept the Disaster Risk Management as one of the prerequisites to building resilience (UNDRR, 2019). This new approach creates window of opportunity in cities and societies to “build international coherence and foster risk-informed policy and decision-making; promote multi-hazard and cross-sectoral approaches to assessing risk; and encourage a deeper understanding of socioeconomic and environmental vulnerability across different sectors and levels of government” (UNDRR, 2019, p.30)

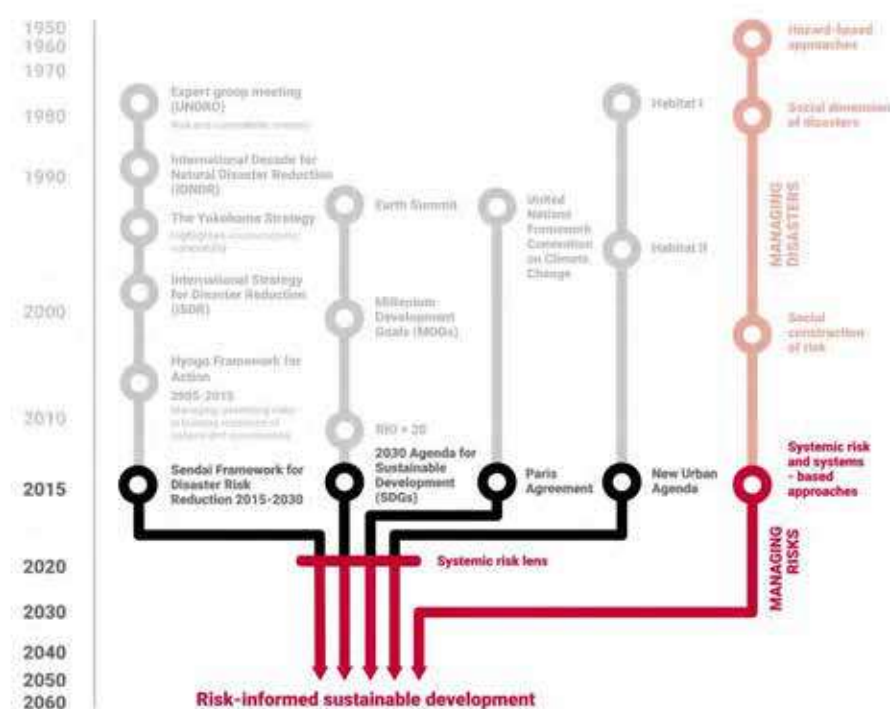

Figure-3: Timeline of Global Disaster Agenda (UNDRR, 2019, p.25)

Sustainable Development Goals (SDGs) for 2030 Agenda, acknowledge the role of risk reduction and resilience in sustainable development policy giving direct reference to the Sendai Framework. In this respect, there exist several indicators and targets related to risk reduction. Another milestone agreement is Paris agreement on climate change where DRR and resilience encrypted in the Agreement’s several Actions include call for actions that have direct implications for disaster risk (UNDRR, 2019). As reviewed in the latest Global Assessment Report on Disaster Risk Reduction, Paris Agreement has common objectives with Sendai Framework related with strengthening communities’ resilience across the full range of environmental, technological and biological hazards. The global framework for financial aspects of development, in post-2015 period is mainly driven by the Addis Ababa Action Agenda where there exist some references to the Sendai Framework. For instance, it reinforces climate and disaster resilience measures in financing development and entails innovative ways of

financing development with allowing prevention and management of risks, enhancing the national and local actors' capacity while managing DRR (UNDRR, 2019). Further, the New Urban Agenda includes visions, principles and commitments related with DRR and resilience. According to NUA, there exist measures including the sustainable management of natural resources in cities for promoting DRR, promoting proactive risk-based, all-hazard and all-of society approaches (Habitat III Secretariat, 2017). For the resilience, there exist commitments of Member States for improving the resilience of cities to disasters with implementing approaches defined in the Sendai Framework (UNDRR, 2019)

As reflected within the global development and disaster risk management agenda, disaster risk reduction and resilience are core of the global policies. In this respect in for understanding how resilience thinking is integrated with disaster risk management the literature related with (urban) resilience to disasters were reviewed. Cutter (2014), highlighted the non-existence of a universal definition of the 'disaster resilience' concept where consensus on some parameters exists. In the majority of the definitions, besides the engineering notion, the disaster resilience concept developed for connecting disaster risk management, disaster risk reduction and envisioning sustainability of communities by adopting several top-down and community-based actions (Cutter, Burton and Emrich, 2010; Cutter, 2014; Johnson and Blackburn, 2014; Parsons *et al.*, 2016; UNISDR, 2017)

The definition adopted in this study is; resilience to disasters is about, capability of a system or a community to prevent, absorb, adapt or recover from the impacts of a disaster while ensuring to preserve, restore or improve its structures and functions (Cutter, 2014). The components of this system or community which also creates the adaptive, coping and transformative capacity are described as; resilience of ecological, social, economic, institutional and physical (built environment).

Finally, the development of the concept of urban regeneration is reviewed with respect to its contribution to and relationship with the disaster context. For these purposes also, the international cases are analyzed. Concluding from the findings of the literature, there exist an increasing emphasis on urban policies and also urban regeneration as a way of pre-disaster mitigation and risk reduction approach and post disaster recovery and reconstruction mechanisms.

Turkish Case: The Law no.6306

Starting with the review of urbanization and policy context in Turkey, the findings shows that the fast urbanization pattern starting from 1980s with taking the economic restructuring in cities into consideration created new urban forms, new production patterns, new relationships between the people and its environment (Tekeli, 2014). These increased densities of people and buildings, new production and consumption patterns, spatial development phenomenon within the urban areas also have an impact on disaster risks and vulnerabilities in cities. As explained Turkish cities are prone to many disaster risks, primarily earthquakes and floods (Şenol Balaban, 2016). But also, the urbanization experience in many cities created new types of risks such as; the reinforced structures constructed in high rates without having technical consultancy, the urban development without allocating the required amount of open spaces, construction of infrastructure without a plan, the location of emergency facilities, the location of industries and ineffectuality of central and local administrations (Balamir, 1996; Şenol Balaban, 2019)

The urbanization pattern and economic restructuring in Turkish cities resulted in the need for regenerating the areas where illegal settlements were built named as Gecekondu, and the historic centers in metropolitan cities which was mainly dominated by industrial activities. For these purposes, several urban regeneration policies were developed with laws and regulations. The first urban regeneration policies were mostly highly centralized policies adopted to the squatter settlements by the central government (Şengül, 2012; Balaban, 2013; Tekeli, 2014). This was followed by a more decentralized urban regeneration laws in 2000s focusing on redevelopment in historic sites, regeneration and development areas with the law no.5393 and no.5366 implemented by

municipalities. Lately, with the law no.6306 a new centralized urban regeneration policy was developed focusing on regeneration of areas under disaster risk with three types of implementation tool; risky buildings, risky areas and reserve area.

The analysis of the policies of the law no.6306 was conducted through the lens of resilience to disasters framework described in the previous section. The analysis shows that the law has protective, preventive, promotive and transformative intervention mechanisms which have an impact on coping, adapting and transforming capacities at different levels and scales. For instance, the risky building and risky area implementations aim to transform the risky building and places and create new and safe living areas for the community. This approach can be identified as a both preventive and transformative intervention mechanism for protecting the people before any disaster take place and transform the system into a more resilient one with creating or sustaining the existing coping and adapting capacity of places and people. Here, the adapting capacity is about the capacity of organizing responses while facing internal or external disturbances in favor of development and coping capacity is about balancing or safeguarding the impacts of any disturbances or shocks related with disaster risks on livelihoods and commodities. Also, it defines a requisite of negotiation in risky area and risky building implementations which also have an impact on the resilience in a community by increasing the transformative capacity with creating a room for developing a new system when the current system is indefensible. However, this analysis shows the possible impacts of the policies defined in the law, neglects the real impacts faced in implementation of these policies.

Lastly in the analysis of risky area implementations; the data about 230 risky areas were collected from the Ministry and studied for providing a comprehensive idea of the implementation principles and methods. When the risky areas studied countrywide, the majority of the risky areas are in metropolitan cities which is in high earthquake hazard zone. However, this analysis expresses limited information and needed to be developed with a multi-risk analysis. Also, when the distribution of the risky areas considered the dominance of metropolitan cities like Istanbul and Ankara proves the fact that regeneration projects were still developed with a knowledge based on previous experience about urban regeneration.

Findings and Conclusion

The analyses about the urban regeneration and disaster resilience in cities explored the connection between urban resilience to disaster concept and urban regeneration policies and show that regeneration policies like within the Law no.6306, contribute to the resilience to disasters in cities but with some limitations and shortcomings. From the analysis of the policies developed within the Law no.6306, it can be said that there exist several measures aiming disaster resilience and providing actions for disaster risk management with the help of urban regeneration. For instance, the law aims creating resilient cities with safe and liveable environments. With including the resilience in the context of a policy which is administered by a central institution as the Ministry of Environment and Urbanization, the law is contributing to the relationship between built environment, planning and disasters. However, even the law includes both building level and area-based implementation tools such as risky buildings and risky and reserve areas, the connection between these measures and regional and city level urban development policies left ambiguous within the law. More, there exist limited policies defined in terms of comprehensive disaster risk management. The instruments within the law targets primarily the regeneration of the built environment. There also exist only several financial instruments and a negotiation method defined in the law which could contribute to social and economic resilience. But as reflected in the theoretical chapter of this thesis, there need to be ecological, social, economic, institutional and physical resilience measures covering all four dimensions of urban resilience.

As a concluding remark, when the current global urban development agenda is recalled, as reflected in the SDGs and NUA, developing *risk-based, all-hazard and all-of society* approaches while setting the objectives for resilient cities and societies is essential. In this respect, the Law contributes to the proactive risk-based

approaches with including policy instruments focuses on risk concept in buildings (risk building) and urban areas (risky area) yet still have shortcoming related with the all-hazard approaches as the implementations of the policies concentrates on earthquake prone areas.

CLIMATE CHANGE IMPACTS IN THREE REGIONS OF GREECE: INTERCONNECTIONS WITH REGIONAL PUBLIC PERCEPTIONS AND PLANNING POLICIES

Dimitra Angra¹, Kalliopi Sapountzaki²

¹*aggradimitra@hotmail.com*

²*sapountz@hua.gr*

Abstract: The purpose of this work is to study and compare the impacts of climate change in three regions of Greece, in particular in Sterea Ellada, Thessaly and the Peloponnese. This crisis refers to the impacts of Climate Change, both current and expected, and concerns the social, economic and natural environment, the perceptions of people and the competent authorities, as well as the planning policies which either incorporate or not appropriate mitigation and adaptation measures. In the present work the authors test the fundamental hypothesis, that outdated regional plans and climatic blind regional policies are inadequate in coping with the challenges arising from new climatic environments which characterize new or more pronounced climatic and meteorological risks and vulnerabilities.

Keywords: Climate Change, Public Perceptions, Regional Planning Policies

«This research is co-financed by Greece and the European Union (European Social Fund- ESF) through the Operational Programme «Human Resources Development, Education and Lifelong Learning» in the context of the project “Strengthening Human Resources Research Potential via Doctorate Research” (MIS-5000432), implemented by the State Scholarships Foundation (IKY)»

1. Introduction

Over the past decade, the parameters that make up our planet's climate have undergone significant changes. Since the 19th century, a rise in atmospheric temperature has begun and an important part of this increase has been attributed to the change in the composition of the atmosphere due to human activity. According to the forecasts of the Intergovernmental Panel on Climate Change (IPCC) this rise will continue in the 21st century in most regions of the world, with an increase expected to range between 1.8 – 4 °C (IPCC, 2007).

This rise is estimated to have a greater impact on the mainland and will help to increase the average sea level and incidences of extreme weather events (IPCC, 2013). Recent studies have shown that in the area of the Mediterranean region the intensity of hot invasions is expected to increase drastically and long duration of drought periods causes constant increase of the risk of forest fires (Giannakopoulos, 2009). These changes are expected to have a significant impact on primary, secondary and tertiary sectors (livestock, fisheries, tourism, natural disasters, urban environments, etc.) (Bank of Greece, 2011).

Climate Change (CC) is increasingly a matter of daily discussion, with international studies proving that it is considered by ordinary citizens to be an environmental problem that already exists (Tsakmakidou, 2013). In the following paragraphs, we present the climatic changes and the implications of CC in three regions of Greece, which are the subject of our study examining the socio-economic and natural environments of these regions, the perceptions of both people and the competent authorities, as well as mitigation and adaptation measures implemented or not by the competent authorities, (Bank of Greece, 2011).

The study of the impacts that CC is expected to cause is of paramount importance in terms of planning for sustainability of these three regions. The three regions under examination are very different from each other in terms of geomorphological, socio-economic and climatic conditions, leading us to some key questions:

- How are the impacts and risks of CC specified in and differentiated between the three regions and the climatic zones included in each case? Are these differences reflected to the response priorities of the competent authorities and organizations?
- What mitigation and adaptation measures are taken or considered by the competent institutions?
- Do planning policies incorporate appropriate CC mitigation and adaptation measures?
- What are the public perceptions of the three regions regarding CC? Is there any feedback to these perceptions on the part of competent institutions pushing forward adaptation and mitigation measures?

The above series of questions is certainly not exhaustive. Whatever the answers they will contribute to (a) better understanding of CC's geography, (b) understanding and mapping of the respectively perceptions of the public and responsible institutions and (c) identification of reflections of the above on regional CC adaptation and mitigation policies

The methodological approach is a process of successive steps as follows: first, consideration of the factors related to the different climatic zones in each region and anticipation of current and future climate changes; secondly, identification of the particularities of each region in terms of regional human and economic geography; thirdly, recognition and mapping of public and competent authorities' perceptions of climate change and fourthly actual climate policies and reflections to the actions of competent institutions. The basic sources supporting the work were climatic variables' statistical data, socio-economic primary and secondary data, reports on sectoral and regional distribution of climate change impacts in Greece, regional planning policy documents and public inquiry data.

2. The physical and socioeconomic geography of the Regions Sterea Ellada, Thessaly and Peloponnese - CC impacts and planning policies

Greece is a country featured by different climatic zones. This is due to interaction of weather systems with its complex topography, resulting in climatic characteristics that change within a few tens of kilometers. The study of the three regions of the country highlighted these differences.

Figure 1: Map of the administrative Regions of Greece, Date of Access: 12/4/21019, Source: Hellenic Oncology Foundation

2.1 Sterea Ellada

Sterea Ellada is located in the southern part of mainland, constituting the second largest Greek Region. It is located in an enhanced geographic location that makes it the hub and corridor of the mainland transportation, communication and energy networks of Central Greece (Ministry of Environment and Energy -MEE-, 2018).

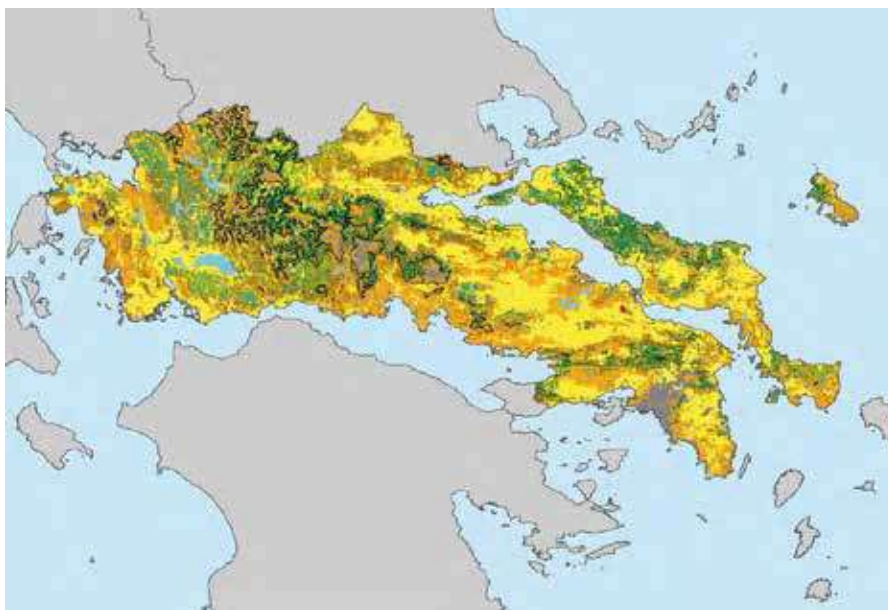

Figure 2: Map of the region of Sterea Ellada, Source: WWF Greece, 2012a

It is characterized by intense mountain volumes, a large number of lakes and several important wetlands and rivers. As a result, the high and steep mountains contribute to the formation of intense climate diversity, with the coasts generally having a smaller annual temperature range, the rainfall being more pronounced in the west often resulting in intense flood phenomena, and the central mountain complex being featured by cold climate with frosts and snows (Zografou et. al, 2012a).

In relation to climate changes, for the time being, desertification or drought phenomena have not been observed, although some areas (Fokida, Evia) are expected to be classified as high risk in the long term. Management and protection of water resources, which are a valuable source of water supply in the region, as well as prevention of natural disasters (fires, floods) with significant socio-economic impacts, are important challenges expected to increase by CC and calling for adaptation measures (Ministry of Environment, Energy and Climate Change -MEECC-, 2013).

The effects of CC are expected to be quite severe due to increasing incidences of extreme weather events and interactions between physical and social systems on one hand and the climate system on the other. According to the report of the Bank of Greece (2011) in the period 2021-2050 the very warm days (and nights) are expected to reach 20 and 40 in the period 2071-2100 in the lowlands and mainland of Sterea Ellada. In addition, the days of extreme rainfall in eastern Sterea Ellada are

expected to increase by 30%, while increases are expected in the periods of consecutive drought days where rainfall will be less than 1 mm per day.

According to the Regional Spatial Framework (RSF) of Sterea Ellada that was approved by a decision signed by the Minister of Environment and Energy (2018), one of the basic policy objectives is *“adaptation to the impact of CC and energy needs, with priority being given to planning development of Renewable Energy Sources (RES) and the restructuring of transportation systems”*.

RSF (2018) provides for primary sector to become the basic tool for extrovert development, exploiting certain advantages of the region of Sterea Ellada for agriculture and livestock farming, forestry, fisheries and aquaculture. Particular attention is also put at the significant activity of mining. Secondary sector pursues an important role for the region in the field of energy and the promotion of designated origin and high quality food products with export orientation. Expansion and growth of the tertiary sector, particularly the tourism sector, is among the priorities of the RSF.

The RSF (2018) provides for the protection of the natural environment by means of basic principles for the management of protected areas and guidelines for tackling pollution and CC.

To ensure the protection of the primary sector, some of the specific directions given are:

- *“Preservation of agricultural land.*
- *Rational management of irrigation infrastructure and land reclamation projects.*
- *Rational management of pastureland.*
- *Organization of fishing facilities.*
- *Interconnection of local nutritional products with tourism”.*

Regarding the protection of water resources, which are a valuable source of water supply for cities and a major input to agricultural production, since 2013 MEECC has promoted management studies per water basin, which are expected to prove particularly useful for the treatment of upcoming drought periods due to CC. According to the RSF (2018) priority is also prevention of natural disasters, such as fires, floods, landslides, etc., having significant socio-economic impacts on settlements and technical infrastructure. Adaptation to CC requires further specialization as it is expected to affect adversely and distinctly several of the region's productive and residential sectors, such as tourism, housing, agriculture, livestock farming, fishing etc. (MEECC, 2013).

2.2 Thessaly

The region of Thessaly is located in a privileged geographic position at the center of the Greek territory and bordering with the region of Sterea Ellada.

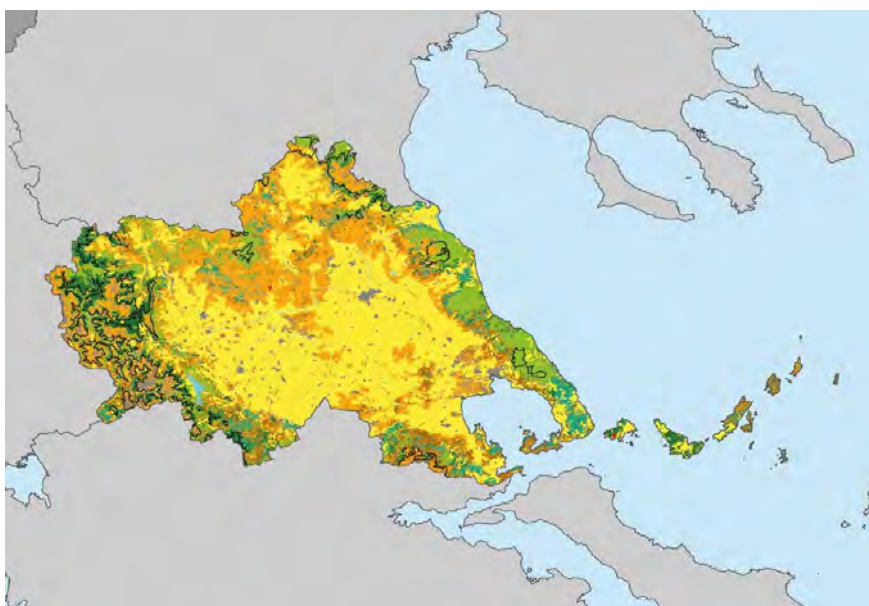

Figure 3: Map of Thessaly region, Source: WWF Greece, 2012b.

It is featured by the Thessalian plain, which is the largest plain of the country. The plain is enclosed by large mountainous volumes, of which the highest is mount Olympus. Its longest river is Pinios, which is fed by several tributaries and its largest natural lake was Carla which was drained in 1962 causing serious problems to both the natural and the social systems in the region. There are also artificial lakes in the region as well as several wetlands. The climate is characterized as Mediterranean, with hot summers and cold winters and rainfall presenting great spatial variability (Zografou, et. al, 2012b).

The impacts of CC are expected to significantly affect the region with greater changes in the climate to be anticipated in the plains and mainland, where change in the number of days with maximum temperature figures up to 20 in the period 2021-2050 and up to 40 in 2071-2100 (Bank of Greece, 2011). According to a study by the Ministry of Environment (1997) there will be a reduction of cotton production in the area up to 29% due to mean temperature increase in the period 2071-2100 in. However, according to IPCC (2007), moderate warming will likely increase crop yields in the temperate zone while according to the Bank of Greece Report (2011) there will be a change in the days of night glaciers in the region, with a reduction between 10 and 15 days in the years 2021-2050 and 25 days in the period 2071-2100, describing this parameter as very important for rural areas, especially those with sensitive crops such as citrus fruits.

By decision signed by the Minister of MEE in 2018, the RSF of Thessaly was approved with the aim of preventing and adapting to climate change, by increasing energy efficiency and promoting RES and co-generation in all sectors (MEE, 2018). Basic aims are to promote the sustainable, balanced and integrated development in accordance with the natural, social and economic particularities; to preserve biodiversity; prevent pollution and improve the quality of life; restrict the dispersed structure and siting of tourism activity infrastructure and maintain significant power plants (Hydroelectric stations of Plastiras and Smokovo Ponds).

According to the RSF (2018), the Thessalian plain is and must retain its role as the most important agricultural area in the country. Sustainable management of this natural resource is of particular importance at both the regional and national level. In order to fulfill this objective, it is necessary to:

- *"Declare agricultural land in terms of its productivity.*

Eliminate building development out of statutory plans exclude uses and activities related to and compatible with agriculture.

- *Implement measures foreseen by water planning of the basins of Thessaly;*
- *Protect and promote the branded/local quality products;*
- *Support the production of "organic" products (including livestock)".*

Livestock farming is an important factor in the development of the agricultural sector of the Thessaly region and it is considered as a first priority policy sector, alongside other compatible uses in the designated zones. Aquaculture plays also a key role in the delta of Pinios, while RES occupies an important position in the development of the area including small hydroelectric works photovoltaic installations and the mining.

Three horizontal guidelines are foreseen by the RSF (2018) for CC mitigation and adaptation in the region of Thessaly: (a) *"Reinforcing the application of the best available practices and technologies to increase energy efficiency"*; (b) *"Promotion of RES and co-generation of energy in all sectors"* and (c) *"Reduction of energy consumption in accordance with national commitments arising from international and European policies for CC"* (MEE, 2018).

2.3 Peloponnese

The region of Peloponnese includes the largest peninsula of Greece and its relief is mainly mountainous and steep. The largest plains meet at the seaside, but also in the valleys of the rivers of the region.

. Figure 4: Map of Peloponnese region Source: WWF Greece, 2012c.

The climate of the Region is characterized as Mediterranean with prolonged droughts during the summer months and mild rainy winters. However, climate differentiation between western, central and eastern Peloponnese is quite noticeable. In the coastal and lowland areas of Western Peloponnese a Mediterranean Sea climate pertains with heavy rainfall. Centrally, the climate is characterized as mountainous, cold, with frosts and snows during the winter months (Zografou et. al, 2012c) and an average annual temperature about 10° C (Bank of Greece, 2011), while in the east rainfall is limited and the climate is characterized as semi-arid (Zografou et. al, 2012c). Rainfall and air temperature are the most important climatic elements of a place. On the coasts of the Peloponnese region, humidity of the air approximates that of sea climates, while the average annual amount of rain received by the mountain ranges reaches 1,600 mm. (Bank of Greece, 2011).

CC is expected to influence the region considerably, as in the years 2021-2050, the number of extremely hot days and nights are expected to reach 20, in southern Peloponnese, while in the years 2071-2100 to reach 40. At the same time, the expected reduction of frost days is 10-15 days for the period 2021-2050 and 25 days for the period 2071-2100 (Bank of Greece, 2011).

Regarding CC and its impact, it is estimated that several parts of the region will be affected, due to the rise of sea levels and parallel salinization of aquifers (MEECC, 2013). According to the report of the Bank of Greece (2011), vulnerability of the coastal regions of northern Peloponnese is expected to increase because the sea level is estimated to rise, until 2100, from 0.3 to 1.5 mm/year as a result of northern winds. In turn it will threaten port and athletic facilities, erode beaches and increase floods and the salinity of rivers, bays and groundwater (Stavropoulou, 2017).

In the region of Peloponnese, there are several areas of sensitive coastal ecosystems, which will undergo geographical changes due to sea level changes which are estimated in turn to affect the extensive alluvial coasts of Western Peloponnese and the alluvial fields of the Messinian, Laconian and Argolic Gulfs (Triptsidis, 2010). In Figure 5 illustrated in red are the coastal areas estimated to be affected by one meter sea level rise.

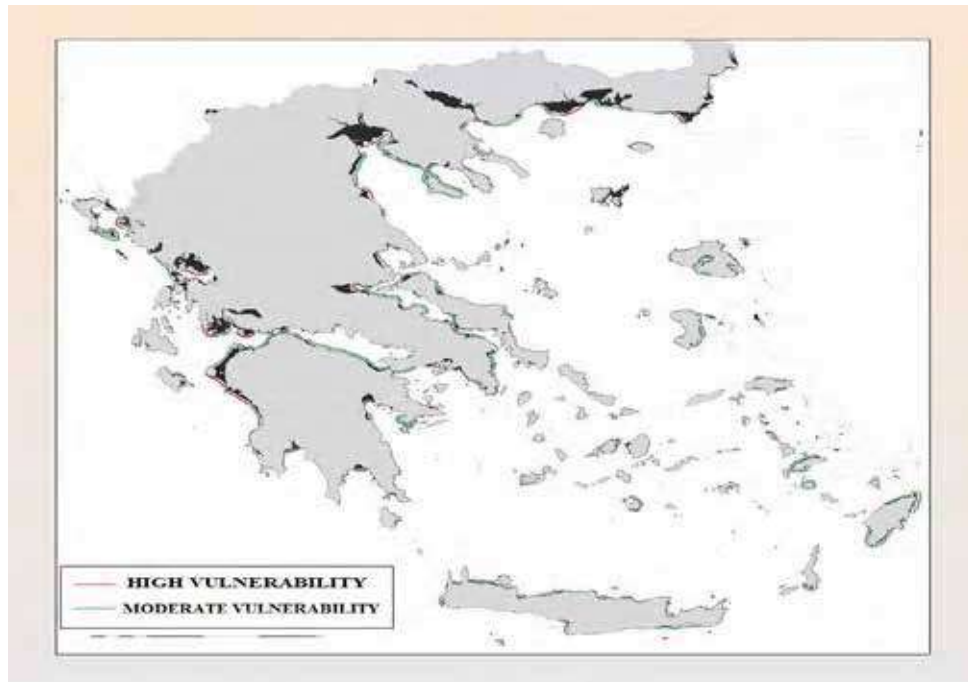

Figure 5: Map of Greece indicating coastal moderate and high vulnerability to the rise of sea level, Source: Bank of Greece (2011).

The effects of the rise in temperature, especially in the urban centers of the region, the tourism destinations and the primary sector (livestock, fishing, agriculture, etc.) are also important. As far as desertification is concerned, several coastal areas are at risk (Argolikos, Laconian Gulf) and some already suffer from aquifer salinization, while areas at high risk of erosion may be found eastwards (MEECC, 2013).

A significant number of environmental studies have been developed for the region and protection zones have been established for both mountainous areas of Parnonas and Erymanthos-Chelmos. In other mountainous areas the protection zones are expected to be institutionalized. As for the water supply of the area, the region is mainly served by boreholes, water tanks and desalination units. During the summer months, there are problems of water adequacy, due to the inadequate water supply network and the always increasing demand in various tourist areas, such as Messinia and Laconia (MEECC, 2013).

As it becomes apparent, there is a pressing necessity for revision of the outdated Regional Framework for Spatial Planning and Sustainable Development (RFSSD) of Peloponnese. Since more than 15 years have gone by its institutionalization a series of substantive and significant new conditions and necessities have appeared: (a) utilization of solar and wind potential, (b) satisfaction of growing tourism demand, (c) protection and sustainability of natural resources, (d) new irrigation projects etc.

3. Public Perceptions

Over the last few decades, CC has become one of the world's most serious problems, already causing and expected to cause more huge impacts in the future, in both social and economic terms. After multiple research projects, the scientific community has acknowledged the challenges of CC and, to some extent, has been mobilized to meet these challenges. However, the communities' and people's perceptions play a crucial role in coping with these challenges. Appropriate education and continuous information dissemination on CC issues can help individuals and societies to understand the serious impacts out of the interaction of the natural with anthropogenic environment and gain knowledge and practical skills for adaptation and mitigation actions. However, before organizing appropriate information campaigns and education programs, we should first obtain knowledge about people's current understanding and perceptions of CC.

According to surveys and polls that have been conducted from time to time, it seems that the majority of people in Greece consider that CC is due to anthropogenic factors while a small percentage of people consider either that it does not exist or it is due to natural causes.

In November 2015, on the occasion of the United Nations Conference, the European Commission carried out an investigation in EU countries. According to the findings Greeks support the need for collective action for CC. Almost nine out of ten respondents in Greece believe that CC is a “very serious” problem, while about six out of ten say that the national governments are responsible for dealing with CC in the European Union (EU). When asked if they have taken any personal action to combat CC in the last 6 months, only four out of ten responded positively. However, when they were presented with a list of practical measures (e.g. effort to reduce rubbish) the percentage of positive answers increased up to 89%, thus proving that many respondents did not associate certain environmentally friendly actions with CC mitigation or adaptation (European Commission, 2015).

The research was repeated in March 2017, with the results showing that 8 out of 10 Greeks considered that CC was a serious problem, while half of the respondents argued that they had taken personal action to combat it. Two thirds of the respondents reported that they were trying to reduce waste and separate them regularly for recycling. A percentage of 14% of respondents have, as they replied, installed solar panels at home, while 20% regularly use environmentally friendly alternatives for their movements and buy locally produced and seasonal food, whenever this is possible, at a rate of 35% (European Commission, 2017).

In June 2017, on the occasion of the World Environment Day, the polling company “Aboutpeople” on behalf of electronic newspaper “Athens Voice”, conducted a poll regarding the view of the Greeks on CC, in a sample of 731 people over the age of 18. According to this poll, 78.2% believe that CC is mainly due to human factors, and 17.2% that it is mainly due to natural causes, while 3.9% believe that it does not exist (A.V. Team, 2017).

In November 2018, the European Investment Bank, in view of the international climate Summit, published a public opinion survey on CC carried out by the polling company YouGov in a sample of 25,000 citizens. According to this research, the middle social class in Greece is more concerned about climate change (96%) than the lowest (90%) and higher (78%) classes. The same research shows

young people more concerned (94%) than the elderly (85%) and women more concerned (94%) than men (89%) (Voutsadakis, 2018).

In our three areas of study, various initiatives have been undertaken from time to time to inform and raise public awareness about CC.

3.1. Sterea Ellada

As far as the region of Sterea Ellada is concerned, public information is primarily undertaken by the local media, through published articles highlighting the dangers of CC and respective consequences on health of the region's residents, as well as on the regional and national economy. They inform people about relevant to CC actions, lectures, workshops and conferences that take place in the region, urging them to take action for adaptation and mitigation, while disseminating wider information about actions of EU citizens.

In November 2015, on the occasion of the meeting on CC in Paris with the presence of 150 leaders from around the world, a demonstration was held in the city of Lamia against any policy degrading and polluting the environment. This was indeed a mass meeting of protesters who gathered to send their own message against climate aggravating activities and forms of development (LamiaReport, 2015).

In addition, on the occasion of the World Wetland Day, in January 2019, a group of cCitizens carried out an informative intervention in the city of Chalkida for the rescue of Kolovrechti. This activist initiative aimed to remind the inhabitants of the region of the importance of protection of the environment and the necessity to preserve the remaining natural wetlands in Greece, thus contributing to the planet's climate balance (Pantiora, 2019).

Since the beginning of 2019 the Municipality of Lamia, has organized a series of actions to raise awareness and inform citizens about CC, with the slogan: "Let's Do It Lamia 2019". The initiatives aimed at raising concern and protect the natural environment and reinforcing the spirit of voluntarism besides. This was attempted through promotion of the volunteering school week (with the assent of the Ministry of Education and Religious Affairs), where each school organizes its own actions and cooperate with the municipality for supportive assistance. The overall objective has been to inform and sensitize pupils and students at all levels (Municipality of Lamia, 2019).

3.2. Thessaly

In Thessaly, mainly the local media has taken over the task of informing and sensitizing citizens by posting scientific articles raising citizens' awareness and motivating them to act individually and collectively to combat CC. In November 2015, the "Global Climate Action" was held on the beach of the city of Volos enabling citizens to send a strong message to the governments' representatives attending the climate conference in Paris, including claims as "turning to green energy" (e-thessalia.gr, 2015).

In June 2017, the 1st Panhellenic Congress on CC was held in the city of Karditsa, where many local people participated and were informed about the significant impact of CC on the environment and humans. Almost two years later, in March 2019, on the occasion of World Forest Day, the Association of Forest Guards of Central Greece, invited all citizens of Thessaly to ask for a new forestry policy providing for a new single forest protection body (Association of Forest Guards of Central Greece, 2019).

Finally, in April 2019, the gymnasium of Platykampos, acted and marched against CC in the city of Larissa, in the context of the event "School open to society", sending the message that it is the responsibility of the young people to act for the sake of the climate with slogans such as: "Save the Earth" (OnLarissa, 2019).

3.3. Peloponnese

As with the previous two regions, the local media mainly have undertaken the task of informing and sensitizing the people of the region of Peloponnese about CC. However, in this region the local mass media hardly mention the negative impact that CC is expected to bring to the region. Citizens are informed mainly through scientific reports, conferences and lectures on the overall impact of CC, without particular reference to the specific locally expected negative impacts. The reason maybe related to political orientation of those controlling the local media or simply to lack of knowledge.

In January 2008, a public event was held in Patra. It was organized by the MESOGEIOS SOS network in collaboration with the environmental education offices of primary and secondary education and the Association of Environmental Organizations of the wider region. During the event the response of the public was particularly warm, and the discussions indicated that CC concerns considerably the residents of the region, who seemed to realize the need of mobilization (MESOGEIOS SOS Network, 2008).

In November 2015, a group of citizens, in view of an environmental protection event, made an internet call inviting the public to claim for the transition to 100% clean energy, thus protecting the future for the next generations and demanding an agreement from world leaders that would release clean energy for all (Tempo24, 2015).

4. Results and Discussion

The three regions presented, although very close to one another differ considerably in terms of their natural, geomorphological and climatic characteristics; also in terms of their socio-economic profile differ to a quite large extent. the three regions illustrate perfectly the strong spatial dimension of CC and its impacts on the diverse human activities affecting consequently spatial policies and regional development (Kartalis et.al., 2017). According to Davoudi (2009), there is a two-way relationship between CC and spatial planning, since spatial planning has the potential to mitigate the effects of CC, while CC may lead to a revision of the basic norms, objectives and directions of spatial planning.

According to research and statistical analyses, CC spatial variations, cause diverse and different pressures on the natural and anthropogenic environment, where the challenges that are posed to many sectors of the economy differ from one region to another (European Environment Agency 2005, 2008, 2012). Indicative cases of such sectors are tourism, energy production, agriculture, fisheries, etc. (European Commission, 2009).

In recent years, the regions have taken a number of initiatives to adapt to CC. Below are three tables comparing the three regions in terms of: (a) physico-geographical and climatic features and challenges; (b) the predominant economic activity and income sectors and (c) the impacts of CC on urban, tourist, agricultural and forestry areas.

Source: author's elaborations

It becomes evident that the effects of CC are expected to affect to quite a large extent primary sectors of all three regions, as well as in the secondary and tertiary. Significant changes have been recorded and are anticipated also in various climatic parameters, such as temperature, rainfall, snowfall, sea level, etc., while heat waves, extreme weather phenomena (including extreme precipitation) and droughts are expected to increase. Most of these impacts are negative as they are expected to affect the agri-food sector of these regions by increasing cooling costs during the summer months and reducing tourism due to extreme temperatures and shortages in water supply availability. All of the above are a priority in drawing up plans for adaptation to CC with linkages with sectoral and spatial policies (Kartalis et. al., 2017).

The region of Sterea Ellada is expected to suffer mainly in the primary sector where it bases most of its economy while the energy sector follows. The region of Peloponnese is expected to suffer the largest impact, since it will affect all regional sectors to a large extent. The region of Thessaly will be affected also, but in some cases of the primary sector it will benefit besides, for instance due to the anticipated increase in the production of citrus products.

Our research also revealed the perceptions of the people about CC, that relate to their individual actions regarding CC mitigation and adaptation with an emphasis on issues regarding consumption of energy and the use of environmentally damaging products. After analyses of statistical and poll data, it was found that the Greek middle class consider the problem of CC and acts to tackle it, in a higher percentage, than the higher and lower social classes.

Conclusions

The Mediterranean has been recognized internationally as a vulnerable area to the impacts of CC (Bank of Greece, 2011). This study presents the impact of CC in three regions of Greece, Sterea Ellada, Thessaly and Peloponnese, with climatic conditions appearing to change in urban and non-urban areas. According to the methodology used, potential impacts of CC and the exposure and sensitivity of each region and sub-regions have been addressed. According to the findings of a series of climatic simulations and the IPCC reports (2007, 2013), by the end of the 21st century the temperature in Greece will increase significantly, while the height of precipitation is expected to continue decreasing, with a parallel significant increase in the number of events of temperature extremes and extreme rainfall values (Bank of Greece, 2011). Because of these conditions, the dry areas will become even drier due to the reduction of water resources, the productivity of forests will decrease, and the number of forest fires will increase. Forestry and agriculture have at times shown their susceptibility in the increasing trends of heat waves, droughts and floods, while coastal wetlands are vulnerable to the long-term rise of the sea level. The most acute negative impacts are expected in the western Peloponnese and the lower in Thessaly and southern Peloponnese (Kartalis et. al., 2017).

According to the results of the present study, the impact of CC on the three study regions, especially in the sectors of agriculture, tourism, energy, livestock and public health will generally be negative, without, however, bringing equal results in all three regions. In some cases, CC can produce positive results, for example Thessaly may experience an increase in agricultural production due to the reduction of frost nights.

The planning and sustainable development spatial frameworks institutionalized in 2003 include only with a few references to CC with a visible deficit in the spatial specialization of the counter-actions concerned.

As found in this study, informing people in three regions is being conducted by local media with limited school penetration and limited information by the state, both at educational and operational level. As reflected through the research of "Public Issue" in 2008, Greeks consider that the CC exists primarily in the agricultural sector and not in the urban areas, leading us to the conclusion that information through the local mass media is inadequate, as local media may be biased with the CC or lack the necessary knowledge.

In spatial frameworks, it was found that CC appears at the target level, but not at the operational level, while absent from the urban space and planning. In the field of spatial legislation, CC is practically absent, but there are often references to energy issues, but through the technical prism of the energy infrastructure, not CC. The same applies to urban planning legislation (Kartalis et. al., 2017).

Urban green spaces in transition: Urban social-ecological resilience in the region Frankfurt Rhine-Main—A review

Pinar Bilgic¹

¹*Technical University of Darmstadt, pinar.bilgic@stadt.tu-darmstadt.de*

Abstract: This study reviews the fundamental literature and emphasizes the significance of urban green spaces (UGSs) of the studied case, the Frankfurt Rhine-Main region (FRM). UGSs as natural resources provide benefits against main climate-related urban hazards—floods, droughts, and heat waves—and are considered as essential components of climate adaptation. Also, UGSs are spatial resources for densification, a key instrument against sprawl. UGSs' competing functions cause urban land-use conflict in many growing metropolitan regions. FRM, with its increased frequency, randomness, and severity of climate hazards and peaking rates of housing demand, is no exception to this trend. In this study, the literature review is guided by a conceptual framework which assigns urban land-use competition as the point of departure and the concepts of regional economic development and environmental protection as entry points to urban social-ecological resilience. Although resilience, as a theory of social-ecological system property, is already studied extensively, it still needs to be unpacked to be operationalized in planning practice. This work looks at the links among theory, policy, and practice and suggests that resilience is most purposeful when it is approached rather as an integral process to planning and management than an end destination. (195 words)

Keywords: urban green spaces; urban social-ecological resilience; urban transformations; Frankfurt Rhine-Main

Introduction

Background

This study emphasizes the significance of urban green spaces (UGSs) in urban planning practice and looks at their contribution to urban social-ecological resilience in the context of the Frankfurt Rhine-Main (FRM) region in Germany. In the face of ongoing urban transformations triggered by the peak housing demand, ensuring sustainable urban growth in planning practice is a major concern. Improving and sustaining the benefits UGSs provide, especially during times of inevitable urban transformations and a changing climate, is essential.

Since the preindustrial times, FRM has been a region of high economic activity. Today, after its industrialized and de-industrialized phases, the region is still home to production, commerce, and high international financial activity, administration, and services. The region performed relatively stable during the global financial crisis of 2008-2009, and a reason for this has been the diversity economic

activities and socio-demographic composition. As this diversity and stability is attracting an unprecedented rate of domestic (mainly due to shrinking and declining cities in some German and European regions) and international migration (mainly due to refugee situation since 2015 and Brexit, as the city of Frankfurt is assumed to carry further some financial functions of London in continental Europe), activating spaces to provide housing requires immediate responses from national and subnational levels of administration. Recent prognoses showed that additional regional housing supply until 2030 should number approximately 184.000 dwellings (Regionalverband FrankfurtRheinMain, 2016). According to a recent analysis, the region can actually provide 220.000 new housing units through densification (106.000 units), through new development on open land (100.000 units), and through promoting mixed-use in available industrial and commercial zones (14.000 units) (*ibid*). A great majority of this potential (183.000 units) is located at the areas with well-connected public transportation facilities. The motivation behind providing more housing at the areas with well-connected public transport is to directly contribute to less car dependency (Figure 1).

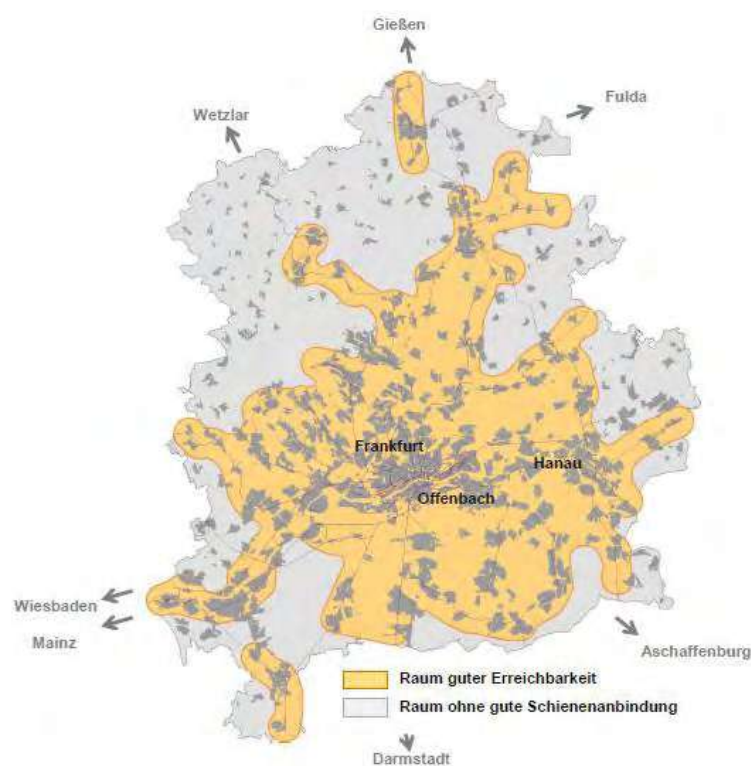

Figure 1: The area of well-connected public transportation with a housing provision potential of 183.000 dwellings (yellow) mostly through densification (source: Regionalverband FrankfurtRheinMain, 2016).

Problematization

Due to the accelerated rates of housing demand in regions with high economic activity, urban growth should be spatially controlled and managed to avoid sprawling over natural landscapes and urban densification is a strategy often employed in achieving this. At the same time, the impacts of increased frequency, randomness, and severity of main urban hazards—namely flood, drought, and heat wave—on human wellbeing become more severe, as urban densification might take place at the expense of UGSs.

In this regard, UGSs can fulfill two mutually incompatible roles: as natural resources for climate adaptation and as spatial reserves for urban growth. These competing functions of space bring about a major challenge in urban land-use planning and management in many growing metropolitan regions in the world. The FRM region, with its peaking rates of housing demand and increased damage of urban climate hazards, is no exception.

Purpose of this study

The aim of this work is to discuss and reflect on the results of an extensive literature review. The texts with the greatest potential to inform the concept, content, and context are reviewed. The most relevant previous work is identified and input from key scholarly body is brought together. The reviewed body of literature is compiled, thematically grouped, and critically reviewed between December 2018 and March 2019. The relevant literature body is found out by systematic searches in major scientific databases (Web of Knowledge, Scopus, Google Scholar) and the University and State Library of Darmstadt University of Technology. Following keywords are used with various combinations: urban green spaces; land-use conflict; urban densification; urban sprawl; regional economic growth; environmental protection; climate adaptation; resilience; social-ecological systems (SESs). Initial output is narrowed down by a category (architecture, urban planning, urban development, urban studies, landscape ecology) and document type filter (articles, books, book sections, proceedings, policy documents). Among these, 55 documents inform this study. The workflow to carry out the literature review has been as follows: 1. defining review questions based on the research problem (i.e. urban land-use competition); and 2. selection and review of relevant key literature. The below conceptual framework guides the review:

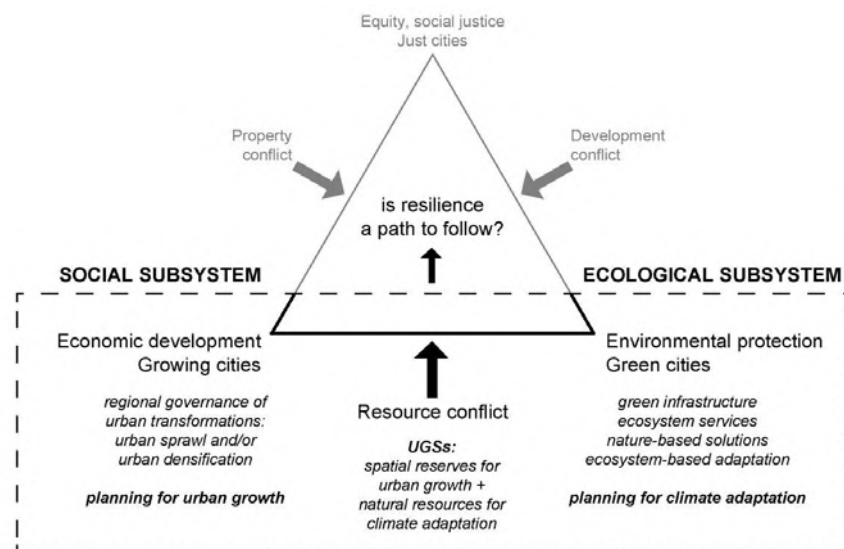

Figure 2: Conceptual framework: a model of priorities, relationships, and conflicts associated with the components of SESs (source: adapted from Campbell, 1996).

Resource conflict

Land as a scarce resource

Urban areas are where most of the global population and economic activity is concentrated. As hubs of knowledge and innovation, they are the engines of national economic growth. As dynamic systems

being constantly exposed to both abrupt and steady change, today's urban areas face massive social, economic and environmental challenges which calls for a restructuring in conventional planning and management to adequately address human wellbeing.

The aftermath of Second World War marks the beginning of an era in which human activities have started to alter the environment more extensively and rapidly than any other time in human history, with increasingly devastating environmental impacts (Grimm *et al.*, 2008). Although cities are not covering more than around 3 per cent of Earth's overall land surface, these devastating global impacts are attributed to cities (Alberti *et al.*, 2003; Grimm *et al.*, 2008; Gago *et al.*, 2013). Growing evidence shows that the functioning of urban systems is dependent on the environmental benefits provided by UGSs. How urban growth takes place influences the quality and quantity of UGSs and their benefits to a great extent: *growing in* (urban densification) might tend to take place at the expense of green spaces *within* an urban area; whereas *growing out* (urban sprawl) might tend to cause a significant loss of green spaces *around* an urban area. Furthermore, it cannot be ignored that both economic and ecologic systems need an interconnected critical mass of land to be sustainable, and that "the continuity of one system invariably fragments continuity of the other" (Campbell, 1996, p. 20)

Arguably one of the most comprehensive works produced in reframing the conflicts and tensions inherent in planning discipline is Campbell's "Green cities, growing cities, just cities? Urban planning and the contradictions of sustainable development" (1996). This article invites to rethink what sustainability is and to acknowledge the inevitable conflicts in planning discipline so that we no longer romanticize our sustainable past, as this attitude seems to be misleading in addressing contemporary problems. In preindustrial times communities had no alternative but be sustainable, because the feedback mechanisms were too short-term: if our ancestors destroyed vegetation, they would die out. Today, the scope of our alterations on nature is so massive that we do not necessarily suffer the consequences of these alterations (*ibid*). As Neuman (2005) also agrees, urban models from old, preindustrial European and North American cities keep inspiring us as sustainable models of urban form, however, today's complexities require thinking beyond that.

Campbell (1996) describes the resource conflict, the conflict between economic growth and environmental protection priorities as the '*Ur-Konflikt*' (p. 6). Resource conflict is mostly evident in urban land-use, as it is nearly always a tradeoff between social, economic, and environmental goals, a result of decisions that are irreversible, long-term commitments (European Environment Agency (EEA), 2015). Because of this, drivers and consequences of, and control for land-use is always a societal matter: land-use decisions shape the built environment and determine where and how economic activity takes place, where communities develop, and how natural and built environment is configured and reconfigured (Goetz *et al.*, 2004).

Studies aimed at classifying and qualitatively assessing the state of understanding on global trends in land-use found out that urbanization is one of the major drivers of massive change (Lambin *et al.*, 2001; Alberti *et al.*, 2003). It is also observed that massive changes in land-use and land-cover often overlap with new practices motivated by regional incorporation into a world economy. Triggered by globalization, transformation of urban-rural linkages at regional scales is taking place quite intensely and, consequently, ecological footprints of a city-region in the developed world might expand over several hundred times of the actual surface it covers (Grimm *et al.*, 2008; Gago *et al.*, 2013).

Compact versus sprawl

Based on above discussions on globally driven urbanization and its consequences on land-use and land-cover change, this subsection focuses on a particular spatial form of urban land-use competition: compact versus sprawl. This is of crucial relevance to UGSs, because what remains as inner-city green spaces after implementation of urban densification strategies can tell much about the extent of densification practices.

In Europe, urban development in the form of sprawl first appeared after the Second World War. In parallel to economic and population growth, planning and management of urban growth promoted a spatially expansive model and resulted in the formation of large peripheral extensions to existing urban settings. These extensions were not limited to provision of new housing as more expansion required more social and technical infrastructure, which eventually triggered progressively more sprawl (Olofsdotter *et al.*, 2012). Today, this spatial configuration has important costs as it fragments landscapes, degrades water quality, demands a great deal of provision and upkeeping of social and technical infrastructure (Alberti *et al.*, 2003).

Sprawl indicates an urban form that is to be avoided and connotes not only a massive loss of natural environment but also an increase in car dependency, greenhouse gas emissions, air pollution, high infrastructure investment, operation, and maintenance costs, and social segregation. Today, sprawl is found out to be the most dominant form of urban transformation as several studies have found out that even some shrinking European cities are sprawling, and it cannot be claimed anymore that population or economic decline and spatial shrinkage are directly tied (EEA, 2006; Kabisch & Haase, 2012).

Based on this, compact urban form with higher density receives recognition as a key remedy against urban sprawl (Olofsdotter *et al.*, 2012; Davern *et al.*, 2017). The ideal of compact urban form is however not unproblematic (Olofsdotter *et al.*, 2012). Although the compact city approach as a key response to urban sprawl has benefits such as limiting ineffective land-use and subsequent problems, provision and conservation of UGSs during densification is a major challenge in planning practice (Dallimer *et al.*, 2011; Haaland & van den Bosch, 2015). Urban densification is associated with increased impervious surfaces and decreased vegetation cover. It is also necessary to highlight that the parking spaces for the additional housing provided by densification is a great contributor to the increase in impervious percentage. This, in turn, is one of the main drivers of the urban heat island effect and increased risk of water-related hazards (Grimm *et al.*, 2008) and, therefore, requires alternative ways of densifying urban areas, through implementations such as adding floors on existing buildings and using underutilized parking spaces for new construction.

Moving beyond urban form

The root causes of the resource conflict are not always only spatial, and it could not simply be eliminated by just a ‘spatial fix’ (Campbell, 1996, p. 13). Similarly, Neuman (2005) argues “one cannot overlook the fact that form is both the structure that shapes process and the structure that emerges from a process. Yet the question that should be asked is whether the process of building cities and the processes of living, consuming, and producing in cities are sustainable” (p. 22).

A unifying concept: Rethinking resilience thinking

The aforementioned urban land-use competition in general and the conflicting views on compact and sprawled urban form in particular can be framed under the resilience concept, because the regional economic development end of the tension aligns with the social subsystem and the environmental protection end of the tension aligns with the ecological subsystem of the SES thinking.

The existing resilience literature covers various disciplines, has different starting points and different definitions and a fragmented structure (Chelleri, 2012). In this study, normative assumptions and prescriptions of how to become resilient are of little importance. The discussions rather revolve around the components of what makes resilience thinking a rich concept that is capable of informing today's highly complex challenges in urban planning. Therefore, it is acknowledged that cities are complex, adaptive systems of constant steady and abrupt change ongoing with a degree of uncertainty and UGSs are approached as SESs by unpacking SES thinking that is actually embedded in planning discipline.

As the aim is to operationalize the resilience concept in urban planning, it is necessary to briefly revisit some key definitions in the evolution of the concept and how it made its way to planning. At an earlier stage, engineering resilience is defined as “the ability of a system to return to an equilibrium state after a temporary disturbance” (Holling, 1973, p. 14). This definition emphasizes the capacity to *bounce back*, to return to original state and being fail-safe. To *bounce back* is however not always favorable. There are cases that it is better for a system not to return back to previous equilibrium or stable state, as it might actually mean returning back to status quo which caused the system's current problems at the first place (Eraydin, 2012). Holling (1996) then defines ecological resilience as “the magnitude of the disturbance that can be absorbed before the system changes its structure” (p. 33). Here, the emphasis is rather on the capacity to *bounce forward*, the amount of disturbance a system can take before reaching a new stable state.

What is common in both descriptions is the assumption that there is an equilibrium state to return back or to reach to. However, such an ideal of equilibrium is “too mechanical to reach” in planning discipline and can be misleading (Davoudi *et al.*, 2012). Instead, evolutionary, *i.e.* social-ecological, resilience is described as the ability of complex SESs to change, adapt, and transform while undergoing change (Folke *et al.*, 2010). This approach is promising in planning discipline as it acknowledges not only fast and abrupt (*e.g.* disasters) but also slow and cumulative (*e.g.* hazards) changes which might also bring extreme outcomes (Davoudi *et al.*, 2012).

SES thinking is as central to planning as it is to resilience. As cities are being acknowledged as human-dominated ecosystems, this approach brings together otherwise separated domains of natural and social sciences in explaining how the interactions between humans and ecological processes create cities (Alberti *et al.*, 2003). Resilience Alliance (2010) defines SESs as “an integrated system of ecosystems and human societies with reciprocal feedbacks and interdependence” (p. 52). Human-nature interactions are closely coupled in cities (du Plessis, 2008) because “cities are SESs and should be studied as such” (Grove *et al.*, 2015).

This is particularly important as resilience is, broadly speaking, the study of what systems do while undergoing change (*e.g.* in this study: change that is reflected in form (land cover) and function (land-

use). To ignore or to resist to change has costly consequences: it creates a vulnerable condition for the system, as it foregoes emerging opportunities and limits its options (Walker & Salt, 2006). Still, a thorough understanding of today's societal and environmental change is no simple task to tackle. Today, as we are transitioning from "known extremes to unknown extremes" (Coaffee & Lee, 2016, p. 135), regardless of how well we study and learn from past patterns, the new patterns of change tend to unfold in unexpected ways. Resilience thinking, as it emphasizes humans-in-nature perspective, integrates SES thinking in urban studies, and embraces system attributes such as complexity, adaptability, and uncertainty, is a positive vision of human wellbeing as for it proposes tools to understand change (Pizzo, 2015).

Social subsystem: Housing must be provided

In order to analyze the drivers and consequences of regional economic growth and what it entails within the social subsystem, some phenomena and trends must be well-understood. Perhaps one of the most discussed trends in the scholarly literature is the impact of globalization and global networks on emergence and functioning of urban regions, as today's cities are competing and cooperating to belong to a socioeconomic network that operates at a global scale (Alberti, 2003). Supranational governmental and corporate institutions have enabled the rise of global city networks and this influences the urban processes to a great extent (Neuman & Hull, 2009). Within the inter- and transnational hierarchy and ranking and the complex global network, internationalization of resource flows has the power to shape contemporary cities (Sassen, 2005), their forms and processes.

In the midst of the global pressures, it is of critical importance how scarce land resources are used: is the benefit of society as a whole a central concern in terms of economic prosperity and quality of life? (Goetz *et al.*, 2004). As previously discussed, population growth is a predictable outcome of regional economic development, which in most cases requires immediate responses from public and private actors to activate spaces to accommodate the growing population. Accustomed technical planning options are to grow inwards through densification, grow outwards through sprawl, grow upwards through high-rise, and various combinations of these. Whichever path is followed has strong societal, environmental, and economic implications (*ibid*). It is therefore necessary to understand how these processes are planned and managed.

Based on this, regional governance appears as an important field of investigation within the social subsystem. Regional governance can be defined as the interaction among public and private actors in an institutional context with a normative basis to address and solve societal problems. It either builds bridges and has a supportive nature, or it builds barriers and has a restrictive nature (Bressers & Bressers, 2016). Complementarily, Resilience Alliance (2010) defines governance as "the interactions of diverse public and private actors, their sometimes conflicting objectives, and the instruments chosen to steer social and environmental processes within a particular policy area" (p. 51) emphasizing the fact that different actors will potentially bring different and conflicting objectives, and this, too, is a part of governance.

An important attribute of governance in the context of resilience and SESs is its adaptability. Adaptive governance is defined as "institutional and political frameworks designed to adapt to changing relationships between society and ecosystems in ways that sustain ecosystem services" (*ibid*, p. 51). It promotes interactions across levels and scales of conventional administration, including

interactions between formal (laws, constitutions, rights, etc.) and informal (social and behavioral norms of society) institutions of a governance system. Adaptive governance emphasizes the capacity to adapt to changing interactions between social and ecological subsystem in a way that it sustains its functions and services. When adopted, adaptive governance can be a switch from rigid to flexible, exclusive to inclusive, uniform to diverse, and conventional to innovative.

Ecological subsystem: Environment must be protected

Although regional economic growth priorities tend to exploit the nature simply to sustain growth, environmental protection is also a major goal in planning research and practice, because growth is dependent on the environment. Therefore, the ways to ensure that this dependence is a healthy dependence instead of a parasitic one should be understood. There is growing recognition that the natural environment provides tremendous benefits to human wellbeing, and that urban areas can only function depending on these benefits. The benefits of UGSs—as crucial contributors to adapting the local outcomes of a changing climate—cannot be separated from some key concepts that landscape ecology introduces to urban planning. Of course, applying ecological knowledge to cities is nothing new, though a revolutionary approach has been to investigate the ‘ecology *of* cities’ rather than the ‘ecology *in* cities’ (Grove *et al.*, 2015), which has found the separation of the natural and unnatural in a city rather artificial, and observed the city as a whole.

The increase in the frequency, randomness, and intensity of the three primary climate-related urban hazards, namely floods, droughts, heat waves (Depietri *et al.*, 2012; EEA, 2012; Chen *et al.*, 2016), is coupled with and aggravated by urbanization. In Europe, flooding is the most important hazard in terms of economic loss (EEA, 2010). UGSs have a big capacity to absorb excess, runoff water, unless their quality is not reduced by poor land-use practices (Depietri *et al.*, 2012). Even small patches of vegetation cover in urban areas, such as pocket parks, are contributing to the natural hydrological cycles (Grimm *et al.*, 2008; Green *et al.*, 2016) and decreasing the pressure on the aging and mostly centralized water infrastructure in post-industrial cities of Europe (Green *et al.*, 2016). Drought, on the other hand, is not directly visible in urban areas as flood is (Bressers & Bressers, 2016), but it has dramatic interruptive and costly consequences such as the damages in agricultural supply. This imbalance between too much water and too little water is damaging economies. UGSs are an important component of water-sensitive urban planning and design especially because their contribution to closing water cycles, vegetation cover is to be protected and provided in contribution to harvesting and reuse of water to tackle drought (EEA, 2010).

Heat waves are associated with long-term high temperatures with notable impacts on human mortality, regional economies and ecosystems, and have been the most important hazard in terms of fatalities (EEA, 2010). As a local impact, urban heat island (UHI) phenomenon has also been studied quite extensively. Due to UHI urban areas tend to have higher temperatures compared to their rural surroundings, especially at night (Grimm *et al.*, 2008). Its magnitude at a local scale far exceeds its impacts on global climate (*ibid*). Based on their quality and size, the cooling effect of UGSs can reach up to 50 to 100 meters offset in the built environment. It is therefore important to involve protecting and providing green in response to heat waves and UHI effect.

These are some major outcomes of a changing climate that has local impacts and can be addressed locally through integration of adaptation measures into planning. Adaptation is defined as “the ability

of a system to adjust to climate change (including climate variability and extremes) to moderate potential damages, to take advantage of opportunities, or to cope with the consequences” (IPCC, 2007). Adapting to the outcomes of climate change does not entail that negative impacts are to be eliminated through climate-proofing, rather it addresses reducing the severity of these impacts in a way that is not solely physical, but also political, institutional, and even behavioral. At its core, adaptation differs from mitigation measures, which has a supranational motivation to slow down the pace of climate change. Although UGSs have benefits in climate change mitigation efforts, as well, the scope of this study is deliberately limited to the local scale and it focuses on benefits of UGSs in local climate change adaptation.

Grove *et al.* (2015) propose four main propositions to be integrated when studying at the intersection of urban studies and ecology: 1. The ecology in and of cities looks at the entire metropolitan land-use and land cover system, not just the rural green. 2. It embraces the spatiotemporal and scalar complexity of urban mosaic. 3. It integrates knowledge from the social and ecological sciences and highlights the need to integrate diverse disciplines within the abovementioned layers of complexity. 4. The overarching aim is to be useful both for decision-making and science (p. 2, 7, 9). In order to make full use of and derive benefits from UGSs in adapting the impacts of local climate change hazards, it will be necessary to borrow some key concepts from landscape ecology (green infrastructure, ecosystem services, nature-based solutions, ecosystem-based adaptation) (Figure 3) and integrate them to theories and practices of urban planning. As these four concepts are gaining prominence both in theory and policy, it is therefore necessary to have a clear understanding of what they entail.

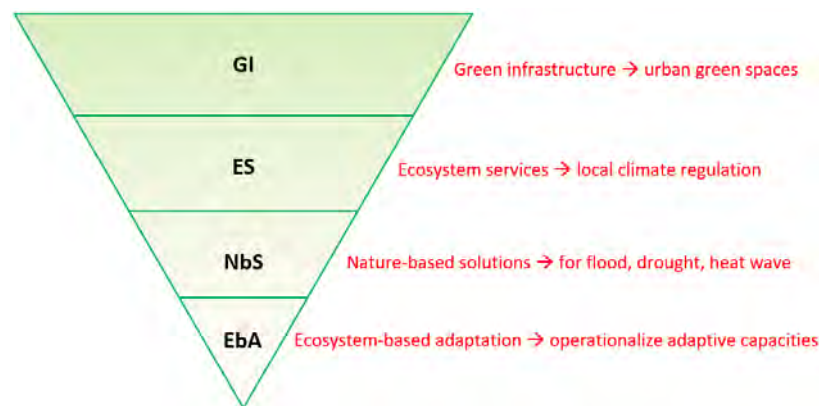

Figure 3: Four key concepts of landscape ecology in urban planning (source: author).

Green infrastructure is “an interconnected network of green space that conserves natural ecosystem values and functions and provides associated benefits to human populations” (Benedict & McMahon, 2002, p. 7). Similar to any other infrastructure, major physical components of green infrastructure are its nodes (*e.g.* parks, gardens) and connections (*i.e.* green corridors). Connectivity is an essential quality and characteristic, because it enables the green network to function as an ecological whole (*ibid*; EEA, 2004). The ‘infrastructure’ approach to UGSs is actually more than just a metaphor, since in planning discipline it is planned and managed as such.

Ecosystem services is defined as the benefits people obtain from ecosystems (Millennium Ecosystem Assessment (MEA), 2005). Costanza *et al.* (1997) listed 17 ecosystem services from gas regulation to

cultural; MEA (2005) further developed these categories as provisioning services; regulating services (including local climate regulation); cultural services; and supporting services. Due to the abstract nature of the concept, grouping and regrouping ecosystem services have not eased the difficulties in practical use of ecosystem services (Niemelä *et al.*, 2010), particularly in planning.

Nature-based solutions are defined as the “actions to protect, sustainably manage, and restore natural or modified ecosystems that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits” and approach ecosystem services as resource-efficient and adaptable responses to societal challenges (Cohen-Shacham *et al.*, 2016, p. xii). These societal challenges entail water and food security, human health, disaster risk reduction, and climate change (*ibid*). Nature-based solutions is a relatively newer concept which can be quite helpful in translating the knowledge of ecosystem services to urban planning. According to Faivre *et al.* (2017), nature-based solutions have the capacity to turn ecosystem services into innovative responses to “optimize the synergies between nature, society and the economy” (p. 509).

Ecosystem-based adaptation is a subset of nature-based solutions (Pauleit *et al.*, 2017) and defined as “the use of biodiversity and ecosystem services to help people adapt to the adverse effects of climate change as part of an overall adaptation strategy” (Convention on Biological Diversity, 2009, p. 9). Another definition by Munang *et al.* (2013) is as follows: “fundamentally, ecosystem-based adaptation is the use of natural capital by people to adapt to climate change impacts, which can also have multiple co-benefits for mitigation, protection of livelihoods and poverty alleviation” (p. 67). The concepts nature-based solutions and ecosystem-based adaptation are implementation-oriented and, therefore, frequently utilized policy arena. This is promising in terms of benefitting from the richness of the ecosystem services concept, which has so far mostly studied in the scientific literature. Moreover, the intersection of urban studies and ecology is rather concerned with the identification of root causes of SES change as a whole, than to figure out a ‘quick fix.’

Theory-policy and policy-practice interface

Up until this point, this study has been a summary of an extensive critical review of the major scientific literature, guided by the concepts urban land-use conflict, social-ecological resilience, regional economic growth, and environmental protection, with limited reference to context-specific implications. Given the importance of operationalization of theoretical knowledge in practical knowledge in the field of urban planning, it is necessary to integrate the main findings from the key policy literature to understand the transition (*i.e.* social and ecological change) in the specific contexts of international (mainly Europe), national (Germany), and subnational levels of administration.

International level: Among the concepts which constitute the conceptual framework of this study, the resilience concept is quite frequently forming the basis of many international policy documents created by international organizations such as the World Bank, OECD, ICLEI. There seems to be a tendency that these policies are aiming at ‘making cities resilient,’ referring to resilience as a quality that is with no exception preferable, a state of being that is to be achieved. Another tendency is that the resilience concept is employed often in the context of disasters, though it can still be a key policy element in response to transitions through which slow, gradual change has great impacts on urban systems.

European level: Europe is a small but a very densely populated continent. More than a quarter of its land is affected by urban land-use, around 80 per cent of its population is living in these areas (EEA, 2006). Though urban sprawl in the Anglo-Saxon literature is mostly observed as a challenge that is specific to north American and Australian cities, sprawl poses great challenges for European cities, too (*ibid*). Because of this, European-level policies are inclined to promote compact city ideal in parallel to green growth strategies. Having the majority of its member states located in Europe, a similar tendency can be observed in OECD's policies, as well (OECD, 2011).

National level: Federal-level planning principles in Germany prioritize strategies against sprawl, *e.g.* reducing daily open land consumption from 113 hectares to 30 hectares by 2020 (*30-ha-Ziel*) and by protecting natural environment through "inner before outer development" (The Federal Government, 2002). Although this ambitious goal will probably not be reached (NABU (2017) pointed out that in year 2017 daily land consumption was still around 66 hectares per day), this strategy urges sub-national governments to protect natural environment and to adjust urban growth strategies accordingly. Since this strategy gives a clear vision and a direction, it is arguably a practice-oriented goal towards an optimal land-use. As a response, from 2006 onwards, the dual inner development policy started to appear in policy literature. According to dual inner development strategy, spatial reserves in an urban area should be utilized in favor of urban densification, while at the same time green space qualities (proximity, accessibility, connectivity, etc.) are secured (Böhm *et al.*, 2016). However, the question of whether an increase in urban green space quality can offset the decrease in urban green space quantity requires more investigation (Haaland & van den Bosch, 2015).

Subnational level: This level of administration is divided into two sublevels in itself (federal states, *e.g.* Hesse, and their governmental districts, *e.g.* South Hesse) and of strategic importance as it provides data for federal-level policymaking and also for local-level implementation. For instance, regional land-use planning falls under the responsibilities of the governmental district of South Hesse, to be prepared in cooperation with the towns and municipalities.

Municipal level: Local administrations in Germany have full authority and responsibility within their administrative boundaries. As in the example of FRM region, some municipalities in metropolitan regions are members of regional authorities. The Regional Authority FRM with its 75 member municipalities including the city of Frankfurt, is the governance body of the metropolitan region, in charge of creating regional-scale concepts to address current regional challenges through enabling vertical and horizontal dialogue and bridging federal and subnational levels of administration. For instance, Regional Authority's task for the urban land-use competition has been to develop a strategic plan for its member municipalities that addresses regional (economic) growth on one hand and environmental protection on the other. In cooperation with the governmental district of South Hesse, the Regional Authority provides its municipalities with information and guidance in implementing social and ecological measures. It is also important to note that, as Keil (2011) argues, the FRM region has had continuous economic growth while undergoing massive industrial restructuring, which urges for a restructuring in its governance mechanisms.

Conclusions

What this study amounts to is that by critically reviewing a multidisciplinary body of literature it emphasizes the significance of UGSs in urban planning practice. To understand the context of the

studied case, the FRM region, the findings from key policies are also integrated. The point of departure is a major challenge in planning: how to activate spaces to provide housing while at the same time protecting the natural environment. Urban growth should be spatially controlled and managed to avoid sprawling over natural landscapes and to also to avoid densification if it is at the expense of UGSs.

Many studies argue that compact urban form is the most sustainable urban form, while many others argue the opposite, and there is empirical evidence for both. And yet, there is a third group agreeing that sprawl is not a sustainable urban growth pattern, and also being critical about the viewpoint that just because compact urban form is the opposite of sprawl, it does not mean that compact is necessarily sustainable, for whatever positive meaning the word sustainability entails. Therefore, it seems like the question of either compact or sprawl is flawed: focusing only on urban form is inadequate and can be misleading in addressing the highly complex urban growth challenges. That is why it is necessary to think beyond the urban form and consider involving urban processes in the equation.

At this point, resilience concept is employed to align regional economic growth and environmental protection with the functioning of SESs. It is acknowledged that cities are complex, adaptive systems of permanent change, ongoing with a certain degree of uncertainty. Whether or not resilience thinking can help open up new ways of embracing and working with change will largely depend on its operationalization as an integral part of and parallel to urban processes.

In planning, resilience can be a very useful concept as it can make actors involved in planning and management processes to consider the social and ecological components of an urban system and how these subsystems are in constant interaction and producing and reproducing themselves. Resilience thinking also calls for acknowledging system properties such as resistance, adaptation, and transformation, and to embrace attributes such as complexity, uncertainty, and adaptive capacity. It is argued that in order to operationalize the resilience thinking in planning practice, it should be rather approached as a process that is integral to planning and management processes, than aimed as an end destination. Only then can resilience be effective in reaching the elusive goal of sustainable urban growth in general, and the sustainable development goal (SDG) 11 “make cities and human settlements inclusive, safe, resilient and sustainable” in particular.

Abstract: Due to global climate change and rapid urbanization, the increasing impervious areas has resulted seriously human lives and property loss during flood disaster. The design standard of structural engineering measures could not stand with the extremely intensified flood disasters. In addition, such structural engineering measures might mislead the public that such areas are safe. In fact, urban stormwater integration planning and management has been implemented in the worldwide. After setting the flood protection "protection standards" for the region, the plan is adopted according to the standard. As a whole, it is the key to setting a reasonable, objective and scientific regional "protection standard" for the city. Therefore, the study will then clarify the theoretical connotation of "protection standards" and collect domestic and foreign past protection standards. Afterwards, the study will then develop a framework for "protection standards" suitable for operation in Dali River Basin in Taiwan. The cost-benefit analysis will then be applied to do the calculation.

Keywords: Global Climate Change; Protection Standard; Cost-Benefit Analysis; Floods

Introduction

Global climate change is very likely to increase the uncertainty of future water resources, and in particular there will be more extreme patterns in rainfall (Gelt et al., 1999; Serrat-Capdevila et al., 2007; Gallo et al., 2013). The report released by the United Nations and World Bank indicating that more people in urban area will suffer in the next 20 years for the influence of climate change, the extreme heavy rainfall caused by urban floods is more likely to expand its economic losses risk of today's 50 times. United Nations Office for Disaster Risk Reduction (UNISDR) stated in the Global Assessment Report on Disaster Risk Reduction 2015 that global economic losses might increase up to \$300 billion every year. Due to global climate change and impermeable surface in urban settlement, the torrential rain and surface runoff put cities in increasing risks and threats than ever before.

Flooding is a challenging issue in the worldwide (Line and White, 2007). Traditional flood management relies on structural engineering measures largely including reservoirs, levees and flood walls, improvements to channels and the floodways (Thampapillai, 1985). However, multiple weaknesses have been identified. The risk of building damage and the loss of life are possible wherever development is allowed in hazardous areas. Taiwan is an island country, and may be the place on Earth most vulnerable to natural hazards, with 73 percent of its land and population exposed to three or more hazards (World Bank, 2005). With the global climate change, there is an increasing rainfall in warmer world and will likely intensify typhoons in south-western Pacific where

Taiwan located. In order to cope with serious flood issues, we have relied on hydraulic engineering heavily. According to Special Act for Flood Management in Taiwan, project of flood-prone areas has been budgeted 3.8 billion US dollar for eight years since 2006. Nevertheless, urban development changes land-use coverage directly which affects overall performance of hydraulic engineering and eventually leads to flood disaster (Beighley et al.,2003; Haase et al.,2009).

In the past, the government has been planning flood management via setting appropriate design standard for waterways. The design standard for flood management has been adopted to ensure the flooding capacity of the waterway under certain return period. However, the existing flood management and drainage facilities have been largely completed, and there is financial limitation to the increase in the amount of engineering facilities in response to runoff (Ministry of Water Resources and Water Resources Planning Laboratory, 2014). From the past flooding events - Netherlands, although the design standards have been continuously improved, it is impossible to avoid flooding. The design criteria for setting the 10,000-year return period in the coastal areas in the Netherlands have failed, and it occurred in the 1993 flood event.

As a whole, in order to cope with the above-mentioned engineering disaster reduction measures with their limits, and in response to climate change impacts on urban areas, Taiwan's water management measures have gradually changed into integrated flood management in recent years. Currently, the government is advocating the establishment of "Regional Flood Protection Standards" and the degree of protection specified by the protection standards, through engineering and non-engineering means to share floods to achieve a certain degree of protection in the region. International countries, especially the Netherlands, Japan, and the United States, have incorporated the concept of protection standards into flood management and developed protection standards. If the protection criteria are clearly defined, the governments can allocate a limited budget and resources for engineering and non-engineering measures in advance to maximize the efficiency of flood management. By promoting the concept of protection standards to the public, people's awareness of disasters is raised. Through the information disclosure of such flooding disasters, people can fully prepared in advanced with complete information. Therefore, this study attempts to review the practices of countries around the world in the protection standards, and attempts to develop a framework for possible operations in Taiwan.

Protection Standard

The term protection standard is derived from the risk evaluation criteria for technological hazards and is often used in hazardous installations such as nuclear industry, chemical industry, aviation transport, and rail transport etc. (European Maritime Safety Agency, 2015). In these categories of industries, it is basically inevitable that risk accidents will occur, even if such accidents are unlikely to occur, but if they occur, they may cause harm and loss to humans, the surrounding environment and economic aspects. Therefore, in order to ensure its safety, a "safety benchmark" is often established, and further safety measures are taken to reduce the risk level to protect human life and protect public safety. Nowadays, this concept is gradually applied to the field of flood management in natural disasters (Vrijling, 2001).

As far as the domestic situation is concerned, the concept of "protection standards" is often confused with the meaning of "design criteria" for water conservancy facilities for two main reasons. First, since the past flood management was limited by manpower, budget and technology, it was only managed in a "point" or "line" mode. Therefore, the so-called "protection standard" refers to flood management and drainage works. In fact, the implication is that in the past, the "design criteria" of the region were regarded as "protection standard." Secondly, in response to the impact of climate change, according to the comprehensive water management strategy to improve flooded areas, the protection standard has been revised to "regional flooding safety benchmark for flood disasters."

Netherlands is located in the western coastal areas of Europe. As the same time, due to the low terrain and two-thirds of the country's land below sea level, it is vulnerable to floods and tides. In 1953, Netherlands experienced the worst flooding in the country's history, invading the coastal areas of Netherlands, killing about 2,000 people and inundating more than 200,000 ha. Of land (Klijn and Deltares, 2013). Therefore, the Delta Committee was established the following year and is responsible for the improvement of the national flood management plan. When the Delta Plan was released in 1958, scholar Dantzig (1958) proposed a method for exploring design criteria using cost benefit analysis. Through this analysis, Netherlands has set design criteria for 14 coastal dike areas and decided to protect this extremely important and extremely vulnerable area for 10,000 years (Kind, 2014).

In 1993, the province of Limburg in the southeastern part of Netherlands was still suffering from flood, with more than 180 square kilometers of land accumulating 1.5 meters of flood; this time, water experts recommended dredging riverbeds, setting up flood detention areas and capping dikes. In 1995, just two years later, the scale of floods in the same location was once again surpassing the past. Although there were no major disasters at this time, the two flood threats forced policymakers to reflect on the traditional way of "fight against the water" and "living with water." The Netherlands launched the 21st Flood Protection Project and began to develop new protection standards and conduct necessary research. Because the country has experienced major flood losses and caused tens of thousands of deaths, it has placed great emphasis on the protection of "life" in flood prevention and mitigation strategies. Therefore, the concept is the threshold value that individuals can bear to ensure that everyone achieves the lowest level of safety.

Figure 1 Protection Standard in the Netherlands

In the past, due to over-exploitation of the land, Japan's impervious surface continued to expand, so that the rainwater could not be infiltrated smoothly, the collection time was shortened, and the natural water circulation rules were disrupted. As a result, when the urban area encounters heavy rain, it is prone to flooding. In order to solve the flooding disaster, the Japanese government began to implement the "Integrated Water Management" in 1977. The purpose is to meet the impact of rapid increase in surface runoff due to insufficient water retention

and flood detention skills after rapid urbanization. Japan's flood management mainly targets the basin, and breaks the boundaries of the territories according to the different characteristics of each river basin.

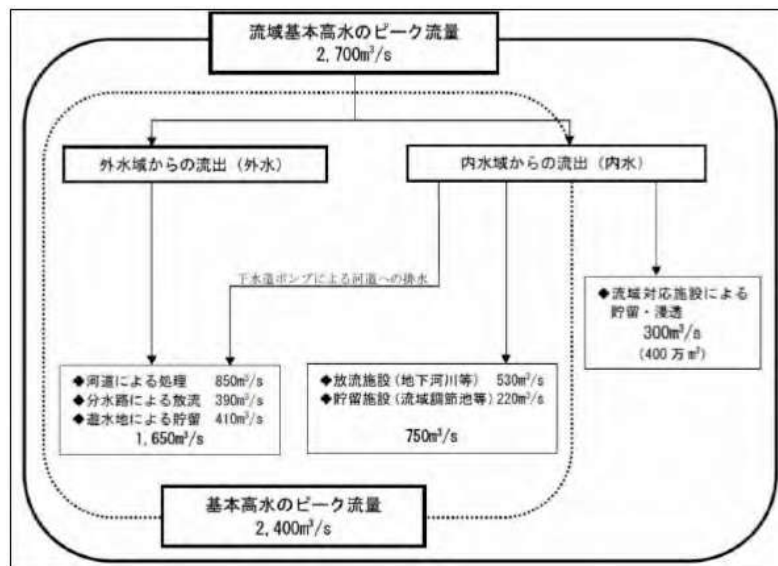

Figure 2 Flood management in Japan

New Orleans area is located on the delta plain of the Mississippi River in the United States, and the unique natural environment surrounding it makes the area vulnerable to flooding. Except for most of the area surrounded by water, it is estimated that more than half are below sea level, and some areas are below average sea level of 9.4 feet. Floods caused by storm surges have affected New Orleans, such as Hurricane Betsy in 1965, which flooded 164,000 houses and caused huge losses. Later, New Orleans began to work on the flood protection works, but it failed to withstand the unprecedented disaster caused by Hurricane Katrina. Therefore, the New Orleans began to review and discuss the protection standards in the local areas. The US protection standards are fairly similar to those in the Netherlands, and mainly use the concept of personal risk criteria as described above to ensure that everyone achieves a minimum level of safety.

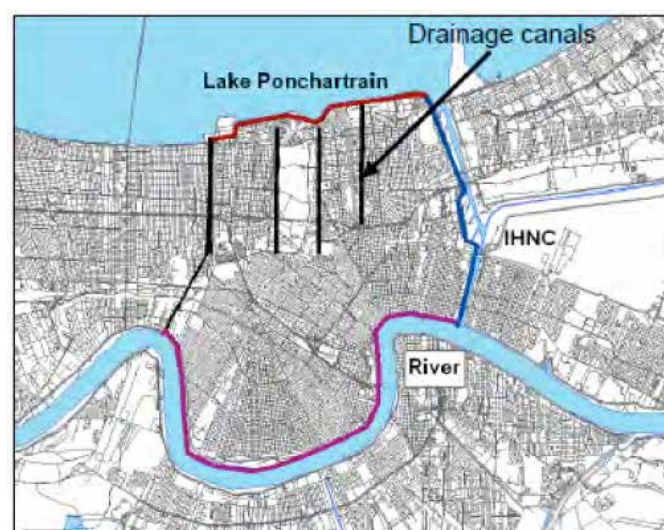

Figure 3 New Orleans

Research design

The study selected the Dali River Basin as the verification area. Dali River is located in the middle reaches of Wuxi River Basin. Dali River is an important tributary of the middle reaches of Wuxi. It originates from the hilly area in the east and flows into the Taichung Basin to the west. Because of the loss of the binding of the upstream valley in the downstream area, the actual flooding in the past floods are concentrated in the intersection of the lower reaches of Dali River and the other tributaries. Dali River flows through the highly developed area of Taichung City, Taiwan. The river basin contains and spans a total 12 urban planning areas. The threat of flooding to the industrial economy and the safety of life and property cannot be ignored. Therefore, it is necessary for the Dali River Basin to be planned for flood prevention.

The Dali catchment area belongs to the secondary catchment area of the Wuxi River Basin. There are 10 sub-catchments with a total area of 400.72 square kilometers, of which 35% are urban planning areas and 52% are non-urban land. Among them are 12 urban planning areas, mainly distributed in the western half, with the largest number of residential areas (32%), followed by scenic areas (19%). Non-urban land use zones are dominated by hillside conservation areas (65%), followed by specific agricultural areas (20%). According to the present land use, the Dali River basin is dominated by agricultural land (26%) and forest land (33%), and is distributed in the eastern and southern parts of the catchment. The land used for conservation (18%) is concentrated in the west and is consistent with the distribution of urban planning areas. As a whole, urbanized areas are concentrated in the western portion.

Figure 4 Study area

This study used the third-generation flooding prone map produced by the Water Resources Planning and Research Institute of the Ministry of Economic Affairs in 2014. The simulation considers the river, hydraulic structures (pumping stations, seawalls, etc), rainwater and underground waterway systems (rainwater manholes, rainwater pipelines etc), and has integrated the results of the flood management plan. Therefore, if the water cannot be withstanding by the engineering facilities might be regarded as flood disaster.

(h) 500-year return period

Figure 5 The various return periods

Cost-benefit analysis is often used in decision-making by evaluating the cost and benefit of a comparison program to achieve the most cost-effective option (Kuiyu, 2001). In the field of disaster prevention, the cost is regarded as the amount of cost of disaster reduction engineering costs; “effectiveness” refers to disaster losses that can be avoided or reduced by disaster reduction projects (Kron, 2005; Penning-Rowsell, 2013). In the cost-benefit analysis, it can be further divided into “financial benefit analysis” and “economic benefit analysis.” The financial benefit analysis is usually based on the view of operating revenue and expenditure. The analysis of the project from the perspective of “financial aspects” measures financial profitability; and the economic benefit analysis is based on the perspective of social benefits and social costs, from the “financial side.” The “economic aspect” and “environmental aspect” are three kinds of aspects to analyze the plan and measure its economic rationality.

According to the research topic, the setting of protection standards is quite high by the society and the public. As the same time, referring to foreign experience, such as Netherlands, it is seen in the cost-benefit analysis of the protection standard. The study not only considers the financial and economic aspects but also considers the elements of the “environmental surface” of the flood, such as nature, landscape, and cultural heritage (Kind, 2014). Based on the above, the study applies “economic benefit analysis” as a research tool to explore regional flood protection standards, and then explores its elated costs and benefits.

Results

The meaning of the “cost-benefit analysis” in this study is the benefit value that can be obtained for every cost of 100 million NT dollars. Therefore, if the result is less than 1 indicating that the structural engineering measures are inefficiency based upon the economic perspective. However, if the result is relative high indicating that such structural engineering measures are cost effective. In the 200 and 500 years of the recurrence period in the table, the profit ratio is less than 1, which means that if the protection standard in the Dali River Basin is increased to 200 and 500 years, the cost-effectiveness may not meet the economic benefits of flood control and disaster reduction. Although the protection ratios of the protection standards 2, 5, 10, 25, 50 and 100 are both greater than 1, they are still different in economic sense. At the same cost, the five-year economic benefit of the protection standard will be the most significant, which means that the basin can cost the same cost in the situation, but can achieve relatively high disaster reduction benefits. The protection standard for 10 years is second to none, and the second is the standard of protection.

Figure 6 Study area

Conclusions

In the face of uncertain global climate change in the future, “no flooding” is an unrealistic goal and a misinformation that might leads people to confront relative high risk. In order to let the public know the threats and challenges, we should clarify the concept of “protection standards.” Therefore, this study proposes a framework for the protection that Taiwan can operate, and discusses the protection standards that Taiwan can operate. The basin was used as the main spatial unit while there are 10 sub-catchments in the basin and the socio-economic environment is quite different from the sub-catchments. Therefore, it is more appropriate to explore the regional protection standards form a relative smaller scale to improve such accuracy.

Abstract: Climate justice reveals inequitable coping capacity to climate change impacts among socially vulnerable groups. As extreme events have become more frequent and intense under climate change, increased flooding risks have threatened communities around the world, and the hardest hits are the socially vulnerable populations. How can planners assess climate justice and manage integrated risks? What is the role of planners for addressing climate justice and enhancing resilience of vulnerable communities? Climate justice and risk assessment are aligned to integrate exposure to climate change associated hazards (ecological vulnerability), sensitivity (social vulnerability) and adaptability (technological vulnerability) assessment. The framework was applied to case studies in Michigan, USA, and Tainan, Taiwan. Employing Geographical Information Systems, climate justice hotspot in three cities were identified in the Huron River watershed, Michigan, USA. Interviews with planners gauging their institutional capacity towards climate change adaptation revealed that Ypsilanti is the most climate unjust because of a lack of resources to act on climate change. In the case for Rende District, Tainan, Taiwan, the community is identified as one of the most flood-prone districts in addition to a growing aging population of 65 years old and older, which is considered a climate justice hotspot. A series of technical interventions were conducted with district leaders and residents and demonstrated a range of adaptive capacity among the seniors with various arrangement of dwelling unit. Additionally, the leadership to mobilize community-based risk management integrating smart technology and residents' participation in risk management has enhanced their coping capacity to climate change-induced flooding. The two case studies implied that planners can bridge the gaps between calculated and perceived risks by applying both quantitative and qualitative assessment in order to identify and address climate justice in local communities. Finally, the community-engaged climate change adaptation with the strength of local leadership and stewardship can ensure the long term sustainability and resilience of the community.

Keywords: climate justice; social vulnerability; integrated flooding assessment and management; aging population; Taiwan; USA

Introduction

Urban planning investing infrastructures for flood mitigation, risk management, and resilience building in the communities is urged to integrate climate change planning and prioritize investment to address climate justice (Cheng 2019). Socially vulnerable groups (e.g., female, children, the elderly, low socio-economic status,

migrant and minority groups, people with special needs) who are likely possessing less coping capacity for climate change-induced natural hazards, thus constructing *climate justice* describing inequitable burdens for socially vulnerable people who suffer more under the condition of higher ecological vulnerability as a result of climate change impacts (Cheng 2016). Integrated risk assessment incorporating social-ecological-technological systems (SETs) vulnerability assessment framework provides a critical tool for assessing complex and wicked urban challenges in the built environment under climate change impacts (McPhearson et al. 2016; Cheng 2016). Climate change-induced flooding refers to the increased intensity and frequency of rainfall events and associated flooding as a result of changing precipitation and temperature patterns under global warming impacts (IPCC 2014), which affects hydrological cycles and flooding hazards in the watersheds for local communities (Cheng et al. 2017a). This paper applies an integrated climate justice and risk assessment and management framework and discusses two case studies in Michigan, USA, and Tainan, Taiwan, to investigate vulnerability of place and opportunities and challenges in implementing risk management strategies and addressing climate justice in communities.

Michigan's Case

Study Area and Context

The Huron River watershed drains more than 2,300 km² covering seven counties in southeast Michigan, USA, due west of Detroit. The watershed area has a population about 500,000 across 65 municipalities. Based on the previous study, a climate justice index was created based on social-ecological vulnerability assessment (Cheng 2016). Social vulnerability index was constructed based on Cutter's method (Cutter et al. 2003) using 33 socio-economic indicators in 220 census tracts. Ecological vulnerability index was derived from climate change-induced flooding hazard built upon a hydrological model, toxic and waste facility sites, and water quality impaired stream data. The intersection of the high social vulnerability and high ecological vulnerability analysis units constructs climate justice hotspots. Three cities were identified as climate justice cities: Ann Arbor, Ypsilanti, Wixom. A follow up study was conducted to survey the use of climate justice map information in gauging the changing risk perceptions of vulnerability to climate change (Cheng et al. 2017b). Wixom is a middle-class and family oriented suburban city; Ann Arbor is where the University of Michigan is located and has the highest median household income; Ypsilanti has the lowest income level among the three cities in 2015 census. The watershed is predominately white (83.5%) while the climate justice cities are more diverse with African Americans (29.2% in Ypsilanti and 11.1% in Wixom), Asians (14.4% in Ann Arbor), and Hispanics (4.3% in Wixom). This case study focuses on additional interviews with managers in the climate justice cities.

Method

A structured interview of ten questions with managers who oversee long-range planning, public works, and sustainability in the three climate justice cities was conducted. The questionnaires include a) responsibility in the institution and in relation to climate change planning, b) access to resources for climate change planning, implementation, and management, c) equity goals in city's plans, d) incentives and obstacles to implement climate change actions, e) trans-boundary coordination, f) green infrastructure as a strategy for climate change planning and its implementation challenges.

Results

In general, the three managers revealed several challenges in coping with climate change: 1) the general obstacle in city's operation with a lack of resources both internally and externally and motivation to go beyond day-to-day tasks, 2) a lack of strong leadership in addressing climate change and equity in long range planning, 3) inability to integrate multi-disciplinary tasks across departments, 4) short-term project driven rather than

achieving sustainability goals, and 5) a lack of community-driven and place-based planning process. For example, one city has a Climate Action Plan

“but it was prepared by a consultant. They did a lot of public input and they’ve got a plan that looks great, but it’s not something we’ve been in the habit of incorporating into decision making and all that good stuff. It did feed into our master plan, which we did in 2013, but a lot of the pieces that are in this are things that aren’t quite underneath our purview or things that just aren’t feasible for a community of our size, to incorporate green building standards into incentive programs. We don’t have a whole lot of incentive programs, so this is kind of a meaningless.”

In terms of moving forward, *“I think that very much relies on strong leadership...and we don’t have that right now. We have multiple competing priorities.... It’s that sort of thing. Between these two projects, most of our discretionary funds are being used, and even some nondiscretionary funds are being allocated to these things.”*

Taiwan’s Case

Study Area and Context

Taiwan is a Pacific island country exposed to multiple ecological vulnerability such as earthquakes, typhoons, floods, and droughts. This study investigates the social-ecological-technological impacts from two extreme and disastrous flooding events in the past decade: Typhoon Morakot on August 8, 2009, and the “823 floods” on August 23, 2018. Typhoon Morakot attacked Taiwan with a record-high daily precipitation resulted in the worst floods in Taiwan since 1959 (MOEA 2009) and the accumulated rainfall reached the world’s record of heaviest storm event in the 24- and 42-hour durations (Figure 1). The associated flood damages have resulted in a total loss of 1.6 GDP. The “823 floods” was signified by a short duration but heavy rainfall. The precipitation exceeded design standards of many drainage systems and resulted in heavy flooding.

Figure 1. Rainfall duration in the typhoon Morakot compared to the world record

The flood-prone areas in Taiwan are located in western coastal low-lying areas susceptible to land subsidence. Some areas are lower than the sea level, as much as one or more meters below. Under this circumstance, drainage systems applying gravity flow to achieve drainage was very difficult. Therefore, excessive water could only be drained away by intense pumping equipment.

In terms of social vulnerability, Taiwan is becoming an aged society with increasing percentage of population are equal or greater than 65 years old (typical retirement age). Rende district in Tainan, Taiwan, is a community at outskirts of the city and composed of 13.82% of aged population in 2017, increased from 10% in 2012, and continues to grow. The most predominate housing type in this community is multi-story single family house or townhouses without basement. In order to accommodate aged population in the built environment during flooding events, this study explored the interactions between technological (flood-proof building infrastructure) and social vulnerability and resilience (physical and mental state of adaptive capacity).

Method

Targeted interviews and measures of their physical and mental state of the elderly and their realistic needs are conducted. In addition, an integrated management with smart technology and collaboration between home security industry, China steel Security, and community on flooding monitoring and preparation is implemented in two houses that are in flood-prone areas (point 1 and 2 in Figure 2) based on the interviews and entrusting the local community leader to select the appropriate locations.

Figure 2. Locations of smart monitoring devices in point 1 and point 2 within flood-prone areas Rende District, Tainan, Taiwan

According to the United States Federal Emergency Management Agency (FEMA), the disaster prevention architecture flood-proof design is necessary to incorporate the following equipment: a) water level sensor, b) security reporting system, c) CCTV camera, d) security host, and e) the 24-hour control center (Figure 3). The water level sensor is located at the low-lying location to collect water level information during the flood. The CCTV camera is installed in a position where the water level change is clearly observed remotely by the security control center. The video data from the CCTV camera can be combined with the video host to set the video recording time and provide query images of historical data. The water level sensor's signal will be connected to the security host, and then the security host will pass through the ADSL or dedicated lines sending the signal back to the control center. Whenever the water level sensor's signal exceeds the warning value, the signal will be transmitted back to the control center through the security host. The control center will contact the emergency contact person and the lieutenant of the community to visit and investigate the needs of the observed residents.

Results from Users Experience

The US Federal Emergency Management Agency (FEMA 2017) provides four resilient design suggestions for flood-prone buildings: 1) Relocation, 2) Elevation, 3) Wet-proof, and 4) Dry-proof. The most common dry-proof approach taken in Taiwan is to install the floodgate. However, according to interviewees, there are several obstacles and dilemmas for implementing technological solutions:

1. There is no sufficient monitoring and evaluation for the performance of the floodgate. Many owners lack the knowledge of maintenance and drill procedures.
2. The access route is blocked once the floodgate is installed, causing risk for residents to escape from emergency situations.
3. Residents living in flood-prone areas are constantly facing enormous psychological pressures, especially during the rainy seasons, due to the difficulty in making decisions on an appropriate timing of floodgate installation.
4. A lack of maintenance on existing panels of floodgate could cause malfunction and fail to prevent from flooding in the dwelling unit.
5. A large portion of the elderly or physically disabled individuals who live alone need various help from others to install the floodgate.
6. When flooding occurs, water usually back flow from drain pipe, causing serious public health issues (Figure 4). Therefore, if there is no satisfying solution to these problems, it is suggested to elevate their living unit and life-support equipment to avoid such affliction.

Figure 4. Floodwater back flowed from drain pipe into the building

7. Building with basements and elevators (such as hospital, nursing home) will encounter another problem. Water intrusion in elevator pits is common in the rainy season. Given that the elevator pits are usually on the lowest elevation in a building and therefore water accumulates there and disable the elevator. This will seriously threaten the daily lives of the elderly, especially those with disabilities (crutches, wheelchairs, bed-ridden) who rely on the elevators for transportation (Figure 5).

Figure 5. Water intrusion in an elevator pit

Discussion

Bridging the gaps between calculated and perceived risks

Based on Michigan's case in a previous survey with residents, there exist a gap between calculated and perceived risks (Cheng et al. 2017b). People who have recently experienced flooding would consider less susceptible to future events. Similar findings from Taiwan's case that residents tend to think that the devastating floods will not come to their life again. In Taiwan, people have developed different attitudes towards installing floodgate in different regions. Acceptance of floodgate was affected by the individual's experience, opinions of the elders who have lived long in the neighborhood, community associations, and government's attitudes. Most interviewees cannot picture the level of inconvenience and particular accommodation that the elderly will face and need to prepare in advance. In addition, most elders felt that they are incapable of doing any changes to their own buildings or even influence their own resilience to cope with emergency situations. However, regular seasonal flooding has already become a part of their lives and become a source of cyclical psychological pressure for residents.

Place-based integrated risk management

Due to the close relationship between the neighborhoods and local government such as community leaders (elected officials) in Taiwan, the access to local community resources and support is the most immediate and

effective way for risk management and disaster relief before upper level government resources would arrive. As a result, the accumulated local wisdom from the elderly plays an important role for place-based risk management and disaster relief efforts.

Challenges for technology and resource-intensive strategies

Implementing advanced technology systems often rely heavily on external resources, which can lead to vulnerability to the community once the access to the resources is constrained. An integrated central and local government disaster prevention units require sufficient funds, manpower and capacity to coordinate across institutional scales and boundaries. In Taiwan's case, connecting the industry with community and governmental resources to facilitate the dispatch from all parties to carry out disaster relief is the key to the success of the smart technology system. Finally, the intervention of technology should not be limited to the planning of infrastructure and software development. Technology plays an important role in assisting decision-making across institutional scales and various sectors, connecting individual to national security.

Strong leadership in building resilience

It is the leader's ability to communicate the common goals and motivate the public as well as the enterprises to work in collaboration to achievements the common goods. In Taiwan's case, strong local community leaders with well-supported and connected network internally and externally is critical to gain trust and resources needed for building community's resilience. For example, the community leader has effectively mobilized community-based risk management integrating smart technology and residents' participation in risk management, which in turn has enhanced the community's coping capacity to climate change-induced flooding. On the other hand in Michigan's case, a weak leadership leads to a lack of hope and incentives for envisioning futures and implementing strategies that can benefit long term suitability and resilience of the community in lieu of day-to-day tasks and short-term priority projects.

Conclusion

The two case studies implied that planners can bridge the gaps between calculated and perceived risks by applying both quantitative and qualitative assessment in order to identify and address climate justice in local communities. Finally, the community-engaged climate change adaptation with the strength of local leadership and stewardship can ensure the long term sustainability and resilience of the community.

Abstract: Land policy as an all-encompassing practice has been providing a wide variety of instruments to proactively and reactively deal with disasters and promote resilient territories. Historical experiences related to periods of post disaster recovery (the rebuilding of cities after World War II, earthquakes, fires, floods) have revealed the importance of the land policy system as well as the institutional structures that in combination to planning policy determine the efficacy of the safety environment of the affected areas. The operation of expropriation and compensation mechanisms, land re-allocation provisions, land amalgamation and readjustment and the re-distribution of land development rights have proved to be highly critical in disaster management cycle, and principally, during the recovery-reconstruction and the prevention-mitigation phases. What has to be underlined in this respect is the way the aforementioned tools and mechanisms have developed historically under accentuated demands posed by crisis or disaster conditions and are implemented in different institutional vis a vis spatial planning contexts aiming to fostering resilient communities. Set in this context, the aim of this presentation is to examine the effectiveness of land policy in two distinct settings of flood risk management: the Evros River Basin in Greece and the Scheldt River in Belgium. This comparative approach allows to identifying the different obstacles and potentials that could contribute to the formation of an integrated land and safety-resilience strategy.

Keywords: land policy; flood risk management; property rights; risk governance

Introduction

The recent series of catastrophic events in Europe define exceptional situations that have partly overturned advanced civil protection systems and at the same time have forcefully brought back in the agenda the catalyzing importance of the social political and planning milieu in determining a safe environment. From an evolutionary perspective, this situation is determined by two different level processes: at a broader level, the evolution of state policy as a whole and at a more specific level, spatial policies aimed at sustaining safe development. More specifically, historical experiences demonstrate that crisis conditions and exceptional forms of demand caused by natural or manmade disasters might -though temporarily- enforce a radical transformation of state policy. This could

engage the extraordinary transfer of economic (and other) resources to those in needs and to the imposition of political power (expansion of state authority) in ways that contradict prevailing policy patterns and priorities during normal development periods. Thus, disaster demands are in principle accompanied by “exceptional forms of state intervention”, the character of which is specific by definition; it relates to the affected population strata, to damaged economic sectors and obviously to affected geographical (disaster) areas. These demands also have an urgent-time limited character and embody a potential for exerting structural influence on socio-economic systems and developmental trends (O’Connor, 1987; Fine, 1984, 1999; Sernini, 1979, 1994). In addition, they inflict changes on pre-existing institutional-organizational structures by involving the joint mobilization of state agencies of various tiers, competences and by generating new relationships of “trust” between the state and society (Beck, 1992, Giddens, 1999, Wisner *et al.* 2004: 18).

Land policy has been strongly influenced by the implementation of distinct recovery policies (Grebler, 1956: 151) and/or those aimed at increasing future safety. In order to meet the demands posed by disasters and recovery processes, state institutions (national, regional, local) have been obliged to change the existing framework of operation especially in the land policy field (Mileti, 2001: 26). The land policy system is defined as the whole complex of socioeconomic and legal prescriptions that dictate how the land and the rights of use and access to land are to be allocated (UN/ECE, 1996). It incorporates a wide range of tools (expropriations rights, compensations mechanisms, land redistribution, value capture and property rights re-allocation) that guide state and social action for the control, acquisition and management of landed assets (Delladetsimas *et al.*, 2019). What is interesting in this respect is the way the aforementioned tools and mechanisms have developed historically under accentuated demands posed by crisis or disaster conditions and are implemented in different institutional vis a vis spatial planning contexts aiming to foster safe and resilient communities. At the same time the efficacy and evolution of land policy has relied strongly on the interrelationships structured with spatial planning, safety planning and socio-economic strategies; and how these are mobilized to meet exceptional demands.

Figure 1: Interconnected policy fields related to spatial development and safety planning.

This paper places land policy within the emerging trends of disaster mitigation planning in European regions. The rationale for such analysis associates to the identification of key issues that could be

possibly revealed from the comparative case study approach of two distinct risk environments and already adopted disaster (flood) mitigation policies. Clearly the European setting embodies exceedingly different experiences and policy patterns for the protection of local economies and societies. In this respect, empirical evidence is provided from the Greek case of the River Evros Basin, and the Belgian Scheldt River. The selection of the two countries/case-study areas is based on the key common characteristic defined by the dominance of small private land ownership (Delladetsimas, 2006; Broeck and Verachtert, 2016) and the way this affects safety policy; since natural disasters might pose demands and increase land shortages resulting in more competition for and increased conflict over land.

Land policy in a safety and planning rationale

The land policy system as implemented at the national, regional and local context has been reciprocally shaped by its interrelationships to spatial planning (land use plans, regional plans, development control), safety planning (emergency planning, recovery-reconstruction planning, risk prevention-mitigation planning), and socio-economic development (economic zones, economic incentives, compensations, agricultural policies). All these imply the structuring of strong links between decisions on land tenure and decisions on land uses made in the context of implemented plans. In addition, land policy and its impact on land tenure rights and rights of access to land allow for the development of improved land management as a component of adaptation to natural disasters. There have been, for instance, many cases in which the land policy system has historically assimilated risk mitigation demands and emergency management experiences; which in turn have been dialectically combined with the development of an effective spatial planning system, stipulating also a favourable (safe) environment for socioeconomic development. This has been the case of the Netherlands, for example; a country exhibiting a long-standing tradition in safety planning (water and polder management, land reclamation and flood prevention infrastructure). This tradition has led to highly effective processes of upgrading and institutionally upholding land policy instruments, which has reciprocally shaped the development of an elaborated spatial planning system that further provided a complimentary spatial setting for socioeconomic development.

The spatial structure and urbanization history of Greece are tightly associated to disasters (earthquakes, landslides, floods, fires, man-made disasters) and the subsequent recovery processes, involving distinct rebuilding experiences for numerous cities, relocation of towns and villages, and the development of considerable safety practices, especially in the development control domain (seismic code, fire safety code, building regulations). Evidently we are dealing with an exceedingly multi-risk environment (earthquakes, floods, forest fires, extreme weather events), in which -interestingly enough- the land policy system has not developed strong links with spatial planning. It is worth mentioning that the Hellenic Cadastre was introduced in 1995 (Law 2308/1995) and is not yet completed. When it comes to safety planning and disaster recovery periods, implemented policies are limited to mere compensations of affected landowners and re-parceling procedures in urban expansions, as well as disjointed applications of expropriation policies and land use changes in compliance to land-use plan provisions. The prevailing role of land policy is mostly evident in economic development priorities as expressed (partly independent from spatial policies) in conjunction to major infrastructural works (expropriations), the long-standing experience of agricultural re-parceling and land systemization and on the whole to measures related to sectoral policy incentives (fiscal measures, economic incentives especially in agriculture). In relation to safety

policy, the land policy system is regarded as more active in emergency planning (land confiscations-expropriations for emergency sheltering) and in the recovery-reconstruction processes (rebuilding loans, crops compensations, business recovery programmes). Land policy proves to be rather inert or forgotten when it comes to prevention strategies and disaster mitigation planning. At the same time, safety planning exhibits two discrete features: a prevalence of structural technical priorities and an overwhelming emphasis on emergency planning as a mere civil-defense (command-control) practice. On the whole, the interrelationship between all these domains in Greece is highly disjointed and weak since each one appears to be following an independent trajectory. The situation is further conditioned by the proliferation of spatial governance systems for the implementation of safety measures, and by the absence of an effective land policy as a safety practice.

In the case of Belgium, the risk environment is determined by coastal, pluvial and fluvial flooding, and by numerous man-made industrial hazards. The country however, assumes particular importance as a multi-level governance setting (OECD, 2017) in relation to safety policy, conditioned by its decentralized system with the autonomous status of the three regions (Flemish, Walloon and Brussels-Capital Region). In the federal state of Belgium, competences on safety policy (especially flood protection and water management) and spatial planning have been transferred to the regions. In each of these, spatial planning and flood risk management thus fall within different legal trajectories and policy patterns (the central state however maintains overall competences related to crisis management and safety insurance policy). It could be argued that flood risk management and spatial planning are institutionally intertwined. A first bond is clearly revealed in the "2003 Act on Integrated Water Policy" (Flemish Government 2003), which clearly states that the water system is one of the ordering principles in spatial planning, meaning that the water system is amongst the first priorities when developing an area (Mees *et al.*, 2016). Second, a spatial planning instrument used for risk mitigation purposes is the so-called 'signal areas' (*signaalgebieden*); endorsed in disaster prone zones in which spatial development objectives contradict with water management priorities, demanding particular spatial planning decisions to alleviate them. It should be stressed however, that both the Flemish and the Walloon Regions have established Coordination Committees in order to foster the co-operation between different water management agencies and spatial planning authorities (*Coordination Committee on Integrated Water Policy* and *Interdepartmental Flood Group* accordingly). Moreover, the Strategic Advisory Council on Spatial Planning provides advice during the preparation of water management decrees, while in the same context, Water Tests (*water toets*) present the assessment of the impact of a proposed plan on the water system, further fostering the compatibility of planning and water policies. Water assessment thus relates to plans, programs, and licenses not only with regard to building activities but also to environmental licenses (De Smedt, 2004). Within this context and in terms of land policy, water management institutions are equipped with the competence to exercise expropriation and pre-emption rights within their jurisdictions. Furthermore, the 2003 Water Policy Act systematized the enforcement of pre-emption rights and land acquisition processes in flood risk prone areas and signal areas (Mees *et. al.*, 2016). In certain cases, a property owner may demand that the government acquires the property, for example, when the owner is confronted with a delineation of a retention area. With respect to development control, building requirements are enforced aiming to avoid rainwater damages by requiring a minimum storage capacity of 5,000 liters per property for (uni)family homes unless a green roof has been provided (Rainwater Regulations 2014). On the whole, the system requires the assessment of potential effects and in turn the adoption of mitigation or compensation measures. In Belgium, safety policies are also extended in the potential recovery-

reconstruction period with the inclusion of flood damages in the general fire insurance. After modifications of water management legislation in 2010 and 2013, advice by water authorities has now become mandatory in the formation of spatial planning and its scope has been broadened even further to ‘leave more room for water’ (Mees *et al.* 2016). Hence the Belgian (Flemish) experience has been adjusting to the presence of small property structures diversifying its policy and moving towards “flood risk and flood risk prevention” and also to preparedness and to (potential) recovery-reconstruction measures as a proactive rationale.

Insights from the case of the Evros River Basin

In the Eastern Balkan Peninsula, Evros River extends on the borders between Greece and Bulgaria and between Greece and Turkey. Only 6,3% of its total length extends in the Greek state (3,340 sq.km) having as the main tributaries the rivers Ardas and Erythrotamos. A plethora of activities related to Evros have been historically developing and vary from irrigation, domestic water supply, urban sanitation and power supply, corroborating the high contribution of the river to the socioeconomic trajectories of the wider area. More than the 70% of the total dry cotton and sunflower seeds production in Greece, among others, comes from the Evros region. Due to the fact that the fertile agricultural land uses alongside the river basin has been systematically contributing to the local as well as national economy, land policies implemented in the regional unit of Evros has been focusing on the increment of agricultural efficiency. Land consolidation and readjustment measures have been undertaken during ‘50s, ‘60s and ‘90s adding plots for cultivation designated as ‘highly productive agricultural land’ alongside the river. In 2018, a new wave of land consolidation plans came into force for 50.000 acres in the regional unit of Evros, as a consequence of constant pressures by local farmers.

Figure 2: The location of the Evros River basin on the country borders of Greece, Turkey and Bulgaria (Ministry of Environment and Energy [MEE], 2016:8).

At the same time, the areas of high agricultural productivity experience accentuated social and economic vulnerability. The long-standing riverbed management and numerous interventions revolving around the pressures of the farmers to preserve arable land have reduced the capacity of the flood plains (Chouvardas and Papapostolou, 2016). Moreover, the land consolidation plans were not followed by the necessary flood risk infrastructure development, further aggravating the existing flood risk levels (Tsesmelis, 2006). Devastating floods have been a constant concern for local communities as well as for local and regional authorities, while the capability of national response amid extreme weather events is being questioned. Flood risk management works date back to 1934, when the Greek and the Turkish government signed an mutual agreement (The Agreement on the Installation of Hydraulic Systems to start hydraulic and flood protection works on both sides of Evros river). In 1963, the Protocol on the rehabilitation of the Evros River Basin, brought the issue of flood management back to the two countries agenda. The development of infrastructure initiated at that time, lasted until the mid '70s through a number of bilateral agreements and included channels alignment, the construction of levees and dams-reservoirs. It was further accompanied by land policy measures for agricultural land reclamation and state border adjustments. During the same period - although with less conflicts- similar policies were agreed upon Greek and Bulgarian state for their shared part of the river. The aforementioned works remain up to present the dominant flood control engineering structures and have oftentimes proved inefficient to address severe floods (Kanellopoulos *et al.*, 2007). Besides, agricultural activities have expanded and intensified through time without the proportional development and enhancement of the irrigation system, the pumping stations, and the flood control infrastructure (Tsesmelis, 2006).

Some of the most recent flood disasters records denote the huge damages inflicted on infrastructure and agriculture in 2005, the evacuation of two settlements as well as damaged transportation and water supply networks in 2006, the flooding of several households in 2010, and severe damages in 2018. Since 2005, risk management actions undertaken by local and regional authorities, as well as by the General Secretariat of Civil Protection are merely based on: (1) the restructuring and the improvement of engineering infrastructure (embankments, drainage systems etc.), (2) command-control emergency management including the evacuation of households and settlements and the controlled flood events in order to protect inhabited areas, and (3) post disaster relief measures based on compensations for affected population and cultivated land. Indicative of the focus of the prevailing disaster management system on emergency response and post-disaster recovery is the distribution of local and regional expenses. In 2018, for example, the Greek army received in Evros region received 6.000.000 euros to strengthen disaster preparedness, and disaster recovery costs were around 400.000 euros only for Didimoticho municipality (Kritou, 2018). In 2019 compensations to affected population in the area reached 1.164.013 euros. Set in this context, it could be argued that the risk management system regarding Evros floods focuses on tackling flood impacts rather than mitigating flood risk. Land policy instruments are almost absent in flood prevention, with the exception of cross-border land readjustment alongside the Evros River basin.

What has to be underlined here, is that even in the Evros Flood Risk Management Plan (FRMP), enacted in 2018 (Law 2639/2018) -in compliance with the European Commission's Directive- the preservation of agricultural land appears as its outmost priority. More specifically, in the FRMP report it is stated that any flood risk mitigation measures and interventions should be implemented with a view to preserving agricultural land and to avoiding land use fragmentation; especially in the case of

High Agricultural Productivity lands, where any proposed work or activity should not jeopardize the preservation of its qualitative characteristics (Par.1.4.-L2639/2018). Furthermore, the FRMP proclaims the restructuring of agricultural crops in the inundation zones, but not involving land consolidation and land use reallocation processes, but for incentivizing the cultivation of certain species that could operate as a barrier to future flood hazards (Par.1.8. - L2639/2018). On the whole, it could be argued that land policy measures implemented through the years have not been combined to flood risk mitigation, but have acted autonomously and what's more have aggravated the vulnerability conditions of the area.

Figure 3: The operation of the Greek land policy system in conjunction with other policy sectors. Emphasis is given to tools that serve planning implementation and socioeconomic priorities (related to agricultural development in the case of Evros River Basin).

Insights from the case of the Scheldt River Basin

The Scheldt River flows from the northern part of France, crosses Belgium, and reaches the North Sea through the Dutch territory. It constitutes an important waterway, having a long navigable part and several canals that connect the river with significant industrial areas of Belgium. What is more, its banks host one of the largest European ports, in Antwerp. However, major fluvial and pluvial floods have been recorded on the Scheldt River Basin (1953, 1976, 1998, 2002, 2010) and have historically demanded for particular water management actions. Until the end of the '90s, flood management included merely engineering projects and infrastructure works for dams, dikes and water barriers. Since European Directives on Water and Flood Management emerged and were incorporated into Flemish and Walloon legislation, flood management became part of an integrated water policy that operates in line with spatial development strategies, urban and regional plans and environmental protection guidelines. One of the most indicative examples that reveal the crucial and leading role of

spatial planning in coordinating policies of flood management, land use regulation and environmental protection in Belgium is the *Sigma Plan*. After the devastating floods that hit the wider area of the Scheldt River in 1976, the Belgian government launched a plan, named ‘Sigma’ from the initial letter of the river Scheldt, inspired by the Dutch Delta Plan. Since 2005, the Plan has been updated and several Sigma projects have been developed integrating different strategies and measures associated with flood prevention, spatial development, land use planning and environmental protection. Moreover, the Sigma Plan forms a legal-institutional underpinning for the coordination of multiple actors, ranging from Agencies in charge of Sigma projects, namely the Agency for the Management of Flemish Waterways (De Vlaamse Waterweg nv) and the Agency for Nature and Forests (Agentschap Natuur en Bos), to several public and private actors such as local and regional authorities, the Flemish Land Agency, farmers associations, NGOs etc.

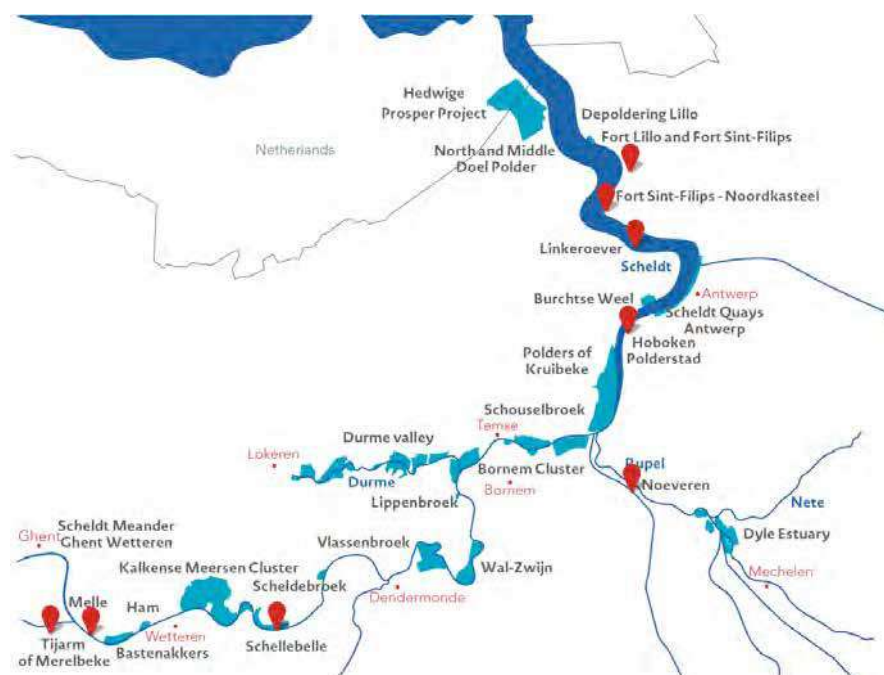

Figure 4: Scheldt River and Sigma Plan projects (source: *sigmaplan.be*).

The nexus developed between flood management and spatial planning has provided a fertile ground for the integration of land policy tools into several phases of the Scheldt’s flood management cycle, especially in mitigation strategies. These include land reclamation, expropriation and compensation, land exchange through the Flemish Land Bank, compulsory land purchase, re-parcelling and land swap. Land expropriation and land swap have taken place either to ‘move’ plots located in vulnerable areas to low-risk zones, or for the permanent evacuation of flood control areas and the construction of hydraulic engineering. One of the largest expropriation projects was implemented in the Kruibeke-Basel-Ruppelmonde Flood Control Area (KBR-FCA) for the complete transformation of 600 hectares land uses and the removal of a quarter of the local community. Despite the conflicts and the resistance by farmers, who apart from ceasing their agricultural activities, were consequently excluded from related European subsidies supported by the European Agricultural Policy, the project was realized and the area was transformed into a flood control zone, a meadow for protected bird species, a sustainable tourism destination and recreational services (Bruzzone, 2013). Moreover, *signal areas*

have been defined alongside the river Scheldt, where land-use allocation and rezoning options are examined (De Smeldt, 2014). In signal areas, a wide range of land policy tools can be implemented in order to minimize flood disaster risk. For instance, re-parcelling with land swap can be effectuated in line with the Decree on Land Organisation for transferring population located on high vulnerable areas to safer zones, followed by related provisions for land expropriation and compensation. However, several procedures are ‘time and money consuming’, thus take a long time to be completed. In this regard, expropriations and compensations often constitute a significant economic burden for local authorities, given the extremely high land values in the Belgian territory, hindering the implementation of re-parceling and land swap in flood prone areas. Especially in Wallonia, such mechanisms are followed by negotiations on land prices that even lead to Peace Court, often resulting in spatial development halts (Mees *et al.*, 2016).

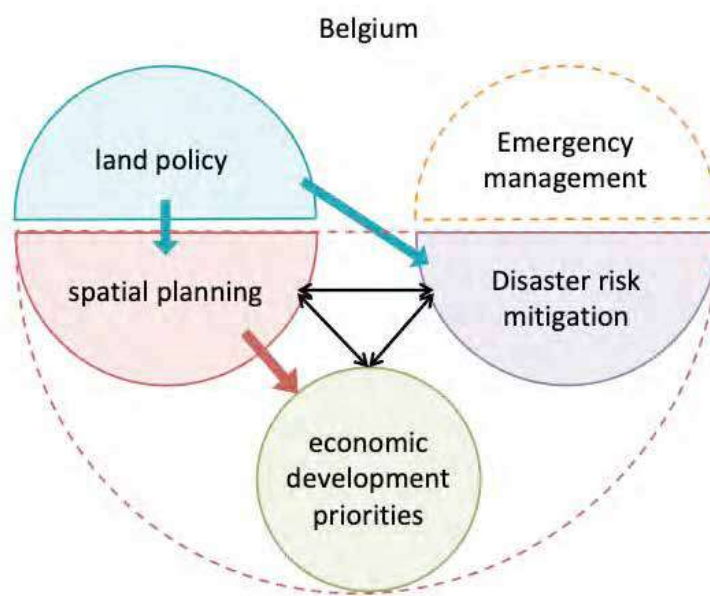

Figure 5: The operation of the Belgian land policy system in conjunction with other policy sectors. It provides tools for the implementation of spatial plans, flood mitigation strategies and environmental protection policies.

Two additional flood risk mitigation instruments have to be highlighted here. First, the 2013 modification of the Decree on Integrated Water Policy (DIWP) introduced the “*duty to inform*”, with which risk mitigation measures are incorporated in all real estate transactions in Flanders. Consequently, all actors involved in private contracts for selling or renting out properties alongside the River Scheldt, as well as for transferring usufructs, leasehold, and superficies (notaries, owners, brokers) are obliged to inform candidate buyers and tenants whether the assets are located on flood vulnerable areas (Doorn-hoekveld, 2017). Second, of particular relevance are the complementary regulation on insurances and disaster compensations. Flood affected population and buildings used to be compensated by the National Disaster Relief Fund if the flood was recognized as a natural disaster. Since 2003, the Belgian Federal government enforced a mandatory insurance coverage against floods as an extension of the fire insurance policy, and only damages caused by very exceptional events are

eligible to compensation by the Belgian State (Boardman *et al.*, 2010). Moreover, the disaster fund used for compensations has been transferred from the central state to the regional governments, aiming to better align prevention and recovery strategies (Mees *et al.*, 2016). The aforementioned provisions are partially implemented and still lack institutional clarifications and legislative improvements especially in the Wallon Region (Mees *et al.*, 2016:47). Nevertheless, it can be argued that in the case of the Scheldt River, the Belgian land policy system provides a plethora of tools that can be mobilised within the competences of other policy sectors (spatial planning, water management, flood prevention), and even in real-estate market, to achieve safe and resilient land development.

Conclusions

The two cases presented in this study demonstrate how the interconnectedness between land policy and risk management may determine the vulnerability of a given area, and thus the amount of losses and damages in cases of extreme disaster (flood) events. First, the Greek case reveals the disjoint operation of spatial planning and flood disaster management, but also the aggravation of flood disaster risk caused by previously implemented land policies. In the wider area of the Evros River Basin land consolidation measures adopted during different periods, since 1950 and up to 2018, were the result of social demands aiming to safeguard and improve the agricultural sector. Flood damages that mostly hit cultivated land in the same area are addressed through post-disaster relief measures and high compensations. On the other hand, in Belgium, land policy instruments are applied in flood risk mitigation projects strengthening the relationship between spatial development and flood prevention. Moreover, spatial planning appears as an institutional ‘umbrella’ for the integration of different sectoral policies (environmental, agricultural, economic) and for the cooperation between several public and private actors involved. In this context, the Sigma Plan operates as a basis for coordinating actions in different areas under its jurisdiction and principally those emanating from the Scheldt water management strategies. This study has also underlined the differentiated operation of compensation mechanisms in Greece and Belgium; a policy tool whose use seems to further influence the links between spatial policy and risk management. Belgium, adopts disaster compulsory insurance as a proactive tool for a potential recovery-reconstruction phase. In Greece, the policy system heavily gravitates on post-disaster recovery compensation relief measures; thus acting as a mechanism to cover the weaknesses and voids of spatial plans, safety regulations and implemented land policies. On the whole, the cases examined present two crucial differentiations that are both associated to the focal role of private landownership and the embeddedness of the land policy system into spatial development and risk management. In the case of Belgium, land policy has been an active domain making use of distinct tools (expropriations, pre-emption rights, re-parceling) in co-ordination (relatively) and combination with other policies (spatial planning, water management, flood prevention-mitigation). Thus the whole system departs by inherently recognizing the role of land tenure relations and realistically structuring a coherent safety strategy. In Greece, the aforementioned domains remain disjointed, while land policy mechanisms are mostly activated in compliance to demands posed by landowning groups related mostly to the economic sustainability of the existing tenure regime and the associated land-use patterns. Thus, as a result, disaster mitigation and prevention appears as an “external” (exceptional) policy domain, shifting the emphasis to emergency and post-disaster recovery measures.

Study on countermeasures and spatial potential of China's coastal cities in response to heatwave and flood hazards

Ning Feng¹, Yang Li²

¹*Ning Feng, ziyunzhiyi@qq.com*

²*Yang Li, 804635002@qq.com*

Abstract: Global warming has caused frequent occurrences of various extreme events. Coastal cities are facing a series of severe flood hazards led especially by rising of sea level and threats caused by severe heat island effects and extreme heat waves. This article first summarizes the shortage of planning actions in coping with extreme climate of flood and extreme heat wave hazards faced by coastal cities in China. Then sorting out international experience of technologies and policies in mitigating and adapting to flood and heatwave hazards, and focuses on the main problems solved by applied technologies and the indicators involved (including time, costs, etc.). Through the identification of quantitative techniques, the spatial potential of the two major types of extreme climate disasters in downtown Shanghai and the priority application of mitigation and adaptation technologies are identified. Finally, from the technical and policy aspects, suggestions for mitigating and adapting to two types of extreme climate disasters in Shanghai's central urban areas are proposed.

Keywords: heatwave and flood hazards; mitigation and adaptation technology; downtown Shanghai

Introduction

Issues such as rising sea levels, global warming, and frequent extreme weather have become common challenges for cities around the world. China's coastal cities are areas of strong economic activity and key areas for the construction of marine ecological civilization, facing the dual challenges of natural and human activities. At present, flood hazards has become a major economic loss in coastal cities, and heatwave has affected the health of people. In the face of these hazards, coastal cities have made some planning actions in the context of national

policies, such as the construction of hazards prevention facilities. However, these cities still lack detailed and scientific technological framework and policies to mobilize enthusiasm and implementation. Therefore, from the perspective of international experience, this article expounds how international cities respond to flood hazard and heatwave in terms of technology and policy. Finally, taking Shanghai as an example, this article studies the spatial distribution of hazards in downtown Shanghai, and give suggestions on how to deal with the heatwave and flood hazards from two aspects of technology and policy, combining international experience. At present, the research on climate change in the field of urban planning in China mostly focuses on national macro-policy research, urban design methods under the background of climate change, trade-offs of mitigation and adaptation actions, and planning technology and policy research for specific hazards or specific urban types is still lack. Other fields are targeted at hazard risk assessment, hazard distribution characteristics, quantitative estimation of hazard intensity, etc., strategies and methods for dealing with hazards are also lack. Therefore, this article combines the two aspects to enrich the technical and policy research on specific hazard types in the urban planning field.

1. Heatwave and flood hazards faced by coastal cities in China and insufficient planning actions

Under the background of global climate challenges, China's coastal cities face severe climate hazard risks. On the one hand, China's coastal cities have some characteristics, such as high population density, intensive economic activity, and high levels of urbanization. Cities with more populations, resources, industries, and infrastructures are more negatively affected by climate change. Large-scale human activities make the region more vulnerable to climate hazards. Climate change overlaps with urbanization. The Organization for Economic Cooperation and Development ranked coastal cities exposed to global flood risk by population and social assets in 2070. The results showed that the coastal cities of China, such as Guangzhou, Shanghai, Tianjin, Ningbo, Hong Kong and Qingdao, were listed in the top 20 cities with the greatest risk (Yuanyuan Zhang *et al.* 2017). On the other hand, China's coastal cities are affected by complex hazards due to the interaction between land and sea. China's coastal areas are close to the Pacific Ocean. Due to the subtropical monsoon climate, floods caused by extreme weather such as typhoon and rain are highly prone to occur. In particular, coastal cities such as Tianjin, Shanghai, and Guangzhou are high-risk areas threatened by floods and submerged in lowlands. Based on the three aspects of ecological environment vulnerability, climate change impact risk and socio-economic exposure, a study on natural hazard risk assessment of coastal cities in mainland China shows that the high-risk areas of natural hazard are concentrated in Liaodong Bay, Laizhou Bay, Hangzhou Bay, some coastal areas of Zhejiang, Eastern Guangdong, Pearl River Delta and Haikou Sea Port (Figure 1). These areas are not only the areas with high vulnerability of natural ecological environment, but also the high-risk areas affected by climate change. They are vulnerable to more serious natural disasters (Hui Chen and Chenyan Ma, 2018). The following is a brief introduction to flood hazards, urban heat island effects and heatwave hazard faced by coastal cities in China.

Figure 1 Results of natural hazard risk assessment in coastal cities of mainland China (Hui Chen and Chenyan Ma, 2018)

1.1 Flood hazards

China's coastal cities are facing the risk of flooding in the low-lying areas of coastal cities on the background of rising sea levels. According to the China Sea Level Bulletin, the sea level changes in China's coastal areas are generally fluctuating upward trend. From 1980 to 2018, the sea level rise rate in China's coastal areas was 3.3 mm/year, which was higher than the global average of the same period. Internationally, coastal areas below 5 m above sea level are considered to be dangerous areas for climate change, sea level rise and storm surge disasters. Most of the coastal cities in China, such as Shenzhen, Guangzhou, Shanghai, Suzhou, Qingdao, Tianjin, etc., have an elevation of only 2.0 to 3.0 m. The Yangtze River Delta is a low-lying area with an elevation of 11,000 square kilometers below 2.0 m. Most of the Pearl River Delta has an elevation of less than 1.0 m (Suocheng Dong *et al.* 2010). As a result, most coastal cities in China are at risk of submergence due to rising sea levels. In addition, sea level rise will increase the extent of intrusion into the ground freshwater layer of land. Coupled with the problem of over-exploitation of groundwater in coastal cities such as Dalian, the contradiction between supply and demand of freshwater in coastal cities has intensified.

In addition, storm surges and floods are major sudden hazards that threaten coastal cities. In 2018, there were 16 storm surges on the coast of China (the statistical scope was the storm surge process reaching the blue and above warning levels), resulting in direct economic losses of 4.456 billion yuan, accounting for 93% of the total direct economic losses of marine hazards in 2018. Storm surges can cause seawater backflow, they can also cause urban flooding when meet the river flood peaks. Coastal cities are generally rich in water systems, which aggravates the chain hazards caused by storm surges (Yue Zhao and Baishi Zhang, 2017). In addition, the

coastal cities have a large population and the urban area is expanding constantly. In the process of urbanization, a large number of reclaimed development activities such as reclamation, over-exploitation, and disorderly development of rivers have destroyed the ecologic and resilience of coastal areas. During the 30 years from 1980 to 2010, the reclamation area was as high as 3577.93km², and the large-scale extensive behavior has produced many negative effects. The urban ground's ability to cope with short-term heavy rainfalls is reduced, and the flood risk is increased (Honglei Yu 2015).

1.2 Heatwave hazards

China's coastal cities are an important area for China's economic development. High-density cities such as Shanghai, Guangzhou and Shenzhen are all located in coastal areas. The urban heat island effect has become a common problem in high-density urban centers. Some scholars used daily temperature range to quantitatively assess the intensity of urban heat island in remote sensing. They found that the intensity of urban heat island in eastern coastal areas of China was increasing (Zhongli Lin and Hanqiu Xu, 2018). The heat island effect can exacerbate the negative effects of heatwaves. During the period of extreme heatwaves, the effect of heat island is obvious at night, which will reduce the temperature difference between day and night in the urban center. The heat island effect also creates a low-pressure vortex that causes the accumulation of atmospheric pollutants and exacerbates air pollution. Under the background of global warming, there are more and more heatwave events, which have brought enormous adverse effects on human health, agriculture and ecosystems. Heatwave are characterized by variability, sustainability, and predictability, and are related to weather-scale circulation systems, urban heat island effects, subsidence warming, and topography. Heatwave can cause discomfort to residents, fires, endanger crops, increase water and electricity consumption. Among the coastal areas of China, the southeast coastal cities are affected by the subtropical high-pressure climate and become an area with sweltering heatwave hazards. Due to the short coastline, northern coastal cities often suffer from dry heatwave hazards (Xinyu Wang 2017).

According to the distribution map of China's high temperature days published by the China Meteorological Administration (Figure 2), it can be seen that the high temperature phenomenon in the southeast coastal cities is relatively serious, especially in the Zhejiang section, which can last for nearly 30 days. The distribution characteristics of coastal cities can be seen from the temporal and spatial variation characteristics of heatwaves in China (Figure 3, Figure 4, Figure 5, Figure 6). The frequency of heatwave and the number of days of high temperature have both showed higher in southeastern coastal cities and Zhejiang ranked the highest. In the linear variation trend of frequency and number of days of heatwave, the southeastern coastal cities showed a significant increase trend, while the northern coastal cities showed an increasing trend

(Dianxiu Ye *et al.* 2013). Combined with the heatwave warnings that have appeared in China's meteorological bureaus in recent years, the heatwave phenomenon in China's coastal cities has increased and the coastal cities need to take measures to face them positively.

1.3 Insufficient planning actions

In the face of global climate change, China has been proactive in taking action. For example, the state has launched the National Climate Change Plan (2014-2020) and provincial-level special plans, China's Special Action on Climate Change Science and Technology, China's National Independent Contribution to Enhancing Action on Climate Change, and the Action Plan for Cities to Adapt to Climate Change. Coastal areas have actively carried out the construction of marine ecological civilization and the construction of climate-adapted cities, as well as the pilot work of climate-adapted urban construction. China has made some progress in mitigating climate change, adapting to climate change, improving institutional mechanisms, strengthening capacity building, encouraging local action, and raising public awareness. Coastal cities are actively responding to national strategies, such as Shanghai drew up “13th Five-Year Plan for Energy Conservation and Climate Change in Shanghai”. However, there are still many shortcomings in Chinese cities in terms of planning actions to address climate change.

In the planning and management system, the Shanghai 2035 Master Plan proposes to build a more sustainable and resilient city of ecology, and clearly articulate measures to deal with sea level rise, to mitigate extreme climate impacts, and urban heat island effects. However, the task of coping with global climate change has not yet been clearly stated in the urban planning and management for many coastal cities. Urban planning does not refine and deepen specific planning techniques and methods (Zuda Ye 2017). The lack of technical content will affect the planning response to climate change.

In the planning of macro-policies and local actions, the content of energy-saving emission reduction and low-carbon actions is too much, and the content of improving infrastructure adaptability is relatively little (Quan Zhou *et al.* 2016). There is a lack of integrated regional coordination mechanisms among local governments (Dongfeng Yang *et al.* 2017). Some local governments have taken into account the financial shortage, other economic and social problems, cost of human capital, risk of damage to their own economic interests, and relatively less serious climate hazards. They are not active in facing regional cooperation (Yan Song *et al.* 2011). In addition, national or local policies lack classified guidance, while different cities in coastal cities face different status and challenges.

At the level of planning control and design, domestic cities mostly carry out the construction planning of low-carbon city, resilient city and sponge city, which responds to the ecological concept from the aspects of land use, traffic planning, infrastructure planning, open space design, ecological green space system planning, wind corridor planning, green building, municipal engineering system planning, hazard prevention and mitigation planning, etc. Such as low-impact development, roof greening, and cold microclimate construction. However, in addition to hazard prevention and mitigation planning, these control designs are often fragmented, and there is a lack of systematic, direct and in-depth guidance and linkages with specific climate disasters. Some designs are too microscopic and formal, and it is difficult to exert effects (Weiwen Zhang and Liangjiang He, 2009). Planning and climate change are likely to be tightly integrated if there is a framework for multi-level planning and design control that responds to climate change mitigation.

In short, faced with heatwave and flood hazards, China's coastal cities lack legal, scientific, cooperative, proactive, targeted and systematic planning. These coastal cities need to draw lessons from other countries' technical and policy strategies.

2 International experience in mitigating and adapting to heatwave and flood hazards

There is growing recognition and awareness that nature can help provide viable solutions that use and deploy the properties of natural ecosystems and the services that they provide in a smart,

'engineered' way. These nature-based solutions provide sustainable, cost-effective, multi-purpose and flexible alternatives for various objectives. The European Union (EU) defines it as Nature-Based Solutions (NBS), it refers to the sustainable management and use of nature for tackling socio-environmental challenges. In Table 1 and Table 2 , a series of relatively mature NBS solutions are collected and sorted out according to internet sources.

2.1 Heatwave hazard solving technology

Table 1 summarizes the technical indicators and construction costs and effectiveness of different scales to mitigate and adapt to heatwave. As can be seen from Table 1, although the scale of solutions for heatwave hazard is different, the construction of green facilities plays an extremely important role, and the greening of the surface is particularly emphasized from the building, the block to the city scale. The small-scale greening facilities are more suitable for the transformation of the built-up areas, and generally can achieve significant results in a short period of time, and are easier to be implemented. The common greening method is to provide more green vegetation coverage. It is generally divided into two major types of plants, planting trees and grass. The average effective time for increasing tree coverage is shorter than the average effective time for increasing grass. Studies have shown that there is an extension effect on the cooling effect of the green area. Although it is not clear whether there is a minimum scale, the effect of cooling extension with the increase of green area has been verified. The cooling extension effect of a 156-hectare park can even be reach the park boundary 1 km away (Diana E. Bowler *et al.*, 2010). This extension and cooling effect beyond the boundary of the green area indicates that the cooling effect of parks of different scales can be preliminarily considered in the urban park system planning to effectively reduce the heat island effect. Another study also shows that mosaic-style dense and frequent small green space improves the urban thermal environment better than large concentrated green space (Xinyu Wang and Jian Zeng, 2017). Therefore, for the dense construction area, the green transformation is more suitable for increasing the horizontal or vertical green vegetation coverage through the dense plaque method.

In addition to the green transformation, providing different cooling spaces are also effective strategies for heatwave, especially for the more vulnerable groups (such as the elderly over 65 years old, the poor, the population with low educational level). The cooling space can be used effectively not only to provide a sufficient amount of cooling space (air-conditioned indoor space and shaded outdoor space), but also ensure accessibility to these spaces, especially vulnerable people (Babak J.Fard *et al.*, 2016). The elderly group is at a disadvantage in terms of physical fitness, and they are inconvenient to move. It is easy for them to be limited by the distance cost and cannot reach the cooling space far away for them. The poor and low-educated people are more likely to be low-income people, and the accessibility to air-conditioned indoor

space for low-income people is often subject to cost constraints. The accessibility to cooling space is thus often limited by cost. Therefore, adequate cooling space and good accessibility must be seriously considered.

Table 1 Technical methods and reference indicators for mitigation and adaptation to heatwave at different scales

Scales	Methods	Costs	Expected efficacy (year)	Descriptions
Building	Wetland roofs	——	< 1	A special type of extensive green roof which is evenly planted with wetland or marsh plants. It can help slow things down and spread the impact of heavy rain out over a longer period along with rainwater collectors.
	Green roofs	Initial costs: 100-250 €/mq Maintenance: 10-15 €/mq per year	< 10	It refers to the space on the top of a building that is covered partially or entirely with vegetation that is planted in a growing substrate.
	Green facades	——	< 1	It is comprised of plants grown in supported vertical structure attached to an internal or external wall or freestanding.
District	Shade provided by trees	Initial costs: \$50-80 per tree Maintenance: \$.10 - \$.22	< 1	Planting vegetation on streets, squares, parks creates shade and evapotranspiration and therefore has a cooling effect.
	Green bus shelters	Initial costs: \$14.500	< 1	Bus shelter provided with green roof for water retention and cooling and with all the smart facilities that make waiting times more comfortable.
	Tree-lined streets	Initial costs: \$50-80 per tree	< 10	It is the street that has trees on either side.

		Maintenance: \$.10 - \$.22		
	Communi- ty gardens	Initial costs : \$3,750 to \$7,500 Maintenance: \$50-\$100 per year	< 1	It is an urban, suburban or rural piece of land in which it can grow flowers, vegetables or a community. It can be one community plot or many individual plots which are located at different scales.
Overall city	Increasing total vegetation index	Initial costs: \$50-80 per tree Maintenance: \$.10 - \$.22	Trees: < 10 Grass: < 1	Increasing green areas by planting trees or growing grass.
	Access to cooling facilities	——	——	Cooling facilities refer to indoor buildings with air conditioners and outdoor spaces shaded by vegetations.

2.2 Flood hazard solving technology

On the scale of building, the usual solution is still the green transformation of the roof. It not only achieves the cooling effect, but also fully utilizes the rainwater. It is a low-cost solution that can effectively solve the heatwave and flood hazards at the same time. It should be noted here that different forms of the roofs have significantly different effects on the speed of the stormwater runoff. The rainwater flow rate on the sloping roof is much faster than that on the flat roof. Therefore, in order to achieve efficient mitigation and full utilization of the stormwater runoff, the flat roof and slope roofs take different forms of treatment, which is evident in the solution of wetland roofs as is seen in Figure 7 (retrived from website).

Figure 7 The wetland roof

The block-scale accommodates more diverse flood disaster resolution technologies, which are characterized by increasing surface permeability and slowing down surface runoff and runoff velocity during rainstorm periods. Most of these measures are low-cost and easy to implement, and can achieve results in the short term. This method can be summarized into two categories: one is to increase the vegetation cover on the surface, while playing a role in mitigating heatwave; the other is to design small-scale surface engineering, such as building infiltration ditches.

Overall city scale. Such measures are usually applied to large-scale urban ecosystems, such as suburban parks, wetlands, etc., and require a large amount of technical and engineering quantities and financial support. What's more, the general construction period is longer. However, once such measures are successfully implemented, they can greatly improve the overall capacity of cities to cope with disasters.

Table2. Technical methods and reference indicators for mitigation and adaptation to flood hazards at different scales

Scales	Methods	Costs	Expected efficacy (year)	Descriptions
Building	Wetland roofs	——	< 1	A special type of extensive green roof which is evenly planted with wetland or marsh plants. It can help slow things down and spread the impact of heavy rain out over a longer period along with rainwater collectors.
	Green roofs	Initial costs: 100-250 €/mq Maintenance: 10-15 €/mq per year	< 10	It refers to the space on the top of a building that is covered partially or entirely with vegetation that is planted in a growing substrate.
District	Permeable paving	Initial costs: €4 - €8/ sqft Maintenance: 0,5-2 euro cents / sqft annually.	< 1	It is a type of paving that allows fluids to seep through them and are commonly used on pedestrians and light vehicle pathways.

	Bioswales	Initial costs: €5,17/m ² (Bioswale) ; €8,97/m ² (Sewage) Maintenance: €0,37/m ² (Bioswale); €0,26/m ² (Sewage)	< 1 or < 10	It is a long, channeled depression or trench that receives rainwater runoff and has vegetation and organic matter to slow water infiltration and filter out pollutants.
	Living Garden	Initial costs: solar panel 3 € per watt, green area 20 € Per sqm and structure 40 € per sqm	< 10	Concept developed by the Dutch Garden and Landscape Contractors Association in which green and sustainable gardens for private or public spaces are proposed, in which water, energy, soil and edible greenery are concentrated.
	Rain garden	——	Depends on the scales	A low-cost rain garden can be built to prevent rainwater runoff from the roof, the various impermeable surfaces of the building and its perimeter from being directed into the stormwater drainage system (Mélissa Giguère <i>et al.</i> 2016).
	Gutter	——	< 1	Gutters are wide and shallow simple form of channels, which are above ground that carry the storm runoff in excess of the capacity of the minor drainage system from streets and squares.
	Infiltration strips and meadows	Initial costs: 1,73 €/lineal foot	< 1	Infiltration strips and meadows are green or permeable areas that provide opportunities for slow transportation and infiltration of water.
Overall city	Urban wetland	——	< 10	A wetland is a zone where the distribution of living beings is mainly characterized by the presence of water, whatever its degree of

				salinity or its persistence during the year.
	Re-meander rivers	Initial costs: £ 100-300/m	< 10	Re-meander rivers (where they have been artificially straightened) to help reduce speed and height of flood peaks.
	Rainwater run-off ponds	—	< 10	A system for purifying polluted rain and run-off water, preventing direct infiltration.

2.3 Policies for urban mitigation and adaptation to heatwave and flood hazards

Policy on heatwave hazard solutions. The most common action is the heatwave warning system, the most important of which is when to issue an early warning. In determining publication time, the most effective method is comparing historical local daily mortality data with complex weather data for time periods when mortality rates exceed normal averages (Carlson and Ann E., 2008). Heatwave are closely related to the age of the population. As the health of the elderly is more fragile, they are more vulnerable to heatwave. Heatwave can lead to more health problems for the elderly. By investigating the effect of urban heatwave early warning for the elderly population, some scholars found that when cities issue heatwave early warning to the elderly population through traditional media, the effect of early warning is significantly improved than that without heatwave early warning for the elderly population (Carlson and Ann E., 2008). In the cities surveyed, the heatwave warning awareness rate is between 83% and 91%. Therefore, there are three important technical indicators in the heatwave early warning system: historical local daily mortality data, complex weather data for time periods when mortality rates exceed normal averages, elderly population distribution data.

Policy on flood hazard solutions. Private flood protection measure has long been implemented in the German Rhine River, which has received increasing attention in flood risk management measures across Europe and even at the global level. Private flood protection measures are long-term flood mitigation and response measures maintained by private households. They can be understood as a private sector's liability system for flood damage, such as flood-adapted building use or the deployment of flood barriers. The key to the long-term sustainability of the system is that a series of major flood events have become an important trigger for the implementation of accelerated mitigation measures. An analysis of private sector actions after the floods in the Rhine section of Germany in 1993-1995 and 2011 confirmed that flood experience has a strong impact on pre-disaster precautionary measures. Moreover, there is a strong positive correlation between the number of flood incidents reported each year and the

number of flood response measures adopted, which continuously strengthens the private households' sense of responsibility to solve flood problems (P. Bubeck *et al.*, 2012). Interestingly, in the process of implementing pre-disaster preventive measures, personal preventive behavior is often strongly influenced by the behavior of others, which makes the flood experience not only enhance the sense of responsibility through its own experience, but also expand the positive behavior of pre-disaster prevention through upstream and downstream flood events in the waters. The three important positive aspects of flood hazard experience, key reports, and preventive behavior impacts have played a very positive role in maintaining the long-term effectiveness of the private flood control responsibility system.

3 Study on countermeasures and spatial potential of China's coastal cities in response to heatwave and flood hazards

3.1 Spatial distribution of heatwave and flood areas and potential areas in downtown Shanghai

Figure 8 Administrative district map of downtown Shanghai

The research scope of this study is the central area of Shanghai (Figure 8), including Xuhui, Changning, Jing 'an, Putuo, Huangpu, Yangpu and Hongkou.

Spatial distribution of vulnerable areas of heatwaves. Figure 9 and Figure 10 respectively show the surface temperature changes in downtown Shanghai from 1989 to 2013 (Rong Jiang, 2016) and surface temperature retrieval in 2014 (Jian Cai, 2017). It can be seen from Figure 9 that the overall thermal environment increase in Shanghai is mainly concentrated in the central area of the city and its marginal areas. Only Changning District and Xuhui District have plaques with greatly reduced temperature, and the remaining areas are only show slightly and scattered plaques of temperature reduction . The overall thermal environment changes slightly, indicating that the heat island effect has not been significantly improved.

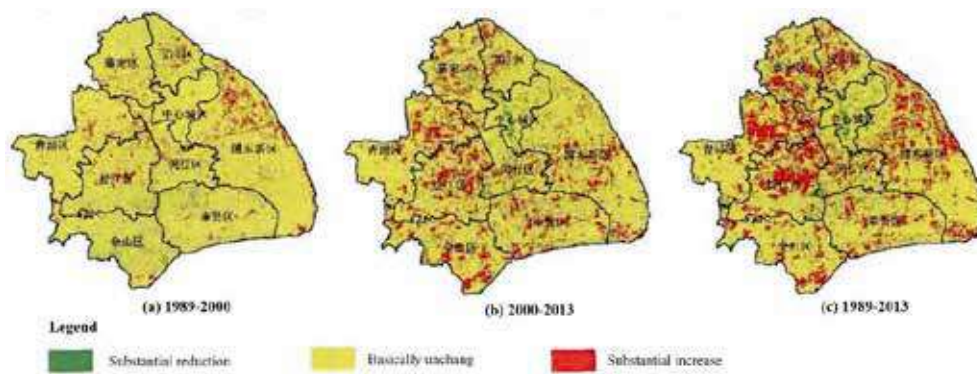

Figure 9 The changes in Shanghai's land surface temperature

Figure 10 Land surface temperature retrieval of Shanghai

According to the data downloaded from the OSM map, the natural waters and different types of green spaces within the central area of Shanghai are extracted. The green space shown in Figure 11 is urban green space. As is seen in Figure 11, the total amount of green space in the central urban area of Shanghai is extremely scarce. There are not enough large green spaces or dense plaque green spaces. The lack of green space is particularly acute in Jing'an District, Huangpu District and Xuhui District. There are a large number of buildings in the downtown area that have not been remodeled with any green roofs and green facades, but it must also be noted that there are also a large number of slope roof buildings in this area. Due to the lack of accurate building roof data, the buildings with 6 floors and below were initially considered as sloping roofs based on the Shanghai building data provided by the Urban Data Party. The rest were considered as flat roofs, which can roughly estimate the distribution of the two types of buildings. When the green roof is reconstructed, the cost and difficulty of the renovation of the flat roof is lower, so it can be considered as the object that can be prioritized for transformation.

In contrast, the proportion of flat roofs in Yangpu District, Hongkou District, Putuo District and Changning District is higher, and the proportion of slope roofs in Huangpu District, Jing'an District and Xuhui District is higher.

Figure 11 Distribution of Shanghai's green areas

Spatial distribution of vulnerable areas of floods. The 2017 Shanghai Digital Elevation Model (DEM) data with a precision of 30m*30m is downloaded from the Geospatial Data Cloud. Based on this data, the distribution of river networks in the central city of Shanghai was analyzed through ArcGis hydrological analysis tool (Figure 12). Firstly, the data is padded to reduce the error caused by the concave area of the image data; then the water flow direction data is extracted; for the next step, the cumulative amount of confluence of water flow direction data is calculated according to the natural water flow from the place where the elevation is large to the place where the elevation is small; finally, the streamnet is obtained by extracting grids with a cumulative amount greater than 100. Excluding the flood period of the Huangpu River, according to this data processing principle, it can reflect the distribution of the largest surface runoff value in the central city of Shanghai. The greater the density of the river network, the more likely it is that urban flooding is likely to occur. As can be seen from Figure 12, the density of the river network can be divided into two levels: the denser areas are Xuhui District, Putuo District, Changning District and Yangpu District; and the sparse ones are Huangpu District, Hongkou District and Jing'an District. However, for the Yangpu District, Hongkou District, Huangpu District and Xuhui District along the banks of the Huangpu River, the huge flood threats of the Huangpu River during the flood season cannot be ignored. Although Changning District and Xuhui District have more natural river channels than other districts, it can be found in comparison with Figure 12 and Figure 13 that the natural river network and the streamnet accumulated by the convergence do not overlap, indicating that the river network is not the only important reason that easily leads to the waterlogging in these two districts. The causes of flood vulnerability reflected by different districts vary.

Figure 12 Analysis of river network in downtown Shanghai

Figure 13 Distribution of Shanghai's natural river

3.2 Countermeasures and suggestions to solve the heatwave and flood hazards in downtown Shanghai

Different districts in downtown Shanghai face different major disasters. In addition to the threat of floods in the flood season that may be brought by the Huangpu River, Changning District, Putuo District, Yangpu District, Hongkou District and Pudong District are facing more flood threats. The heatwave hazard in Huangpu District and Jing'an District are more severe, while Xuhui District faces the challenges of both hazards. Each district should propose different and targeted measures to adapt to and mitigate extreme climate disasters based on the primary problems it faces. In addition, for technical measures such as green roofs that can

simultaneously solve heatwave and flood hazards, more cooperation should be carried out between administrative districts, which should be incorporated into one system and effectively implemented from planning and design to planning implementation and regulation.

In order to effectively implement a series of measures to adapt and mitigate heatwave and flood hazards, each department should first make accurate survey about the distribution of vulnerable population (such as people more than 65 years old, low-income groups, etc.), not just consider engineering technology. By this way, departments of downtown Shanghai can determine the priority implementation area, reduce time and cost waste, and improve the efficiency of problem solving.

In addition, government departments must provide a corresponding set of supporting implementation policies, make full use of and mobilize the power of social resources, and ensure that all adaptation, mitigation of heatwave and flood hazards can be effective in the long run, rather than just construction, regardless of subsequent maintenance.

4 conclusion

Through the analysis of the internationally adopted technical measures for mitigating and adapting to heatwave and flood hazards, the green-oriented solution plays a very important role in solving both hazards, both on the micro and macro scales. The technical method can solve two kinds of hazards at the same time, effectively reduce the repeated implementation costs, and achieve two goals. Therefore, the green-oriented solutions must receive sufficient attention in the future when coastal cities in China responding to extreme climate hazards. In the application of technology, we must first clarify the scope and type of different technology adaptations, and systematically summarize correspond requirements according to the technical details, in order to achieve efficient mitigation and adaptation to heatwave and flood hazards. For different districts of the city, unified technology cannot be fully adopted, and each city must have its own targeted classification guidance program. The technical considerations for adapting to and mitigating heatwave and flood hazards should be incorporated into the planning and design system and management system at the same time, so that design, implementation and maintenance are closely integrated. Disaster mitigation and adaptation measures are not the final result of the application of technology. Subsequent maintenance is an important link as well. Therefore, in the process of dealing with extreme climate disasters, planning, design, implementation, and planning management must attach great importance to mobilizing the enthusiasm and participation of the society from the beginning, shaping the sense of responsibility of individuals and collectives, and learning from the long-term maintenance effectiveness of the German private households. Actively supervise the mechanism and implement responsibility to individuals. China's coastal cities face serious challenges of heatwave and flood hazards. The methods of adapting to and mitigating hazards are also extremely complicated to operate. They must pay special attention to the legality and scientificity, systematicness, cooperation and initiative in the implementation process.

Erratic Climate Change Planning: The Gold Coast's Alternating Transition

Michael Howes¹, Aysin Dedekorkut-Howes²

¹ *Cities Research Institute, Griffith University, m.howes@griffith.edu.au*

² *Cities Research Institute, Griffith University, a.dedekorkut@griffith.edu.au*

Abstract: Planning the future spatial development of coastal cities is a challenge that has become even more difficult due to the impacts of climate change, governing institutions that were not designed to address such wicked problems, and the reluctance of some right-wing governments to respond. The Gold Coast, Australia, provides a case in point. The city is highly vulnerable to the impacts of climate change having been hard hit by storms, floods, heatwaves, and droughts over decades. The governing system for the region is part of a complex three tiered hierarchy involving national (Commonwealth), state (Queensland), and local governments (City of Gold Coast). Governments periodically swing between a right-wing Coalition (of the Liberal and National parties) and the left-wing Labor party (sometimes with the support of the Greens party). In the period 2007-2012 all levels of Australian government had started to take the first steps in addressing the challenges posed by the need to adapt to the impacts of climate change. The shift to right-wing governments during the period 2012-15, however, saw many climate plans and policies and plans reversed due to the combined effects of: gaps in the three tiered system of government; the ideology of the right-wing parties in power; powerful economic interests; electoral politics; fears of legal liability; and, the unique features of the Gold Coast. Since 2015 there has been a divergence with the state-based Queensland Labor government moving back into the climate change adaptation space but the national Coalition government still refusing to act. The science is clear: climate change is happening, the impacts are serious, and low-lying coastal settlements like the Gold Coast are highly vulnerable to its effects. The constant policy and planning reversals over the last decade, however, have made consistent long-term planning and investment in building resilience very difficult.

Key words: climate change adaptation; resilience; policy reversals; Gold Coast.

Introduction

The Gold Coast has experienced erratic swings in policy and planning over the last decade with regards to climate change adaptation. Queensland is highly vulnerable to the impacts of climate change and parts of it, including South East Queensland, have been identified by the IPCC (2007, 2012) as climate change hotspots. The Gold Coast is Australia's sixth largest city and is located on the coastal fringe of the state of Queensland in the north east of the country. It is particularly vulnerable because of its sub-tropical climate, coastal geography, settlement patterns and socio-economic profile (NCCARF 2016). In recent decades the population has grown rapidly with much of the urban development occurring along the low-lying coastal zone (Torabi, Dedekorkut-Howes & Howes 2018; Dedekorkut et al. 2010). Over the same period the region has experienced severe droughts, fires, storms, floods, and coastal erosion (Howes 2013a).

Australian governing institutions were designed in the 19th century and have had difficulty dealing with the challenges posed by climate change (Torabi, Dedekorkut-Howes & Howes 2018; Howes et al. 2015; Heazle et al. 2013; Howes & Dedekorkut-Howes 2012). Australia has a hierarchical three tiered governing system that encompasses one national (Commonwealth) government, six states (including Queensland) plus two territories, and 537 local councils. Elections occur every three to four years for each level, with government periodically swinging between a centre-right coalition of the Liberal-National parties and the centre-left Labor party. A similar periodic swing in governing parties occurs in

many European countries, although the dramatic shifts in policy direction analysed here are more akin to North American politics (Dryzek et al. 2003; Howes 2005). Between 2007 and 2012, all levels of government had begun to implement a set of strategies, plans and policies that could have increased the resilience of the city of the Gold Coast (Howes & Dedekorkut-Howes 2012). After 2012, however, each level of government started to wind back their climate change adaptation governance, despite the risks being better understood (Matthews 2013, Climate Council 2014, Dedekorkut-Howes & Howes 2014, MacCallum et al. 2014, Mustelin and Burton 2014). In 2015 a change in the Queensland government brought reintroduction of some climate adaptation policies at the state level.

The periodic policy vacuum at higher levels leaves local governments to their own devices in combatting climate impacts, which results in a range of responses (Dedekorkut-Howes and Vickers 2017, Torabi et al. 2017a, 2017b). By July 2017 a total of 35 local governments had signed up to the *Cities Power Partnership* that committed them to act on both adaptation and mitigation. Three participants were located in Queensland (Noosa, Bundaberg and Douglas Shire) but the Gold Coast was noticeably absent, although it did get a mention for investing in transport infrastructure (Climate Council 2017a, 2017b). This paper examines the causes and consequences of lack of a consistent policy direction in climate change adaptation through a multi-level policy review of the case of the Gold Coast over the last 12 years. The next section briefly outlines the environmental, social and economic features of the region, as well as its vulnerability to climate change. An explanation of the structure of government is then presented. After this, the growth in climate change policies and plans from 2007 is explained up to its peak in 2012. The demise of these responses to 2015 and subsequent renaissance of state-level planning in Queensland is then summarised. A brief analysis of the causes and consequences of the constant reversals are then offered.

A Snapshot of the Gold Coast

The Gold Coast covers an area of 1400 square kilometres that is bounded to the east by 57 km of coastline with a string of beaches interspersed with headlands and estuaries. In terms of the natural environment, the Gold Coast is a low-lying coastal city built on a network of canals and rivers. It has a sub-tropical climate and is prone to severe storms during the long, humid summers (GCCC 2013a). The urban form is a mixture of clusters of high-rise apartment blocks along the coast, with low and medium density developments centred on the waterways and estuaries behind (Torabi, Dedekorkut-Howes & Howes 2018; Dedekorkut-Howes and Bosman 2015).

The region has experienced rapid population growth, with the numbers of residents rising from 88,000 in 1976 to 606,774 in 2018, and it is expected to climb to 730,000 by 2026 (CoGC 2019; GCCC 2013a & 2013b; DIT 2013; Spearitt 2009). This growth has put stress on urban infrastructure and led to questionable developments in vulnerable areas such as floodplains and sand dunes (Torabi, Dedekorkut-Howes & Howes 2018; Dedekorkut-Howes & Bosman 2011; Bosman et al. 2016, Torabi et al. 2017c). Socially the region is a magnet for retirees and the area has a significantly higher proportion of its population over 60 (20.3%) compared to the nearby city of Brisbane (17.0%) as well as a higher proportion of low-income households (20.8% versus 17.8% respectively) (CoGC 2019; GCCC 2013c, 2013d, 2013e & 2013f). Finally, the region is heavily reliant on tourism, with the beaches adding an estimated \$106-\$319 million to the local economy (DCC2009; GCCC 2013e & 2013f). The lower incomes and health issues due to age make retirees a vulnerable group. Low-income residents employed in the service sector are transient in nature making them less socially connected and therefore lacking coping capacities to deal with disasters (Torabi et al. 2017c). These features make it particularly vulnerable to the physical, social and economic impacts of extreme weather events, flooding and coastal erosion, which will be exacerbated by climate change (NCCARF 2016; IPCC 2012 & 2007; DCC 2009). The Gold Coast has experienced more than forty-five floods since 1925, is subjected to severe storms every spring and summer, and experienced its largest flood event in 1974 (City of Gold Coast 2017). It was fortunate to avoid the worst of the flooding that hit Brisbane in 2011.

Hierarchical Government

At the local level, the City of Gold Coast is governed by an elected council made up of a mayor and fourteen councillors (each representing a different geographical division). The residents of the region

elect ten members of the Queensland state parliament (which has a total 89 seats in a single chamber) and five members of the Commonwealth House of Representatives (out of a total of 148). This makes it a politically significant entity, particularly at the state level.

At the national level, the powers of the Commonwealth government are defined by the Australian Constitution (Australian Parliament House [1900] 2012). Anything not specified as a power of the Commonwealth is deemed to be a residual power and falls to the states (this includes powers relating to the environment, planning and climate change adaptation) (Brown 2006; Howes 2005; Toyne 1994). The Commonwealth has therefore adopted three intergovernmental strategies: 1) leaving some issues to the states; 2) cooperating with the states on other issues; or, 3) selectively intervening by creatively interpreting its powers. It has used its external affairs power (i.e. to sign and enforce treaties), for example, in conjunction with international environmental agreements to halt some damaging developments (Howes & Dedekorkut-Howes 2012; Howes 2005). Local councils are created, merged or abolished by acts of state parliament, as happened in Queensland in 2007 when the number of councils was reduced from 156 to 72 (ABC News 2007). Further, any council may be sacked by a state government and replaced by an administrator, as happened on the Gold Coast in 1978 (Queensland Government [1978] 2009).

The resulting hierarchical three tiered system has created ongoing power struggles between the different levels of government (Ghazarian 2012; Rolfe, et al. 2009; Brown 2006). This has an impact on many policy areas, including climate change adaptation, environmental protection, water resource management, regional development, health care, and education (Howes et al. 2015; Heazle et al. 2013; Howes & Dedekorkut-Howes 2012). All levels of government have moved to find methods for improving the system. One of the main strategies has been to establish organisations that encourage intergovernmental cooperation (Howes et al. 2015; Howes, et al. 2013; Heazle et al. 2013). The Council of Australian Governments (COAG), for example, includes the leaders of the Commonwealth, state and territory governments, as well as the president of the Australian Local Government Association. It has played a key role as a forum for negotiating agreements to tackle issues such as the environment, transport, health care and education (COAG 2011).

Despite the best efforts on networking and partnership-building, the hierarchical Australian system of government still has difficulty in addressing major policy issues (Heazle et al. 2013; Berwick 2006). There remains considerable disconnection between the different levels that manifests itself in administrative duplication, resource wastage and disputes that undermine collaborative organisations (Ghazarian 2012). In addition, the jurisdictional turf wars between departments and agencies persist (Howes et al. 2013; Rolfe et al. 2009). These structural problems can impede efforts to find effective, efficient and appropriate responses to complex issues that cut across borders and portfolios. Wicked problems, such as climate change, exacerbate the situation further because they are also difficult to understand, there is a lack of agreement on an appropriate response, they require a whole of government approach, and need the cooperation of business and the community on a large scale (Howes et al. 2015; Heazle et al. 2013; Howes et. al. 2013; Howes & Dedekorkut-Howes 2012; Australian Public Service Commission 2007). The Gold Coast is on the frontline of such issues.

The Rise of Adaptation Responses up to 2012

By early 2012 a plethora of policies and plans had emerged that influence how the Gold Coast would respond to climate change. These emerged at the national, state, regional and local levels – the key ones, along with more recent developments, are presented in Table 1.

The National Climate Change Adaptation Framework (COAG 2007) is the main agreement that has guided work between the different levels of government. It had ‘building understanding and adaptive capacity’ and ‘reducing vulnerability of key sectors and regions’ as two key areas for action and coastal regions were named as one of the priority areas (COAG 2007, 6). The National Climate Change Adaptation Research Facility (NCCARF) was established to inform policymaking and planning at all levels by networking researchers across the country and funding strategically targeted projects (NCCARF 2013). It was initially funded for five years and gained another five years of funding at a

reduced level in 2012 so that it could focus on developing tools that would help coastal settlements build their resilience (NCCARF 2016).

At the state level, ClimateQ, the SEQ Regional Plan 2009-2031 and the Draft SEQ Climate Change Management Plan were of particular importance to the Gold Coast. These all promoted further research into the vulnerability and the provision of better information to the community. ClimateQ focused particularly on the areas of disaster management, water use and biodiversity protection. The Queensland Office of Climate Change was established in 2007 to coordinate the state's response, review existing policies, and provide advice to government.

At the local level, in 2008 the Gold Coast City Council developed its own Climate Change Strategy 2009-2014 (GCCC 2009). This summarised the problem, acknowledged the vulnerability of the Gold Coast, promoted further research into resilience building, called for coordinated action across all levels of government, audited the operations of council and called for further funding.

Although many of these initiatives were quite modest when compared to the size and urgency of the risk, they represented important first steps that could be built on in later years. Many of the policies did not get the opportunity to be fully implemented, however, before the elections of 2012-13.

The Decline of Responses Post-2012

Election at the local and state levels in 2012, and at the Commonwealth level in 2013, saw governments at all levels change from Labor to the coalition Liberal-National parties across most of the country. The incoming governments were dominated by leaders who were either sceptical of climate change or placed greater importance on economic development. This led to major reversals in policy (Matthews 2013, Climate Council 2014, MacCallum et al. 2014, Mustelin and Burton 2014; see also for a more detailed history of these changes see Howes & Dedekorkut-Howes 2013). At the national level, the Abbott government moved quickly to abolish the Climate Commission, reduce climate change from departmental status to a unit within the Department of Environment, and draft legislation to repeal the *Clean Energy Future* policy (Metcalf 2013; DoE 2013). Both the Prime Minister and the new Minister of Environment were quick to deny any connection between the 2014 bushfires in the state of New South Wales and climate change, despite 2013 breaking several climate-related records with regards to heat (CC 2014; Grant 2013; Howes 2013a). The government's bill to abolish the greenhouse gas emission trading scheme (more popularly known as 'the carbon tax') was passed by the senate in July 2014, although other cuts were blocked. NCCARF did survive with reduced funding after 2012 but was only kept going after 2017 by funding from Griffith University.

At the state level, the Queensland election in March 2012 ended fourteen years of Labor government and brought to power the conservative Liberal-National Party (LNP) with Campbell Newman as the new Premier (QEC 2012). The party went to the election with an *Action Plan* to ‘Grow a Four Pillar Economy through focusing on tourism, agriculture, resources and construction and by cutting red tape and regulation’ (LNP 2012). None of their policies mentioned climate change or adaptation. In power the government abolished the Queensland Office of Climate Change (OCC) and abandoned the climate policies developed by the previous Labor government (Queensland Government 2012; Ironside 2012). Their *Sustainable Planning and Other Legislation Amendment Bill* (2012) focussed on cutting ‘red tape’ and green tape’ in order to speed up the approval of developments. Queensland’s main planning law, the *Sustainable Planning Act 2009* was replaced. The *Queensland Coastal Plan* originally required coastal development to consider the projected effects of climate change such as sea-level rise and increase in the maximum cyclone intensity and local government authorities to prepare a coastal hazard adaptation strategy for areas that are at risk (Dedekorkut-Howes & Howes 2014). Its replacement transferred the task of land-use planning and development in coastal areas to the 2013 *State Planning Policy* which did not address climate change but mentioned climate variability. The *Queensland Plan*, the new 30-year vision for the state, only mentioned climate change in passing. This was quite different from its predecessor, *Toward Q2*, which was developed specifically to tackle the challenges of rapid population growth and climate change and was followed up by the state strategy *ClimateQ: toward a greener Queensland*. In May 2013, a review of the South East Queensland Regional Plan was commenced with no mention of climate change.

These changes suggest that there had been a significant shift in state-level planning and climate change adaption policies which affect not only the Gold Coast but the whole state (Matthews 2013, MacCallum et al. 2014, Mustelin and Burton 2014, DEHP 2016). Neither climate change nor adaptation was a priority in any of the LNP’s policies, either before or after the election, and it does not appear in any of the legislative changes outlined above. The party has been consistent in its pursuit of its ‘four pillar’ policy of economic development, with environmental and planning laws being streamlined if they are considered as inhibiting development. Further, there has been a deliberate move to hand back more responsibilities to the local level of government without the necessary increase in funding and capacity building.

After the local council elections in May 2012, a new government took over the Gold Coast City Council and the attitude towards environmental protection, climate change and development shifted in parallel to the changes in the state government. While the council website stated that climate change was one of the biggest challenges, the climate change department was abolished in 2013 (Weston 2014). The *Gold Coast Climate Change Strategy* expired and was not replaced. A comparison of this strategy with that of the Sunshine Coast revealed that the Gold Coast considered lower end of the IPCC climate change projections in its strategy (Torabi et al. 2017a). A more holistic evaluation of the local planning schemes, disaster management plans, and the climate change strategies of the two cities indicated that Gold Coast policies were less integrated, did not incorporate climate adaptation and disaster resilience well, contained less detail regarding allocation of resources and identification of roles and responsibilities (Torabi et al. 2017a), and focused mostly on coping approaches to climate resilience rather than transformational adaptation (Torabi et al. 2017b).

Divergence of State Policy from National and Local Levels after 2015

The 2015 state elections brought the Labor party an unexpected victory and subsequently state climate policy trajectory started to diverge from the federal and local levels. At the national level, the Coalition Federal government introduced the *National Climate Resilience and Adaptation Strategy* and ratified the Paris Agreement. The strategy articulated how Australia is managing climate risks for the benefit of the community, economy and environment and is anchored by the 2007 *National Climate Change Adaptation Framework*. It outlined the Government’s vision for the future as: “We act together to support prosperity and wellbeing in Australia and beyond by building the resilience of communities, the economy and the environment to a variable and changing climate” and identified a set of principles to guide adaptation practice and resilience building and establishes priority areas for future consultation and action. The guiding principles include shared responsibility between all levels of government, businesses and communities; factoring climate risks into decision making; an evidence-based risk

management approach; helping the vulnerable; collaborative, values-based choices, and revisiting decisions and outcomes over time. The priorities for national engagement are understand and communicate; plan and act; check and reassess; and collaborate and learn. While the vision and the principles are admirable, their implementation and impact at policy level is yet to be seen as the strategy does not set out how they will be realised, rather it compiles examples of leading practice from around the nation.

The divergence between different levels of government on climate change policy has been clearly indicated in recent developments in mitigation and energy policy. Australia made a commitment to reduce its emissions by ratifying the Paris Agreement, but how this commitment will be met is extremely controversial due to disagreements on the nation's energy policy. The Coalition government repeatedly refused to countenance any sort of price on carbon, either as a cap and trade or energy intensity scheme, which puts them at odds with the Labor opposition. The 2017 the Chief Scientist's report offered a way to break the deadlock by focussing on clean energy targets rather than carbon pricing (Finkel 2017). This won support from the federal opposition and Labor states, but the Coalition government rejected the idea and continued with a direct action policy after being returned at the 2018 election. This variance bears all the hallmarks of a wicked policy problem and bodes ill for the development of consistent adaptation responses.

At the state level, the current Queensland Labor Government updated the State Planning Policy (SPP) in 2016 to better align the content with current government policies and priorities and to ensure it supports a balanced planning system focussed on liveability, sustainability and prosperity. The SPP identifies state interests important enough to require protection and enhancement within the land use planning and development system. It reintroduced the term "climate change" to replace "a variable climate", considerably expanded the natural hazards section to include risk and resilience, and introduced discussion of climate change. A new version of SPP came into effect in July 2017 with the launch of the Queensland Planning Reform. The 2017 SPP integrates climate change fully into the planning agenda as an important consideration for planning at all levels and discusses impacts of climate change for all state interests.

The state government developed the *Queensland Climate Adaptation Strategy* (Q-CAS) in 2015. The first steps were the release of *Queensland Climate Adaptation Directions Statement* and *Advancing Climate Action in Queensland: Making the transition to a low carbon future* in 2016. Together they cover adapting to the impacts as well as transitioning to reduced emissions as well as integrate climate adaptation considerations into planning. In 2017 these were followed by *Queensland Climate Adaptation* policy and *Transition Strategies* (see Table 1). Industry-led Sector Adaptation Plans (SAPs) were released progressively over the following years covering: Built Environment and Infrastructure (2017); Agriculture (2017); Emergency Management (2018); Human Health and Wellbeing (2018), Biodiversity and Ecosystems (2018); Tourism (2018); Small and Medium Enterprise (due 2019); and, the Industry and Resource Sector (due 2019) (Queensland Government 2019). The state government also provided A\$12 million in the *Coastal hazards adaptation program—QCoast₂₁₀₀* to help coastal local governments adapt to the impacts of climate change.

Adaptation and resilience building are also prominently featured in regional level plans. Both the revised South East Queensland Regional Plan, *Shaping SEQ* (September 2017), and the update to the *South East Queensland Natural Resource Management Plan* include strategies on adaptation and resilience to natural disasters.

However, at the local level climate change continued to be downplayed. A review of the local planning scheme and disaster management plan found that in the lengthy *Gold Coast City Plan*: "the term 'climate change' appears only nine times in passing ... and 'adaptation' does not appear at all. ... In one of the most vulnerable cities in Australia ... it is as if the threat of climate change does not exist" (Torabi et al. 2017a, p. 6). More recently, the council has signed up for *QCoast₂₁₀₀* funding from the state government to develop an adaptation plan.

Why the Reversals?

The risks that climate change poses to the Gold Coast are increasing and are better understood than ever before (IPCC 2012 & 2007; DCC 2009), yet adaptation policies and plans at all levels of government have been erratic. What are the possible explanations for this situation? Limited space does not allow for a detailed analysis, but we would like to offer some observations based on this research that might be useful to follow up with later investigations.

First, the three-tiered structure of the Australian system of government may create a situation where a wicked policy problem can fall between the gaps because each level argues that it is the responsibility of the others (Howes & Dedekorkut-Howes 2012). In this case, the Commonwealth sees climate change adaptation as a state government responsibility, the Queensland government passes it onto local councils, but local governments argue that they do not have the necessary resources to respond (DCC 2010; Bitá 2012; Westthorp 2012). This ‘buck passing’ is exacerbated by the wicked nature of the problem.

Second, in Australia there is a strong correlation between centre-right political parties and climate denial (Pearse 2009; Jacques, Dunlap & Freeman 2008). The predominance of Liberal-National Party (LNP) governments at the state level 2012-15 and at the national level since 2013 inhibits action because climate change challenges three strongly held beliefs of the right-wing of Australian politics (Howes 2013b). First, it shakes faith that the market leads to the best allocation of resources by pointing out a large negative externality (i.e. greenhouse gas emissions undermine the climate services on which the economy depends). Second, it runs counter to the suspicion of ‘big government’ by highlighting the need for intervention to correct this market failure. Third, it challenges the view that environmentalists who warned of serious climate change were wrong. The challenge posed to these core beliefs has even led some Liberal senators to claim that climate change is not happening and is a conspiracy of the left to attack capitalism (Howes 2013b). When the Labor party took back power in Queensland in 2015 another reversal occurred. The Premier and Minister of Environment’s message at the front of the climate action discussion paper accuses the former LNP government of: “systematically [dismantling] the forward-looking climate policies of previous governments, leaving Queensland unprepared” and promised to get Queensland back on track (DEHP 2016, p. 2). This ideological barrier is acute on the Gold Coast with the LNP holding a majority of the state and federal parliamentary seats for the region.

Third, there are significant economic forces at work that discourage action on environmental issues in general, and climate change in particular, that are due to the peculiar structure of the Australian economy (Howes et al. 2010). The coal industry is a significant part of the domestic economy, a major export, a large employer in regional areas, as well as a major source of tax revenue and royalties for different levels of government. The industry has therefore been exposed as having undue influence in shaping the climate policies of Liberal-National parties when in government (Pearse 2009). This is why the LNP opposes or neglects climate change policies. This is prevalent in Queensland that has a significant coal industry.

The fourth point comes down to electoral politics, where a party leader might see a switch to opposing action as a way to both differentiate themselves from their opponents and a way to pick up marginal seats. This was the case with the Commonwealth elections in 2010, where the Liberal-National opposition made great gains by promising that removing the emissions trading scheme, more popularly known as the ‘carbon tax’, would reduce household energy bills (Tranter 2011). The strategy helped them win the 2013 election even though they had originally supported the scheme and has made formulating a coherent climate and energy policy extremely difficult ever since (Howes 2013b).

Fifth, some governments might be reluctant to acknowledge the impacts of climate change and impose restrictions on development because they are concerned about the potential legal liability for economic losses that may result (England 2007). This has been a particular concern for the City of the Gold Coast with respect to the recent public release of flood mapping that identifies the risks for individual properties and developments (Weston 2014).

Finally, the Gold Coast has a unique social, economic and political environment, so local factors could also be at work (Howes & Dedekorkut-Howes 2012, Bosman et al. 2016). In Australia, scepticism of climate change and support for centre-right parties is historically higher than average in older citizens (Reser et al. 2012; Watson 2011) and the Gold Coast has a significantly higher proportion of older residents. Further, the economy and politics of the region is dominated by developers, who oppose restrictions being placed on where they can build.

Conclusions

This brief history gives an indication of the erratic adaptation policy and planning that cities like the Gold Coast have suffered over more than a decade. In the period 2007-2012 all levels of Australian government had started to take the first steps in addressing the challenges posed by climate change. The shift to centre-right governments 2012-15 saw many policies and plans reversed due to the combined effects of: gaps in the three tiered system of government; the ideology of the parties in power; powerful economic interests; electoral politics; fears of legal liability; and, the unique features of the Gold Coast. Since 2015 there has been a divergence between the different levels of government, with state-based Labor governments such as Queensland moving back into the climate change adaptation space. The science is clear: climate change is happening, the impacts are serious, and low-lying coastal settlements like the Gold Coast are highly vulnerable to its effects. Erratic policy/planning reversals, however, have made consistent long-term planning and investment in building resilience very difficult.

Abstract: Nowadays cities are widely considered as main actors in the challenge against climate change, since they act both as generators of climate-related hazards and as vulnerable targets to their impacts. Although the issue of climate change has been for long addressed on a global scale, the key-role of cities, required to translate global objectives and strategies into tailored to the site actions, is nowadays widely acknowledged. However, climate urban strategies are often largely pushed by international initiatives. This contribution focuses in particular on the 100 Resilient Cities Initiative, launched by the Rockefeller Foundation and addressed to financially support cities all over the world in developing and implementing strategies capable to increase urban resilience in order to better cope with multiple shocks and stress factors, including climate change. In detail, the contribution provides a comparative analysis of 2 selected case studies, Rome and Athens, focusing on their resilience profile, their goals and objectives, the governance of the resilience building processes (actors involved, engagement of local communities, etc.), the set of the proposed actions, highlighting strengths and weaknesses of the whole process as well as the relevance assigned to climate issues and the potential impacts of climate-related actions on cities' resilience.

Keywords: urban resilience; climate change; 100 Resilient Cities; Rome and Athens

1. Enhancing Cities' Resilience: why and how

Cities are nowadays at the core of the international planning debate, due both to their rapid growth that will further increase in the next decades, and to the multiple and heterogeneous challenges, mostly social and environmental, that require urgent attention since they are seriously threatening their current livability as well as their future development. As pointed out some years ago by the Italian planner Bernardo Secchi (2013), social inequalities, which are more and more exacerbated by migration flows, and the impacts of climate change are probably the most important aspects of a "new urban question" that demands new approaches and tools.

The Agenda 2030 provides large emphasis on the need for renewing and planning our cities in order to reduce their impacts on environmental resources and on the global climate systems. In particular, The Agenda 2030 for Sustainable Development includes a specific goal, the 11th, that aims to "make cities inclusive, safe, resilient and sustainable", stressing on the need for "adopting and implementing integrated policies and plans towards

inclusion, resource efficiency, mitigation and adaptation to climate change”, enhancing their resilience to disasters, in line with the Sendai Framework for Disaster Risk Reduction 2015-2030.

Thus, how do we cope with the multiple and heterogeneous challenges threatening cities? How to outline new directions for a responsible urban development, capable to achieve the goals established by the Agenda 2030? What are the new approaches and tools capable to guide cities towards future and largely uncertain development scenarios?

According to numerous scholars, the polysemic concept of resilience, enriched over time by multiple meanings and interpretations thanks to its migrations across different disciplinary fields (Galderisi, 2018), can be nowadays considered as a key principle to “frame scientific and political discourses on cities” (Sharifi, Yamagata, 2018), paving the way to new urban development strategies capable to overcome sectoriality and specialisms (Gabellini, 2018). In the last decades the resilience concept has gained more and more prominence, also thanks to numerous international initiatives aimed to translate this concept into practice, by providing both a theoretical frame and operational tools capable to support the resilience building at city scale, in order to enhance their capacity to deal with current and emerging environmental, social and economic challenges.

The numerous on-going initiatives largely differ from each other, as they are promoted by different organizations, pursuing different aims. The most relevant ones, in terms of number of involved cities, are the ‘Making Cities Resilient’ Campaign, launched in 2010 by the United Nations International Strategy for Disaster Reduction (UNISDR) and the 100 Resilient Cities Initiative (100RC), promoted in 2013 by the Rockefeller Foundation.

Figure 1: The City Resilience Framework. Source: (The Rockefeller Foundation/ARUP 2016)

We will focus here on the 100RC Initiative, which aims at supporting cities, both in economic and organizational terms, in developing and implementing strategies capable to increase urban resilience in the face of a wide range of stresses and shocks, ranging from migrations to water shortage, from earthquakes to climate change (The Rockefeller Foundation/ARUP, 2016). This Initiative provides an interpretation of resilience as “the capacity of individuals, communities, institutions, businesses, and systems within a city to survive, adapt, and grow no matter what kinds of chronic stresses and acute shocks they experience”¹.

¹ <http://www.100resilientcities.org/resources/>

Thus, it seems to combine an “adaptive” perspective, aimed to continuously adapt cities to a constantly changing context, with a “transformative” one, which implies actions aimed to change and innovate the existing state of urban systems, providing new answers to new contexts. Moreover, in order to support the selected cities in the building up of a Resilience Strategy, a set of tools are provided. The ‘City Resilience Framework’ (CRF), set up by the Rockefeller Foundation in cooperation with the global design firm Arup, represents the main reference to measure and assess cities’ resilience (Figure 1).

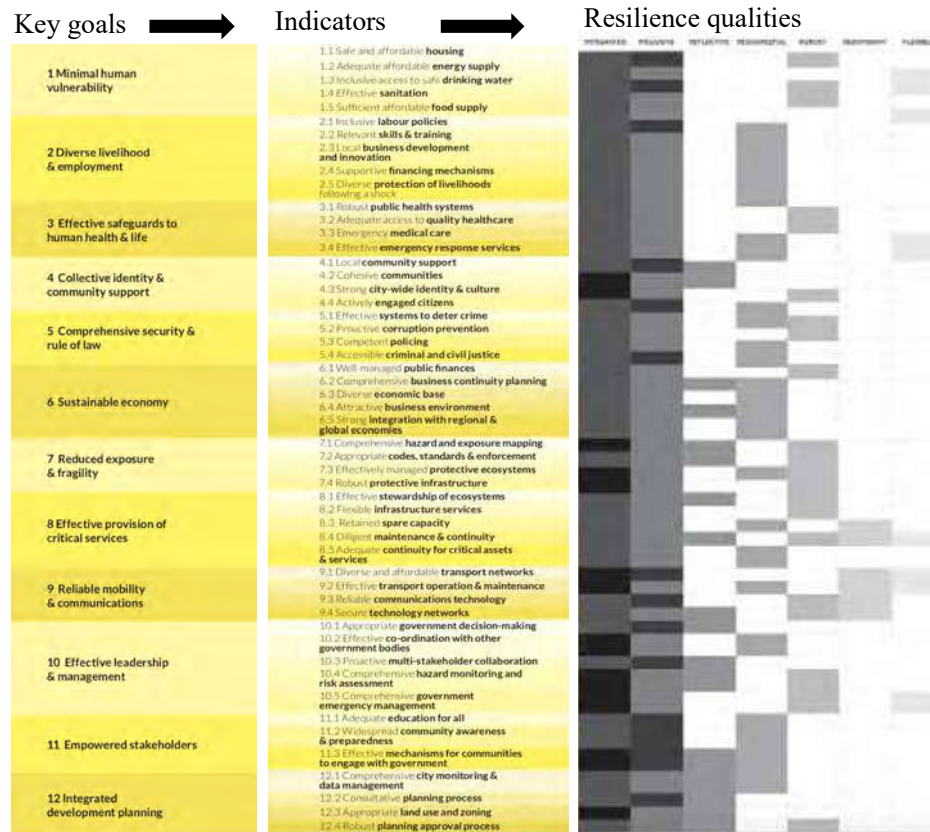

Figure 2: The City Resilience Framework: key goals, indicators, resilience qualities. Source: (The Rockefeller Foundation/ARUP 2016)

The CRF is structured as a circular model composed by different rings and sectors: it identifies four dimensions (Health & Wellbeing; Economy & Society; Infrastructure & Environment; and Leadership & Strategy) and 12 key goals (3 for each dimension) that cities should achieve for improving their resilience. Then, in respect to the 12 key goals, a set of 52 indicators, and the most adequate qualitative or quantitative metrics for their measurement and assessment, are provided. Finally, each indicator is related to the seven qualities that a resilient system should strengthen to effectively withstand, respond and adapt to shocks and stresses, and namely: inclusiveness, integration, reflectiveness, resourcefulness, robustness, redundancy, and flexibility (Figure 2).

This paper, based on an in-depth analysis of two selected case studies, Rome and Athens, provides a brief overview of their resilience profiles as well as of their goals and objectives; then, a methodological path for analyzing and comparing the resilience strategies carried out for the two cities, with a specific focus on the climate mitigation and adaptation measures, will be outlined. The main aim of this contribution is to critically analyze which is the relevance assigned in the two case studies to climate issues, which type of actions have been outlined in respect to each context, how these actions contribute to achieve both the key goals and the seven resilience qualities identified by the CRI.

2. Cities' profiles

As mentioned above, the scope of the 100RC Initiative is to support cities all over the world in enhancing their resilience features in order to better cope with environmental, climatic, social and economic challenges. In the following section, the profiles of the two selected cities, Rome and Athens, will be briefly outlined in order to show the main criticalities as well as opportunities that characterize the two contexts.

2.1. Rome: the city profile

Rome, the Italian capital, with its about 2.900.000 inhabitants and a territorial extension of more than 1.280 square kilometers, is the fourth largest city by population and one of the widest in Europe. From an administrative point of view, the city is composed of 15 Municipalities with managerial and financial autonomy, which refer to the Mayor and the Capitoline Assembly. The Municipalities are articulated in 155 urban zones for land management. The development of the city has been largely shaped by the presence of the Tiber river: since the ancient times, the Tiber represented an attraction as well as a constraint, and often a threat, for the city, as largely documented by Tacitus, who devoted large room in the *Annales* to the frequent floods affecting the city as well as to the numerous efforts, never succeeded, to reduce flood risk. Thus, over time Rome has constantly tried to achieve a balance between limits and constraints set by the natural environment and urbanization dynamics. In the last century, the population growth and the societal development let arise new demands, contributing to further exacerbate the fragile balance between the city and its natural environment (Resilient Rome, 2018).

Current urban structure reflects the demographic growth of the city over the years: the dense city center, where about 500.000 inhabitants currently live, with high levels of population density, the post-war belt, which hosts about 1.600.000 inhabitants and the peripheral low-density areas, with about 750.000 inhabitants.

The index of social disease highlights the significant difference, in socio-economic terms, between the central districts and the suburbs, characterized by a severe social marginalization. In addition, the old age index and the increasing migration flows require more adequate services, capable to better respond to the needs of the most disadvantaged categories (elderly, immigrants, low income population), by increasing their opportunities to access public facilities, promoting social inclusion and ensuring higher safety levels.

The historical, cultural and natural heritage, which represents one of the main strengths of Rome, suffers from the lack of effective maintenance policies as well as of an integrated governance of the urban system; moreover, although green areas cover more than the 60% of the municipal area, public green areas represent only the 5%. Even the infrastructural networks suffer the effects of the economic crisis: the aging and scarcely maintained transport, water supply, waste disposal networks struggle to satisfy the population needs. Moreover, the low efficiency of public transport contributes to the continuous growth of the car-based mobility and, consequently, to the increase of GHG emissions and air pollution.

Finally, it has to be underlined that land take and soil sealing in flood prone areas have significantly exacerbated flood risk in the municipal area: almost the 82% of the total land take in the Municipality occurred in flood prone areas, while soil sealing seriously increases surface runoff and, consequently, the damage due to extreme rainfalls (Munafò and Polverini 2018)

2.2. Athens: the city profile

The City of Athens, characterized by an important and intricate historic and cultural heritage, has a population of 664.046 inhabitants (2011 Census), covers the central area of the Attica Region and is one of the most densely built and populated municipalities in Greece. The Region of Attica presents a complex and interesting

morphological landscape, with the city of Athens located in the immediate vicinity to mountains, protected areas (Natura 2000 network, National Park), forests and coastal areas and to the Port of Piraeus, which is the largest in Greece and one of the biggest in the Mediterranean area and Europe.

According to the Resilience Strategy, urban environment is characterized by high population density, insufficient planning as well as by a low quality and aging built urban fabric, narrow streets and lack of green (public) open spaces. Uncontrolled land take and soil sealing (more than 80% of the Municipality surface is waterproof), coupled with the depletion of peri-urban green areas and the covering of the majority of the natural water network of the Attica plain, intensify phenomena such as Urban Heat Island (UHI), flash-floods and low levels of air quality. Moreover, since Athens is highly exposed to earthquakes, the dense and aging built environment largely contributes to increase the potential damage levels. Furthermore, the major flash-floods and forest fires occurred in the last years in the Attica Region clearly demonstrate how unprepared the city is to cope with these kinds of events.

For several years the city has been facing a serious socio-economic crisis (an aftermath of the global financial crisis of 2007-2008), resulting in severe austerity policies and measures. Among the main consequences of the resulting recession were declining incomes, growing personal debt, high real estate taxes as well as increasing levels of unemployment, poverty and homelessness, leading to violence and civil unrest. Moreover, austerity led to significant cuts in local government's budget and thus in public works and social services, which deeply affect the most vulnerable population.

At the same time, the large flows of refugees and immigrants in the city, intensified the social pressures and the feeling of mistrust between citizens and local Authorities. Currently, about 20.000 migrants and refugees are living within the municipality of Athens, with an increase of about 5% of urban population. This shock, however, has provoked a wave of citizens' mobilization and solidarity networks, and the growth of civil society responses, including non-profit organizations and informal groups. Gradually, it became clear that refugees may represent an opportunity for the city's crucial problem of sharply declining and aging population. This changing in demographic features affects city's cultural mix and identity. It is worth noting that the City of Athens, in contrast with the other municipalities of the Region, is a socially mixed area, characterized by the existence of vertical social differentiation² (Maloutas & Karadimitriou, 2001, Maloutas, 2004, Maloutas & Spirellis 2015). City's urban structure with multi-story residential building and mixed uses has enabled, to some extent, this vertical differentiation among social classes and ethnic identities, thus avoiding the creation of urban "ghettos" (Resilient Athens, 2017).

2.3. Rome and Athens: common challenges

Both Rome and Athens have experienced several changes and transformations throughout their history, and they stand now at the crossroads of challenges, many of which common to other cities in Europe and beyond, but also of opportunities for triggering more responsible urban development processes.

Climate-related impacts, such as flash floods, heat waves, forests fires, represent a major challenge in both cities, also due to a highly vulnerable built environment: high population density, inadequate infrastructures, lack of public green areas as well as of effective maintenance policies result into a limited capacity of both cities to cope with more and more frequent climate-related hazards. Moreover, in the last decade economic crisis and migration flows significantly affected both cities, increasing poverty and social inequalities, in particular in

² There is however a northwest part of the municipality mainly occupied by lower-middle class.

Athens, where large-scale flows of refugees, combined to the severe consequences in terms of loss of jobs, reduction of incomes and increase of taxes, led to acute social conflicts.

Thus, Rome and Athens are here assumed as representative of two main aspects of the “new urban question” (Secchi, 2013): the impacts of climate change and the growing social inequalities. The two selected cases study could provide useful insights on the effectiveness of a resilience-based approach in tackling the different challenges threatening urban future development and, in particular, climate change.

3. The resilience building process

In December 2013, Rome was selected as one of the first 32 cities to be included in the 100 Resilient Cities network. After the start of the activities in June 2014, with the Agenda Setting Workshop in Rome, the selected working team started the first phase of the resilience building process, aimed to outline the reference scenario for the resilience strategy (Figure 3). Athens was selected in 2014, in the second round, to join the Initiative and in the spring of 2015, through the Agenda Setting Workshop, it presented the framework and the methods of the 100 Resilient Cities program (Figure 4).

The Agenda Setting Workshop represented for both Rome and Athens an opportunity to trigger a participatory, interdisciplinary and innovative decision-making process, by engaging a number of stakeholders from public and private sectors, Councilors and Directors of the different Departments of Municipality, local and regional administrations, NGOs or local organizations. In particular, the participation of Rome in the 100 RC network was part of a wider action promoted by the Urban Transformation and Environment Department and aimed at launching urban innovation pathways in a context characterized by a significant lack of internal resources (Coppola, 2016). When the city joined the 100RC initiative, local administration was characterized by a culture strongly rooted in traditional procedures and tools and scarcely innovation-oriented (Tocci, 2015). In Athens, the Office of Resilience and Sustainability (ORS), established in February 2016, laid the foundations for drafting and implementing the resilience strategy with the participation of 130 individuals from the municipality, the public, private, non-profit and academic sector as well as the civil society. The ORS gained official status as part of the Mayor’s Office in December 2016 (Government Gazette No 3812/B’/28-11-2016). In both cases, the first phase of the resilience building process was carried out through open seminars and focus groups and addressed to outline: current socio-economic context and governance, strengths and weaknesses of each city, as well as shocks and stresses affecting them, existing plans, programs and related actions.

Based on these activities, the working group of Rome’s Strategy drafted 4 intermediate reports in September 2015 and, finally, published the Preliminary Resilience Assessment (PRA) in January 2016. The Preliminary Resilience Assessment highlights strengths and weaknesses of the city and identifies 5 main vulnerable assets: economic recession and vulnerability of the population, integrated governance, quality of life, land safety and climate change, maintenance of the city’s heritage. The vision for a resilient Rome, arising from the preliminary activities, outlines an inclusive and supportive city with an exceptional natural, historical and cultural heritage, capable to safeguard its past and to develop it by promoting environmental sustainability, economic development and public well-being (Resilient Rome, 2018).

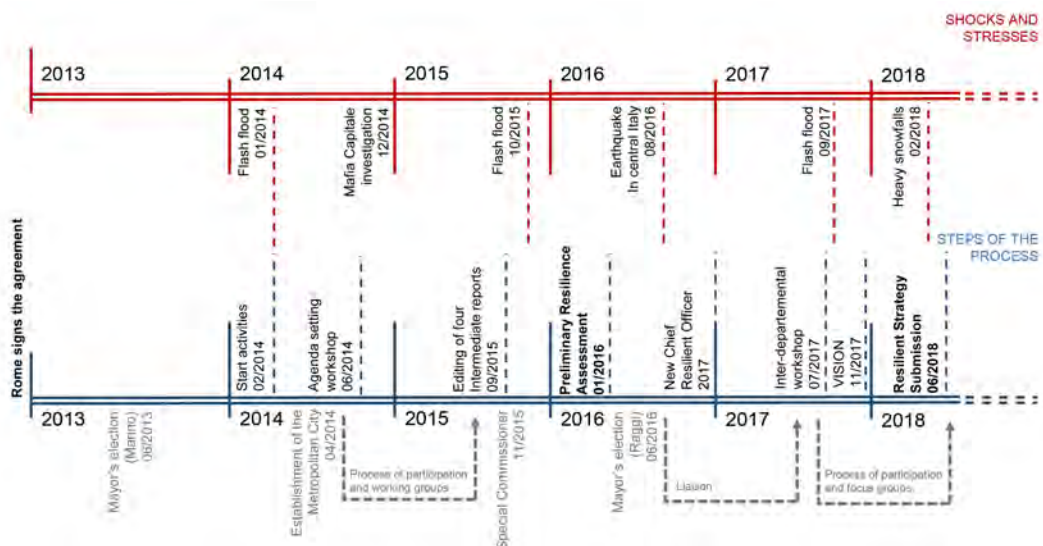

Figure 3: Occurred shock and stress events (red) and steps of the process aimed to outline the Resilience Strategy in Rome (blue).
Source: Resilient Rome (2017)

Citizens' engagement was one of the most important goals of the Athens' Strategy too, thus stakeholders mapping and the development of an integrated Stakeholder Engagement & Communication Plan were the first steps of the process (Resilient Athens & ADDMA S.A., 2016). During the first phase of the drawing up of Athens' Strategy (February - June 2016), 11 focus groups³ were created. The participants were interviewed about city's critical assets, shocks, stresses and vulnerabilities and their personal view about what makes Athens resilient. Based on the above diagnostic activities, in July 2016, the PRA was released: it presented 5 discovery areas that Athens had to explore in detail in the second phase, in order to discover opportunities that would contribute to resilience building. Moreover, the vision for a resilient Athens was shaped, namely a city that is open, green, proactive and vibrant (Resilient Athens, 2017).

It is worth noting that during the process aimed at building up the Resilient Strategy, Rome suffered numerous climate-related events (Figure 3) that have probably contributed to increase citizens' and decision-makers' awareness on climate issues. In the case of Athens, the major events that affected the whole Attica Region in the time span of reference are reported (Figure 4). It is worth mentioning that every year this Region is affected by numerous flash floods (the several less intense events occurred are not mentioned in Figure 4). Moreover, in 2018 severe wildfires, which exacerbate climate change impacts, hit the Attica Region: however, they are not reported, since the city of Athens was not directly hit by the event.

Following the release of the PRA, Rome has gone through a phase of strong political instability leading to a slowdown of the activities. After the establishment of the new City Government, in September 2017, a new Chief Resilience Officer (CRO) was appointed. This transition led to a review of the identified challenges, according to the political agenda of the new Mayor, and significantly affected both the timing of the process and the involved actors. Hence, after the selection of the new CRO in September 2017, the working group outlined the final Resilience Strategy that was officially launched in June 2018.

³ City districts' council members, advisors to the Mayor, architects, start-uppers, tour guides, young entrepreneurs, CSOs, NGOs, migrant women, homeless street paper vendors and elders.

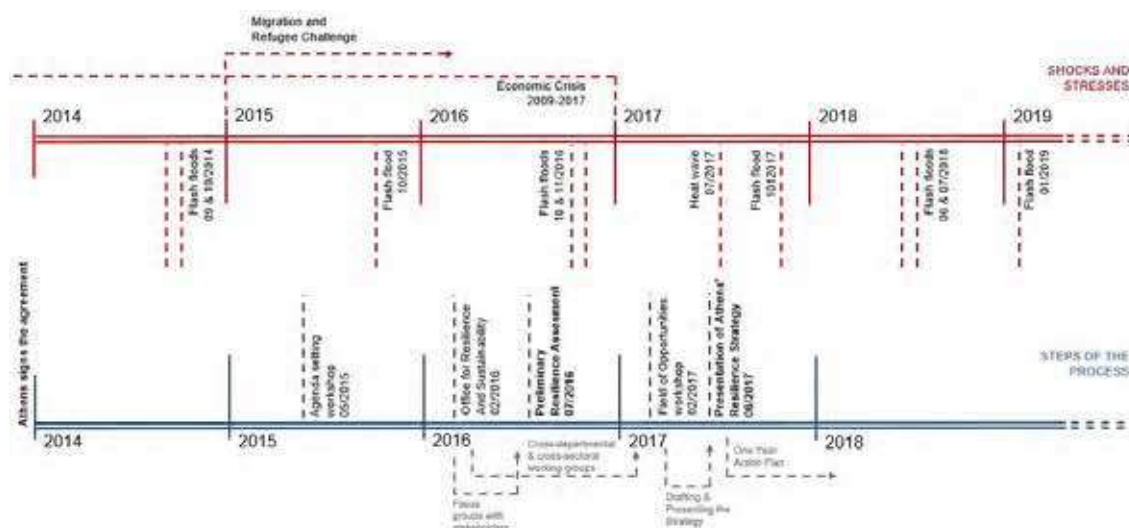

Figure 4: Occurred shock and stress events (red) and basic steps of the process aimed to outline the Resilience Strategy in Athens (blue).

Source: Resilient Athens. (2017) meteo.gr, www.hnms.gr/emy/

From March to June 2017, the Athens Resilience Strategy was drafted and presented to the Mayor of Athens, the city Council, the municipal Executive Committee, the Resilience Steering Committee (RSC) and the municipal political parties. Its official public launch was held in June 13, 2017. Finally, Phase III (from July 2017) has included the launch of the One Year Action Plan and the start of the Strategy's implementation.

Hence, by comparing the timelines, it is evident that, despite being chosen in the second round (one year later), Athens filled the temporal gap, by surpassing Rome in terms of speed of the Strategy building process. Moreover, while the process in Athens was linear, in Rome it was considerably affected by the political instability of the city.

In both cases, stakeholders' engagement was very relevant through all the different steps of the process and allowed the working groups to:

- ground on heterogeneous perspectives and approaches in defining critical issues and visions for the cities' future development;
- increase the stakeholders' awareness about challenges and opportunities of the contexts at stake;
- ensure an active stakeholders' engagement in the implementation of the Strategies.

4. Rome and Athens Resilience Strategies: the relevance of climate related actions and their role in enhancing cities' resilience

4.1. A methodological path for analyzing the Resilience Strategies

The analysis of the Resilience Strategies carried out in Rome and Athens has been addressed to understand, firstly, the relevance assigned in both strategies to climate issues; then, the potential impacts of climate-related actions on the resilience qualities identified by the CRI. To pursue these aims, a common methodological path has been outlined. The latter has been structured according to the following steps:

- the identification of the most relevant shocks and stresses as perceived by the stakeholders, with a focus on the relevance assigned to climate issues, and of the key challenges that, according to the stakeholders' opinions, each city has to face;
- the identification of the key goals that the two cities should improve, according to the stakeholders' opinions;
- the singling out of the actions directly or indirectly addressed to counterbalance climate change, in respect to the whole set of actions outlined by the two strategies, by distinguishing mitigation actions, adaptation actions or actions that could address both;
- the qualitative analysis of the potential impacts of the actions directly aimed to counterbalance climate change on the set of 52 indicators identified, in respect to each dimension and related goals, by the CRI;
- the qualitative analysis of the potential impacts of the actions directly addressed to counterbalance climate change on the resilience qualities that, according to the CRI, depends on the relationships between the indicators (to which each action is positively or negatively related) and the resilience qualities;
- the relationships among the Resilience Strategies and other existing plans/programs/initiatives specifically addressed to counterbalance climate change.

The different steps have been developed through an in-depth analysis of both the Preliminary Resilience Assessment and the Resilience Strategy carried out by each city.

It is worth underlining that the potential impacts of the actions directly addressed to counterbalance climate change on the set of indicators provided by the CRI have been evaluated according to a qualitative judgment structured as follows: positive, indifferent/no, and negative. The provided qualitative judgments are based on the description of the actions provided by each Resilience Strategy and refer to potential impacts, since only few actions are currently in progress, while most of them have to be still implemented; thus, their actual impact is not evaluable at this stage.

Moreover, the potential impact of the identified climate-related actions on the resilience features, expressed according to a binary qualitative judgment (increase/decrease), has been singled out according to the relationships between the indicators to which each action is positively or negatively related and the seven resilience qualities identified by the CRI (Figure 2).

4.2. The baseline assessment

In the case of Rome, the PRA, released in January 2016, described the current situation of the city, by providing qualitative and quantitative data on population, economy, services and infrastructure and governance. During this phase, stakeholders' engagement was addressed to define both the most relevant shocks and stresses and the main challenges that cities had to face. According to the stakeholders' opinions, natural hazards (earthquakes) and climate-related events (pluvial and river floods, landslides, sinkholes, heat wave) represent the most relevant shocks, while the numerous identified chronic stresses refer to the lack of integrated planning, to the soil, water and air pollution, to the loss of ecosystem services, to the poor maintenance of public areas, infrastructures and building, to the inadequacy of public transport and the lack of citizenship (Figure 5).

Moreover, they identified five main challenges that Rome has to cope with, referable to the economic recession and the increasing vulnerability of population, the need for a more effective and integrated governance, the urban safety, in respect to both geological and climate-related hazards.

MAIN STRESSES	Lack of integrated and updated planning Insufficient communications and information shared by offices Slow and inefficient bureaucracy Limited access to broadband telecommunications Air, water and soil pollution Critical issues in the urban solid waste cycle Loss of ecosystem services Degradation of a part of the areas and public buildings Lack of citizenship Aged infrastructure A high level of commuting Inadequate public transportation system Limited redundancy and continuity of services and critical infrastructure Increase in the number of arrivals of migrants with the right to asylum Impoverishment of the population Housing emergency	MAIN SHOCKS	Flash floods River floods Flooding due to bad surface water runoff Earthquakes Sinkholes Landslides Heat wave Heavy snowfall Instability of trees Infrastructure failures and accidents Blackout Vandalism Forest and weeds fires Cybercrime
	THE MAIN CHALLENGES Economic recession and vulnerability of the population Effective management of the impact that the global economic recession has had on employment, on social networks, on vulnerable groups, and on increased migration trends. Integrated governance Supporting efficient and effective governance of the city by encouraging better communications and transparent information as a result of the use of digital media and overcoming the limits caused by slow red tape procedures. Quality of life Encouraging well-being and the quality of urban life of citizens: from access to housing to the efficiency of public transport; from cultural projects to improving differentiation and recycling of post-consumption materials. Land safety and climate change Monitoring and planning to secure the region against geologic problems (earthquakes, opening of sinkholes, subsoil pollution, geological instability) and predicting and mitigating the impacts of climate change (heat islands, drought, floods, landslide, etc.). Maintenance of the city's heritage Protection, preservation and valorization of the ecological, cultural and landscape heritage of the city, by encouraging sustainable tourism, and urban regeneration processes.		

Figure 5: Rome: shocks, stresses and challenges perceived by the engaged stakeholders.

In respect to the key goals identified by the CRI, the engaged stakeholders recognize the need to improve all the key-goals related to the *leadership and strategy* dimension, and namely to an integrated development planning, considered as a precondition for achieving the key goals related to the *health and well-being, economy and society, infrastructure and ecosystems*. As a matter of fact, an integrated development planning would also contribute to enhance city's resilience and, namely, city's *robustness*, transformability and adaptability to hazardous events, especially those related to climate change.

Athens' PRA, released in July 2016, describes Athens' current status at that time, regarding the demographic and social analysis of the urban area, the economy, the physical and man-made infrastructures, the cultural resources, the development strategy, the funding tools as well as the administrative structure. Three basic tools were used for a diagnosis of Urban Resilience: a perception tool based on the stakeholders' opinions, an action tool and an asset and risk tool. The perception tool was addressed to collect the perceptions about city resilience from a wide range of stakeholders. Based on their answers, shocks and stresses as well as the main challenges that the city have to cope with were identified: also in the case of Athens, natural hazards (earthquakes) and climate-related events (heat waves and flash floods) are perceived as important shocks to be faced, combined with civil unrest (largely due also to the pressure of the economic crisis) and cybercrime. Regarding chronic stresses, less numerous than in Rome, the most relevant ones refer to the impacts of economic crisis, to the aging infrastructures and to the increasing migration flows. The identified main challenges, also in this case five areas, range from the urban decay to climate impacts (Figure 6).

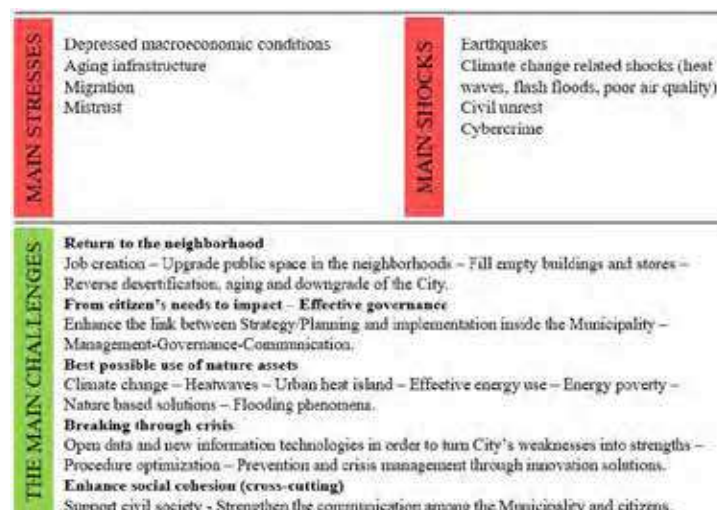

Figure 6: Athens: shocks, stresses and challenges perceived by the engaged stakeholders.

In respect to the key goals identified by the CRI, the engaged stakeholders ranked citizens' participation and the cohesion of the communities as an area of strength for city's resilience (*Goal 4: Collective identity and community support*): this positive rating depends on the widespread idea that, despite the weakness of the local authorities that generally fail in communicating with citizens, in providing access to information and education, and in taking into account citizens' needs, citizens are active and mutually supportive. On the opposite, they provide a negative evaluation of the Goal 8 (*Effective provision of critical services*), 12 (*Integrated development planning*) and 10 (*Effective leadership and management*). The criticisms revolve around the issues of the emptying out of the city, the aging infrastructure, the abandoned buildings, the lack of public services as well as of open and green spaces, the traffic congestion. They also complain the lack of long-term planning and of an effective coordination among different plans and actions.

4.3. Resilience strategies: relevance and impacts of climate related actions

The Resilience Strategy carried out for Rome is based on four pillars, mirroring the strategic vision outlined for the city. In respect to each pillar, some priority actions, directly linked to the pillars, the key goals and the actions that will allow the city to achieve these goals have been identified (Figure 7).

Figure 7: The structure of the Rome Resilience Strategy.

It is worth noting that in respect to the whole set of priority actions and actions outlined by the Strategy (58), more than half are related to climate issues (Table 1). All the climate-related actions have been classified according to their role in counterbalancing climate change, by distinguishing mitigation actions, adaptation actions and actions that could address both; moreover, these actions have been distinguished according to their direct or indirect impact on climate change.

	CC RESPONSE	IMPACT
PILLAR I: AN EFFICIENT CITY AT THE SERVICE OF CITIZENS		
PRIORITY ACTION 1: Create an operation and management center	Mitigation & Adaptation	Indirect
PRIORITY ACTION 2: Establish a Resilience Office	Mitigation & Adaptation	Indirect
GOAL A: Make the city's administration more efficient, transparent and participatory; ensure the monitoring of procedures		
I.A.1. Link the budget commitments to the three-year annual program of the Departments' activities	-	-
I.A.2. Reorganize the running of Departments and encourage synergies with other institutions	-	-
I.A.3. Create a unique communications interface between private citizens and Public Administration with the help of new technologies	-	-
I.A.4. Establish guidelines to optimize the planning, construction and management of projects	-	-
GOAL B: Incentivize centralized governance actions		
I.B.1. Complete the implementation of the 'Rome' laws required to ensure greater governance autonomy of the region (e.g. archaeological parks, rivers, etc.)	-	-
I.B.2. Create a unique geographical database that may be updated and shared	Mitigation & Adaptation	Indirect
I.B.3. Establish a Geological Survey of Rome to unite the governance of the urban subsoil	Adaptation	Indirect
GOAL C: Implement the Smart City plans		
I.C.1. Introduce guidelines for updating the Open Data platform	Mitigation & Adaptation	Indirect
I.C.2. Upgrading the public Wi-Fi network and coverage	-	-
I.C.3. Construct a Smart Grid	Mitigation	Indirect
PILLAR II: A DYNAMIC, STRONG AND UNIQUE CITY		
PRIORITY ACTION 1: Govern the relaunch of the River Tiber by implementing projects coordinated by the Special Office for the Tiber	Adaptation	Direct
PRIORITY ACTION 2: Evaluation of the resilience potential of the regeneration of Ostiense Marconi district	Mitigation & Adaptation	Direct
PRIORITY ACTION 3: Change the perception, use and promotion of the archaeological and cultural heritage sites in Rome for citizens' everyday life	-	-
GOAL A: Promote the cultural life of the city		
II.A.1. Reorganize the management of the cultural sector	-	-
II.A.2. Support stakeholders in the contemporary cultural sector in the dissemination of the cultural offer	-	-
II.A.3. Organize seasonal programs of cultural events throughout the city	-	-
II.A.4. Assign a new role to public libraries by organizing innovative socio-cultural programs for the local communities	-	-
II.A.5. Start the application to list Ostia Antica as a UNESCO World Heritage Site	-	-
II.A.6. Fashion Relaunch Plan of Rome	-	-
GOAL B: Promote urban regeneration		

II.B.1. Activate Fabbrica Roma (Rome Factory), a regeneration plan for abandoned public buildings	Mitigation & Adaptation	Indirect
II.B.2. Upgrade the Building Regulations according to new housing and working needs	Mitigation	Indirect
II.B.3. Regenerate the Tiburtina Stations and Pietralata areas	Mitigation	Indirect
II.B.4. Reorganize the network of public and private transportation to streamline the mobility system (tram lines, bus lanes, cable cars, etc.)	Mitigation	Direct
II.B.5. Establish incentives to facilitate the transfer of know-how between small-medium businesses, start-ups, institutions and research centers	-	-
GOAL C: Promote the landscape and natural heritage in the urban environment		
II.C.1. Restore and/or reorganize the use of and access to the Roman coast by implementing the Utilization Plan for Rome's Coastline	Adaptation	Indirect
II.C.2. Implement the management reorganization of parks and historic villas by establishing a Curator who would also be responsible for planning the fundraising processes	-	-
GOAL D: Encourage the farming tradition of the city		
II.D.1. Relaunch farming companies managed by the Municipality	Mitigation	Indirect
II.D.2. Develop new markets for farmers to support the direct sale of produce and products to consumers	Mitigation	Indirect
II.D.3. Increase food forests and urban vegetable gardens	Adaptation	Direct
GOAL E: Improve the attractiveness and the safety of Rome		
II.E.1. Create tourist facilities to promote youth and student tourism	-	-
II.E.2. Plan activities to promote the attraction of urban areas by increasing the number of cycling tracks, environmental islands and use of the public transport system	Mitigation	Direct
II.E.3. Regulate businesses in the historic center in order to protect the quality of products and craftsmanship so as to preserve the identity of the historic center	-	-
GOAL F: Ensure the safety of the public and private heritage in the city		
II.F.1. Protect infrastructure, public buildings, and schools	Mitigation & Adaptation	Direct
GOAL G: Prepare city's adaptation to climate change		
II.G.1. Create green and blue infrastructure to reduce urban heat islands	Adaptation	Direct
II.G.2. Assess the impacts of climate change and raise awareness among citizens	Adaptation	Indirect
II.G.3. Create infrastructure and pilot projects to reduce the risk of flooding	Adaptation	Direct
PILLAR III: AN OPEN INCLUSIVE AND SUPPORTIVE CITY		
PRIORITY ACTION 1: Implement a program to encourage everyone into sports to enable social integration of diverse communities	-	-
PRIORITY ACTION 2: Implement the new social integration program for asylum seekers and other people covered by international protection	-	-
GOAL A: Promote a hospitable city that respects diversity		

III.A.1. Implement a program to strengthen and extend the support network for vulnerable communities	Adaptation	Indirect
III.A.2. Establish assessment criteria to assign public spaces under concession to NGOs, associations and organizations that promote social inclusion, education and sustainability	-	-
III.A.3. Finalize Public Housing Development Programs and develop new energy-efficient social housing	Mitigation	Direct
GOAL B: Promote the cultural growth of the vulnerable population		
III.B.1. Introduce projects for the inclusion of children in the cultural life of the city in collaboration with other institutions	-	-
III.B.2. Implement the new intervention policies for unaccompanied foreign minors to facilitate opportunities of growth and integration	-	-
PILLAR IV: A CITY THAT PROTECTS AND ENHANCES ITS NATURAL RESOURCES		
PRIORITY ACTION 1: Renew the public vehicle fleet and introduce eco-sustainable buses	Mitigation	Direct
PRIORITY ACTION 2: Optimize separate waste collection of post-consumer materials	Mitigation	Indirect
GOAL A: Protect the ecological system and restore the value of the water resources		
IV.A.1. Implement sustainable urban forestry principles to protect biodiversity, enhance and protect parks and nature reserves	Adaptation	Direct
IV.A.2. Protect and enhance local water resources	Adaptation	Direct
GOAL B: Promote the use of renewable energy sources		
IV.B.1. Incentivize the use of renewable resources	Mitigation	Direct
IV.B.2. Introduce incentives to secure the safety and energy efficiency of private real estate property	Mitigation	Direct
IV.B.3. Review the green credential and safety of the public structures	Mitigation	Direct
GOAL C: Create sustainable mobility and introduce solutions to reduce pollution and GHG emissions		
IV.C.1. Develop an efficient and economic transport model for people and goods	Mitigation	Indirect
IV.C.2. Develop sustainable electric mobility plan	Mitigation	Direct
IV.C.3. Test new technologies for decreasing emissions into the atmosphere	Mitigation	Direct
IV.C.4. Develop the pedestrian and cycle network and sharing transport schemes	Mitigation	Direct
GOAL D: Promote a zero-waste circular economy		
IV.D.1. Open centers for the direct processing and reuse of post-consumer materials	Mitigation	Direct
IV.D.2. Develop sustainable waste plants	Mitigation	Direct

Table 1: The whole set of priority actions and actions outlined by the Rome Resilience Strategy and the actions addressed to counterbalance climate change.

Once the actions aimed to counterbalance climate change have been identified, the potential impact of each action, limited to those directly related to climate change, on the set of 52 indicators provided by the CRI, has been evaluated. Then, based on the outcomes of the qualitative assessment and according to the relationships between indicators and key goals identified by the CRI (Figure 2), the examined actions are expected to have a positive impact on the key goals 8, 10, 11, 4 and, consequently, on the related dimensions *Infrastructure and Ecosystems* and *Leadership and Strategy* (Figure 8).

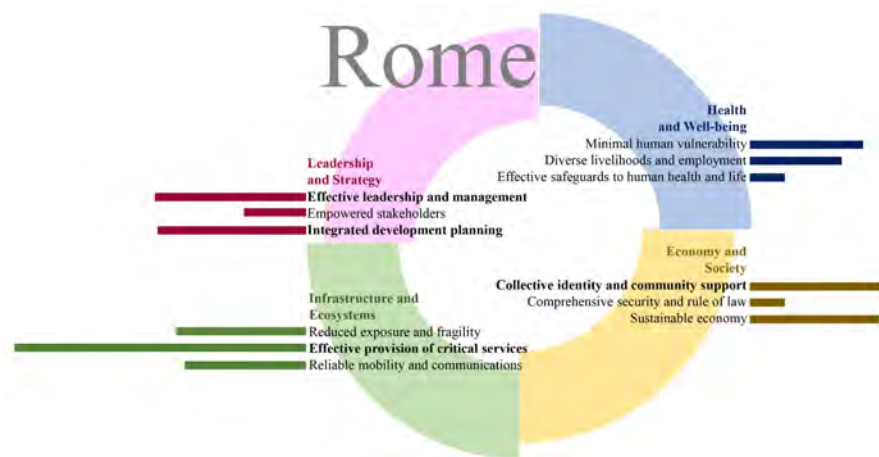

Figure 8: The potential impacts of directly climate actions on CRI's key goals.

The potential impacts of the actions have been largely regarded as positive or neutral and only in few cases as negative, even though some of them could induce, once implemented, some negative externalities related, for example, to an increase in soil consumption or to the occurring of gentrification phenomena. However, it is difficult to assess such externalities, only based on the general description of each action provided by the Resilience Strategy.

Finally, the potential impacts of the selected actions on the resilience qualities that, according to the CRI, depends on the relationships between the indicators (to which each action is positively or negatively related) and the resilience qualities, have been assessed. Based on this, it is possible to highlight that the selected actions could contribute to significantly enhance at least three out seven resilience qualities, making Rome a more integrated, inclusive and robust city, and contributing to a lesser extent to enhance the other resilience qualities (Figure 9).

Figure 9: The potential impacts of the climate actions on the resilience qualities.

Athens' Resilience Strategy has been structured into 4 pillars, 13 goals, 44 actions and 55 supporting actions. Each goal of the Strategy is related with the goals of the CRI (Figure 10).

ATHENS 41344

pillars goals actions

Figure 10: The structure of the Athens Resilience Strategy.

Among the 44 actions included in the Strategy, the ones addressed to counterbalance climate change have been identified, by identifying those contributing, directly or indirectly, to the reduction of GHG emissions as mitigation actions, those related to the adjustment and regulation of urban system as well as to changes in behavior in order to better cope with the more and more frequent climate impacts, as adaptation actions. There are, of course, actions that address both mitigation and adaptation (Table 2). This analysis indicates that more than the half of the actions concerns climate-related issues (28 out of 44 actions), half of which are directly related (15 out of 28).

	CC RESPONSE	IMPACT
I. An Open City		
GOAL A. Become more transparent and accountable		
A.1 Open data	Mitigation & Adaptation	Indirect
A.2 Communication campaigns	Mitigation & Adaptation	Indirect
A.3 Major public events impact assessment	-	-
GOAL B. Enhance and streamline the city's processes		
B.1 Digital agenda	Adaptation	Indirect
B.2. Smart operational center	Adaptation	Indirect
B.3 Health & social service centers	-	-
B.4 Map of the public realm	Mitigation & Adaptation	Indirect
GOAL C. Foster collaboration and engagement		
C.1 Thematic stakeholder platforms	Adaptation	Indirect
C.2 synAthena platform	Adaptation	Indirect
C.3 University and City Synergies	Adaptation	Indirect
C.4 Athens Partnership Fund	-	-
C.5 Athens Culture Net	-	-
II. A Green City		
GOAL A. Integrate natural systems into the urban fabric		
A.1 Climate Change adaptation action plan	Mitigation & Adaptation	Direct
A.3 Triple green development project (Mega Resilience Project)	Mitigation & Adaptation	Direct
A.4 Elaionas: a resilient district (Mega Resilience Project)	Mitigation & Adaptation	Direct
GOAL B. Make our city cleaner		

B.1 Waste management action plan	Mitigation & Adaptation	Direct
GOAL C. Promote sustainable mobility and co-create public spaces		
C.1 Sustainable mobility roadmap	Mitigation & Adaptation	Direct
C.2 Public space rejuvenation initiative	-	-
C.3 Public space co-development framework	Mitigation & Adaptation	Indirect
GOAL D. Foster sustainable food systems		
D.1 Sustainable food policy plan	Adaptation	Direct
GOAL E. Establish sustainable and equitable energy system		
E.1 Climate Change mitigation action plan	Mitigation & Adaptation	Direct
E.2 Energy poverty mitigation roadmap	Mitigation & Adaptation	Direct
E.3 Renewable energy cooperatives	Mitigation	Direct
III. A proactive city		
GOAL A. Enhance planning in the face of serious challenges		
A.1 Crisis preparedness and management plans	Adaptation	Direct
A.3 Metropolitan Authority and other legislative and policy making reforms	-	-
A.4 Detailed resilience studies	Mitigation & Adaptation	Direct
A.5 Old building retirement	Mitigation & Adaptation	Direct
GOAL B. Empower the municipal workforce and elected officials as well as the voice of the local community		
B.1 Municipal neighborhood network	-	-
B.2 Municipal capacity building	-	-
GOAL C. Engage with our neighborhoods		
C.1 Schools open to the neighborhood	-	-
C.2 Migration integration action plan	-	-

IV. A vibrant city		
GOAL A. Enhance the City's identity and promote new types of belonging		
A.1 Athens ID	-	-
A.2 Creative economy strategic plan	-	-
A.3 Holistic city brand	-	-
A.4 Green and cultural urban corridors	Mitigation & Adaptation	Direct
A.5 Sustainable municipal Real-estate management	Mitigation	Indirect
A.6 City center development project	Mitigation & Adaptation	Direct
GOAL B. Maximize existing City assets and support employment		
B.1 Vacant buildings: crucial urban resource	Mitigation	Indirect
B.2 Employment action framework	-	-
B.3 Social housing program	-	-
B.4 Old train stations refurbishment	-	-
B.5 Expropriation and greening of abandoned lots in Athens	Mitigation & Adaptation	Direct

Table 2: The whole set of actions outlined by the Athens Resilience Strategy and the actions addressed to counterbalance climate change.

Following the methodological path previously outlined (see paragraph 4.1) and based on the potential impact of the actions that directly address climate issues on the 52 indicators provided by the CRI, it is possible to state that the selected actions have a positive impacts on the Goals 4, 8, 10, 12, whereas the least positive impact is on the Goal 5 (*Comprehensive security and rule of law*) (Figure 11). Comparing these results with the stakeholders' opinions previously mentioned, we can argue that these opinions have been largely taken into consideration in

the drawing up of the Strategy. However, a potential negative impact, in social terms, of the numerous regeneration projects included in the Strategy, should be highlighted. The potential gentrification effects of these projects may significantly affect Goal 1. Thus, in the implementation of the foreseen actions the potentially negative social impacts should be carefully analyzed and compensated through appropriate measures.

Figure 11: The potential impacts of directly climate actions on CRI's key goals.

Finally, based on the correlation between the indicators and the resilience qualities provided by The Rockefeller Foundation & Arup (2016), the potential impacts of the selected actions on the resilience qualities have been assessed. According to the outcomes of the evaluation, the selected actions might help the city to become more integrated, inclusive, reflective and resourceful while also increasing, to some extent, its robustness. However, redundancy and flexibility should become more prominent (Figure 12).

Figure 12: The potential impacts of the climate actions on the resilience qualities.

4.4. The relationships with other urban strategies, plans and policies

One of the main opportunities for cities that decide to adopt a resilience strategy is to systematize and link all the heterogeneous actions planned by different actors and included in different planning tools, framing them into a common and shared vision for future development.

The attention devoted to create links among actions already included in other plans and programs, approved or with a still pending approval, is surely a strength of the Rome Resilience Strategy. The number of actions already in progress at the time of the adoption of the Strategy and framed into the strategy is double in respect to

the new actions. As clearly stated in the Strategy, this may contribute to guarantee both their implementation and a higher continuity in the city's development policies. Hence, the Rome Resilience Strategy is closely linked to numerous existing plans and projects (plans for urban regeneration, plans for sustainable mobility, urban greening, etc.). All actions aimed at building platforms for the dissemination of knowledge, involving citizens, creating a unique interface between public and private actors, stakeholders and decision makers, updating and integrating data and information from different specific sectors, can be traced back to the Digital Agenda of Rome (2016) , addressing the digital transformation of the public administration. Moreover, as regards the relationships among the Rome Resilience Strategies and other existing plans/programs/initiatives specifically addressed to counterbalance climate change, it is worth noting that most of the actions classified as mitigation actions are already in progress, being already included into previously approved plans, although not fully implemented (e.g. the SEAP submitted in 2013). On the opposite, adaptation actions are generally new, due to the lack of a previous adaptation plan: the Municipal Council, that took office in 2016, joined the New Covenant of Mayors for Climate and Energy in 2017, with the commitment to submit the SECAP by November 2019. The objectives set up for the SECAP are fully in line with the actions aimed to counterbalance climate change included in the Resilience Strategy, namely in the second and fourth pillars, mostly addressed to promote urban regeneration, to ensure a sustainable development in mobility, to improve public green areas. Despite the numerous links among plans carried out by the different sectors of the Municipality, it has to be underlined the persisting lack of coordination among different Public Bodies. In particular, the actions related to the goal "Prepare city's adaptation to climate change" could have benefited from a closest relationship between the Strategy and the 10-year program of actions designed by the River Basin Authority to guarantee the safety of Rome from floods, landslides and sinkholes (River Basin District Authority 2018), which is not even mentioned in the Strategy, probably due to its recent adoption.

Athens' Resilience Strategy also draws upon other local, regional, national and international strategic documents and it seems to be aware of the lack of communication among the different municipal departments and public bodies and, consequently, of the lack of coherence among policies and plans. Moreover, it clearly acknowledges the citizens' need of more information and mechanisms allowing them to better engage with decision-making processes. Hence, the Strategy supports and creates information platforms, for municipal departments, stakeholders and communities, promotes partnerships with national and international networks and favors linkages with other plans, programs and initiatives (throughout its four pillars). These endeavors make data and services available to everyone, ensure the comprehensive dissemination of relevant information and raise the awareness about resilience issues. As regards the relationships among the Athens Resilience Strategy and other existing plans/programs/initiatives specifically addressed to counterbalance climate change, it is worth noting that the Athens Climate Change Adaptation and Mitigation Plan represents a fundamental part of the Resilience Strategy. This plan, which includes 2 parts, respectively focused on mitigation and adaptation, outlines specific actions aimed at improving quality of life, mostly in respect to increasing temperatures, flash floods and poor air quality. Many of the Adaptation and Mitigation Plan's actions are incorporated in the Strategy as new actions (apart from the supporting action "Enhance Green infrastructure in city", which is already on-going). Other actions are linked with urban, regional and national plan and programs for sustainable mobility, waste management, energy saving, as well as with the economy strategic plan, the migrant integration action plan, the public space co-development framework, the crisis preparedness and management plans and the sustainable food policy plan.

Finally, it is worth reminding that in November 2017 Athens entered the Smart Mature Resilience (SMR) project, which responds to the need for enhancing resilience in European cities. Athens is one of the Tier 3 cities (as well as Thessaloniki): thus, it is one of the 'engaged' cities that receives training in the use of finalized tools (which are piloted in a group of three core cities/Tier 1) (Grimes, 2018). The engagement of the city into this project could represent a further opportunity to strength awareness, capabilities and skills within the different sectors of the public administration and to empower, in so doing, local institution, making the latter more autonomous in respect to the leading role hitherto assumed by the Rockefeller Foundation.

5. Concluding Remarks

The two selected cities, Rome and Athens, show numerous similarities both in terms of shocks and stresses that the two cities have to cope with, and in terms of strengths and opportunities. Climate-related impacts are recognized as a major challenge exacerbated, in both cities, by a vulnerable built environment: high population density, inadequate infrastructures, lack of public green areas as well as of effective maintenance policies. Although economic crisis, migrants and refugees are mentioned as chronic stresses in both cities, their relevance in Athens is significantly higher, while the lack of integrated and participatory governance represents a very sensitive issue in both cases.

Due to the relevance assigned to climate issues by the stakeholders engaged in the resilience building process activated in the last years in the two selected cities, the examined Strategies include a significant number of climate-related actions that represent, in both cases, more than half of the total. However, while in the case of Rome these actions are mostly addressed to mitigation issues, being adaptation a new challenge for the city, in the case of Athens, most of the foreseen actions contribute to address both mitigation and adaptation issues.

By joining the 100 RC Initiative, Rome and Athens brought resilience into the urban political agenda, relying on a set of tools for understanding, assessing, and improving their capacity to cope with different stresses and shocks and raising meanwhile community and decision makers' awareness on resilience issues. The engagement of multiple stakeholders and the collaboration among different sectors of local governments can be interpreted as an opportunity for both cities to overcome the still prevailing "silo" approach to urban policies (Proust *et al.*, 2012) and to promote more participatory decision-making processes. However, the case study examples, and mainly the case of Rome, clearly show how sensitive is the resilience building process to the political leadership: the weakness or the frequent change of the latter could significantly affect the resilience building process that, to be effective, requires continuity on a long-term perspective.

For both cities, the Resilience Strategy represents an opportunity to address some critical issues related to different urban dimensions (society, economy, environment and governance), grounding on a shared vision for future development, capable to systematize into a common frame new measures and on-going actions already included in different tools (e.g. climate plans, urban regeneration projects, etc.).

However, being the resilience building process only at a first stage or, better, at a "planned stage", it is quite difficult to assess its effectiveness in the long term. Numerous actions could induce negative impacts if not adequately designed and implemented, as in the case of neighborhoods' redevelopment projects that could increase social inequality while improving environmental quality.

From the Viewpoint of Ecosystem Services: A Study of Functional Regionalization in Chiayi City, Taiwan

Chia-Ming Lin ¹, Hsueh-Sheng Chang ²

¹ Department of Urban Planning, National Cheng-Kung University, p26054151@ncku.edu.tw

² Department of Urban Planning, National Cheng-Kung University, changhs@mail.ncku.edu.tw

Abstract: In order to achieve the sustainable development goals on the spatial development of Taiwan's future land space, we need to comprehensive and systematic analysis of environmental resources. After the implementation of the Spatial Planning Act, all land is divided into four districts that are National Territorial Preservation district, Agricultural Development District, City-Country Development District, and Marine Resources District, with subsequent each county (city) need to according to the National Territory Planning Act, and propose their county (city) land plan. This study tried to explore the ecosystem service of Chiayi county area, and quantification of ecosystem services. Then applying spatial mapping and k-means cluster analysis, mapping bundles of ecosystem services. An understanding of the location and characteristic of different bundles of ecosystem services, may take us a step further to mapping systems that have direct policy and decision-making relevance for sustainable resource management and land use planning.

Keywords: Ecosystem service, Ecosystem services bundle, Spatial Planning Act.

1. Introduction

1.1 Background

On 18 December 2015, the Spatial Planning Act bill was passed by the Legislative Yuan in Taiwan. This Act specifically establishes guidelines concerning measures to be taken to cope with climate change, assure land use safety, conserve the natural environment and cultural assets, promote the reasonable allocation of resources and industries, strengthen land consolidation and management mechanisms, and restore sensitive areas and damaged land in pursuit sustainable development.

According to the provisions of the Spatial Planning Act, the central competent authority shall announce the National spatial plan within two years after this Act takes effect, which including the

establishment of functional zone demarcated priorities and principlesd(environmental conservation zones, marine resource zones, agricultural development zones and urban-rural development zones). Then the competent authorities of municipalities and counties (cities) shall according to those functional zone demarcated priorities and principlesd, demarcate the county (city) functional zones and land use control measures.

In order to echo the legislative spirit of the sustainable development of the Spatial Planning Act, this research try to lead into the concept of ecosystem services into the demarcation of the municipality and county (city) functional zones and enforcement of land use control measures. The key to sustainable development is achieving a balance between the exploitation of natural resources for socio-economic development, and conserving ecosystem services that are critical to everyone's wellbeing and livelihoods(Falkenmark et al., 2007). Ecosystem services is an excellent way to understand human well-being and regional sustainable development, and can also be viewed as an important part of land use planning and ecosystem management (Daily et al., 2009).

1.2 Ecosystem services

According to the website of the World Forum on Natural Capital, natural capital can be defined as the world's stocks of natural assets which include geology, soil, air, water and all living things. It is from this natural capital that humans derive a wide range of services, often called ecosystem services (ES).

For the specific ecosystem functions or processes that contribute to human well-being, MEA (2005) classifies the various benefits of ecosystems into four categories based on the 17 service classifications proposed by Costanza et al. (1997):

- Provisioning Services: Provisioning Services are ecosystem services that describe the material or energy outputs from ecosystems. They include food, water and other resources.
- Regulating Services: Regulating Services are the services that ecosystems provide by acting as regulators eg. regulating the quality of air and soil or by providing flood and disease control.
- Support services: Ecosystem services that are necessary for the production of all other ecosystem services. eg. provisioning of habitat.
- Cultural services: Refers to the benefits of non-material benefits that humans derive from ecosystems through entertainment and aesthetic experience, including aesthetics, entertainment, cultural heritage, spiritual religion, and science education.

Since Daily (1997) and Costanza et al. (1997) proposed 13 and 17 types of ecosystem services respectively, the literature related to the type of service and the way it is classified is still being discussed and updated. However, Costa Zanza et al. (2017) compares the following four of the main ecosystem services classification systems used worldwide and their differences and similarities: 1) Costanza et al., 1997; 2) Millennium Ecosystem Assessment, 2005; 3)TEEB, 2010; 4) CICES (v.4.3). While there are differences in the details, these classification systems are broadly very similar.

1.3 Ecosystem services bundles

In addition, since each ecosystem service is not independent, but instead exhibits complex interactions (Nelson et al., 2008). When ecosystem services are subject to interactions between themselves, as a result of natural processes (i.e. ecological drivers) or management decisions (i.e. socio-ecological drivers), “trade-offs” and “synergies” may emerge (Bennett et al., 2014). In simple terms, a trade-off between ES is characterised by the decrease in the provisioning of one or several ES as a result of increasing the supply or flow of one ecosystem service (Turkelboom et al., 2016). A synergy refers to situations in which two or more ecosystem services are simultaneously enhanced or simultaneously reduced (Li Peng et al., 2012).

Regarding the interactions among ecosystem services bundles, cluster analysis was mostly applied. Cluster analysis based on mapping is a powerful tool to identify ecosystem service bundle types and analyze ecosystem services trade-offs and synergies (Raudsepp-Hearne et al., 2010). This approach maps ecosystem service clusters based on where we find recurring services throughout the landscape, and their distribution is often interpreted as a distribution of known major human activities or land use in the area, so it is believed to help communicate the potential impact of management decisions to policy makers (Crouzat et al., 2015).

Nada Saidi et al. found that in recent years, related research generally uses statistical clustering analysis for detection. The most common types can be divided into the following two types:

- Cluster analyses (k-means or hierarchical).
- Graphical/tabular detection using lower dimensional projections with PCA, factor analysis, multiple correspondence analysis (MCA) or multidimensional scaling.

The most straightforward way to conduct spatial mapping research is by clustering landscape units (grids or administrative units), using cluster analysis methods such as k-means or hierarchical grouping. **Materials and methods**

2. MATERIAL AND METHODS

2.1 Study site

Chiayi County is a county in southwestern Taiwan surrounding. It is the sixth largest county in Taiwan. Chiayi County borders Mount Yu to the east, Taiwan Strait to the west, Tainan City to the south and Yunlin County to the north. It spans over 1,903 km² (735 sq mi). Chiayi County is located along the Tropic of Cancer. On the North of The Tropic of Cancer is temperate zone, while on the South is tropical zone. This is also a dividing line for agricultural climate as tropical and subtropical climates.

Bordered by mountains on one side and sea on the other side, Chiayi County holds three major national parks, which are Alishan National Scenic Area, Southwest Coast National Scenic Area and Siraya National Scenic Area, each represents a unique view of nature's wonders, from mountains, plains to ocean views.

2.2 Ecosystem service indicators and assessment tools

Wood et al. (2018) used a bipartite network analysis to plot the 178 ES-T interactions of ‘High’ perceived importance by each SDG target. In the pooled surveys, provision of food and water and habitat & biodiversity maintenance services were the most frequently evaluated; Followed by carbon storage & sequestration; Water quality, water regulation, raw material provisioning and recreation & tourism also contributed a number of sustainable development targets. If we consider the trade-offs and synergies between ecosystem services, we need to increase erosion control and pollination. Therefore, we collected proxies for ten different provisioning, regulating, supporting and cultural services.

Integrated modeling tools, the most commonly used tool is Integrated Valuation of Ecosystem Services and Trade-offs (InVEST). The InVEST mode is characterized by its ability to interface with the GIS interface and to perform different levels of elastic analysis based on the amount of data, so that the results are more clearly presented. In addition, users can use the functions of GIS for front-end or mode simulation. Subsequent analysis allows users to process the resulting data more efficiently.

In order to meet the data type requirements of the InVEST model, this study converted the land use data from vector data (shapefile) to grid file (shapefile). We use the ArcGIS10.3.1 for the grid transformation, which has the highest proportion of land use area in the grid, represents the land use category of this grid. In addition, when assessing and mapping ecosystem services, the spatial extent (scale) and resolution (analysis unit) will affect the interpretation and application of the assessment results. However, Jung-Wen Hsiao(2013) suggested the most appropriate resolution for modeling ecosystem services is 100m*100m. The resolution is 100m*100m, so this study converts the land use map with a grid size of 100m*100m.

Table 1 Ecosystem service indicator calculation

Classification	Ecosystem services	Significance	ES Calculation process
Provisioning Services	Food	Ecosystems provide the conditions for growing food. Food comes principally from managed agro-ecosystems.	The agricultural development zone Type 1~4 are assigned 1, 0.75, 0.5, 0.25, respectively, and the other assignments are 0.
	Raw materials	Ecosystems provide a great diversity of materials for construction and fuel including wood, biofuels and plant oils that are directly derived from wild and cultivated plant species.	Assign the plantation to 1 and the other to 0.
	Fresh water	Ecosystems play a vital role in the global hydrological cycle, as they regulate the flow and purification	The first and second water resources protection zones are assigned 1 and 0.5 respectively, and the other

		of water. Vegetation and forests influence the quantity of water available locally.	assignments are 0.
Regulating Services	Carbon sequestration and storage	Ecosystems regulate the global climate by storing and sequestering greenhouse gases. As trees and plants grow, they remove carbon dioxide from the atmosphere and effectively lock it away in their tissues. In this way forest ecosystems are carbon stores. Biodiversity also plays an important role by improving the capacity of ecosystems to adapt to the effects of climate change.	Calculation of comprehensive carbon stocks of four major carbon pools of surface organisms, underground organisms, soil and humus through the InVEST model ----- Total carbon stock (mg/pixel)
	Moderation of extreme events	Extreme weather events or natural hazards include floods, storms, tsunamis, avalanches and landslides. Ecosystems and living organisms create buffers against natural disasters, thereby preventing possible damage. For example, wetlands can soak up flood water whilst trees can stabilize slopes. Coral reefs and mangroves help protect coastlines from storm damage.	Average annual production (mm/watershed/year, mm/pixel/year)
	Waste-water treatment	Ecosystems such as wetlands filter both human and animal waste and act as a natural buffer to the surrounding environment. Through the biological activity of microorganisms in the soil, most waste is broken down. Thereby pathogens (disease causing microbes) are eliminated, and the level of nutrients and pollution is reduced.	Water purification by ecosystem nutrient retention (kg/basin/year, kg/pixel/year)
	Erosion prevention and maintenance of soil fertility	Soil erosion is a key factor in the process of land degradation and desertification. Vegetation cover provides a vital regulating service by preventing soil erosion. Soil fertility is essential for plant growth and agriculture and well functioning ecosystems supply the soil with nutrients required to support plant growth.	Calculated using the modified universal soil loss equation (RUSLE model). Calculate the amount of soil erosion in the bare land: $RKLS = R \times K \times L \times S$, and the amount of soil erosion with management measures and vegetation cover: $USLE = R \times K \times L \times S \times C \times P$, and then obtain soil retention: $RUSLE = RKLS - USLE$. Where R is the rainfall erosivity, K is the soil erodibility factor, L is the slope length factor, S is the slope factor, C is the vegetation coverage factor, and P is the soil conservation factor. If there

			<p>is no significant difference in rainfall in the area, the rainfall erosivity R is taken as a constant 1. Other factors are based on soil data, DEM and land use data, and are obtained by reference to the InVEST model specification.</p> <p>-----</p> <p>Average annual erosion (ton/watershed/year, ton/pixel/year); average annual sediment retention (ton/watershed/year, ton/pixel/year)</p>
	Pollination	Insects and wind pollinate plants and trees which is essential for the development of fruits, vegetables and seeds. Animal pollination is an ecosystem service mainly provided by insects but also by some birds and bats.	Pollinator abundance index (relative abundance/pixel, relative abundance/watershed)
Supporting Services	Habitats and Biodiversity Maintenance	Habitats provide everything that an individual plant or animal needs to survive: food; water; and shelter.	<p>The InVEST model is used to analyze the combined effects of various threats to habitats in the matrix, including: the relative impact of each threat, the relative sensitivity of each habitat type to each threat source, habitat patches and threat sources. The distance and the extent to which the land is protected by law. The legal protection of land in the study area is effective and the value is 1; the threat factors include farmland and orchard in addition to roads of all levels, various types of construction land, industrial and mining land, because agricultural fertilization and spraying of pesticides also directly threaten the original The survival of species. Refer to the InVEST model specification and expert opinions to determine the weight value of the threat factor and sensitivity factor and the maximum impact distance of the threat source on the habitat. Finally, input the InVEST model to obtain the habitat quality distribution map.</p> <p>-----</p> <p>Habitat degradation index; habitat quality index</p>

Culture Services	Rwcreation & Tourism	Ecosystems and biodiversity attract tourists, and natural beauty brings considerable economic benefits. It is an important source of income for many countries, and culture and ecotourism can educate people about the importance of biodiversity.	The country forest parks, large urban parks, important public service centers, important cultural activity centers and other areas are assigned importance values of 1, 0.7, 0.5, 0.3, and 0 according to their importance, and then the distance is interpolated to obtain the distribution map of the importance of the whole tourist attractions.

2.3 An analytical framework for ecosystem service bundling

The research design architecture can be divided into three phases:

- The first phase is the evaluation of individual ecosystem services: We chose ten ES for bundle analysis, which could be classified into provisioning, regulating, supporting and cultural services. Application of GIS spatial analysis function and InVEST model for assessment of various ecosystem services
- The second phase will predict the ecosystem service bundles (ESBs): determine the optimal number of clusters by Elbow Method(with the smallest total variation within the group), and identified ESBs by using K-means clustering. This phase had four main goals as follows: (a) to assess spatial patterns of multiple ES; (b) to characterize the interactions between each pair of individual services, (c) to detect ESBs and identify the main characteristics of each bundle, and (d) to discuss the influencing factors of trade-offs between each pair of services.
- The third phase identifies the relationship between the ecosystem service bundles and the land use: Calculate the distribution ratio of the corresponding ecosystem service clusters according to each country's functional zone. Try to understand the main ecological functions of each functional zone. Finally, through the relevant cases in the literature review, the reference recommendations for the follow-up management strategy for the land function of the Chiayi area will be given.

Results and Discussion

The definition and functional classification of ecosystem services is not only the basis for the formulation of relevant ecological policies, but also the issues that must be clarified before urban development and formulation of management strategies. It is related to the rational use of land resources and the sustainable development of human society.

Follow-up will take the Chiayi area as an example. The research results may provide a reference for the future development of the land area management strategy in the Chiayi area. It is expected to respond to Taiwan's vision of sustainable development of the future land space.

Research on the Construction of Sponge Campus from the Perspective of Low Impact Development

——A Case Study of Jiangpu Campus of Nanjing Tech University

Lin Ling¹, Shenzhi Dai²

¹ College of Architecture and Urban Planning, Tongji University, jsdtll2009@163.com

² College of Architecture and Urban Planning, Tongji University, szdai2606@126.com

Abstract: The rapid development of cities has caused serious damage to the urban ecological environment and has caused great changes in the global climate. In recent years, sponge city planning and construction have been carried out in many cities. As an important part of the city, the waterlogging problem of universities should also be paid attention to. Taking Jiangpu Campus of Nanjing Tech University as an example, through field investigation, we found that there are 9 locations with serious water accumulation on campus, 4 locations with different water accumulation degree were analyzed and selected. The causes of water accumulation were analyzed by controlling variables (including green space scale, green space density, terrain height difference, permeable pavement area, drainage facilities, etc.). Among them, we selected two indices include green space scale and distribution, using FRAGSTATS3.3 software, to describe the characteristics of green space patch landscape of 4 locations in detail. The analysis shows that the causes of waterlogging in the campus. Based on the study of 6 classical cases in China and abroad. Eight measures for building the campus as a "sponge campus" are put forward from two aspects of construction technology and management, in order to alleviate campus waterlogging, improve water environment quality and increase water recycling.

Keywords: Low Impact Development; campus waterlogging; sponge campus; strategies

Introduction

With the acceleration of urbanization and the expansion of urban scale, extreme weather occurs frequently in the world. At the same time, the change of urban land use pattern leads to the change of hydrological effect and the increase of the proportion of impervious surface, which leads to the continuous increase of urban rainwater runoff and the coexistence of waterlogging and "Thousand Island Effect" in cities. This series of problems are also prominent in our university campuses. Nanjing University of Technology is located in the rainy southern city, and its waterlogging problem is particularly evident in the rainy season. The construction of sponge city is an effective way to maintain a good ecological environment and alleviate urban floods. Therefore, applying the concept of sponge city to the construction of campus and forming "sponge campus" is an important means to solve campus waterlogging and maintain a good ecological environment of campus.

Drainage Status and Existing Problems of Jiangpu Campus of Nanjing University of Technology

1. Campus introduction

Geographic location: Jiangpu Campus of Nanjing University of Technology is located in Jiangpu Street, Pukou District, Nanjing City. It is located at the foot of Laoshan Forest Scenic Area. It faces Puzhu South Road in the south, Yanshan Avenue in the north and Flower Avenue in the west. Pukou District of Nanjing City is located on the North Bank of the Yangtze River in Nanjing City. It is located in the north latitude of 31 degrees 14'-32 degrees 17', east longitude of 118 degrees 20'-119 degrees 13'. It faces the Yangtze River in front, followed by Chu River, Laoshan Mountains in the middle, and hills in the west. There are alluvial continents along the rivers. According to the topographic differences and geomorphological characteristics, four major areas are formed naturally, namely, the polder along the river, the polder along Chu, the mountainous areas, the nearest hills and the distant hills, as shown in Figure 1.

Figure 1 Nanjing University of Technology Campus Plan

Climatic conditions: Jiangpu Campus of Nanjing University of Technology is located in the middle and lower reaches of the Yangtze River. It belongs to the subtropical monsoon climate zone. Rainfall varies greatly between years and seasons, with obvious abundance and drought and uneven distribution of rainfall. According to many years' data and statistics, the average annual rainfall in the whole region is 1102.2 mm, 1778.3 mm in flood year (1991), 465 mm in dry year (1978), 712.1 mm in flood season (May-September), 1324.5 mm in flood season (1991), 248.8 mm in minimum rainfall (1978) and 301.9 mm in maximum daily rainfall. (5 July 2003). The local annual average runoff is about 262 million cubic meters.

Topographic features : Jiangpu Campus of Nanjing University of Technology is located in the hilly area at the foot of Laoshan Mountain. It is an irregular rectangle, about 2200 meters in length from north to South and 920 meters in width from east to west. The terrain is low in the South and high in the north, with an elevation of 10 to 60 meters. The campus is a multi-channel alluvial land separated by many hills, with large fluctuations and scattered land use, as shown in Figure 2.

2. Current Situation of Drainage in Campus

Research object : During the rainy season in Nanjing, Jiangpu Campus is often affected by rainstorms, resulting in campus waterlogging. The survey selected nine places with serious water accumulation in the campus, which were: (1) the front square of Yifu Library; (2) the entrance of Pujiang Canteen; (3) the South downhill of Dongyuan Canteen; (4) the front of Thick School Building; (5) the main road of the campus; (6) the east side of the school gate; (7) the music platform; (8) the south side of Building A of Pujiang River; and (9) the west side square of Building C of the Zongpujiang River. The distribution of nine places is shown in Fig. 4. According to the average water depth of nine places, the severity of waterlogging in nine places is sorted. The order from heavy to light is the entrance of Pujiang canteen, the South downhill of Dongyuan canteen, the main road of campus, the front of thick school building, music platform, the east side of school gate, the west square of Pujiang C building, the south side of Pujiang A building and the front square of Yifu library, as shown in Figure 3.

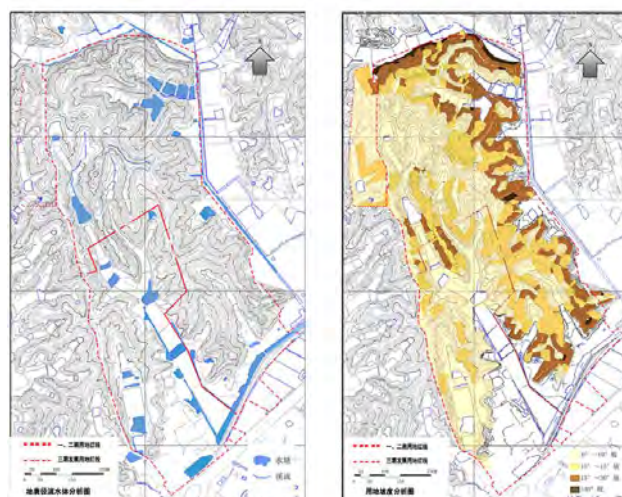

Figure 2-1 Distribution of Surface Runoff System in Jiangpu Campus, Nanjing University of Technology (left)

Figure 2-2 Analysis of Land Slope in Jiangpu Campus of Nanjing University of Technology (right)

Figure 3 9 Distribution of Severe Points of Water Accumulation

Interpretation of the Current Situation: According to the above survey data, it is preliminarily speculated that the formation of campus waterlogging is mainly related to the degree of green space coverage, and secondly to the height difference within the campus and the area of water area. Therefore, this paper selected four sites with different water accumulation degree to analyze the control variables. The four points selected are: A Music Platform; B East Court basketball court; C Pujiang Canteen Gate; D Houxue Building Gate (see Figure 4). Firstly, the landscape pattern characteristics of green space patches around are described from two aspects: the scale and distribution of green space. Two landscape indices, Class area and Patch Density, are selected (see Table 1). A window with a length of 50 m and a width of 50 m is established. The moving window is calculated by FRAGSTATS3.3 software, and the landscape spatial distribution characteristics of each patch are obtained (Yin Xuewen, 2014).

Figure 4 Four Control Variable Analysis Locations

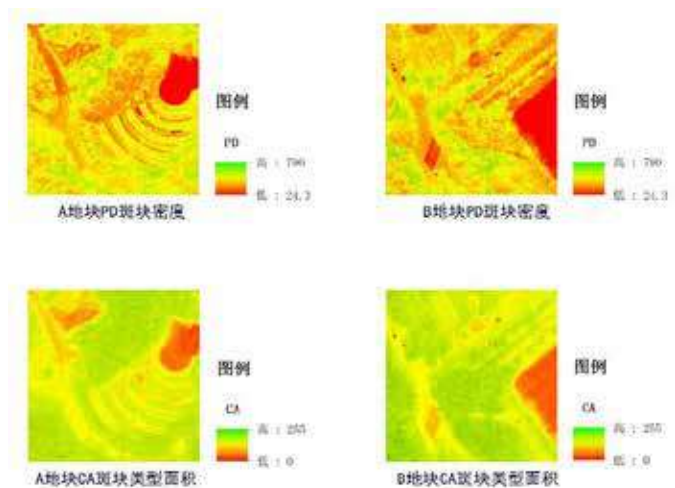

Table 1 Green Space Scale and Distribution Landscape Index

Evaluation content	Name of Landscape Index	Definition of Landscape Index	Implications in this study
The Scale of Green Space	Class area, CA	$CA = \sum_{i=1}^n a_{ij}$	Total area of urban green space in a certain range (m^2)
Distribution of Green Space	Patch Density, PD	$PD = \frac{n_i}{A}$	Patch Density Reflecting Urban Green Space in a Certain Range
	Landscape Division Index, LDI	$LDI = 1 - \sum_{j=1}^n \left(\frac{a_{ij}}{A}\right)^2$	Reflecting the fragmentation degree of urban green space patches in a certain range, when $LDI = 0$, it shows that there is only one patch in the area, and the closer LDI approaches to 1, the more fragmented the patches are

(Note: a_{ij} is the area of a certain green patch type, n_i is the number of green patches in a certain range, A is the total area of the landscape.)

(1) Contrast between A Music Station and B Dongyuan East Basketball Court

According to the software analysis, the following four pictures are obtained. From the PD and CA maps of A and B blocks, we can see that the green patch density and patch type area of the two blocks are comparatively similar. But from the field investigation, we can find that the water accumulation in the red area of A block is more serious than that in the red area of B block. By analyzing the similarities and differences between the two plots, it can be found that the height difference between the red area and the green area on the southwest side of Block A is larger, about 1.5 meters, and the pavement in the red area is hard

impermeable pavement, while the green area is good permeable grassland. The red area in Block B is permeable and flat, as shown in Fig. 5.

Therefore, the analysis shows that Table 2:

Table 2 Comparisons of plot elements and water supply in A and B

Land	PD	CA	Height difference	Permeable pavement area	Drainage ditch	Accumulation of water
A Music Station (Red Area)	Low,	Low,	Large	NO	More	Serious
A Music Station (Green Area)	High	High	Large	Large	Less	Slight
B Dongyuan East Basketball Court (Red Area)	Low,	Low,	Small	Large	More	Slight

Comparing the red area of Block A with the green area, under the same height difference, the factors affecting the water accumulation are the coverage area of green space and the area of permeable pavement; comparing the red area of Block A with the red area of Block B, we can find the factors affecting the water accumulation when the green area is also small. There are height difference and permeable pavement area.

(2) Contrast between A Music Station and the entrance of Pujiang Canteen

According to the software analysis, the following four pictures are obtained. After comparison, the green patch density and patch type area of A plot are higher than those of C plot. Through field investigation, it is found that there are certain height differences in A plot and C plot, even the height difference in A plot is greater than that in C plot, but the water accumulation in C plot is obviously more serious than that in A plot. See Figure 6.

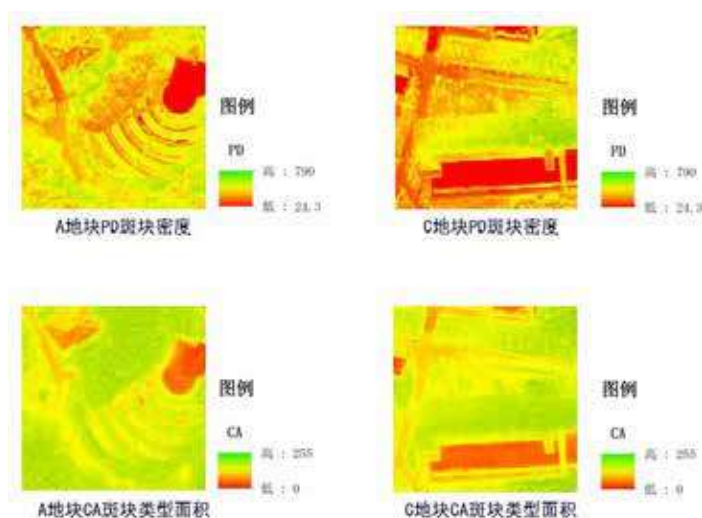

Figure 6 Comparison of Landscape Index of Blocks A and C

Therefore, the analysis shows that table 3:

Table 3 Comparisons of plot elements and water supply in A and C

Land	PD	CA	Height difference	Permeable pavement area	Drainage ditch	Accumulation of water
A Music Station	High	High	Large	Large	Commonly	Slight
C Pujiang Canteen Gate	Low,	Low,	Large	NO	Commonly	Serious

Comparing A plot with C plot as a whole, under the same condition of large height difference, the factors affecting water accumulation in plot A are the coverage area of green space and the area of permeable pavement. Even the plots with large elevation difference are more conducive to rainwater evacuation because they have more green space coverage.

(3) A comparison between the basketball court on the east side of B Dongyuan and the entrance of D Houxue Building

According to the software analysis, the following four pictures are obtained. From the PD and CA maps of Block B and D, we can see that the green patch density and patch type area of the two plots are comparatively similar, but from the field investigation, we can find that the water accumulation phenomenon in Block D is more serious than that in Block B. By analyzing the similarities and differences between the two plots, it can be found that the plots B and D are located in the relatively flat area in the campus, but the plot B is close to more landscape rivers, as shown in Figure 7.

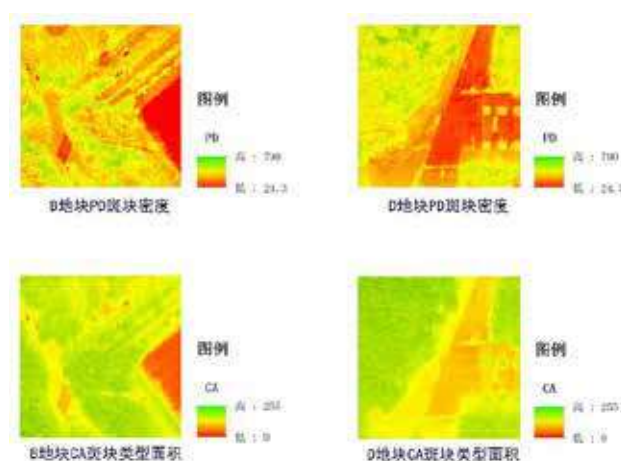

Figure 6 Comparison of Landscape Index of Blocks B and D

Therefore, Table 4 is drawn from the analysis.

Table 4 Comparisons of plot elements and water supply in B and D

Land	PD	CA	Height difference	Permeable pavement area	Drainage ditch	River	Accumulation of water
Near the East Basketball Court of B Dongyuan	Commonly	High	Small	Large	Commonly	Near	Slight
Door of D Houxue Building	Commonly	High	Small	Small	Commonly	Far	Serious

Comparing Block B with Block D as a whole, under the similar conditions of green patch density, patch type area, elevation difference and drainage channel, the factors affecting water accumulation in Block B are the area of permeable pavement and river system.

3. Causes of Campus Waterlogging

After analyzing the current situation of drainage in campus, it is preliminarily concluded that campus waterlogging is closely related to the coverage rate of green space, terrain height difference, permeable pavement area and river course. Further analysis of these four factors can lead to the following reasons for campus waterlogging.

Higher relief: The Jiangpu Campus is built in the aftermath of the National Forest Park Mountains. The whole campus is integrated with the mountain body and built in accordance with the mountain. Therefore, the campus interior is low in the South and high in the north. It is separated by many hills into multiple impacting areas. The land is scattered and the height difference is large. In rainstorms or continuous rainstorms, the rainwater flows rapidly to low-lying areas under the guidance of gravity, resulting in the accumulation of rainwater at low places and the formation of campus waterlogging. At the same time, in the process of water flow, small waterfalls will appear on the slopes. It has seriously affected the travel of teachers and students.

High impervious pavement rate in some areas: Jiangpu Campus covers a large area with dense road network and more vehicles. It needs more parking space. Most of the parking lots in the current campus are impervious pavement. At the same time, the school provides more venues for teachers and students, and also for hard impermeable pavement. The large proportion of impervious pavement in the campus has greatly affected the infiltration of rainwater, resulting in many water accumulation in the campus, as shown in Figure 8.

Figure 8 Water accumulation in impervious pavement

utting off bends and straightening up rivers to weaken the links of "stagnation": The natural river course is meandering and winding. The meandering bank can effectively reduce the speed of flow. With the natural grassland revetment, the impact of water stays in the river course increases the permeability of water. In the construction of Jiangpu Campus, many rivers are straight landscape rivers. Straight rivers seem to be able to drain rainwater quickly, but in fact, rainwater will be accumulated in the lowest place after passing through the rivers quickly, forming a campus waterlogging. Most of the landscaped riverbanks in the campus are artificial hard ones, which not only increase the beauty of the campus, but also reduce the infiltration of water and increase the drainage pressure of the riverway in rainy season.

The water system is dispersed and its circulation is not strong: Jiangpu Campus takes "landscape campus" as its design concept and plans a large number of rivers (see Figure 11 for details). These water bodies form a certain water network structure on the plan, but more of them are blocked in the middle, forming the characteristics of water system dispersion, affecting the flow of water, so when rainwater floods, it will form a serious phenomenon of local water accumulation in the campus, as shown in Figure 9.

Figure 9. Distribution of water system in Campus

Drainage ditches are covered to prevent rainwater seepage: Walking in the campus, we can often see fallen leaves, food bags, express bags and other garbage

piled up in the drainage ditches. As a result, when the rainstorm comes, the drainage ditches can not fully play their role, which leads to flooding of the road surface and hindering the travel of teachers and students.

Case analysis and experience summary at home and abroad

1. Case Study of Foreign Countries

In recent years, low impact development (LID) has been effectively used and promoted in the United States. Many famous universities and professional institutions have cooperated to formulate the rainwater management project plan for each school, and ingeniously combine campus landscape design with low impact development technology. The University of Pennsylvania and Yale have worked out sustainable campus rainwater management plans; the Massachusetts Institute of Technology of Harvard University has built ecological rainwater landscape in the process of campus renovation; and the University of Maryland has carried out experimental studies on campus. The practice of low-impact development technology in American universities is mostly to transform the environment after land development, so as to improve the quality of the environment and ecological benefits and form a sustainable ecological landscape on the basis of not destroying the existing concurrent work.

Sunolun Landscape Laboratory: Underwood Family Sonoran Landscape Laboratory, also known as "Home under the Tree", is located in Tucson, AZ USA, See Figure 10.

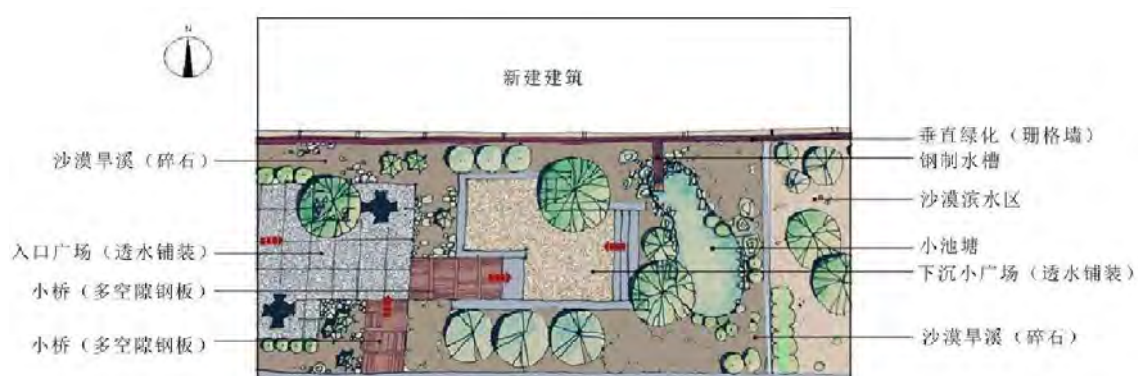

Figure 10 Plane of Suloren Landscape Laboratory

Sunolun Landscape Laboratory fully embodies the concept of sustainable development. Its greatest feature is the collection of rainwater and the recycling of water resources. Through a series of low-impact development facilities, the laboratory has slowed down the speed of rainwater runoff, fully recycled rainwater resources and reduced waterlogging.

Central Plaza, Southwest Residential Area, MIT: The Massachusetts Institute of Technology Southwest Residential District Central Plaza Renovation Project was designed by Stephen Stimson Landscape Design Firm of the United States. The original monotonous and dilapidated square was designed and renovated, and a humanized sustainable open space was created. A visual rainwater system consisting of rainwater conveyor belts and rainwater gardens was constructed, which reduced the impervious pavement rate of the site from 70% to 40%. The coverage of natural vegetation and permeable pavement increased from 30% to 60%, as shown in Figure 11.

Figure 11 Rainwater system plan of site

In the design, the North-South long green corridor symbolizes the Connecticut River, which is the main channel for collecting and transmitting rainwater from surrounding squares and roofs. The corridor links the blocks of green space between buildings, symbolizes the pasture and farmland in the valley, and is also the main place for rainwater purification, infiltration and teachers' activities. The north-south rainwater transmission bandwidth is 1-1.5 meters, consisting of stone strips, metal plates and plants, and equipped with a certain number of log seats for teachers and students to use, as shown in Figure 12.

Figure 12 Cross-section of rainwater transport belt

Figure 13 General Plane of the Institute of Biology, Arizona State University

ASU Institute of Biological Design: ASU Biodesign Institute, located in Tempe, Arizona, USA, covers an area of about 16188 square meters. In order to create a sustainable development space, rainwater harvesting facilities were set up in each site to realize the collection and utilization of rainwater resources. Rainwater collection of the project is mainly embodied in rainwater garden, rainwater retention area and permeable material pavement. Through these facilities, water resources are recycled, as shown in Figure 13.

2. Domestic Case Analysis

At present, the construction of sponge campuses in China lags behind the developed countries slightly, mainly in the application of technology, standards, policies and regulations and the overall awareness of co-management. In recent years, the construction of sponge campuses with low impact development has been paid more and more attention in our universities. Tsinghua University, Duke University of Kunshan, Tongji University, Beiyang Campus of Tianjin University, Hunan Agricultural University, Shenyang Architectural University and other universities have carried out the construction and research of rainwater control and utilization projects.

Shengyin College of Tsinghua University : Shengyin College is located in the west of the southern section of the traditional central axis of the auditorium of Tsinghua University. It is one of the modern classroom housing groups of Tsinghua University. With the reconstruction and construction of the school, the surrounding terrain has been constantly raised, and it has gradually become a low-lying area. Every rainstorm will cause serious campus waterlogging.

In the renovation of Shengyin College, the historical style of its architectural heritage was maintained, and the low-impact

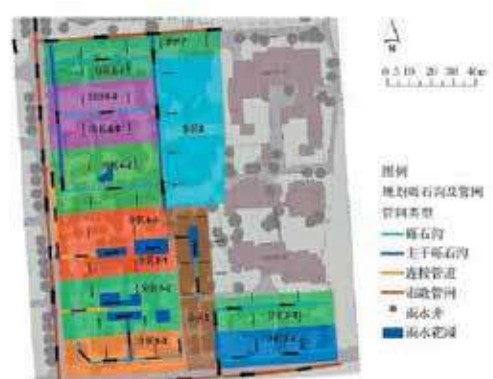

Figure 14 Sewerage Zone of Shengyin Courtyard

development technology facilities and landscape construction were integrated to achieve the collection and utilization of rainwater resources and effectively alleviate the problem of campus waterlogging. Rainfall management facilities in Shengyin Hospital include rainwater garden, dry pool, gravel ditch, grass ditch and so on. See Figure 14.

Duke University of Kunshan: Duke University of Kunshan is located in Yangcheng Lake Science Park, Kunshan City, Jiangsu Province. Its campus covers an area of 1,200 mu (about 130,000 mu). In 2016, Duke University became the first LEED green campus in China to be certified by the American Green Building Commission. Its ecological landscape design and highly hydroelastic "sponge campus" feature are the international leading certification. One of the key elements (Zeng Ying, 2017).

The design of the project combines the characteristics of the space demand of campus users and the change of the water quantity of the central landscape lake, and integrates the analysis of time, space and water level. The central landscape lake will be built as the center of collecting and managing rainwater systematically. Through collecting rainwater from the roof and square of the campus, the original campus will be greened on the West side. The zone is transformed into an ecological park with a series of purified pools connected to the Central Lake, forming a "living water" system circulating and reciprocating in the campus, as shown in Figure 15.

Figure 15 The "Live Water" System of Duke University in Kunshan

In the transformation of Duke University, unlike other universities, the design defines the submergable and non-submergable areas. It describes the elasticity of the sponge campus as allowing the departmental areas to be submerged, but this "submergable" scope and state are controlled within the design scope, as shown in Figure 16.

Figure 16. Different relationships between landscape platforms and water surfaces

Hunan Agricultural University: Hunan Agricultural University is located in Furong District, Changsha City. Its campus covers an area of 2.27 square kilometers. The design of the "Red Axis" landscape in its campus uses the invisible water storage system model. Instead of setting up obvious engineering facilities on the surface, it combines water saving, water storage and other measures with the green space construction and landscape construction of the campus.

Hunan Agricultural University put forward its water storage model based on the current situation of massive waste of energy and resources. The characteristics of this model are to build a series of rainwater utilization facilities by using the accumulation of hard materials such as waste bricks, sandy pebbles and cement blocks, to maximize rainwater storage, to supplement the water retention of groundwater and soil, to improve the growth conditions of plants, to save and adequately water resources, and to reduce them. The pressure of light Rainstorm on drainage pipeline network will build sponge campus.

3. Summary of Case Experience

Adapt measures to local conditions and retain local characteristics: During the renovation of Sunolun Landscape Laboratory, the unique desert landscape was preserved, and many native plants, such as butterfly rattan and mutton tree, were used. These functional elements and social elements were skillfully combined to form a unique and innovative "small sponge" city, which is a demonstration site in the arid and barren southwestern region of the United States.

Analyse the rainwater and flood, study the site sufficiently : The renovation of Shengyin College of Tsinghua University is based on the division of rainwater gathering areas in the site, and then the direction of drainage pressure in each area is analyzed. Finally, the corresponding low-impact development facilities are selected according to the flow of each area, and the implementation location is determined according to the layout of the green landscape. Therefore, a full analysis of the current situation of the plot is the necessary measure for the construction of sponge campus under the concept of low impact.

Recycling and utilizing rainwater in combination with landscape: The Sunorom Landscape Laboratory also has a relatively complete system of reclaimed water in buildings. Designers collect rainwater from roofs, condensate from air conditioners and reclaimed water from automatic water dispensers in buildings through a water tank with a total capacity of 11,600 gallons placed in buildings to meet the needs of inadequate water supply in the site. At the same time, the water can also be diverted to a small pond simulating the desert dry stream by using a steel tank, which can increase the water level and salinity of the small pond and realize the water cycle of the site.

The MIT Square Renovation Project also uses north-south rainwater conveyor belts to collect rainwater runoff and roof rainwater from the site and reuse them after purification of the sunken rainwater garden.

Designers at ASU Biological Design Research Institute set up small gravel-covered basins in the site as reservoirs for rainwater collection.

The renovation of Shengyin College of Tsinghua University integrates the rainwater management facilities with the historical landscape environment, carries out reasonable vertical design, increases the infiltration capacity of the surface, effectively controls the rainwater runoff at the source, and uses the green landscape to treat, recycle and reuse rainwater.

Constructing rainwater recycling system combined with waterscape can not only create a systematic and ecological campus landscape, reduce the phenomenon of water accumulation in the campus, but also greatly save the irrigation water in the campus.

Increase permeability and use permeable pavement : In the design process of Sunolun Landscape Laboratory, many low-impact development technologies were introduced. Permeable pavement was used extensively to increase the infiltration and purification of rainwater. The Massachusetts Institute of Technology (MIT) square renovation increased the permeable pavement rate by 30%, greatly increased the infiltration of rainwater during the rainy season, and reduced surface runoff. Similarly, in the project of ASU Institute of Biological Design, a large number of permeable pavement materials are used to increase the infiltration of rainwater so that groundwater can be recharged and water resources can be conserved.

Optimizing green space and increasing rainwater treatment: Through the analysis of the above six cases and the sponge campus construction of other universities at home and abroad, it is found that green landscape plays an extremely important role in the construction of sponge campus. Its role runs through the whole system, covering the source, middle and end, as shown in Table 5.

Table 5 Landscape Rainwater Disposal Measures for Green Space

Control process	Name	Measures	Function
Source	Roof Garden	Engineering measures for greening roofs, roofs or balconies of buildings or structures	Reducing peak runoff and total rainfall runoff
	Rain garden	Engineering measures for planting shrubs, flowers and plants in low-lying areas, using the biochemical and physical characteristics of plants, bacteria and soil to purify and store the total amount and quality of water in landscape	Purify Rainwater, Increase Evaporation, Blue and Green Space Conversion Place
	Permeable pavement	Engineering measures for the use of pervious materials or engineering practices as engineering measures for the treatment of pervious materials	Rainfall Infiltration Rate Improvement
	Concave green space	A concave green space 50-150 mm below the surrounding hard pavement	Rainwater harvesting, groundwater recharge, blue-green space conversion site
	Landscape tree array	Matrix planting of humidity-tolerant and Saline-Alkali-Tolerant trees at a certain distance to form a characteristic landscape space	Alleviating heat island effect and increasing rainwater infiltration rate
Middle	grassed swales	Landscape Surface Channel Drainage System for Planting Vegetation	Reducing surface runoff velocity and increasing rainwater infiltration
	Gravel grooves	Landscape surface ditch drainage system filled with gravel	Increase rainwater infiltration and purify water quality
End	Wetland	Natural or artificially formed swamps and shallow water areas with stationary or flowing water bodies can provide habitats for birds and fish.	Purify water and precipitate toxic substances
	Landscape water body	Natural or artificially constructed landscapes with water elements, such as concave pools, concave sculptures, dry streams, etc.	Stormwater storage

Divide the area and make sure whether it is submerged or not: When the campus encounters continuous heavy rainfall for many days, even if there is a good water infiltration system and enough river water system to accommodate water, it will cause water accumulation in some areas and form campus waterlogging. At this time, through the division and positioning of the campus area, it is necessary to determine which areas can be submerged and which areas can never be submerged, so as to accommodate rainwater to a greater extent, so that the places with transportation, distribution and other functions in the campus are not affected by waterlogging.

Technical Measures for the Construction of "Sponge Campus" in Jiangpu Campus of Nanjing University of Technology

To build "sponge campus", we must apply the six-character concept of sponge city - infiltration, stagnation, storage, net, use and arrangement to the construction of campus. Based on the investigation and analysis of the current situation of Nanjing University of Technology, combined with the experience of domestic and foreign cases, this paper tries to put forward corresponding measures for the construction of "sponge campus" in Jiangpu Campus of Nanjing University of Technology from the perspective of six-character concept.

1. Infiltration

Green Roof : Green roof has the function of saving energy and reducing emission. It can collect a lot of rainwater in rainy season, control roof runoff, and reduce the pollution of runoff, so as to facilitate the recovery and utilization of rainwater. The southern part of Jiangpu Campus of Nanjing University of Technology is relatively dense, so reducing roof runoff is one of the important tasks of building sponge campus, as shown in Figure 18.

For flat-roofed buildings, when building green roofs, it is necessary to ensure that the roof load, waterproof performance and other indicators meet the construction standards; for sloping roofs, the requirement for building green roofs is that the roof slope should not be greater than 15 degrees. At the same time, green roofs are divided into two types: simple roof and garden roof. The design indicators of the two types of roofs are different, as shown in Table 6.

Table 6 Suggested Indicators for Green Roofs

Form	Greening Roof Area/Total Roof Area	Greening Planting Area/Greening Roof Area	Paved garden pavement area/green roof area	Landscape Art Area/Greening Roof Area	Matrix depth
Simple	$\geq 80\%$	$\geq 90\%$	—	—	~150mm
Garden	$\geq 60\%$	$\geq 85\%$	$\leq 12\%$	$\leq 3\%$	$\geq 600\text{mm}$

Permeable pavement: Permeable pavement has the functions of seepage, stagnation and storage, which can temporarily store a small amount of rainwater. Its main function is to promote the infiltration of rainwater to supplement groundwater and reduce the water volume and speed of surface runoff. In this paper, the analysis of the current situation of Jiangpu Campus shows that most of the water-logged areas in the campus are impervious pavement, such as parking lot, distribution plaza, etc. Therefore, it can be considered to use pervious pavement to update and improve it, as shown in Figure 19.

Figure 18 Green Roof Profile

Figure 19 Diagram of Permeable Pavement Section

Natural revetment: From the analysis of the present situation of Jiangpu Campus, we can see that many of the campus landscape rivers have adopted the design of artificial hard revetment, which gives people a beautiful feeling from the visual effect. But when facing the rainstorm, these hard revetments will only increase the flow rate of rainwater and aggravate the phenomenon of water accumulation in low terrain. Therefore, in the construction of "sponge campus" in Jiangpu Campus, we should Restoring the original natural revetment of the river system and increasing the infiltration of water in the river course, at the same time, the original ecological characteristics of the original Jiangpu Campus conform to the theme of its "landscape campus".

2. Stagnation

Concave green space: The concave green space has the natural seepage ability, and can use its concave terrain to block the surface runoff of rainwater, and to a certain extent can store rainwater. The concave green space can be widely used in the reconstruction of campus. It has the advantages of low construction complexity, low

construction cost and saving irrigation water. At the same time, the concave depth of concave green space should be determined according to the drowning resistance of plants and the permeability of soil, generally 100-200 mm. In the construction of sponge campus in Jiangpu Campus of Nanjing

Figure 20: Concave green space profile

University of Technology, the corresponding concave green space should be constructed in the low-lying areas according to the topographic characteristics of the campus itself, so as to increase the process of rainwater "retention", as shown in Figure 20.

Biological Retention Land: Biodetention is a facility for storing, infiltrating and purifying rainwater through plant, soil and microbial systems in low-lying areas. It includes not only rainwater gardens, but also biological detention zones, high flower beds, ecological tree pools and so on. There are a large number of forest areas and low-lying terrain in the northern part of Jiangpu Campus. The construction of biological retention areas in these areas can not only make rainwater retained, collected and purified to a certain extent, but also make rational and efficient use of rainwater to attract teachers and students. In the construction of biological detention areas, the catchment areas with serious pollution need to be treated and discharged, while the roof runoff and rainwater can be directly connected by rainwater pipelines.

In the analysis of the present situation, we know that the waterlogging of the main road in Jiangpu Campus is serious, so we can construct biological detention land in the green belt on both sides of the road. At the same time, when the slope of the road is more than 1%, we need to set up a weir/platform to slow down the flow rate and increase the water permeability. Leakage prevention treatment is needed near the roadbed to prevent the impact on the stability of the roadbed.

Abandoning straight and bending: In the analysis of the current situation, more water bodies in Jiangpu Campus are linear. When the rainstorm comes, the rainwater quickly passes through the river channel and then accumulates at the lowest point, forming a campus waterlogging. Therefore, in the construction of "sponge campus" in Jiangpu Campus, we should abandon the straight river to bend where the waterlogging is serious, and reduce the flow velocity of the water body through the curved river, so as to achieve the effect of "stagnation".

3. Storage

Reservoir: The function of regulating and storing pond is to collect, regulate, save and purify rainwater. It is an intermittent water landscape. It can temporarily collect rainwater and then discharge it slowly according to need. Reservoir pond can lighten the burden of drainage pipe to a certain extent, at the same time, it can increase the water landscape of campus, and create a good hydrophilic environment for teachers and students. When water storage ponds are laid out in Jiangpu Campus, the original catchment depression in the site can be used to increase the value of recreational use combined with recreational and recreational venues, as shown in Figure 21.

Figure 21 Section Diagram of Reservoir Reservoir

Constructed wetlands: Constructed wetland is a surface water body constructed artificially and operated artificially. It is generally composed of intake, pre-pond, swamp area, outflow pool, overflow pipe, revetment slope, etc. When the constructed wetland is laid out, the mixed plant planting method can not only increase the diversity of campus organisms, but also help to improve the permeability and purification rate, so as to maintain the stability of campus water circulation system, as shown in Figure 22.

Figure 22 Profile of constructed wetlands

4. Net and Useful

Rainwater treatment and reuse system: After the seepage, stagnation and storage of rainwater, the collected rainwater should be treated and reused. Combined with the facilities of rainwater garden and reservoir mentioned above, the rainwater purified can be used as irrigation water for vegetation, miscellaneous water for teachers and students, emergency water and fire fighting water, so that the rainwater collected can flow. When conditions permit, small-scale rain water purification facilities can be built to produce drinking water up to standard for use by teachers and students in schools.

5. Row

Grass planting ditch: Grass planting ditch refers to the landscape facilities planted in ditches to control flow, transport rainwater and improve water quality. On both sides of the road and around the parking lot square in Jiangpu Campus, the corresponding grass planting ditches can be arranged in parallel with the green space, so as to ensure that the campus ecological environment is not affected, and the rainwater can be drained smoothly. At the same time, pebbles can be set on both sides of the slope of the paper straw ditch, which can slow down the runoff and also reduce the erosion of the slope by rainwater.

Arid stream: Dry stream is a kind of facility to simulate natural streams. It has high flexibility. The streambed has a winding linear distribution. It has no permanent water body. It is usually in the rainy season and dry season. The construction of Arid stream can prevent the soil from being directly washed away by rainwater and reduce soil erosion. At the same time, the combination of layout with campus green space can increase the richness and hierarchy of campus landscape. In the construction of sponge campus in Jiangpu Campus, it can be arranged at the core landscape nodes, such as the side of Junzi Lake, the central landscape belt and Yiqing Tongji Lake.

Measures for the Construction and Management of Sponge Campus in Jiangpu Campus of Nanjing University of Technology

The previous chapter elaborated how to build "sponge campus" under the concept of low-impact development at the technical level. Through the investigation and research of the current situation, it is found that not enough technical means can be adopted to build "sponge campus" well, and the construction of "sponge" city can not be separated from efficient and effective management. Therefore, this paper also puts forward several management measures, as follows:

1. Overall coordination and overall development

Campus as a relatively independent system in the city, is also an important part of the city, so its internal changes often affect the changes of the surrounding and even the whole city. Therefore, in the construction of "sponge campus", we need to consider the construction of the whole city's sponge city as a whole, in order to ensure the coordinated development between the campus and the city.

2. Distribution and recycling of rain and sewage

When rainwater is discharged, the rainwater and sewage should be diverted and treated directly into the sewage pipe, while rainwater can be collected and reused after purification. Therefore, in the construction of sponge campus in Jiangpu Campus, we should strictly implement the rainwater and sewage diversion system.

3. Optimizing water body to ensure water quality

The current situation of water pollution in Jiangpu Campus is serious. Serious pollution has led to the slowdown of water flow rate and the reduction or even disappearance of self-purification ability. Therefore, regular cleaning of water body is necessary to ensure the water quality. At the same time, suitable microorganisms and aquatic animals and plants can be selected and cultivated in the water body to construct a perfect natural ecosystem and water microcirculation system.

4. Zoning and Strict Control

In the "Technical Guidelines for Sponge City Construction - Construction of Rainwater System for Low Impact Development", five regions are divided into five areas to be controlled by indices. Because the terrain of Jiangpu Campus is quite different, and there are differences in the form of building density in different functional areas, the construction of sponge campuses in Jiangpu Campus should also be divided into corresponding zones. The zoning should be carried out from the beginning of the current situation investigation. In the optimizing construction stage, the appropriate facilities should be selected, and which parts of the zones can be controlled. What is submerged in the enclosure must not be submerged. At the same time, it is clear which areas have the most serious waterlogging, so that runoff can be strictly controlled by means of on-line monitoring.

5. Strengthen management and timely maintenance

Investigation shows that more drainage ditches in the campus are covered by leaves and garbage, which affects the infiltration of rainwater. With the development of campus construction, the campus environment is changing constantly. The problem of long-term use of drainage ditches and the old rainwater facilities can not adapt to the changes of the environment are becoming increasingly prominent. Therefore, the construction of sponge campus must strengthen management, timely cleaning of rubbish in rainwater circulation system, and regular maintenance, renewal and repair of drainage facilities.

6. Resource Bearing and Supply-Demand Balance

The purpose of building "Sponge Campus" is to promote the coordinated and balanced development of the campus and water resources, and to realize the optimization of functions while protecting the campus environment. The campus drainage system is planned and constructed according to the number and scale of school development in a certain period of time. In recent years, with the vigorous development of education in China, the expansion of campus enrollment has aggravated the burden of drainage facilities on campus, resulting in waterlogging and other problems. For example, the Central Landscape Department of Jiangpu Campus has developed a large number of departments of the New College of green space construction, resulting in a serious reduction in green space area. Therefore, it is necessary and sufficient to expand the staff and construct the campus under the conditions of resource supply.

Summary

The construction of "Sponge Campus" is based on the existing water system and within the affordable environment, taking scientific measures to carry out in a suitable intensity and manner. The current situation of Jiangpu Campus not only has the problem of waterlogging, but also ignores the "resource" of rainwater. In this paper, the drainage status of Jiangpu Campus of Nanjing University of Technology has been fully investigated and analyzed, and combined with the domestic and foreign cases of "sponge campus" construction, the construction method of "sponge campus" in Jiangpu Campus under low-impact development has been put forward. However, the construction methods mentioned in this paper are relatively general, and only stay at the macro level of what areas can be built. Therefore, it needs further research and textual research on how to improve and improve each existing facility in the campus.

CONVENING REGIONAL CLIMATE COLLABORATIVES: A CROSS-COMPARISON OF US CASES

Richard D. Margerum¹, Steve Adams², Josh Bruce³

¹*School of Planning, Public Policy and Management, University of Oregon, rdm@uoregon.edu*

²*Institute for Sustainable Communities*

³*Institute for Policy Research and Engagement, University of Oregon*

Abstract: Collaboration has been increasingly used to address complex regional problems that cross political boundaries and jurisdictions. The roles, approaches and implementation issues associated with collaboration strategies and networks have been widely discussed in the research literature, but there has been less analysis of the approaches and deliberations associated with convening collaborative efforts. This paper explores the issues, dialogue and framing of collaborative efforts through a cross case comparison of climate change mitigation and adaption actions plans across the United States. In this first phase, we present the findings from our content analysis of documents, agreements and web sites. When analyzed by strategy (mitigation versus greenhouse gas reduction) and approach (alignment versus joint action), we found two distinct groupings: (1) efforts largely focused on mitigating effects through alignment; and (2) efforts drawing on joint action and alignment to consider mitigation and greenhouse gas reduction. Our next phase of the project will use interviews to analyze the political, institutional, and other factors affecting this framing.

Keywords: climate change collaboration; regional governance; consensus building

Introduction

Across the United States, groups of administrators and elected officials are launching collaborative efforts to address climate change. The collaborative efforts involve a wide range of government, nongovernment and private stakeholders responding to calls for convening efforts to create change. These efforts have emerged from the growing concerns about greenhouse gas emissions, impacts from climate change, and the increasing number of severe storm events. They have also emerged from a lack of international and national leadership in addressing climate issues.

The roles, approaches and implementation issues associated with collaboration strategies and networks have been widely discussed in the research literature (Forester, 2013; Healey, 1997; Innes & Booher, 2009; Koppenjan, 2008; Margerum, 2011). There has been less analysis of the approaches and deliberations associated with convening collaboration. Some researchers have identified common processes and issues associated with convening (Carlson, 1999; Margerum, 2011), but have not explored in detail the process of gathering diverse stakeholders prior to the formal launch of a collaboration effort. This paper seeks to understand more about the people and processes that led to the convening of climate change collaboratives. In particular, we are interested not just in its emergence in the places where we would expect it to appear, but also in places where the politics and attitudes towards climate policy are less conducive to action.

In the following sections, we summarize the existing literature on convening collaboratives, discuss the methods we are using to investigate this topic, and summarize the findings to date on this project

Research on Convening

Although there has been considerable research on collaboration, there has been relatively little research on the factors that lead to convening collaboratives. Our review of the literature highlights several themes.

Problem Context

Margerum (2011) notes that the Institutional Rational Choice literature identifies several factors hypothesized to affect collaborative formation. First, there are the attributes of the issue such as whether the problems are severe and whether knowledge about the problem is very good. Second, there are attributes of the institution, such as the initial transaction costs, whether existing institutions are effectively addressing the problem, and whether higher level institutions grant local autonomy. Finally, there are attributes of the community, such as the extent of the social capital, diversity of beliefs and potential costs and benefits related to the issue (Ostrom 2005; Leach and Sabatier 2005).

While these factors are clearly important, collaborative governance is only one tool that leaders could use to address these issues. Scott and Thomas (2017) highlight several reasons why leaders in a given situation may pursue collaborative governance, as compared to different strategies or no action. First, collaboration may improve the quality of decision making through additional research, information and expertise. Second, collaboration may create a broad consensus that allows more actors to become involved—thereby increasing validity of efforts. Third, collaboration allows decision makers to span boundaries with other mechanisms are absent. Fourth, it allows participants to bridge hierarchies between for example, local and state government. Fifth, collaboration allows economies of scale when developing policies and strategies with other jurisdictions. Finally, it allows the diversification of issues, such as combining land use, hazards, and community health through cross-cutting themes.

Convening Roles

A second body of literature summarized by Margerum (2011) relates the convening of collaboratives to specific roles of leaders or conveners. Carlson (1999) identifies the roles of sponsors and conveners. Sponsors are individuals or organizations that support the initiation of a group. Conveners help with the process of identifying stakeholders, bringing stakeholders to the table, and often finding resources to support the process (Carlson 1999). Researchers examining the role of inter-agency and boundary spanning efforts cite the communication networks and external relationships of these individuals as being important to build bridges across organizations (Chrislip and Larson 1994; Morse 2010; Crosby and Bryson 2005). In some cases, sponsoring organizations may hire or solicit a third party or neutral party to help convene a collaborative to avoid perceptions of bias (Gray 1989). The Institute for Sustainable Environment (Adams, Crowley, Forinash, & McKay, 2016) reviewed its role in convening resilient regions and identified several key issues. First, they found that a neutral facilitator was an important asset to allowing each party to represent their views. Second, local goals and context were important for determining membership. Third, as goals evolve it is also important to reassess and iterate to determine the most effective strategy and participants.

Convener characteristics

Carlson (1999) outlines some of the common steps in the convening process. First, there is the step of initial assessment where a convener needs to identify the issues, determine what the collaborative wants to accomplish, identify potential stakeholders, identify the convening steps and potential obstacles, and identify potential resource needs. Second, there is the step of identifying and engaging participants. Third, the necessary resources to convene the effort needs to be secured, including resources for training, hiring

support and reaching out to constituencies and the public. Finally, there is the planning and organization of the consensus building process.

Margerum (2011) also summarizes the characteristics of the convener from the literature. One of the most common characteristics is for conveners to appear as unbiased or trusted. Gray (1989) notes that if conveners are suspected of bias “other stakeholders may refuse to participate.” Another characteristic that can be important for convening some groups is the power of the convener, such as the power of holding formal office or the power of the courts to require parties come together. Researchers also cite more nuanced skills, such as a sense of timing, and the ability to identify stakeholders (Carlson 1999; Gray 1989). Gray suggests that they also need to have appreciative skills, which means that “they need to appreciate the potential value of collaborating”(Gray 1989).

Methods

To research this topic we identified over 20 climate change collaboratives across the United States from prior studies and web sites. We selected cases that (1) were initiated and the local or regional scale; (2) involved a cross-section of government and non-government stakeholders; (3) were using terms such as climate collaboratives; and (4) are mature enough to analyze plans, strategies and agreements.

After selecting the cases, we conducted an analysis of the web sites, plans and reports. This analysis examined the:

- Descriptions of the purpose of the collaborative
- Information about the rationale or motivation for creating a climate collaborative
- Major objectives or types of actions

In the second part of this project, the research team will be interviewing individuals from the cases involved in convening the collaborative. In particular, we are focusing on the nature of interaction and “behind the scenes discussions” prior to the public launch of the effort.

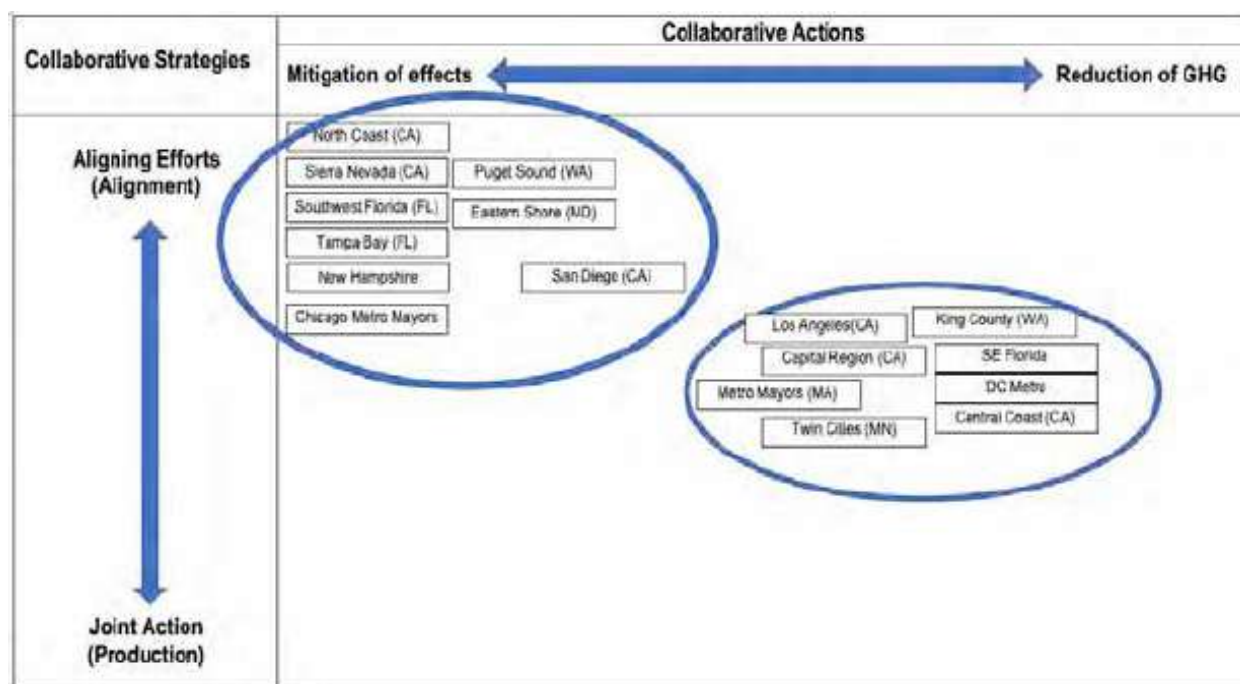

Table 1: Case Studies

State	Collaborative

Findings

Our research will examine both the content of documents and interviews with those involved in the processes to understand the “behind the scenes” discussions and debates. This paper summarizes the findings related to the content analysis. The interviews with participants is currently in progress (see Figure 1)

Figure 1: Preliminary Analysis of Climate Collaborative Cases

Content Analysis Findings: Collaborative Actions

Our review of the content contained in plans, documents and web sites revealed a range of strategies and approaches to address climate impacts. There were two factors that commonly distinguished the strategies from each other: (1) the type of actions being addressed; and (2) the focus of these strategies and efforts.

The type of action spectrum ranged from those focused on mitigating effects to those focused on reducing greenhouse gas emissions. Typical mitigation actions are those that document and quantify risks from flooding and sea level rise on local jurisdictions. For example the Maryland Eastern Shore Climate Adaptation Partnership cited a primary goal as to “be prepared for immediate long-term coastal hazards and able to survive, adapt, and prosper in the face of uncertainty and vulnerability.” Similarly, the North Coast Resource Partnership (California) emphasizes “solutions to failing infrastructure, degraded ecosystems, emissions reduction, and community health and safety”; its document contain few references to climate change or greenhouse gas reductions. A typical greenhouse gas reduction strategy appears in the Massachusetts Metro Mayors Coalition for Climate Preparedness, which advocates for each jurisdiction to pledge to meet measurable and complementary GHG reduction targets.

Most documents we reviewed contained some elements related to the mitigation of effects. In particular, these collaboratives recognized the need to improve data regarding the accuracy of severe events and long term trends, and share strategies for adapting to this change. The motivations for this relate to the goal of improving the quality of outputs and span geographic boundaries (Scott and Thomas 2017). These are

strategic responses with relatively less political risk because they are contributing to efforts that will reduce future risk. From the interviews, we expect that this kind of outcome will resonate across a broader spectrum and therefore be an easier objective to promote in a collaborative process.

Less common among the plans were strategies focused on reducing greenhouse gasses. Regions such as D.C., Boston (Massachusetts), and the Twin Cities (Minnesota) all proposed specific steps to reduce greenhouse gases, which relate more to increasing the legitimacy of a regional approach and diversifying approaches for a more comprehensive approach (Scott and Thomas 2017). These kinds of actions require more significant policy strategies, such as regulation, surcharges, taxes or other measures to achieve outcomes. We expect the discussions relating to these kind of objectives to highlight more political differences and policy debates.

Content Analysis Findings: Collaborative Strategies

A second dimension used to analyze the plans was to examine the extent to which collaborative strategies focused on aligning efforts versus joint action. Aligning efforts refers to tasks of data sharing, mapping, best practices or other information to support individual decision making. Joint action refers to organizations agreeing to work together on policies, programs or decision making. This is a far more challenging level of activity, because it requires organizations to give up and share decision making authority.

An example of aligning efforts comes from Sierra Nevada Climate Adaptation and Mitigation Partnership (California), which focuses on capacity building, education, and convening. Similarly, the Metropolitan Mayor's Caucus (Illinois) focuses on sharing data, strategies and expertise. In contrast, the Central Coast Climate Collaborative (California) emphasizes the engagement of community leaders to "identifying opportunities for regional action" and providing a voice ". The Southeast Florida Regional Climate Change Compact promotes the creation of a regional climate action plan, hosting leadership summits to identify emerging issues, and working together to advocate for state and federal funding.

Implications

The next stage of this research project is to conduct interviews with the principle parties involved in the convening of these collaboration efforts. These interviews will focus on:

- Issues involved in framing collaboration efforts
- Types of tensions involved in convening collaborative efforts
- Common principles that allowed different parties to come together
- Strategies used to bring different parties together
- Actions and efforts that have helped maintain stakeholder involvement

Preliminary Issues to Explore

Based on the content analysis and previous research, we present several preliminary ideas about the relationship between problem context, policy and institutional context, and the collaborative approach. Because we are focusing only on regions where collaborative efforts have emerged, we interested in two main issues: (1) what motivated participants to address climate issues; and (2) what motivated participants to take a collaborative approach.

Motivation to Address Climate Issues

Our preliminary analysis of the cases and other research highlight several factors that appear to motivate a range of leaders and organizations to address climate issues

- **Recent major events:** Several regions have experienced major storms and events that have raised awareness of changing climate conditions. This has created public and political support for taking action—even in places where there may not be strong political consensus about human induced climate change.
- **Science and data needs:** In many regions, changing climate, increasing storms, and concerns about issues such as sea level rise have created questions about outdated information and policies. Local jurisdictions are motivated to work collaboratively to generate more accurate data and analysis; they also recognize the benefits of more consistency in this technical information.
- **State policy:** In states such as California, there is a proliferation of work around climate collaboratives, many of which are motivated by state policy requiring actions to reduce greenhouse gases.
- **Funding:** Many regions recognize that their efforts will require significant resources to address issues such as infrastructure vulnerability or reduction in vehicle miles. Therefore, leaders see the value of organizing local jurisdictions to acquire more funding from state and federal sources.

Motivation to Pursue a Collaborative Approach

Many individual organizations in the US have undertaken climate or resilience plans, but it has been less common for regions to take a collaborative approach. Based on our preliminary analysis and research, we believe there are several factors likely to explain the emergence of a regional collaborative.

- **Convening resources:** foundations and other funders have played a key role in providing the resources, facilitation expertise and funding to convene collaborative efforts. Particularly important has been the role of third party facilitating organizations that provide a neutral convener and facilitator, and add capacity and experience to organizing these efforts.
- **Peer motivation:** Elected officials and administrators interact on a national stage with other jurisdictions and regions. There is a sharing of ideas and competition for innovation that may play an important role in replicating regional collaboration efforts.
- **Interorganizational problem solving:** Many of the issues involved in addressing climate adaptation and greenhouse gas reduction require solutions that cross jurisdictional boundaries. This motivates jurisdictions to reach out to build a regional consensus among more diverse partners.
- **Lack of Political Consensus:** In many regions across the United States, there does not appear to be public or political consensus on climate-related issues. Even where this consensus does not exist, leaders recognize the value of convening a cross section of political perspectives to address impacts or make regions more resilient to events and changing weather patterns.

Table 1: Case Study Document Analysis

Case	Rationale	Objectives
Puget Sound Climate Preparedness Collaborative	<ul style="list-style-type: none"> Climate change risks Prepare for impacts Prepare and build resilience through adaptation strategies 	<ul style="list-style-type: none"> Build a shared understanding...and facilitate access to climate preparedness tools, research, recommendations, and best practices. Empower regional practitioners through peer-to-peer climate preparedness programming Engage and collaborate with local communities [to understand effects on residents and impacts related to disparity] Communicate and improve the accessibility of information. Identify opportunities for joint research Ensure efforts address equity and existing inequities.
King County-Cities Climate Collaboration	<ul style="list-style-type: none"> Action needed Responses can be disjointed Locals must overcome financial, technical, capacity and institutional obstacles 	<ul style="list-style-type: none"> Outreach: Develop, refine, and utilize messaging and tools for climate change. Coordination: Collaborate on adopting consistent standards, benchmarks, strategies. Solutions: Share local success stories, challenges, data and products. Funding and resources: Collaborate to secure grant funding and other shared resource opportunities to support climate related projects and programs.
North Coast Resource Partnership	<ul style="list-style-type: none"> Focused on achieving outcomes on the ground for North Coast communities and watersheds. Embraces a set of integrated goals related to water quality and supply, ecosystem function, economic vitality, collaboration, climate adaptation and energy independence, and the health and safety. 	<ul style="list-style-type: none"> Watershed restoration Wastewater and water infrastructure Emergency water and water resources resiliency
Capital Region Climate Readiness Collaborative	<ul style="list-style-type: none"> ARCCA was formed in early 2012 out of the urgent need to prepare California for the emerging impacts of climate change, including extreme storm events, heat waves, droughts, and sea level rise. Through ARCCA, member regional collaboratives have come together to amplify and solidify their individual efforts, as well as to give a stronger voice to regionalism at the state and federal levels. 	<ul style="list-style-type: none"> develop a common understanding of regional vulnerabilities and strategies. Identify regional priorities, efforts, projects, strategies and research needs. Forum for local and regional leaders. Coordination support. Identify and obtain resources. Unified voice for the Capital Region. Facilitate information and best practice sharing.
Central Coast Climate Collaborative	<ul style="list-style-type: none"> address climate change mitigation and adaptation. involves representatives from local and regional government, business and agriculture, academia, and diverse community groups to share information and best practices, leverage efforts and resources and identify critical issues and needs. 	<ul style="list-style-type: none"> Identify opportunities for regional action and serve as a clearinghouse. Coordinate grants development and funding. Provide a voice to communicate a consistent message. Inform and empower organizations, communities, leaders and public officials . Educate the next generation of climate professionals and identify research needs.

Case	Rationale	Objectives
San Diego Regional Climate Collaborative	•	<ul style="list-style-type: none"> • Areas of focus • Energy efficiency • Coastal resilience • Climate smart water • Climate action planning
Sierra Nevada Climate Adaptation and Mitigation Partnership	<ul style="list-style-type: none"> • bringing together key voices within the region to vet policy solutions • ... engaging urban downstream communities • ... have leaders from major cities invest in the upper watershed. • mechanism for ensuring that the connection between urban population centers and the rural resources they depend on is recognized and valued. 	<ul style="list-style-type: none"> • Educate and engage • Convene Sierra stakeholders • Develop and strengthen connections. • Catalyze on-the-ground climate demonstration projects in the region. • Build stakeholder capacity by providing climate action resources, education, and technical support.
Twin Cities Metropolitan Council: Climate Change and Emissions Team	<ul style="list-style-type: none"> • Climate vulnerability • Climate adaptation • Inform regional strategies about GHG reduction 	<ul style="list-style-type: none"> • Reduce energy consumption for regional wastewater • Increase efficiency of metro transit • Communities choosing to reduce their contributions can: develop more compact land use patterns, reduce auto dependency, improved pedestrian experience, improve urban forestry
Metropolitan Mayors Caucus: Greenest Region Compact	<ul style="list-style-type: none"> • “Improve the environment” • Help each other do better environmental planning 	<ul style="list-style-type: none"> • Consensus environmental strategic plan for the region • Sharing strategies and approaches • Sharing data
New Hampshire Coastal Adaptation Workgroup	<ul style="list-style-type: none"> • Reduce the risk and vulnerability from extreme events and climate change 	<ul style="list-style-type: none"> • Educate • Improve local planning • Support legislation implementation • Assist with strategies to protect shorelines • Improve economic resilience in light of storms and events
Metro Mayors Coalition Climate Preparedness Taskforce	<ul style="list-style-type: none"> • Prepare the region for climate change and to reduce greenhouse gas emissions. 	<ul style="list-style-type: none"> • Enhance Local Alignment and Capacity Building • Mitigate Heat Impacts across the Region • Mitigate Flood Impacts across the Region • Deepen Regional, State, and Federal Coordination on Public and Private Infrastructure Activities
Eastern Shore Climate Adaptation Partnership	<ul style="list-style-type: none"> • As one of the country's most vulnerable landscapes to flooding, erosion, and sea level rise, the Eastern Shore can become a national model for coastal resilience in rural communities. A resilient Eastern Shore will be prepared for immediate and long-term coastal hazards and able to survive, adapt, and prosper in the face of uncertainty and vulnerability. 	<ul style="list-style-type: none"> • 1) Identify and support local champions of climate adaptation; • 2) Engage collaborative partnerships; • 3) Integrate climate adaptation strategies into planning processes and policies ; • 4) Encourage the state to expand support for local adaptation; and • 5) Collectively, move the ESCAP toward a sustainable funding and governance model
Metropolitan Washington Council of Governments: Climate Energy & Environment Policy Committee	<ul style="list-style-type: none"> • supports the Region Forward vision and Climate Change Report goals by providing leadership on climate change, energy, green building, alternative fuels, solid waste and recycling issues, and by supporting area governments as they work together to meet regional goals 	<ul style="list-style-type: none"> • The Action Plan offers a variety of voluntary and flexible options for local jurisdictions to implement, including options that directly address emissions from government operations and options that support community action

Case	Rationale	Objectives
Southeast Florida Regional Climate Change Compact	<ul style="list-style-type: none"> • reduce greenhouse gas emissions and build climate resilience • allow local governments to set the agenda for adaptation, while providing state and federal agencies with access to technical assistance and support 	<ul style="list-style-type: none"> • RCAP is meant to serve as a tool for municipal and county local governments, • includes a broad set of best practices to guide implementation of emission reduction and resilience-building actions that each jurisdiction can implement. • a framework for concerted regional action rather than a set of directives for specific projects or programs at the local level. • Compact objectives include: (1) advocate for funding; (2) create a regional climate action plan; and (3) support a leadership summit
Los Angeles Regional Collaborative	<ul style="list-style-type: none"> • Measures to reduce emissions • Develop a more climate resilient region 	<ul style="list-style-type: none"> • Recognizing the need for cross-jurisdictional collaboration • Serve as a convening body to ensure consistency of performance, • Facilitates the exchange of information.
Tampa Bay Regional Resiliency Coalition [Tampa Bay Regional Planning Council]	<ul style="list-style-type: none"> • Resiliency • Natural hazards • Sea level rise 	<ul style="list-style-type: none"> • Members shall develop a Regional Resiliency Action Plan which shall include strategies for coordinated regional preparation for adaption •
Southwest Florida [Southwest Florida Community Foundation?]	<ul style="list-style-type: none"> • work to build a coalition of residents across key community sectors, including health, education, faith, business and the environment. • “The partnership is an outgrowth of the climate change survey results released in February,” said Eileen Connolly-Keesler, president and CEO of the Community Foundation of Collier County. “The results were very clear. Southwest Florida residents believe now is the time to take action on this issue. Collective action means we are more powerful when we work together – within and across sectors.” • The recent survey also found that attitudes are changing, and the vast majority of Southwest Florida residents are concerned about the changing climate and believe action is necessary to protect the region’s future. 	<ul style="list-style-type: none"> • Engage stakeholders through educational- and awareness-building efforts • Empower community members and leaders to initiate change. • Understanding of the importance of withstanding the impacts of a changing climate, such as sea level rise, increased extreme weather events and flooding. • Build climate literacy ...and adapt to be more resilient . • Protect natural assets: help the community connect the changing climate to Southwest Florida’s treasured environment, including mangroves, wetlands and dunes that protect the shoreline.

Abstract For several years ecological and environmental issues have become a priority in all global political agendas. The transformations due to climate change oblige us to rethink our development model, stimulating us to look for new solutions able to decrease its negative effects. In these fields, urban planning plays an important role equipping itself with innovative tools, technologies and methods, which can contribute to increasing its effectiveness. The paper aims to report the studies that the interdisciplinary research group has conducted in this direction, with particular reference to the new technologies applied to mitigate climate change. In the first part of the paper we will outline a picture of the current regulatory framework, focusing on the Italian situation. In the second part, we will describe the methods and tools used today to acquire data, in order to outline a state of the art that highlights their strengths and weaknesses. Finally, we will describe the main concept of "Precision Environmental Planning", a methodology borrowed from agricultural sciences to analyse the ecological conditions of small portions of the city.

Keywords: climate change, smart city, innovation technologies, sensor network

Climate changes resulting from human activities.

Until a few decades ago climate change was considered the alarmist hypothesis of a small group of scientists, but now the sensitivity of public opinion on these issues has profoundly changed. Well over 90% of scientific publications agree in affirming the close correlation of these phenomena with the increase of CO₂ in the atmosphere, mainly due to the use of fossil fuels. Although the Earth has seen important climatic changes in its long history - just think of the several ice ages - however these changes have occurred on very large timescales, hundreds of thousands of years and they were due to external causes such as the orbital variations of the planet, or extensive volcanic eruptions on a large scale. Today we can observe very rapid climate changes measured in decades. Scientists no longer speak of reducing phenomena, as they did a few decades ago, but of stabilizing current levels. The effects of climate change are visible to everyone: extreme atmospheric phenomena, modified biodiversity, melting glaciers, rising sea levels, desertification of agricultural soils, etc. And health risks are therefore increasing, both because of the pollutants - in the air, in the water and in the soil - and because of the warmer temperatures that favour the hatching of the main vectors of infectious

diseases, such as the *Anopheles mosquito*¹. This situation was generated by many factors, but it is certain that most of them are attributable to the actions of man and above all to the way in which in the last two centuries he has organized his economic model and his lifestyle. The need for a change is therefore evident, a change on the awareness of phenomena, on the knowledge of the causes that determine them and on the identification of actions that can be put in place. From this point of view the city is a primary place to act on, due to the fact that it is the place where the world population is concentrated most and where the main environmental pollution processes take place.

The world climate summits.

The environmental issue was already introduced into the global political debate in the 1970s, but it is in the 1980s that the contours of the problems began to be more defined with the 1987 “Brundtland Report” and the “Intergovernmental Panel on Climate Change” of 1988. Although climate conferences have since taken place regularly, the results in terms of global agreements and commitments made by the signatory nations cannot be considered satisfactory. In the panorama of world climate summits we can mention: the 1992 “World Conference on the Environment and Development” of Rio de Janeiro, where it was outlined a global picture of the planet's problems, both from an environmental and social point of view; the “Kyoto Protocol” of 1997, which became enforceable only in 2004, when they ratified that 55 nations producing 55% of greenhouse gas emissions; the “Paris Climate Conference” (COP21) of 2015, which provides indications regarding the energy transition from fossil fuels to renewable sources through a global action plan ratified by 195 countries. In these international summits, the subscriber states sign agreements that should then be translated into legislative acts. However the list of signatory states often excludes those most responsible for CO2 emissions - such as developing nations or USA. Moreover in many treaties the signing of the commitment is a voluntary act, which is not followed by any coercive action.

The Italian framework.

So what are the concrete measures that are being implemented in this direction? And what is the Italian situation? First of all, it should be emphasized that at the moment there are no legislative instruments that oblige institutions to apply the actions required by documents produced at European level. Nevertheless some documents on climate change are already available. The Ministry for the Environment Sea and Land (MATTM), together with the Euro-Mediterranean Centre on Climate Change (CMCC), produced in 2015 a “National Strategy for adaptation to climate change” (SNAC) whose main objective was « to elaborate a national vision on how to deal with the impacts of climate change, including climatic variations and extreme weather and climate events; to identify a set of actions and guidelines to deal with, so that through the implementation of these actions (or part of them) it will be possible to minimize the risks deriving from climate change, protect the health and well-being and the assets of the population and preserve the natural heritage, maintain or improve the adaptability of the natural, social and economic systems as well as taking advantage of any opportunities that may arise with the new climatic conditions ” (MATTM, 2015: 10). This is a clear

¹ These topics were studied in depth during a series of interdisciplinary lessons on climate change held at the Architecture Department of Pescara (D'dA) in 2019. More on: <http://www.paolofusero.it/didattica/>

document which could be used immediately as a standard to coordinate the actions at the local level, in order to make them mandatory. Unfortunately nowadays it is just a *vademecum* for the most virtuous regions or municipalities. Then we can consider the "Covenant of Mayors for climate and energy", a more stringent document but still not mandatory: here the signatory mayors undertake to face the challenges linked to climate change (Covenant of Mayors, 2008). Specifically, they commit themselves to act concretely:

1. to reduce CO₂ emissions - and possibly other greenhouse gases - in the city by at least 40% by 2030, specifically through energy efficiency improvements and greater use of renewable resources;
2. to increase city's resilience by adapting them to the effects of climate change;
3. to pool visions, results, experience and know-how with other local and regional authorities of the EU and beyond the Union through direct cooperation and peer exchange.

The objective of these actions is to obtain in 2050 decarbonized, resilient, safe and sustainable territories, striving to maintain the promise made during the Paris COP to keep the global temperature below 2 ° C. To date in Europe there are about 7,000 signatories of the pact, more than 3,000 are from Italy. These municipalities have taken the commitment to deal concretely with climate change, implementing what has been called the "Sustainable Energy and Climate Action Plan": a series of guidelines to help the municipalities to put into practice climate strategies, through a process that alternates operational phases with monitoring phase (Bertoldi *et al.*, 2018). We can therefore consider the "Covenant of Mayors for climate and energy" a first document adequately structured, albeit general, to implement mitigation and adaptation actions. However it does not seem to get the desired results. A few years after the first signature, the general level of Italy's commitment to these issues still seems to be highly inadequate. And the causes could be twofold, linked on the one hand to the fact that adhering to the pact is not mandatory - while to obtain concrete results we would need a complete and widespread mobilization throughout the national territory - on the other hand that there are no rewards or sanctions for the work done, repercussions that would be necessary to spur concrete actions, especially in this first start-up phase.

The availability of environmental indicators.

To draw up environmental planning tools such as "Plans for Adaptation to Climate Change", Strategic Environmental Assessment (VAS), Environmental Impact Assessments (VIA) or simply to monitor the environmental conditions of a specific urban environment, the first problem is to find the right environmental data. The indicators can be referred to the atmosphere (air quality, temperature, dryness index, carbon dioxide emissions, acid gases...), to the soil (permeability, presence of chemical products...), to water (surface water and groundwater quality...), to noise, etc. Unfortunately these indicators are not always available and, even when they are, they almost never have the level of definition expected for a punctual investigation. The missing data must be first integrated with specific detectors necessary to complete the information framework, then compared with the national data and with the sub-regional ones - if they exist. Furthermore, the environmental databases are collected on areas that do not necessarily coincide with the project scale, and they are not easily scalable by interpolation operations. To measure the achievement or non-achievement of specific objectives is therefore not always guaranteed. However, we live in an age in which technology

provides us with sophisticated detection tools, great computing and archiving capabilities, which can help us to remedy this problem.

The sensors network.

Our cities are very complex organisms and it's quite difficult to monitor their climate features. Just think of the different landscape that we can find there: historic centres, peri-urban agricultural landscapes, industrial areas, residential areas, etc. It is difficult to outline an accurate picture of the urban scenario using traditional environmental analyses. Take for example the surveys on air quality: authorities in charge collect the data using fixed machines able to detect the different substances present in the air. The costs of these stations are high, as well as the necessary calibration and maintenance operations. Consequently the number of control units in a medium-sized city rarely reaches ten units. In order to have a complete mapping of the territory it is therefore necessary to use sophisticated calculation models that estimate by interpolation the parameters in the missing areas. So, even considering the high capacity of these models, the result of the operation don't give us a degree of precision satisfactory if we want to operate at the neighbourhood scale. Let's think of the air quality index (IQA), and consider all the series of parameters that can have negative effects on human health: nitrogen dioxide, ozone, sulphur dioxide, PM10 particulates and PM2.5. The data may have substantial differences if we measured it close to a major road or in a peri-urban agricultural area, or in a central urban park. The Euro-Mediterranean Centre on Climate Change (CMCC) has recently created the "CLIME" platform, which offers to users the possibility of conducting climate analyses by their own, using the research centre's databases. Although this platform is at the forefront, the maximum data resolution is 12 km², evidently still insufficient for a precision analysis on a specific neighbourhood. Therefore, the control units currently used allow us to have accurate information but at a low resolution. They also have high costs that do not encourage their spread throughout the territory. It is necessary to looking for alternative methodologies for the detection of environmental data, methodologies that allow us to obtain a level of precision of the surveys at least at the neighbourhood scale.

For some time the use of low-cost sensors is spreading. The price of this kind of sensors is around hundreds of euros, and this make suitable to widespread them above the territory. In this way we can considerably increase the number of surveys, obtaining detailed information that, for example, allows to identify with precision the critical points of the city on which to intervene with punctual environmental recovery actions. A further advantage of these low-cost technologies is precisely the minimum value of the investment, which allows a broad diffusion of these sensors even outside the professional scientific context. Greater diffusion of detection systems means more data available in open source mode, but above all it means greater involvement of citizens on environmental issues. Experiences of this kind are already underway, such as community of citizens who monitor the pollution levels of their neighbourhood through their own low-cost equipment. It must be said, for scientific correctness, that not all scholars agree on a systematic use of low-cost sensors, expressing perplexity on the accuracy of the surveys. Among the most discussed devices there are precisely those for measuring air quality. In an article published on Nature, Lewis and Edwards express their scepticism in this regard and urge us to consider them as valid tools exclusively for educational or informative purposes, avoiding using them to guide decisions that may affect the future of the city (Lewis and Edwards, 2016). A similar position is expressed by the Senseable Lab which in 2017 conducted a specific research on this theme, placing low-cost sensors in Nairobi to measure the quantity of pollutants in the air (De Souza *et al.*, 2017). If on the one hand this approach has allowed to obtain relevant evidence - e.g. to identify some causes of pollution, as well as their location and

peak periods - on the other hand the study showed how the data obtained were influenced by external environmental conditions, and therefore low accurate. The problem of the low reliability of low-cost devices gets worse if we consider that they are used to a large extent by non-experts. Therefore, disseminating low-cost sensors on the territory seems not to be the most effective solution at the moment. Just as the opposite strategy does not seem feasible: to invest in a few very high-performance instruments.

Precision Environmental Planning.

The term *Precision Environmental Planning* refers to the possibility of using ICT technologies to carry out surveys on the health status of restricted urban areas (a neighbourhood, a street, or even a single building), in order to identify the “suffering” areas and the actions to rehabilitate them. The contribution of new digital technologies to monitor the environmental performance of a city can be tested through the experimentation of an easy installation low-cost tool composed of:

1. a system of sensors to detect environmental index
2. a hardware/software platform to process data
3. an adequate system to visualize maps.

Compared to what is already present on the market, the environmental data acquired through such a tool have the characteristic of being customizable by the user who will have to carry out the environmental remediation actions. Moreover data are collected through punctual surveys carried out on site and not through interpolation of existing data obtained from monitoring stations kilometres away from the place of analysis.

An "ordinary" cheap sensor system that is easily available on the market can easily measure:

- temperature, humidity, pressure;
- wind direction and speed;
- solar radiation;
- air pollution;
- electromagnetic fields;
- noise;
- pollen / allergens;
- water permeability;
- urban canopy (covering canopy of trees);
- state of health of the vegetation.

The database acquired in this way could be processed through a dedicated hardware/software platform that compares the data collected by our sensors, those collected from the institutional control units and the open data supplied by users on the various existing platforms. Data could be visualized using parametric representation methods in order to provide dynamic maps. The maps could be of two types: a) "measurement" maps, which show the state of affairs for each measured parameter; b) "parametric" maps, in which the measured parameters are related to threshold values, in order to show the risk level of that area. Once we know all the environmental features of the area, we can design actions that depend on the objectives chosen: from the diversion of traffic flows, if the problem is the reduction of atmospheric pollutants in a given neighbourhood; natural shading or reflective materials,

if you want to counter urban heat islands; usage of sound-absorbing materials or micro barriers, if we want to reduce the sources of noise emissions; etc. The project of a tool for environmental monitoring could be developed within a university spin-off. The innovative idea behind the project consists in making a kit of sensors + hardware / software platform for data processing + maps of parametric representation which, in addition to monitoring the "state of health" of an urban environment, indicate the solutions to improve the area from an environmental point of view, showing, through appropriate communication techniques, how the performance of a neighbourhood can be improved through punctual and targeted actions.

Abstract: This paper discusses the necessity to develop approaches to urban and regional planning and management for climate proof and resilient cities that incorporate the perception of risk associated with climate change. Our paper advocates for seeing community resilience as a process of social learning and highlights how risk perception could play a key role in it, which is crucial for envisioning and learning collectively how to produce more just and resilient socio-ecological urban and regional systems. Public risk perception is usually thought to have overriding importance in community resilience as it plays an important role in shaping community preparedness to risks. Our paper argues that in order to play a relevant role in constructing cities that are resilient to climate change, risk perception should be considered as a socio-cultural construction that embodies citizens' experience of risk and its associated tensions between frames of crises and frames of change. Through a case study we show how the use of the categories that describe the tensions between the frames of crisis and change can be decisive in the constitution of resilient cities and spaces of learning. We call these categories cooperative bridges and discuss their role in building community resilience.

Community resilience and risk perception

Risk has become part of our everyday life (Beck, 1986; Douglas, 1992). In a world undergoing a profound metamorphosis (Beck, 2016), dealing with risks associated with climate change involves more than trying to prevent or mitigate them. “Living with risk” requires overcoming the view that risk is a quantifiable and controllable entity, and conceptualizing risk as a complex and fuzzy social construct. For, as underscored by cultural and symbolic approaches to risk, as well as ones that work within Foucauldian or the “risk society” perspectives (Beck, 1992; Giddens 1999), risk and its perception have collective roots, and are not exclusively individual constructs.

The recent years have witnessed the emergence of resilience as a promising conceptual framework for addressing risks associated with processes of urbanization which carry on under climate change. While the notion of resilience has been defined and interpreted in different ways (Costache, 2017), its overarching meaning seems to roughly coincide with a system's ability to prepare and plan for, absorb, recover from, and more successfully adapt to adverse events. As highlighted by Wilkinson (2012) in planning theory and practice resilience helps to analyse cities and regions as complex adaptive systems focusing on the relationships between communities and the environment and the role that cultural and social relations play in the production of local ecology and habitat.

The degree of success which the concept of resilience enjoys within the field of urban planning and management depends on several factors. Its emergence has highlighted the necessity to overcome linear or otherwise static approaches to disaster risk reduction. Such approaches typically rely on engineering solutions to adaptive planning practices that embrace uncertainty, change and complexity, and propose to cope with risks through iterative processes of monitoring, assessment, and scenario making. The emergence of the concept of resilience has also emphasized the role which communities may play in order to strategically reshape unsustainable socio-ecological relationships (Park et al., 2013), and to promote the planning and management of urban adaptation. Overall, resilience has provided a useful conceptual framework for defining concrete and operative actions which are designed to react to the effects of climate change.

Resilience has also been severely criticized for being a depoliticizing concept which allows for the reproduction of unsustainable processes of urbanization (MacKinnon and Derickson, 2012). For example: while self-reliance might be perceived as enabling communities to become better prepared for facing floods, the focus on self-reliance may also allude to governmental disengagement from local intervention, and to government's devolution of responsibilities to community and voluntary groups (Davoudi, 2012). It has also been alleged that what constitutes the resilience of a community is not at all clear, nor is it what helps a community to function well throughout and in the aftermath of disasters, nor again what allows for incorporating their newly acquired knowledge into new practices and strategies such as may foster the survivors' strengths and resilience.

Some studies have adopted a critical approach to resilience. While trying to grasp its positive challenges to planning and management of risks, they have also tried to descry the factors which may affect the resilience of a community. Some of them have foregrounded strong social bonds, local identity, a lively democratic environment and its preparedness to face risks as preconditions for the existence of a resilient community (O'Brien et al., 2014). Opposing the notion of resilience as a community's property, others have argued that community resilience should be conceptualized as a process which consists in coping with a problematic situation (Prati e Pietrantonio, 2006) through which a community is instituted for the sake of identifying, analysing, reflecting, adapting and transforming its frames and practices so as to live in an uncertain world.

Resilience approaches provide communities with the opportunity "to break down silos and barriers, enabling actors to look across sectors and scales" and to rework social power relationships, as the benefits of resilience may not be distributed equally within and between communities (Twigg, and Calderone 2019: p. 6) Overall, community resilience appears to consist in a community's multi-faceted capacity of adapting to multiple long-term future climate change risks, of reducing the impact of climate variability and extremes through preparedness and planning, and of facing—as well as managing—adverse conditions or emergencies within a given social-ecological system.

While relevant resilience and community resilience cannot be taken as a panacea to risks and disasters reductions, Béné et al. (2012) insist that it is necessary to develop such approaches as are oriented to challenging the status quo so as to transform unsustainable socio-ecological systems of relationships. In this case, community resilience is thought of as a space of social learning that activates unexpected interactions between networks of adaptive/transformative capacities (e.g. robustness, redundancy and responsiveness) and local resources. Coping with climate change and its associated risks requires more than resilient communities: it requires utopian, transformative communities. Thus, even upon

embracing a transformative perspective toward community resilience, the latter appears to be just one piece of a more complex picture. Becoming resilient should be conceived as one among the several important processes that a community should pursue in order to cope with risks and disasters. As opposed to mere adaptation, community resilience is here seen as a space for learning how to live in a changing and uncertain environment.

Resilience as a relational process should be opened to different actors and assets of knowledge and change knowledge/power relations. As a result, we should accept that community resilience is not immune from being entrapped and manipulated by existing and unjust knowledge/power relationships. Following this last stream of thinking, this article inquiry into the role of risk perception in shaping community resilience seen as a space of social learning which mobilizes different assets of knowledge including citizens knowledge and risk perceptions with the aim of acting together.

While it is often thought to be crucial to enhancing preparedness to facing risk and therefore to activating community resilience, the role of risk perception remains quite underexplored in such field of policies and research. In this paper, we pay heed to the insight that community resilience is a process, a space of social learning, and explore the role which risk perception plays in its constitution. We ask: can risk perception allow for the production of knowledges which are not only adaptive but also transformative? Can it activate transformative processes of knowledge production into an immanent and constitutive search for practices of place making, which may enable a profound and radical transformation of unsustainable processes of urbanization?

In order to achieve this goal, our research draws on a cultural theoretical framework developed by Mary Douglas (1992) which portrays risk as the result of a social process which depends on the conventions that "govern" a settlement in a given territorial context. In this paper we suggest that, if seen as a receptacle of everyday collective experience, risk perception can contribute to identifying categories of cooperation between different worlds of cognitions and actions, such as enable the emergence of new ecologies of knowledge that are both adaptive and transformative. As such, risk perception could help community resilience as social learning by favoring forms of co-evolution and risk management which lie beyond the horizon of current unsustainable processes of urbanization and managerial perspectives.

Explorations: a cultural perspective on risk perception

Discourses about resilience and risk perception are inescapably interwoven. Within different approaches to resilience, risk perception is often mentioned as a key factor for developing community preparedness and adaptation. However, the meaning of risk perception is just as often glossed over. As a result, it is still hard to envisage how risk perception and community resilience relate to one another. In order to cast some light on this issue, one may choose to follow either of two ways of considering risk perception (Slovic, 2000): an individualistic/psychological approach, or a socio-cultural/collective one. In this paper, we shall consider risk perception as a socio-cultural collective construction which is tightly connected to places and to the formal and informal institutions which surround them.

Cultural approaches do not aim at denying that risk and dangers exist as rational entities and psychological individual constructions. They rather underscore that risk is also socially constructed, and that as such it can be re-constructed, based on an examination of the beliefs and rationalities of

the various actors which participate in its making (Douglas 1992). The use of a psychological or technical-scientific understanding of risk seems insufficient for grasping its complexity as social construct. Furthermore, using risk as an abstract category amounts to severing the ties between community and territory, risk and territory, hazard and politics within socio-political reality (Douglas, 1992). By forgetting that risk is the result of a particular social and economic order, the technical-scientific vision of risk downplays its political and cultural roots. This helps to maintain the existing dominant boundaries between different cognitive structures, to preserve the status quo underlying unsustainable processes of urbanization, and to avoid removing the causes producing risks. Thus construed, risk depoliticizes decision-making processes. By contrast, if approached as a collective experience of risk, in spite of its emotional and irrational features, risk perception incorporates common knowledge, social memory, processes of knowledge production, local populations' fears, as well as their understanding of existing knowledge/power relationships. The perception of risk, observed as a socio-cultural construct which lies at the crossroads between structures of power, private life, and social interaction, embodies a network of meanings that exists and is shaped in the public and social dimension of life through a process of constitution and transformation (Geertz, 1998).

The socio-cultural perspective opens up some possibilities of inquiry into the role that risk perception plays in community resilience, understood as a space of social learning. From a socio-cultural perspective, risk perception embodies the social memory and challenges taken-for-granted categories and dominant points of view. Thus, risk perception may allow to recognize the tension between the frames of crisis and frames of change, through which members of a community develop strategies of risk-management by drawing on their everyday experience of risk.

Inquiry into community resilience as a space of learning: a methodological approach

Taking risk as a socio-cultural construct, we aim to examine which role, if any, risk perception plays in building community resilience, understood as a space of learning in which people produce strategies for coping with risks associated with climate change. To do so, our research focuses on risk perception as an embodiment of frames of crisis and frames of change. In order to grasp these, our research builds upon interviews of citizens and local stakeholders, and upon the participatory observation of formal plans and programs, as well as of self-organized groups of action in which citizens try to manage flood risks. Our objective is to discover shared frames of crisis and change, and to shed light on their underpinning categories by describing tensions and dialectics between crisis and change. Our research is centred upon storytelling: we pay attention to narratives of crisis and of change that people develop in order to express their own experience of risk in relational terms.

Storytelling builds narrative mechanisms by following which individuals are led to self-identify with certain archetypes and to conform to determinate standards of social practice. Each story unfolds in a place, at a given time and within a culture. It also fulfils a certain political purpose: it stages a definite reality for the sake of countering other statements, whether these be implicit or explicit. Each story is thus intended to fulfil definite purposes, to communicate a set of values, spur feelings, and suggest certain behaviours. What remains to be determined is the degree is a story's effectiveness, and people's ability to recount it and to make it memorable. In what follows, we report the results which we obtained in two different contexts where local populations experienced the impacts of extreme

rainfalls. We seek to illustrate local populations' awareness of risks and its correlations with risks and resilience.

We complement the ethnographic research with the analysis of scientific and political reports and documents as well as newspaper articles and other materials available through social media. Interview and research materials are collected by using the factors that characterize cultural risk perception (Renn and Rohrman, 2011). The questions which were asked throughout our interviews concern five topics: collective and individual heuristics that individuals and groups employ when forming judgments about risks; cognitive and affective factors that influence their perception; the social and political framework in which individuals and groups operate; the cultural context in which socio-ecological relationships unfold. Through a qualitative analysis of the content of the interviews, we interpret the interviews and seek to identify local frames of crisis and of change, as well as the tensions between these.

Coping with floods in a semi-arid region

During the last ten years, several small and medium towns, urban and rural areas in Apulia—a semi-arid region in Southern Italy—have experienced unusual pluvial flooding events determined by the extreme rainfalls caused by climate change. In urban areas pluvial flooding is generated by overland flows before the runoff enters any watercourse or sewer. In rural areas flooding is caused by the inappropriateness of hydraulic systems and profound transformations of the territory which were carried out in order to transform humid lands into agricultural or urbanized ones. A series of events including hurricanes, haling, rainfalls, flash floods have been occurring since the early 2000's in several places in the Region . These events have been consistently followed by long periods of draught characterized by high levels of humidity, usually above the seasonal mean value. As highlighted in several studies (see i.e Boenzi et al. 2007) the increased frequency of rainfalls has been accompanied by a decrease in the number of rainfalls during the year. The reduction of daily rainfall is particularly problematic for the recharge of the local groundwater system. Hurricanes are a result of the rapid tropicalization of the Mediterranean sea.

The occurrence of extreme rainfalls, an unusual event in a semi-arid region, has been catastrophic for agriculture and for the built environment in urban settlements. In urban areas, local administrations have typically reacted to such events by carrying out adjustments of urban drainage systems to the new meteorological regime, for the sake of reducing any future risk of flood. Until a couple of years ago, the resilience of local communities has not been a relevant topic for policy-oriented discussions on climate change in Apulia. More recently, resilience has come to be associated with a scientific-technical intervention aimed at reducing hydrogeological instability.

Ginosa

Ginosa is a small town with around 22.500 inhabitants. It is a rural town in the middle of the Western Arco Ionico, a territory which underwent reclamation works at the outset of the 1900's in order to provide poor people with agricultural lands of which they would themselves be owners. The morphological elements characterizing Ginosa are ravines, deep erosive valleys of karstic origin carved by ephemeral streams. The town is indeed delimited by the two streams of Gravinella e Lagnone Tondo. Its oldest settlement was built upon the slopes of the ravine in which the Gravinella 'flows'. Therefore, the settlement is highly vulnerable. Due to the geological and morphological

configuration of the territory, and to the ephemeral nature of its water regimes, the ravines are naturally subject to hydrogeological instability, when certain thresholds of intensity and rainfall duration are exceeded. The existence of cave settlements in artificial or natural cavities further increases the degree of vulnerability of the ravine and of the town which was built upon it. The greater part of these cavities lie in a state of abandonment and their stability is precarious at best. That is both due to the lack of human maintenance, and to the natural degradation of the mass of rocks which is caused by aggressive humidity, by meteorological agents, and by the presence of fractures, some of which facilitate the infiltration of water. The presence of man-made cavities was a matter of common knowledge, as some of these were owned by local citizens themselves, and entrances thereto were visible from the ravine's riverbed. Still, in spite of the territory's great geological complexity, no study was carried out until 2013 in order to map the exact distribution and the degree of stability of the cavities which lie beneath the town's centre, which rests upon a vast surface of calcarenitic rocks.

In 2013, extreme rainfalls (in October and December) produced an unexpected flow of water in the Gravinella that caused 4 victims and swept away any object or people on its way and the fall of a part of the old city which was built on the ravine's slope. After these floods, which also damaged hectares of vineyards, the public was interdicted from accessing the urban areas surrounding the collapsed buildings in the old town. In order to protect the local population from future pluvial floods, hydraulic and infrastructural works were carried out, and some were designed in order to draw new funds. Some of the works that were proposed in order to restore the area, as well as to mitigate the future risk of further hydrogeological instability, included the consolidation of the slopes of the ravine characterized by the high density of cavities, the development of a monitoring system of the microclimatic conditions of hypogeum, the demolition of ruins and collapsed buildings, and the elimination of all relevant interactions between liquids and rock mass.

A story of flood: interpreting the research materials

As a first step, we analyse the content (fig. 3) of the interviews. By compounding the interviews with other research materials, we seek to reconstruct the story of flood as it took shape through the interplay between the local frame of crisis and frame of change.

Frame of crisis

Citizens perceive climate change as a series of adverse situations ranging from heat waves to extreme rainfalls.

"There is a huge problem: the tropicalization of the climate. I have been fishing in the Galaso river since I was a little child but it had never happened to me to find orange or yellow crabs."

"In recent years events have become extreme: hailstorms, air horns, more frequent snowfalls. Citizens are not very aware of this, perhaps farmers a little more, but we have now adapted."

"After 2013, when it rains people does not feel longer to be safe...they are afraid."

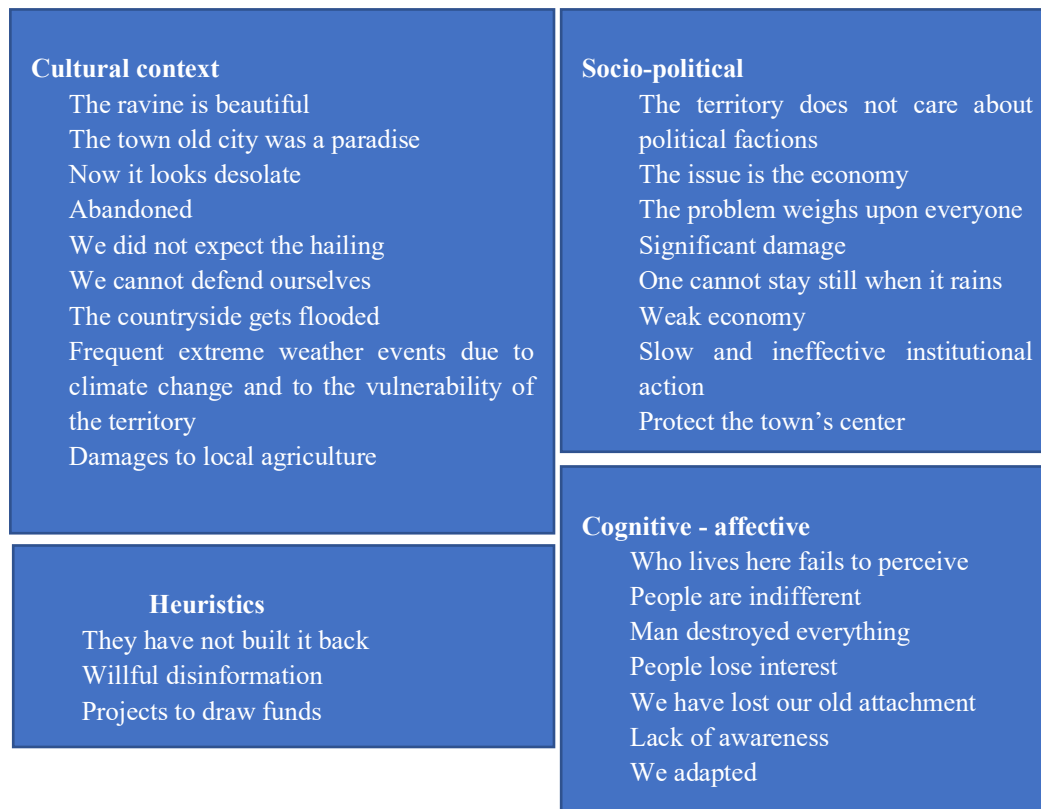

Figure 3: Field work: the analysis of content of the interviews

Awareness about the nature and effects of climate change diminishes with the age of interviewed as well as the interested in the risks. When interviewed, elderly citizens replied:

“We do not know much about climate change.”

or limited themselves to remarking that:

“It is sad when it rains. When the sun shines you feel better.”

By contrast, adults are deeply aware and afraid of the increased frequency of extreme events following climate change because such events will increase the risk that disasters such as the ones that occurred in 2013 will reoccur. The most recently built areas of Ginosa seem to be safer than the most degraded parts of the old city and than the rural areas where floods are quite recurrent. The local population does not feel responsible for the disasters caused by climate change. They rather identify local cultural and socio-political factors as the source of risks associated with disasters.

“Climate change does not depend on us, we cannot do anything to oppose the occurring of extreme events”; “humans are at the base of disasters”.

The origins of risk also tend to be identified with the self-interested behavior of citizens, which threatens the existence of a political community capable of acting and envisioning its future, and in the lack of appropriate public information:

“The local community is divided: the majority are not interested in dealing with the effects of climate change. The ones who are concerned about climate change would like to be heard by public administrators, but exercise no influence whatsoever on local policy making and politics”.

“I have lived abroad for several years so I can see what local inhabitants are unable to see or perceive. If you go and visit the old town you can understand the origin of the problems...Here is the reign of indifference”.

“Human beings have destroyed everything! Nobody takes care of the land and young people leave...”.

“Citizens’ indifference also depends upon the fact that the local administration has not involved and informed the local community so as to explain what happened in 2013. After the disaster, it commissioned several technical-scientific studies in order to mitigate the hydrogeological risks and protect the local population. After the collapse of buildings in via Matrice the administration did not explain to the local population what had occurred and why. It assured citizens that public works would commence immediately in order to restore the damaged areas...Misinformation is planned...Nothing has been rebuilt until now.”

Five years after the collapse of via Matrice, the following evictions of local inhabitants, and the ban from accessing two portions of the historical center have brought about a ghostly silence and fostered the abandonment of this area. And even when citizens’ attachment to these places seems to emerge, it is not accompanied by attachment to the rural area.

“Last Sunday a hailstorm occurred. The countryside is now flooded, it’s raining this morning. Young people do not care! Here the problem is the economy. People become disinterested, they no longer feel the same attachment that they had in the past and they move away.

The countryside is completely abandoned. Agriculture suffers from extensive damage from climate change, but then the problem weighs upon everyone”.

Detachment is accentuated by a non-connected and non-connective community that feels deprived of shared perspectives, values, and vitality. Furthermore, grassroots participation in the preparation of actions for the mitigation of hydraulic instability was very low, as the owners of the collapsed houses and the evicted were the only citizens who took part in these projects. As a result, the institutional and technical-scientific world had limited chances, if any, of communicating with the local community.

Frame of change

This frame involves the projecting of crucial operations, including: the mitigation of risks of hydrogeological instability, the attempt to contrast of abandonment by regenerating the old town, the protection of rural areas and a new approach to the local economy.

The mitigation of risk has been dealt with by scientific and policy experts. Geological and hydraulic technical-scientific studies that aim at consolidating the slope of the ravine (Rapporto CNR IRPI, 2014; Spilotro, 2016) have been produced and conferences have been organized in order to debate issue concerning “Territorial fragility: from hazard to risk”.

The studies which have heretofore been carried out have cast light on how ongoing changes in the climate and their effects, including floods, disrupt the delicate territorial equilibrium and lay bare the fragility of the territory, which is both due to its hydro-geomorphic characteristic and to intense anthropization. These studies suggest that a one-sided vision is insufficient. Acting on the territory without considering the local impact of climate change would constitute a failure to analyse the potential feedbacks that ensue from the increased frequency of extreme weather events. Conversely, focusing solely on the global dimension of climate change would result in an immobilization and the removal of responsibility of institutions and citizens. It is necessary to develop an integrated vision of climate and territory since the effects which climate change will yield at the local level will increasingly challenge populations to learn how to produce resilient socio-ecological systems and to protect dwelled environments. Ignorance, or poor knowledge of the complexities and weaknesses of a territory will make for its population’s incapacity to manage the risks associated with extreme weather events.

While studies and expert reports underscore the necessity of mitigating future risks, popular voices in Ginosa suggest that the rebirth of the local community should set off with the mobilization of the local memory which is embedded in the old town and in the latter’s ties to the ravine, as well as a renewed interest in agriculture and economic innovation. The current state of abandonment in which the old town lies well reflects the opacity of its inhabitants’ vision of the future of Ginosa and of its territory.

“When the old town was all inhabited, living here felt like being in paradise. Nowadays we are in a desolate landscape which is abandoned to itself. I call on our politicians to protect our historical centre by preparing and submitting projects for funding to regenerate it.”

A key step toward contrasting urban decay and abandonment consists in contrasting the flooding of rural areas. Thus, a renewed interest in local agriculture should be promoted.

“We did not expect the hailstorm, we cannot defend ourselves from extreme rainfalls but we can try to understand that everything is connected here: if the rural areas are also flooded we cannot survive as butchers, fruit vendors, or bakers.”

In order to reach these goals, a new idea of Ginosa as a political community should emerge out of the prevailing indifference.

Tensions

Comparing the local frame of crisis and frame of change related to the disasters provoked by floods occurred in 2013 and thereafter leads to highlight certain key tensions. The paralysis which characterizes Ginosa is a result of an ongoing transformation in the processes of local urbanization. The occurrence of this change has not been accompanied by the flourishing of any debate about it. On the other hand, it is underpinned by significant changes economic relations. For while the depopulation of old towns in Apulia carries on side by side with the erosion of local agricultural economies, the coastal areas of those same municipalities become destinations for tourism. Citizens of Ginosa are aware of these transformations, and perceive the risks of flood which are associated with climate change to have facilitated them. Indeed, the abandonment of Ginosa is itself a sign of the transformation affecting the relationships between the territory and the local population and, at the same time, constitutes a dynamic which increases the risk of floods. In a municipality where people forget their relationships to the historical places citizens feel helpless and incapable of taking action for the sake of solving the problem. In a territory where agriculture has traditionally constituted the focus of territorial development and the fulcrum of natural ecological dynamics, floods facilitate the structural abandonment of rural areas. The protection of the environment is perceived as something out of people control. Surely, the ravine should not be seen as a threat to, but a symbol of the dynamic combination of water, karst landscape and human settlements. It is necessary to work on issues which concern how to dwell in the territory in a responsible and synergetic—as opposed to predatory—way, aimed at preserving and recreating a connection with places.

Citizens' ideas of adaptation to climate change and rainfalls in Ginosa speak of a widespread resignation to the impossibility of constructing a different way of inhabiting the local territory. No committee or group of citizens has been set up in order to address the risk of floods, even in spite of the fact that climate change permeates their own daily life. In short, no collective strategy such as might target the flood problem has heretofore emerged. That means that, in Ginosa, it is not possible to speak of community resilience as a form of adaptation. Neither is it possible to speak of community resilience, if we consider resilience as a property, or if we consider it as a process without dealing with the tension among frames. Were we to approach resilience in such terms, floods would merely be considered as events to be controlled and mitigated through technical solutions.

Cooperative Bridges

In the case of Ginosa, the tensions between the two frames of crisis and of change can be described through some categories. Some of them are already known, including change of governance, change of knowledge/power production, and so on and so forth. However, in dissecting risk perception as a tension between frames of crisis and frames of change, we have seen some specific and crucial conceptual categories emerge, which are key for opening up spaces of social learning concerning floods. These are: re-appropriation of place, knowledge (re-)generation, and environmental citizenship.

We call these categories cooperative bridges. Each of them embodies the complexity of the meanings involved in the experience of risk of the local population and reflects a category of connection between thinking and action, which is necessary for activating the local community with respect to issues associated with the risks of floods. We call these categories cooperative bridges because they are bridges between knowledge and action, citizens and local institutions, and community knowledge and scientific and technical knowledge.

The re-appropriation of a place is a way of rethinking the life cycle of a city and of reinserting places within it (Cellamare & Cognetti, 2014). As a place-based perspective, it helps to understand the capacity of communities to withstand or adapt to change or, alternatively, to change its own ways of living. It includes multiple forms of urban life which are based on self-organization as well as a necessary organizational change, which is meant for adapting the structure of institutional governance to risks and disasters (Carson, 2011). This is not only a problem concerning the inclusion or exclusion of actors in a governance process but implies a rethinking of the very idea of the organization of a small community, which is necessary for triggering the latter's creativity, improving or changing unsustainable socio-ecological relations, and promoting social and environmental justice. From the perspective of re-appropriation, knowledge (re-)generation is key to community resilience. It involves the integration and co-production of knowledge, as a way of challenging and redrawing well-established boundaries which delimitate different assets of knowledge, and lie at the base of risks associated with climate change. Re-generating knowledge aims at valorizing existing cognitive, environmental, organizational and relational resources, and above all, at reconnecting them by overcoming silo approaches. Finally, environmental citizenship is a first step to rewrite in a more responsible way the stories of places.

Conclusions

Cooperative bridges are key to developing a place-based perspective to resilience (Mehmood, 2016): they enlarge the horizons of understanding of—and of action upon—risks, and expand the opportunities for defining place-based efficient actions (Frisullo, 2015) so as to nurture social learning. If community resilience is about local communities learning to adapt and transform under change, guidelines and procedures to facilitate the social learning processes are necessary. And yet, it is difficult to see if these processes can foster the learning of categories of cognition and of action that generate practices of management of risks which may transform unsustainable socio-ecological relationships.

One month after we terminated our fieldwork, the Apulia Regional Government funded the project aimed at mitigating the risk of hydrogeological instability and the reconstruction of via Matrice in the municipality of Ginosa. This event suggests that—when mobilized—risk perception can propel local administration to acting for the sake of coping with climate change. At the same time, by ignoring risk perception as embodying cooperative bridges, the mitigation actions built new obstacles to the opening of spaces of social learning and to the emergence of a resilient community. From our point of view, the opening of such spaces is crucial for opposing the political desertification and the abandonment of small, rural towns. If considered as socio-cultural constructs, cooperative bridges and risk perception may offer a key to avoiding the depoliticization of risk-mitigation (Douglas, 1992) in Ginosa and to activating processes of planning and management such as may trigger community resilience. Using the cooperative bridges which are embodied in risk perception can help to manage risks in resilient cities by considering issues of democracy of places, social justice and environmental protection as a compass for community learning and resilience.

Abstract: For the last fifteen years the Italian government has been building the Experimental Electromechanical Module floodgates (MOSE) in the inlets from the Adriatic Sea to the Venetian Lagoon, to protect the historic city of Venice from flooding events. At the same time MOSE represents just one technological solution for the climate resiliency of Venice and its surrounding islands--in the face of additional varied and complex socio-environmental threats. Broader threats include subsidence, infrastructure degradation, the pressures of mass tourism, and a decline in the resident population on the islands of the lagoon. MOSE's construction site, a 180,000 square meter concrete platform, at the Malamocco inlet represents a uniquely massive space to respond to these forces. A team of Massachusetts Institute of Technology students use site and environmental systems planning approaches to suggest three hypothetical visions for this site that serve the residents of Pellestrina and the larger socio-economic development for the lagoon islands, while ensuring that these options bolster residents' ability to respond to urban disaster risk. The design concepts explore a range of demolition and reuse possibilities for the site in their three explorations: deconstruction and sustainable fishing, contextual tourism that can shift to disaster resilience, and a potential reuse of the most elevated area on Pellestrina to form a new village in the face of sea level rise.

Keywords: Climate Change, Resiliency, Infrastructure, Venice

Introduction

The most devastating flooding of Venice, when nearly two meters of water inundated the city, occurred in November, 1966. Since then, the Italian State has been focusing on planning initiatives to protect urban areas from high waters, safeguard the coastal islands from storm events, restore lagoon ecosystems, and plan for socio-economic development on the islands within the 550 km² area that makes up the lagoon area. Pellestrina, an island of fishing and agricultural villages spread along the 11 km coastline, has always acted as part of the

larger infrastructure protecting Venice and the Lagoon, but administrative attention has rarely focused on a comprehensive approach to sustaining the economy, culture and social cohesion of Pellestrina itself. As the construction of Venice's Experimental Electromechanical Module floodgates (MOSE) nears completion, the project leaves behind a gargantuan construction site on the northern shores of Pellestrina Island--larger than Piazza San Marco (Figure 1).

Figure 1: Size Comparison Piazza San Marco vs. Site

In the spring of 2019, on behalf of their client the Consortio Venezia Nuova (CVN) students in the Massachusetts Institute of Technology (MIT)'s Department of Urban Studies and Planning (DUSP) site planning course explored potential futures for the former construction site that increase the vitality of Pellestrina itself. Students analyzed the site, Pellestrina and the larger Veneto context using a multifaceted approach, integrating a study of topography, hydrology, sea level projections, mobility and infrastructure networks, land use, and settlement patterns; as well as spatial and temporal relationships between individual site factors and local and regional contexts. The MIT team combined the traditional site planning approach along with interdisciplinary learnings from oceanography, engineering and urban design to formulate strategies for the site. These strategies for coastal resilience included awareness of physical and cultural infrastructures, housing and economic development, and flood responsive landscapes. The strategies respond to an uncertain projections of sea level rise and climate adaptation, and aim to achieve long-term economic and social sustainability by more flexibly responding to the diverse demands of Pellestrina, as well as the Venice municipality as a whole. Students formulated three hypothetical site plans for the land remaining at the north end of Pellestrina Island following the upcoming completion of the MOSE project, after exploring two central questions:

As the MOSE project nears 90% completion, the Venice Water Authority and Consorzio Venezia Nuova is investigating how this land can best serve the residents of Pellestrina and the larger socio-economic development for the lagoon islands. How can this land reclamation and infrastructure be reimagined?

Ultimately the students developed three hypothetical design options:

1. *The Future of Fishing*: REPURPOSE MOSE's infrastructure for a modern-day local economy based on new and traditional fishing technologies. Utilizes the uncertainty in sea level rise as an opportunity for adaptive aquaculture management.
2. *Resilience in Reuse*: BUILD new form of coastal defense that builds on the site's historic assets, bringing life to the MOSE platform and preparing Pellestrina for a new era.
3. *Murazzi 2.0*: TRANSFORM divisive infrastructure into a connection. This project proposes design elements that connect the villages of Pellestrina to their history, to the Adriatic and to a site of new opportunity.

Course Context

Since its first offering in 1935 MIT's site planning course has been taught by only a handful of instructors including Kevin Lynch, Donald Appleyard, Tunney Lee and Gary Hack. In 1956 Kevin Lynch took what was seen as a mainstream course in site engineering and turned it into a whole-system approach to planning the built and natural environments. Under the direction of Eran Ben-Joseph, the class began incorporating hands-on, client-based projects dealing with a variety of sites. Today, Mary Anne Ocampo brings her experience as a practicing urban designer to continue the whole-systems approach pioneered by Lynch and in this course was able to build upon longstanding relations between MIT, CVN and IUAV (Università Iuav di Venezia). MIT researchers have been involved in the evaluation of multiple steps of MOSE engineering and construction since as early as 1997 (Merali, 2002; Munaretto et al., 2012).

Study Area and Site Context

Figure 2: Site Context

Pellestrina and her northern neighbor, Lido, are two crucial barrier islands that separate the Venetian Lagoon from the Adriatic Sea. Pellestrina stretches for nearly 12 kilometers, but is often less than 500 meters wide and in some places as narrow as 50 meters. The island's population of approximately 4,000 people living in 4

villages has declined in recent years due to the lack of affordable housing and employment on the island. With rising environmental hazards, the closing of a major shipyard, and fishing regulations, the island has suffered economically and environmentally for the last decade. An additional impediment is the island's remoteness: the island is removed from the historical city center of Venice and administratively from the adjacent city of Chioggia. Access to Venice and larger employers in Mestre are only possible with arduous travel. Travel to Venice requires transferring from bus to vaporetto (water taxi) on a trip that takes over an hour and up to 2 hours depending on your location

For over one thousand years the site and the island of Pellestrina have served as a vital barrier between the historical city of Venice and the Adriatic Sea. Since its first description in the historical record, Pellestrina has been a place formed by the struggle between the destructive forces of the ocean and human resistance, where storm surge has ripped away earthen dikes, beaches and landfill and the people of the Venetian lagoon have rebuilt even stronger defenses (Goy, 1985).

The worst flooding in Venice's history struck the lagoon in 1966, with some of the greatest devastation occurring on Pellestrina. A combination of sirocco winds, swollen rivers and a low pressure storm brought a devastating high tide, "acqua grande" to Venice on November 4. The storm ripped away the boulders of the murazzi and water levels in the lagoon reached record highs, with a peak at 194 centimeters above the tidal gauge at Punta della Salute. The tides would stay at over 100cm for nearly 24 hours, inundating homes, churches and storefronts. On Pellestrina 4000 people—nearly the entire population of the island—evacuated, as the storm flooded homes, salinized the soil and caused an estimated of 40 billion lira in damage across the lagoon (Gugliuzzo, 2018).

In response the flood of 1966, the Italian government established special legislation for the safeguarding of the city of Venice and the Venetian Lagoon in 1973, which recognized the idea of mobile barriers. A second law in 1984 created a national committee, the Comitato and entrusted design and implementation of to the Consorzio Venezia Nuova (CVN), a concession of the national Ministry of Infrastructure. Multiple designs for the MOSE were considered, but a system of mobile floodgates was finally selected because of their buoyancy, and requirements that the floodgates be invisible when not in use.(Munaretto et al., 2012)

Figure 3: Site

The construction of the MOSE system required a new site near the inlets which occurred in 2005 Initial construction focused on a sheetpile outline of the future platform, which was filled with dredged material, which was then covered with cement and reinforced by jet grouting to stabilize the soil 20 meters below sea level. Here the four-story tall 4200 ton cascons rose at a busy worksite, next to a worker's camp constructed for the large number workers needed for the project. Eventually a "syncrolyft" was constructed on the end of the island that had been a semi-public beach and woodland area, with part that some locals used as a dumping ground. Upon the completion of the construction of the cascons, the MOSE platform has also been used as a storage and staging area for the MOSE floodgates. With the final floodgate installed, this massive piece of infrastructure holds remnants of all of the phases of construction that happened there—anchors, heavy equipment, shade tents and hundreds of concrete piles.

2019 marks the completion of the MOSE floodgate installation and the end of use for the MOSE platform. The current post-construction plan for the site, referred to informally as the "Europe Plan" calls for the deconstruction of the platform in order to restore and reconstitute protected habitats affected by the construction. The plan requires that "For each of the community habitats and species affected by construction activities, one or more compensatory measures have been developed, with a precautionary approach, aimed at the reconstitution or redevelopment of areas that are increasingly larger than those temporarily and permanently occupied by the work." (*Piano delle misure*, 2016)

This plan includes a number of measures for environmental restoration, including seagrass transplantation, rebuilding the barene and reconstructing dunes. At the MOSE site itself the platform is to be removed and replaced with a beach at an estimated cost of € 3,520,000. The worker camp and adjacent area is to be reforested and historical structures renovated as part of a nature park, at an estimated cost of €5,500,000. The MOSE site is situated in a unique position, where both historic military and hydrological defenses sit side by side. These protective structures are located at the entrances to the Venetian Lagoon, and have acted as the first line of defense against man-made and natural threats. (*Piano delle misure*, 2016)

Site Analysis

Environmental and Military Protections

The Venetian Lagoon, which houses Pellestrina Island, is a man-made ecosystem in constant need of protection against natural forces. What began as a shallow estuary formed by natural processes transformed into a haven for communities fleeing from the aftermath of the collapse of the Roman Empire, where the preservation of the lagoon environment became an essential part of the security of the Venetian republic and naval power. The Serenissima would ultimately divert major rivers over the course of centuries to prevent the sedimentation of the lagoon.(Bondesan and Furlanetto, 2012; Tosi et al., 2009)

Throughout the history of the Serenissima, Venetian authorities sought to enhance the defense capabilities of the historical city by fortifying the edges of the protective lagoon. In places like Pellestrina, fortification sometimes included military facilities along lagoon entrances. Hydrological structures--dams, dykes and seawalls--often served a similar military purpose--to maintain the protective characteristics of the shallow Venetian Lagoon. The need to fortify the edges of the lagoon from the encroachment of the sea was a reoccurring theme over the history of Venice. Ultimately flooding led Venetian authorities to embark on a 40 year construction project beginning in 1741 to build 20km long seawall of Istrian stone across Chioggia, Pellestrina and Lido. (Charlier et al., 2005; Goy, 1985)

The Flood of 1966 spurred two special laws for Venice, which resulted in the selection and construction of mobile flood barriers, MOSE, as a protective measure at the entrances to the Venetian Lagoon. Beyond the floodgates, CVN has engaged in restoration and climate adaptation projects within the lagoon itself, including protecting and reconstructing the environment of the lagoon--replanting seagrass, rebuilding the partially submerged islands called *barene* and restoring Adriatic dune structures.

Ranging between 2.5 and 3 meters above sea level, the MOSE platform is one of the highest elevated sites on Pellestrina island, where much of the land is only between 1 and 2 meters above sea level, though is protected by the 5.2m high murazzi wall. A wide range of ecological habitats can be found throughout Pellestrina Island. In general, there are four types of environments: woodlands, littorals, meadows, and areas with sparse amounts of flora. The northern and southernmost edges of the island contain mature woodland and shrub ecosystems. The interior of the island is primarily comprised of agricultural and urban managed landscapes. Meanwhile, the Adriatic Sea-facing edge of Pellestrina is populated by growing dunes, and vegetation to support dune formation. ("Altimetria, Carta Tecnica Regionale del Veneto," n.d.; "Microrilievo della pianura del Veneto," 2015)

Demographics, Culture, and Economy

An analysis of the demographics reveals similar trends across the lagoon: an older generation and declining population due to age and emigration. Since 2014, the city has lost approximately 6% of its residents. Pellestrina's population is also declining, despite regular births and new immigrants to the island. The lives of the residents of Pellestrina are closely tied to other islands in the lagoon and the mainland. Pellestrina residents are dependent on the lagoon for jobs and daily services. Venice's population is declining ("Popolazione," 2017; "Stradario e Popolazione," 2010).

The culture and history in the Venice city center is the most popular tourist attraction within the lagoon. Most tourists come to see Venice's unique art and architecture. Tourists also frequent the historic villages on Murano, Burano, Torcello, and Chioggia which offer crafts, shops, and restaurants. Lido and Sottomarina feature popular beaches that attract tourists. Pellestrina does not maximize the potential economic benefits from tourism, and

there lacks a strong tourism anchor to promote on the island. The nature reserve Ca'Roman is the main attraction on Pellestrina, along with the free beaches and vision of a “real” lagoon community. Pellestrina’s economic history is rooted in agriculture and fishing. However, the sector is declining and local residents are dependent on other areas within the lagoon for jobs and daily services. Most of the surveyed permanent residents of Pellestrina responded that they: were in favor of developing Pellestrina for tourism, believe the island could benefit from tourism, are concerned about changes to daily life, damages to buildings and environment, and trash (“Pellestrina Summer School Survey of Island Residents,” 2018)

Venice is a part of a larger regional economy, the Greater Veneto Region, which it is connected to by road and rail. The region’s public transportation company, Azienda del Consorzio Trasporti Veneziano (ACTV), provides an extensive transportation network by land (buses and trams) and sea (frequent small passenger ferries known as vaporetti). Additionally, international airports connect the Greater Veneto Region to international travelers. ACTV’s transportation system allows access to the barrier islands of Pellestrina, Chioggia, and Lido. Vaporetti flow from Venice to outlying islands and south, via a bus connection, to Chioggia. Flows of water traffic within the lagoon also include pcean-going passenger ships use the Lido inlet, ommercial traffic destined for Porto Marghera through the Malamocco inlet as well as local traffic is comprised of smaller personal boats and fishing craft. The city of Chioggia has a fishing fleet of 221 fishing vessels which use the Chioggia inlet to travel between the lagoon and the Adriatic.

Climate Change Risk leading to 2100

This study used dramatic sea level rise scenarios of 110cm and 160cm for 2100 to guide site designs. The study sought to look further than 2050 given that infrastructure has a long useful life beyond 30 years from today. Global sea level rise projections, which have a wide range of uncertainty, cannot be applied directly to the Mediterranean Sea for several reasons (Centro Euro-Mediterraneo sui Cambiamenti Climatici, 2017; Galassi and Spada, 2014; Hoegh-Guldberg et al., n.d.; Marcos and Tsimplis, 2008): A) Global models do not accurately take into account the Mediterranean Sea. The models’ grid scales are too large to capture the Strait of Gibraltar, the narrow waterway through which the Mediterranean is connected to the Atlantic Ocean. The vertical resolutions of the models also do not capture the shallow Adriatic Sea. B) Globally, thermal expansion of water from increases in temperature is the major contributor to rising seas. However, in the relatively contained Mediterranean, salinity is another key driver to changes in sea levels . Greater evaporation from warmer temperatures and decreases in precipitation lead to increases in salinity of the water body. Greater salinity results in more dense water, which may decrease water levels. The density of the water in the Mediterranean also impacts the outflow and inflow from the Atlantic through the Strait of Gibraltar.

Sea level rise projections are relative to mean sea level. However, note that the datum reference points from which sea level is measured differ for bathymetry and altimetry: Bathymetry tidal heights refer to the tide gauge at Punta della Salute as the 0 reference point. Punta della Salute is currently 23.5cm above the altimetric datum due to subsidence and other factors. Currently, the actual mean sea level is 30cm higher relative to this reference point. Meanwhile, altimetry refers to the IGM 1942 datum, the official datum of the Italian national altimetric network (Città di Venezia, n.d.). Topographers use this datum as the 0 reference point and refer to it as “mean sea level.” It is 23.5 cm above the Punta della Salute reference point. Currently, the actual mean sea level is 6.5 cm higher relative to this reference point.

Given uncertainty in projections, the MIT team sought to plan for a range of possible future scenarios and developed designs to be adaptable. Good planning and design needs to incorporate a myriad of future conditions rather than be limited by a single future scenario amidst uncertainty in projections or assume that the future will be the same as the past given a changing climate.

Figure 4: Sea Level Rise Under 110 & 160cm Scenario

Figure 5: Tidal Ranges under 110cm and 160cm Scenarios

Significant portions of Pellestrina will be permanently inundated from the lagoon side under the 110cm scenario. Most of Pellestrina will be permanently inundated under the 160cm scenario. Flooding will be exacerbated with acqua alta events as study flood maps do not take into account storm surge associated with acqua alta events. A team of international experts verified that MOSE gates would be able to protect against sea level of only 50cm (Munaretto et al., 2012). Because of this Pellestrina and the rest of the lagoon may need to undertake adaptation measures to ensure resilience under these future sea level rise scenarios, such as increasing the height of the mini-walls on the lagoon side. It is critical to note that these flooding maps are preliminary and the methodology needs to be refined. The methodology (from MIT Summer Workshop 2017) is based on land elevation points scattered throughout the island rather than sea level and flood modeling. The methodology does not account for a 20 cm mini-wall adaptation measure on the lagoon side of the island, which may mean fewer areas may be permanently inundated under the 110cm scenario. The mini-walls are between +1.30 and +1.40 m high with respect to the IGM zero of 1942 (Franco and Tomasicchio, 1992). Lastly, the analysis was not conducted at a granular scale, which would be particularly useful for site planning purposes. Recent climate conditions serve as a baseline for understanding future projections. In the Veneto region, summers have been hot and mostly dry, and winters have been cold and wet. Over the past 50 years in the Veneto region, temperatures have increased significantly during every season, especially summer and winter maximums and summer minimums. Winter rainfall has decreased over the past 50 years. According to the Italy 2017 National

Plan for Adaptation to Climate Change, in the Venice climate region: temperatures are projected to continue to increase, the wet winter season will become wetter, and the dry summer season will become drier (Centro Euro-Mediterraneo sui Cambiamenti Climatici, 2017). Intensification of winter rains may cause riverine flooding in the drainage basin and exacerbate water levels and acqua alta. Climate projections between 2021-2050 for the Venice climate region under the greenhouse gas emissions scenarios RCP4.5 vary (moderately low emissions scenario) and RCP8.5 (business as usual) but overall trends are projected to continue into 2100.

Design Options

Taking each of these portions of analysis into account, the authors of this study each formed design teams, which formulated three hypothetical design options for the site.

The Future of Fishing: Repurposes MOSE's infrastructure for a modern-day local economy based on new and traditional fishing technologies.

Figure 6: Future of Fishing Site Plan

The Future of Fishing design option re-envision the MOSE construction platform as a hub for a revitalized fishing economy where Pellestrina can be the 21st century leader of sustainable aquaculture, researching how to integrate floating vegetation with fish pens to provide water purification while at the same time producing low-impact food for the region. Furthermore, this site and environment can function as a nursery for species that have been declining within the lagoon and can help to revitalize and repopulate species that have been threatened as a result of the overexploitation and pollution to date. Our design idea centralizes Pellestrina as the focus for this type of environmental research and local economic hub that supports the residents of this island and allows for a reasonable amount of public access to tourists and visitors that can see and be inspired by the leadership of Pellestrina's sustainable food production and lagoon management.

The design recognizes the history of fishing guilds on Pellestrina, which from the 1500s exercised considerable political influence in the region although the work itself was difficult. In the 1880s a cooperative movement arose to unite resources amongst fishermen and protect against the potential economic downfalls associated with the fishing industry. At this time, Pellestrina Island was home to two fishing villages and cooperatives. Until the 1960s fishing was strong, when manufacturing and industry began producing harmful ecological and economic effects. Subsidence, chemical waste, and dredging for commercial shipping damaged many of the habitats of the lagoon that had sustained rich fishing resources. Fishermen either moved away from lagoon resources to the resources of the Adriatic open sea fishing or switched to the manufacturing economy. Today, the continuation of fishing traditions is uncertain, as young Pellestrinans seek job opportunities outside of the islands' bleak economic prospects by moving to the mainland centers of Mestre, Padua, and Treviso. Lack of lucrative job opportunities in fishing, agriculture, and/or tourism puts the island's socio-cultural future at risk and exacerbates the pressures of the tourism industry, shifting the Venice lagoon archipelago from a city structure to a 'park', utilized primarily by outsiders rather than its own inhabitants (Cipriani, 2017).

Lagoons are ecologically important habitats: they provide marshlands for migratory bird species, they filter nutrients in water through vegetative uptake, and they provide marine species nurseries to grow their young. They are also economically rich places, offering their inhabitants a local economy. In 1994, the Venetian lagoon business contributed to \$80 million in economic benefits, directly and indirectly. At that time and into 2000s, the Venetian lagoon contributed 33% of Mediterranean fishery production. In 2011, after years of slow decline of the fishing industry and increase in the aquaculture industry, aquaculture businesses surpassed those of fishing in the lagoon (Rosetto, 2000; Zaccariotto, 2014)

This design team considered the wide range of possible "natures" to be preserved on the site, as between two spectrums, from platform permanence to complete platform removal, and high use and management to low use and management. If the platform is kept, high use could involve a heavily landscaped waterside destination park. An intermediary among these extremes involves partial removal of the platform and moderate management – an ideal opportunity to incorporate Pellestrina's economic history in order to have the site serve as a learning environment for adaptive aquaculture.

This partial platform deconstruction reuses that platforms' concrete, while retaining much of the platform's originally constructed border of filled sheetpile. Deconstruction could retain most of the border, break up the concrete material to repurpose for a new breakwater, and remove the dredge material for appropriate depths for aquaculture. The new breakwater is designed a few meters north of the existing breakwater in order to protect the aquaculture area from currents around the Malamocco inlet. The remaining concrete from the platform could be reused to reinforce the muraizi along the rest of Pellestrina.

Pneumatic and hydraulic breakers could facilitate platform demolition and are often used in concrete demolition projects involving foundations and pavement, including underwater. Demolition could also involve cutting concrete for reuse, as well as pressure bursting, which involves pressure in boreholes to split the concrete. Lastly, wrecking balls and explosives are used for large volumes of concrete but may create a lot of noise, dust, and vibration which may cause damage to the surrounding structure. Pneumatic and hydraulic breakers may be the most suitable for deconstruction of this platform site and would require consultation with civil engineers.

Resilience in Reuse: A new form of coastal defense that builds on the site's historic assets, bringing life to the MOSE platform and preparing Pellestrina for a new era.

Figure 7: Resilience in Reuse Site Plan

The MOSE platform presents a unique opportunity for the Island of Pellestrina. Rather than destroy the platform, the national, regional and local governments could work together to explore possibilities for productively reusing the site. The site's elevation means that it is relatively secure from flooding and the threat of sea level rise and its size means that it can accommodate a variety of different uses. The location on the north end of the island, on the outskirts of the closest village but near public transportation and a beach, make it an ideal spot to develop tourism on the island without disrupting life for current residents. Resilience in Reuse is structured around the notion that different activities can share space, and that existing forms can be repurposed for new uses as the need arises.

In the short term, the site can be used for tourism and events. Though the impacts on the lagoon are still uncertain, climate change will impact Pellestrina and likely lead to increased risk of flooding. In the long term, the site can easily transition to a base for flood disaster response and recovery operations. The short-term uses provide new economic opportunity to the island, while long-term maintenance of the platform ensures islander resiliency in the face of an uncertain future. In addition to the concrete platform, existing assets like MOSE gates and CVN activity could be incorporated into future uses. This design idea provides a venue to celebrate Venice's history of coastal defense and defiance of flooding, surge and sea level rise in the near future. This design concept considers how to protect the island's residents.

While the island is relatively secure from flooding at present, Pellestrina will be at risk of flooding from storm from future disasters like the catastrophic flood of 1966. Space for disaster evacuation and response activities are included in the buildings on the site. It also envisions on-site activities to increase community resiliency, like retrofit construction demonstrations, and a public learning center focused on climate change.

The MOSE platform is higher than most of the rest of island, making it an asset for the island, and a perfect site for recovery and evacuation in the case of disaster. In the future, should parts of the island become permanently flooded, housing built on the platform will be available for resident resettlement.

The Protezione Civile is the government body that manages disaster planning in the Venetian Lagoon. It has an office in Pellestrina and a disaster management plan in place for the island. However, this plan is focused on present risks and does not take the effects of climate change on water levels into account. In the future, the organization may want to change its plan and locate its evacuation, relief, and recovery efforts on the site, because of its proximity to the ferry, space for large crowds, and relative security from flooding.

A small survey of Pellestrina residents completed during MIT's 2018 Pellestrina Summer School found that residents were generally in favor of developing tourism on the island. This design idea would bring a hotel, campsite, and bungalows to the North side of the island. Visitors would enjoy amenities on site, but would have easy access to the ferry or to the villages to the South. Major events could also be hosted on the platform for short periods of time, as an alternative location to sites in the already crowded historic Venice. This level of tourist activity could enliven the economy, but would not overwhelm Pellestrina residents because the site is detached from the nearest village.

Murazzi 2.0: Transforming divisive infrastructure into a connection. This project proposes design elements that connect the villages of Pellestrina to their history, to the Adriatic and to a site of new opportunity.

Figure 8: Murazzi 2.0 Site Plan

Squarely facing the risks of climate change this proposal sites a new village on the highest point in Pellestrina, the MOSE platform, returning the lagoon side to a more natural state that allows for agrotourism. The north side of the platform is now a pier and market and the south side is the commercial and retail pier. The structures of

the blocks are based off of the size and the location of caissons during the manufacturing process for MOSE. This size allows the incorporation of housing and open space, mitigating the amount of concrete expose on the platform. This typology also connects physical structures to the history of resilience and adaptation on the island.

Pellestrina's long history as a barrier island and protector of the region as created infrastructures that have divided island life, both north-south and east-west. The site is located at the north end of the murazzi, at an elevation that is secure from most flooding predictions. It is close by to public transportation, the beach and a natural marshland that makes it an ideal spot for both tourism and a more recreational lifestyle that is well-connected to the region. Easy access to the Adriatic and agricultural space supports the existing fishing and gardening industries on the island. Murazzi 2.0 begins with a transformation of the murazzi from a seawall into a pleasant and active pathway that leads the villages of Pellestrina directly to the MOSE platform site. A development at this site, with the appropriate programming, can provide a destination the brings the villages on Pellestrina together, highlights the island's histories of coastal protection and economic development, and provides a physical and intentional opportunity to open the island to the Adriatic and its uses.

The Murazzi wall separates the beach from the rest of the Island with few points of access. At it's widest, the beach and Murazzi make up to 1/3 of the Island's width and at its narrowest, it is almost 1/2 the width of the Island. The seawall creates a spine, driving development orthogonally with the majority of buildings facing the lagoon side. The sea wall becomes the back and with it, the Adriatic. Sea side is more barren and less utilized. In Murazzi 2.0, the seawall is redeveloped into a multi-modal pathway that connects the villages and ends at the MOSE site. This identity will be celebrated in Murazzi 2.0, by reclaiming the connection with the Adriatic, hosting a MOSE museum that features the history of protection on Pellestrina, and tourism that highlights the design of the site based on past structures. Developing commercial and retail space on the site focused on creating local jobs as well as developing housing and transportation for ease of access to the region is key to the project. In 2016, the cultural association was evicted from their long-time office and they needed to find a new space for the lacemaking school and lace collection. The new development will bring a community space for lace making and other artist spaces for both living and working in. As a destination for these activities, Pellestrina's local economy and tourism may benefit from connecting to the larger region known for its crafts.

Conclusion

The MOSE platform is young infrastructure. The site provides an opportunity to reenvision a controversial, enormous purpose built parcel with knowledge of the value of it's solid base, a foundation on which to build or repurpose. The site is unique, but it has many parallels as other piers and other oceanside developments in the developed world have seen their uses diminished and many have been abandoned or rebuilt for a different use.

Given the size of the parcel approximately 170,000 square meters, or the size of two dozen soccer fields, and its rectilinear shape, the site is well-positioned for a redevelopment which can dovetail with the needs and desires of the surrounding community. At the same time the current Europe plan recognizes the value of adjacent sensitive habitats, and seeks to restore the site's former life as a beach. This course believes the cost and scope of this project may be underestimated at € 3,520,000 for platform removal and beach restoration and €5.500.000 for naturalization of the work camps into nature park preserves (*Piano delle misure*, 2016). As such, the range of options in this study offer paths other than costly destruction, providing options that mirrors the range of development across Pellestrina itself, where villages range in development from densely built Pellestrina to remote Ca'Roman.

The student researchers also kept in mind the reason for the structure itself: the MOSE flood protection system. While Alta Acqua is most visibly present in Venice itself, this student team was keenly aware of how higher

water will affect the MOSE platform site and the surrounding area in Pellestrina. With this in mind, constructing resilient infrastructure, building structures which can accommodate changes in climate in both the long and short terms, and building infrastructure is crucial to sustain Pellestrina's history, culture and economy.

The future of the MOSE platform in Pellestrina is in flux: whether and how long it will stay in place. For the MIT student team, these questions prompted an exploration of the potential futures outside of the Europe Plan.

Students began with the "Future of Fishing": a partial removal, where the resulting structure will form a miniature lagoon adjacent to the MOSE project, and one which will become a new, Adriatic-side, fishing village, complete with supporting structures but without significant permanent population (Figure 9).

Figure 9: Future of Fishing Perspective

The next more intensive use, "Resilience in Reuse," will keep some of the MOSE uses on the site, but retain some new structures for various temporary uses, from large events to emergency evacuation shelter, as well as building some permanent structures on the platform itself, while still retaining significant open space with less programming to promote creativity and happiness (Figure 10).

Figure 10: Resilience in Reuse Perspective

Finally, the "Murazzi 2.0" will reimagine the platform as a dense village, building a relationship between the Adriatic and the island and developing the local economy and using the Murazzi to connect the Adriatic side of the island to the Lagoon rather than to separate it (Figure 11).

Figure 11: Murazzi 2.0 Main Road Perspective

Given forward movement on the Europe Plan, the site may not even exist in a matter of years, so the student team sought to uncover a number of alternative possibilities to provoke questions about the tradeoffs and synergies between construction and destruction, naturalization and reuse. The course recognized the legal background for the Europe Plan, as well as a changing European Union environment, where such the future of such a large undertaking may rise and fall based on local, regional, national and even Eurozone politics, finances and policy. Ultimately, the class found a reevaluation of the site's future compelling given the

uncertainty around projected environmental changes due to global warming and the even more uncertain projections about localized environmental changes in the Venetian Lagoon and the Adriatic Sea.

The future of the study site remains to be determined. If current plans proceed, the site must be dismantled and deconstruction of hundreds of thousands of square meters of fill and concrete must be removed sustainably to develop a new beach will form along the lock and breakwater. If the site is kept, a longer range vision for sustainable futures on the littoral islands could be created. Seemingly just as likely, if the site is kept in a state of limbo, the site could serve useful purposes even if retained temporarily. Each of this study's plans begin to address these options, and the authors' hope that the plans, or at least elements thereof, can help planners and policymakers in the Veneto region widen the possibilities planned for the future of this site. This site is at a crossroads, and provides the potential to link sea and lagoon, beach and murazzi, and past, present and future.

While the MOSE platform on Pellestrina is not old, it faces, like much of the infrastructure from other eras, an uncertain future. Yet in many cases, this infrastructure has been creatively reused, creating iconic places out of infrastructure once considered an eyesore. In any number of cities, old, disused piers have been converted in to parkland or even used for housing. Imagine if New York had torn down old West Side Line railroad instead of redeveloping it into the High Line. Disused infrastructure can be an opportunity, and our study of this site seeks to bring the principles of urban design to the site.

Planning and architecture for climate adaptation: the experiences of the "structure-territories" in low and high density city

Silvia Serreli, Gianfranco Sanna, Giovanni Maria Biddau, Nesrine Chemli, Pier Paolo Spanedda*

**Department of Architecture, design and urban planning University of Sassari, serreli@uniss.it, giasanna@uniss.it, gmbiddau@uniss.it, chemlinesrine@gmail.com, ppspanedda@uniss.it*

Abstract: The paper reflects on the awareness that climate adaptation planning becomes more effective when it is dealt with a local context. This approach focuses on the relationship between vulnerability, adaptation and urban regeneration processes in territories of a low and high density. It refers to new balances of the urban ecosystem in the two case studies. The experiences highlight fields of experimentation of new forms of the urban project that take into account the peculiarities of each territory. Some urban areas are experimenting new ways of cooperation between public and private stakeholders which, although belonging to two different situations of low and high settlement density, are dealing with the issue of resilience and adaptation in both fields urban planning and architecture. The experiences of these different contexts, spread urban forms in Sardinia and high settlement density in the city of Tunis, reflect on how to rethink the structure of the city through adaptive urban strategies such as the design dispositive of "Structure Territory". This planning approach aims to promote the adoption of new design solutions that satisfy the contemporary needs of inhabitants and, at the same time, are oriented towards the nature-based solutions.

Keywords: Structure-Territory, Climate adaptation, Vulnerability, Urban regeneration

Introduction. Climate adaptation and place-based proximity

The increase in the frequency and intensity of some phenomena related to climate change, such as urban floods, heat islands, land consumption and desertification increase the level of risk to which cities are exposed. If we interpret the contemporary environmental crisis, we can argue that all territories are vulnerable and that the implementation of urban transformation projects must take that into account the different sensitivities and peculiarities of the individual territories from the environmental and socio-cultural point of view.

In this scenario, how the tools of projects and the government of the urban territory can incorporate the processes of adaptation to climate change. What planning actions on the territory can build forms of governance capable of making the solutions adopted durable?

The experiences conducted by the research group investigate project devices in relation to some experiences that implement adaptation actions addressed in relation to the micro-situations of a local

context. The “local” has the meaning of “proximity relational space”. The “localized” approach to changing climate adaptation processes aims to identify more general forms and processes starting from local needs, making the logical link between apparently distant phenomena explicit.

In this direction, the adaptation processes are implemented through the project of transformations that create an anchorage to the place (Augé, 2000), which favour the redefinition of the relationships between territories and inhabitants, which in turn stimulate their ability to take care of the space in which they live, even in situations of environmental fragility. Adapting to the changing climate, which does not always respond to forecasting models and mitigation technologies, means facilitating and preparing the conditions for creating a network space, ensuring that the most vulnerable places in our cities are involved in a process of regeneration that involves new forms of community (which may include institutions, organized social groups, individual citizens, etc.), not necessarily characterised by physical proximity. The regeneration of places as an adaptive process is the instance of one or more communities and their action incessantly, animated by the proximity of interests for places that need not be overwhelmed by climate change. The adaptation calls for a sharing of objectives, the ethics of responsibility, the passion for the same territory, an awareness that local processes have important global repercussions. This is the perspective that the 17 objectives of the 2030 Agenda open up.

The local dimension of the experiences dealt with refers to two distinct situations: the urban territories of low settlement density that regards urban areas, such as the small cities of Sardinia, characterized by a dispersal of settlements and a pervasive environmental dimension; the territories of high settlement density, which we study in relation to complex cities, such as Tunis, where urban growth multiplies the effects of urban concentration that are not always positive.

The “adaptive” project actions we have experimented are based on a close relationship between vulnerability, adaptation and urban regeneration processes in reference to the two territorial situations of Sardinia and Tunisia. What the two experiences have in common is the search for a design approach that makes the strategies of adaptation contextual that different countries both in Europe and in North Africa are implementing. Starting from the sharing of the need to maintain the socio-ecological balance of a city, we explore two devices for planning and governing the territory:

_a *governance* model that realizes it that we have called “adaptive”, recalling some research that calls into question models based exclusively on the central role of institutions. The space of the networks in this second device refers to the new forms of “alliance” (Albrecht *et al.*, 2010) between public and private subjects and those in Europe and more recently in Italy, are fuelling environmental protection policies through the so-called “lagoon contracts”, the “river contracts”, and the “coastal contracts”.

_a spatial device that in our research we have called “territory-structure” to present new urban equilibriums through the settlement transformations, starting from the fragile situations that occur both in small cities and in large urban areas.

Through these devices, we study actions and policies of reconstruction, re-use, redevelopment, having in the background the possibility to design and govern the existing settlement heritage of our territories, to develop scenarios that adapt to climate change as a continuous process of urban and the environmental regeneration of our cities.

Climate change and adaptive governance

The scenarios of the Fifth Report on the Intergovernmental Panel on Climate Change (2013) and the National Strategy for Adaptation to Climate Change highlighted the urban effects and risks associated with climate change. The study confirmed that it is no longer a question of determining whether the climate is changing, rather how quickly it is changing (IPCC et al., 2014). As we know, various critical factors emerge, including drought and a lack of water resources, extreme meteorological events and hydrogeological risk and heat waves. Cities, in this sense, need to evolve with respect to adaptation strategies no matter the action they bring into their urban transformation processes, governance and land management (Wamsler et al., 2013), operating at the local scale which is the level at which we can avoid those that have been called “maladaptive actions” (Swart et al., 2014).

Climate adaptation cannot be separated from the cultural, political, economic, environmental and development contexts in which it occurs and therefore, it is only part of a series of social responses to change. Adaptation has been considered highly specific in relation to the territorial and urban peculiarities of a place, as it depends on its specific climatic, environmental, social and political conditions (Füssel, 2007). For this reason, the adaptation actions involve a wide range of measures aimed at reducing the economic, environmental and social vulnerability to climatic factors (Füssel 2007; Walker et al., 2013).

The extreme events that occur at the local level have more and more repercussions in a wider context, generate new sensitivities and partially influence the public policies of the government of the territory. These events can be considered “catalysts of adaptation actions”, despite the difficulty in realising planning paths and government policies that develop with continuity and strategic visions for the future. The main “adaptation mechanisms” have been institutional (for example, providing guidelines and outlining public address policies) and financial (for example, providing financial support). However, interventions that promote climate change adaptation actions or that focus on vulnerable social groups (marginalized groups, the elderly or children) have been limited (Berrang-Ford et al., 2011; Ford et al., 2011).

The need for effective climate adaptation actions, both in urban areas and in large areas of the territory, is a widely recognized issue, as it is shown that its critical effects on social and natural systems increase. However, efforts to adapt to climate change, as reported in the literature of the last decade, have not produced processes and actions that address planning strategies and environmental policies on the local scale with continuity of the “safe” territories despite considerable investments in adaptation sciences. Furthermore, the actions implemented were mostly focussed on interventions that address sectoral aspects; more systemic and transformative long-term actions are less frequent.

Recent decision-making processes aim to overcome this situation and are framed as “adaptation paths” to emphasise the need for a solid decision-making process within adaptive processes in the face of uncertainty and intertemporal complexity. However, to date, these paths have focused mainly on contexts with clearly identified decision-makers and unambiguous objectives; consequently, they generally assume that prevailing governance regimes are conducive to adaptation and therefore limit responses to the causes of vulnerability.

Responding to global change is a challenge for society. The theoretical developments and the operative researches of some authors in relation to the models of “adaptive governance” allow to

highlight that one particularly difficult and challenging reason are the top-down processes that control systems (Gorrdard, Colloff et al., 2016). In Ostrom's reflections, it is pointed out that "the complexity of social-ecological systems precludes policy and management panaceas and requires decentralized knowledge (Ostrom et al., 2007; Norgaard, 2010, quoted by Gorrdard et al., 2016).

Adaptive governance needs to focus not only on the role of institutions: they "may provide a focus for leadership, but institutional change requires coordinated efforts by people with agency in diverse roles at different levels within a social-ecological system" (Stirling, 2014 quoted by Gorrdard et al 2016). Still Gorrdard, Colloff et al. underline that "the required reflexive analysis of the societal context in which these actors are embedded is innately difficult. Decision makers may be unaware of the influence of societal structures such as norms, practices, cultural regimes, technologies and regulations (Ostrom, 2010, 2011; Leith et al., 2014), especially if such structures have been stable and thus taken for granted" (Gorrdard, Colloff et al., 2016 p. 62).

Achieving greater effectiveness of planning actions and *adaptive governance models* to implement urban transformations of adaptation to the climate can be investigated through the study of decision-making processes defined according to two perspectives (Gorrdard, Colloff et al. 2016). They highlight and question the fact that adaptation should not be addressed as a decision problem, which provides answers to the impacts of climate change within government processes centered on decision-making perspectives, "it is therefore unsuitable for addressing complex, contested, cross-scale problems". The reflections of Australian researchers broadening the *decision-making perspectives* according to a broader perspective that define *decision-context perspective* that focusses on an interconnected system of values, rules and knowledge that creates and limits the set of practical and admissible decisions

Decision-context perspective and project for new "urban alliances"

Adaptive governance refers to the need to understand how the social contexts of a decision-making process can influence choices and how the inhabitants of a territory can intentionally influence these contexts to plan the future of cities. Adaptation projects that focus on *decision-context perspective* represent a pragmatic alternative to the current *decision-making perspective* adaptation. The latter is a perspective based on a top-down approach that is based on the logic of control and has shown over time its ineffectiveness, both in relation to the different time constraints imposed by the actors and to the institutional resources made available. In this perspective, the choices for implementing adaptation actions are based on processes, values and knowledge treated as independently defined variables, which implies that "a decision maker can incorporate any relevant knowledge and values in order to reach a decision within the bounds of the societal rules that enable the decision process" (Gorrdard, Colloff et al., 2016, p. 62).

We exemplify the decision-making perspective according to two project areas. In the first case, there are approaches of "sustainable architectures" that promote punctual transformative actions in the city. In this case, the adaptive capacity of the project is measured through the improvement of the building's characteristics, its durability; adaptability is understood as the improvement of the user's well-being in relation to comfort, health, safety and the quality of the internal environment; the sustainable building counteracts the effects of climate change by becoming more efficient by reducing the consumption of resources and energy, also in relation to the exploitation of technological innovations (Kronenburg, 2007; Schmidt, Austing, 2016). In the field of urban planning, adaptation brings in crucial aspects for the evolution of settlements, especially in relation to fragile environments (such as wetlands, river

corridors or coastal areas). However, the actions implemented are still sectoral and attempt to counter the vulnerability of environmental systems through plans and programmes, to study their susceptibility to change, their capacity to absorb the stresses imposed by the city's infrastructure, while maintaining their ecological functioning and dynamics.

In both cases, it is a process governed by public stakeholders (agency focussed perspectives) and experts from the different sectors who formulate values, knowledge systems, rules and application guidelines to make choices within and within the limits imposed by the context.

The implementation of projects and policies based on decision-context perspective shifts the focus to societal structures and the influences they exert in the decision-making process: they define the role of the actors and whether these roles allow effective and legitimate actions. From the *decision-context perspective*, values, rules and knowledge are “interdependent conceptual systems that represent a particular way of viewing and framing the world” (Gorrdard, Colloff et al., p. 62). In this second approach, our research experiments with territorial projects that attempt to develop responses to climate change adaptation at the local level to contribute to the complex problems of global change.

The durability of urban transformations is proposed in the two experiences illustrated in this article, in Sardinia and Tunisia, through the study of the interdependence between knowledge, values and rules that govern the spatial organization and socio-ecological functioning of the urban territories explored. The environmental regions in which these relations are expressed are defined by us as territorial ecologies of water, “situations in which the forms and processes of the environment contribute to achieving a spatial structure and a structural economy oriented in an environmental sense”. These regions recall the territorial relations with which any transformation project will have to deal at different scales to respond to the need to avoid sectoral approaches that simplify the relational importance of water.

Territorial ecologies do not derive from an a priori perimeter of ecosystems and are not pre-defined by decision makers: it is the project that reveals the structural genesis of physical space and establishes the limits and levels of degradation below which that specific ecosystem cannot be modified without the loss of certain vital functions and attributes (Sechi, 2003). For this reason, transformative choices are the result of a process of co-design and responsible action by all the actors involved, public and private, who assume reciprocal commitments to activate effective actions that are legitimized by the context in which they operate. This “structural perspective”, defined in the studies of Gorrdard, Colloff et al., shows that the actors who enter the process build a sort of “new alliance”, a pact to implement adaptive management strategies, sharing project objectives and future visions for the territory they live in.

The experiences

The experiences pertain to what we illustrate try to highlight how it is possible to open “structural perspectives”, from recognition to the selective representation of environmental matrices of a city. The trend scenarios at both extremes highlight forms of physical and social desertification (Mahmoud, 2017; Spooner and Mann, 1982), which are at the base of an urban regeneration project. In particular, we have concentrated on both in Sardinia, with the city of Oristano as a case study, and in Tunisia in reference to the Grand Tunis – on the water dynamics and related ecologies for developing proposals

for the “reconstruction” of a relationship between fragile lagoon environments and settlements that have progressively invaded natural strategic areas.

The project hypotheses, both in the high-density settlement areas of Tunis and in the low-density areas of Oristano, use *territory-structure* (Maciocco, Sanna and Serreli, 2011). This tool pertains to projects that connect spaces and resources that can create interdependencies between ecological dynamics and settlement spaces. They create new spatial configurations, by selecting resources present in the territory: the project action builds new relationships starting from reality, organising the universe of elements placed in the field by the environment and by the history that resists the succession of transformation processes as seen in Figure 1. This encourages the relational evolution of urban and environmental fragments, even in places obscured by intensive settlement and city infrastructure, reconfiguring them within a common project, thus participating in a single transformation movement.

The adaptive capacity of the project in fragile areas such as coastal and lagoon environments is understood as an ability to “structure”¹ the settlement’s resources and the environment by first interpreting the constituent components of the geo-environmental systems and their interrelated connections between continental processes and marine-coastal processes, dominated by the morphodynamics of river systems, by the wave regime, through the currents coastlines (Costa, 2013).

The urban regeneration project for Oristano and Tunis, albeit with due differences, starts from these premises.

¹ It refers to the definition Anglo Saxon structure to “arrange according to a plan [and provides] give a pattern or organisation”.

Figure 1: *Tendential scenario lagoon strategic areas of Oristano and Tunis.*

Regeneration of the terrain vague in the low density of settlements in Sardinia

The meaning of the territories-structure as generative spaces of the urban project and architecture is interpreted through the design process of *Oristano Est*, a project recently financed by the Presidency of the Council of Ministers in Italy and approved by the Municipal Administrations in the city of Oristano, a small city located in the centre of the west coast of Sardinia².

The project addresses the issue of urban regeneration by extending the field of action to a wider territory than places defined as “peripheral”, as per the criteria of the competition announcement. The urban area taken into consideration extends beyond the compact structure of the city to be refocused with respect to its constituent environmental elements: the river environment to the north and the lagoon area to the south. Thus, the project extends the concept of a centre to several spaces of the urban territory, compared to the “historical” perspective usually recognised as the only place from where to derive the peripheral gradient of the different contexts of Oristano as seen in Figure 2.

Figure 2: *The territory-structure recovers various areas along the compact urban edge of the city and selects and organises the sequence of spaces that create an extended urban and infrastructure corridor placed on the east side and the south of the city.*

1) Oristano-Santa Giusta lagoon; 2) agricultural park dedicated to rice production; 3) area returned to the lagoon environmental processes and intended for urban park; 4) Oristano; 5) Santa Giusta

In the project for Oristano, the territory-structure incorporates the role of an urban director able to relate and interact with areas affected by different phenomena of peripheralisation and degradation: derelict public areas affected by the progressive abandonment by the inhabitants, areas that are no longer discontinued functional in the current urban organisation, connection spaces no longer accessible and areas subjected to flooding processes. Their succession defines three urban directions: western, eastern and southern, configuring three new urban parks that have been termed as “generative contact spaces” (Choay, 2003). These include interstitial spaces that are *terrain vague*, in areas of the

² The project was proposed by the LEAP research group of the Department of Architecture, Design and Urban Planning of the University of Sassari, responding to the need for a global approach to the problems of the territory and, in particular, to the theme proposed by the notice on the redevelopment of the peripheries of the capital cities of Province in Italy. Through the project, the Municipality of Oristano received a loan of 17 million euros. It is currently under construction.

residual agricultural network and set in the current settlement plots. They incorporate punctual elements, such as ancient villas, recent industrial archaeologies, disused areas of the railway network and obsolete areas awaiting new functions. The selection of the fields defines for this or a new urban arrangement, including them in a new spatial organisation. Thus, the park's territory-structure is a catalyst for the relations of spaces and functions, both different actors. Additionally, the generative device that can accommodate both the economic and productive demands of the inhabitants, places of residence and leisure, simultaneously making the city's environmental resources central (river and lagoon), which are currently obscured by the settlement structure that has relegated them to a mere background.

Private subjects and public partners have been called on to participate and present proposals, to share the strategies of the design device. Participation, given the modest size of the city, received a response beyond expectations, both in quantitative and qualitative terms. Thus, the project has to begin an unprecedented evolutionary process involving the city's strategic geographical areas, as an alternative to the logic of current urban evolution with different critical issues related to the environment. The attractiveness of the spatial device of the park and of the areas incorporated by it has had precise feedback owed to multiple requests for participation received from private subjects who, interested in taking an active part in the realisation of this project, have highlighted the potential of reinterpretation and the re-signification of existing settlement assets operated by the park.

The territory-structure of the park for this project can include pre-placing a connection structure that welcomes the public and the private bodies of the city. Furthermore, this could operationally launch a public works program aimed at achieving its feasibility.

The park guidelines initiated by the general project are in this sense new strategic centralities:

- places open to public enjoyment that recall different collective services for recreational, educational and social housing activities;
- attractors of new urban economies, resulting from the location of new services for the city and private individuals;
- places of cultural integration, as welcoming spaces that can trigger processes of social innovation as Oristano recalls different profiles of inhabitants (permanent and temporary residents, stable and occasional workers, different types of tourists, and new migrant citizens); and
- spaces that favour safety conditions, allowing inhabitants to experience public spaces without risk to their physical integrity, often induced by forms of inaccessibility. Additionally, urban security is understood as environmental security, favoured by an awareness of some places that call for a greater sensitivity to the environmental protection of public areas by inhabitants.

The Oristano's territory-structure project symbolises potential spaces still able to accommodate a regeneration process in spaces obscured by incoherent spatial organisations: "spaces in which to act, in which to create new local economies, new stories, new ways of belonging" (Sassen, 2015, p. 238).

The urban directions involved in the project that continuously involve different areas of marginality and peripherality – currently fragmented spaces adrift – have assumed the role of priority and strategic

places from which to start again for a re-foundation of the city as well as for places of re-territorialisation and re-signification.

High density in Grand Tunis and the environmental issue after the "Arab Spring"

The complexity of the Grand Tunis has seen a long process of metropolitan construction over the years. The phenomenon of high urban density has been transformed into a critical reality, with which the city has existed for almost 30 years. The search for new models has been increasingly in line with foreign real estate investments, exposing the city to new forms of spatial and social vulnerability and producing urban approval processes that have involved strategic resources, such as lagoon environments.

The urban lagoons represent the strategic spaces of the city, the places of safeguards necessary to address regeneration interventions: they recall the demolition of solid pollution forms, the mitigation of risks of flooding of neighbouring urban spaces, the creation of public areas for environmental use, the achievement of a quality of residence and related/other services. These are essential questions to start a sustainable regeneration process.

Tunis and its inhabitants, rooted in their territory with an identity, historical and cultural structure, have protected the codes of their civilization through multiple historical periods. However, the political and economic changes, increasingly influential in Tunisian society in recent decades, are the basis for the search for new models increasingly in line with the canons of a contemporary European city. Is a different future possible for the Tunisian metropolis starting from a regeneration scenario based on the historical matrices of the settlement and on urban policies capable of countering the physical and social desertification of the territories?

Starting from recognising ecological dynamics that characterise the lagoon environments of the city being explored, in collaboration with the University of Carthage, evolutionary scenarios based on adaptation strategies with particular reference to the residual areas that are yet unaffected by the progressive consumption of soil are the focus of recent infrastructure investments. Considering factors that can influence urban policies, we have experimented with the spatial nature of the territory-structure to outline alternative settlement models.

As it emerges from the images, Tunis highlights an urban growth where urbanisation and the environment are entities that seem to have been mutually ignored over time. The city's evolution towards areas subtracted from the lagoon has given rise to residual spaces where settlement and environmental dynamics often conflict. These are where settlement forms have generated spatial imbalances, loss of content and pre-existing meanings.

Moreover, around the coastal and lagoon areas, the environment becomes fragile – the level of degradation is increasingly evident. The environmental criticalities are particularly derived from the settlement pressure exerted on the ecosystems of the wetlands, from the proliferation of solid pollution and from the vulnerability of the territory to hydrogeological risks (Chouari, Belarem, 2017).

The popular uprising has fostered the emergence of different and contradictory strategies. In this transitional phase, the environmental and ecological question has assumed a high level of criticality, that remains ignored by the social movements that arose during the revolution³.

The futuristic projects of the new infrastructural investments aim to raise the level of the Tunisian economy, while reducing the unemployment rate. Therefore, proposing different research and strategies to current situations, to look at how to preserve the integrity of the historical landscape and the entire ecosystem of the territory under study, by combating the proliferation of urban density is a good means for change.

Such a scenario would have several serious consequences for the new planning for Tunis, involving different aspects, such as the environmental considerations, identity, social concerns and the landscape dimension of the city. The ecology of the lagoon is explored. The processes governing the integrity of the system has been compromised by the complete cementation of the coastline for the intensification of urban density, with significant modifications associated with the removal of water spaces, without excluding the increased importance of eutrophication phenomena, caused by the increased concentration of pollutants and suspended sediments in the water. Such environmental degradation is already present due to urban expansion on Lake Tunis.

Furthermore, the expansion of the coastline would lead to the alteration and elimination of aquatic vegetation, leading to a reduction in primary production, accompanied by significant changes in microclimates and the impossibility of maintaining the lagoon banks naturally. Therefore, besides the practices of new building expansions, the phenomenon of increasing urban density would not be limited to the alteration and degradation of the ecological processes that govern the lagoon system. Instead, this would extend to problems of identity related to the historical image of the city, since the planned construction dedicated to the entire coastline would permanently disfigure the landscape of Tunis, supported over time by its dominating position on the lagoon.

These new urban projects are influenced by foreign models, where the Tunisian population is practically excluded from this territory, due to the socio-economic contrast and physical and social separation. These future financial centres and high technology elements will be a kind of refuge for Tunisians and the foreign rich, while generating neighbourhoods that are “monosocial”⁴. They would create a road network barrier against Tunis because of their isolation and their confinement on themselves.

³ Tunisia was the driving force behind the so-called “Arab Spring”. The country is faced with important demands for change and renewal by large sections of the population. The social and economic issue is at the centre of the concerns of the Tunisian government and society that triggered the “Arab Spring” until the fall of the regime of former President. The citizens’ revolt concerned in particular the crisis of the social pact that materialised in the request for more employment (see De Facci, 2014), equal rights, social equality and access to housing for the poorer classes. What matters is not the movement itself, but the direct and indirect impact that the “Arab Spring” has had on society (see Mahmoud, 2015). “The environment is the first victim of the revolution”, says environmental activists. The natural environment of Tunisia seems more vulnerable, as Prime Minister states that the environmental situation has deteriorated sharply in recent years, with “negative consequences on the quality of life” of Tunisians.

⁴ Bahri Maroonian, Tunis marine. Une « métropole » au bord de l’eau. EPFL. www.archivesma.epfl.ch

The spatial device of the territory-structure selects, within the problematic urban environments, elements that can be regenerated in the lagoon context of Lac de Tunis. In the tendential scenario, the environmental dimension of the lake is considered as a backdrop for infrastructural actions that saturate the lagoon edge areas, distorting them and irreversibly inhibiting their dynamics and processes.

The size and extension of the Tunisian metropolitan territory, the continuous saturation of spaces apparently without a role, pose countless questions related to the survival of ecologies of the natural environment, which, due to the action of densification by the settlement system, show areas of high criticality and are often characterised by situations of irreversibility. The design of a new spatial organisation reverses the figure-background relationship (Kanizsa, 1993), involving and highlighting vulnerable natural environments, historical pre-existing features, soils taken from their original uses and derelict areas.

In the inversion between the figure and background, the territory-structure changes the connotations of some places that have remained at the edge of the urban organisation as well as the perception that inhabitants have of the same. Its representation, and therefore the selection of the elements of the city, highlights areas of possible connections that can encourage unprecedented relations between pre-existing settlement areas with high criticality and the areas of regeneration of the lagoon. In this manner, the lagoon and its feeding system are taken as a strategic area of the city. The project being proposed for the Grande Tunis restores to the lagoon its spaces of belonging, the seats of dynamics and the vital processes for the lagoon's survival. Thus, large infrastructure investments for residential purposes proposed as the primary figure of the actions of transformation in the trend scenario are placed outside the sensitive areas. The objective of regeneration is the implementation of the most-favourable conditions for creating a lagoon park, interpreted by the territory as a structure of environmental centrality for the entire urban system. Its dimension is not limited to the water mirror, but extends to the whole proximity territory, the seat of dynamics and related processes.

Figure 3: *The territory-structure the lagoon city of Tunis.*

1) North saltworks, Sabkhet Ariana; 2) South saltworks, Sabkhet Essijoumi; 3) Area returned to environmental processes in the lagoon and destined to be an urban park and 4) The Medina.

A possible future scenario, which can be the basis of any reasoning that pursues climate adaptation objectives, makes the lagoon the primary figure of the urban organisation. Thus, it can assume the role of environmental centrality in the city. This possible scenario contributes to orient any future transformation action that pursues the maintenance of the lagoon as a public urban space to be defended.

The adaptive actions of the territory-structure in the strategic areas identified can create the following conditions:

- requalifying spaces that favour the conditions of reorientation of the pre-existing scenario, characterised by areas of fringe marked by significant forms of abuse;
- giving meaning to open spaces and to the components obscured by the prevaricating action of real estate investments;
- favouring the anchoring to environmental elements that can assume the role of a public space, open to the relationships and to different ways of use by various types of inhabitants and
- regenerating the environmental spaces where natural dynamics take place to activate forms of sustainability: thermoregulation, the absorption of CO₂, evapotranspiration, purification, reuse and lamination of rainwater and the improvement of the hydrological response of soils.

The territory structure thus outlined lays the foundations for future planning processes, trying to counteract settlement methods inspired by expansive practices and anchored to the logic of arbitrary occupation of land, regardless of any form of process and dynamics of environmental schedule present within the territory. The project hypotheses reveal the need for a reflection, allowing to arrive at alternative and urgent solutions to put a stop to the phenomena of desertification and de-territorialisation.

Urban generative structures and resilient societies

In our research, we have explored the themes of adaptation in relation to fragile areas, such as the lagoon, in two different contexts. The need for interdependence between conceptual and design devices, such as territories-structure and the implementation of adaptive governance models, continues to fuel our questions.

If, on one side, the *territories-structures* expose explicit urban regeneration projects in certain places to the extent of desertification and deterritorialisation, we try to experiment the methods of implementation of projects through subjects that often have opposing interests, different roles and skills, on the other. In contrast to the current planning and design devices that are based on predefined analysis scales as well as standardised government models, often coming from sectorial disciplinary approaches, the territory-structure offers the possibility to recognise and select the dynamics of a territory using the project as an “exploratory sensor”. It represents a scheme to take action that is anchored to the historical and environmental dimensions of the city, implementing a novel connection between the different urban fragments, to begin forming perspectives of resilient development.

The search for “new urban alliances” puts in the foreground, according to our reflections and experiences, the crucial role played by the “project” and, consequently, “the importance of identifying values, aims, tools and, most importantly, actors in this challenge within structures of government that are changing themselves” (Gambino, 2015).

The protection of vulnerable contexts, such as the lagoon settlement areas of Sardinia or Tunisia, push the research to deepen the ways in which *governance* as an adaptive practice can be addressed on open and flexible approaches to contributing to change attitudes and aspirations as well as to advance a different idea of the city. The territory-structure selects *process-oriented* actions, enhancing the educational quality of the environment and creating the premises for new alliances between subjects (as is the case with the Oristano project), and it favours new learning processes that intensify relations between different actors.

Regardless, the project action arises, therefore, as a learning tool that can contribute significantly to the increase in the level of knowledge and awareness of the subjects that are in focus: “a self-training process that becomes a new socio-political and cultural model of recognition of the established structures of ecological-urban control of the territory” (Clement, 1974, p. 35).

The adaptive capacity is also understood as the ability to *give space* to the term: we believe that the territories-structure are able to counter the rigidity of the canons of functionalism, formalism and standardisation to find new perspectives for the urban project. The adaptation understood in these terms recalls the requirement of interscalarity, a correspondence between micro and macro, a reference to the value of small transformations with respect to their reference context, an anchoring to the reasons of the territory, even when it appears more fragile (Serreli, 2013).

The concept of “adaptation” and “coevolution” requires, as various authors have explained, a process of continuous and reciprocal learning, the overcoming of sectorial disciplinary glances, the affirmation of interdependencies between different configurations of reality, to bring a territorial and urban context towards new evolutionary states. The reconstruction of the vulnerable places in our cities can be triggered by “adaptive architectures” that the territories-structures select: they are projects that have the ability to contextualise themselves with respect to the environmental, settlement and ecological dynamics to modify the space and its functions homologating through minimal transformations to meet the needs of the evolving context. Adaptations subsequent to the different conditions of reality also allow the territories to evolve through small modifications that record variations and changes not only of proximity. In this sense, even existing settlements subjected to multiple pressures, and thereby apparently unfit to innovate the city, may have new opportunities for regeneration. In the urban territories of the lagoon landscapes, the modifications are actions “enzymatic” (Boeri and Gregotti, 2006), which favour the ability to use unusual energies present in the territory to make the context evolve even in situations of fragility and vulnerability. Additionally, they can also develop in normally unsuitable settlement environments (confined, commodified, standardised, and so on), reworking the different components of contextual reality but simultaneously interacting with new rules that arise from the context.

The two experiences of Oristano and Tunis illustrate that the capacity for resilience is the capacity for resistance and recovery (Odum, 1988) of values, rules and knowledge, as described in the “decision-context perspective”. The need for adaptation to the new conditions that the lagoon settlements of the two cities are subjected to have higher priority and will have to be part of a wider design that starts from the “local” dimension and aims to build “resilient societies”, just as many require of the political agenda of all countries. The new alliances between institutions and between institutions and citizens engaging differently in the reorganisation of one’s living spaces are possible thanks to the sharing of a future project to initiate processes of change and lasting learning.

Flood

Can Miami learn from Venice (or the opposite)

Christophe Washer, direction@isuru.be

Abstract: On the one hand, “la Serenissima”, a millenary city, which saw its heyday between XIII and XV centuries. On the other “the Magic City”, famous for leisure and pleasure, born in the late nineteenth century from the encounter of two American pioneers. Apparently, they have nothing in common. Yet they share a lot in common. They are both situated in lagoon areas. They rely heavily on tourism and port activity for their economy. And, they find themselves at the frontline of climate change. Venice has always been confronted to flooding, but this condition has been worsening, due to over extraction from aquifers, which caused the city to subside, and to sea level rise. In contrast, flooding isn’t part of Miamians’ culture and tradition. In recent years, however, with climate change bringing about higher rainfalls and storm surges, and causing sea level to rise, Miami has been experiencing more and more floods. Both cities are now highly jeopardised. After developing on the differences and similarities between Venice and Miami, this article proposes to investigate what answers these cities come with to address climate change effects, and to question what they could learn from each other.

Introduction

Upon my first visit to Miami¹, seven years ago, looking at the city from a boat, I felt the same amazement as when, 30 years earlier, I saw Venezia for the first time: a city built not on land, but on water! This vision triggered my interest and I soon started wondering: why isn’t Miami River as busy as the *Grand Canale*? Is Miami also subject to *acqua alta*? My first impression was that, contrary to my idea of Venezia, an aristocratic old lady who lives on in a long term, complex and enduring relation with water - at once ally and foe - Miami is an *enfant gâté*, whose relation to the ocean is mainly hedonistic, apparently unconcerned by either its dangers or the opportunities its offers. Soon I discovered how fragile this *enfant gâté* really was, and how ignorant of his condition he seemed to be. I wondered: how could the old lady last so long in middle of water, lacking everything? I kept asking myself if there was anything the *enfant gâté* could learn from her about surviving with water.

I followed a simple methodology: I spent a lot of time looking around and I asking myself questions. I tried to imagine possible answers, then I looked for elements to corroborate or better to refute them. These elements came from publications, books, or other media. They sometimes resulted from discussions. At a certain point, I tried frame my iteration by summarising factual information that seemed relevant to the matter. I collected most of the data I used from 2015 through 2017.

I chose to include here non-academic references, first because they give an idea of what information non academics might have on the subject, second because non-academic information often refers to academic information, which may encourage further investigation that I did not engage in. Third and most importantly because they participate in the “Zeitgeist.” Indeed, the question that haunts me is how can we really begin to think climate change in the way that it is totally transforming the backdrop of our lives?

Some facts

Geography

Venice and Miami share the condition of being located in coastal lagoons.

A lagoon is a body of water separated from a larger body of water by a barrier. Coastal lagoons are situated along flat continental coastal plains. They are separated from the ocean or the sea by a sandbar also called

¹ I use “Miami” as a generic term designating Miami Dade County

“outer bank”. Coastal lagoons have brackish water, because of the freshwater they receive from rivers and the saline water that enters through inlets in the outer bank.

Lagoons are fragile and unstable environments, sensitive to sea level variations, which can either submerge them or dry them out, and to embankment, due to the settling of sediments carried by the rivers.

Many rivers originally carried freshwater to the “Laguna di Venice”, in particular, the Bracchiglione, the Brenta, the Dese, the Sile, the Piave and the Livenza. Some, including the Brenta and the Piave, were channeled out of the Laguna in an effort to stop silting. The outer bank of the Laguna di Venice is now known as the “Lido,” and Venice itself was built in the middle of the laguna, on four islets.

Miami is located on the coastal side of a lagoon called “Biscayne Bay,” whereas Miami Beach is located on its outer bank. Biscayne Bay receives freshwater from the Everglades, now mainly through the channeled “Miami River” but also from aquifers.

Both lagoons have comparable geology, typically consisting of layers of sediments, brought by the rivers, and confined aquifers, separated from the sediment layers by thin layers of clay. But in the Venice laguna, these sediments are mainly composed of sand, whereas in Biscayne Bay, the sediments consist of limestone.

One of the major differences between these lagoons is their respective coastal geography. In the case of Venice, the continental relief, first characterised by the large plain of the Pô, rapidly rises northward into the Dolomites and the Alps. Whereas in the case of Miami, it consists of the Everglades, a marshland that runs across the Florida peninsula, no higher than two meters above mean sea level, and has been partially drained and urbanised. Another major difference between Miami and Venice is their respective climate: subtropical in Miami², Mediterranean in Venice.

Economy

Venice and Miami rely mainly on tourism and maritime transport for their economy. Venice receives 20 million visitors each year and is one of the favourite destinations of Mediterranean cruise boats. Miami Dade County welcomes 16 million visitors each year and the Port of Miami is now the first cruise ship harbour in the world, with almost 5 million passengers in 2016-2017, Port Canaveral and Port Everglades, also located on the Florida East Coast are respectively second and third. In Miami, real estate is the other essential economical sector, whereas in Venice, petrochemical industry has been an important sector during the 20th century. But it is now in decline³.

History

The two cities differ totally in their respective histories. Venice goes back more than a thousand years, and saw its zenith in the Late Middle Ages, whereas Miami is only 125 years old and is still booming. Obviously, they developed in very different historical contexts and “Zeitgeists,” but both cities exemplify why and how human groups came to live in unwelcoming marine environments, and the specific technical and intellectual resources they developed for achieving that.

In the Venetian laguna, virtually in the sea, the first settlements in date from 500 AC.

This extremely unwelcoming environment was the natives’ best answer to escape invading barbarians. Facing barbaric perils, they preferred the perils of the sea. Or rather, they chose to put themselves under the protection of the sea. A very risky gamble, but one which would prove to have been a winning one. Indeed, the sea not only protected the Venetians from invasions for more than a thousand years, it also made their fortune. From very precarious premises, Venice developed to become one of the most important and richest European ports, dominating the eastern Mediterranean for three centuries⁴, compelling admiration and amazement from visitors⁵ with its astounding settings, its beauty and wealth. Venice’s existence in the middle of the sea, which

² Miami is actually the only metropolitan area of the western world with a subtropical climate

had to be constantly fought for, fuelled the notion among visitors but above all among the Venetians themselves, of a Venetian myth, or even of a Venetian miracle⁶. A myth and a miracle that the Venetians political power relied on, nurtured and often orchestrated. Every year, on Ascension Day, the Venetians would celebrate la Sensa, re-enacting their marriage with the sea. The city itself became the theatre stage where architecture acted out the Venetian miracle, while, backstage, the struggle against water went on.

The conquest of Constantinople by the Ottomans, in 1453, is generally seen as having initiated the economic decline of Venice⁷. Very interestingly, it seems to have also triggered the implementation, by the Venetian Republic, of remarkable resource management policies and, in an apparent paradox, its unique cultural radiance. Both lasted until 1797 when Napoleon invaded the Veneto and Venice lost its independence.

Regarding resource management, one needs to bear in mind that, because of the city's settings, it lacked everything, except that which could be harvested from the sea, such as fishing products and salt. Rainwater had to be gathered in wells to provide fresh water⁸. Everything else, food (other than fish), construction material, timber, firewood, had to come from the mainland. Timber and firewood shortage were a major and constant concern, because the city needed enormous amounts of wood for its shipyard, its building activity, for the maintenance of its network of breakwaters and levees, and for domestic and industrial heating. As long as the Venetian fleet dominated the Mediterranean, commerce provided wood, but as of the capture of Constantinople by the Turks, the Venetian Republic saw its area of influence shrink, while its needs continued to grow. To the Venetian Authorities, the lack of wood became just as great a peril as flooding or invasion. Aware that they had to rely on a limited supply area, and despite their reluctance to interfere in the "terraferma," they decided that the Republic should take control of surrounding mainland forests so as to secure its wood provision, stop deforestation by the local population, whom they designated as the main cause of wood shortage because of their selfish, improvident and profligate behaviours which ran counter to common interest and natural order⁹. Seeing themselves as guarantor of natural and common interests, they set themselves to monitor and maintain forest ecology on the mainland in the same way that they had been doing for centuries with sea ecology, in the complex lagoon water system. And their motive was the same: survival, which they saw as depending on working with nature rather than against it. On the mainland, however, the peril did not come from nature itself, but, according to the Venetians, from the populations inhabiting it. The Venetian authorities adopted complex and innovative legislation, which notably designated vast forest estates as common goods, in order to make them inalienable (public good, "res publica," was an intrinsic value of the Venetian Republic), and they developed an unprecedented forestry bureaucracy to implement it¹⁰. Remarkably, their actions dramatically contrasted with the dominant contemporary European ideology, which promoted individual fulfilment through the improvement and privatisation of nature¹¹.

On the 12th of May 1797, Venice finally fell into the hands of the invader.

That day Napoleon Bonaparte's troops took the Veneto, putting a brutal end to the Venetian Republic, with its millennial independence, its comprehensive approach of environment, its sacrosanct principle of common goods, and of course of its arsenal. Napoleon immediately replaced the long enduring Venetian institutions and their organic value system by new ones, based on the values of the enlightenment which ruled the dominant European nations. External domination and mechanical values forced Venice to an abrupt and much deferred plunge into "modernity"¹². The subtle, challenging and painstaking convergence of ecology, public and private interests which characterised the Venetian miracle no longer ruled, indeed the time of miracles had long since

⁶ See Crouzet-Pavan, E. (1997). *Venise, une invention de la ville (xiii^e–xv^e siècle)*, coll. « Époques », Champvallon,

⁷ Another cause is the new navigation routes, which, as of 1492 would replace the old spice and silk routes

⁸ As Venetian historian and diarist Marin Sanudo (1466-1536) wrote : "Venice è in acqua ma non ha acqua"

⁹ For a detailed analysis of the relation between the Venetian Republic and the mainland forests, see Appuhn, K. (2009) *A Forest on the Sea: Environmental Expertise in Renaissance Venice*. Baltimore: Johns Hopkins University Press

¹⁰ Appuhn (2009) Op. cit p.114

¹¹ "The rhetoric of a providential nature that was favoured by Venetian forestry officials, reflects the persistence - in Italy - of Renaissance ideas of an organic, mystical nature, during a period when (...) Protestant Europe was often concerned with demystifying and desacralising nature." Appuhn, K. (2009) Op. cit. p.283

¹² I use "modernity" in the sense of the Modern Era as historical period and value system

ended, Now was the time for heroes subduing and dominating nature. And it was no one less than the champion of modern heroes, Napoleon, the true incarnation of Weltgeist according to Hegel, who finally brought an end to the Venetian miracle. From then on, the resources, which had to be protected before, would be exploited; nature, which had been seen as perfect, would require serious and constant improvement and common good would submit to private interests. This new set of values triggered a dynamic which probably culminated with the construction of the Malamocco-Marghera “canale dei Petroli” and petrochemical complex (1920-1968), which, as Pignatti and Seminara (2009) insist, caused irremediable alterations to the lagoon geology and biology¹³. Furthermore, in the course of the 20th century, over-extraction of groundwater by local industries caused Venice to subside by more than 10 cm while global sea level to rise by the same amount.

Nevertheless, Venice is still there, considered by many as the most beautiful city in the world. It now relies on its glorious heritage for its economy. Indeed, with twenty million visitors each year, in relation a population of now only 53.000 in the historic centre, tourism is Venice's main if not unique source of income, to such an extent that it jeopardises the future of the city as much, if not more, than sea level rise.

When the first Europeans arrived in what is now Southeast Florida, around 1500 AC, the Tequesta, had already been living there, at the mouth of rivers, since the 3rd century BC. But by the time Spanish Florida was traded to the British, in 1763, they had disappeared. A vast number had been decimated by the diseases the Spaniards had brought with them, others perished during their massive relocation to Cuba by the Spanish missionaries. The rest had dissolved into Christianity or into other minorities. Because of the omnipresent marshes, the heat, moist and the mosquitos, Southern Florida stayed basically uninhabited. The first European settlements remained extremely limited and strictly localised along the shoreline. But as of the beginning of 18th century, natives, chased Southward by the second wave of European colonisers coming from the Northeast, began to migrate into the vast and “uninhabitable” Everglades. To quote the above paragraph, you could say that “this extremely unwelcoming environment was the natives’ best answer to escape invading barbarians”. The story of their exodus into the uninhabitable marshlands began like that of the Venetians, but it developed in a dramatically different way. As the “Laguna” protected the Venetians, the wetlands sheltered the Seminoles from their enemy. Indeed, from 1816 through 1858, the US Government carried three long and expensive wars against them without totally submitting them. When the last diehards retreated deeper into the Everglades, the US Government gave up, because of the cost and because it was believed that no white settler would ever want to live there. However, this unwelcoming but vast and very sunny territory, populated by a few hundred natives, kept attracting more and more bold frontiersmen (and women). William and Mary Brickell, Julia Tuttle, John S. Collins, the Lummus brothers, Henry Flagler, Carl Graham Fisher are the heroes of this other American frontier. Today, their names punctuate the cities of Southern Florida¹⁴. But, in a strange analogy with Venice, the hero who must truly be credited for the development of Southern Florida, was also called Napoleon Bonaparte. Indeed, with mottos like “Drain that abominable, pestilence-ridden swamp¹⁵,” Napoleon Bonaparte Broward was elected to the office of Governor of Florida from 1905 until 1909. Draining the Everglades had been on US legislators’ agenda as early as in 1842, after all, the US had inherited the mechanist values from the European enlightenment and the belief that nature had to be improved to render it economically productive¹⁶. In 1906 Broward commissioned an engineer, James O. Wright, to establish the drainage plans and in 1908 the works started, launching a still ongoing process that would deeply modify the Southern Florida

¹³ Pignatti, S. & Seminara, G. (2009). *The future of coastal ecosystems: learning from Venice*. IN Rendiconti Lincei Url: <https://doi.org/10.1007/s12210-009-0048-6> Last consulted on May 23, 2019

¹⁴ In 1871 William and Mary Brickell settle on the south bank of Miami River. In 1891 Julia Tuttle settles on the north bank of Miami River, in Port Dallas (which would become Miami), In 1896, with the Brickells, she convinces Henry Flagler to bring the East Coast Railway down to Port Dallas, Flagler will actually extend it all the way down to Key West in 1905. In 1895 John Edgar and J.N. Lummus settle in Miami. In 1901 John S Collins settles on the barrier island that would become Miami Beach. In 1912, he builds the first bridge across the lagoon, with financing from the Lummus brothers and Fisher. In 1910 Carl J. Fisher buys land on the barrier Island, he is credited for naming it Miami Beach In 1911 Mary Brickell builds Brickell Avenue, running from the mouth of Miami River down to Coconut Grove and develops the area until her death in 1922. In 1912, the Lummus brothers buy land from Collins and start building modest family homes. In 1914 Carl J. Fisher Dixie builds Highway and joins in the development of Miami Beach.

landscape and bring its population from a few thousands to more than 8 million¹⁷. Unforeseen consequences, such as flooding, drought, peat fires, subsiding of the arable peat layer and salt water intrusion (not to speak of flora and fauna destruction) were felt as soon as in the 1920s¹⁸, but the process went on regardless and it is only in the 1970s, when it became clear that draining the Everglades would deprive Southern Florida of drinking water, that it was called into question¹⁹.

Drainage of the Everglades wasn't the only factor that made Southern Florida's demographic explosion possible, as Anthony Oliver Smith puts it: "Technological innovations such as pesticides, air conditioning and mass transportation have transformed Florida from a problematic environment for human habitation into one which is now inhabited by millions. In turn, population growth, agribusiness, tourism, and specific patterns of urban development have seriously affected the fragile ecology of Florida²⁰."

Actually, the technological developments made during the 20th century didn't transform this problematic environment, but they substantially reduced its impact on humans. Set them aside, and the environment is just as problematic as it ever was. Worse, at the scale of the planet, these developments contributed to sea level rise and extreme climate episodes intensification (such as hurricanes), which both particularly threaten Florida. Thus today, this environment inhabited by millions, with its affected ecology, is an outpost on the climate change front line.

Nevertheless, Miami is there today. Like Venice, it is a myth and a miracle, but in a different way. Over a period of the few decades, this somewhat provincial but sunny resort for middle class retirees became an international metropolis.

Sea level rise

For dominant scientific research sea level rise is an effects of climate change, caused by the combustion of carbon rocks (coal, oil and gas). Melting of continental ice caps is the principal factor of sea level rise. Sea level rise isn't homogenous throughout the planet, other factors such as thermal expansion, currents, winds and vertical movements of the lithosphere interfere with it. Its principal consequences include shoreline recession, land and fresh water salinisation, fauna and flora migration. Based on 2006 data, some 100 million people would be affected by a 1m sea level rise²¹. But sea level rise could reach 2,5 meters by 2100²², and population is scheduled to keep growing at least until 2050.

Like all existing lagoon areas, Venice and Miami are highly sensitive to sea level rise, but the risks they incur are different, due to their respective conditions in terms of vulnerability, preparedness and

responsiveness, but probably also because of cultural specificities, which can act as invisible barriers, distorting the perception and hindering adequate reaction.

Venice:

Risks

In Venice, the main stake seems to be: “Save the landmark.” It is the principal leitmotif of local and international publications. Even more so since the listing of Venice as a World Heritage Site in 1987 by UNESCO, which forces the Italian Government to take measures to insure its protection²³. But as Antonella Marsico *et al.* (2017) demonstrate²⁴, it is not only Venice that is jeopardised by sea level rise, but the whole highly²⁵ populated, industrial and touristic Northern Adriatic region. Indeed, Marisco’s maps shows that even with IPCC ARS 8.5²⁶ minimum scenario of 0,53 m. rise of mean sea level by 2100, 4.616 km² would be flooded, and the coastline would move back as far as 60 meters.

Preparedness

After the damaging November 1966 acqua alta, Venice began to study answers to flooding. Pressure increased when the city was listed among World Heritage Sites. Institutions at state, regional and local level have the mission to deal with it, but they seem to have been “treading water” because of ill-adapted legislation, poor coordination and corruption²⁷. Academic institutions have been producing abundant research on the subject, faculties have included “ambiente climatico” and “aumento del livello del mare” in their curricula. Concrete measures are being taken, at large scale with the still unfinished Modulo Sperimentale Elettromeccanico (MoSE) project²⁸, at local scale with the renovation of the canals and of building foundations. An environmental approach is also developed, notably with the works of the biologist Davide Tagliapietra²⁹ and engineer Alberto Barausse³⁰.

Responsiveness

One might well doubt if the MoSE will help. First, because one may question if it will ever be completed. Second, because, as Jeff Goodell (2017) observes³¹, the MoSE was initially designed to face high tides of more than 110 cm and up to 270 cm, but not to face sea level rise. In 1987 and the UNESCO listing however, the project was adapted to what was then a “pessimistic scenario” of a 30 cm increase of mean sea level by 2100. But since then, pessimistic scenarios became more pessimistic, many foresee a 50 cm increase by 2050.

Regarding the protection of the cultural heritage, the existing situation is daunting, because mean sea level is already higher than the waterproof stone that forms the base of the constructions, and the city suffer from worsening floods. On the other hand, the uniqueness of Venice and its international positioning as inescapable hub of ancient and contemporary art attracts sponsors and donors worldwide and the environmental approaches which reconnect with the Venetian tradition of working with nature rather than against it might open the way to a more global and complex approach of the issue.

Invisible barriers

As Molinaroli *et al.* (2018)³² insist, corruption and extreme political imbroglia stop useful initiatives from developing and drain away financial resources. They add that because public administrations wouldn't resort to public participation and area-based management, locals grew demotivated. Indeed, as Mitchell (2017) insists³³, maintenance of the levees and of the canals went on for as long as Venice was independent, and Venetians acted as a community. When their exclusive competence and responsibility to manage their environment was assigned to external agents³⁴, such as the Italian Government or even the UNESCO, the Venetians no longer cared.

Miami:

Risks

"Save the assets" is the motto of in Miami. The Union of Concerned Scientists estimated in 2018 that, only for Miami Beach, \$6.4 billions of real estate value could be lost by 2045, causing a loss of \$91 millions of property tax³⁵. What about under-privileged neighbourhoods and their inhabitants? In 2013, Miami Dade County had a population of 2.6 million, with a poverty rate of 21%, which places it on the poor side of US counties and increases their vulnerability. Other crucial stakes are of course saline water intrusion in the fresh water aquifers³⁶ and contamination of sea water by polluted soils.

Preparedness

Despite abundant publications as of the late 1980s³⁷ very little was done in Florida regarding climate change and flooding for almost 3 decades. Denial regarding climate change, or blind trust in the ability of technology come up with answers, seem to have prevailed. In the last decade, things started to change. Public authorities adapted their agendas, new agencies were created³⁸, with new officials, like the chief resilient officer³⁹. New

zoning plans were drawn. The service sector saw the multiplication of actors. Academic institutions adapted curricula and developed research. Coordination between all these actors was provided for with the creation of The Southeast Florida Climate Change Compact⁴⁰. As for fieldwork, so far, it consists mainly in raising street level, raising sea walls, upgrading water drainage systems, beach sand replenishment, dune build-up, etc. These measures, and their potential effects, are timid if compared with the Venetian MOSE or with the Dutch flood defence, but similar measures would not serve in Miami, because of the porous nature of its soil.

Responsiveness

Miami's awakening to the reality of sea level rise is not simple. The new public and private agencies spent a lot of time debating on definitions and projections. At an institution level, the Climate Change Compact produced guidelines, but even administrations fail to implement them. Indeed, between 2008 and 2016, new zoning plans covered most of the areas of Miami Date County that should be directly impacted by sea water rise. A non-exhaustive list of these plans comprises:

- Coconut Grove Waterfront and Spoil Island Master Plan (2008)
- Museum Pak Master Plan (2008)
- Virginia Key Master Plan (2010)
- Downtown Miami Masterplan (October 2009)
- Miami Beach Strategic Plan (2011);
- Port Miami 2035 (November 2011);
- City of Miami Beach Stormwater Management Master Plan (2012);
- Overtown Mobility Plan (2014);
- The Underline Framework Plan (December 2015);
- Neighborhood Revitalization District (May 2015);
- PlanNoBe proposed North Beach Master Plan (2016 draft);
- Mana Wynwood SAP (2016);

But remarkably, out of these twelve plans, only three (PlaNoBe, Port of Miami and Miami Beach SWMMP) mention sea level rise. Of those three, only two (PaNoBe and Miami Beach SWMMP) describe measures to address it. Basically, the strategy consists in rising urban zones above water before water rises above urban zones. Academic institutions focus mainly on design, technical and engineering solutions⁴¹ when there seems to be major educational and cultural deficiencies.

The physical measures show limits. Beach sand replenishment is a Sisyphean task. Sea walls induce erosion and scouring, they also constitute basins once they are overflowed. Rather than adapting to sea level rise, these two measures protect private property and business at the detriment of public good. Street rising turns private properties into basins, which require pumping when it rains. When they don't fail, pumps spill pollution into the ocean. Geologist Harold Wanless⁴² says that these measures are "just the tiniest little Band-Aid for a cost of hundreds of millions of dollars, and they certainly won't get us to the middle of the century⁴³." He isn't the only expert who has doubts about their effectiveness: Dutch sea level rise expert Henk Ovink called Miami

the “New Atlantis”⁴⁴.” Despite all of that, interesting social work is made with disadvantaged communities to reduce their vulnerability and increase their preparedness and responsiveness to flooding⁴⁵.

Invisible barriers

As in Venice, “non-physical” factors complicate this already challenging picture. These non-physical factors are political, like climate scepticism at the head of the nation and of the state, and the consequent muzzling of administrations, or election deadlines which do not facilitate long term perspective. They are structural, with a system based on individualism, private interest and private property. They are economical, with a booming tourism and real estate business which masks the problem, and with a tax system grounded on real estate. They are social, with a high poverty level, and high social disparities⁴⁶, which in turn cause high social vulnerability. They are cultural, with blind confidence in technology⁴⁷, or with the concept of a war between man and nature, which the presentation of the “Miami Beach Rising Above” project during the Philip Levine Mayoral Office (2013-2017) exemplified: « The goal of these actions is to leverage existing resources to develop a mutually-beneficial solution that helps **combat** [emphasis mine] sea level rise challenges in Miami Beach and other coastal municipalities⁴⁸.»

Discussion: What made Venice so long enduring?

Let us at once dismiss that it might have been an amazingly favourable set of circumstance, it would be hard indeed to believe that it might have lasted so long. Environmental determinism, should also be ruled out, because if Venice developed in the laguna, earlier settling in the same environment, such as Spina and Ammiana⁴⁹ on the West side of the laguna didn’t. History shows however that the Venetians held a strategic and naturally protected position on the Middle Ages trade routes. But it also shows that it took them daunting efforts to live and flourish there. From these premises, living in the sea required technologies and competences, social consensus, excellent governance and resource management.

Premises

The humble premises of Venice are essential. Indeed, the first settlers did not come to live in the laguna as conquerors, but as runaways. They preferred the dangers of the sea to those of the barbarians. But once the danger had gone, the settlers never returned to the mainland. Why?

If, fleeing from a dreadful enemy, you placed yourself under “something’s” protection, and if this “something” really scared you enemies off, you would probably be at once grateful, respectful and fearful, and soon you would establish some sort of ritual. This view was shared by French archaeologist Salomon Reinach (1858-

1932), who saw in “La Sensa” the Christian re-appropriation of a pagan propitiation and reconciliation ritual⁵⁰. The ritual lasted as long as the Republic did⁵¹, reminding Venetians that their union with the sea must always be renegotiated. It is the basis of the Venetians’ concepts of power, community and property. Human power is limited by forces beyond mankind. In the sea, the individual is helpless, but the community can navigate. If you live on the sea, you know you can’t own it.

Technology and Competence

The Venetians had to develop specific technologies in fields such as marine environment construction, shipbuilding, fresh water harvesting. They also had to develop competence in fields such as hydrology and navigation. And because they had to secure their food supply, they also became strategists and masters in the art of war. They used these technologies and competences with nuance. They managed their unstable sea environment through constant monitoring and careful maintenance. When needed, however, they would actively intervene on it, not to dominate it or to transform it, but to keep it in what they saw as an optimum natural state. Similarly, the Venetians dealt with a challenging geo-political environment with active and astute diplomacy, in order to maintain an favourable equilibrium in the “game of powers.” But when needed, they were ready for war. Maintaining these equilibria was extremely costly. It required a social consensus and an excellent governance.

Social consensus

The Venetians were like the rowers on a “galeazza⁵²,” rowing in the same direction at the same pace. As Elisabeth Crouzet-Pavan (1997)⁵³ insists, the myth or miracle of Venice consisted at once of the impossible longevity of the Venetians in the sea, their surreal city, and the stability of their institutions, which the Venetian institutions exploited to reinforce consensus.

Governance

Governance also played a crucial, with three remarkable qualities: long term vision, provision, pragmatism. These qualities stand out in many episodes of Venetian history, as when the Doge Enrico Dandolo used the 4th crusade to bring down Constantinople, or when Venice decided to divert rivers out of the laguna to stop silting. Abundant documentation shows that the Venetians have always been aware that the survival of their City, in the face of submersion, required constant and towering action.

Resource management

Resource management played a key role in Venice’s longevity. Because of Venice’s permanent need of fresh water and wood. As Appuhn (2009) demonstrates, the question of wood shortfall was a permanent concern. It brought the Venetians authorities to overcome their reluctance to interfere in mainland affairs, in order to enforce as of 15th century, forestry management based what would now be called sustainable exploitation. The Venetians understood that the optimum of private agents operating on high discount rates, was to cut forests clear and convert them into field or pasture, whereas the continuous flow of wood they needed meant low discount rates, which could only be expected if the forest were either communal or state owned. They also understood that they had a limited supply area, and that therefore, the forest must be allowed to replenish. To ensure this, they created “commons” when in the rest of continental Europe and England, enclosure of commons had already been ongoing for a long time. I would argue that, very interestingly, as their knowledge of forestry developed, the Venetians progressively implemented almost all of the eight design principles which, according to Elinor Ostrom, are illustrated by long enduring common pool resource institutions⁵⁴.

⁵⁰ Reinach, S. (1906) *Le Mariage avec la Mer* IN Cultes, mythes et religions, t. II, p. 206-219, Ernest Leroux, Paris Url: https://fr.wikisource.org/wiki/Le_Mariage_avec_la_mer Last consulted on May 30, 2019

⁵¹ It was reestablished in 1966

⁵² XVI Century Venetian boat

⁵³ Crouzet-Pavan, E. (1997). Op. cit

⁵⁴ Ostrom, E. (1990) *Governing the Commons: The Evolution of Institutions for Collective Action*. Cambridge University Press

As a reminder, these principles are: 1) Clearly defined boundaries; 2) Congruence between appropriation and provision rules and local condition; 3) Collective-choice arrangements; 4) Monitoring; 5) Graduated sanctions; 6) Conflict-resolution mechanism; 7) Minimal recognition of right to organise; 8) Nested enterprises⁵⁵.

Conclusion

Venice is the result of an alliance between man and sea. As their dominance over the Mediterranean declined, the Venetians developed awareness of their finite environment and of resource scarcity. They passed another alliance, this time with the Forest. Because of where the Venetians came from, their culture fostered community rather than individuality, common goods rather than private ones, complexity rather than simplification, soft approaches rather than hard ones.

Miami did not rise from the same premises as Venice. The forces that created Miami were similar to those that defeated the Venetian Republic. And if, like the early Venetians, the Seminoles had no better choice but to live in the Everglades, the white settlers, who came after them and triggered the spectacular development of Miami, did not come because they had no better choice. On the contrary, Julia Tuttle, William Brickell, John S. Collins, the Lummus brothers, Henry Flagler, Carl Graham Fisher, etc., had all the possible choices. They did not have to adapt to this environment, they came to adapt it to their visions. The “Magic City” developed at the cost of its resource, the Everglades and their fresh water. The values of conquest, domination and transformation of nature go in a different direction. They brought the world in an environmental deadlock. And that environmental deadlock now particularly threatens both Venice and Miami.

On which forces should Venice and Miami rely for their future?

On the forces of an alliance between man and nature, which carried Venice for a thousand years? Or on the forces of the domination of man over nature, which, a little more than a century, have imperilled both Venice’s and Miami’s future?

Maybe the old lady and the enfant gâté should share their stories.

⁵⁵ It would be extremely interesting to analyze Appuhn’s research from this perspective

A Comparative Analysis of Local Climate Change Adaptation Plans for Natural Disaster Risk Reduction in South Korea

Dong Keun Yoon¹, Seong Yun Cho², Yeon Woo Choi³, Jung Woo Jang⁴

¹Yonsei University, dkyoon@yonsei.ac.kr

³Yonsei University, tjrrms3@naver.com

⁴Yonsei University, myzzang95@naver.com

Abstract: As abnormal weather phenomena due to climate change globally continues, the frequency of natural disasters and human and economic losses from floods, typhoon, heatwaves and heavy snow are constantly increasing in South Korea. For the last ten years (2008~2017), the total disaster damage cost was expected to be about \$3 billion in South Korea. In response, South Korea established climate change adaptation plans based on the Low Carbon and Green Growth Act enacted in 2010. Local governments adopted detailed implementation strategies to mitigate and adapt climate change based on water management, energy, health and natural disaster management since 2011. This study compared 218 local climate change adaptation plans regarding natural disaster reduction strategies. Using content analysis, this study evaluated natural disaster reduction strategies based on natural disaster types and the stage of disaster management. Moreover, this study examined the regional differences in priorities of natural disaster risk reduction strategies to implement through spatial analysis. The result of the analysis shows that the local climate change adaptation plans are mainly focused on the improvement and reinforcement of physical structures to prevent damage from typhoon and heavy rain in South Korea. This study is expected to provide keys and knowledge for basic local governments to establish the next climate change adaptation implementation plan.

Keywords: climate change, natural disasters, local climate change adaptation plan, South Korea

Introduction

Climate change is perceived as a global issue. The phenomenon affects various sectors such as healthcare, environment and energy, and is becoming even more intense. In 1990, when the IPCC First Assessment Report was issued, the main concern was to determine the existence and impact of climate change. However, as climate change incurred various environmental changes, the approach to alleviating the impact of climate change has been expanded to the approach to adapt since the 2000s (Kim et al., 2014). Furthermore, the IPCC emphasized the importance of ‘climate change adaptation’ in the Fourth Assessment Report in 2007.

Climate change causes an extremely cold climate and incurs severe property and human damages in fields such as healthcare, infrastructures, ecosystem, agriculture, etc. In particular, Korea is suffering damages every year due to heat and cold waves, local heavy

rains and typhoons caused by climate change. Thus, the government is establishing climate change adaptation policies to reduce damages from climate change and improve the adaptation capacity of each local government. The ‘Climate Change Adaptation Action Plan’ as a plan to adapt to climate change is established at the national level, as well as in the upper-level and lower-level local governments. Currently the central government and upper-level local governments established the 1st Plan in 2012 and then the 2nd Plan in 2016. Lower-level local governments have begun to establish the 1st Plan in 2013 considering the circumstances of each region, and currently all lower-level local governments except four regions have completed the establishment of the plan. In addition, the central government is advising each region to revise and improve the details of the plan in light of the climate change policy implementation details every year. However, the revisions have not been properly assessed, and it turned out that there are still certain inadequacies in terms of content (Kim et al., 2014).

Accordingly, the present study conducts a content analysis on the details of the Climate Change Adaptation Action Plan of 221 lower-level local governments in Korea, and suggests matters to improve for effective establishment and implementation of the climate change adaptation plan.

Literature Review

Planning may perform the role of supporting decisions for public interests under complicated circumstances, and its level may vary depending on the purpose and contents of the plan, or the conditions and circumstances in which the plan is established (Hopkins, 2001). In other words, it is important to analyze the contents of the plan since it is essential for the right function of planning to operate properly. Moreover, it is also important to analyze whether the plan can effectively deal with the uncertain future (Berke et al, 2012), and also whether it includes the optimum strategies to accomplish the goal of planning (Wildavsky, 1973).

Studies that analyzed planning mostly defined its success or failure, and are evaluating plans by organizing evaluation principles and indexes. Most previous studies evaluated planning based on content analysis, and the evaluation principles and indexes used in each study were based on a basic evaluation framework.

Alexander et al. (1989) conceptualized the evaluation criteria to distinguish ‘good’ and ‘bad’ planning, and presented an evaluation system utilizing the criteria. They presented the policy-plan/programme-implementation-process (PPIP) model for evaluation of planning and detailed criteria for evaluation such as conformity, rational process, optimality ex ante, optimality ex post, and utilization. Brody (2003) evaluated the plan to mitigate national hazards using content analysis. He provided three evaluation principles such as fact base, goals, and action, and evaluated the plan by developing detailed evaluation indexes. Berke et al. (2005) presented an evaluation method focused on plan implementation to resolve the issue of evaluation focused on contents. They defined successful planning as ‘how well plan implementation is done’, and developed detailed items such as plan equality, enforcement style and awareness building. Baynham et al. (2012) used content analysis to evaluate the climate change action plan in terms of adaptation and reduction. They presented fact base, goals, policies, and implementation as the evaluation principles, and used detailed indexes for evaluation. Baker et al. (2012) used multi-criteria analysis to evaluate the climate change plan. They focused on planning-based policies rather than the contents of the plan, or the improvement level through business, and used total 8 evaluation criteria for evaluation. Berke et al. (2012) conducted research on evaluation of the coastal hazard mitigation plan using content analysis. They divided evaluation principles into internal and external indexes, presenting goal, fact base, mitigation policy, and implementation and monitoring for the internal indexes and interorganizational coordination and participation for the external

indexes. Lyles et al. (2014) used content analysis to evaluate the local hazard mitigation plan. They divided evaluation principles into direction-setting and action-oriented principles, with presenting goal, fact base, and policies for the direction-setting principles and participation, inter-organizational coordination, implementation, and monitoring for the action-oriented principles. Kim et al. (2014) evaluated the Climate Change Adaptation Action Plan of 16 upper-level local governments in Korea using the logic framework analysis (LFA). They presented 4 evaluation principles such as goals, fact base, decision making, and implementation and evaluation, and evaluated the plan using 17 detailed evaluation indexes.

As a result of the literature review, it was found that previous studies were organizing the principles of evaluation based on the components of the plan contents. General components of contents are comprised of fact based analysis, vision/goal setting, policy establishment, implementation and maintenance planning, and participation planning. Previous studies defined 'fact base analysis' and 'vision/goal setting' all equally as 'fact base' and 'goal' (Baynham et al, 2012; Berke et al, 2012; Brody, 2003; Kim et al, 2014; Lyles et al, 2014), but defined 'policy establishment' in different ways such as 'policy' (Baynham et al, 2012; Lyles et al, 2014), 'mitigation policy' (Berke et al, 2012), and 'decision' (Kim et al, 2014). They also defined 'implementation and maintenance planning' as 'implementation' (Baynham et al, 2012; Lyles et al, 2014), and also considered 'monitoring' (Berke et al, 2012) or 'evaluation' (Kim et al, 2014), or even newly defined it as 'action' (Brody, 2003). They defined 'participation planning' by considering both 'participation' and 'inter-organizational coordination' (Berke et al, 2012, Lyles et al, 2014).

Moreover, most evaluations were focused on the contents, and also outcomes of planning as well. In other words, previous studies conceptualized the success of planning as the adequacy of content and performance. That is, previous studies mostly analyzed and evaluated the contents of planning using content analysis with regard to the adequacy of contents, and empirically analyzed and evaluated the possibility and outcomes of planning and plan implementation with regard to the adequacy of performance. In this aspect, this study is an evaluation focused on the contents of a plan, and is differentiated from previous studies as it evaluates the climate change plan in terms of disasters.

Climate Change Adaptation Plan (CCAP) in Korea

Korea is establishing the Climate Change Adaptation Action Plan as a means to improve the adaptation capacity of the nation and local governments to climate change. The Climate Change Adaptation Action Plan is a five-year plan established at the level of the nation as well as upper-level and lower-level local governments. The government enacted the Framework Act on Low Carbon, Green Growth in 2010 as well as its Enforcement Decree, and made planning mandatory by law.

The government established the 1st National Climate Change Adaptation Plan in 9 sectors such as public health, water management and agriculture in 2011. Based on the above, the Action Plan for each of the local governments was established: upper-level local governments since 2012, and lower-level local governments since 2013. Then in 2016, the 2nd National Climate Change Adaptation Plan was established based on adaptation as well as economic, social and environmental sectors. Accordingly, upper-level local governments established their 2nd plan, whereas lower-level local governments still only have the 1st plan considering their regional circumstances.

Methodology

Subjects

The present study analyzed the contents of the Climate Change Adaptation Action Plans of lower-level local governments in Korea. To this end, the subjects were the Climate Change Adaptation Action Plan of 221 out of 226 lower-level local governments, excluding 4 regions that did not establish the plan (Dongdaemun-gu of Seoul, Ongjin-gun of Incheon, Dong-gu of Daejeon, Jangsu-gun of Jeonbuk) and 1 region from which data could not be obtained (Yanggu-gun of Gangwon).

Analysis method

The analysis process of this study is as follows: 1) data organization, 2) coding of a detailed plan, 3) comparative analysis by region and disaster type, and 4) correlation analysis between disaster damage and plan contents.

To begin with, to analyze the disaster plan in the Climate Change Adaptation Action Plan, this study came up with total 1,684 detailed plans by organizing data based on content analysis. Then, this study set the dimensions for coding of detailed plans, with reference to the principles used in previous studies for evaluation as well as the components of the climate change plan in Korea.

The Climate Change Adaptation Action Plan in Korea is comprised of overview, climate change adaptation status and forecast, goals and detailed strategies, action plans for each field, plan implementation and management. The overview of the plan includes contents about the background and

purpose of planning, basis, and establishment procedures. The climate change adaptation status and forecast include vulnerability analysis on climate change. The goals and detailed strategies include visions, goals and detailed strategies to achieve them. The action plans for each field include the details of the adaptation plan, and plan implementation and management include specific details of implementation such as plan, schedule and budget as well as future management plans.

Previous studies are using fact base, goal, policy, implementation, and participation as the basic framework of plan content evaluation. In association with the Climate Change Adaptation Action Plan in Korea, fact base refers to the overview and climate change adaptation status and forecast, goal refers to goals and detailed strategies, policy refers to action plans for each field, and implementation and participation refer to plan implementation and management. This study ultimately used fact base, goal, policy, and implementation & participation as the dimensions for the content analysis of the Climate Change Adaptation Action Plan in Korea.

Next, the present study provided the operational definition of each dimension. Fact base is defined as ‘Which of the physical, socioeconomic, and institutional vulnerability due to climate change is considered in priority?’. Goal is defined as ‘Is the action plan establishing climate change adaptation and reduction measures considering environmental factors?’. Policy is defined as ‘Is the action plan a structural measure or a non-structural measure?’. Implementation & participation is divided into the point of plan implementation and participation. The point of plan implementation is defined as ‘When is the policy established in the action plan implemented: before, during or after a disaster?’ and participation is defined as ‘Does the action plan consider participation?’. Table 2 below shows the operational definition of each dimension. Based on the definitions, this study coded each action plan, after which it conducted a comparative analysis by region and disaster type and analyzed the correlation between disaster damage and plan contents. Finally, this study came up with the tendency of the contents of the Climate Change Adaptation Action Plan in Korea based on the analysis.

Table 2. Operational definition of each dimension

Dimension [↗]	Operational definition of dimension [↗]	Criteria [↗]	Code [↗]
Fact base [↗]	Which of the physical, socioeconomic, and institutional vulnerability due to climate change is considered in priority? [↗]	Physical vulnerability [↗]	P [↗]

Analysis & Result

National-level analysis results of the Climate Change Adaptation Action Plan

<Figure 1> shows the national-level analysis results of the planning ratio of each dimension. The results showed that the Climate Change Adaptation Action Plan of lower-level local governments were not based on the environmental aspect. Physical vulnerability was analyzed as most important, followed by the institutional and socioeconomic vulnerability. Most plans had policy-related plans carried out before disaster, while participation is barely considered. In addition, there was almost an equal distribution of the ratio of planning related to the structural and non-structural measures in terms of the policy. This implies that the Climate Change Adaptation Action Plan in Korea does not consider the environmental aspect and participation overall, includes policies for before disaster considering physical and institutional vulnerability, and has an equivalent distribution of structural and non-structural measures.

Figure 1. National Climate Change Adaptation Action Plan content analysis

Analysis results of the Climate Change Adaptation Action Plan by region

<Figure 2> shows the results of the comparative analysis on fact base by region. The results showed that physical vulnerability was considered most important in each region, followed by the institutional and socioeconomic vulnerability. Socioeconomic vulnerability was not considered important in all regions, and the ratio was lowest at 4.4% in Jeollabuk-do. This result indicates that the vulnerability factors considered important vary among regions depending on the current state of disaster vulnerability and circumstances, but they share the similarity that all regions did not consider socioeconomic vulnerability as an important factor.

Figure 2. Content analysis of the Climate Change Adaptation Action Plan by region (Fact base)

<Figure 3> shows the results of the comparative analysis on goal by region. The results showed that all regions were establishing plans almost without considering the environmental aspect. In particular, Gwangju and Daejeon did not establish any plan that considered the environmental aspect. This result implies that all regions did not perceive the environmental aspect as an important factor of climate change adaptation.

Figure 3. Content analysis of the Climate Change Adaptation Action Plan by region (Goal)

<Figure 4> shows the results of the comparative analysis on policy by region. The results showed that there were relatively more regions that utilized more no-structural measures. Structural measures accounted for a high ratio in Busan, Gangwon, Chungnam, Jeonbuk and Gyeongnam, while non-structural measures accounted for a high ratio in Seoul, Daegu, Incheon, Gwangju, Daejeon, Ulsan, Gyeonggi, Chungbuk, Jeonnam, and Gyeongbuk. This result implies that the regions were establishing policies suitable for them considering disaster vulnerability status and circumstances, and adopting structural or non-structural measures accordingly.

Figure 4. Content analysis of the Climate Change Adaptation Action Plan by region (Policies)

<Figure 5> shows the results of the comparative analysis on implementation and <Figure 6> on participation by region. The results showed that all regions mostly established plans related to policies for before disaster. Moreover, there were relatively fewer plans related to policies required during disaster, and Gwangju in particular did not establish any relevant plan at all. As for participation, all regions were mostly establishing plans that did not consider participation, with Gyeongnam showing the lowest ratio of participation at 3.7%. This result implies that all regions were laying more stress on the role of related institutes and organizations than participation in terms of the Climate Change Adaptation Plan, and focusing on reducing damages through prevention like the conventional disaster management plans.

Figure 5. Content analysis of the Climate Change Adaptation Action Plan by region (Implementation)

Figure 6. Content analysis of the Climate Change Adaptation Action Plan by region (Participation)

Analysis results of the Climate Change Adaptation Action Plan by disaster type

For comparative analysis by disaster type, this study came up with 12 types of disasters such as general, flood, heat wave, cold wave, typhoon, landslide, heavy snow, etc. focusing on disasters covered in the disaster sector of the Climate Change Adaptation Action Plan.

<Figure 7> shows the results of the comparative analysis on fact base by disaster type. The results showed that disasters that considered physical vulnerability as important were damages from storms and floods such as flood, typhoon, landslide, sea wave, tsunami, etc. as well as a heat wave. Disaster types that considered institutional vulnerability were general, heavy snow, and cold wave, and socioeconomic vulnerability was considered most important in cold wave and combined. In other words, socioeconomic vulnerability was considered the least by disaster type, and not considered at all in typhoon, wildfire, sea wave and tsunami. This result implies that disaster policies for damages from storms and floods and heat wave due to climate change were mostly plans to reduce physical vulnerability. For disaster policies in the winter, plans to reduce institutional and socioeconomic vulnerability were being established. On the other hand, socioeconomic vulnerability was not much considered.

Figure 7. Content analysis of the Climate Change Adaptation Action Plan by disaster type (Fact base)

<Figure 8> shows the results of the comparative analysis on goal by disaster type. The results showed that action plans were established in all disaster types except drought without considering the environmental aspect. There were no plans at all considering the environmental aspects for cold wave, wildfire and tsunami, and the percentage of considering the environmental aspects was approximately 3.6% even in the landslide disaster that requires environmental consideration. On the other hand, all plans of drought were established considering the environmental aspects. This result implies that most disaster types were adopting climate change policies without considering the environmental aspects, even in disaster types in which they can be sufficiently considered. In other words, like the analysis results by region, the environmental aspect was not perceived as a major factor to consider in the Climate Change Adaptation Plan in Korea.

Figure 8. Content analysis of the Climate Change Adaptation Action Plan by disaster type (Goal)

<Figure 9> shows the results of the comparative analysis on policy by disaster type. The results showed that there were more disaster types using structural measures than non-structural measures. Yet, there was a difference in methods adopted based on the characteristics of each disaster type. For example, disasters such as flood, typhoon, sea wave, landslide, etc. mostly adopted structural measures, whereas heat snow mostly adopted non-structural measures. This result implies that methods that can effectively deal with disasters were adopted for each disaster type, which tends to be similar to the plan contents that had been traditionally established in disaster management planning.

Figure 9. Content analysis of the Climate Change Adaptation Action Plan by disaster type (Policies)

<Figure 10> shows the results of the comparative analysis on implementation and <Figure 11> on participation by disaster type. The results showed that plans related to policies before disaster accounted for the highest ratio in most disaster types, while plans related to during and after disaster accounted for a relatively lower ratio. In particular, most plans had policies before disaster established for flood, typhoon, landslide, wildfire, drought, and tsunami. In the combined disasters, plans related to policies after disaster took up the biggest portion. As for participation, climate change plans that are not considering participation were established in all disaster types. In particular, participation was not considered at all in all disaster types except general, flood, heavy snow, and combined. This result implies that participation is almost not considered in the climate change plan contents of all disaster types, and policies mostly for prevention or preparations are being planned.

Figure 10. Content analysis of the Climate Change Adaptation Action Plan by disaster type (Implementation)

Figure 11. Content analysis of the Climate Change Adaptation Action Plan by disaster type (Participation)

Correlation analysis between disaster damage and the Climate Change Adaptation Action Plan

<Table 3> shows the results of the correlation analysis between plan contents by dimension and disaster damage. The results showed that there was a positive correlation between physical vulnerability and level of human damage, and a positive correlation between institutional vulnerability and property damage. However, the socioeconomic vulnerability had little correlation with disaster damage. There was a negative correlation between consideration of the environmental aspect and property damage, and the non-structural measure had a negative correlation with property damage and a positive correlation with human damage. Consideration of participation had a positive correlation with property damage, and there was little correlation between disaster damage and a number of plans. This result implies that regions with many property damages are concentrating on institutional vulnerability without considering the environmental aspect and tend not to adopt non-structural measures, and rather tend to adopt plans other than disaster response based on participation. Moreover, regions with many human damages mostly focus on physical vulnerability and tend to adopt non-structural measures.

Discussion

The analysis by region showed that all regions were establishing the action plans without considering the environment and participation as important. Moreover, most regions were establishing plans related to physical vulnerability, as well as plans for ‘prevention’ or ‘preparations’ implemented before disaster. Yet, while there were relatively more regions

establishing plans based on structural measures, there was not much difference among the methods.

The analysis by disaster type showed that the environmental aspect was not considered as important in all disaster types except drought, and participation also was not considered as important in all disaster types. Physical vulnerability was considered important in most disaster types, but generally, cold wave, heavy snow, and wildfire considered institutional vulnerability and combined disasters considered socioeconomic vulnerability as important. While there were relatively more disaster types establishing plans based on structural measures, there was not much difference among methods. Furthermore, most disaster types were establishing plans for ‘prevention’ or ‘preparations’ implemented before disaster.

Based on the results above, this study comes up with the following implications about the tendency of the Climate Change Adaptation Action Plan in Korea. First, lower-level local governments in Korea tend to establish the Climate Change Adaptation Action Plan for before disaster without considering the environment and participation. This implies that lower-level local governments have limitations in considering the environment and participation when establishing climate change plans. Above all, this indicates that such factors are not perceived as important factors of climate change plans in the disaster sector. Furthermore, they are focusing ‘climate change adaptation’ in disasters on reducing disaster damages that may be caused by climate change.

Consideration of vulnerability by region varies depending on disaster vulnerability status due to climate change and regional circumstances, but it was found that physical or institutional vulnerability was considered important, while the socioeconomic vulnerability was barely considered. This implies that efforts are made actively to reduce physical or institutional vulnerability due to climate change, but socioeconomic vulnerability is considered relatively less importance. In other words, socioeconomic vulnerability does not take up many portions of disaster vulnerability in the region and is considered less important.

Similarly, climate change policies were adopting different methods depending on disaster type. For example, disasters with damages from storms and floods such as flood, typhoon, sea wave, etc. had a higher ratio of structural measures, while heavy snow had a higher ratio of non-structural measures. However, considering that the major disaster type according to climate change in most regions is damage from storm and flood, the ratio of structural measures is higher in many regions.

As a result of analyzing the correlation between disaster damage and plan contents, plans to reduce physical vulnerability had a positive correlation with human damage, and plans to reduce institutional vulnerability had a positive correlation with property damage. This implies that the action plans in Korea were using plans to reduce physical vulnerability in regions with more human damages, and plans to reduce institutional vulnerability in regions with more property damages. However, the low correlation of socioeconomic vulnerability shows that it is relatively not considered much in the plans by region.

The negative correlation between property damage and consideration of the environmental aspect indicates that regions with greater property damage were establishing plans without considering the environmental aspect. This is because regions with more property damages were more preferentially considering policies that can produce quicker damage reduction effects than long-term measures considering the environmental aspect.

Non-structural measures had a negative correlation with property damage and positive correlation with human damage. This indicates that lower-level local governments tend to more prefer adopting non-structural measures to reduce human damage, but rather tend not to prefer non-structural measures to reduce property damage.

Conclusion

The present study analyzed the Climate Change Adaptation Action Plan of lower-level local governments in Korea by region and disaster type using four dimensions. In addition, it analyzed the tendency to plan contents by analyzing the correlation between the details of each dimension and damages due to disasters. The results showed that many of the Climate Change Adaptation Plans in Korea were establishing adaptation measures that can be performed before the disaster in order to reduce physical vulnerability. There was a difference in the ratio of structural or non-structural measures depending on region and disaster type, but overall there was a balanced distribution. However, the environmental aspect and participation were not considered in most policies.

Regions with many property damages tended to establish plans based on participation in order to reduce institutional vulnerability. On the other hand, they tended to prefer policies based on methods other than non-structural measures without considering the environmental aspect, and plans to implement in stages other than during disaster. Regions with many human damages tended to prefer policies based on non-structural measures to reduce physical vulnerability.

In conclusion, the Climate Change Adaptation Plan of lower-level local governments in Korea were analyzing disaster vulnerability due to climate change faced by each region. However, there were limitations in considering aspects of the environment and participation in the contents of the plan. This indicates that most regions were not considering the environmental aspect as important in establishing disaster policies within the climate change plan. Furthermore, there is lack of consideration for participation as planning is carried out 'top-down'. This tendency may be an obstacle to improving the autonomous adaptation capacity of each local government for climate change and establishing more sustainable plans and policies.

To overcome these limitations in plan contents, the following matters can be improved. First, it is necessary to add policies to induce participation in the Climate Change Adaptation Action Plan. It is important to improve the abilities of major institutes and agencies to deal with disasters caused by climate change, but it is more essential to improve adaptation capacity and knowledge of individual citizens. This is necessary for the nation to effectively handle climate change, based on which the overall climate change adaptation capacity of the nation can be secured.

Second, the Climate Change Adaptation Action Plan must also actively consider the environmental aspect to establish sustainable climate change adaptation and reduction policies. Considering the environmental aspect in climate change adaptation and reduction measures in terms of disaster management indicates that damages can be reduced by improving the nature's and ecosystem's ability to adapt to climate change. In other words, the Climate Change Adaptation Action Plan considering the environmental aspect will improve environmental competencies in the long run, ultimately contributing to improving adaptability to disasters, and can be used as a more sustainable adaptation plan for climate change.

Third, the Climate Change Adaptation Action Plan must further add consideration of socioeconomic vulnerability. Socioeconomically vulnerable groups are more vulnerable to disasters due to climate change, and thus planning to protect them must be considered. This is the nation's duty and obligation to improve the safety of the society overall toward disasters due to climate change, and must be considered additionally in the contents of the climate change plans in the future.

Resilient Planning of Chinese Delta Cities Under Climate Change

Xinyi Zhang¹, Cheng Shen²

¹Tongji University, 15221373783@163.com

²Tongji University, 1064974373@qq.com

Abstract: Contemporary cities and territories are facing significant challenges of natural disasters due to climate change impacts. Urbanized deltas represent some of the most vibrant and diverse ecosystems. However, its unique conditions of low altitude, land subsidence, and rapid urbanization make it more vulnerable when being subject to risks such as tide, storm surge, rainstorm, etc. caused by climate change. Firstly, this article reviews recent studies on theories and practice of city and regional resilience, and analyzes the spatial implications of it. Secondly, it analyzes the geographical characteristics, regional urban system, economic and social correlation, multi-scaled life cycle, and so on of China Yangtze River Delta cities. On the basis of this, it puts forward several problems in resilience planning practices faced by the Delta area. Thirdly, it proposes that general resilience development objective of delta cities is to promote their ability to deal with climate change. Some strategies including basic principles and steps of resilience planning such as plurality and diversified infrastructure, redundancy and multi-scaled networking, self-organized and self-renewal region / neighborhood / architecture / landscape layout are put forwarded. Lastly, the key thoughts in the China Yangtze River Delta Cities resilience planning are systematically exploring uncertainties related to future trends and disruptive events, thinking through the impacts of each sector on other sectors and the area as a whole, and making joint visions and identifying strategic projects not only among public actors but also with private and civic actors.

Keywords: regional resilience; delta cities; network structure; planning and design

1. Introduction

Urban resilience is of great significance to the sustainable development of cities. As a complex social ecosystem, they have always suffered from various disasters. In order to improve their ability to cope with uncertain risks and enhance the recovery capability after major impacts, it is necessary to conduct research on the resilience of cities and regions. Because of the large population and the developed socio-economic environment, the delta cities have become an important part of the world's urban system. However, due to its special geographical location and complex artificial ecosystem, the delta cities are frequently affected by extreme weather. Therefore, they need to deal with uncertain climate disasters and the changing external environment with more resilient development strategies. As an important area of China, the urban agglomeration in Yangtze River Delta is a node connecting the “Belt and Road” and the Yangtze River Economic Belt, and plays an important role in the national social and economy development. However, the unique geographical location makes the region face the severe challenges caused by uncertain disasters. So building a resilient regional network and making relevant urban planning is very important for the sustainable development of them. This article reviews the theories of city and regional resilience, and proposes corresponding planning and development strategies based on network structure analysis of the Yangtze River Delta.

2. Research on urban and regional resilience

2.1 The resilience theories

The concept of the resilience was first proposed by Canadian ecologist Holling in his article "Resilience and stability of Ecological systems", which means that the object returns to its original state after being damaged. Then the concept has experienced several evolutions. Its meaning gradually shifts from traditional engineering and ecological resilience to evolutionary resilience. The focus of relevant research has also shifted from a linear system that seeks to achieve stability to a nonlinear system that seeks continuous adaptation, and further emphasizes learning and adjustment to the next disturbance.

2.2 Urban resilience

Since the 21st century, resilience has gradually been applied to urban research and planning, forming the concept of resilient cities. Alberti first defined urban resilience as the ability of the city's structure and function to maintain its original state after the internal and external driving forces of urban development changed. The Resilience Alliance proposes that urban resilience is the ability of a city or urban system to digest and absorb external disturbances while maintaining the original main features, structures, and key functions, and they also summarize and construct a framework for resilient urban research. Wilbanks argues that the urban resilience refers to the ability of urban systems to prepare, respond to, and recover from specific multiple threats, minimizing their impact on public safety, health, and the economy. It can be seen that the urban resilience not only refers to the ability of the city to recover after being disturbed, but also pays attention to the city's ability to predict disturbances and disasters.

Scholars from different fields have analyzed the characteristics of resilient cities from multiple perspectives. Verdowski believes that resilient cities should be characterized by dynamic balance, multiple compatibility, efficient flow and moderate redundancy. Bruno believes that resilient cities should have the ability to cope with changes in terms of technology, organization, society and economy. Allan argues that resilient cities should have adaptability, innovation, responsiveness, capital reserve capacity, and ecosystem service capabilities. Overall, urban diversification, cross-scale network connectivity, high adaptability and moderate redundancy are the main characteristics of resilient cities.

2.3 Regional resilience

As the resilience theory is gradually applied to regional scales, research on regional resilience development has received increasing attention. Regional resilience is a comprehensive measure of multi-scale social ecosystems, including prevention of potential threats, defense against disasters, and the ability to recover from disturbances. Compared with urban resilience, it emphasizes the connection between cities and the construction of regional network, which means that by building a resilience framework through urban nodes and their connections can not only enrich and stabilize the regional development process but also promote the inner cities of the region as a whole to resist uncertain disasters and risk. Regional resilience is mainly reflected in four aspects of engineering, economic, social and ecological resilience.

Engineering resilience refers to the ability to promote the coordination of different cities and effectively resist disasters by constructing regional infrastructure networks. Economic resilience refers to improving the adaptability of cities in dealing with external disturbances through the rational distribution of industries, technologies and labor in the region. Social resilience refers to the ability to maintain the stability of social systems in different cities through the cooperation of multi-level organizations. Ecological resilience refers to the ability of diverse and extensive ecosystems to absorb disturbances and maintain original ecological functions.

3. Delta regional resilience

3.1 Delta city and regional characteristics

In recent years, due to frequent climate disasters, the resilience of the delta urban area has become the focus of related research. As a special artificial ecosystem, due to the topographical conditions formed by the impact of water flow, the foundation settlement caused by a large number of constructions and the ecological damage caused by urban sprawl, the delta urban area is more vulnerable to natural disasters such as tides, storm surges and heavy rains. These factors lead to uncertainty in the future development of the Delta urban area. With the increasing climate change, the current economic development-oriented spatial planning is difficult to promote the resilience of the delta region. How to build a network between cities and enhance regional resilience is a question that must be considered in the future sustainable development of the delta urban area.

The Yangtze River Delta region is one of the most important urban agglomerations in China. It is located in the alluvial plain of the Yangtze River estuary and has typical delta natural geographical features. Moreover, the social and economic development of this region is rapid, the population is gathering, and the density of the cities is continuously increasing, forming a complex social ecosystem. This paper evaluates the resilience of this region from the perspective of urban network structure and spatial distribution pattern, and identifies the problems existing in the development process. Based on the above analysis, planning strategies for optimizing the regional network structure are proposed, which provide suggestions for the delta regional resilience development.

Fig. 1 Research framework for Delta region resilience

3.2 Factors influence the regional network structure resilience

The network consists of nodes and the connections between them. Nodes and connections are the two basic elements of the network. The regional network refers to the urban groups formed by the close integration of the cities as nodes through the flow of elements. And the network structure refers to the state it presents in space, including the size, number, and location of the cities participating in the construction of the network and the strength and concentration of connections between them. The ability of the network structure to cope with external disturbances and gradually restore, maintain and improve the characteristics of the original system is the resilience of the network structure. The attributes of the network structure and the characteristics of its internal systems directly affect its function and resilience. Researches consider that the location and hierarchy distribution of nodes; the heterogeneity, hierarchy, connectivity and aggregation degree of connections are important factors affecting network function and structure.

This paper takes 26 cities in the Yangtze River Delta region as the research object, and uses the complex network theory and UCINET social network analysis tools to evaluate the structure resilience of the region from engineering, economic, social and ecological aspects and proposes planning strategies. Combined with relevant research, this paper takes hierarchy, transmission and aggregation as important indicators to measure the structural resilience of the regional network. Hierarchy is represented by the number of cities of different levels in the network. A strong hierarchy means that the high-level cities in the network are dominant, which will lead to a more vulnerable structure. Transmission is used to evaluate the length of the connection path between nodes.

If it is short, various elements can be transmitted at a lower cost and faster speed, thereby improving the structure resilience of the network. Aggregation reflects the compactness of the network. A network with a low degree of aggregation contributes to the inflow of external information, thus improving the resistance to external disturbances.

3.3 Construction and evaluation of urban networks

On the basis of determining the evaluation indicators of network structure resilience, this paper constructs the transportation, enterprise, information and ecology networks in the Yangtze River Delta region from four aspects of engineering, economy, society and ecology, and analyzes their structure characteristics.

3.3.1 Construction of urban system networks

(1) Transportation network: Passenger and cargo transportation in the Yangtze River Delta region mainly relies on roads and railways. This paper calculates the traffic connection between cities by long-distance bus shifts, regular and high-speed train shifts. According to the formula:

$$T_{ij} = \frac{(Q_i + Q_j)/Q + (C_i + C_j)/C}{2D_{ij}^2}$$

the strength of the connection between cities can be determined, and then the regional transportation network model can be constructed. In the formula, T_{ij} represents the traffic intensity of i city and j city, Q_i and Q_j represent the total passenger traffic of roads and railways between two cities; C_i and C_j represent the total freight volume of roads and railways between two cities; Q and C respectively represent the average passenger traffic and average freight volume of roads and railways between the cities in the Yangtze River Delta; D_{ij} represents the sum of highways and railways between the two cities.

(2) Enterprises network: As typical multi-location organizations, enterprises have branches in many cities among the region for the purpose of expanding their scale and preempting their share, thus forming a complex enterprise network. By analyzing the financial links between the cities where the headquarters and their branches are located, urban nodes and connection matrices can be constructed to study the structure and flow relationship of the economy network. According to the formula:

$$V = \sum_{j=0}^m v_j(a, b)$$

the strength of the connection between cities can be determined, and then the regional enterprise network model can be constructed. In the formula, V is the sum of the capital connections between all the companies in the two cities, that is, the contact value formed by the city a and the city b through m enterprises; a and b are the cities where the headquarters and branches of the company j are located, and $V_j(a, b)$ is the total investment of the company j in these two cities.

(3) Information network: The regional information network is constructed through the information links between cities reflected by the web search index. The web search index is a data statistics platform based on user behavior data. It is an indicator that reflects the attention of website users and mainstream media to some keywords. This paper obtains the web search index between cities in the Yangtze River Delta. And according to the formula:

$$M = A_b \times B_a$$

the strength of the connection between cities can be determined. Then the regional information network model can be constructed. In the formula, M refers to the information flow intensity between City A and City B; A_b refers to the average value of the web search index from A to B; B_a refers to the average value of the web search index from B to A.

(4) Ecology network: Based on remote sensing images in the Yangtze River Delta, the land in the region is divided into forest land, grassland, cultivated land and other types. The areas with better integrated ecological service functions are selected as ecological sources, and the ecology network is constructed by using the least cost path model. Due to the different costs of ecological corridors passing through various types of land use, this paper first gives values for multiple land use within the region. Then according to the formula:

$$MCR = f_{\min} \sum_{j=n}^{i=m} (D_{ij} \times R_i)$$

In the formula, MCR is the minimum cumulative cost value, f_{\min} is the minimum cost value between ecological sources, D_{ij} represents the spatial distance from source j to landscape unit i , and R_i represents the cost value of landscape unit i . The value of $(D_{ij} \times R_i)$ can be used to measure the accessibility of a species from unit j to unit i .

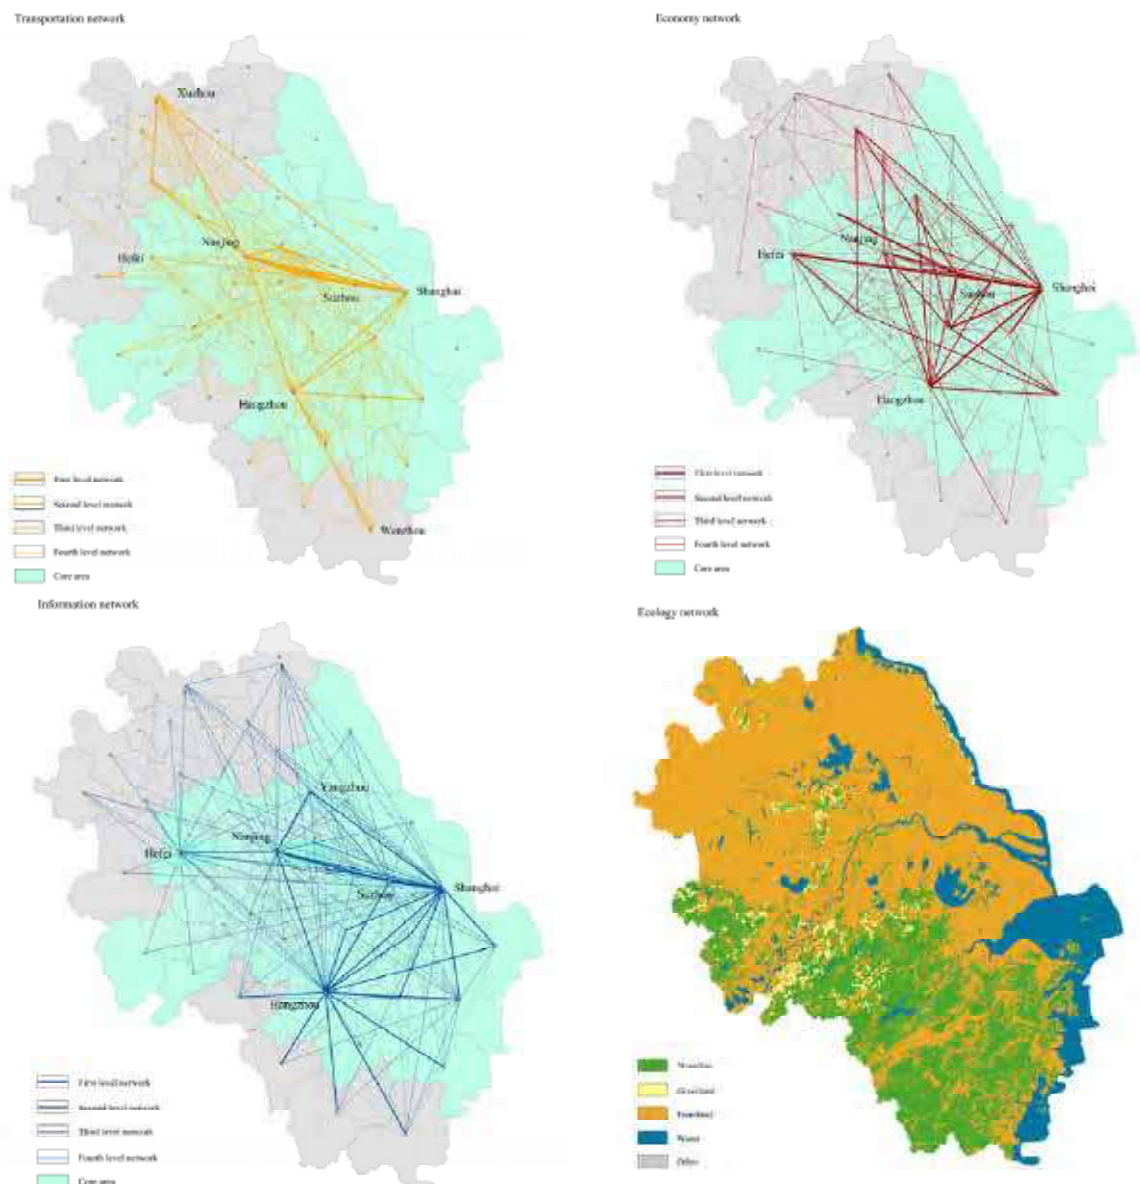

Fig. 2 Transportation, Enterprises, Information and Ecology networks

3.3.2 Evaluation of network structure resilience

(1) Hierarchy evaluation: This paper evaluates the hierarchy of regional network by degree distribution. Degree refers to the number of connections between a node and others in the network. And the distribution of degree reflects the overall structural characteristics of the network. According to the formula:

$$\ln(K_h) = \ln(C) + a \ln(K_h^*)$$

In the formula: K_h represents the degree of the node h ; K_h^* represents the rank of its degree in the network; C is a constant; a represents the slope of the degree distribution curve.

The results show that the slopes of the four networks' degree distribution fitting curves are large, and $|a|$ is between 0.6 and 0.9. This means that the Yangtze River Delta regional network has a high level of hierarchy, indicating that there is a core city group with strong dominance in the region. Among them, the hierarchy of enterprise and information networks is higher and the core cities are more prominent which means that these networks have the characteristics of heterogeneity, while the transportation and ecology networks have flat features.

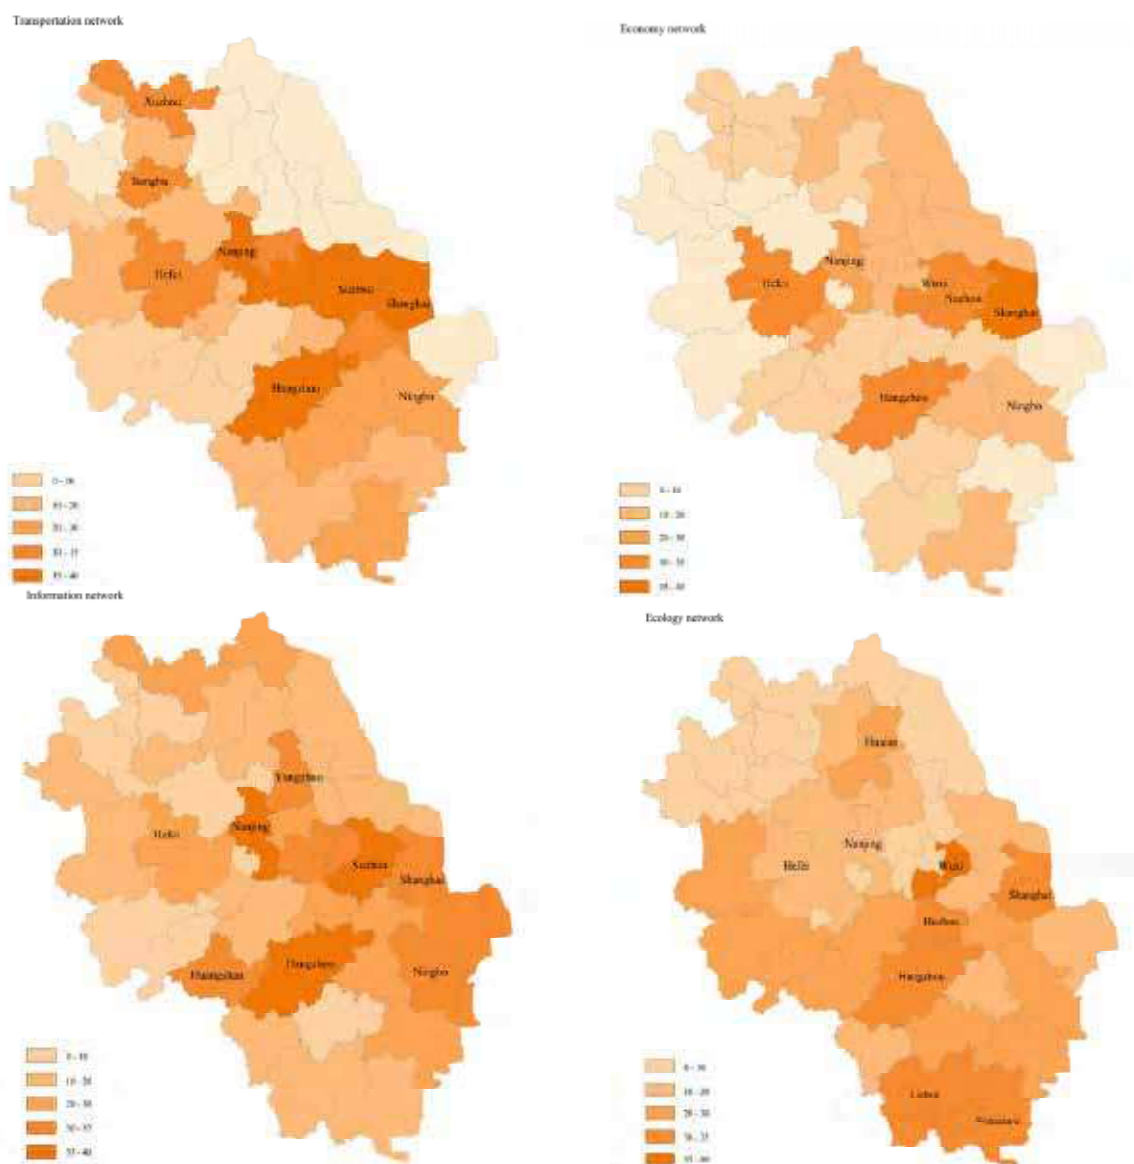

Fig. 3 Degree distribution of transportation, Enterprises, Information and Ecology networks

(2) Transmission evaluation: This paper evaluates the transmission of regional networks by the average path length. The longer the average path length of the network, the more time it takes for elements to spread from one node to another, indicating that the transmission efficiency of the network is lower, and vice versa, the diffusion effect of the network is stronger. Its formula is:

$$L = \frac{1}{1/2n(n+1)} \sum_{i \neq j} d_{ij}$$

In the formula, L is the average path length; n is the number of nodes; and dij is the distance from node i to j.

The results show that the average path lengths of the four networks are between 1.3 and 1.7, which means that the transfer of elements between cities requires only 2 nodes. It indicates that the network transmission efficiency in the Yangtze River Delta region is generally high. The average path length of the transportation network is 1.526, which is the shortest path among the four networks, and its regional accessibility and diffusivity are stronger. The average path lengths of enterprise and information networks are 1.585 and 1.573. The efficiency of factor transmission between cities is lower than that of transportation network, resulting in relatively high additional costs for activities such as personnel mobility, technology diffusion and information transmission. The average path length of the ecology network is 1.625, indicating that the number of ecological corridors in the Yangtze River Delta region is small and the connection between ecological sources is loose. It can be said that the ecological resilience of the region is not ideal.

Fig. 4 Topological diagram of transportation, Enterprises, Information and Ecology networks

(3) Aggregation evaluation: Network aggregation can be evaluated by local and average clustering coefficients. The local clustering coefficient is a parameter that describes the degree of aggregation of network nodes. Since it calculates only the aggregation of a single node to neighboring ones, the overall aggregation of the network can be evaluated by calculating the average clustering coefficients of all nodes. Its formula is:

$$C_i = \frac{2E_i}{k_i(k_i - 1)}$$

In the formula: k_i is the degree of node i , which is the number of nodes adjacent to it; E_i is the number of connections between node i and the neighboring ones.

The results show that the average clustering coefficients of the four networks are all around 0.8, which indicates that most cities in the network have connections with their neighboring cities and form groups, and there are only a few isolated nodes. The regional network is well aggregated. If the local clustering coefficient of a single node city is calculated, it can be found that the values of core cities such as Shanghai, Hangzhou, and Nanjing with higher degrees are all around 0.37~0.53. It means that there are fewer connections between low-level cities which are connected to those core cities. The ordinary cities in the regional networks have more one-way connections with core cities, while the interaction between them is less.

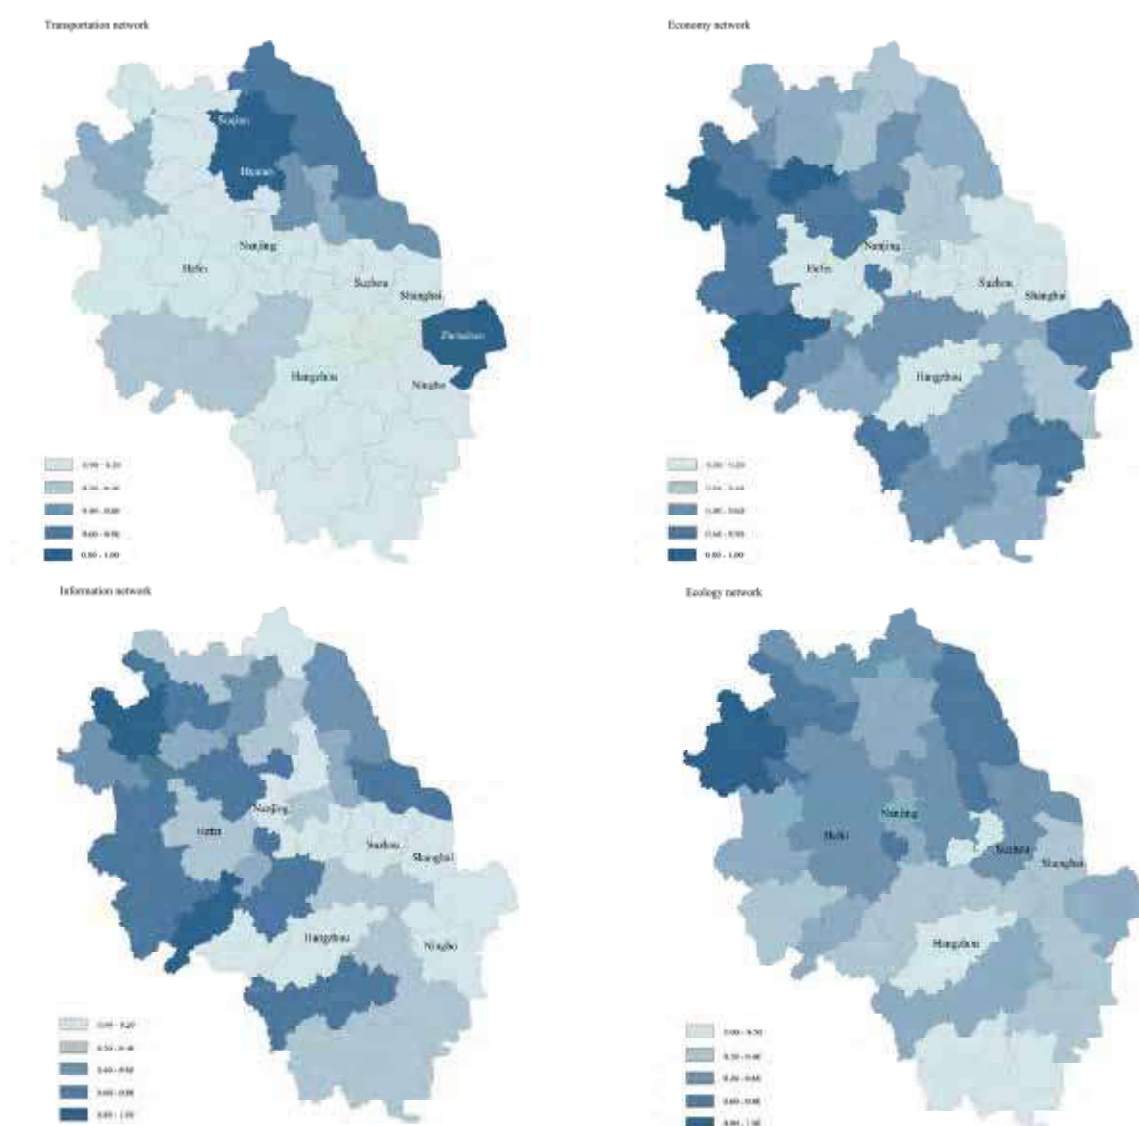

Fig. 5 Clustering coefficient of transportation, Enterprises, Information and Ecology networks

3.3.3 Network structure resilience characteristics

Overall characteristics of the network structure. Through the evaluation of the network structure, it can be seen that the central node groups of the above four networks are composed of provincial capitals such as Shanghai, Hangzhou and Nanjing, which makes the Yangtze River Delta region network forms a core-edge structure with these important cities as the core nodes. Analyze the structural characteristics of the four networks separately. In terms of transportation network, the highway and the railway system form the skeleton of the contact network in the Yangtze River Delta region, and the node cities located on the axis have a high degree of correlation, showing the core-edge structure characteristics. In addition, with the construction of high-speed railway network, the traditional structure is gradually shifting to a flat, uniform structure. The economy network in the Yangtze River Delta region has significant hierarchical characteristics. Shanghai is the absolute core of the region; Nanjing, Hangzhou, and Suzhou are at the second level as sub centers and ordinary cities in the region are in the third level. As the cores of the region, Shanghai, Hangzhou and Nanjing have high network connectivity and form a cohesive city group with the cities around them. The structure of the regional information network is relatively balanced and is gradually forming a compact information exchange circle. Shanghai, Hangzhou, Nanjing are the hubs of the network, and the intensity of information flows between them are huge. As economy and transportation connections rising, the information links within and between provinces are gradually increasing. The regional ecology network has formed a structure in which the Tai Lake is the core and several ecological corridors are connected to each other. A number of ecological sources in the area are connected along the Yangtze River Ecological Corridor, the Hangzhou Bay Ecological Corridor and the Central Ecological Axis. It can be said that the regional ecological structure framework is basically formed, but the resilience ability still needs to be strengthened.

Tab. 1 Summary of measurement results of four kinds of network structural resilience

	Hierarchy	Transmission	Aggregation
	Degree distribution	Average path length	Clustering coefficient
Transportation Network	-0.827	1.526	0.826
Enterprises Network	-0.852	1.585	0.785
Information Network	-0.815	1.573	0.819
Ecology Network	-0.844	1.625	0.751

Diversified characteristics of network connections. According to the evaluation results, the gap between the four networks in terms of transmission and aggregation is not obvious, but there are some differences in their hierarchy. Specifically, the radiation capacity of economy network is weak. The economic connections within the region have strong near-regional jurisdiction, which occur mainly between provincial capitals and cities close to them. There is not much interaction between the central urban agglomerations and the cities farther away from them, even the cities across the province. However, the radiation capacity of information and transportation networks is relatively strong, and there are more interactions between central cities and peripheral cities, which leads to cross-administrative areas connections. In addition, the hierarchy of the information network is weak, which means that it has rich and diverse contact paths while having some strong central city groups with radiation capability, make it respond quickly in the face of external disturbances. Therefore, it has good resilience. The regional ecology network has weak radiation capabilities and its hierarchy is high, which leads to its core-edge structure. The concentrated distribution of ecological sources and the insufficient number of ecological corridors will have an impact on its structure resilience. In summary, the resilience of the information network is the best, the transportation network is second, the economy and ecology networks' resilience needs to be strengthened.

It can be seen that the urban network with the core-edge structure has basically formed in the Yangtze River Delta, and the multi-system networks such as economy, society, space and ecology all have certain development resilience. This single structure reduces the radiation and connection capacity of the system. When the external conditions change drastically, the network may be broken, unable to reconnect, and reduce the resilience of the region. However, with the improvement of regional coordination capabilities and the development of transportation-communication technology, the urban network of the Yangtze River Delta will gradually transform into a center-periphery structure, forming a diverse and stable process of resilience development.

4 Strategies for optimizing network structure in the Yangtze River Delta

4.1 Promote the network structure transformation

The development of the Yangtze River Delta region spans multiple scales, involving social, economic, and environmental factors. There are extensive and complex internal connections between them. In order to enhance the resilience of the regional network structure, it is necessary to take advantage of the core urban groups' promotional capacity to drive the development, and comprehensively consider the hierarchical relationship of cities within the region to guide the coordinated development of large, medium and small cities. The improvement of regional resilience should not only clarify development goals, but also strengthen the radiation capacity of core cities which are the concentration of resource elements, and enhance regional influence and competitiveness. At the same time, it is necessary to increase the connections between cities of various hierarchy, enhance the ability to cooperate, and carry out functional division, coordinate industrial space, and share infrastructure according to the cities' advantages. In the end, it is necessary to achieve a reasonable distribution of the cities' scale and function in the network by structural adjustment, so as to improve the regional resistance to cope with external disturbances.

4.2 Enhance the flow of elements between cities

The current transmission efficiency and diffusion capacity of the Yangtze River Delta regional network is good, and the flow of factors between cities can be further improved in the following aspects. Strengthen the concentration and cooperation of enterprises. The division of functions between cities and the organization of industrial spaces are the important strategies for regional resilience development. By building advantageous industrial clusters across cities and relying on the development axis along the Yangtze River, it is possible to promote the concentration and cooperation of regional industries. Construct information exchange spaces. By implanting knowledge information carriers and focusing on cultivating high-tech innovation parks, research centers and university towns, we can promote the prosperity of regional science and technology. Accelerate infrastructure construction. It is necessary to focus on strengthening the main axis of transportation, making it a comprehensive channel with complete functions and strong transportation capacity. At the same time, we should also integrate the internal transportation networks of each province and cities, improve the carrying capacity of rail transit, and accelerate the construction of expressway and intercity railway networks. Adjust the structure of the ecosystem. In the context of national land planning, we can integrate the current ecological resources and organize existing ecological sources and corridors. And cities of different types and grades should adopt corresponding ecological protection measures, focusing on strengthening the governance and control of fragile urban areas.

4.3 Take into account multiple subjects in the regional resilience development

There are a large number of cities in the Yangtze River Delta, so the resilience development needs to take into account the diversified requirements of multiple subjects. Affected by administrative boundaries and participating entities, the current development goals and speeds of cities are different. As a whole, the Yangtze River Delta needs to eliminate the adverse effects caused by it as much as possible, so it is necessary to consider the demands of different regions. At the regional scale, a city collaborative management platform should be established to actively promote the inclusiveness of resilience development from the aspects of urban planning, industrial development, spatial convergence and infrastructure construction. At the city level, we need to ensure

the exchange of information between governments, developers and community residents, so that communication and inclusion can be used as an entry point for the development of urban resilience. Whether it is the construction of multi-functional sites or the mixed use of land, all the subjects in the city must be as compatible as possible.

5 Conclusion

Resilience is an important trend in the development of the world's cities. It is also the path that China's delta urban agglomerations must choose when they face a changing external environment. The theory of resilience planning has positive significance for both urban and regional planning. Based on the theory of urban and regional resilience development, this paper analyzes the network structure resilience of the Yangtze River Delta from the aspects of hierarchy, transmission and aggregation by constructing four networks of transportation, economy, information and ecology in the region. Overall, the region has basically formed a core-edge network structure, and multiple systems have a certain level of resilience development. The network structure of different systems has diverse characteristics, and there are differences in hierarchy, transmission, and aggregation. Among them, the resilience of information and transportation networks is strong, but the economy and ecology network has weaker resilience due to their poor radiation capability; Based on the above analysis, this paper proposes some planning strategies for optimizing the regional network structure, such as promote the structure transformation, Enhance the flow of elements and take into account multiple subjects. By studying relevant theories and conducting empirical analysis on the Yangtze River Delta, this paper hopes to explore the rational path for the resilience development of the delta urban agglomeration and improve their social ecosystem's ability to resist external disturbances.

Abstract: Over the last decade, the concept of circular economy has gained momentum among practitioners, politicians and scholars thanks to its promise of achieving sustainability goals. However, there remains a need to demonstrate and assess its positive environmental impacts. With respect to the building sector, circular economy is still a relatively new topic. To date, research has tended to focus primarily on the macro-scale (cities or eco-parks) and micro-scale (manufactured products or construction materials). Nevertheless, the often-neglected built environment is also expected to play a crucial role due to its high contribution to various environmental impacts.

Accordingly, this paper aims to contribute to this growing area of research by reviewing four case studies of 'circular neighbourhood' projects in Europe. First, a conceptual framework analysis is defined and applied to the cases. Second, circular economy initiatives and actions are identified and classified using interviews and document analysis. Third, the use of assessment tools within these circular economy projects is investigated. The results demonstrate a diverse representation of the circular economy paradigm and a growing role played by the assessment tools.

Keywords: Circular Economy; Life Cycle Assessment; Urban Project; Circular neighbourhood.

Introduction

Over the last 10 years especially, the concept of a circular economy (CE) has been gaining momentum in politics, business and academia (Reike, Vermeulen, and Witjes 2017; Kampelmann 2016) in the pursuit of overcoming the contradictions between economic and environmental prosperity (Geissdoerfer et al. 2017). Indeed, the current economic model, which can be characterised as 'linear' based on a 'take-make-consume-throw away' approach of resources, is presently reaching its limits. Conversely, the CE forms an "economic system of trade and production which, at all stages of the product lifecycle, aims to increase the efficiency of resource use and reduce the impact on the environment, while developing the well-being of individuals" (ADEME 2014). For these reasons, CE already represents the core theme of major European plans and regulations (Petit-Boix and Leipold 2018), such as the 'Circular Economy Package' adopted in 2015.

Today, CE is studied by several disciplines ranging from economics to urban planning, though it remains closely linked to sustainable development issues (Kirchherr, Reike, and Hekkert 2017). However, to date, no univocal and shared definition of CE has yet been developed, despite a wide dissemination of the concept (Prieto-Sandoval, Jaca, and Ormazabal 2017). Thus, CE constitutes an

evolving notion (Merli, Preziosi, and Acampora 2018), rather ambiguous and vague (Korhonen et al. 2017).

The built environment, given its important contribution to several environmental issues, is supposed to comprise one of the main targets of CE strategies. However, current scientific literature on this subject remains limited, and concrete application of the principle is slow to be implemented (Densley Tingley, Giesekam, and Cooper-Searle 2018; Adams et al. 2017; Pomponi and Moncaster 2017). Furthermore, little general consensus exists concerning how to best approach and deal with this concept, and the knowledge and tools required to enact it remain to be developed (Leising, Quist, and Bocken 2018).

This is especially true for the building sector, to which CE remains a relatively new topic (Adams et al. 2017; Bocken et al. 2017). Furthermore, there is still a need to demonstrate and assess its positive environmental impacts. Indeed, implementing CE initiatives not only generates potential benefits, but also a number of environmental risks. ‘Closing the loop’ does not always positively affect the environment, and therefore, ‘circularity’ should be analysed against relevant indicators (Petit-Boix and Leipold 2018; Kampelmann 2016). In addition, it is also necessary to ensure that the most environmentally relevant initiatives are realised. For this reason, the need for systemic methods and tools to validate the environmental relevance of the CE applied to the built environment is now evident (Haupt and Zschokke 2017; Haupt, Vadenbo, and Hellweg 2017).

Accordingly, this paper aims to contribute to this growing area of research, which currently remains in its infancy. The results indicate a diverse representation of the CE paradigm and confirm that assessment tools could bring a useful contribution because if CE remains a vague trendy expression, there is a high risk of greenwashing. Life cycle assessment (LCA) appeared in the early 1990's and even if the expression CE was not used at that time, most ideas corresponding to CE were already integrated. For instance, recycling was one of the aspects studied in order to reduce environmental impacts of the built environment. A method has been elaborated that accounted, among other aspects corresponding to the CE approach, for environmental benefits of recycling at the fabrication stage but also after deconstruction (Polster, 1996).

CE in the built environment: from the ‘circular city’ to the ‘circular neighbourhood’

As mentioned, the CE approach is gaining momentum in the field of urban sustainability. Several studies, as well as some international meetings, have investigated the role that the CE can play in ensuring a more sustainable city, and the literature on this subject continues to grow (Cities Foundation 2017; Ellen MacArthur Foundation 2017; Prendeville, Cherim, and Bocken 2018).

According to Pomponi and Moncaster (2017), three scales of CE deployment can be identified from the scientific literature: the ‘macro scale’ of the city, the ‘meso scale’ of the buildings, and finally, the ‘micro scale’ of the construction elements. However, while academic research is more consistent concerning the macro scale (particularly in urban metabolism and eco-parks), as well as the micro scale (particularly in materials and building components), the meso scale remains poorly explored (Pomponi and Moncaster 2017).

Considering their pressures on the environment, to date, the scientific literature on CE has focused more attention on the ‘circular city’ topic.

Several cities, such as Berlin, Rotterdam, Paris, London, Milan and Amsterdam, have recently adopted strategic plans and are launching specific actions and projects to make their economy more circular. In 2014, for instance, the city of Amsterdam adopted ‘The Circular Metropolis Amsterdam 2014–2018’¹, a strategic document aimed at transforming the city into a competitive and sustainable European metropolis. This document, which comprises part of the Amsterdam Smart City initiative, is based on the ‘The City Circle Scan’ approach, enabling areas to be identified where major CE progress can be made. Thanks to this tool, Amsterdam has decided to focus on the construction sector as well as the organic production and biomass sector. In addition, in 2016, Amsterdam became a Fab-City, an international initiative bringing approximately 20 cities together with the goal of becoming self-sufficient². Similarly, the city of Rotterdam also linked the EC to the smart city initiative, adopting the ‘Roadmap Circular Economy Rotterdam’³ in 2016. The proposed actions to ensure the city’s sustainable and circular development by 2030 are based on the results of the ‘Rotterdam Metabolism’ study, which provided a comprehensive picture of urban flows. Rotterdam’s EC strategy focuses primarily on the city’s port area for implementing biosourced projects (Prendeville, Cherim, and Bocken 2018).

More recently, London and Paris also presented guidance documents in 2017. Following the 2015 General Assembly of the Circular Economy, Paris adopted its first ‘Circular Economy Plan 2017–2020’⁴ and its operational roadmap. London similarly published a ‘Circular Economy Route Map’⁵, containing actions involving the construction, food, textile, plastic and electrical industries. This document is accompanied by an economic analysis, which estimates the benefits to the economy in terms of wealth creation, activities and employment at £2.8bn.

Initiatives and actions are multiplying and global networks are being created, bringing together several cities. The Circular Europe Network (CEN)⁶, for example, brings together dozens of European cities to promote the exchange of best practices. At the international level, the Open Source Circular Economy (OSCE)⁷ collects innovative solutions linking EC and open data.

Otherwise, current research on CE has dedicated little attention to the meso scale, whereas some authors have stressed the importance of orienting CE research towards the built environment (Leising, Quist, and Bocken 2018; Pomponi and Moncaster 2017; Glass, Greenfield, and Longhurst 2017). Indeed, in Europe, the built base represents almost half of the total energy consumption, and more than 50% of all extracted materials (European Commission 2011). In France, nearly 40% of energy consumption and 60% of electricity are attributed to this, which is also responsible for the emission of approximately a quarter of national greenhouse gases (ADEME 2012). In addition, the construction sector generates nearly three-quarters of the national waste⁸ volume and consumes approximately 600 km² of natural areas per year⁹.

⁹ <http://www.developpement-durable.gouv.fr/Etalement-urbain-et.html>

In this context, the built environment could truly represent an essential cornerstone for implementing effective CE strategies in the city. Concerning the meso scale, several authors have pointed out that the ‘neighbourhood scale’, the link between the city and the building, is the most relevant for addressing numerous environmental problems (Lotteau 2017). In Europe, the attention paid to the neighbourhood scale has even become central to the sustainable city discourse (Souami 2009). By contrast, however, limited research has been conducted concerning the application of CE principles in neighbourhoods, and there is a lack of comprehensive studies summarising recent development. Nevertheless, a number of pathfinder projects are beginning to emerge in the practice. Assessment tools have been developed (Popovici et al., 2004; Herfray et al., 2010; Roux et al., 2013) and applied to the design at neighbourhood scale in Lyon, Champs sur Marne and Paris (Peuportier et al., 2005; 2012 and 2015).

On these bases, the present paper aims to address the two following questions:

Q1) How can the CE be implemented in a neighbourhood?

Q2) What assessment tools are used?

Methodology

The study proposes analysing and comparing four case studies concerning a ‘circular neighbourhood’. The case study method was selected because this enables integrating theory and practice, aptly suiting the exploratory nature of this research (Leising, Quist, and Bocken 2018).

To begin, a literature review was undertaken to identify relevant ‘circular neighbourhood’ cases. Attention was dedicated not only to scientific papers, but also to other types of documents, such as reports and urban planning documents. Indeed, scientific literature was mostly limited to theoretical discourse and only little attention was given to the neighbourhood scale. The research was conducted in English, French and Italian. A total of only four case studies were found and selected: the first case concerns the neighbourhood of Buiksloterham (Amsterdam), which will develop into a sustainable district based on circular principles; the second neighbourhood is Kera (Espoo), an industrial area destined to become a ‘liveable circular economy neighbourhood’; the last two cases are based in Paris, namely, the Groues and Saint-Vincent-de-Paul eco neighbourhoods, both considered an ‘EC living lab’. All these cases were selected on the basis of two fundamental criteria: the willingness to implement the principles of the CE at the neighbourhood scale and the presence of a comprehensive CE strategy at the city level, within which the project fits in.

Following the case selection, CE initiatives and actions were identified and classified using document analysis and integrating data collected through semi-structured interviews with local stakeholders involved in the projects.

Finally, a conceptual framework analysis was defined based on three main criteria: CE practices, strategic city scale integration, and tools employed. This analytical framework has been applied to the four case studies in order to compare them.

Case studies analyses

Four case studies were selected based on their innovative character and central relevance of the CE. Indeed, in all these cases, CE is put forward as one of the key pillars for the urban projects.

Case	Buiksloterham	Kera	Les Groues	Saint-Vincent-de-Paul
City and Country	Amsterdam, Netherlands	Espoo, Finland	Nanterre, France	Paris, France
Size	1000 hectares	22 hectares	65 hectares	4 hectares
Site	Requalification industrial areas	Requalification industrial areas	Requalification industrial areas	Requalification hospital complex
Main Objectif	“key innovation zone for circular development”	“a showcase district for circular economy”	“circular economy living-lab”	“a privileged space to develop and test circular economy”
Starting date	Around 2015	Around 2018	Around 2018	Around 2018

Table 1. Case studies.

As illustrated in Table 1, despite the differences in size and location, the analysed neighbourhoods present some common features. For instance, all four cases constitute urban regeneration projects, and at the same time, they are also experimental and function as showcases to test the CE principles. Moreover, it is important to underline that all the projects are recent and have not yet been carried out or completed. For this reason, this analysis can only be based on the design phase.

Buiksloterham, Amsterdam

Amsterdam represents one of Europe’s pioneering cities in terms of CE. In fact, CE comprises one of the main pillars of the Sustainable Amsterdam Agenda (2015), which aims to, by 2020, reduce energy consumption by 20% and increase renewable production by 20% compared to 2013 (van der Hoek, Strucker, and de Danschutter 2017). In this strategic document, the Buiksloterham neighbourhood is considered “an engine for the broader transition of Amsterdam” (Metabolic 2015) towards a circular city.

Part of a larger redevelopment plan of the northern banks of the river, Buiksloterham is characterised by abandoned factories, wastelands and docks. In the city’s vision, however, this neighbourhood, once the site of Amsterdam’s most polluting industries, can become “a key innovation zone for circular urban development” (Metabolic 2016). Furthermore, the municipality proposed a bottom-up approach for the area’s redevelopment in order to develop a more comprehensive sustainability strategy. For this reason, in 2015, the ‘Circular Buiksloterham Manifesto’ was signed by approximately 20 stakeholders, including local actors, organisations, associations and companies. This innovative manifesto includes the shared guiding principles for redeveloping Buiksloterham, such as the zero-waste objective, the implementation of clean technologies or the use of biosourced materials. Recognising the urgency for a clear operational strategy, all the stakeholders involved commissioned an Urban Metabolism Scan in order to understand the neighbourhood’s complete workings from a systemic perspective. The analysis, carried out by the Metabolic and published in 2015, was divided into three stages (context analysis, stakeholder analysis and metabolism analysis). This ‘Urban Metabolism Scan’ focused on material and energy flows, biodiversity, environmental conditions, socio-economic factors, local actors, urban planning documents and plans, health, and living environment.

Following this analysis, a study was conducted concerning the neighbourhood's CE potential. On these bases, the priority objectives for redeveloping Buikloterham as a 'living lab for CE' by 2034 were divided into eight priority issues (Table 2).

OBJECTIVES	
Energy	Buikloterham is energy self-sufficient with a fully renewable energy supply
Materials & products	Buikloterham is a zero waste neighbourhood that with a near 100% circular material flow
Water	Buikloterham is rainproof and has near 100% resource recovery from waste water
Ecosystems and biodiversity	Buikloterham's ecosystems are regenerated and its base of natural capital is self-renewing
Infrastructure & mobility	Buikloterham's Infrastructure is maximally-used and local mobility has zero emissions
Socio-cultural	Buikloterham has a diverse and inclusive culture, and a high quality, livable environment
Economy	Buikloterham has a strong local economy that stimulates entrepreneurship and encourages the creation and exchange of multiple kinds of value (social, environmental, cultural)
Health & wellbeing	Buikloterham is a healthy, safe and attractive environment with recreational activity space for all residents.

Table 2. Buikloterham's objectives.

In particular, with regard to the built environment, it is interesting to note that a 'Circular Building Standard' will be introduced for all renovations or new constructions. This innovative assessment tool, which is still in the development phase, would allow tax credits once the standard has been reached. Among the key recommendations, all building roofs are equipped for clean energy production and rainwater collection, and all materials are registered in a digital passport to facilitate their identification. In addition, prefabricated building elements are preferred, facilitating deconstruction and reuse.

To ensure these objectives, a first action plan was developed. The proposed actions consist of two types: systemic actions, aimed at ensuring the district's long-term transition, and technical actions, concerning more specific issues. For the definition of the actions, prioritisation work was carried out. In particular, the actions considered most urgent consist of those related to new construction and infrastructure. Consequently, the priority actions concern the energy efficiency of the built stock, the flexibility of new infrastructures, the development of fresh mobility, water recovery and management.

Kera, Espoo

The city of Espoo, Finland is one of the pioneering cities in terms of sustainable development, as demonstrated in a comparative assessment study of 15 European cities carried out in 2017 by the University of Tilburg¹⁰. Indeed, initiatives led by the municipality within the framework of the Helsinki Metropolitan Plan, as well as the Helsinki Metropolitan Area Smart and Clean Cooperation project, are multiplying, with the objective of becoming carbon neutral by 2050¹¹. In most cases, CE constitutes a central issue in these initiatives.

In this context, the Kera neighbourhood, located within the eastern part of Espoo and close to the train station, represents a unique opportunity for the municipality to experiment in innovative CE solutions. Previously an industrial area, and the headquarters of the Finland's largest distribution group, Kera will thus be transformed into a mixed-use and dense neighbourhood of 14.000 residents. In addition to

¹⁰ <https://www.espooinnovationgarden.fi/en/espoo-innovation-garden/media/news/espoo-remains-the-most-sustainable-city-in-europe/>

¹¹ https://www.espoo.fi/en-US/Housing_and_environment/Sustainable_development

commercial services and offices, the project includes day-care centres, schools, sports and recreation services¹².

The municipality's objective is to transform this industrial park into a liveable neighbourhood with a strong CE focus by 2035. The goal of this project is to make Kera "a showcase district for circular economy"¹³, as well as "an international example of circular economy"¹⁴. It is with this perspective that the case of Kera was presented as an example of a 'circular neighbourhood' at the World Circular Economy Forum of 2017¹⁵.

The ongoing project was the winner of the Kera Challenge¹⁶, launched in 2015 with the aim of identifying a vision and project for Kera's future, based on the principles of sustainable urban planning and EC. In the winning project, Co-op City, CE is supposed to be achieved through a "large range of different measures, from boosting resources efficiency and creating closed loop systems to involving the local residents"¹⁷.

The main solutions to support circular economy put forward in the project were analysed and summarised in Table 3:

Green Infrastructure A network of multifunctional public places	Urban Fabric Sustainable Planning and Construction process	Function and Services Mobility Services in a 20 minute city Sustainable energy solutions	Social Environment Livability through co-creation
Ecosystem services Implement green and blue tools Design for multifunctional Evaluate generated values	Cyclical flexibility in buildings Material cycles Temporary use of the logistics Reuse and recycling of asphalt Recycling of the logistic halls	Mobile platforms for emerging services models Autonomous vehicle traffic Logistics Lab Access and smarter use of the spaces Smart parking and shared cars 100% renewable energy On site energy Smart energy grid Passive energy optimization	Participatory processes Common spaces Social engineers Affordable housing

Table 3. Kera's EC actions.

In particular, with respect to the built environment, the EC practices to be implemented are contained within the 'Kera Design Manual'. In the manual, all constructions are required to be biodegradable or fully recyclable in order to gradually phase out construction waste. Indeed, the flexibility of the constructed buildings represents one of the document's first fundamental points. In fact, this flexibility provides the basis for the possibility of a future 'circular regeneration' of the built stock. In this perspective, LCA will be mandatory. In addition, for new constructions, all materials used are required to be fully biodegradable or recyclable in order to reduce construction waste.

¹⁷ <http://uusikera.fi/wp/wp-content/uploads/2016/06/COOP-CITY-Illustrations.pdf>

Concerning reuse and recycling, attention is paid to both existing materials, such as asphalt, which must be recovered, and to the construction elements of existing halls, such as beams, slabs and columns. In addition, the temporary use of some existing buildings is highlighted as an EC practice. For example, during the building construction, the ground floor of the halls will be used as for temporary storage for materials and elements to be reused or recycled. Furthermore, the halls' structure will be reused in constructing new buildings or outdoor spaces.

In addition, it is interesting to note that 100% of the primary energy demand will be produced from renewable sources, some of which will be produced on site. Solar, geothermal and wind energy are planned and will feed into an intelligent energy grid. For new constructions, passive solutions are preferred.

Les Groues, Nanterre

The urban redevelopment project of the Groues in Nanterre, led by the Etablissement Public d'Aménagement de la Défense Seine-Arche (EPADESA), aims to create a mixed district, offering housing, office space, shops, services and equipment and accommodating nearly 12.000 inhabitants and new jobs¹⁸. Near the business district of La Défense and served by a future line of the Grand Paris metro, the Groues neighbourhood, covering approximately 65 hectares, is characterised by numerous wastelands and distressed buildings. The project is recent, as is its realisation. In 2015, a Strategic Operational Project was approved by EPADESA, and in December 2016, the Concerted Development Areas (ZAC) were created. The first lots are currently being awarded, and the operation is expected to continue until 2030 (ADEME 2017).

The goal of the Groues development project is to become a “laboratory for a dynamic, green and inclusive neighbourhood”¹⁹, and more generally, to become “an experimental laboratory for the sustainable city of tomorrow”²⁰. In particular, the project aims to be exemplary in environmental matters and to obtain the EcoQuartier Label, becoming a positive energy territory²¹.

The project is based on five strategic axes:

Objectives				
Energy transition and the fight against climate change	Biodiversity and respect for natural resources	Protection against nuisances and creation of healthy and comfortable environments	Creation of an economic innovation ecosystem integrating a diversity of actors and co-design approaches	Laboratory of circular and solidarity economy

Table 4. Les Groues' objectives.

As such, CE represents one of the main pillars of the project's sustainable development strategy. Winner of the Call for Expression of Interest 'Circular Economy and Urban Planning' launched by the Ademe in 2015, the Groues project offers a place to experiment with a CE at the neighbourhood and territorial scale.

¹⁸ <https://fr.calameo.com/read/00398144113f3e65fce93>

¹⁹ EPADESA. 2016. Les Groues. Plan Guide.

²⁰ <https://fr.calameo.com/read/00398144113f3e65fce93>

²¹ <http://fr.calameo.com/read/0039814413c1330021bdd>

As presented in the figure above, the actions planned for CE are multiple. In particular, concerning the built environment, attention is paid to the local management of construction site waste (choice of materials, grey energy, local management of backfill/burial) (ADEME 2017). In addition, the ZAC project plans to place the built environment at the centre of EC's approach, as well as the project's overall energy efficiency ambition. To this end, 'lifecycle thinking' is encouraged here: "The building must be understood in all its spatial and temporal integrity by real estate operators, who must understand the lifecycle of their building: its manufacturing processes and materials, its duration over time and its capacity to adapt and evolve up to its deconstruction"²². In addition, the concepts of 'grey energy' and 'transformation capacity' are central. Other EC practices are highlighted as well, such as rainwater harvesting, building flexibility and modularity, neighbourhood waste harvesting and reuse of existing buildings.

In addition, in 2016, EPADESA launched two calls for projects, aimed at inspiring innovative reflections and experiments on the CE theme. The first one concerns temporary urban planning approaches, allowing the lifespan of existing buildings to be extended. The ephemeral initiatives presented were highly diverse, ranging from soil remediation to the reuse of building materials, or even innovative start-up incubators. The second one directly concerns new constructions and aims to develop innovative CE solutions in the construction sector. LCA has been applied to the design of 5 office buildings, and the environmental benefit of recycling has been studied.

Saint-Vincent-de-Paul, Paris

Located in the 14th arrondissement of Paris, the Saint-Vincent-de-Paul ancient hospital remained under decommissioning for approximately 10 years. In 2014, however, it was acquired by the municipality of Paris with the aims of transforming it into an innovative eco-neighbourhood (City of Paris 2017a). Covering an area of 3.4 hectares, the redevelopment project of the former Saint-Vincent-de-Paul Hospital represents a rare opportunity for urban transformation in the heart of Paris' particularly dense urban fabric.

In particular, the objectives pursued by Paris are as follows:

Objectives			
Create a predominantly residential area, promoting social diversity	Lead an exemplary environmental approach, making Saint-Vincent-de-Paul an innovative and emblematic eco-neighbourhood for the city	Think of public and open spaces as green spaces, whether on roofs, floors or facades	Enhance the heritage and history of the site

Table 5. Saint-Vincent-de-Paul's objectives.

In December 2016, the ZAC was created and granted to the developer Paris Batignolles Aménagement. The construction work began in 2018, and the planned programme provides for approximately 60,000 m² of total floor area, broken down in housing (including 50% social housing), facilities, equipment (including a school and a gymnasium), shops and a public garden²³.

²² EPADESA. 2016. Les Groues. Plan Guide.

²³ <https://www.paris.fr/services-et-infos-pratiques/urbanisme-et-architecture/projets-urbains-et-architecturaux/saint-vincent-de-paul-14e-2373>

Concerning the built environment, the future district aims to become an exemplary showcase for the entire city thanks to an ambitious environmental approach. Specifically, as stated in the Resilience Strategy adopted in 2017, Saint-Vincent-de-Paul aims to be the city's first resilient and carbon-neutral neighbourhood (City of Paris 2017b). In compliance with the city's framework documents, the project thus aims to create a "pilot district for sustainable development" (City of Paris 2017a), reducing its impact on the environment and promoting innovative technologies while also involving the inhabitants. In this perspective, the new project provides for reversible buildings, pooling resources, converting 60% of existing buildings, developing renewable energies, certifying new constructions, optimising energy systems and recovering waste.

In addition, ZAC Saint-Vincent-de-Paul aims to be "a privileged space to develop the principle of CE"²⁴. Several different actions are being put forward in the field of CE, and the project must respect the orientations of the Parisian CE plan. With regard to the built environment, attention is being paid to reusing certain buildings, which would make it possible to limit demolitions, short circuits and temporary occupation of existing buildings, as well as to ensure continuity with the ephemeral urban planning experimentation of the Grands Voisins, including the smart grids, urban agriculture and bio-waste.

More specifically, regarding waste, more attention is paid to the construction phase, and the following objectives in particular:

- Source reduction of the quantity of waste;
- Material recovery by reuse in place or elsewhere (in particular, building elements such as doors, windows, etc., which can easily find a new use, or concrete waste and bricks, which can be used as aggregates);
- Energy recovery from waste;
- Storage in a technical centre, reserved for final waste.

To this end, a process of recovering dismountable elements likely to be reused is planned for all site operations, thanks to an inventory distributed to various local, potentially interested structures. In this respect, a specific project management assistance service for sustainable development is planned from the project's amelioration. Applying LCA to the design of a project including deconstruction, renovation and new construction is planned in the frame of the PULSE-PARIS project funded by ADEME²⁵.

²⁴ http://www.paris-batignolles-amenagement.fr/pba/sites/default/files/publications/dp_svp_1506_deflite_bd.pdf

²⁵ The PULSE-PARIS research project aims to improve the relevance and operability of eco-design approaches for urban projects in line with the CE strategic plans of the City of Paris. In particular, the project focuses on life cycle assessment (LCA) tools at the neighborhood scale, which are still in their infancy. The project will synthesise strategic approaches at the city scale and eco-design approaches on the urban project, in order to verify the coherence and articulation between these decision-making levels. The evaluation of CE practices on this scale using LCA is innovative and would make it possible to better understand the environmental benefits of these practices. (The research project is led by EIVP and MinesParisTech).

Cross-case comparison and discussion

The results of the analysis are summarised in Table 6 and are compared by applying the analytical framework based on the following criteria: CE practices, strategic city scale integration, and tools employed. Following this three-step analysis, some significant similarities have been pointed out.

	Buiksloterham	Kera	Les Groues	Saint-Vincent-de-Paul
Strategic city scale integration	Sustainable Agenda Smart City Initiative Circular Amsterdam	Lien stratégie durabilité et smart city	EcoQuartier Label	Resilience Plan Territorial Climate Plan CE Plan
Tools employed	Circular Building Standard Materials digital Passport MFA	Kera design manual LCA Buildings	(Perspective cycle de vie)	LCA Building Carbon Footprint Municipality's assessment tool
CE practices	Energy	100% renewable energy PassivHaus Label Local energy production	70% renewable energy	40% electricity by photovoltaic panels PassivHaus Label
		100 % energy recovery from wastewater	Energy recovery from wastewater	Smart Grid
	Waste and materials	Reuse materials	Reuse of materials and existing buildings	Reuse of materials and existing buildings
		100% « circular material flow »	Local management of construction and demolition waste	Local management of construction and demolition waste
		Deconstruction	Waste recovery and valorisation	Waste recovery and valorisation
	Water	Rainwater collection	« Green and Blue Tools »	Rainwater collection
	Other	Temporary occupancy of buildings Buildings flexibility Prefabricated constructions and structures Auto-construction Urban agriculture and local food production	Temporary occupancy of buildings Buildings flexibility Urban agriculture	Temporary occupancy of buildings Urban agriculture Short circuits CE stakeholders point of reference

Table 6. Cross-case comparison

First of all, the four projects are integrated into the strategic documents regarding the sustainable development and EC of each city, such as the Smart City Agenda, Climate Change Plan, and so on. Furthermore, in these documents, the projects are always presented as ‘experimental demonstrators’ of CE in urban projects. However, it is important to note that, in all the cases reviewed, CE is often seen as one of the pillars of sustainable development, and sometimes, no distinction is made among the proposed actions between those related to the CE or to sustainable development.

Second, the analogies are also evident with respect to CE practices identified in the projects. Following the case studies analysis, it is possible to classify four categories of recurrent practices: energy, water, waste and other. In particular, all cases insist on flexibility and temporary occupancy of buildings, the reuse of both building materials and existing buildings, and eco-construction. On this subject, an important focus is placed on the energy aspects of new buildings, with precise standards to

be achieved. Other practices highlighted by at least two cases relate to waste management, particularly construction site waste, as well as water management and urban agriculture.

More generally, the comparative table indicates that the vast majority of the CE practices highlighted by the cases focused more on environmental issues. In fact, the other two pillars, economic and social, would not appear to be central.

However, no consensus is present concerning the tools employed. The Dutch and Finnish cases, for instance, are based on ad hoc assessment methodologies still under development. Furthermore, only in the case of Buiksloterham is a material flow analysis (MFA) conducted. This well-identified assessment tool is often coupled with CE, but according to Elia et al. (2017), it is not sufficient for validating the pertinence of CE practices, because it does not enable explicitly accounting for all of the environmental impacts. Indeed, MFA is an important territorial knowledge tool, but it does not allow to prioritise and make decisions among the different CE actions. Other tools, such as the LCA, could conversely support such decisions.

In this regard, it is interesting to note that the ‘lifecycle perspective’ seems to be central in all cases, but it is not necessarily associated with lifecycle assessment (LCA) tools. The LCA method seems to be the most complete methodology for assessing environmental impacts and CE requirements (Elia, Gnoni, and Tornese 2017), but nevertheless, in the Kera cases, LCA is planned only at the building scale and for new constructions. The assessment of CE practices is not directly mentioned except in Saint Vincent de Paul. This can lead to contradictions, because as demonstrated during the 63rd discussion forum on LCA²⁶, ‘circularity’ does not always positively affect the environment.

Finally, it is important to note that all these projects are currently underway or were recently started, probably contributing to a lack of precision regarding the performance that will actually be achieved upon delivery.

Conclusions

The literature review reveals a lack of research concerning the application of CE principles to urban projects and their assessment. Accordingly, this paper aims to provide a comparative analysis of four ‘circular neighbourhood’ case studies in order to discuss the CE practices implemented and the assessment tools utilised.

The results of this analysis indicate a large panel of CE practices and a limited use of indicators and assessment tools. Further steps in this research field are required concerning the study and analysis of other cases and tools. Moreover, several authors have highlighted the interest of LCA in evaluating CE (Ghisellini, Ripa, and Ulgiati 2018; Zanni et al. 2018; Elia, Gnoni, and Tornese 2017; Giorgi, Lavagna, and Campioli 2017; Haupt and Zschokke 2017; Fregonara et al. 2017). Two key characteristics of LCA are highlighted by these authors: the ‘life-cycle thinking’, which should also be the basis for EC, and the environmental impact assessment. Thus, the relevance of LCA is also becoming increasingly legitimate to experts, who are beginning to emphasise the importance of LCA to implement EC strategies. In this context, one of the objectives of the PULSE-PARIS project

²⁶ www.lcaforum.ch

involves the concrete application of the LCA method for evaluating the identified CE practices in order to study its relevance and propose possible improvements.

Acknowledgement

This article further presents some of the first results of the PULSE-PARIS research project, currently still in progress and financed by Ademe.

Urban Metabolism and the Circular Economy, The Capital Approach

Peter Hunt

PhD Candidate, Built Environment Faculty, UNSW Sydney, p.hunt@student.unsw.edu.au

Abstract: As global human population continues to increase society is shifting toward more concentrated urbanisation. Urban settlements require adequate, appropriate infrastructure and accommodation to satisfy the increasing population needs. A circular economy is an inclusive approach relying on integrated systems that feedback into the production process. Humanity has reached a position where we must utilise the stock of natural capital more efficiently to ensure that replenishment of stock can occur. An appreciation of the circular economy is required to ensure that the stock and flows of capital can meet the metabolic rate of urbanism. The circular economy provides an opportunity to transition from the linear economy to satisfy sustainable development objectives.

Keywords: Capital, Circular Economy, Stocks, Flows

Introduction

The primary function of our cities is to ensure that an adequate level of well-being is provided for all occupants throughout their lifetimes.

As the increase in human population continues, we are simultaneously experiencing a steady shift of the global population towards cities. This concentration of human occupation within the urban environment is increasing the pressure on the ability for cities to meet the needs of their occupants. Cities are increasingly expected to provide adequate housing, workspace, leisure facilities, education programs, transport and infrastructure, in a functional, safe and secure environment.

This urban pressure is manifested in three forms:

- developing the built environment stock to satisfy the growing population needs;
- providing the flow of adequate services including reliable energy, clean water, materials and infrastructure to allow the urban system to function and operate to meet needs and requirements of the population;
- ensuring the built environment is maintained to a level to meet the utility needs of the changing demographic profile.

These three requirements constitute the stock of the urban fabric and the flows of essential services.

Urban Metabolism

The concept of urban metabolism was introduced by Abel Wolman in 1965. In the paper ‘The Metabolism of Cities’, Wolman identifies:

“three metabolic problems that have become more acute as cities have grown larger. These three problems are the provision of an adequate water supply, the effective disposal of sewerage and the control of air pollution (Wolman, 1965 p179).”

Since that time the global population has more than doubled and has transitioned away from rural areas toward urban settlements. The three identified urban metabolic problems are still relevant to today’s society, but many other components may now be added as essential to a functioning city. The provision of reliable energy, information and communication technology, and effective transportation systems may be seen as first world urbanisation issues, but they are becoming increasingly important and demanded by global urban inhabitants.

Urban metabolism is measured as a response to the population pressure on the urban fabric and is calculated as “the magnitude, rate and size of the flows, required to respond to the demands of the urban environment (Roggema, 2019).” The urban metabolic rate increases as a result of a growing population, the increasing and changing demand for resources and processes required to keep a city functioning for the benefit of the community inhabitants.

The Linear Economy

The first sequel to the *Limits to Growth*, ‘Beyond the Limits’ (Meadows *et al*, 1992), stated:

“The earth is finite. Growth of anything physical, including the human population and its cars and buildings and smokestacks, cannot continue forever. But the important limits to growth are not limits to population, cars, buildings, or smokestacks, at least not directly. They are limits to *throughput* – to the flows of energy and materials needed to keep people, cars, buildings and smokestacks functioning.”

“The human population and economy depend upon constant flows of air, water, food, raw materials, and fossil fuels from the earth. The limits to growth are limits to the ability of the planetary *sources* to provide those streams of materials and energy, and limits to the ability of the planetary *sinks* to absorb the pollution and waste.” (Meadows *et al*, 1992)

From the commencement of the industrial revolution and throughout the twentieth century, the global economy has primarily functioned on a linear basis. This process was manageable, although not desirable, as natural capital stocks were seemingly in abundance and the ecosystems were generally capable of servicing, absorbing and regenerating to allow a functioning environment to serve the needs of the expanding human population. When the human population reached 5.5 billion in the 1990’s it was estimated that some of the natural systems operating under a linear approach, were at capacity (Meadows *et al*, 1992). Past this point, the regenerative flow capability of these natural

ecosystems was failing to keep pace with demand and pressures imposed by human occupation and production processes.

The Circular Economy

“The circular economy is an economic model wherein planning, resourcing, procurement, production and reprocessing are designed and managed as both process and output, to maximize ecosystem functioning and human well-being (Murray *et al*, 2015 p369).”

Creating a circular economy is necessary to meet the growing demand pressures created by the increasing urban metabolic rate. For the circular economy to be effective, a regenerative process that optimises the utility value of inputs, through the efficient distribution of outputs while eradicating negative impacts, is desirable. A balanced approach which optimises resource utilisation within boundaries and limitations is required.

The process modelling behind these concepts date back to the 1970's based on the system dynamics, World3 modelling from the Limits to Growth team of researchers headed by Dennis Meadows (Meadows D H *et al*, 1972). The five key areas central to the *Limits to Growth World3* model were exponential population growth, agricultural production, industrial production, natural resources and pollution. The *Limits to Growth* modelling highlighted the linear and circular flows of human habitation through system dynamic processing of data associated with the five identified areas. The analysis considered feedback loops and predicted time lags, indicating degeneration and the estimated regeneration capacity of natural systems and the ability of these systems to cope with increasing human population pressure (Meadows, 1972).

When *Limits to Growth* was published in 1972, the global human population had grown to an unprecedented 3.7 billion. In the past four decades global human population has now doubled to 7.4 billion. This increasing population level, combined with a shift toward urbanisation compounds the demand for appropriate accommodation and suitable infrastructure to supply services including the adequate provision of energy, clean water, effective transportation methods and supply chains for material goods and food. This compounding effect is manifested in the increasing rate or velocity of urban metabolism. The circular economy is an appropriate method to respond to the increasing rate of urban metabolism.

Asset Based Capital Approach

A consideration of the stocks and flows of capital is necessary for the circular economy to be effective. Environmental economist, David Pearce outlined an asset-based approach that combined capital from four interrelated perspectives (Pearce *et al*, 1993). The four capital stocks outlined were **natural, human, manmade, and social**.

Natural Capital

Natural capital stock covers a wide spectrum of environmental assets, including soil fertility, forests, fisheries, fossil fuels in the form of oil, gas and coal, the ozone layer and biological chemicals. (Pearce *et al*, 1994).”

The flows of natural capital can be further expanded to include ecosystems services: the capacity to assimilate waste, photosynthesis, evapotranspiration, renewable energy, the water, carbon, nitrogen and sulphur cycles and the ecological systems that allow cohabitation of all species.

Human Capital

The stock of human capital includes the human population and the level of education and skills. The flows are the number of births and deaths, the demographic aging profile and the utilisation of knowledge, skills and labour.

Man Made Capital

The stock of man-made capital constitutes the existing built environment and produced goods. The flows of man-made capital are through the manufacturing process. The built environment flows consist of the processing and utilisation of materials through the development process and the use of energy and materials in the operation of premises including repairs and maintenance.

Social Capital

Social capital considers public health, access to education, non-discriminatory employment opportunities, public safety (law and order), privacy, freedom of association, indigenous rights, non-corrupt and equitable systems of governance (Gleeson-White, 2014)

The social capital stock is created as a result of the other capitals. Social capital can evolve from human capital flows. Social capital can improve as a consequence of man-made capital stock. Social capital can be impacted by natural capital stocks. As Jane Jacobs articulated in *'The Death and Life of the Great American Cities'*:

“development for the sake of development can sometimes have negative social consequences, whereas investment in improving the existing social fabric that has positive attributes can produce even greater positive outcomes (Jacobs, 1967).”

As Jacobs highlighted, heritage, culture and community, all are important social capital benefits.

The circular economy from a processing perspective is “virtually silent on the social dimension (Murray *et al*, 2013 p376)”, where the social capital perspective is central to sustainable development outcomes. This can be explained by the circular economy taking a quantitative analytical approach, whereas many social capital outcomes may be considered more qualitative.

Societal well-being is a consequence of the flows of human and man-made capital, which provide inputs to serve social capital, but social capital can only exist within a thriving natural capital environment.

Social capital preservation is the dominant theme in *'Our Common Future'* (Brundtland, 1987), concept for sustainable development: -

“Humanity has the ability to make development sustainable – to ensure that it meets the needs of the present without comprising the ability of future generations to meet their own needs.

Sustainable development requires meeting the basic needs of all and extending to all the opportunity to fulfil their aspirations for a better life (Brundtland, 1987 p8).”

The theory behind sustainable development is determined by ensuring social capital stocks are enhanced over time.

“The concept of sustainable development suggests that a development path is sustainable if and only if the stock of overall capital assets remains constant or rises over time. To be on a sustainable development path, then, a nation must be living within its means, which in this context means not decreasing its overall capital assets.” (Pearce *et al*, 1993 p84)

Capital Stocks and Flows

It is essential to understand that natural capital systems operate as a complex arrangement of circular flows that provide eco-system services essential to support all species. The difference between natural capital and the other forms of capital is natural capital does not require human activity to build or maintain its stock. Natural Capital is a fundamental requirement for the development of the other capitals (Costanza et al, 2017) when interacted with human capital and man-made capital.

“These four general types of capital are all required in complex combinations to produce any human benefits. Ecosystem services thus refer to the relative contribution of natural capital to the production of various human benefits, in interaction with the other forms of capital. These services do not simply flow to human well-being without these crucial interactions. (Costanza *et al*, 2017 pp4-5).”

Humanity cannot survive without adequate life supporting natural capital stocks, produced by positive natural capital flows. Essential human life supporting attributes of natural capital stock include the air we breathe, the availability of fresh drinking water, soil and the nutrients required for plant growth. Each of the other forms of capital are reliant to some extent on natural capital stock and the natural systems regenerative flows. Natural capital is exploited by the other capitals to a position whereby the regenerative capacity of natural capital through ecosystems services is insufficient to keep pace with human production demands and urban metabolism.

Both urban metabolism and the circular economy are based around the concept of stocks and flows. Once the stock of the capitals has been identified, it is critical to understand the flows of these capitals.

“The critical aspect is to understand the stock, flows and impacts when incorporating natural capital into the capital equation. Stocks may be both sources and sinks of natural resources, while flows may be both inputs and outputs that increase or decrease stocks (Meadows, 1998).

Moreover, stocks and flows of resources are also characterised by different regeneration rates (Wall, 2002), which determine whether resources are referred to as renewable or non-renewable. (Costanza and Daly, 1992) (Mancini *et al* 2017 p125).”

Each of the capitals cannot be treated in isolation, but rather a cross capital approach is required to ensure that optimal performance or outputs are achieved within the boundary limitations.

The atmospheric cycle is one example of where man-made linear flows, the emission of carbon dioxide into the atmosphere has now reduced the natural stock holding capacity, by exceeding the flow rate capability of the atmosphere to absorb carbon emissions. The concentration of carbon dioxide in the atmosphere has already surpassed 410 parts per million (ppm), (Mauna Loa Observatory, 2019)¹ where 350ppm is the recommended position to avoid global warming and the effects of climate change.

- Fossil fuels remain the primary fuel source to provide energy for transport, the operation of building services, heating and cooling systems and the energy for the production process of materials for construction.
- Carbon dioxide is emitted by the burning of fossil fuels.
- Carbon dioxide accumulates in the atmosphere.
- The absorption rate of carbon dioxide out of the atmosphere is slow, with the lag or processing time estimated to be up to 100 years.
- The atmosphere and oceans act as sinks, but as they have reached their optimal processing capacity, the outcome of this oversupply of carbon dioxide manifests into the predicted consequences of global warming, resulting in increased frequency of drastic weather events, increased ocean warming, ocean acidification and rising sea levels.

These outcomes have potential severe existential consequences to humanity, but we continue to emit into a system that has passed its effective processing capacity.

From an urban metabolism approach, we should ensure that development and occupation of cities limit the output of carbon emissions to decrease the impacts and consequences of climate change and associated risks. This requires a shift to renewable energy as a substitute to carbon emitting fossil fuels, to a level that meets the energy demand of the population and reduces carbon emissions to levels that can be effectively absorbed into the atmosphere and oceans without negative consequences.

An effective circular economy should be designed to ensure that the projected outcomes contribute to the replenishment of the stock of capital and meet the rate of urban metabolism. From a circular economy perspective, systems should be developed and integrated to ensure that carbon dioxide emissions are reprocessed prior to entering the atmosphere.

¹ According to <https://www.co2.earth> , The Mauna Loa Observatory, Hawaii, recorded atmospheric concentrations of carbon dioxide in April 2019 at 413.52 ppm.

Boundaries

How can we be sustainable if the human population is already using 1.7 planets worth of resources and waste absorption capacity (Global Footprint Network, 2019) and depleting the stock of natural capital to a position where the ecosystems services are incapable of providing adequate regenerative flows?

Linear processes primarily utilise stock(s) as inputs, create waste during the production process and dump the residue. This approach fails to provide the feedback loops to allow systems to regenerate effectively. As we have now reached capacity in some systems and deteriorated natural capital stockholdings, a linear approach is no longer a satisfactory approach.

If we have passed the regenerative capacity limits of natural capital and are now depleting natural capital stock, a virtuous circle response must be adopted with the aim toward preserving and enhancing natural capital to provide positive social outcomes.

For the circular economy to be effective, the process must provide positive benefits across all the capitals and therefore be considered to operate in a virtuous manner. If all the flows are positive, adding to the stock holding of all the capitals without diminishing or exploiting one for the benefit of the other, then it could be said that this is a sustainable approach.

One problem with the circular economy is that some approaches may plan for virtuous outcomes, but when all the capitals are considered there may be vicious circles embedded within the system resulting in a negative flow from a capital. For this situation to be sustainable, it is a matter of quantifying the positive and negative responses within the system to determine the true value proposition, ensuring that a gross positive outcome is achieved over the long term.

Urban Metabolism - Sydney Urban Planning

Sydney is the most populous city in Australia, with a current population of approximately 5 million. The commercial business district of the city is located alongside the banks of Sydney Harbour near the coastline of the Pacific Ocean. The geographical boundaries of the metropolitan area are largely contained by the natural geography of the Pacific Ocean to the east, national parks to the north and south coastal regions and Blue Mountains to the west. The urban expansion of the city therefore spreads from the city centre predominately west outwards 50kms to the base of the Blue Mountains escarpment.

The Sydney basin is 12,367square kilometres, including the national parks. The urban area is currently 4,064 square kilometres with an urban density of 1,237 persons per square km. (City of Sydney 2019).

The climate of the City of Sydney is classified as subtropical. As the city is located alongside the harbour and situated near the coast, the city itself does not suffer from the characteristics of the urban heat island effect to a level detrimental to human habitation. The air temperature along the densely populated coastal suburbs and inland to approximately 8kms remain mild within the subtropical/temperate zone throughout the year. These suburbs are cooled by circulating sea breezes and coastal weather systems.

Figure 1 Greater Sydney Metropolitan area

Post-World War II urban expansion has generally been to the west of the city with the population geographically centred around the western Sydney centre of Parramatta, approximately 20kms from the coast. Residential expansion continues to spread further inland into the Sydney basin to the north

west, west and south west. The climate and temperature in these areas is significantly different to the coastal areas, as cooling sea breezes don't penetrate this far inland.

Most of the recent urban population growth has spread further west with the provision of available land, allowing the development of large suburban homes on small allotments. These sprawling suburbs lack appropriate infrastructure in the form of public transport. Motorways have been developed throughout this area to cope with the increased motor vehicle use. This area of western Sydney accommodates over half the metropolitan residential population of Sydney, in-excess of 2million people and has been planned for a further 3million over the forthcoming decades.

To accommodate this population growth, Sydney has experienced the continued clearing of native bush and agricultural land for suburban settlement within the western Sydney basin. Major city centres have been developed in Parramatta and Blacktown in the west, Liverpool and Campbelltown in the south west.

The New South Wales State Government Planning Department has undertaken numerous detailed urban planning strategies to accommodate growth for Sydney over the forthcoming decades. The latest urban expansion masterplan 'A Metropolis of Three Cities - The Greater Sydney Region Plan (Greater Sydney Commission, 2019)' considers a planning strategy for Greater Western Sydney to provide upgraded and investment in new infrastructure including a second airport, new employment centres and the provision of new residential accommodation. It is a detailed urban development plan providing a strategy for growth and development for the western Sydney urban area, based on the economic grounds of consolidated urban development with proposed employment centres.

The Vicious Circle

Western Sydney Urban Planning

- Increased urbanisation of this metropolitan region results in a reduction of the rural landscape, resulting in a reduction of low-level vegetation and the tree canopy.
- New suburbs are created through subdividing broadacre land.
- Roads are constructed with black asphalt bitumen.
- Homes have been built on small allotments with predominately black or dark roof tiles with narrow eaves and poor shading.
- Little residual space for landscaping and any established tree canopy.

The existing suburbs are now suffering from the suburban heat island effects, due to the reduction of green space replaced with black or dark fabricated surfaces. As these suburbs are located inland, they do not benefit from any coastal sea breezes.

- Average annual temperatures continue to rise and remain hotter for longer periods.
- The further inland, the higher the temperature increases.

- Dwellings are ineffectively designed to benefit from passive solar shading and natural breezes and therefore require cooling from air conditioning systems.
- There has been a slow take up of photo voltaic electricity cells, requiring electricity generated predominately from coal fired power stations.
- Where these dwellings are poorly orientated and are constructed with inappropriate materials for the environment, they require increasingly more energy for cooling.
- The cost per unit of energy continues to increase.
- Lower land values and low-cost building materials indicate that houses are “more affordable” but unsuited to a changing climate.
- Increasing building operating expenses and additional transportation costs equates to increasingly unaffordable living expenses.

Future residential subdivision will further reduce the green space within these suburbs.

- With increasing temperatures, tree leaf canopy transpiration and plant photosynthesis are negatively impacted.
- Increasing heat events with temperatures consistently over 35degree Celsius days are experienced throughout an extended summer period.
- This region is getting hotter and it is staying hotter for longer.
- The heat is being trapped overnight, therefore these suburbs don’t experience adequate heat relief.
- Artificial cooling through air conditioning is required for longer periods.
- Increased energy use requires more burning of fossil fuels creating higher levels of green-house gas emissions, resulting in increased warming.
- High temperatures reduce green space growing ability along with a lack of available water for irrigation, creates heat stress on plants.
- More people require more cars, alongside a lack of appropriate public transport infrastructure. This creates traffic congestion and continuous demand for transport infrastructure improvements.
- More vehicles on the roads for longer periods creates more carbon emissions leading to global warming.
- Changing climatic conditions affects the supply of water. As the population increases the provision of water per person is diminished.

The City of Parramatta are conscious of this warming phenomenon and are installing heat monitors and sensors throughout the city as part of a smart city initiative, but this action does not mitigate the problem, it only identifies it. (City of Parramatta, 2018)

This development cycle has now reached a stage where the continued residential expansion of this region is now negatively impacting the natural capital stock and flows to a detrimental level of social well-being. The heat stress impact on this area is worsening.

The proposed urban development plan effectively ignores this issue and does not offer any solutions to this worsening situation. The problem is that the metabolic rate of the existing urban population is creating a compounding affect with urban heat retention and has broader global warming implications. This affect will be further compounded as the metabolic rate increases to meet the demands proposed population expansion.

The plan proports to consider a sustainable development approach but fundamentally it considers development from a linear economic approach. The plan fails to consider a holistic approach considering the four capitals, urban metabolism and the circular economy. Being based primarily on job creation and economic considerations, the plan fails to recognise the importance of natural capital and the environment being the critical capital component determining the consequential social outcomes.

We have available land, but do we have suitable or appropriate land for residential expansion? The impact of urbanisation is affecting the climatic conditions in this region to a position that is becoming unsuitable for human habitation.

This region is experiencing the effects of global warming now, which is impacting social well-being, health and safety, resource use and furthering the depletion of natural capital stocks. We have created a vicious circle though a linear urban planning approach, but little consideration has been had for the urban metabolism. This urban planning strategy fails, as it fails to meet the needs of society and negatively impacts natural capital stock holdings. The plan proposes to increase economic performance. When the capitals are taken into consideration, this plan does not enhance well-being, it negates it. It does not create wealth, it depletes it.

Conclusion

When we consider that the stock of natural capital is now a non-negotiable asset, the endowment of natural capital stock must be protected. The operating paradigm for sustainable development must be within the functional ability of natural capital regenerative flows. We can no longer allow natural capital stocks to be used as a sink if the regenerative process fails to meet the absorption capacity as this will further deteriorate the stock of natural capital.

A linear economic approach is now redundant as a linear approach cannot satisfy the objectives of sustainable development and meet the needs of urban metabolism in a balanced and secure manner. A circular economy is necessary to enhance natural capital systems and provide appropriate social capital outcomes. We must transition to a circular economy to ensure continuous improvement and to increase our overall stock of capital assets. This will provide the opportunity for a sustainable outcome.

We still require an adequate resource base and systems to satisfy social needs through the supply of manmade products. A circular economy can assist in meeting the demands of urban metabolism, but

the rate of renewal and regeneration and use of critical resources must provide an overall virtuous response to the key limited areas.

With an increasing global population, changing demographic patterns and a shift toward urbanization, the urban metabolic rate continues to increase. The primary priority is to provide a process whereby we can continue to operate within natural capital limits to protect environmental reserves (stock) and renewal by ecological systems (flows), while satisfying social needs to enhance equitable prosperity. This needs to be achieved in addition to ensuring that the expanding human population needs are met through the provision of new capital works and the repair and maintenance of existing systems. If all these outcomes can be achieved through a virtuous circular economy approach, then we have satisfied the demands of urban metabolism in a sustainable manner.

Urban metabolism and circular economy

Local manufacturing systems in the piedmont area.

New scenarios for an inland metabolism.

Maria Leonardi

University IUAV, Venice

Abstract:

The Italian alpine foothills territory (IAFT) has gone through various "seasons of manufacturing" that determined different representations of it. Today, in the context of an exceptional transition phase, foothills local manufacturing systems (FLMS) need an overall reinterpretation. Even if we can still recognize the IAFT as one of the most economically relevant areas of Italy, we are unable to understand its complex transformation, due to the large amount of investments, their transience, and their multifaceted implications on the territory as well as on the environment as a whole. After the economic crisis of 2008, interesting possibilities for coexistence and collaboration were vexed by a set of important and hardly controllable forces, mostly due to the imposed combination of divergent local clusters' FLMS evolving levels and their relation to different types of economies. Apart from the traditional type of FLMS, some types are constantly growing, taking in consideration the proximity between diversified and specific industrial basis that allows for new complex products to be invented and for the economy to grow in the long run. Conversely, other FLMS have suffered a setback, which is related, firstly, to the exhaustion of resources that drew on the adjacent mountain environment, and, secondly, to the lack of local adequate competences and skills. Finally, a third type of FLMS follows a "third road", based on an innovative approach to handicraft and to the cultural industry, which favors new forms of experiential tourism. My research aims to elaborate on a set of efficient modalities, combining the existing knowledge of the biophysical flows together with an informed insight into the socio-economic transitions of the different FLMS, which are understood as part of an unique system, oriented towards a circular metabolic perspective.

Keywords: manufacturing; transition; territorial metabolism

Introduction

This paper is based on a set of considerations that have been developed as part of a PhD research in progress, at the PhD school “Architecture, city and design”, University IUAV of Venice, within the specialization of urbanism [1]. The thesis focuses on the investigation and representation of an Italian specific area, which has been called “Italian alpine foothills territory” (IAFT). This territory can be identified as a strip of land extending longitudinally from the foothills of the Alps towards the district of the springs (which generally overlaps with the A4 highway route), and, transversally, from Biella (Piedmont) to Manzano (Friuli Venezia Giulia).

Roles and scenarios of the IAFT

In this essay, IAFT is identified as a territorial typology, broadly discussed – over the course of the last century – in a number of prospective projects and political hypotheses regarding the Italian territory.

The aim of this paper is not that of analyzing the whole of the definitions – and, accordingly, of the divergent functions – that have been attributed to this territory, but instead, that of considering some relevant case studies.

In 1965, in the study promoted for the inter-municipal plan of Milan, Bacigalupo, Corna, Pellegrini e Mazzocchi argue that “the goal of the development process is not to be understood as that of realizing a physical urban continuity, but, instead, that of residing in constructing roads and public transport routes as well as in distributing them around residential areas and production sites [...] the development structure under discussion is, accordingly, able to do away with the centralized model of the polarizing metropolis, and to effectively solve the issues of the relations between transportation infrastructures and settlements.” (Bacigalupo, Corna, Pellegrini e Mazzocchi, 1965). In this proposal, which approached the subject through geographical and historical lenses, the authors sharpened the focus on the significant discontinuity that historically characterized the piedmont area. In 1967, in the context of the research undertaken by Centro Studi and of the economic studies concerning the first state plan for the regional development of Italy, scholars proposed a “linear model resulting from the combination and arrangement of three different kinds of territorial typologies” (Moroni e Marcialis, 1967). The entirety of the concept of the piedmont area is comprehended within this image, as each space “has its own name and function, as part of a mechanism that grinds, perforates and connects” (Mazza, 1992). Finally, in 1992, a study, commissioned by the Agnelli Foundation, combined a number of reflections on the 1990’s Italian economic and social geography with the very themes scrutinized in the undergoing reform of the republican state, which was considered necessary, not only in the context of the political crisis, but also in that of the future economic potentialities (Marcelo Pacini, 1992).

In this paper, the piedmont territory is contextualized within the debate regarding the new definition of the Regione Padana, which is understood as “the sum of relatively mutually autonomous sub-systems” (Marcelo Pacini, 1992) [2].

Manufacturing in the IAF. A pervasive trend. The different seasons of manufacturing

Taking into consideration several studies that, within the context of the future development of Northern Italy, built a set of implicit scenarios of the IAF, it appears that IAF begun to be acknowledged and taken into account almost exclusively with regard to its evident contribution to the economic production of the country. Indeed, it must be noted that this territory was increasingly and progressively being understood as a significant area, mainly because of its prevailing role in the Italian manufacturing sector. Before that, there was nearly no mention of the IAF in the studies of the other elaborate scenarios for the project (Mazza, 1992). Throughout the first decades of the twentieth century, the IAF was understood as fundamental in the axis composed by the valley floor and the railway/highway system connecting Turin, Milan, Venice, and Trieste. At that point, the idea of a linear territory connecting medium-small cities, new centers of expansions, and open land emerges. Namely, this very territory is understood as “a great axis for the development and balancing of the process of centralization in few big-size poles”. Thus, in the context of the analysis of the piedmont area, we cannot ignore the manufacturing drive around which it is structured. Indeed, the IAF lived through a various series of “seasons of manufacturing”, which, most of all, determined its different representations.

Up until the nineteenth century, the most representative image of this area was that of “the proto-industrial nebula” (Lanzani, 1993).

After, the IAF was referred to as a “territory of widespread industrialization” (Bagnasco, 1977 and Fuà, 1983), or a “territory governed by the traditional model of the manufacturing district” (Boeri, Lanzani, Marini, 1993). As a matter of fact, this is a representation that corresponded with the period of the peak influence and relevance of the model of the local manufacturing district (LC), which was widely considered as “the foundational cell of the Italian economic system of the second half of the twentieth century” (Cerruti But, 2018). LC is a concept that G. Becattini borrowed from the theories of Marschall, and which was postulated as a result of the collaboration between many scholars, both Italian and international [3]. Around the same time, several urban planners introduced a visual understanding of the piedmont areas as “reticular” (De Matteis), constituted of a collection of economic-territorial systems, embedded in different contexts.

Specifically, this mosaic-like representation is able to highlight the interdependency between different systems of diverse nature – not necessarily hierarchically – and prove the fallacy of the traditional distinction between the city and the countryside, as well as between the inland and external characteristics of the very territory under discussion (Lanzani, 1993).

It followed a season that coincided with the establishment of the European economic union, as well as with the increasingly open attitude towards the new model of global interconnections. IAF production system, while maintaining its position as the “Backbone of the Made in Italy” (Gurisatti, 2001), “leaked” outside of its territorial borders, thereby subverting the grounds of the traditional concept of industrial district, and redesigning the language and the site of production (Gurisatti, 2017). In this framework, wherein the territorial representation becomes profoundly unhinged from the local territory it refers to, the image of the territorial grid seems to fall apart, favoring, conversely, global-scale network dynamics over the local-scale processes it traditionally sustained (Pasquato, 2016).

More recently, the IAFI has been afflicted by the consequences of the 2008 economic crisis. This structural crisis marked the very end of a once-prevailing social and economic model, due to a set of different processes, that will be investigated later in this paper. Over the course of the last years, scholars have predominantly constructed scenarios elaborating on the concept of land abandonment, as well as on the subject of “local development”. Furthermore, the processes of landscape homologation, investigated by a number of studies on the widespread regional industrialization, have acquired new relevance (Boeri, Lanzani, Marini 1993; Turri 2000).

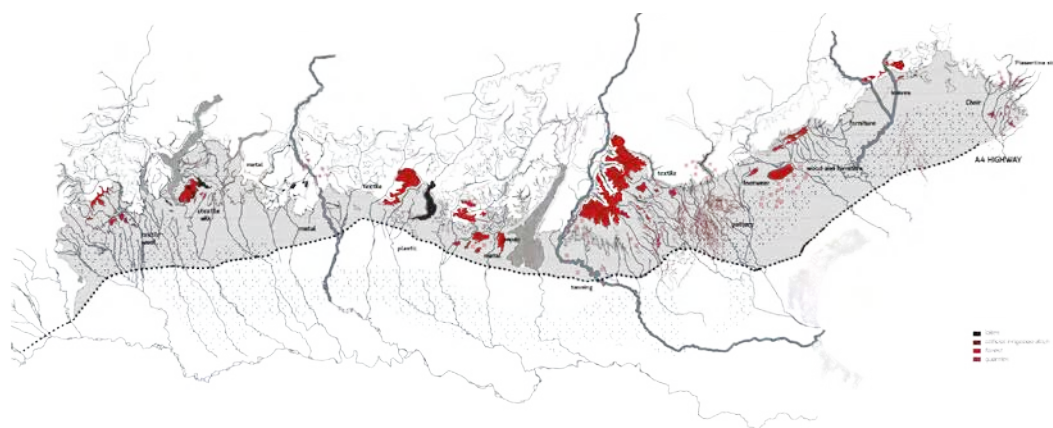

Figure 1. IAFI as “territory of widespread industrialization”

FLMS and the concept of “Designing territorial metabolism (TM)”

Today we are in an exceptional transition phase, wherein the IAFI needs an overall reinterpretation of its manufacturing spaces. As a matter of fact, although we can still recognize the IAFI as one of the most economically relevant areas in the country, we are unable to understand the complex set of its transformations and, specifically, to grasp those related to the evolution of the foothills local manufacturing systems (FLMS). The FLMS are strongly affected by the mechanisms of metamorphosis and redefinition. It is, therefore, crucial to observe this metamorphosis on the basis of different evolutionary actions that question, support, or subvert the district model. In order to understand and address these complex and diverse changes that strongly influence the relation between the city and the environmental resources, I propose to apply the concept of urban metabolism. Thanks to this concept, the shift from linear to circular modalities of production/consumption becomes imperative in order to reduce the external influences on our territories and to meet stricter environmental targets.

Urban metabolism is generally defined as the processing of inflows and outflows of resources and energy within the city fabric (Giezen, Reho, McCarthy, 2019). It is important to underline that this paper, in dealing with the concept of urban metabolism, specifically focuses on the recently conceived notion of “Designing territorial metabolism”(TM) [4]. This notion lays the ground for a paradigmatic shift in connection to three fundamental aspects:

- First of all, the idea of going beyond the boundaries of the consolidated city, in order to further understand the dynamics of the production process and the modalities whereby resources are deployed and allocated (Kampellman, 2018). Thus, as the

question of scale becomes relevant, overcoming the city/countryside dichotomy means equally considering FLMS as a unique system, where different material and immaterial flows interweave, as part of a circular structure [5]. This understanding is not opposed to the idea of simultaneously reinforcing the key roles of the local sector. At the local level, the role of diverse, complex and fragile types of urban economies becomes fundamental in the process of fostering small interventions and urban innovation (Casabella, 2018).

- Second of all, in order provide an operative input for the current practices of policy-making, the intricate and mostly idiosyncratic nature of circular TM must combine the (mostly quantitative) research on biophysical flows with (predominantly qualitative) insights into the socio-economic process of transition. Since the vast number of the socio-ecological factors cannot be expressed in commensurate metrics, the design of a circular socio-ecological system cannot be separated from a qualitative exercise that needs to construct new social, economic, and political institutions. Seizing this opportunity requires a characterization of TM that demands a transition to the circularity of the sole energy and materials flows. It also needs to question its intensity, the spaces, and the agents that underpin the metabolic exchanges. (Kampelmann, 2018).
- Finally, although the notion of TM has mostly been featured in traditional urban studies (for instance, Renzoni and Tosi discussed the idea of “città diffusa” in the region of Veneto in 2018), today we can still posit a novel understanding of it, which is useful in combining urbanism and ecology in addressing a new kind of circular urbanism, and to serve as a new tool for urban planners interested in the TM. In other words, we have to find a new formal language, as well as a set of efficient means through which the spatial/physical elements and socio-political elements of metabolism can be conjointly redesigned; we need new instruments to “reimagine relations between social, technical, economic, and ecological forces in urban areas” (Broto et al., 2012).

My research aims to identify a new set of useful modalities in order to combine the existing knowledge of biophysical flows with a meaningful perspective on the socio-economic transitions of the different FLMS, taking them as a unique system, oriented towards a circular metabolic scenario. This is especially useful in the context of the current Italian political landscape, which lacks both a clear understanding of the circularity related issues, and a fruitful perception of urban metabolism as a way to challenge the current theoretical and practical views of urbanism, promoted by national and local administrations. The first step in this process would be providing a clear overview of the transition phases that affected the different FLMS within the IAF.

The redefinition of space in the FLMS

During the past few years, the district model has been strongly criticized and discussed. For instance, Cerruti But identified three phases in the evolution of the concept of the district, namely (i) the construction of the model, (ii) “the hybridization and the development of the

model”, (iii) the “critique of the model” which, temporally at least, coincides with the crisis of the notion of the district, as noted by Fabio Bracci (2016).

Indeed, it was precisely during this third phase that, following the 2008 economic crisis, the traditional manufacturing-dependent model of district development seemed to reach its endpoint. The causes are multifaceted. Some of them are external, such as the crisis of the global economy, the physical limits to the expansion of the construction industry within the territory, the scarcity of resources caused by the environmental crisis, and a set of social obstacles (e.g. the decreasing interest paid by youngsters to crafts and manufacture). On the other hand, several of them are intrinsic to the very comprehension of the district, which is no longer understood as the site of a one-sector production system relying on physical continuity. Namely, the district territory is no longer delimited by a geographical context defined by the market, but rather defined by a transition to a variable geometry characterized by economic and relational contexts [6]. Thus, the period of the traditional districts today seems over, and replaced by a new one, wherein a diverse set of the development processes of the FLMS coexist in a non-homogeneous manner.

As of today, it is extremely difficult to understand the FLMS changeability. Neither “the modalities of zenithal perspective” (adopted by scholars in urban planning in the study of the case of the widespread industrialization in the nineties), nor the closer analysis via photographic means (which focuses on the sole exterior aspects of the production sites) are sufficiently apt (Basilico, Boeri 1996, Aimini 2017). As most of the novelties reside inside the very sites of production, it is necessary, in order to grasp them fully, not to limit ourselves to an outside view regarding them (Lanzani, 2014). For this reason, it was decided to undertake this research – a “new journey” – in the IAFI, focusing on interviews with the main stakeholders and the direct field survey of some area of FLMS.

While exploring the IAFI, it is necessary to return to the observation of the constellation of the manufacturing production sites, often considered “ordinary”, that for decades were the backbone of the economy of the one of the most dynamic territories in Italy.

First of all, it is critical to identify the various generative processes involved in the systems of production, which imply a set of differences, not only in terms of the foundational aspects of economy, but also with regard to their own geographical organization, thereby questioning the very concept of “designing territorial metabolism”.

Although this paper is part of a research still in progress, the choice of the FLMS under discussion is purposely inconsistent with what is today defined by the regulations concerning the industrial policies [7]. As discussed by Viesti, the currently classifications employed show inherent limitations and merely analytical potentialities that, most of all, are exclusively normative and non-exhaustive [8].

With full awareness, it was considered that, while conducting the operation of selection, these modalities would not be apt to relate to the final target, which is that of observing FLMS’s differences and anomalies, current limitations, and potentialities, with specific attention paid to the spatial and territorial features.

Thus, it was chosen not to focus on the “district” per se, as much as on the territories that still show the marks – sometimes more visible than others – of what is left of the productive system, as well as on the transformations exerting their influence on the physical capital, thereby purposely overlooking the analysis of the economic/production features of the district, which have been already brilliantly described by numerous renowned scholars.

First Hypothesis of rereading and classification of the FLMS

In the following paragraphs, a first attempt at classifying different kinds of FLMS will be presented, which is based on a direct in-field observation. It must be stressed that the four classes of elements presented here are not distinctly ideal types, and that they can be preexistent in a given territory. Thus, the dynamics defining them can be easily juxtaposed and interwoven. This classification is, therefore, necessary in defining a shared representation of the phenomena of metamorphosis of the FLMS.

1. Dwindling local districts (DLC). Exhausted and fragmented territories

DLC are particular districts that have suffered a setback. DLC might comprise both the traditional districts, based on the processes of mining and extraction of natural resources, and the districts relying on the supply chain of the textile industry.

The setback is, firstly, related to the exhaustion of the resources drawn from the adjacent mountainous environment. Mountains have always superficially been considered merely a “reservoir of resources”, thereby overlooking their limitations. Many of the resources that were crucial in the founding of and development of these districts, in the first place, were already being exhausted in the last century. Some others, instead, are still in the process of being exhausted, thereby forcing the sectors of production relying on them to question their own future [9]. Another example of DLC is the “Verona stone district”, located in the foothills of the Lessini mounts, where high-hill and medium-mountain environments blend. The district is the epicenter for the Italian production of marble and granite, and, additionally, is the most important in the global production of agglomerates. The territories of this district are today sites where economic activities, tourism, repurposing and safeguard of the environment struggles to meet. In this forgotten landscape, due to the inadequacy of regulations concerning the process of excavation, slabs as tall as 100 meters have been produced, regardless of the delicate environmental balance that is, today, thoroughly subverted, and which cannot be reestablished.

Some quarries still lay in the open air, despite the fact that their function as mining sites is exhausted, others are still in use, and some others are under evaluation, in order to find a right compromise between what has been removed from the landscape and what should be given back to it.

The main issues concerning these FLMS, as well as similar others, emerge on two different levels. The first is caused by the inequalities in the supply chain as well as by the employment of the resources. Indeed, marble is today mostly imported, as the preexistent quarries are no longer sufficient to match the internal demand. Thus, marble is only refined in this territory, mainly by important companies relying on a dense network of tertiary contractors, and, then, exported back again, thereby causing an enormous environmental impact. Moreover, in the last years, much of the backfilling material defined as “cappellaccio”, which is necessary for an adequate reinstatement process, has been taken away from the original extraction site, and, in the light of profit-maximization, moved to construction site located outside the district.

As a matter of fact, there are very few cases of natural reactivation of the abandoned and exhausted quarries [10]. Indeed, as noted in “Rapporto Cave 2014”, the absence of a real plan regarding this sector caused a widespread and irregular development of the mining activities. The actual necessities required by the process of production, as well as those related to the safeguard of the environment, were ignored. Today, in a period characterized by the crisis of the extraction sector, this negligence manifests itself as nearly a hundred inactive sites. For these reasons, these territories are subjected to growing environmental issues, which point to the disconnection between economy, society and territory (Savinio, 2005). The decisions influencing the future of these quarries expose clashes in the attribution of the jurisdiction between the different administrative hierarchies involved (Regione, Provincia e Comuni).

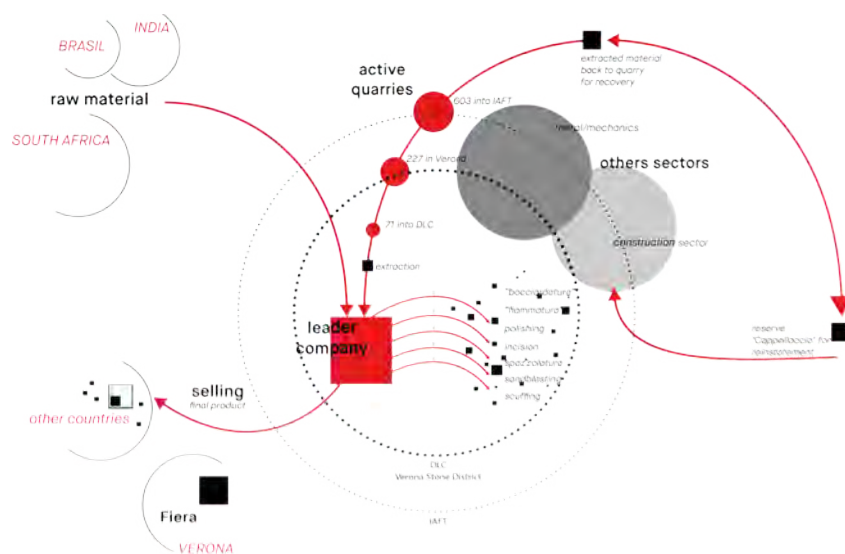

Figure 2. Personal interpretation “Verona stone district”

Secondly the setback of this second type of DLC is related to the lack of an adequate body of local competences and skills. This is one of the effects of the process of internationalization, whose consequences impacting on this class of FLMS are easily identifiable in the process of deterioration of the production chains.

From an historical perspective, the internationalization of the production processes concerning the piedmont companies can be broken down into three different periods. (i) The first phase, which spanned the last two decades of the past century, led companies – specifically those part of the fashion industry – to delocalize production, in order significantly reduce the manufacturing costs; (ii) during the second period, which stretched from the beginning the twenty-first century to beginning of the 2008 financial crisis, the companies involved in the stage famously labeled as “quarto capitalismo” have become the main actors in the process of internationalization: investor pools has widened, thereby including small and medium size companies. During this phase, the number of the investments in the foreign markets decreased, and yet the process of internationalization reached its peak in spread and intensity. (iii) The third one, beginning in 2008, has been characterized by a slowing down of the foreign investments in the territory: the repercussions of the financial crisis on funds and prospective revenues have forced companies to slim down the undergoing initiatives as well as to postpone a great number of pending projects (Fedreghini and Perugini 2015).

In some of territories under discussion, the constellation of small-size and medium-size companies, once the core of the supply chain of the district, fell apart. Thus, we are left with nothing more than “the crumbles of important and renowned historical producers” [11]. Moreover, many of the intermediary actors facilitating the sustainability of the process of production, such as consortiums, citizens led communities, and sectorial associations, were forced to merge, as the result of the economic crisis and of the cuts in the public funding. This led to the current absence of institutional benchmarks – with strong ties in the territory [12] – that had been previously critical to development of both the economical aspects and the social actors operating in the territory.

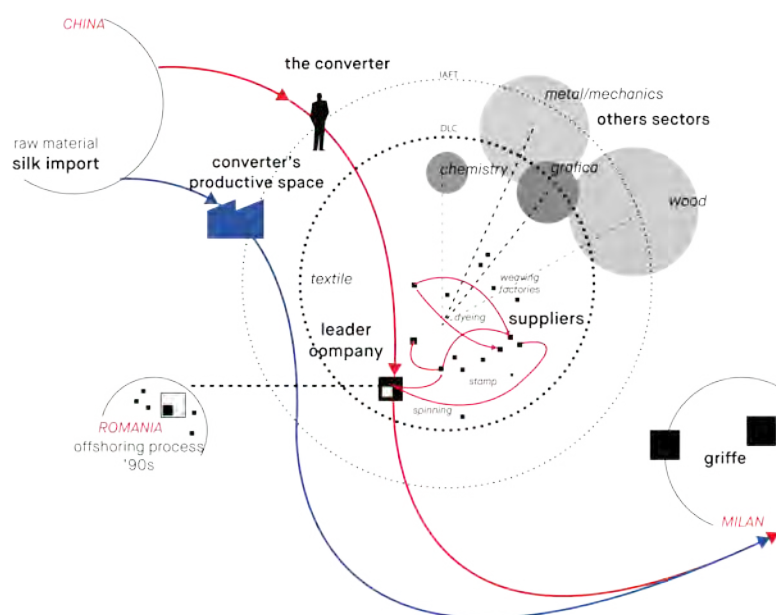

Figure 3. Personal interpretation silk district in the area called Comasco

2. Traditional districts (TLPC)

TLPC is a class of FLMS that, while maintaining the traditional economic/production structure, are still capable of achieving good results in terms of growth, revenues and profitability. In this framework, the presence of both competent human capital and a set of developed services (design, consultation, research) is vital. In this case, the manufacturing district is still economically relevant as a dense “fabric” of micro companies (many of which are still family-managed), which are still considered complementary to the process of construction of “actual medium-size companies, distinctively specialized in both the design and commercialization of products” (Becattini and Dei Ottati, 2006).

Specifically in the context of these FLMS, the companies standing out are those investing in the territory and presenting themselves as firmly environmentally aware. Thus, the reduced impact on the environment becomes a competitive factor for companies, which are keen to invest for the safeguard of the very sites and ecosystems their own production is depended upon.

However, this tendency is still today very much rhetorical. Indeed, useful and actual territorial implementations – to be focused on concepts such as *circular economy* and *sustainability* – are not yet fully comprehended, as these concepts are currently addressed from the sole standpoint of productivity.

New tools are needed, which are able to design fruitful relations between the social, technical, economic, and ecological forces operating in the territories of TLPC, as well as to trigger a set of virtuous synergies in the operations of waste reduction and recycling – with specific focus put on the large amount of polluting waste that is often disposed directly in the territory.

A new virtuous environmental approach has been showed, for instance, by the TLPC of Concia in the Agno valley (Veneto), whose dynamism is best epitomized by a collection of institutionally-supported artistic projects [13].

In this area the country's largest amount of water supplies can be found, thanks to the presence of both subterranean reservoirs and perennial springs.

This abundance favored, firstly, the development of the craft of leather tanning, and, secondly, the construction of the tanning industry, which was highly impactful at the environmental level. Indeed, factories used to dispose waste and leftovers – rich in lime and sulfides – directly into the rivers, which, consequently, would turn red, brown and grey according to the polluting agents involved. [14]

In the 1978, with the installation of a purification plant, a virtuous set of initiatives was started, which is still oriented towards sustainability, and which has progressively co-involved the whole of the companies operating in the area – thereby allowing for an appropriate process of water treatment for Chiampo (Boriello, 2019).

However, several environmental issues are still embedded in this territory, mainly due to a greater degree of pollution in both air and water.

3. Adaptive local clusters (ALC). Their new roles within the territory

ALPC is the class of FLMS allowing for a “third road [...] related to the creative craftsmanship and to the cultural industries focused on the development of different economic models inclined towards forms of experimental tourism” (Ostanel, Panozzo, Tosi, 2018). In this case, in order to adapt to the new economic configurations, the concept of FLMS hybridizes with a set of tertiary and immaterial functions. It is thereby “extended to other sectors and new combinations: agricultural, rural, touristic, cultural” (Dematteis, 2005: 12).

Thus, ALPS, in this way, lay down on the territories a dense network of new sites and equipment.

These ones originate from the repurposing of abandoned buildings, whose historical role was that of possessing important functions within the supply chain.

They are fundamental sites promoting the knowledge and the understanding of a specific industrial sector. They can assume the form of factory museums [15], as well as of different types of craftsman workshops that valorize an attentive and sustainable process of repurposing that combines traditional know-how and innovation. In this context, a renewed focus on recycling and on the employment of sustainable energy is effectively brought about.

A useful instance might be found in the ceramics district in Nove and Bassano. In this territory, several abandoned and anonymous industrial buildings were turned into sites of research and experimentation, in order to find innovative waste-minimizing solutions.

The findings of this study showed that the piedmont districts are still benefiting from a proximity-based network of production, which allows local companies to peer-review the process of innovation, mutually share a diverse set of know-hows, and reshape the supply chain according to a locally incremented distribution system.

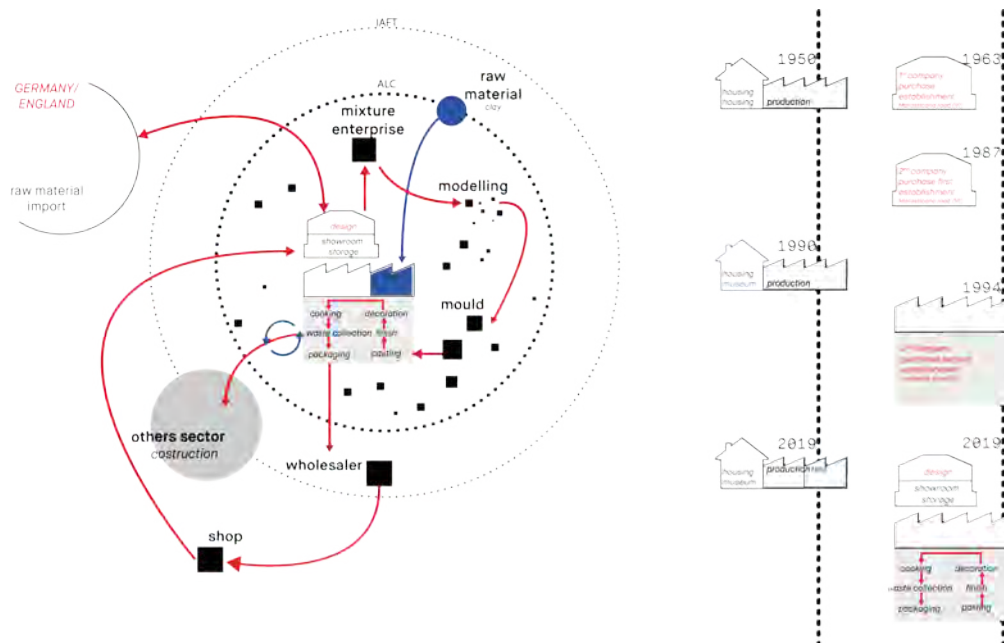

Figure 4. Personal interpretation Ceramics district of Nove e Bassano

4. Beyond the district: clusters. An extended and redesigned territory of production

These types of FLMS are continuing to grow and they are, most of the time, identified as “productive clusters” [16] (PC).

In the PC territories the SMEs understood that the proximity between diversified and specific industrial base inside a metropolitan space allows for the invention of complex products and the growth of the economy in the long run (Hausmann, Hidalgo et al. 2011).

Thus, the frame of reference is broadened, and a new set of new links is established, which connect the piedmont territories to the nearby urban poles hosting important tertiary services. Clusters allow for a novel perception of the territories they are located in, as well as for the construction of a new vocabulary redefining the territorial scenario [17].

Thus, newly introduced terms are useful in positing that the “boarders exceed the simple geographical edges as well as the administrative limits: PC is a complex industrial system, abundant with top-notch producers in many industrial fields [...] PC fosters an understanding which is complementary to, not opposed to, the orthodox one (which considers only the industrial activities located in the province), which offer a more comprehensive perception of the actual dimension of manufacturing” (Fedreghini, Perugini, 2015). Companies are today able, thanks to this superstructure connecting them, to merge into a unique system that is beneficial to all.

Clusters propose a more complex, and yet more unifying, representation of the system of production, which, additionally, makes companies more interesting for potential foreign investors.

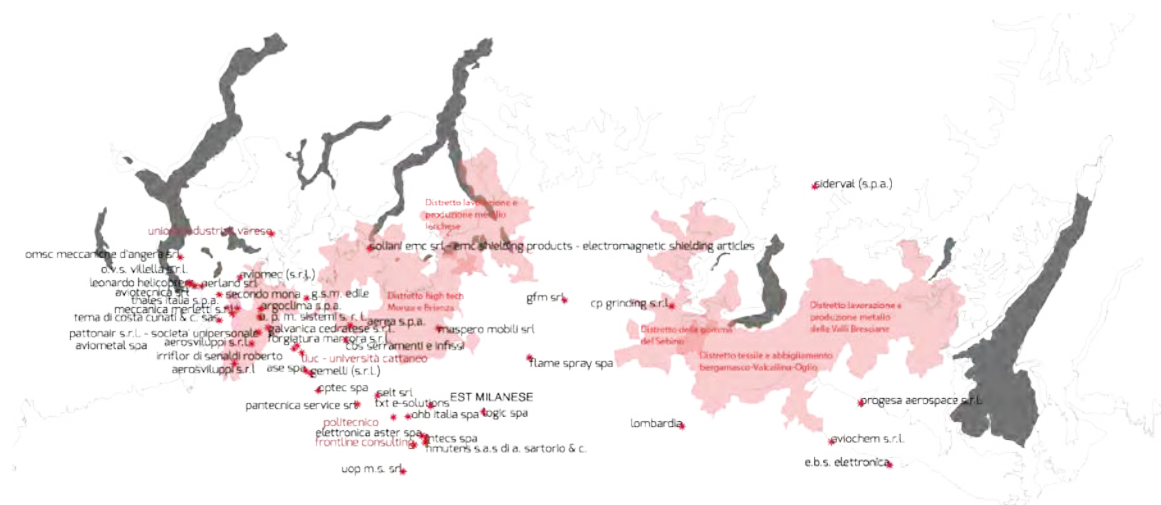

Figure 5. Personal interpretation Cluster aerospace

PCs can be considered, from a metabolic standpoint, the first attempt at creating strong links between the different flows of production, be they material or immaterial.

As far as immaterial flows are concerned, the will to collaborate, heterogeneous set of production sectors, is transposed within the urban contexts as the profitable trend of transforming formerly decommissioned sites into multifunctional spaces. This collaboration originated, in the first place, in tackling the issues related to the significant expenses involved in the process of innovation, as well as to systemize comprehensive programs of training and knowledge sharing.

Thus, these very spaces become sites for the “social innovation”, where different actors, such as entrepreneurs themselves, reutilize physical structures (most of the times decommissioned warehouses), which previously held no purpose whatsoever [18].

The cluster is conceived of as “fluid urban agglomeration”, able to establish a set of new connections between different innovative forms of production.

However, what is still lacking in these territories is a clear and shared vision, necessary to address a circular process, based on productively balancing inflows and outflows of both energy and resources within the cluster.

Considering the strength with which the local supply chain still operates within these territories, despite the massive implications of the process of internationalization, it might not be inconsiderate to promote a solid interfacing between local companies, in order to favor this very circular approach.

The aim would be that of reducing waste generally speaking – not only energy waste and industrial waste – thereby adopting a set of resolutions that cross over the limits of the single-sector system.

Indeed, cooperation between the different sectors would also imply a greater degree of systematization of the different flows, which, in turn, could be reutilized and, therefore, minimized within an open bigger-scale system. This very system should be able not only to coordinate the aforementioned material flows, but also the immaterial ones. However, this

aspect is still at very early stage of development, inasmuch as companies still operate according to an individual, rather than synergic, logic.

Conclusion

In conclusion, IAFIT is today living through a hybrid existence. It is a territory whose core is built by a “mix of companies running at different speeds”. It is no longer a homogeneous unitary site of widespread industrialization, but rather a territory where big-size, medium-size, and small-size companies locally coexist. Generally speaking, the heterogeneous combination of these different companies triggers new favorable mechanisms of centralization, hierarchization, and polarization, thereby remodeling the territories of the widespread production.

Analyzing the IAFIT and its complexities, as well as classifying the different evolutionary processes of the FLMS, are useful tools in the systemization of these important forms of production, which, nowadays, are no longer attributable to a unique and unitary evolutionary process. Today, each of them is observed to undertake a different development path, thereby defining its own trajectories and its own relations with the specific territory it is inscribed in.

Thus, the classification proposed above is intended to serve as a support for the construction of a platform that, crossing the traditional boundaries, is able to show a variably geometrical landscape, where new relations can be fostered and established. These very relations, that might be economic, spatial, or social, must be considered in conjunction with a set of both material and immaterial flows, in order to meet shared targets such as waste minimization and resource enhancement.

This is a useful platform for questioning, planning and formulating a synergic and unifying model, as well as to test and systematize a set of actions required in the development of a fundamental metabolic territorial system, which is today still missing in the spectrum of the Italian politics.

Acknowledgements

[1] The research is still in progress. The field research will be concluded in October 2019. The results will be featured in the PhD thesis, which will be concluded by November 2020.

[2] In this study the focus is sharpened on the two ramifications composing the notorious “triangolo Milano, Bologna, Padova”, which, in turn, can be divided a Northern segment “the old industrial triangle in Lombardy (Milano, Varese, Como)” and an Eastern part, namely “the new vector connecting Vicenza and Pordenone” which complete the “pulsating heart of the Padano system”.

[3] S. Brusco, A. Bagnasco, and G. Fuà also took part in the process formulation of the concept of LC. All the scholars acknowledge the “social embeddedness” of the economic processes (Granovetter, 1985), that is “a series of historically alimented socio-institutional infrastructures, such as networks, regulations, conventions and interactions, based on trust and mutual horizontally mutual relationships” (MacLeod 2001).

[4] This concept has been introduced in the book by G. Grulois, M. C. Tosi, C. Crosas (eds.) *Designing Territorial Metabolism*. JOVIS, 2018.

[5] Today, the main line of reasoning – elaborated in favor of economic forms sustaining the concept of urban metabolism – is, conversely, centered on the small-scale of the individual district, thereby overlooking a systemic view of the problem.

[6] An ever more complex vocabulary regarding the identification of the various FLMS emerges, which originates in the continuous alternation of different regulations at the level of regional industrial politics (“production district”, “meta-district”, “conglomerates” “cluster”, “multi-located supply chain”). In the context of this new complexity, it is worth mentioning the discordant attention paid to the territory. In Lombardy (Legge n.29 del 23 novembre 2016) and in Friuli Venezia Giulia (Legge regionale 20 febbraio 2015, n. 3, art. 15) the concept of *Productive Cluster* (PC) is employed. There is no longer mention of a specific district, but the Region as a whole is taken into account. Conversely, the Veneto Region proposed to update the notion of the district by substituting it with that of the RIR (Rete innovativa regionale). RIRs are the result of the regional Smart Specialization Strategy, which defines strategic thematic areas on a regional scale. The notion of traditional production systems endures within the context of a limited territory.

[7] The local production systems of the territory here analyzed are to be found in Veneto, in the Ceramics district of Nove e Bassano, the Sportsystem district in Asolo and Montebelluna, the Verona Stone District, the engineering in the area called Alto Vicentino, the stainless steel district. Others are in Friuli Venezia Giulia, such as the Arredo Casa Cluster, the COMET (cluster della meccanica regionale) Cluster, the former “knife district” and the DITEDI (distretto industriale delle tecnologie digitali) Cluster. Others are in Lombardy, such as the aerospace cluster, the silk district in the area called Comasco, the engineering district in the area called Lecchese, the automotive cluster, the former water fittings and cutlery district, and the district of the area around the Arno valley.

[8] In the past years, in Italy, we witnessed a significant proliferation of mappings and classifications, each of them bearing its own different approach, according to the different purposes underpinning these operations. Specifically, we can identify two main tendencies in the description of the Italian districts: a statistical approach and one that, conversely, focuses on the potentialities of the local districts.

[9] Reference is made, for instance, to the Piasentina stone district in Friuli Venezia Giulia.

[10] An example is that of the quarry on the Loffa Mount in Sant’Anna d’Alfaedo, where a gigantic, 20 meters cut has been replenished with backfilling material and then converted to a grass field.

[11] The supply chain of the textile industry is that suffering the most. For instance, the former textile district in the area called Alto Vicentino is, since 2017, no longer officially acknowledged by the Regione Veneto, due to the lack of a shared project for the area (LR8/2003), via a development agreement (see note number 6). Moreover the silk district in Como, Lombardy. There it remain a collection of big-size companies, which still are the beacon of a their own sector, and yet, most of the times they show no interest in the development of the territory.

[12] In Veneto, companies always had, and still have, a strong organizational structure based on consortiums, which, in turn, used to hold a significant influence over the regional government.

[13] Among them “Tanneries” (M. Power) and “Water”. In this photographic reportage the main elements are the frantic activity of the river Chiampo, the territories that are brushed by it, and the essential interventions needed in the water purification, which aims to preserve its vibrant colors of the water – despite the industrial processes the river is involved in.

[14] A fictional investigation portraying the water pollution in the Chiampo valley is featured in the novel “Il fiume sono io” (A. Tasinato).

[15] For instance, the paper mill Museum in the paper mill Valley, located nearby Brescia.

[16] The traditional production districts are widely acknowledged entities, thanks to their ability to aggregate and promote “development agreements”, a to represent a diverse set of shared and communal targets.

[17] For instance, “Grande Brescia Manifatturiera” (Fedreghini and Perugini, 2015).

[18] With reference to LEF, namely the training school focused on the topics such as the lean production and the concept of 4.0 industries. Moreover, LAMA, a shared workshop pivoting around the technological skills transfer from universities to Regione (institution). Both of these programs are hosted in formerly decommissioned warehouses.

[19] For instance, in the context of a structural analysis, commissioned by the Comet cluster, it appears to be clear that, nowadays, companies are able to find the efficiency, the competences and project-related skills they need at the local level. In this scenario, the main factor underpinning important logistic decisions is – as it used to be during the season of the traditional industrial districts – proximity.

Abstract: The city is a complex system, and the relationship between the city and the natural environment is very close, especially the interaction and relationship between water resources and water environment becomes more complicated in the city system. In recent years, there have been more and more researches on metabolism and recycling economy. This paper will use the concept of water cycle to carry out water system planning research. The study believes that the urban water system is an important part of the complex large-scale system of the city. It is the system of the natural circulation of water and the coupling of social circulation and urban space. According to the theory of water cycle, the final study divides the urban water system into rainfall, river system, water supply and water distribution system, urban water usage system, sewage treatment, water reuse, and rainwater discharge system. Based on the study of the relationship between traditional urban water-related planning and Integrated Urban Water System Planning(IUWSP), the theoretical framework structure of IUWSP(Integrated Urban Water System Planning[IUWSP]) is proposed. The planning system consists of the following modules: planning target determination method, standardized investigation content and method, and demand forecasting method, supply and demand analysis, comprehensive evaluation.

Keywords: water resources management, water cycle, water system planning method, theoretical system

1 What is the water cycle?

(1) Natural water circulation

The natural water cycle is the rainwater phase transition and the recurring process in the form of water vapor evaporation, water vapor transport, rainfall, runoff, and infiltration in the natural world, which Under the action of solar radiation and gravity.

As early as 1931, Horton studied the process mechanism of evaporation, condensation, sedimentation, runoff in natural water circulation (Horton, 1931).

The natural water cycle follows the law of conservation of mass, the change of water storage S_0 = annual precipitation P_0 - annual runoff R_0 - annual evaporation F_0

$$S_0 = S_{10} + S_{20} + S_{30} + S_{40}$$

In this equation, S_{10} —changes in soil water storage capacity; S_{20} —changes in water storage in Tanggu; S_{30} —changes in water storage capacity in rivers and lakes; S_{40} —change in water storage capacity in wetlands

$$\text{Runoff coefficient } \alpha_0 = \frac{R_0}{P_0}$$

(2) Social water cycle

The social water cycle has emerged along with the development and utilization of water resources by human beings. It is a process of human “water intake – water supply – water drainage”, and it is in the continuous flow of space and the process of recurrence.

In 1997, Merrett first introduced the concept of hydrosocial cycle, which was attached to the natural water cycle due to engineering activities and incorporated urban water and wastewater treatment services into the social water cycle (Merrett, 1997). Compared with evaporation, condensation, sedimentation, runoff and other processes in the natural water cycle (Horton, 1931), the process of social water cycle is represented by seven major engineering activities: water intake, storage, water treatment, water distribution, wastewater collection, wastewater treatment and wastewater discharge (Merrett, 1997).

Wang Hao divides the social water cycle into water intake, water usage, water drainage, backwater. The water intake system is the beginning of the social water cycle, the water usage system is the core, and the drainage system is the sink end (Wang Hao, 2011). Wang Hao also proposed that the social water cycle is a composite water cycle with a “natural-artificial” binary driving force and structure (Wang Hao, 2003).

(3) Urban water cycle

The urban water cycle is a complex cycle body formed by the natural water cycle and the social water cycle highly coupled in the urban area.

The discipline that studies urban water cycles is urban hydrology, which is developed on the basis of hydrology. Due to the more complex hydrological cycle and more external influences and interventions in urban areas, the urban water cycle should be studied separately. The main research contents include the impact of urbanization on hydrological processes, urban water supply and drainage, urban water environment, urban flood control, urban water resources, urban hydrological models and hydrological prediction, and urban water conservancy engineering.

The urban water cycle is a cyclical process that takes place in urban areas and is based on the natural water cycle and dominated by the social water cycle (Shao Yisheng, 2014).

UNESCO has studied the various components of the urban water cycle (UWC) and the main pathways of water flow, as shown in Figure 1 (UNESCO, 2006). In the urban water cycle, the natural water cycle has changed due to the influence of urbanization.

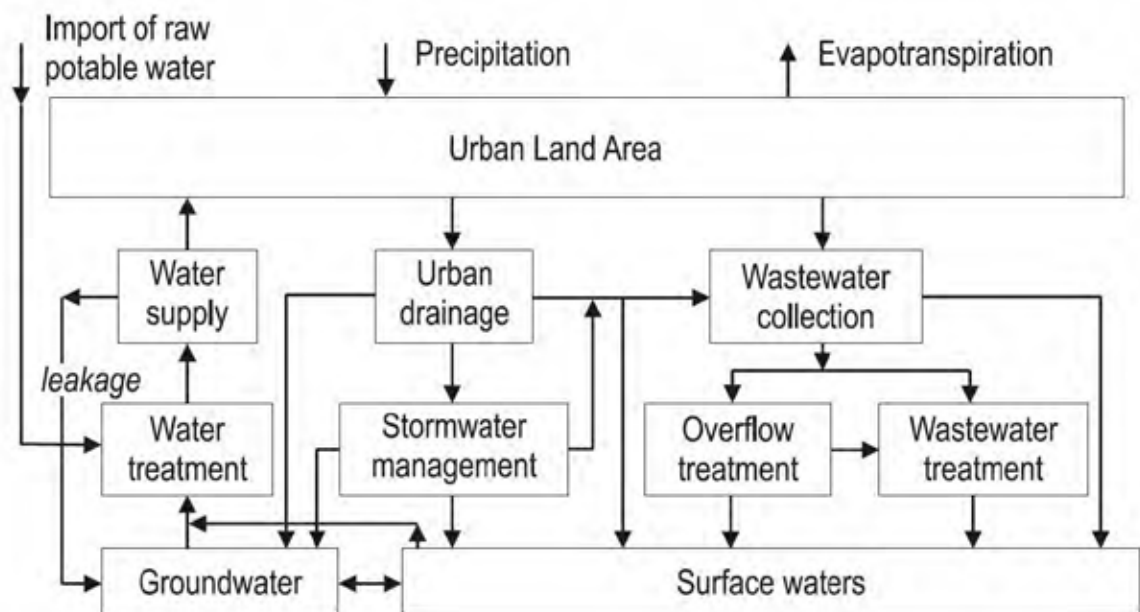

Figure 1 Urban Water Cycle - Major Composition and Water Flow Path (UNESCO, 2006)

2 What is the relationship between urban water systems and the water cycle?

(1) System overview

System science is a science that specializes in the evolution of complex systems and studies system composition, structure, feedback, and control. The purpose of systematic research is how to understand and control the system.

(2) Urban water system concept

The urban water system is based on the water cycle. The water system infrastructure is the carrier, and the comprehensive system is aiming at ensuring urban water security and improving the water environment. The urban water system is an important part of the urban complex system. The general term for systems in the urbanization area contain flood control, water source development, water supply, water transport, water use, drainage, sewage treatment and reuse, and trans-regional water transfer, using, governance, configuration, conservation and protection. The urban water system involves the whole process of urban water resources development and utilization, protection and management (Chen Jining, 2014, Li Shuping, 2015, Shao Yisheng, 2004, Shao Yisheng, 2014). Urban water circulation system, including water source subsystem, water supply subsystem, water usage subsystem, drainage subsystem, recycling subsystem and rainwater subsystem.

(3) Urban water system problems

The development of urban water system from the solution of water, sewage, rainwater discharge to ecological civilization development process, most of China's cities have basically built a complete water supply and drainage system network and the corresponding water system supporting facilities. However, because the traditional urban water-related planning method is a single plan for their respective functions and services, and does not consider the overall water system service demand, therefore, the water system construction process in many cities in China does not conform to the development law of the water cycle, and the city lacks water. The problems of water scarcity and water pollution still exist, water resources are not fully utilized, water environment quality

is deteriorating, and urban water problems are still the limiting factors affecting urban economic development and people's living standards.

From 1978 to 2016, the urban water use population increased from 62.67 million to 450 million people, and the urban water supply scale increased from 7.875 billion m³ to 58.069 billion m³. The traditional urban water system has brought about a series of complex urban water problems in the process of adapting to the development trend of large cities and urban agglomerations, resulting in urban water disasters (Wang Guangtao, 2012, Cheng Xiaotao, 2009). The 2016 State of the Environment Bulletin shows that the quality of the national water environment is not optimistic. The lack of urban water resources has always been a major problem that has plagued most cities in China. Among more than 600 cities in China, there are currently more than 400 cities with insufficient water supply, including 110 cities with severe water shortages. The annual water shortage in the city is 6 billion cubic meters. Tianjin, Hebei, Shanxi, Inner Mongolia, Gansu and Qinghai The water resources of eight provinces, autonomous regions and municipalities directly under the Central Government, such as Ningxia and Xinjiang, are in short supply. On the other hand, in many cities in the Yangtze River Delta and Pearl River Delta regions where China's economy is developed, due to water pollution, some cities with rich water resources are also facing water shortage problems, and have to transfer water from remote areas with good water quality. But the treatment rate of sewage and the reuse of water resources are also low. The ecological crisis of the basin is largely due to the irrational development and utilization of urban water resources (Cheng Xiaotao, 2002).

There are also many severely water-deficient cities in coastal open cities such as Shanghai. The city can only rely on regional water transfer to solve urban water problems. Over-exploitation of water resources and trans-basin water transfer are the main means of solving most of the current water-deficient cities.

Figure 2 China's urban water supply over the years (sources: 1978-2016 China Urban Construction Statistical Yearbook)

In addition, the situation in China is also quite severe. According to the statistics of the National Flood Control and Drought Relief Headquarters Office, in 2010, 258 cities in China were in flood, most of which were torrential rains. From the distribution of the water retention points on June 1, June 19, and July 6 in Wuhan city (Seen in Figure 3), there is an increasing trend of change. The water retention points on July 6 is the most extensive, with as many water retention points and water retention road sections as more than 100 places, almost all three towns in Wuhan were flooded.

Figure 3 Schematic diagram of the city flood in wuhan city

In Hebei (North China), Zhejiang (East China), Harbin(Northeast), Guangzhou (South China), Wuhan (Central China), Northwest, Southwest(Wei Jun, et al,2018, Li Xuesong,et al,2018, Lin Changchun,et al, 2018, Zhai Jianming, et al,2017, Xie Zhiqiang, et al, 2017, Gao Feng, 2015), there have appeared varying degrees of urban flood, and urban flood has become a universal phenomenon throughout the country, not just the unique phenomenon of rainy cities in the south china.

Figure 3 Schematic diagram of urban water system problems (left: flood; medium:drought;right:Black stinky water body)

In the process of urban flood, the urban sponge system was occupied by urban construction land, resulting in water nowhere to go, resulting in urban flood. The water surface rate of rivers and lakes and the density of river networks have decreased, and there has been a situation in which people compete with water. For example, in the history of Wuhan, famous as“Yunmengze”,the area of sand lake was nearly 666.7 ha , but now it is less than 8 ha; Donghu lake has reduced 73 ha. The surrounding of Nanhu and Tangxun Lake are high-rise buildings, and Fanhu disappears.

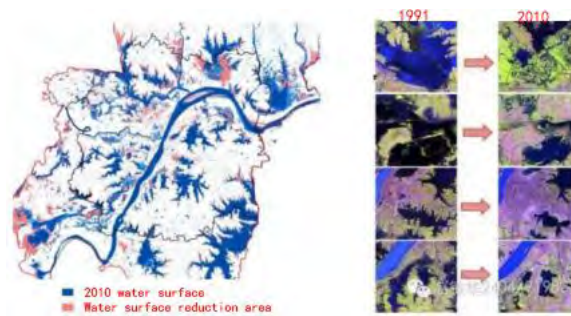

Figure 4 water area change situation in wuhan city (1991-2010)

(4) Analysis of the causes of urban water system problems based on water cycle theory

The causes of urban water system problems is, from the perspective of natural water cycle and social water cycle, urban development has brought the following effects to the urban water cycle:

1) Changes in the structure of the rainwater cycle

Most of the literatures believe that urbanization has brought about an increase in ground water impermeability. The traditional urban rainwater rapid discharge mode has led to an increase in rainwater runoff, a decrease in the rate of rainwater Infiltration, a change in the path of rainwater circulation, and a change in the structure of the rainwater circulation. These changes(Seen in Figure 5) arde prone to urban flood. At the same time, with the development of urbanized areas, natural channels and riverbeds were replaced by artificial channels and sewage pipe networks, resulting in profound changes in the way of runoff. Overall, these changes increase the rate of runoff propagation.

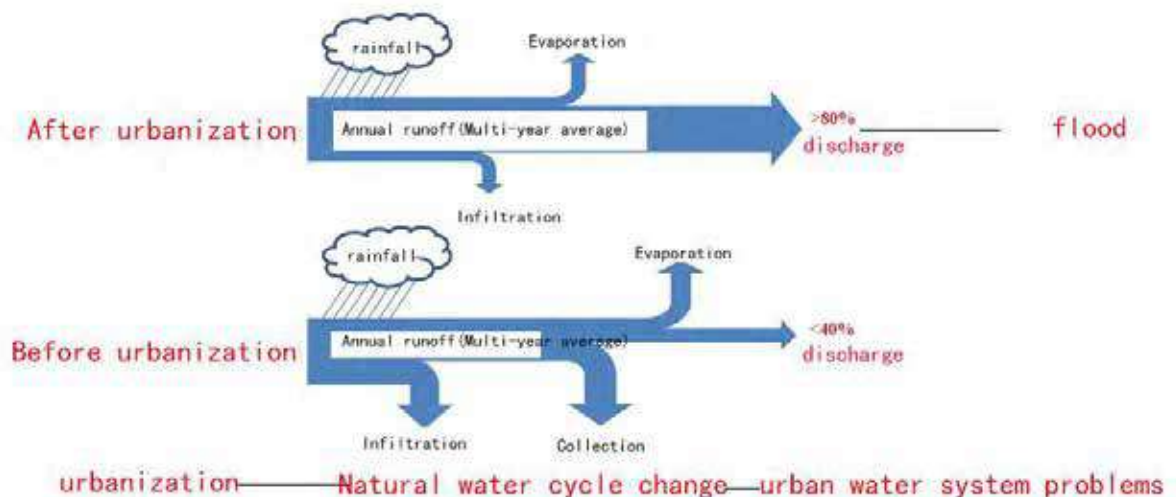

Figure 5 Schematic diagram of the impact of urbanization on the natural water cycle

In order to avoid changes in the natural water cycle caused by urban development and rapid urbanization, China proposed to build a sponge city and return to the hydrological state before urban development. Sponge City is to build a low-impact development rainwater system, that is, to follow the low-impact development concept in urban planning, implement low-impact development control objectives, and set up some low-impact development facilities to achieve the purpose of runoff control, runoff peak control, and rainwater resource utilization. Low-impact development facilities mainly include infiltration technology, storage technology, conditioning technology, transfer technology, and sewage purification technology, such as permeable paving,

green roof, sunken green space, penetrating pond, etc. Storage technology includes rainwater wetlands, rainwater tanks, etc. The adjustment technology includes regulating ponds, etc. The transfer technology includes planting ditch, infiltration pipe, etc., and the sewage interception and purification technology includes vegetation buffer zone and initial rainwater abandonment facilities. These technologies can be applied to various land types. Because they are different from traditional rainwater treatment measures, it is necessary to implement rainwater control schemes in various land types through the transformation of planning and construction, so as to make the path of rainwater circulation can be slower and shorter through microcirculation.

2) The social water cycle needs improvement

In the traditional water mode of one-way water cycle(Seen in Figure 6), the development of the city brings about an increase in water consumption, thereby reducing the reduction of groundwater recharge, while the increase in water consumption will lead to an increase in urban wastewater, resulting in pollutants in urban water bodies. The increase has thus aggravated the shortage of urban water resources, and the social water cycle lacks a closed link.

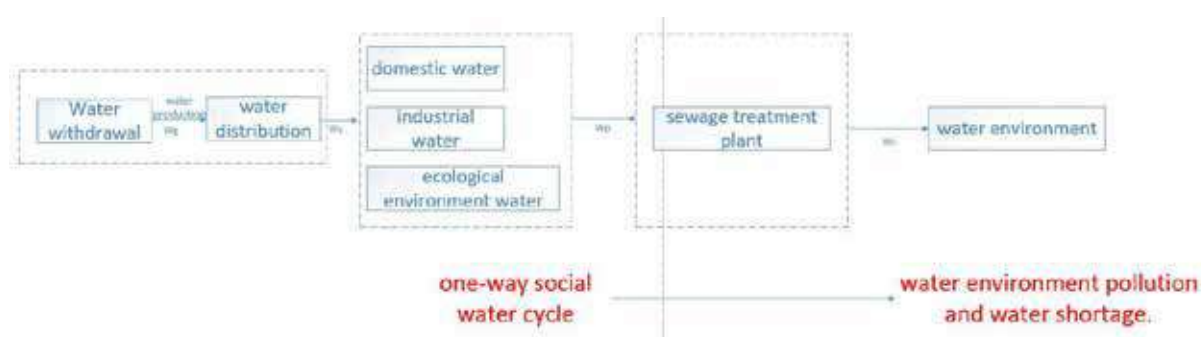

Figure 6 Schematic diagram of urban water pollution and water shortage caused by one-way social water cycle

Therefore, a benign circulation system for water resources should be constructed through the management of the urban water circulation system, composed with urban water intake, water supply and water distribution and drainage(Seen in Figure 7). Specifically, the following social water cycle improvement measures can be adopted:

- Improve sewage treatment rate and sewage treatment level, and reuse sewage,
- After the advanced treatment of wastewater, wastewater reaches the water quality of the corresponding water category, which will make wastewater re-enter the water supply system to reduce the water intake of fresh water in the city.
- Two major urban water systems, domestic water and industrial water systems, promote water reuse and establishment of micro-circulation of urban water systems.
- In industrial water, the industrial system is divided into industries that can recycle water internally, such as electricity and heat. The system consumes less water and has a high recycling rate. The amount of fresh water should be reduced.
- Centralized treatment of polluting industries: construction of industrial sewage treatment plants in industrial areas and centralized treatment of wastewater, including textile printing and dyeing industry, chemical industry, petroleum, papermaking, food processing, etc., can avoid environmental pollution.

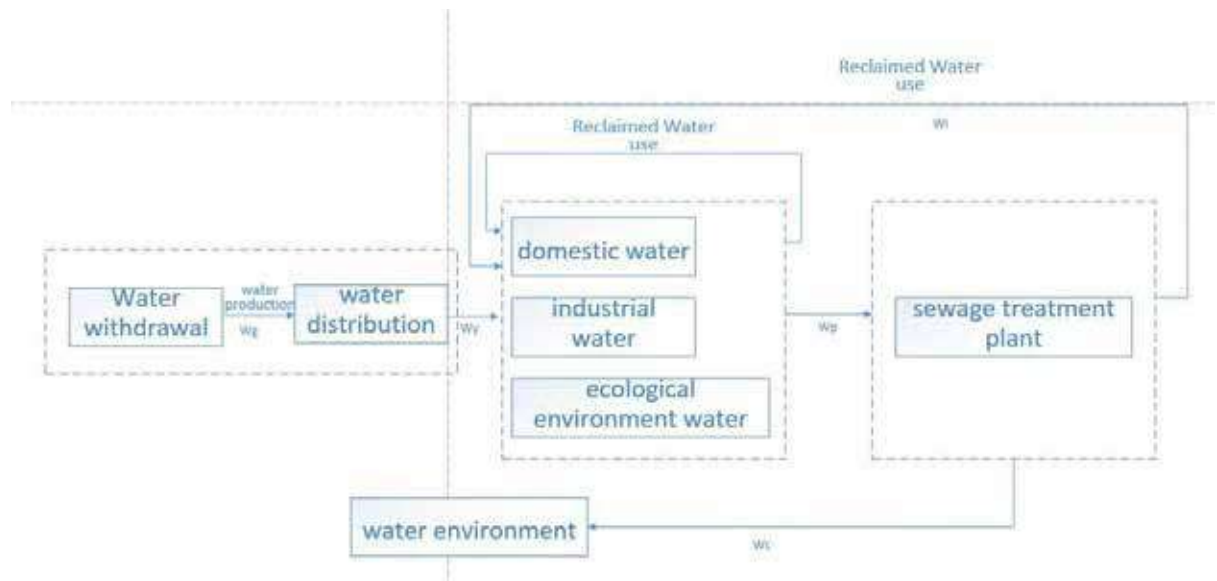

Figure 7 Schematic diagram of the construction of social water cycle system

- Control urban water consumption and reduce urban social water circulation flux:

The city is a densely populated area with a high intensity of water usage. The water consumption per capita and the water consumption per unit land are large. The surrounding agricultural land will decrease with the expansion of the city. Compared with agricultural and rural water use, urban water use mainly relies on centralized water supply system to provide urban residents with water for living, public services, municipal environment, etc., to ensure the basic domestic water demand of urban residents.

Urban water consumption is mainly related to urban development factors and urban water use indicators. It can be expressed by the following formula:

$$Q = D \times E$$

In the formula, Q represents the total amount of urban water; D represents the factors related to urban development, including population size, industrial development, land scale, environmental level, etc.; E represents indicators related to urban water use efficiency, including living water consumption per capita, the water consumption of the unit industry GDP, the water consumption per unit land, and the leakage rate. The system dynamics relationship among urban water consumption, urban development factors and urban water use efficiency indicators is as following Figure 8:

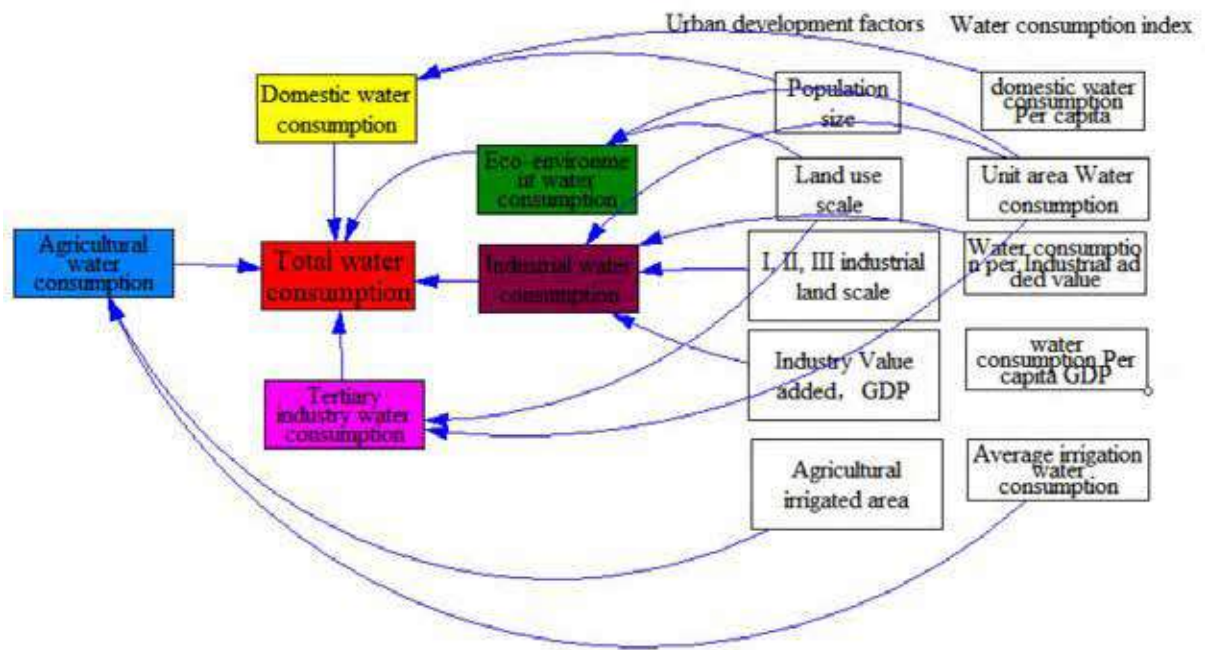

Figure 8 Conceptual diagram of system dynamics of urban development factors and water consumption (conceptual model)

Therefore, according to the city's own water resources, we should plan a reasonable population size and industrial structure, and reduce the social water circulation flux by improving water use efficiency. It can also effectively solve urban water environmental pollution and water shortage problems.

In short, in the case of meeting the the same amount demand for water in cities, the social water cycle process of urban water systems that directly serve the daily activities of the city (including urban water intake and water supply, water distribution, water usage, water treatment systems), by optimizing the system structure and operation Management measures (such as closing the circulating water, improving the sewage treatment level and reuse rate, reducing the leakage of water supply and drainage pipe network and facilities) can reduce the amount of water collected by the city from the natural water cycle system and the amount of water discharge after use. The water quality of wastewater has a negative impact on the water quality of the natural water cycle system. Conversely, the use of inappropriate and unscientific system structures and operational management measures will increase the burden on urban water distribution and water treatment systems, worsen the environmental quality of urban and regional water systems, and reduce the availability of urban and regional water resources.

3 Why should we prepare IUWSP?

Shao Yisheng (Shao Yisheng, 2004, Shao Yisheng, 2014) believes that China's current urban water-related planning is very diverse, the content is very rich, the professional foundation is relatively solid, the distinctive features of professional labor division, departmental management and system division is shown, and more subjects are planned and implemented. However, the current urban water-related planning lacks overall consideration based on the law of water circulation. There are obvious limitations. The systemic, hierarchical and coordination of planning is insufficient. The preparation and implementation of the planning is not satisfactory. Systematically solving the urban water problems is not working well.

At present, the urban water-related planning carried out in China mainly includes special plans for sponge cities, special planning for drainage projects, comprehensive planning for drainage (rainwater) and flood control, special planning for urban flood control, urban water system planning, urban water supply engineering planning, urban reclaimed water utilization planning, and comprehensive planning of urban water resources, comprehensive planning of water pollution prevention, etc. The content of urban water-related planning is very rich, and there are many main bodies in planning, and the planning scope and planning level are not uniform. The main targets and planning main objectives are different. The management and implementation departments are different, the time of planning appearance is different, the planning effect is not uniform, and it is difficult to coordinate effectively.

4 What is the IUWSP?

(1) The concept of IUWSP

IUWSP takes the urban water system as the research object, comprehensively solves the urban water problem, constructs a benign urban water cycle, and creates an effective planning means for urban space such as urban water resources, water security, water ecology and water environment.
